WILLIAM PAUL, F.L.S.,

THE SIXTY - THIRD VOLUME OF "THE GARDEN"

Is dedicated.

MR. WILLIAM PAUL, founder of the Royal Nurseries, Waltham Cross, is a son of the late Mr. Adam Paul, and was born in 1822 at Churchgate (about two miles from the present Waltham Cross Nurseries), where his father had purchased a nursery in 1806. He was educated privately, and joined his father in business in due course. In 1847, after the death of Mr. Adam Paul, Mr. William Paul inherited his father's share in the business, and became an equal partner with his brother in the old firm of "A. Paul and Son." This firm was dissolved in 1860, the present firms of "William Paul and Son, Waltham Cross," and "Paul and Son, Cheshunt," dating from that year.

In the course of a long life this famous rosarian has been associated with most of the well-known writers and workers in the field of horticulture, including London, Dr. Lindley, Sir J. Paxton, Dr. Hogg, Thomas Moore, and Robert Fortune, and has been a frequent contributor to the horticultural Press. Darwin, in "Animals and Plants under Domestication" (second edition, vol. ii., page 216), alluding to Mr. Paul's writings, says: "How well this practical horticulturist appreciates and illustrates the gradual and accumulative force of selection."

Although Mr. Paul is known as a rosarian, he has devoted much attention in the past to Fruit trees, Hollyhocks, zonal Geraniums (as introducer of the late Donald Beaton's seedlings), Camellias, Hyacinths, Rhododendrons, and other flowers, and has lectured on these subjects before the Society of Arts, the Royal Society of Literature, and other learned societies. He was also one of the promoters of the first National Rose Show, held in July, 1858; also an active worker in the great International Horticultural Exhibition held in London in 1866, and an Associate Commissioner for the Paris Exhibition of 1867.

Mr. Paul's best known work is "The Rose Garden," the first edition of which appeared in 1848, and he has written also treatises upon the Cultivation of Roses in Pots, Hollyhocks, Villa Gardening, and Rhododendrons and other American plants.

Mr. Paul is an enthusiastic collector of horticultural books, and in his library at Waltham House there are many rare editions. In his beautiful home, for many years the residence of Anthony Trollope, this great horticulturist, one of the few links between the past and present generation of horticulturists, still lives an active and interesting life. May he long continue to do so.

Grafting, stock and scion, 200
Grape, bunch of Barbarossa, 11
Grapes packed for market, 149
Gunnera manicata, 127

H.

Hazel catkins, 165
Hemsley, W. Botting, F.R.S., 246
Herbarium at Kew, the, 247; interior of the new wing, 247
Hollies, one of Messrs. Clibrans' standard, 378
Hollyhocks, single, at Beechwood, 21
Hydrangeas in the south-west, 437

I.

Ilex camellifolia at Shipley Hall, 424; *nobilis* at Shipley Hall, 423
Iris, alpine, the home of the, 26; new intermediate, 27; *tingitana*, flower of, 260; *tingitana* in a Penzance garden, 41

Irises and other flowers by path, bold massing of, 74; Japanese, at Wisley, 16

J.

Jamesia americana in flower in the Botanic Gardens, Edinburgh, 105
Japanese garden, view across dell in, 336; tea-house at Glen Hall, 335
Jasminum nitidum in Messrs. William Bull and Son's nursery, 60

K.

Kitchen Garden at Malshanger, entrance to the, 102
Kniphofia longicollis, 92

L.

Laelia anceps var. *sanderiana*, 113; *digbyana*, 45
Laelio-Cattleya Dora Magnifica, 321; *Fascinator splendens*, 396
Lampot, at, 269, 270
Latham, Mr. W. E., 386
Lavender walk in a Surrey garden, 210
Lily, fasciated, 108
Lilies, bulbs of, 198
Lilium aratum var. *macranthum*, 95; Henryi, layered stem of, 188
Lithospermum prostratum, 117
Love-in-a-mist, seed of, 165
Lupine, tree, group of, 309
Lysimachia crispideus in the alpine house at Kew, 389

M.

Mackellar, Mr. R., the late, 151
Marica gracilis, 37
Marigold, French, the dwarf, 24
Marrow, Custard, Improved White and Prince Albert, 79
Marrows, Vegetable, under glass in Aldenham Gardens, 43
Merendera caucasica, 75
Moore, Mr. Frederick William, A.L.S., V.M.H., M.R.I.A., 227
Miscari *praecox*, 75
Mushroom, the common, 13
Myosotidium nobile in Cornwall, 233

N.

Narcissus Salmonetta, the new, 393
Narrow Water, house and garden at, 129

O.

Odontoglossum Adrianae var. *Swoboda*, 250; *Bradshawae*, flower of, 184; *cirrhosum Pitt's* var. *576*; *crispum Cooksoniae*, 133; c. var. *Persimmon*, 273; c. *truffautiana*, 443; *waltoniana*, 78; *wilckeanum venerandum*, 397
Olearia Fusteri (Hook. F.), 47; *Gunnii* in a southern garden, 313
Orphan Asylum, British, at Slough, 93

P.

Peonia albiflora Whitleyi, 352
Palm house at Glasnevin, 226, 314
Pampas Grass, groups of, in Seaham Hall Gardens, 213
Pappyrus antiquorum and a Japanese Bronze in the garden at La Mortola, 67
Pea, the famous new, Edwin Beckett, 29; white Everlasting, jarful of, 157
Peach Royal George on wall outdoors at Ditton Park Gardens, 395
Pear Passe Crassane, fruit of, 185
Pelargonium, house at Chester, 430; zonal, Barbara Hope, 7
Pelargoniums, zonal, a group of Mr. Gabriel's (winter), 6
Persian Cyclamen in Messrs. Clibrans' nursery, 378
Pettigrew, Mr. Andrew, the late, 305
Phlox Avalanche, 405
Phytenua betonicifolium, 57; *comosum*, 39; *confusum*, 39; *Hollieri*, 58; *hemisphericum*, 39; *humile*, 40; *paniculatum*, 40; *Scheuchzeri*, 40; *spicatum*, 56
Picea pungens glauca in Edinburgh, 280
Pink, the old white, 162
Pinus pallasiana, the fine specimen of destroyed by the recent gale, 249
Pleached Lime Alley at Hoar Cross, 201
Plum, the Kelsey or Japanese, 122
Polygonum compactum by pathside, 56
Primrose, a hill slope of, 257

R.

Primula farinosa alba, 406; *marginata* in the alpine house at Kew, 261
Pritchardia filifera and *Dahlia imperialis* in a Riviera garden, 25
Prunus subhirtella, the rare, in flower, 177

Raisins, drying, in Southern California, 262
Rehmannia angulata, a new plant from Central China, 317
Rhododendron delicatissimum at Regent's Park, 415; *Duchess of Portland*, 340; *Rosa Mundi* in flower at Kew, 369
Rock garden, a natural, 8; at Abbotsbury, portion of, 350; at Glasnevin, portion of, 232; at Greenway, 421; at Narrow Water, County Down, 125; at Trevellis, Cornwall, 193; heap of rubble made into a, 89; in new public park at Wellington, unplanted, 258; showing planting completed, 259

Rocks, natural stratified, in the garden of Mr. Ford, Lymouth, 163
Rodriguezia fragrans at Kew, 355
Roof garden, a, 230
Rose Aglaia in Mr. Goodwin's garden at Kidderminster, 73; Anna Olivier, the largest plant in England of this variety, 91; arch in kitchen garden at Strathfieldsaye, 279; *Blush Rambler*, 364; *Enchantress*, 365; *Fortune's Yellow outdoors*, 373; *Hybrid Perpetual*, Baroness Rothschild, 9; *Violette Bouyer* in the garden of Mr. F. G. Lloyd, Langley House, Bucks, 300
Ruscus aculeatus in fruit, 292; *moluccanus*, 408

S.

Sassafras (*Laurus officinale*) at Claremont, 167
Saxifraga burseriana major, 75; *Grisebachii*, the new, 135; G. in flower at Exeter, 180; (*Megasea*) *cordifolia grandiflora*, 197
Shinto Torii gateway and stepping-stones at Glen Hall, 335
Shrubs on rocky ground, natural grouping of, 81
Siene alpestris, 231
Sophora japonica with branches chained together, 211
Spiraea discolor at Saltwood, Hythe, 195
Spring flowers, a bank of, in the Botanic Gardens, Bath, 316
Stachyurus praecox, 267
Strawberry Odette, 199
Sweet Pea Emily Henderson, 156

THE GARDEN

No. 1624.—Vol. LXIII.]

[JANUARY 3, 1903

NEW HARDY FLOWERS OF 1902.

THE following list comprises plants that have been given either an award of merit or a first-class certificate by the Royal Horticultural Society in 1902. It is not a formidable one, and it is regrettable that the number of plants given a certificate of the first class is not large. This, however, may be regarded from two standpoints. One is, Is the standard for first-class certificates set too high? We think not. It is best in the case of an untried novelty to err on the side of giving the lower award, for if the plant be worthy and its owner or introducer has sufficient faith in it the plant will assuredly appear again, entered doubtless for the higher award. This is much the best course, as to distribute the first-class certificate broadcast is to realise, a little later, that very few of the plants deserve the honour. It is noticeable also that a large percentage of the certificated plants are species of recent introduction, the novelties resulting from cross-bred or hybridised plants, if we except the Daffodils, *i.e.*, the genus *Narcissus*, being in quite a minority. This is not as it should be, and not a few genera among hardy plants are merely waiting some energetic worker or enthusiast to take them in hand and to try his utmost to improve them. In this direction the field is open and very wide, and in the near future we hope to see the honours list more equally shared between these new comers from other lands and the cross-bred plants raised in gardens and nurseries at home.

In this list F.C.C. indicates "first-class certificate" and A.M. "award of merit."

Alstroemeria Mrs. Salter.—Apparently a vigorous form of *A. aurantiaca*, the large heads of flowers being of quite exceptional size and almost globular in form. In the examples shown at the time there were between two and three dozen flowers, and these, supported on long pedicels, created quite a feature in this valued section of hardy plants. A.M., July 12.

Anemone japonica Queen Charlotte.—There is not the least doubt that when established this will prove one of the most valuable additions to the autumn-flowering kinds; indeed, such a plant was required, as the only pink-flowered kind hitherto was rather pale and did not grow well in all gardens. The present plant, although not a novelty of 1902, was never seen so fine as last year. In the form of its petals and the largeness of the flowers generally it is a great improvement, and

should prove quite a first-rate plant. A.M., October 21.

Astilbe chinensis var. Davidii.—This is without doubt the greatest acquisition to hardy plants, not of 1902 only, but for many years past, and from it will probably come through hybridisation a distinct and interesting race. The plant, so far as European gardens are concerned, is remarkable, and equally so its effect when grouped in the garden. This novelty and acquisition opens a large field for the expert plant breeder, and we know that it will not be for any want of skill or trial if a group of intermediate forms be not soon forthcoming. It is also very hardy. The colour is also exceptional, in truth remarkable in its tone of violet or reddish purple. Growing fully 6 feet high, perfectly hardy, vigorous, and free-flowering, it is certainly an acquisition. Already the plant has produced good seeds in England and young plants. In the capable hands of Messrs. Veitch we feel assured no opportunity will be lost in making the most of this fine new perennial. From Central China. F.C.C., August 5.

Corydalis thalictrifolia.—This is also a valuable new species. It is only 1 foot high, forming a compact free-flowering mass; indeed, it is almost always in bloom, from the beginning of May till sharp frosts occur. The pedicels are long and slender and furnished with bluish, deeply incised lobes, that together produce quite a charming feature, while the flowers are yellow. The plant has a shortly rhizomatous rootstock and is deciduous, in fact almost disappears from view. Having proved hardy and being a good seeder, this *Corydalis* will probably become very popular. Not only will it make an excellent rock garden plant, but for ruins, old walls, or even carpeting beds of choice things it will be found useful. From Central China. F.C.C., June 10.

Cimicifuga japonica.—This is not a novelty, but it is an excellent plant. The pure white flowers are very beautiful, and the plant attains 4 feet high or thereabouts, the flowers clustering closely on long cylindrical spikes. The foliage is finely cut. A.M., October 21.

Delphinium Kitty Wardell.—As this is the only Larkspur certificated by the Royal Horticultural Society during the past season, it may fairly be conceded that perfection in certain directions has been well-nigh attained. The flowers are semi-double, large, and violet-blue in colour; the spike is very handsome. A.M., July 8.

Fritillaria askhabadensis.—An entirely new species, vigorous, and very free-flowering. The fine example as exhibited by Miss Willmott, was upwards of 2 feet high, and crowned by a leafy erect tuft, and from eight to ten greenish yellow openly campanulate flowers. This interesting species comes close to the Crown Imperial, the flowers being smaller, but the leaves and inflorescence are the same. This species was discovered growing in calcareous soil near the village of Kasakala, near the

town of Askhabad, on the Russian border. A.M., March 25.

Heuchera brizoides gracillima.—An elegant plant, which attains nearly 18 inches high, and produces numerous light and elegant spikes, on which the dainty rosy scarlet flowers are arranged. It is a hybrid kind from the continent, apparently between *H. micrantha* and *H. brizoides*, and may be classed among the most hardy and graceful of dwarf perennials. A.M., June 10.

Iris Sarpedon.—This is one of the flag Irises, and said to be a hybrid between *I. asiatica* and *I. pallida dalmatica*. In the hybrid the vigour of the latter is well seen, while the colour partakes of the other kind, the standards being of a deep azure blue, and the falls violet-purple. A.M., June 10.

I. Sunshine is also of the flag section, the colour a pleasing combination of soft yellow and creamy white. A.M., June 24.

I. orientalis Snow Queen.—Hitherto in the forms of *I. sibirica* and their near allies no good pure white kind existed, and as this *Iris* is white and free-flowering it will doubtless prove a valuable addition. The habit is the same as that of the type, the only difference being in the pretty and very pure blossoms. A most welcome plant. A.M., June 24.

I. Barnume.—A rather dwarf member of the *Oncocyclus* group, with almost self purple flowers. It is curiously fragrant at certain stages, and is certainly one of the hardiest of the race. A.M., May 20.

I. Sofarano magnifica.—This is also of the *Oncocyclus* group, and is a really handsome and vigorous kind; indeed, there is almost the boldness of *I. susiana*, and in other respects it may be regarded as nearly intermediate between this and *I. atrofusca*. A very handsome variety. A.M., May 28.

I. Tauri.—A new species of the *I. persica* group, which has now been grown for two seasons. In the earliest examples that came before us there was a marked freedom of flowering, which has not in the same decisive way been maintained. The plant, however, is one of the best, and if a variable species, which it is undoubtedly, there is hope and the pleasure of even better forms to come. In all its variations the plant displays some shade of violet or this with purple. It is very useful for any warm position in the rock garden in very sandy loam, and next to *I. Heldreichi*, is one of the finest of the earliest Irises. A.M., January 14.

I. Warleyensis.—Some surprise was expressed quite early in the year when it was announced that this kind on eminent authority was regarded as a new species. It is now admitted, however, to be a member of the *I. orchoides* group, and a very beautiful one. It is not easy briefly to describe the many colour variations in this plant. The predominant note is pale to deep violet, the deeper shade being upon the blade of the fall, which again is distinctly margined white. From

Eastern Bokhara, at an altitude of from 5,000 feet to 6,000 feet. F.C.C., March 25.

I. Bucharica.—Another beautiful species, belonging to the same group as the above, though even more widely distinct and charming. It is, however, in the exquisite combination of colours that this lovely plant appeals to all lovers of beautiful flowers. The predominant colours are the pure white as seen in the upper portions of the flower and the rich golden-yellow of the blade and crest. In many other respects is this one of the most fascinating Irises we have seen. From Eastern Bokhara. F.C.C., April 8.

Kniphofia Rufus.—A very striking kind with spikes of scarlet and yellow flowers. A.M., August 19.

Liatris graminifolia var. dubia.—Not quite a novelty, but certainly one of the best of this family and not at all well known. The spikes are 5 feet high, columnar, and densely furnished with rosy purple flowers. A.M., September 23.

(To be continued.)

PILGRIMS GO A-RANCHING.

"A-ranching we will go,
A-ranching we will go,
A-ranching we will go—o,
A-ranching we will go."

ACCORDINGLY I write this, eleven miles from San Diego, in the midst of an Orange and Lemon grove in full fruit, while on the lawn and around the house are many fine Rose bushes and climbing Roses just coming in flower, notably La France and Safrano. Towering far above the second-story housetop are large Eucalyptus, while on either side is a gigantic Pepper Tree, whose weeping foliage is most effective. There are Loquats in full flower, masses of Guavas in fruit, and many deciduous fruit trees, while everywhere is a tangle of Blackberries and Dewberries. The solemn hills on every side tempt one to believe that one is actually in Scotland again, only the tropical surroundings belie it. Hot days and cool nights have obtained for the three weeks since our arrival. An eventful journey of five days and nights brought us from Chicago, in somewhat bad shape, it is true, as regards the only male member of the expedition, who injured his knee badly in the cars, and had to be assisted at the various changes, thus somewhat damping the wild enthusiasm of the *tout ensemble*, but the honest German face of our host at the depôt made up for much. Then an eleven mile drive to the cosiest of homes, peacefully nestling under the hills through a boulevard lined with Palms on either side, brought the weary pilgrims to meet a genuine English welcome from our hostess. At Truckee, on entering the State of California, we encountered hard frost, freezing the car windows, but here is no frost. The trip from Los Angeles is surpassingly lovely, 250 miles through beautiful scenery, skirting the Pacific Ocean for a considerable portion of the ride. We passed the largest Olive ranche (supposedly) in the world; this year totally without a crop. Tomatoes are largely grown around here, and fetch now 2½ cents a pound.

Since we arrived everyone who has come in touch with us has endeavoured to "touch us" into buying a ranche. They all have one or two up their sleeve, and produce them on every available opportunity. We have rented this house I write from now for 5dols. monthly; it is hard-finished, two-story, with six immense rooms, two bay windows with a profusion of coloured glass transoms and panelled doors. I can buy this, with large reservoir, 12½ acres

of fruit, and barn, for 2,000dols., or about £400. It is the loveliest spot I have ever seen, and is all piped with water over the entire area. There is a school, church, and village half a mile from here, and a railway depôt two miles off. Provisions are nearly as cheap as in Chicago, while the climate is beyond praise. Unluckily, you cannot live on the climate, and I suspect that accounts for the bargains our ingenious friends have been pressing on us. I went to inspect the ranche we nearly bought from our pious Chicago friend. The mortgage was the only flourishing thing about it. It had been abandoned for a year, and is worth *nil*. I intend giving details of cost of production and market prices in future papers as I acquire this useful knowledge.

La Mesa, California. C. MACQUARIE.

EDITOR'S TABLE.

FLOWERS FROM BEDFORD.

"B. M. B." (Bedford) sends a delightful gathering of outdoor flowers with the following interesting note:—"I send a small bunch of outdoor flowers.

CERASTIUM TOMENTOSUM.

The Chrysanthemum is always the last to remain in bloom, and is still opening its flowers in spite of the severe weather at the beginning of December, when we had as much as 22° of frost. The Wall-flower is Barr's extra early Parisian, which flowers from September to the following June without intermission. Does anyone else, I wonder, use *Limnanthes Douglasi* as a winter carpeting plant? The green is very bright and vivid, no frost seems to harm the foliage, and there are always stray blooms up to January and again in the early spring. Seed can be sown in August. The few Pansies and Violets are not particularly remarkable. I have besides in flower Double Daisies, *Crocus speciosus*, *C. hyemalis*, *Arabis*, *Alyssum*, *Violets*, *Galanthus cilicicus*, and some China Roses; but frost has spoiled most things."

CHRISTMAS HARDY FLOWERS.

Mr. Field, Ashwellthorpe Gardens, Norwich, writes (December 24):—"I am sending a few sweet-smelling flowers for your table on Christmas Day. I was afraid when the early frost set in that it would be all over with the flowers before this, but we can still gather handfuls of Wall-flowers, Winter Heliotrope, Violets, &c., and the Snowdrops will soon be in bloom."

A welcome gathering, comprising the Winter Sweet (*Chimonanthus fragrans*), the Winter Colt's-foot, and Violets.

CLIANTHUS PUNICEUS AND ROSES FROM THE OPEN GARDEN.

Mr. S. W. Fitzherbert sends from Kingswear, South Devon, a gathering of flowers of *Clianthus puniceus* from the open wall, also a few blooms of *Mimulus (Diplacus) glutinosus* from an entirely unprotected plant. Mr. Fitzherbert writes:—"On Christmas Eve I picked a couple of dozen good Roses from bush plants in the open, including Queen Mab, Laurette Messimy, Irene Watts, Leonie Lamesch, and Marquise de Salisbury. We have as yet had no frost to speak of here. The mercury has never fallen below freezing point in the screen, and on the grass only 2° or 3° of frost have been registered."

A BEAUTIFUL VARIETY OF WINTER SWEET.

Mr. Burrell sends from Claremont, Esher, a beautiful variety of Winter Sweet (*Chimonanthus fragrans*). The flowers are very clear in colour, the petals a soft lemon-yellow, and the sepals quite a crimson shade, and they are set more densely on the leafless twig than the ordinary form. Its pretty colouring, sweetness, and freedom make this one of the best forms of the somewhat variable *Chimonanthus* we have seen.

CERASTIUM TOMENTOSUM.

"R. H." sends from Devonshire a few flowers of this *Cerastium* to show the mildness of the weather during Christmas. It is too well known to describe, but we have made a little drawing of it to show how freely it has flowered in a favoured Devonshire nook.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

January 6.—National Amateur Gardeners' Association Meeting.

January 10.—Annual dinner of the Société Française d'Horticulture de Londres.

January 13.—Royal Horticultural Society's committees meet at Drill Hall.

January 14.—East Anglian Horticultural Club Meeting.

January 22.—Gardeners' Royal Benevolent Institution Meeting and Election of Pensioners at Simpson's, Strand.

January 27.—Royal Horticultural Society's Meeting.

February 3.—National Amateur Gardeners' Association Meeting.

"The Garden."—With this issue is presented a coloured plate of Tea Rose Lady Roberts, and a calendar printed in two colours, giving the dates of the principal horticultural exhibitions and meetings throughout the year. This we feel sure will prove useful to many of our readers.

Cup prizes for the National Dahlia Society.—Mr. Tulloch's circular *re* the provision of two £10 cups for competition at the National Dahlia Society's shows, as published on page 422 of THE GARDEN, came before the members of that society in an informal way at the recent general meeting, but did not seem to arouse much enthusiasm. The proposal is simply another effort to rivet the chains of mere show or competitive effort on the society, and does nothing towards making Dahlias popular garden flowers. If someone choose to fling away £10 unwisely elsewhere in similar fashion it does not at all follow that a society having the reputation of the National Dahlia Society should follow. A greater need of the society is a reserve fund to guarantee it against any possible adversities than that it should seek to raise £20 to throw away in probably three years at the outside in cups. It is, indeed, doubtful whether any more exhibits would be seen at the shows than the ordinary prizes now bring were cups offered.—A. DEAN.

Oakwood and Glebe Farm, Wisley Common, near Ripley, Surrey, is to be sold by auction at the Mart, Tokenhouse Yard, E.C., on Tuesday, the 20th inst., at two o'clock. The estate is about 60 acres, and is being sold by the executors of the late Mr. G. F. Wilson, F.R.S.

Prunus Pissardi.—In the notes from Swanswick, page 442, "M. L. W." comments on *Prunus Pissardi* as a prospective fruit-bearing tree which the writer of the "Tuscan Garden" says is grown in Tuscany for its fruit. I am afraid it will not in this respect give much satisfaction to "M. L. W." as in most parts of England fruits are rarely borne. It is only a coloured-leaved variety of the Myrobalan or Cherry Plum (*Prunus cerasifera*, better known as *Prunus Myrobalana*); indeed, in the "Kew Hand List" the name of *Pissardi* is discarded in favour of *Prunus cerasifera atropurpurea*. The flowers are borne so early that the fruit seldom develops, but when it does come to maturity it is fairly good, though not for one moment to be compared with many of the delicious garden Plums. In the climate of Tuscany the fruit probably sets readily, and the brighter sunshine may account for a richer flavour, but here its principal claim is as a good purple-leaved tree.—H. P.

Alterations at Kew.—The most important addition to the establishment during the past year is the new wing to the Herbarium. This extension, which is of the same size as the large hall built at the back of the old building twenty-five years ago, practically doubles the accommodation for dried specimens. It is fire-proof, and each storey is connected by a corridor with the rest of the Herbarium. The architecture and elevation are the same as in the original building, and the front faces Kew Green. It is rapidly approaching completion, and will probably be fit for occupation early this year. The reglazing of the central block of the Temperate house has been proceeded with during the past summer, and the loftier part of the roof is now finished. The use of clear untinted glass and large panes, in place of the narrow green ones, makes the house much lighter and better fitted for the class of plants it contains. The soil throughout the whole of the beds has been renewed and a system of thorough drainage adopted. The greater part of the old soil had been in the beds since the house was built—exactly forty years ago—and no drainage had been provided. As some of the beds were 5 feet or 6 feet deep it is not surprising that the soil had become sour. The northern wing—known as the Himalayan house—has proved a great success. The chief feature is the collection of *Rhododendrons*, but the conditions are found to be admirably adapted for many other warm temperate plants. *Buddleia Colvillei* has flowered here for the first time at Kew, and many other plants are developing beauties that one never previously knew they possessed.—*Kew Guild Journal*.

Schizostylis coccinea.—How sadly neglected this beautiful Kaffir Lily seems to be, for one rarely finds it grown in such quantity as its merits and usefulness deserve. In November we had a brilliant picture with masses of this subject interspersed with the lovely *Sternbergia lutea*. Soon after the *Sternbergia* had finished flowering the severe frosts came and checked the *Schizostylis*, but a few mild days have brought it into flower again. An ideal spot for the *Schizostylis* is at the foot of a warm wall or in a border in front of the glass houses. It likes a light rather than a heavy soil, and well repays such attention as copious waterings during the hot and dry weather. About every third year the clumps should be lifted in the spring, divided and replanted.—A. C. BARTLETT.

Kew Guild Journal.—This annual publication is always of much interest, more especially of course to members of the Kew Guild—that admirable association of those who have worked, and who now are working, at Kew. A portrait of Mr. John Reader Jackson, late keeper of the Economic Museums at Kew, forms the frontispiece of this number. Mr. Jackson held this post for forty-three years, having retired in 1901. Perhaps his most important literary work

is "Commercial Botany of the Nineteenth Century," published in 1890. Many past Kewites will remember with pleasure Mr. Jackson's lectures on "Economic Botany." At the annual dinner of the Kew Guild held in May last 114 were present, when Mr. J. G. Baker, F.R.S., presided. It is interesting to note that the British Botany Club, the Debating Society, and the Cricket Club are all flourishing. Notification of several important appointments serves to show the importance of Kew as a training ground for gardeners. Notes from past Kewites in various parts of the world make most interesting reading. There are notes from South Africa, Morocco, Teneriffe, India, Malay States, West Indies, West Africa, and other more remote colonies. Mr. W. Botting Hemsley contributes an article concerning William Aiton, and there is also a notice of John Rogers, one of the oldest Kewites. Mr. W. Watson has resigned the post of secretary and editor, and has succeeded Mr. George Nicholson in the less laborious position of president. Mr. W. N. Winn is now secretary, and Mr. W. J. Bean is editor and treasurer. In addition to portraits of John Reader Jackson, William Aiton, and John Rogers, the journal contains a full-page illustration of the Rock Garden at Kew. Under the new editorship the general excellence and interest of the journal is well maintained.

New varieties of Apples.—When recently looking over the new branch nursery made by Messrs. J. Backhouse and Son in Yorkshire, my attention was drawn to several new Apples in the fruit quarters. The best were James Grieve, Rivers' Codlin, and Northern Dumpling. The two latter are, as their names will suggest, kitchen Apples. The former is a dessert variety of much promise. Judging by the specimen before me I should say it has some of Cox's Orange Pippin blood in its veins, though the fruit is larger than that variety generally grown in the north. The nursery has only been made two years, so the trees on which the fruits were growing must be young ones.—H. J. CLAYTON, *Tadcaster*.

Tubers on Nephrolepis.—Concerning the question regarding tubers of *Nephrolepis* in THE GARDEN of the 20th ult., I may say that there is one distinct species or garden form, *Nephrolepis Bausei*, in which the tubers afford the only trustworthy means of keeping it from one season to another. It is a very pretty Fern, but is available only for the greenhouse, and, what is more, the entire crown and rootstock usually die, leaving nothing but a few detached tubers, which, when growing, were connected with the parent plant by a slender thread-like substance. These elongated tubers with their roughened exterior greatly resemble the cocoons of some of the moths, but closer inspection reveals the origin. So thoroughly does this *Nephrolepis* appear to die in the autumn that I have known plants of it to be thrown away in the belief that they were quite dead, the small tubers being overlooked. A good way to treat this Fern is to allow it to occupy the pot in which it has grown, and keep it moderately dry throughout the winter, then early in the new year take it from the soil and pick out the tubers. If potted singly into small pots these grow away rapidly and soon form effective plants.—H. P.

Chrysanthemums as shown.—Having visited a great many of the Chrysanthemum exhibitions during the past autumn I was particularly interested in a portion of the article on page 451, over the well-known initials of "C. H. P.," as the writer's ideas entirely coincide with my own. The part alluded to is that in which reference is made to the large coarse flowers that now do duty for the incurved section, which at one time used to be models of symmetry, but that is now all changed, and everything sacrificed to size. The Japanese, too, are very disappointing, the rich coloured flowers being conspicuous by their almost total absence. At many of the exhibitions artificial light is necessary during the greater part of the time, and then whites and yellows appear much the same, while those subtle tints to which such descriptions as lilac, silvery rose, light purple, pale rose, lilac-rose, rosy mauve, and various other

combinations are applied, are indistinguishable the one from the other, particularly as their depth of colouring depends a good deal upon the treatment given to the plants. Such sameness makes one sigh for the time when the rich coloured Edwin Molyneux was in the height of its popularity, or, to go a little further back, when to my way of thinking the most beautiful crimson Japanese that has ever figured at these exhibitions was so generally seen on the show-boards. This was Jeanne Delaux, distributed by that well-known cultivator M. Delaux in 1882, at which time the *Chrysanthemum* was beginning to get popular. It was for a time after its distribution frequently met with in this country as F. A. Davis, for the set which was sent out that year by this well-known nurseryman was rechristened on arriving in this country, a most reprehensible practice, costly to myself and many others, for I obtained the set direct from M. Delaux, and bought several of them again under other names. The flowers of Jeanne Delaux were beautiful in contour, rich in colour, and to my mind vastly superior to the huge blooms now in vogue.—T.

Reinwardtia trigyna.—In the fall light that often prevails during a dull winter's day flowers of an orange tint are more conspicuous than those of any other hue, a great point in favour of this *Reinwardtia*, whose period of blooming is during the winter months. It has been long known in gardens, particularly under the name of *Linum trigynum*, but for some reason or other its merits do not seem to be sufficiently recognised. It is one of those sub-shrubs so common among tropical plants, and was introduced from India over a century ago. If struck from cuttings early in the year and the young plants have their points pinched out two or three times they form neat little bushes, which will bear a cluster of flowers on the point of every shoot. The individual flowers, in shape not unlike a Primrose, are about an inch across, and of a rich glowing orange-yellow colour. A succession is kept up from one cluster for a considerable time. A second species (*R. tetragyna*) has primrose-coloured flowers with a yellower centre. Which is the more beautiful is at least an open question, but for my part I prefer the deeper tinted and older species. A place, however, may well be found for both in most gardens where there is a structure in which an intermediate temperature is maintained during the winter months, as they occupy little space and their cultural requirements are not at all exacting. Red spider is their principal enemy, but if the plants are grown during the summer in a frame these pests do not give so much trouble as when they are kept throughout that period in an artificially-heated structure.—H. P.

Cactus Dahlias for garden decoration.—As intimated, I brought before the members of the National Dahlia Society my proposal that the consent of the Royal Horticultural Society be obtained for a trial at Chiswick of new Cactus Dahlias, sent by raisers specially to show fitness for garden decoration. I was much pleased to have the support to my proposal of the esteemed president, Mr. Mawley, who has higher tastes in relation to Dahlias than by making them mere exhibition flowers, and who intimated that the Royal Horticultural Society would have such a trial at Chiswick at their own option, and urged members to send varieties to that trial. Mr. Wyatt, of the well-known firm of Keynes, Williams and Co., mentioned that "they had two or three varieties specially for garden decoration," and we wish other raisers, now so devoted to the show side of these flowers, would do the same. Showing Dahlias gratifies a few—growing them for garden decoration gratifies thousands.—A. D.

Palms as room plants.—In reference to the terrible slaughter among Palms when treated as room plants, alluded to by your correspondent "M. L. W.," page 443, the blame must, I think, be shared between the producers, the retail sellers, and the ultimate purchasers. The producers in the first place, in order to get the plants in a

saleable state as soon as possible, push them on in a hot steamy atmosphere, the result being that when removed from it they are very susceptible to the cold, while drying winds are equally hurtful. Then the retailer often keeps them in hand perhaps for a long while, exposed it may be to draughts and various other adverse conditions, so that by the time they are bought and taken indoors the roots have received such a check that, though the plants may exist for a time, they will die before regaining their normal health. The hardships that many room plants have to put up with is greatly against Palms, which to be kept in health should be well sponged once a week, carefully attended to in the matter of water, by avoiding drought or the opposite extreme. Above all never allow the water to stand in the saucers. There is also a great tendency, especially among amateurs, to shift them into larger pots, whereas most Palms may be kept in health for years in the same pot. I do not mean to say that all Palms sold finish their career as above detailed, but the great changes they undergo are doubtless answerable for much of the mortality that takes place among them.—T.

A prize station garden.—For the fourth time in succession the special prize of £5 offered by the directors of the Great Western Railway Company for the best-kept flower garden at their stations in the Reading division, which embraces a large number of towns and villages, has been awarded to Mr. Treacher, stationmaster at Theale, near Reading.

Mr. Frank Garrett.—It will be a source of regret to many to know that Mr. Garrett, who for over sixteen years has had charge of the Ornamental Department at Kew, left on October 31 last to take charge of the gardens at Blenheim, a post which is regarded as one of the first prizes in horticulture. Besides his long experience at Kew, Mr. Garrett has served in some of the finest private gardens in this country, such as Longleat, Syon, Downton Castle, and Sandringham. Too modest to seek fame, Mr. Garrett has nevertheless gained it by his successful work at Kew. Scores of young men have benefited by his supervision of their work and by the sound practical doctrine he taught. It may be a larger sphere of labour to which he has moved, but Kew men will not admit it to be a more useful one. He was presented before his departure with a handsome clock as a mark of respect from many members of the staff. Mr. A. Osborn succeeds Mr. Garrett as foreman of the Ornamental Department. He came to Kew in April, 1899, and for two years and a half was sub-foreman in the Ferneries. Previously he had been with Messrs. Sutton and Messrs. Veitch, and had spent some years in private gardens.—*Kew Guild Journal.*

The Flageolet Bean.—It is interesting to note that Mr. Isherwood's query with respect to the old red Flageolet Bean should have just now been made, as it was but very recently when with members of the fruit and vegetable committee of the Royal Horticultural Society at Chiswick we were discussing with Mr. Wright the Kidney Bean trial for next summer, which is to take place there, I asked whether stock of the true old red Flageolet could be obtained now. I thought it might be had from Messrs. Vilmorin and Co. of Paris. There is an impression abroad that it and Canadian Wonder are the same. If it be so it is odd that such fact was not generally known. In such a trial as is proposed a few of the best old varieties may well be included. In a list published forty years ago the Flageolet is not mentioned. The chief ones were Negro, Mohawk, Fulmers, and a few others. It would not be difficult now no doubt to make up a list of thirty varieties distinct so far as ripe seeds are concerned. I hope we shall see the Flageolet at Chiswick. After writing the above, I looked into M. Vilmorin's "Vegetable Garden," where I find he enumerates some fifty varieties of dwarf Beans, many of them unknown here, and several of which are termed Haricot Flageolet. The Chevrier Flageolet is specially praised for its exceeding greenness, extending partially to the seeds. I notice that dwarf Canadian Wonder and the red or scarlet Flageolet are classed as synonymous in

the book. No explanation is given as to the meaning of or reason for such frequent use of the name or term Flageolet. Is it a corruption of the botanical name Phaseolus, or does it convey, so far as the Bean pods are concerned, that they are long and cylindrical? In France dwarf Beans are grown chiefly for their ripe seeds. We prefer the green pods.—A. D.

ROUND ABOUT A GARDEN.

WANDERING through woodland at this season one often comes across a group of trees so gracefully draped and festooned with common Ivy that they make what people call "a perfect picture." Often in summer, too, magical glimpses may be caught, in some jungly dell, of natural arches clustered with wild Rose and Honeysuckle; and I recollect, as a boy, spending part of a half holiday trying to transfer to paper the loveliness of some natural rockwork on Leckhampton Hill, near Cheltenham, which was so garlanded with wild Clematis and tufted with wild flowers as even to compare favourably, to my mind, with the background in the transformation scene of the previous Christmas pantomime, revealing the Fairy Queen in her pink tights and her Enchanted Grot. Often in the Himalayas I wished for a camera to perpetuate the dreams of loveliness woven by flowering creepers round trunks fringed with Fern and Orchid; and only last year in England, passing down a hollow lane, whose high, tangled hedgerows were wreathed from end to end and roofed with fairy tracery in parts by the wide-flung trails of the common wild Hop, I could not help thinking what one might not be justified in spending to transplant, if he could, the whole thing bodily to one's grounds. For several hundred yards the lane wound deeper and deeper into the valley, and at every winding turn a new vista caught the eye, till, at the very bottom where, as in a cellar, it is always cool in summer and warm in winter, you came to the spring that dripped through perennial emerald of clustered Maidenhair.

In grounds which are too extensive for constant horticultural attention in every part you may sometimes happen upon wild nooks of beauty such as these: but to find them you have to wander from the beaten path of trimmed shrubbery and cultivated coppice, and in a small garden, if there happens to be a certain number of trees, they are allowed to remain a certain number of trees, without any attempt being made to add to their beauty. The gardener merely sweeps away all the leaves that fall from them in autumn, and all through the winter the owner sees their bare trunks and leafless branches. Beneath them the grass grows thinly over the clammy brown earth, and for two-thirds of the year "under the trees" is a place to be avoided. It is lovely in spring, of course, when the leaves have burst their buds, and its shade is grateful during hot days of summer, while, as the year wanes, it may afford a limited display of "autumn tints;" but, taking one thing with another, the average householder's view is that as much ground as is occupied by "the trees" is so much ground lost to "the garden."

The exact contrary should, of course, be the case. Any tenant of a bare piece of ground can with a five years' lease convert it into a fine flower-bed garden, but he cannot grow trees in the time, and unless he is (as so few are nowadays, but as our ancestors always seemed to be) content to lay the foundations on which successors may build an ideal garden, he must make shift with artificial structures for climbing plants if he wishes to produce

any really graceful effects in his garden. And this brings me to certain criticisms which have been passed upon my views of pergolas. That these may be beautiful no one who has seen the pillared wealth of blossom upon one that is well established can deny. That they may be useful we have the evidence of those who have found their shade in sultry weather grateful and comforting. Miss Jekyll, who is a high priestess of the temple round whose lowest step I wander among the weeds, has explained the beauty of the pergola and the art of building and stocking it. But still I would venture a wager, if I saw any chance of profit in the transaction, that the gardening books of the future will speak of the pergola as "a horticultural artifice which had considerable vogue at the beginning of the twentieth century, but which, owing to the truer conception of art in the twenty-first century"—you all know how instructive books talk in the introductory chapter?—"has fallen into disuse," or words to that effect.

But which of us is going to live until the twenty-first century? So let no one who loves to see the massed wealth of blossom which well-grown creepers display be deterred from building a pergola for them to creep upon. It will be something very different from his original design before the critics of the twenty-first century arise to point out its artificiality. Still, my opinion holds that in England, where we need fear no snakes or scorpions in the grass, the natural shade of trees in a garden renders the pergola superfluous, and that climbing plants are more beautiful when they climb as Nature taught them upon rocks or trees than upon any manifestly artificial structure. As a covered way leading from a house-door to some other frequented point of a garden a pergola may be so useful and ornamental as to be one of the *best* features of the place; but where, as is now happening in scores of gardens, an elaborate pergola is constructed as one of the *chief* features of the place, breaking up the central vista with its obstructive arches, you cannot help regretting it. When a pergola is stuck out in the middle of a garden as if it was a sort of artistic flower-bed, you go in at one end and come out at the other, like the white ants in India, who construct tunnels for the after pleasure of creeping through them.

Returning, however, to the clump of bare trees, from which we digressed to the pergola, why does it so seldom occur to the owner or occupier of the ground, of which part is filled with the "garden" and part with trees, that the part which is filled with trees ought to be the best part of the garden? That the grass will not grow properly under the trees is true, and that the trees, having had no competitors for many years besides the inch-deep grass, have run their roots so near the surface that nothing else will grow well there—at first—is also true. But it is altogether a mistake to suppose that—except under Beech trees or conifers, which are tyrants in the way that they suppress lesser life beneath their branches—the shaded ground beneath trees is not the very best place for a multitude of the garden's gems. Go into any wood, except a Pine wood or a Beech wood, and its most striking feature is the density and luxuriance of the under growth and the wealth of wild flowers. Each wild tree is a fostering nurse to hundreds of more tender plants, yet in our gardens we are content to leave the trees as bare trees and nothing more. They might as well stand in a pasture where grazing cattle nip off everything green which rises above the level of the grass.

E. K. R.

NOTES ON HARDY PLANTS

GERBERA JAMESONI.

MR. MULES enquires "Can anyone grow it finely outside in this climate? If so, how?" The only answer to the first question is an emphatic "Yes," and it might be added that it is the only way to have it at its best. The second question may be answered in a few words. Plant at the foot of a south wall of a plant house which has hot-water pipes behind it. During summer give it the fullest exposure, and in winter fix a small light over the plant to keep off excessive wet. Do not close it in, but shake a little Bracken or similar material over the plant when the weather is cold. In this way I have had flowers from April to well into September, and a development which could never be obtained by pot culture. A plant I have under this treatment must be nearly if not quite fourteen years old, but this age is too great, and that individual will never again perhaps be so fine as it has been.

R. I. LYNCH.
Botanic Gardens, Cambridge.

DIERAMA (SPARAXIS) PULCHERRIMUM.

THE variety *pendula* is a pale rosy purple form, and does not differ very much from the type, though often called a distinct species. Its leaves are more rigid, the spikes shorter, and the pedicels a little longer than in typical *pulcherrimum*, whilst the flowers are more closely arranged on the pedicels, the weight of which gives the inflorescence a more pendulous habit than that of the type. The *Dieramas* were referred to last week.

FLOWER GARDEN.

GARDEN PUZZLES.

DURING the Middle Ages," says Max Müller, in his "Last Essays, Second Series," "exactly the same idea which now goes by the name of Agnosticism was well known as *Docta Ignorantia*—i.e., the ignorance founded on the knowledge of our ignorance, or of our impotence to grasp anything but what is phenomenal." If our gardeners could know the value of this *docta ignorantia* (instructed ignorance), if they could learn that every yard of their gardens is full of puzzles, the solution of which they can only guess at, and that only in a few cases, they would have made a first and most important step towards becoming *docti* and even *doctores*. Every yard of the garden has its own special puzzle or puzzles, and I think it may interest the readers of *The Pilot* if I walk through my garden and pick out a few such, not with the expectation of being able to explain them, but with the hope of showing how much the study of such things will add to the interest of every garden. A very few will be sufficient to show what I mean.

One of the first plants I come to is a large mass of *Physostegia virginiana*, a very old plant in English gardens which came to us, as its name implies, from the Southern United States. It grows about 4 feet high, a rigid herbaceous plant, with a closely-packed bunch of flowers at the top. The flowers are arranged in four rows, each row facing one point of the compass, so that the whole

set are in the form of a cross, and the calyx of each flower works on a sort of hinge. But any of the rows, or all the rows, can be moved by the finger to face any other than the natural way, and when so moved they remain as placed. This arrangement is technically described as "flowers cataleptic"—i.e., the flowers can be placed in any position and there remain. I do not know whether they can be so moved by the wind or by any other external force, but I believe there is no other plant in the world that has its flowers so arranged; and the question at once arises, what can be the use of this arrangement in the life-history of the plant? When Darwin wrote his excellent work on the movements of plants, he made no mention of this one. I wrote to him and described it, and at once received an answer, written with his habitual unassuming modesty, that "the case is quite new to me and seems inexplicable"; and he hoped to examine it further. But that was in the autumn of 1881, and he died in the spring of 1882, before he could have had the opportunity of studying it. I was also able to put the question to Professor Asa Gray, and as the plant is American, he of course knew it, but he could give

no explanation; he suggested that it was a survival of something that was once useful to the plant, but could go no further.

Close to the *Physostegia* I have a young plant of *Cydonia sianaensis*. It is a recent introduction from North China, and is closely allied to our old favourite the *Pyrus japonica*. It is remarkable for its large fruit, which, however, I have not seen, though I hope to do so yet, for the fruit has been described to me by some as being the size of a cricket-ball, by others as the size of a football. This by itself would be sufficient to make the plant attractive, but it has one peculiarity which makes it to me much more so. Looked at casually, there seems nothing very particular to notice in the leaves, but looked at more closely it is seen that the petioles and the margins of every leaf are thickly set with stalked glands, very much resembling in miniature the glands on the Sundews. Why should this particular *Cydonia* be so provided differently to all other Quinces? I can but guess that in its native country, either from the climate or some other cause, the leaves require an additional breathing apparatus to what is sufficient for its relations in other countries, but this is no more than a guess.

The *Acenas* are plants that always interest me. They form a small family of pretty creeping plants chiefly found in the southern temperate and antarctic regions, especially in New Zealand. They all form burrs that cling to anything, the clinging character arising from spines on the calyx. One would have imagined that, so long as they could cling, one form of spine would do as well as another, but it would not; and so each species is furnished with its own particular form. In one species it is almost invisible, in another it is a simple, straight, sharp spine, in another a spine with a single barb, in another a spine with a double barb. One can only suppose that in each case a different enemy has to be guarded against; and that a defence which would be sufficient in one place against the special enemy of that place would be insufficient against the enemies to be found in another place. But the *Acenas* belong to the *Rosaceae*, which include such large families as the *Roses*, *Brambles*, *Potentillas*, &c., and the same difficulty about the spines meets us in other members of the tribe, especially the *Roses*.

DIERAMA (SPARAXIS) PULCHERRIMA PENDULA AT MOUNT USHER.

Every Rose is more or less protected with thorns and prickles, and each species is almost as much distinguished by its thorns, their shape, and number, as by its flowers, and leaves, and fruit. And speaking of *Roses* and the family of *Rosaceae*, I cannot pass by one very special puzzle. It is a distinctive mark of the whole tribe to have flowers with five petals, whether they are *Roses* or *Brambles* or any other genus. But there is one very curious exception in the *R. sericea* of the Himalayas, which has only four petals. Very rarely a flower may be seen with the normal five petals; but the rest have four petals only, and I believe no vestige of a fifth can be found. This peculiarity can scarcely be put down to anything in the climate or situation because there are many other *Roses* in the Himalayas, all five-petalled. And, speaking of the *Brambles*, I have recently noted a feature in one of the species which can scarcely, perhaps, be called a puzzle, but which I think worth noticing. The dainty little *Rubus japonicus tricolor* dies down in the autumn, but in March it sends up branches of young shoots which are of a deep blood-red colour. As these grow on, the leaves

Additional text from the image, appearing to be a continuation of the article or a separate note, discussing the characteristics of the *Rubus japonicus tricolor* and its young shoots.

A GROUP OF MR. GABRIEL'S ZONAL PELARGONIUMS (WINTER).

become a pale green mottled with pink and white, and then in the autumn the fading leaves put on the same deep red colour that they had in the spring.

I observe the same thing in a shrub of quite a different family, the *Eunonymus alatus* from Japan and other parts of Asia. In the autumn the leaves become of a most lovely rose colour, making the bush at that time one of the richest in autumnal tints; and now I notice that the young shoots are thickly studded with leaf buds of exactly the same beautiful rose tints. This is probably the case with many other plants, but I had not noticed it, and I think it worth noticing, for it seems to me to link together in a very pretty way the two ends of the plant's life; the first childhood of the plants leading to vigorous life, with the second childhood leading to senile decay, just as Wordsworth wished his "days to be joined each to each in natural piety."

One more puzzle, and I have done; for I only wish to point out from a few well-known plants the puzzles which may be found in infinite variety in every plant that grows. The Fuchsias form a family of shrubby plants, which I very much admire, and grow many of them, as being most useful for flowering in the autumn. They are, nearly all of them, from South America and the Andes, and none have been found in Europe, Asia, Africa, or Australia. But two species are found in New Zealand, and it is in these two species that the puzzle lies. It is a distinct genuine mark of all the South American and Andean species that the leaves are opposite, but in the two New Zealand species the leaves are alternate. Now why should these two New Zealanders insist on being unlike all their relations? What advantage comes to them from it, or what is there in their surroundings or climate that makes the difference essential to their well-being? I cannot say, but it was long ago noticed that the products of Australasia had a habit of being alike, yet markedly unlike, their relations elsewhere; so that an early writer described it as a country where "the barometer rises before bad weather and falls before good; where the swans are black and the eagles

are white; where an animal between the squirrel and the deer (the kangaroo) hops on its tail; where the mole lays eggs and has a duck's bill; where the (apparent) Pears are made of wood with the stalk at the broader end; and where the Cherry grows with the stone on the outside." I must leave the New Zealand Fuchsias in this strange company without attempting to account for their peculiarities.

It was not my intention to explain, or try to explain, any of the puzzles which I have noted in this paper, but simply to show that the garden is full of them, and that a gardener who thinks he knows all about his plants is very much mistaken, and that the better state, and the state more likely to lead to a fuller knowledge of plant life is the state of *docta ignorantia*, the knowledge that you are ignorant. Guesses at the answer to the puzzles are good, provided they do not claim to be proofs; they may be the first steps to proofs, but they very often are the first steps to a long series of errors for—

"Men may construe things after their fashion,
Clean from the purpose of the things themselves."

Many and sweet are the uses of a garden. It is at different times a delight, an interest, a friend and a companion, always changing yet always the same. But it is also a teacher, and a teacher of the most winning kind, for it makes no fuss or noise in its teaching, and compels no one to learn but those who are willing. To them it gives every help; book after book it opens for them, which they may read or not. It opens the book of the Primrose, and to the many it is nothing more than a yellow Primrose, but a Darwin passes by, and he reads the book through and through, and he reads between the lines and learns from it some of the mysteries of the cross-fertilisation of plants. I can lay claim to nothing like that, but I have learned much from my gentle teacher, and the best lesson I have learned is the lesson of my own ignorance; and I take to myself the lesson which was long ago sent to Esdras—"Thine own things and such as are grown up with thee thou canst not know; and the more thou searchest, the more thou shalt marvel."

U. N. ELLACOMBE, in *The Pilot*.

TROPEOLUM SPECIOSUM.

"STROUGHTON HOE" asks for details regarding the culture of the Flame Nasturtium. The best plan is to procure tubers which are long and thin and much like the roots of the great Bindweed in the spring, and lay these in cocoanut fibre in a shallow box. Then sprinkle the fibre with a fine rose water-can and stand the box under glass. The tubers will soon show growth, and as soon as this is apparent the box should be placed in a shady position in the open. Sites should now be prepared for the reception of the tubers, holes 18 inches deep and 2 feet in diameter being made and filled with leaf-mould and peat mixed with road grit. These holes should be situated where little or no sun falls upon them, as in the south, strong sunlight falling upon the lower portions of the stem and the soil covering the roots of this *Tropaeolum* generally proves harmful, though in Scotland it grows like a weed in any position. The upper portions of the growth enjoy the fullest sunlight, and the best examples to be met with in the southern counties are usually those which have been planted beneath evergreens, such as Yews or Rhododendrons, which, while keeping the roots and lower portions constantly shaded, allow the sunshine to have full play on the shoots which emerge through their foliage and are glorious in their vermilion colouring through the summer. When the tubers have made from 4 inches to 6 inches of growth they should be carefully removed from the box, together with the fibre adhering to their roots, and planted in the prepared sites. The soil should never be allowed to become dry, and should have copious supplies of water, which soon percolate through the porous compost. *Tropaeolum speciosum* is also readily raised from seed.

S. W. FITZHERBERT.

THE INDOOR GARDEN.

ZONAL PELARGONIUMS IN WINTER.

HEREWITH enclose some photographs of my zonal Pelargoniums which perhaps might be of some use to you. I think it may also interest you to know the way in which I treat the plants. Good strong cuttings are taken in the month of February and potted in the ordinary way in small pots and kept on the shelf in the greenhouse until they are struck, being careful to keep them on the dry side. When struck they are potted separately into 3-inch pots and put back on the shelf and left there till the pots are well filled with roots. They are then potted into 5-inch pots and kept in the greenhouse till the beginning of August, when they are set out on an ash-bed in the garden in a good sunny position, the flowers of course being kept pinched off the whole summer. Then at the beginning of September they are put back into the house where they are to bloom and occasionally fed with weak manure. They will then commence to throw up fine trusses and continue to give a magnificent display of bloom throughout the winter till the cutting time comes again. I consider the secret of success in growing these plants is to be very careful in watering and to keep the atmosphere as dry as possible. I had the photographs of the single heads taken exactly life-size, and if you measure them you will notice that several of the pips are just on 3 inches across.

C. B. GABRIEL.

Easdale, Horsell, Woking, Surrey.

[We thank Mr. Gabriel heartily for sending photographs of flowers so bright and useful in winter as these, and those present at one of the recent meetings of the Royal Horticultural Society will remember with pleasure the brilliant and varied colouring of the flowers in the November light of the Drill Hall. Many readers would, we feel sure, be glad to have the names of the varieties grown by Mr. Gabriel, and the colours of the flowers.—Ed.]

BRUNFELSIA CALYCINA.

We received some time ago a photograph from Mr. J. Tutchter, of the Botanic Gardens, Hong

Kong, under the name of *B. ramosissima*, and, according to some authorities, this should be the name for the so-called species of *Brunfelsia* or *Franciscea* cultivated in gardens as *calycina*, *confertiflora*, *pauciflora*, *lindeniana*, *macrantha*, &c. These may be distinct enough for garden purposes to require distinctive names, but botanists call them all forms of one species, and that one, according to the most recent decision at Kew, is *B. calycina*, the type of which is shown in the *Botanical Magazine*, 4583 (1851). So far the names. With regard to the horticultural merit of the genus one may say that it is considerably greater than is now recognised. There are several beautiful bushes of the form called *macrantha* in the Mexican house at Kew. They are planted in the borders, and receive no more attention than a common Laurel in the open air, yet they grow and flower most profusely every spring. The leaves are not unlike those of the Pontic *Daphne*, whilst the flowers in shape, size, and colour are similar to those of *Achimenes longiflora*; in other words, they are nearly 2 inches across and of a rich purple-blue colour. It is evident from the photograph that in Hong Kong this *Brunfelsia* is a shapely free-flowering shrub. Twenty or thirty years ago big specimens of *Brunfelsia*, or *Franciscea* as they were then called, were familiar objects at our horticultural exhibitions. They are worth a place among present-day popular plants for the warm greenhouse, where they are happiest when treated as above described, that is, planted in a border of loamy soil and kept in bounds by a little timely pinching and pruning.

TREES AND SHRUBS.

LIBOCEDRUS BIDWILLII.]

IN a note on *Libocedrus macrolepis* in THE GARDEN of August 16 last, "H. P." says "the only thoroughly hardy member of the genus is *L. decurrens*," and he mentions *L. doniana* from the North Island of New Zealand as being too tender for outdoor cultivation, but he makes no reference to the other New Zealand species, *L. Bidwillii*, from which I infer it is not well known if it has been introduced into England. This surprises me, as it is very well worth growing, and should prove quite hardy in at least the south of England. In this neighbourhood it formed the greater part of the "bush," now alas! almost entirely destroyed, on the upper slopes of Mount Carzill, a hill which rises to a height of nearly 2,300 feet to the north of the town. It is a much hardier tree than *L. doniana*, and, in the situation referred to it flourishes, notwithstanding its complete exposure to not infrequent snowstorms brought direct from the South Pole by "southerly busters" during the winter. Though naturally the trees did not descend below 1,000 feet from the summit, if, indeed, they came so low, they proved easy of cultivation at lower levels and of more rapid growth than most of the New Zealand forest trees, though that is not saying much, as the growth of most of our conifers is extremely slow. One which I have in my garden, and brought when about 6 inches high from the hills over twenty-five years ago, is a handsome columnar-shaped tree some 15 feet or so in height. It was planted in a poor piece of ground that had never been dug, otherwise its growth would probably have been more rapid. It never attains a very large size, though it yields a durable timber, which was formerly valued for fencing, and at one time was used for making

Venetian blinds in lieu of the Californian redwood, which it resembles in colour. Its distinct habit should render it a desirable acquisition in any collection of coniferae.

Dunedin, New Zealand. A. BATHGATT.

TRANSPLANTING LARGE TREES AND SHRUBS.

MANY landscape gardeners and landowners when laying out new gardens or parks plant the largest sized trees and shrubs they can obtain from the nurserymen, with the idea of minimising, as far as possible, the appearance of "newness" which such places must necessarily have when first planted. Needless to say, those who follow this rule have to pay for it—often in more ways than one—and in many cases much time and money would be saved and far more gratifying results obtained by planting younger, free-growing, though smaller plants. The one great objection to planting

ZONAL PELARGONIUM BARBARA HOPE. (Natural size of flower, 3 inches across.)

"big stuff" is the difficulty of getting it with large balls of earth attached to its roots, and, unless large trees and shrubs have such, they had better be left severely alone, especially if they have to travel any distance before being planted. On the other hand, when trees and shrubs can be removed and planted with the necessary sized balls of earth around their roots, the result is such as to justify the extra expense, for new plantations can be made to appear many years older than they really are without the risk of losing a single shrub. As one can hardly expect to get plants of this description from nurserymen, the practice of planting large trees and shrubs can only be carried out on an estate or in a park where plantations and shrubberies may be thinned out by transplanting from one part to another, and during the winter months there is no work in connexion with the garden more interesting and fascinating than that of transplanting large trees or shrubs.

It sometimes happens, in carrying out an improvement on an estate or in a park that some good trees or shrubs have either to be removed or sacrificed. Of course, if they are young they can easily be transplanted, but if they are over twenty years of age the difficulties are very much increased, as a tree of this age necessarily requires a large ball of earth around its roots if it is to be successfully removed. To undertake the removal of such trees it is almost essential to have a tree-lifting machine of some description, otherwise the risks are very great.

There is nothing more destructive to young and beautiful trees than a rapidly growing town, where whole plantations are ruthlessly destroyed to make room for roads and the various necessities of a town. The authorities in towns of this description might do worse than follow the example of the Cardiff Parks Committee, who four years ago—taking into consideration the number of estates that were being laid out for building purposes and the consequent destruction of numerous young trees—decided to construct a tree-lifting machine of a very simple character, with which they could remove and save trees that would otherwise have been destroyed by the builders. Such a machine capable of lifting ten tons was made by our own smith at a cost of very little over £30. It simply consists of a framework of steel girders and bars bolted together and fixed on iron wheels, with a compound iron pulley suspended at each of its four corners, each capable of raising three tons. It is by means of these pulleys that a large tree with a ball of earth attached to its roots is raised out of the ground and placed on the machine. Every bar and girder can easily be taken apart, and the front and back wheels are detached from the frame by simply removing a couple of bolts, thus making it an easy matter to place the machine around the tree that has to be transplanted.

Several trees ranging from twenty to sixty years of age have been removed from different parts of the town each winter since we have had the machine, but I cannot say that the removals have in all cases been nearly as successful as I should have liked, for, unfortunately, a series of droughts has been experienced in this district for the last few years, and these have not given the trees anything like fair play. The trees found to suffer least are those between twenty and thirty years old, and I consider it is hardly worth the risk to transplant a tree much over thirty-five years of age. W. W. PETTIGREW.

(To be continued.)

THE ROCK GARDEN.

ROCK GARDEN-MAKING.

V.—MORE ROCK BUILDING LESSONS FROM NATURE.

PART III. of these essays, in THE GARDEN of November 29, pages 378 and 379, illustrated the exceedingly bold character of granite or other rocks belonging to the igneous class. The illustration there given in connexion with rock garden geology depicts a scene which illustrates the way in which Nature has piled up bold masses of granite rocks. The picture admirably explains the geological principles on which these rocks were formed by Nature, but these rocks are on such a scale that in making a rock garden in our gardens it would be impossible to reproduce anything a

hundredth part the size of those depicted. Though conveying a lesson, therefore, with regard to the natural disposition of igneous rocks that illustration could never be taken as an actual pattern in rock building.

In the last chapter (Part IV., see THE GARDEN, December 27) I explained one method of building rocks with stones of the igneous class by giving four illustrations from photographs of such work taken at different stages, but all during the same week. It stands to reason that such work depicted immediately after planting cannot show that wild natural charm which another season's growth would have imparted to it. Even the illustration representing the completed

work may be said, therefore, to be, to some extent, still incomplete. But since the art of rock building cannot possibly have a better exponent than Nature herself, I have thought it best to give still another example from the works of Nature in the shape of the accompanying illustration. This, like the illustration on page 378, was prepared from a photograph taken among the granite rocks of St. Michael's Mount, Cornwall. But while the previous picture (page 378) gives the idea of majestic grandeur utterly beyond our reach as far as rock garden-making is concerned, the present illustration shows how among the same rock formation scenes of charming simplicity may occur, such as

would not only be fascinating and picturesque in the extreme, but which—owing to their simplicity—might easily be imitated or reproduced in gardens, not in every detail, to be sure, but in principle.

When making a rock garden the rocks must not be continuous, but should be irregularly disposed with pieces of green sward or other forms of vegetation intervening between the groups of rock or between singly scattered boulders.

Artificial rock gardens generally err through being too pretentious, too massive, or too continuous. Instead of putting all the stones at our disposal, when constructing rock gardens, into one continuous mass, we should, as Nature teaches us, divide and sub-divide them. This will not only enable us to spread them over a much larger area, thus making the rock garden look larger than it really is, but it will give additional charm to our work from the fact that the result will be more in accordance with Nature, and hence more picturesque.

In the picture here given it will be noted that large boulders of rock form the background. In an artificially constructed rock garden such large boulders weighing many tons are seldom available; but we may build—and build successfully—what would appear as large boulders by skilfully combining many small stones in such a way as to look as though they really formed a huge single block. To accomplish this successfully the stones must be fairly large, and as varied as possible with respect to shape, whilst as regards colour they should be as nearly as possible of the same hue.

If in joining such stones it is absolutely necessary to use cement, this must be done in such a way that

no trace of cement can ever be discerned after the work is completed. I find as a rule that—except for the interior of caves or similar places—cement may be almost dispensed with.

If the rocks were built on a solid foundation, and if, therefore, there is no danger of a settlement which may cause the joints to crack, it might sometimes be advisable, in order to make apparently large blocks of rock, to fill some of the joints with cement coloured to match the stone, but in the great majority of cases small stones and ordinary soil will answer the purpose far better, and if small Sedums, Saxifrages, Thymes, Sempervivums, &c., are put in simultaneously with such

A NATURAL ROCK GARDEN WHICH MIGHT BE IMITATED IN OUR GARDENS. NOTE THE CROPPING UP OF THE STONES THROUGH A MASS OF GREENERY.

small stones and soil they will soon grow and obliterate every trace of a joint between the stones much more effectually than cement or mortar of any kind.

In looking again at the illustration it will be noticed how exquisitely the stones were grouped by Nature. In the background the rocks boldly assert themselves. In the centre they form irregular clusters more or less hidden by an intervening carpet of flowers and greenery, while in the foreground they are still more scattered, peeping above the surface only here and there, but indicating or suggesting masses of hidden rock beneath the surface. It is precisely this principle of "suggestion" rather than "obtrusion" which in the making of rock gardens is not practised so much or so advantageously as it might be. Our rock gardens are not sufficiently broken up or varied, and are therefore often not sufficiently natural to ensure that certain indescribable charm which fascinates us when admiring the rocks of Nature. The plants shown in the picture are mostly *Statice*, *Silene*, and *Armeria*.

Elmside, Exeter.

F. W. MEYER.

(To be continued.)

SOME LITTLE-KNOWN HOLLIES.

As a supplement to the admirable article on the common Holly and its varieties, a few words concerning some of the lesser known but desirable species may be of interest. There are several New World species, including the deciduous kinds formerly known as *Prinos*, but in this country at least their ornamental qualities are not great, and

the American representative of the common Holly, known as *Ilex opaca*, is greatly inferior to its European relative. Eastern Asia, however, contributes several species, some of which are very desirable. One of the best is *I. cornuta*, a native of China, which has been grown in this country for over half a century, but even now it is rarely met with. This naturally forms a dense rounded bush, whose limit appears to be about 6 feet in height and as much through. The leaves of this form a particularly striking feature, being about the size of those of the common Holly, and, like it, harsh in texture. They are, however, of a light shining green, while the arrangement of the spines is

noticeable. They are large, and three of them are disposed at the end of the leaf, the centre one being turned down, thus giving to the apex of the leaf a singular horned appearance, hence the name. A larger and a smaller spine occur on either side of the leaf in close proximity to each other. It is a plant of rather slow growth, but in gardens of limited extent this is by no means a disadvantage.

Ilex crenata.—An extremely pretty little Japanese species that forms a dense bush, clothed with dark green lance-shaped leaves, at most an inch long and frequently much less. The branches are rather short and particularly rigid; indeed, it is of such a sturdy growth as to suggest a good hedge plant if it were taller, for here the height of 4 feet is rarely

exceeded, though Professor Sargent tells us that in Japan it sometimes reaches a height of 20 feet, and then forms a Box-like tree. There are two well-marked varieties—*Fortunei*, with leaves much rounder than those of the type; and *variegata*, in which they are irregularly mottled with rich golden-yellow, which is in strong contrast to the dark green of the rest of the leaf. Unlike all other members of the genus, this little Holly strikes readily from cuttings, but despite this it is not a favourite with nurserymen, probably owing to its slow growth.

I. latifolia.—This is widely removed with regard to size from the preceding, as the leaves are the largest of any of the Hollies, being sometimes 8 inches or 9 inches long. They are bluntish ovate in shape, serrated, and of a deep shining green on the upper surface. At a little distance where the serratures are not visible this, from a foliage point of view, bears a considerable resemblance to the evergreen *Magnolia grandiflora*. *I. latifolia* attains a height of 20 feet to 30 feet (in Japan twice that size is reached). Its foliage is sometimes seared by sharp frosts, but at least in the south of England it may, generally speaking, be regarded as hardy. It is frequently met with as *I. laurifolia*.

I. integra.—Another Japanese species, which in general appearance bears a considerable resemblance to a spineless form of the common Holly; indeed, it is sometimes met with as *Ilex Aquifolium* Bessoni.

I. dipyrrena.—A very ornamental species from the Himalayas, which is, unfortunately, rather tender, except in the southern part of the country. It is of upright, tree-like growth, reaching a

height of a dozen feet or more, while the leaves are very handsome. They are about 4 inches long, ovate-lanceolate in shape, sharp pointed, and with very prominent serratures. The veining on the upper side of the deep green leaves is very noticeable.

I. rotunda.—In Japan this species is said to attain tree-like dimensions, 30 feet to 40 feet in height, but the specimens I have hitherto met with in this country are comparatively small. The leaves are roundish ovate, entire, and of a deep shining green.

Of the strictly tender species the finest is *I. insignis*, a native of the Himalayas, and the most interesting from an economical point of view *I. conocarpa*, as from the leaves of this the Paraguay Tea is prepared.

Without claiming for any of the above that they are superior or even equal to our own native Holly, they are all beautiful, and well worth the attention of planters. T.

COLOURED PLATE.

PLATE 1261.

TEA ROSE LADY ROBERTS

FEW Roses of recent years have created greater stir than Lady Roberts, which has been frequently exhibited by the raiser, Mr. Frank Cant, Braiswick Nursery, Colchester. It is almost needless further to refer to it, as it has been described on many occasions, and its beautifully shaped, warm apricot-coloured flowers have attracted much attention at all the shows where the variety has been exhibited this year. That it is a good Rose for autumn is proved by the bunch shown by Mr. F. Cant at an October meeting of the Royal Horticultural Society in the Drill Hall. It is a delightful Rose, beautiful in colour, sweetly scented, and the growth is strong and free. A Rose for all gardens.

ROSE GARDEN.

A PLEA FOR HYBRID PERPETUAL ROSES.

IT seems almost incredible that this beautiful group should need anyone to plead for it. But so it is. The tendency of the present day is to plant Roses for their effect in the mass, and for this purpose few of the Hybrid Perpetuals are suitable. But sooner or later I am afraid there will come a revulsion of feeling against this fashion. Many would-be planters, seeing for the first time fine bunches of the decorative Roses, are, I fear, often disappointed with the somewhat insignificant blooms when seen upon a solitary plant, and to plant in large masses is not always possible. Much as I cherish the Teas and Hybrid Teas, I cannot ignore the great value of the true Hybrid Perpetuals. It may be that as a class they are wrongly named, that many of them should be grouped with the Hybrid Chinese (another misnomer), and that many are dull and uninteresting, yet from the 2,841 varieties M. Leon Simon and M. Pierre Cochet enumerate in their "Nomenclature de tous les

Noms de Roses," published in 1899, I think I could select sufficient variety to make any garden beautiful and fragrant with Roses were all the Teas and Hybrid Teas entirely banished. Nothing is further from my intentions than to attempt to depreciate in the least the merits of these latter groups. They have become deservedly popular, and their exquisite colours are indispensable; but where is there a flower among them to compare to a perfect specimen of Mrs. John Laing, A. K. Williams, Marie Baumann, or a Charles Lefebvre, that has such gorgeous colour and delicious fragrance?

Admitting that the Hybrid Perpetuals as a class do not flower well in autumn, can we afford to dispense with their summer glory? I say decidedly "No." As well might we banish the Rhododendron, the Syringa, the Philadelphus, or any other hardy shrub, because they only flower for a brief season.

If anything has tended to render the Hybrid Perpetual unpopular it has been the formal method of exhibiting the flower at the great Rose shows. Let the more natural style obtain, such as the fine vases of Jeannie Dickson and Captain Hayward at the last Temple show, then will the Hybrid Perpetual be in the ascendant. Still further would I urge upon schedule makers to encourage the natural style of exhibiting this group, I mean with all the lovely buds attached as cut from the bush.

shown; not, of course, huddled together in a market bunch, but arranged with good effect, for this, I think, is quite possible. Never mind about size. We can well dispense with that. Let us have perfection of form, brightness of colour, and a natural arrangement.

There is a common saying that "Old friends are best." Are we wise in discarding so many of the Hybrid Perpetuals as seems compulsory to keep pace with the great influx of Hybrid Teas? I can recall when a boy passing many times by the house of John Hopper, and I well remember with what awe I gazed upon the dwelling, knowing it to be the domicile of one who has been rendered almost immortal by the old favourite Rose. And to-day what have we more beautiful than a really well-grown specimen of this beautiful flower?

I was recently looking through Mr. William Paul's "Rose Annual for 1860-61" (and, by the way, one could wish such an interesting annual were published now), and I found there tabulated names of certain Hybrid Perpetuals that were most popular at the exhibitions of that year: such varieties as General Jacqueminot, Lord Raglan, Mme. Vidot, Mme. Knorr, Mme. de Cambaceres, Jules Margottin, La Reine, and Comtesse de Chabrittant were the favourites.

But to-day how many of them are grown? Yet I question if we can produce a more perfectly formed Rose than the last-named, or one more brilliant and better generally than the first. Julie Louvars is a variety if shown now as a novelty would probably be awarded a gold medal, a somewhat empty honour, considering so many good Roses have not received this award.

I have never been pessimistic regarding the Hybrid Perpetual race. I know it has been said that these Roses are played out. But what about Frau Karl Druschki or Ben Cant, two recent varieties of merit? It is not the group that is played out, but rather that hybridists have neglected it. They have nearly all been working in one direction, for Hybrid Teas, and I think honour is due to the few who have diverged from the beaten track. If Victor Hugo and Suzanne Marie Rodocanachi can give us a Ben Cant surely we may reasonably expect some great results in the near future from similar happy unions.

It is, and perhaps always will be, a moot point as to which are Hybrid Perpetuals and which Hybrid Teas. A cross between Merveille de Lyon and Caroline Testout, resulting in Frau Karl Druschki, is termed a Hybrid Perpetual, yet a cross between Lady Mary Fitzwilliam and Eugene Furst, which resulted in Marquise Litta, is termed a Hybrid Tea. I certainly think this latter should go with the Hybrid Perpetuals. When we remember the parentage of Caroline Testout (Mme. de Tartus x Lady Mary Fitzwilliam) it seems clear that this possesses more of the Tea blood, and consequently is correctly grouped with the Hybrid Teas. I merely mention these instances as showing how much we need a new classification. I would suggest that the matter be carefully considered, placing all Non-Perpetuals as "summer flowering Hybrids," and those that

are really Perpetual, grouping these as "Perpetual flowering Hybrids," sub-dividing the latter into two groups of "decorative" and "non-decorative."

It is a mistake to attempt to obtain large bushes. My advice is to

HYBRID PERPETUAL ROSE BARONESS ROTHSCHILD.

If an artist be asked to paint or draw even a Hybrid Perpetual he would not depict the flower in the severe unnatural style of the exhibitor, but would represent its buds in all stages of development, and so in my opinion this group should be

PRUNE HARD.

I do not mean to say shorten the new wood unreasonably, but cut away all wood over three years old, and reduce the annual well ripened, non-pithy wood according to vigour; those shoots most vigorous retain 12 inches to 18 inches in length, and those of moderate growth prune back to within 3 inches to 6 inches of their base or of last season's pruning. One is often asked what should be done with long pithy-looking growths that spring up late in the season. I say allow them to grow, for they are assisting in the formation of roots, but in spring cut severely back. Remove all worn-out wood, and free the centres of small shoots. Three or four, or less, well hardened shoots are better than a dozen unripened or thin twiggy growths. Plant closely, then this severe pruning leaves no great gaps, and one is rewarded with handsome blossoms equalling show blooms. The uses to which the Hybrid Perpetuals may be put are manifold. They make splendid wall Roses of moderate height, and might be planted with advantage to hide the bare stems of a towering Gloire de Dijon. For

FENCES

they are excellent. Then what grand free-headed standards many of them make. There are no anxious moments when we are visited with a winter as is the case when Teas predominate. I would recommend the more moderate growing sorts as low standards, then their somewhat stumpy appearance is not accentuated. As

PILLAR ROSES,

rising 4 feet to 6 feet in height, the Hybrid Perpetual race gives us many suitable varieties. Who can refrain from admiring a well-flowered pillar of old Jules Margottin, with its exquisite buds and fragrant blossoms? I do not know whether our great Rose amateur Dean Hole has had cause to modify what he wrote concerning this Rose in his excellent and humorous book, when he said, "I would rather that a pyramid of its sweet bright flowers bloomed above my grave than have the fairest monument which art could raise."

HEDGES

formed of strong-growing Hybrid Perpetuals are also a pleasing feature of the garden. For this purpose Mme. G. Luizet, Clio, Heinrich Schultheis, Ulrich Brunner, Crimson Queen, Mrs. John Laing, and Ella Gordon are really first-rate. In their case it is advisable, in order to encourage young shoots, to cut back to the ground one or two growths each season. Then as

POT PLANTS

for the unheated greenhouse these Roses are indispensable. Here we can produce their stately blossoms to the highest perfection, and although they have not the graceful habit of growth of the Teas, yet they make amends for this by their ample foliage and brilliantly fragrant flowers. For all who possess a deep, somewhat heavy soil, I would commend the Seedling Briar as the best stock for this group. The advantages will be manifest in the autumn by a more abundant blossoming if suitable varieties are employed. The Manetti and Briar cutting stocks are best for shallow soils, always providing that the point of union is placed 2 inches below the surface. Most of the Hybrid Perpetual Roses

ROOT READILY FROM CUTTINGS.

The irregular production of new growths from such plants is a characteristic trait of much value, which should not be lost sight of, as by this we are enabled to have their flowers for a much longer season. As to

VARIETIES,

exhibitors will find the catalogue of the National Rose Society a good guide, but as these remarks are addressed to non-exhibitors I venture to submit a selection of fifty sorts which I can thoroughly recommend as being the pick of the collection, combining most of the good points of the group:—Alfred Colomb, A. K. Williams, Beauty of Waltham, Ben Cant, Captain Hayward, Charles Lefebvre, Clio, Comte de Raimbaud, Crown Prince,

Dr. Andry, Duchess of Bedford, Duke of Albany, Duke of Connaught, Duke of Edinburgh, Dupuy Jamain, Ella Gordon, Etienne Levet, Eugene Fürst, Fisher Holmes, Frau Karl Druschki, General Jacqueminot, Gloire de Margottin, Heinrich Schultheis, Helen Keller, Jeannie Dickson, Lord Macaulay, Louis van Houtte, Mme. Eugene Verdier, Mme. G. Luizet, Mme. Victor Verdier, Mlle. Eugénie Verdier, Marchioness of Lorne, Marie Baumann, Marquise de Castellane, Merveille de Lyon, Mrs. Cocker, Mrs. George Dickson, Mrs. John Laing, Mrs. R. G. Sharman Crawford, Paul Neyron, Pride of Waltham, Prince Arthur, Prince C. de Rohan, Sénateur Vaisse, Suzanne M. Rodocanachi, Ulrich Brunner Fils, Victor Hugo, and Victor Verdier.

PHILOMEL.

RECENT PLANT PORTRAITS.

The first part of the *Revue Horticole* for November contains a portrait of two varieties of climbing Clerodendron which require the temperature of a warm house for their successful culture. They are C. Balfourii, with bright scarlet flowers, each of which is surrounded by a pure white involucre or enlarged calyx, which forms a most charming contrast with the flower, and C. splendens, with numerous flowers of a dull shade of scarlet.

The second part of the same publication for November figures *Clematis tangutica*, a variety with yellow flowers shaded at the bases of the petals with light brown, a form of C. orientalis. The first part of the same publication for December has a portrait of *Daphne Verloti*, a pretty small-flowered variety with rosy purple flowers. The second part of the *Revue Horticole* for December figures *Rhododendron hybridum* Mme. Jules Porges, which is an apparently very handsome and free blooming variety.

The November number of the *Revue d'Horticulture Belge* figures *Begonia double var. Marmorata*, one of the tuberous-rooted section, with large and handsome flowers of a pure white ground, heavily and evenly marbled, and edged with bright orange-red, raised by M. C. Vermeire, and *Dahlia decoratif Les Alliés*, a handsome and curious fully double flower, reddish purple, heavily striped with white in the centre, and a deep rose colour on the outside half of the flower. The December number of the same publication figures on a double plate a large yellow incurved Japanese Chrysanthemum, named *M. Lequernay*, raised by M. Nonin of Chatillon, near Paris.

W. E. GUMBLETON.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

THE HORTICULTURAL HALL.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Some of your correspondents, in view of the generally-felt dislike to the published plans, ask why the design was not offered for public competition. Possibly they may not be aware of the difficulties that arise when this is done; difficulties that would probably be quite beyond the control of the present committee. It requires a committee of unusual strength to face the hydra-headed complications that arise from a competition.

ONLOOKER.

WHERE BRACKEN GROWS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—On page 410 of THE GARDEN last year I see that "Bracken is an unfailing indication of a poor, dry, sandy soil." Will you allow me to question this statement so far as the West Highlands are concerned? We grow Bracken in Argyllshire which is not to be beaten anywhere, and often

runs to 8 feet in height. The great question which is troubling sheep farmers is how to keep the plants down; get rid of them you cannot. But invariably wherever you find the finest Bracken, there also you will find the best soil. The poor, sandy, dry soil produces nothing worth talking about. I have personally grubbed up a good many hundredweights of Bracken roots in the last twelve months when making a new garden, and can say, with Ingoldshy, "Believe one who's tried." True, Roses do not thrive very well, although I can grow Maréchal Niel and get good flowers, but that is more due to the fierce winter gales than to the want of soil. I have had a Gloire de Dijon on the house in bloom from April to January.

AN OLD OXONIAN.

[The assertion that the presence of Bracken is an unfailing indication of a poor, dry, sandy soil must certainly be based on merely local experience, since, like most other Ferns, it grows all the stronger for liberal treatment, and, in point of fact, is found to attain its finest growth in loamy soils enriched with leaf-mould or mingled with peat, such as we find in forests and woodlands generally. That it also grows in poor soils is true, but there it is usually more or less stunted, and never under such circumstances attains such luxuriance of growth as elsewhere. Our correspondent "An Old Oxonian" is therefore fully justified in challenging the above assertion, and with regard to the remark anent the difficulty of extirpating Bracken we may say that the best way to effect this is, instead of attempting to grub it up, to carefully cut down all the fronds twice or thrice successively when they are a foot or so high. If the fronds are persistently suppressed the roots grow weaker and weaker, and eventually perish entirely, but the operation must be thorough. In this way a garden would undoubtedly be cleared entirely in the second season, if not in the first. Grubbing is the more likely to be as fruitless as troublesome, as the Bracken rhizomes plunge very deeply and travel very far. Newman, indeed, records a depth of no less than 15 feet as having been ascertained, hence it is obvious that the mode above suggested is at once easier and more likely to be effectual.—ED.]

THE FRUIT GARDEN.

SOME GOOD MELONS.

I N those gardens where Melons are grown (and who is the gardener that does not cultivate these delicious summer fruits?) there is often much time spent in endeavouring to make a selection of useful and satisfactory varieties. With the Melon it is most essential to choose one's varieties with care, for there is perhaps no fruit more disappointing when it is of poor flavour, and few more delicious when the best varieties are grown. There are many who prefer varieties of their own raising, and there is much to be said for the practice of growing only those which are known to be good. At the same time, if one never experiments with other sorts one does not know what may be missed; chances may be lost of greatly improving those varieties the conservative gardener before thought to be impossible of improvement. To those interested in Melon growing, and who, while having great faith in their own powers, are sufficiently liberal minded to try the productions of other raisers, the following notes are offered in the hope that they may serve as a reliable guide amongst the almost innumerable Melons now in cultivation. The varieties are divided into three classes, namely, those with green, scarlet, or white flesh; the following may be relied upon for growing in a house, pit, or cold frame:—

GREEN-FLESHED VARIETIES.

Royal Jubilee.—Handsome large fruit of good flavour and fine depth of flesh.

Windsor Castle.—A large oval-shaped fruit, finely netted, and of rich and delicious flavour.

High Cross Hybrid.—An excellent old green-fleshed variety.

Eastnor Castle.—Still one of the best. Flesh deep green of great depth and delicious flavour.

Gilbert's Victory of Bath.—An old variety of sterling merit.

Middlesex Hero.—A fruit of medium size and of the highest quality and flavour.

Dickson's Exquisite.—This is well named, medium to small in size, free cropper, and certainly one of the best-flavoured Melons known.

Earl's Favourite.—A very promising new variety of exquisite flavour.

The flavour of the green-fleshed Melon I consider richer and more luscious than either the scarlet or white-fleshed varieties, but not so sweet and refreshing as the white, neither is the flesh so firm and satisfying as is the flesh of scarlet varieties. In one respect the green-fleshed Melon suffers from serious disadvantage as compared

one of the sweetest and best, of medium size, prolific, and will keep in good condition for a long time after it is ripe.

British Queen.—This also has a faint tint of green in the flesh. It is one of the handsomest and best. First-class certificate Royal Horticultural Society.

Royal Sovereign (award of merit Royal Horticultural Society).—This is a very handsome Melon of delicious flavour, large size, a heavy cropper, fine for exhibition in collections or for market purposes.

SCARLET-FLESHED VARIETIES.

Blenheim Orange.—Still one of the very best in all respects.

Beauty of Syon.—A variety of medium size, pleasing appearance, and exquisite flavour.

Frogmore Scarlet.—A handsome Melon of oval shape, very deep solid flesh, of rich and exquisite flavour.

Ganton Scarlet.—A new variety of promise.

Scarlet Premier.—A well known general favourite. It is no doubt amongst the best.

Reel's Scarlet Flesh.—An old variety of medium size, and of great excellence.

A. P. II.

THE BARBAROSSA GRAPE.

We have received from Miss Sharp, Riding Mill, Northumberland, a photograph of the large bunched Grape Barbarossa. The bunch shown was exhibited by Miss Muschamp at the Corbridge flower show. It weighed between 7lb. and 8lb., and measured from the top to bottom 18 inches, and the width was 13 inches. There were nine bunches on the vine.

EARLY PEACHES.

IN this house it will be necessary to attend soon to disbudding. Remove a few of the worst placed buds at a time, such as those on the top side of shoots and those that spring from the underside, leaving those that are best placed sideways for future thinning. Always reserve the bud nearest the base of the shoot and the terminal one, as well as those buds where the young fruits are forming. Avoid very hot pipes at night and the consequent arid atmosphere so certain to encourage insect pests. Syringe and damp down walls and floors in proportion to the amount of heat in pipes.

Force chiefly by daylight, and allow the temperature gradually to subside at night so as to give the natural refreshing rest, equally as necessary to vegetation as to humanity. Keep a sharp look out for the first curled leaf, and if the little fruits are not fully and safely set, dust the affected and curled leaves with tobacco powder at once, on the principle that "a stitch in time," &c., and thus hold the fly in check until quite safe to evaporate with XL All, which is an inestimable boon to gardeners. This safe and reliable modern invention is a great advance on the antiquated fumigating with tobacco paper, an operation which has made the writer ill on many memorable occasions.

Madresfield Court.

W. CRUMP.

HARDY FRUITS IN SEASON.

APPLE THE FORGE.

A SMALL consignment of this Apple reached me the other day from a village in the south-east corner of Surrey, and the accompanying remarks may be of interest: "In a season like the present," writes my correspondent, "when Apples are decidedly scarce, the above fully justified the good character it has received as a great and consistent cropper." It is by no means a first-class Apple in quality, although not to be despised when others are not obtainable; the flesh is white, pleasant, and very digestible, and for cooking it is excellent. It is not often found out of Surrey and Sussex, and is most common in the tract of country lying between the north and south downs; standing on Leith Hill on a clear day one can take in nearly the whole of the Forge country. It is not often to be found in fruit catalogues, but I think that Messrs. Cheal of Crawley would most probably include it in their list.

E. BURELL.

ORCHIDS.

CATTLEYA GOLDEN DAWN.

A BEAUTIFUL new hybrid between *Cattleya luteola* var. *Holfordii* and *Cattleya anrea*, which has recently flowered in the collection of Mr. R. H. Measures, The Woodlands, Streatham, is the above-named. It is a flower of perfect shape and charming combination of colour. The sepals and petals are soft primrose-yellow, the sepals stained with a suspicion of red ochre. The petals deepen centrally and especially towards the tips to rich butter yellow. The lip is exquisitely traced and veined, the whole being covered with a delicate network of veins in varying shades of yellow, the interspaces filled with soft magenta-crimson shaded with tawny orange on the front lobe, the edges of which are softened to creamy white, touched and suffused with light magenta. From beneath the column towards the front edge of the lip run three parallel lines of tawny yellow, at the apex of which is a small suffused blotch of magenta. At first sight the flowers of this hybrid strongly resemble those of a deeply coloured *Cattleya Rex*, but the lip is more ornate, owing to the distinctive veining and colouring imparted by the *aurora* parent. In the same collection is a plant of

CATTLEYA LABIATA VERA

with a remarkable dimorphic inflorescence. The stout spike bears two well-shaped substantial flowers, each normal with regard to size and structure, but quite distinct from each other in colour. The left-hand flower is altogether the darker of the two, not only on the sepals and petals, but particularly so on the lip, the front portion of which is entirely of a rich soft crimson, subdued in the throat. The second flower is much lighter, though similar in size. The lip presents the strongest contrast. It is altogether lighter than that of the other flower, the colour being confined to a comparatively small central rayed blotch of crimson with a very broad margin of light magenta. The behaviour of the plant will be watched with much interest next year, as on the last flowering occasion no appreciable difference was noticed in the flowers, while this season they are absolutely distinct. A fine form of

LÆLIA PULCHERRIMA,

a hybrid between *Lælia boothiana* and *Lælia purpurata* was also noticed. The flowers are large, shapely, and of a pleasing deep rose hue, the lip being darker than the sepals and petals, and bearing still deeper veins. A noticeable feature at The Woodlands now is a house of

CYPRIPEDIUM INSIGNE

in full bloom. It contains between 4,000 and 5,000 plants planted out in limestone pockets. Two new varieties may be recorded—Mabel, a true

BUNCH OF BARBAROSSA GRAPE.
(Weight between 7lb. and 8lb.)

with the white or scarlet, that is, in its much less attractive appearance, the skin being generally of a dull green colour, contrasting with the beautiful golden appearance of the white-fleshed varieties particularly.

WHITE-FLESHED VARIETIES.

Frogmore Orange.—This is one of the earliest as it is one of the most handsome, a free cropper, and of delicious flavour.

Hero of Lockinge.—Still one of the most popular and best, and deservedly so.

The Countess.—One of the best.

Davenham Early.—As an early variety this is not so well known as it deserves to be. It is a small Melon, of exquisite flavour, and matures quickly.

The Lady.—This has a tinge of green and pink in the flesh, but still may be legitimately classed among the white-fleshed sorts. In flavour it is

montanum form, a large finely-shaped flower, the dorsal sepal bearing numerous spots, much as in the old *C. insigne* Sylhetense, but the apical half of the dorsal is white, and the spotting is bolder and more distinct, deeper in colour, and highly polished. A milk-white margin makes the spotting more intense. Edgar Cohen is both attractive and peculiar in its markings, the dorsal sepal having the basal and central portions suffused with a deep olive-bronze shade arranged in feather-like flakes. The upper portion is clear white, with a few lilac rounded spots.

*A third variety, *Magnificum*, well deserves the name. It is one of the finest of all. The dorsal sepal has large blackish chocolate spots on a pea-green ground, the white apical area being very solid and pure.

ARGUTUS.

BOOKS.

The Birds in our Wood.*—Though books on country life have been plentiful of late, we think the bird life of woodland and country side has not been overdone, and therefore we welcome heartily this elegant volume. The more familiar birds are illustrated in colours, and the descriptions are readable and instructive. It is a bright gift book, and one to read many times with profit, a book to present to a boy or girl, who should glean much information from the chatty descriptions. Here is a quotation from the notes about "The Tomtit": "The tomtit is the veriest sancebox of a bird. Several of the titmice are perky in their looks and voices, and the way they move about, but none so full of sauce as he. I used sometimes to spread traps for birds, a brick trap or a corn-sieve from the stable. In winter I caught tomtits, as well as great tits and coal tits. The tomtits did not seem so scared when I put my hand in the trap to take them out as they did angry. They would scold and peck. Once I caught a tomtit and took him up stairs and let him loose in an empty room. He was in a fine fluster, and sat on the floor ruffled and panting. I had some Peas in my pocket, of the sort you use for a Pea-shooter. I took one of them out and tossed it to the tit. It rolled along the floor and stopped near him; he forgot his anger and fear and pecked that Pea once or twice to see if it were good to eat. Is there any other English bird that would do a thing of that sort? If so, I should like to meet him. The tomtit belongs to a family of acrobats. All the tits can haog from the branches of a tree head downwards, and swing themselves from twig to twig without ever losing their balance. But the tomtit seems to me the best acrobat, though the bottletit is good, and so are two with black heads, called the coal and marsh tits. He is a great searcher for seeds. The little ripe seeds of the garden Poppy, which I like to rattle about in the dried Poppy head, are one sort the tomtit cares for. It is a dainty sight to watch several of these sharp little fellows sitting on the Poppy heads in the garden at the end of the summer, and raining down blows with their bills. After a while they manage to make a hole in the hard, dry, Poppy head, and then they soon pick out every seed. If you do not want too many Poppies in the garden next year you should be careful not to disturb the tits when they are eating."

Greenwich Park.†—The author tells us in the preface that "this book is the outcome of a paper read before the Blackheath Natural History Society" in 1901, and that "the publication has been delayed by the discovery of Roman remains in the park, a complete account of which it was considered desirable to include in the work." The history of the park is of more than local interest. A petition was made to Parliament in the reign of Henry VI. "to grant to Humphrey, Duke of Gloucester, and Eleanor, his wife, a license to enclose 200 acres of their land, pasture, wood, heath, vurses, and gorse thereof, to make a park in Greenwich." The park was enclosed with a wooden fence by this same Duke of Gloucester in 1433, and by a wall by King James at a cost of

£2,001 15s. 11½d.; this wall was begun in 1617 and finished in 1625. Mr. Webster has told very pleasantly the history of this breezy park by the Thames side, of the fairs held on its grassy slopes in the olden days, of the trees and shrubs, fanna and flora, fungi, and Roman remains. Mr. Webster mentions John Evelyn "as a frequent visitor, and gave advice to the King in reference to the tree planting in the park," but the author should have added that an equally illustrious visitor, Samuel Pepys, was interested in the planting at Greenwich, for an entry in his diary, April 11, 1662, records the following incident: "Sir William and I walked into the Parke, where the King hath planted trees and made steps in the hill up to the castle, which is very magnificent." The chapter on "Trees and Shrubs" is one of the most important in the book, and the writer is more at home with this subject than in the more historical descriptions. On page 54 it is mentioned that "one of the largest Thorns in this country is growing in the grounds of the Ranger's lodge, a little distance from the Blackheath entrance. It is fully 50 feet high, and over 7 feet in girth of stem."

Gardens Old and New: The Country House and its Garden Environment (Vol. II.)‡—The reception of the first volume of this sumptuous work was so gratifying that the publishers were well advised to bring out as quickly as possible a second volume, embracing a further list of the most beautiful and interesting gardens of the British Isles. This second volume is even more welcome than the first, and the gardens described and illustrated include such famous places as Aldenham House, Balcarres, Castle Ashby, Chiswick House, Compton Wynyates, Cranborne Manor, Drumlanrig Castle, Eaton Hall, Frogmore and Windsor, Haddon Hall, Hampton Court (both in Middlesex and Leominster), Harewood House, Holland House, Longleat, Munstead Wood, Pain's Hill, Parham Park, Penshurst, St. Fagan's, Shrublands Park, and Stoke Edith, over seventy in all, and chosen with rare discrimination, as the brief list we have mentioned shows. The introduction is an interesting contribution to the gardening literature of to-day, and descriptive of the many superb photographic reproductions which adorn every page. The illustrations are not merely a pleasure to the eye, but of great historic interest, showing the various phases through which the English garden has passed during successive ages to the garden of the present day, represented by such pleasant places as Munstead Wood and The Orchards, Surrey. The photographs have been taken by that master of his art, Mr. Latham, and we must

* "The Birds in our Wood." By George Dewar. Published by Messrs. Laurence and Butler, 16, Henrietta Street, Covent Garden, London. Price 7s. 6d.

† "Greenwich Park." By A. D. Webster, Superintendent of Greenwich Park. Published by Henry Richardson, Greenwich, and Simpkin, Marshall and Co., London.

‡ "Gardens Old and New: The Country House and its Garden Environment." (Vol. II.) Published at the offices of *Country Life*, 20, Tavistock Street, Covent Garden; and by George Newnes, 7 to 12, Southampton Street, Strand. Price two guineas.

JOHN EVELYN.

(From "Greenwich Park.")

congratulate the printers heartily for reproducing so splendidly the subjects taken with such skill and knowledge of what makes an interesting, instructive, and beautiful picture. It is not possible for all who love gardening to create such glorious domains as are here represented, but the pictures have a great teaching value and should do much to foster a love for a beautiful and satisfying recreation. The volume is edited by John Leyland, to whom the task seems to have proved pleasantly inspiring if we may judge from the enthusiasm and knowledge we can trace in the lengthy introduction. We shall look forward to the third volume of what is likely to prove the greatest illustrated garden book of this generation.

THE KITCHEN GARDEN.

MUSHROOM GROWING IN GARDEN, FIELD, AND COTTAGE PLOT.

(Continued from Vol. LXII., page 431.)

GATHERING THE MUSHROOMS.

A GOOD deal of the success and duration of the crop depends upon the careful way in which this work is done. The Mushroom should be gathered when it is about three parts grown, usually about 3 inches across. If allowed to become larger than this the quality deteriorates, and useless exhaustion is caused to the bed. At the stalk of the developed Mushroom will be found clustering together a group of three or four tiny Mushrooms more attached to the stem than to the bed. These will never attain to any further size or usefulness, and therefore if in collecting the Mushrooms the stalk be cut with a knife, as is the common practice, what remains of

the stalk in the bed perishes, as well as those tiny embryo Mushrooms, causing more or less decay and sourness. This is inimical to success. It will be gathered from this that I do not advise cutting Mushrooms with a knife. On the contrary, they should be taken hold of by the hand and given a gentle twist, when the Mushroom, the stalk, and all the spent part will come away together, leaving the bed sweet, clean, and in the most favourable condition for encouraging the growth of the succeeding young ones. At this time of the year (October) little or no fire-heat will be required, therefore the house will not dry very quickly; but the bed on the surface must never be allowed to get parched, and if bearing very heavily an application of warm water will be necessary at least once a week and sometimes twice. The paths and walls of the house should be moistened over at least twice a day, but not saturated too heavily. The first crop will remain in profitable bearing from a month to six weeks, and after this is exhausted the bed should be brushed over, clearing away any loose bits of soil there may be on the surface, and given a good soaking of water at a temperature of 85°, to which a little common salt has been added—a small wineglassful to three gallons of water. Shortly after this a second crop should result—not so heavy as the first—it will not last in bearing so long, but will give, however, a satisfactory return. When this is over, as it will be in about three weeks, the bed is then exhausted, and must be cleared out, making room for a succession of beds to be formed one after the other according to the quantity of manure available. The last bed should be formed in the house about the first week in May. After this date the crop is not a profitable one in houses such as we have been considering, on account of the hot weather. After this date until April comes round again they will succeed much better in open sheds or even in the open air. Before considering this shed or open air system of culture I ought to mention a word about

TEMPERATURE AND VENTILATION.

Much depends on the size of the house and the number of pipes it is desirable to fix in order to obtain the maximum of heat in severe weather. As strong fire-heat is at all times injurious, two rows of 4-inch pipes fixed on each side of the pathway, not too near the beds, will be ample. Should the weather prove very cold in the depth of winter, rather let the temperature fall to 53° or 56° than force the fire unduly with the object of keeping the house up to a normal temperature of 60°. The roof must be sealed on the inside with lath and plaster, with ventilators in the apex at distances of 12 feet apart. Little or no ventilation is ever required, and the ventilators are more for the purpose of letting out steam than for the admittance of air.

REASON OF FAILURE.

Failure, from whatever cause it may arise, will not be discovered till the bed has been made and the time has arrived for a crop of Mushrooms. If a crop does not appear, say two months after spawning, the best plan will be to dig a hole in the bed to see whether it is wet or dry or whether the spawn has spread or not. If it is dry and the spawn has partly spread the bed will be all right, and after a good soaking of warm water at a tem-

perature previously recommended a good crop may confidently be expected. On the other hand, should the manure be wet and no spawn appear, then the grower had better make up his mind to turn out the bed at once, as it is useless to expect a crop under these conditions. The cause of the failure in the latter case would doubtless be the too wet and overheated (at one time) condition of the manure, leaving it as it were dead and without any recuperative power. At another time the spawn may be at fault or the quality of the manure; its having been collected from drugged horses may be the cause. However, these failures are the exception and not the rule, and should be no discouragement to the greatly-increased growth of this crop as a commercial undertaking, especially in the suburbs of cities where manure is plentiful and cheap, as it is one of the most remunerative crops of the garden. O. T.

(To be continued.)

GARDENING OF THE WEEK.

KITCHEN GARDEN.

PROGRESS in horticulture has been rapid during the last two decades, and in no department has it been more marked than in the production of high-class vegetables. The requirements of employers are greater in this branch than was formerly the case, therefore to obtain the best results possible the gardener has to give a large share of his attention to it, and to keep the work well in hand the whole year through. Arrears in this department, especially early in the year, are difficult to make up unless abundance of labour is obtainable, owing to the multiplicity of operations requiring attention as the season advances. The locality and the nature of the soil have to be considered before digging or trenching is carried out; in many gardens much of this will already be done. As regards

WET CLAYEY SOILS

I am in favour of trenching 2 feet or 3 feet deep, and it may be done at a later date than is necessary or desirable where the soil is light. In the former case the soil has a better chance of becoming pulverised by turning it up rough when drying

winds are prevalent, whilst light soils may be treated with at any time as opportunity offers. Gardens infested with wire-worm should have a slight dressing of gas lime, and this should be spread on the plot and left for two or three weeks before digging it in, in order to allow the strong gases to pass away and to pulverise the lumps. One of the most important operations is to plan methodically where each crop is to be grown for the season, for it goes without saying that a system of judicious rotation has a deal to do with success in vegetable culture. During spells of

FROSTY WEATHER

advantage should be taken to wheel manure or other matter on to the borders and quarters in readiness for digging and trenching when the weather is suitable. It is, of course, advisable to plan where the various crops are to be grown as early as possible before much manure is wheeled on, for whilst one crop will need a good dressing of farmyard manure, another will require none for this season, or possibly a dressing of charred refuse will be better for certain crops instead of manure.

THE SEED ORDER

should also receive early attention if not already posted. A good deal of forethought is necessary in compiling it, for no gardener is desirous of having to send for seeds frequently, and as seedsmen usually execute orders strictly in rotation, and several kinds will be required for sowing in the present month, it will be obvious it should be posted early. The seed drawers should be cleansed in readiness to receive the new seeds, and any old seeds left over destroyed, or in the case of certain kinds they may be retained for later sowing in the garden after testing their germinating properties in heat.

SEAKALE AND ASPARAGUS FORCING

requires no great amount of skill or elaborate structures to keep up a constant supply. Means should be taken to maintain this by introducing a sufficient number of crowns or roots at regular intervals according to the demand. Rhubarb also may be lifted at fortnightly intervals and placed in the Mushroom house or other structure from which full light is excluded. H. T. MARTIN.
Stoneleigh Abbey Gardens, Kenilworth.

THE FLOWER GARDEN.

FUTURE IMPROVEMENTS.

WITH a view to these the beginning of the year should be made an occasion for a thorough survey

THE COMMON MUSHROOM.

of the flower garden. The past will have taught us many lessons, and probably some of the changes effected will have to be amended. Every year adds some store to our knowledge, and it is possible that through experience gained many things we accomplished during the past year must be done in a different way. Make a note of all the alterations it is desirable to effect; consider what shrubs, trees, or plants should be destroyed to make room for better things to be planted out later on and which you have probably taken a note of during the past year. Do not attempt to remove any plant from one part of the garden to another until the weather is favourable.

NEW FLOWER BEDS.

Where space will admit new flower beds should be prepared for spring planting, and care taken that the bed or beds are dug the proper depth. In the process of digging the soil should be well pulverised. If the ground is prepared in this way several months before planting it will be in much better condition for assisting plant growth.

SOIL.

Should the soil be of a loamy nature it will not be necessary to add anything in the way of manure. On the other hand, should it be tenacious and wet, road grit or finely sifted mortar rubbish or burned soil mixed in with the soil is beneficial. Light, hot, sandy soil calls for contrary treatment, and good holding loam will greatly improve it. Depth of soil is of great importance in the culture of the majority of plants. If shallow and the subsoil is hard the flowers will be comparatively poor and short-lived, especially in dry seasons and localities.

ROSES.

The late autumn and severe weather we had last month greatly retarded planting. Should the weather permit all arrears should be pushed forward with as little delay as possible. All newly-planted Roses should be mulched with half-rotten manure, standards be neatly staked, and all the tender and delicate Teas protected from frost. The common Brackens, when it can be procured, is the best material for this purpose. Never be too lavish with any covering. More Roses are destroyed from being covered too much than too little. Always remember that frost follows damp, so that whatever material is used it should be placed so as to allow a free current of air to pass through.

THE SNOWDROP (*GALANTHUS NIVALIS*).

Every spring we make a note of this favourite, and intend to plant it in the autumn in every available spot. When October arrives (the proper time for planting) pressure of other work prevents our carrying out this promise. Snowdrops need not be removed every year, but once in three years. They should be taken up, the ground manured, and the bulbs planted again. They are so hardy that they can be transplanted with success any time before the flowers are fully expanded.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

FRUIT GARDEN.

VINES.

If late black Grapes are still hanging on the Vines lose no time in cutting and bottling them, as nothing can be gained by allowing them to remain. It is now well known that late hanging is quite as detrimental to the Vines as early forcing. Choose a mild day for cutting, sever the wood just above the pruning bud, leave it the full length beyond the bunch, insert in bottles of clean soft water, and ventilate the Grape room for a few days with gentle fire-heat to dry up moisture which may have escaped during the process of bottling. If the Grape room is properly constructed, and not apt to be affected by sudden fluctuations of external temperature, a mean of 45° or a few degrees lower in severe weather will be quite sufficient for all the black kinds, while Muscats will retain their colour for a greater length of time in a temperature of 50°.

When the Grapes are cut, and pruning, cleansing, and top-dressing finished, throw the houses open to the full extent of the ventilators unless the weather is very severe. In cleansing do not strip the bark from the Vines as is so often recommended, for this unnatural removal of Nature's protection is positively injurious. It not only tends to prevent the natural swelling of the stems, but makes them hide-bound. Take every advantage of making untenable the winter quarters of every species of obnoxious insects and their eggs. We are not believers in those tar or other thick-smearing mixtures plastered on the Vine, which seal up the pores of the wood, but work on the system of "Prevention being better than cure," and give all our Vines a good washing with that good and safe old insecticide, Gishurst Compound, 6oz. to the gallon, using an old stubby paint brush. If junior hands are employed at this work we add a little soot and sulphur to the liquid compound, simply as a colouring, to enable us to detect any carelessness or scamping of the work, as the success of the operation depends upon the thorough way in which it is done, as it is intended to loosen the eggs with a hard brush from their adhesive attachment and the fatal insecticide to accomplish their destruction, whether it be red spider, mealy bug, brown scale, or thrip. It is really well to give this harmless washing, whether the Vines have been previously infested or not, because these injurious insects are often introduced into the Vineries by the doubtful compromising proceeding of sheltering quantities of pot plants. Examine inside borders, and if the surface roots have become very dry give a moderate supply of water before the top-dressing is placed over them. Remove the shutters from outside borders, top-dress with good loam and crushed bones, and protect from frost with fresh stable litter. Cut back young Vines which have not hitherto borne a crop of fruit, and allow the points to droop to the level of the pipes, or tie them to the wires in a horizontal position near the front ventilators where they can have a free circulation of air. Also cut down pot Vines intended for growing into fruit canes. Dress the cuts and keep the Vines in a dry cool house until the time arrives for starting.

Select thoroughly ripened eyes, insert in small pots firmly filled with sandy soil, and keep them in a cool pit for three weeks before plunging in bottom heat. If any of the houses require internal painting immediately after the Vines are cleansed and tied down is the best time to get in the workmen. Add a little turpentine to the paint and wash the walls with a mixture of quick lime and sulphur. Early houses from which ripe Grapes are expected in May will soon be fit for the general disbudding, a process which must be regulated by the vigour of the Vines and the position of the spurs. If widely placed two shoots may be left on each spur, the terminal shoot to give the bunch, and the lower one to give the pruning bud next year. As this will be the weaker of the two it may be allowed to supply the greater part of the lateral foliage for covering the trellis. Gradually increase the temperature to 58° to 60° on mild nights when the bunches become conspicuous, but avoid set figures when the weather is unfavourable. Syringe regularly with water a few degrees higher than the mean temperature of the house.

Madresfield Court.

W. CRUMP.

INDOOR GARDEN.

CONSERVATORY AND SHOW HOUSES.

DURING this period the greatest care should be exercised in warming and ventilating these structures, always avoiding damp stagnant atmospheric conditions by applying a little fire-heat when dull or cold weather prevails, and by giving a little air as early in the morning as the weather will admit. Avoid cold currents of air, and be careful to remove all decaying foliage and flowers. A good display can now be made where batches of Begonia (Gloire de Lorraine and its sports are grown and the hybrid forms recently introduced by Messrs. Veitch. These will be followed by B. socotrana

and B. Gloire de Sceaux. These two species will require a temperature of 55° to 60° during the day. Give them a gentle syringing in the early part of the day until the blooms begin to open.

OTHER WORK.

Dutch bulbs that have filled their pots with roots, and when the young growth has been exposed to the light in cool frames, may now be introduced into a gentle heat. Malmeson Carnations now require very careful watering, and be on the constant look out for the dreaded fungus. Every particle of leaf affected should be cut away as soon as the pest is discovered and at once consigned to the furnace. Young plants recently potted into 6-inch pots should be raised on a temporary stage to within 18 inches of the glass, and treated to an abundance of air whenever the outside temperature is over 32°, at the same time having the hot water pipes slightly warmed to keep the air moving. Later batches not yet advanced beyond 3-inch pots, and provided the pots are fairly full of roots, will take a little more water than those in the 6-inch pots, but should not at any time become what is termed wet.

All late blooming Achimenes and Gesneras should by this time be sufficiently ripened to allow all growth to be cut away and the corms stored for the winter. Ericas now require careful watering, and should never be allowed to become too dry. Give plenty of air except when sharp frost prevails. Should mildew attack them resort must at once be had to flowers of sulphur; this to be applied by a proper duster, laying the plants on their sides during the application to avoid the sulphur resting on the surface of the soil. Avoid fire-heat whenever the temperature of the house or pit can be maintained at 35°.

Wendover.

J. JAKUES.

ORCHIDS.

INSECT PESTS.

ORCHIDS, like other plants, suffer in various ways from numerous insects if proper precaution is not taken to exterminate these. The cockroach, green fly, thrip, red spider, mealy bug, various kinds of scale, woodlice, and the *Cattleya* fly injure our plants in different ways. They must therefore be well watched and destroyed. The cultivator cannot be too particular about this, for if they are allowed to remain they greatly mar the beauty of the plants, and the flowers too frequently suffer in consequence.

THE COCKROACH

is one of the greatest pests, and does much injury in a short time. The food they like best is the young and tender roots and flower-stems. The buds and flowers, too, are freely eaten by cockroaches, which must be searched for at night, as then they leave their hiding places in search of food and are more easily caught. There are many beetle powders and phosphoric mixtures that quickly destroy them if put on pieces of tile or slate and laid in different parts of the houses in the evening, the same being collected in the morning and the operation repeated. We use nothing here but phosphor paste, a little being placed on small pieces of Cabbage leaves and laid on the stages among the plants about twice a week, then removed for a week. This is done every other week until they are destroyed.

GREEN FLY (*APHIS*) AND THRIP.

Since the introduction of Richards' XL All Vaporiser these pests give little trouble, though the latter are more troublesome to eradicate than the former. They get far down into the centre of the young growths and axils of the leaves, where no fumes can touch them. Plants so affected with thrip should be dipped in soft soapy water or insecticide, or the same can be worked down into the centre of the young growths and axils of the leaves with a brush. This will generally kill them; if not, it will remove them from their quarters to where fumigating will have the desired effect.

SCALE AND MEALY BUG.

The various kinds of scale that infest our plants—the *Cattleyas* in particular—are all more or less

NEW SINGLE CHRYSANTHEMUM MRS. H. HERBERT.

hurtful, and there is no better way of eradicating these pests than by persistent cleansing with soft soapy water or some insecticide. The small white scale is the most difficult to remove. A little soft soap should be mixed with water and rubbed over the bulbs and rhizomes affected, allowing this to remain on for a day. Then wash off and thoroughly clean the plants. The mealy bug seldom gains a foothold where cleanliness is persisted in. If plants by any means become infested with it, constant watching and frequent cleaning with some good insecticide is undoubtedly the best remedy.

RED SPIDER.

The under surfaces of the leaves are the first to become infested with this, and generally of plants that have positions in the driest and most arid parts of the hot houses, those that are exposed to the greatest amount of sunlight, the Dendrobiums for example. These plants should therefore be observed, and the under sides of their leaves sprayed upon as often as possible without injuring them. Keep the atmosphere in the houses as moist as is consistent with the occupants, and examine the plants at short intervals; any that show the slightest trace of red spider should be well sponged with soft soapy water or some insecticide.

WOODLICE.

These, like the cockroach, are very fond of the young tips of the roots; they feed upon them and in this way do much injury. They should be trapped by cutting some Potatoes in half, scooping out the interior, and placing them on the pots, baskets, and staging. Look over them every night and morning. Small flower pots with some dry moss at the bottom also form capital traps for them; these should be laid on their sides in different parts of the house, frequently examined, and the intruders destroyed.

THE CATTLEYA FLY.

This has done much injury in many collections. Among the Cattleyas and Lælias its work is easily detected, for the young growths begin to swell far above their usual size, and become club-shaped as they grow. This swollen portion contains maggots which feed upon the inner portions of the young

growths. The larv when they are matured change into flies, and become distributed about the house. They begin by piercing the young growths, lay their eggs, which soon change into maggots, pass through their several stages, and in due time become flies, and thus increase and multiply and soon cripple the plants if not destroyed. The remedy adopted to destroy these pests at one time was to cut off the young growths as soon as the unusual swelling is perceived, but at the present time every cultivator does not agree with this practice, though if we had say one or two plants with the same number of growths affected, and we were sure these were the only ones, and no living flies in the house, then this cutting away would be advisable.

These flies, like many other winged insects, are quickly killed by fumigation, and this I consider by far the best plan to adopt, though this will mean a few shillings more outlay in the first place, but is much cheaper in the end. As soon as the unwelcome visitor has arrived fumigate the house with Richards' XL All Vaporiser twice a week, and continue the practice until they are entirely destroyed. Four years ago most of the Cattleyas and Lælias in one house here were affected with the Cattleya fly in a manner I think seldom seen. Nearly every young growth had been cut off, and many of the last made bulbs also. We left the plants entirely alone, commenced to fumigate the house twice a week with Richards' XL, and continued the practice for about five months, and not a vestige of fly has ever been seen since. Every plant purchased and received, newly imported or established, should be thoroughly cleaned before being placed with other Orchids.

F. W. THURGOOD.

Rosslyn Gardens, Stamford Hill, London, N.

CHRYSANTHEMUMS.

SEASONABLE WORK.

SELECTING AND PREPARING THE CUTTINGS.

SUCCESS or otherwise of the cultivator next autumn will much depend on the foundations laid at this season, a fact which cannot be too prominently brought before the notice of the beginner, and, indeed, impressed on the minds of all who wish to excel in bringing to perfection this popular autumn flower. More depends on this apparently small matter than many suppose. This applies to the whole of the large-flowered section, which are required to produce fine massive blooms. No time should now be lost in beginning. Everything should be got ready and every detail studied before starting.

SOIL.

This should be prepared and well mixed a few days before it is used. A fairly light gritty compost is best for a start, such as the water can pass freely through, nothing being better than equal parts of light fibrous loam and well decayed leaf-soil, adding sufficient coarse silver sand to render it porous. Take care not to use it in too moist a condition, which can be easily determined by squeezing it in the hand, and if at all pasty it will certainly require more drying.

There are many methods of striking the cuttings,

many of which are good in their way, but unquestionably the best is to insert them singly in 2½-inch pots, which should be thoroughly clean and dry before using. Even these, small as they are, should be carefully drained, precisely in the same way as the larger ones, only, of course, the material used must be very fine, and over this a small portion of the fibre taken from the loam should be placed to prevent the soil getting mixed with the crocks. As I have often pointed out, it is of the utmost importance that the waterway, especially of the Chrysanthemum, should be kept quite free in all stages of the plant's growth, without which the best results cannot possibly be obtained. The soil should be made moderately firm in the pots and surfaced over with a little fine sand, some of which will find its way to the base of the cuttings when dibbled in. The remainder will be a safeguard against stagnant moisture and also prevent the surface from becoming baked and crusty.

The position where the young plants are to be rooted will much depend on the means available, but if possible choose the stage of one of the houses, such as an early vinery, orchard, or greenhouse, on which should be stood either small frames or hand-lights, wherein place sufficient cocoanut refuse to bring the young growths quite close to the glass. The cuttings can then be attended to during any weather and at any time of the day. Little difficulty should be found in rooting them quickly under such conditions.

Everything being in readiness the cuttings should be carefully taken off, but before doing so fumigate the stock plants to thoroughly free the growths from all insect life. Good stout short-jointed cuttings about 3 inches in length should be chosen, selecting those which come up as root suckers as much as possible, stem growths being more likely to be persistent in making buds. Take off only what can be put in at once, for if allowed to become limp these are never so likely to start away so freely. The work of putting them in is best accomplished in the house in which they are to be propagated. Label each cutting correctly as they are inserted, thoroughly water in, and keep close for a few days. Endeavour to prevent flagging. This can generally be assured by keeping them close and damp over with warm water when necessary, taking care that too much is not given. Give air as required little by little as the cuttings begin to root, after which the lights may be taken off entirely for a few days before removing to the shelves in a more airy position.

There are now a host of varieties, especially in the Japanese section, and it is quite bewildering to the beginner to know which to grow, but if wanted for exhibition one cannot do better than make a selection by taking the names of the kinds which were most generally shown last season and have been reported in the horticultural press. The leading exhibitors may safely be relied on to have most of the best. Unfortunately, many of the old varieties, for some unexplained reason, quickly decline, not that the newer varieties are so much better, but they seem to lack constitution. It is a bold assertion to make, but I am convinced that fifteen or twenty years ago some varieties of the Japanese were exhibited quite equal to any we see at the present day.

I shall hope to deal with some of the most promising new varieties which have come under my notice shortly, and I trust will prove beneficial to those who have not had an opportunity of noting them as many of us near London have.

E. BECKETT.

Aldenham House Gardens, Elstree, Herts.

**NEW SINGLE CHRYSANTHEMUM
MRS. H. HERBERT.**

WITHOUT doubt this is the finest single white variety in existence. The blooms, produced in large sprays, are fully 4 inches in diameter, of perfect shape, with stout flat petals of a pure glistening white without a trace of any other colour. As a decorative plant or for cutting purposes it is unequalled. This variety was also

awarded a certificate of merit at the Birmingham Chrysanthemum show in November, when shown by Messrs. Clibran and Son of Altrincham.

Greenhouse.

Coleus thyrsoides, *Epacris* (in variety), *Moschosma riparia*, *Reinwardtia trigyna*, *Senecio grandifolius*, *Strobilanthes isophyllus*, and other things.

Arboretum.

Chimonanthus fragrans var. *grandiflorus*, *Clematis calycina*, *Erica mediterranea* var. *hybrida*, *Hamamelis arborea*, *H. mollis*, *Jasminum nudiflorum*, and *Lonicera Standishii*.

NOTES FROM SCOTLAND.

It may interest the writer of the notes on "The Compleat English Gardener" to know that the first edition appeared in 1683, and also that the condition of horticulture at that date and much earlier was by no means in the condition that book would lead one to suppose. In the same year other two books on gardening were published, and they are as remarkable for the good advice they contain as that of Mascall's is for the hash-up of long obsolete ideas that form its greater part. It may be doubted if even the "Davey Gentle" Apple was in existence at that time. The remark that "S. G." appears as a kind of editor is not without interest, as we may conclude these initials represent the Rev. Samuel Gilbert, son-in-law to Rea the florist, whose "Florilege" it is supposed he helped to produce. The "Melancholy Gentleman" is the pleasant old designation applied to *Hesperis tristis*, and all the other plants named are good garden flowers still in cultivation.

WANT OF FRUIT.

One of the remarkable features of the present position of fruit production in the North is the total inability of Scotch growers to supply Scotch consumers. Not so many years ago it was customary to send Grapes to English markets, particularly London and Manchester; but now no Grapes, or practically none, go South. On the other hand, the best shops in

Glasgow, Edinburgh, and Dundee, while relieving Scotch growers of their crops, are obliged to supplement these supplies from England, and the fruit has to be of very high-class quality. In the case of hardy fruits it is perhaps not so noticeable, because Pears and Plums more especially have long been imported across the Border; but with Apples the demand increases yearly, and quantities of good English Apples find their way northwards, and I believe always at paying prices. Strawberries, too, are sent North in very large quantities—trainloads daily in the season—but against these, tons are sent South from Scotland later in the year when English fruit is past.

These facts do not indicate a decreasing supply from home growers, because more fruit is being grown than ever; but they show a greater desire for good fruit among the people of Scotland, and that not only in the cities and towns, for it is extending to country villages as well. While that is so it is on the surface somewhat strange that so few hardy fruits are cultivated in small gardens. Hereabouts quantities of Tomatoes are produced in frames in cottage gardens, but few Apples or other hardy fruits are grown. One reason may be that no one is sure of gathering his crop after growing it, but the only way to suppress this pilfering is for everyone to grow fruits and make them so common that the custom of helping one's self to one's neighbour's goods will fall altogether into disuse. B.

MISCELLANEOUS.

NOTE FROM TORTOLA, WEST INDIES.

Writing in August, 1902, Mr. Fishlock says:—"The Virgin Islands form the most northerly presidency of the Leeward Islands Colony, and they lie between St. Kitts and Porto Rico. They are a number of small islands belonging to Great Britain, Denmark, and the United States. The chief British ones are Tortola (from

Spanish words meaning 'the land of the turtle-dove,' on account of the numbers of that bird which once lived on the island); *Virgen Gorda* ('the fat Virgin,' as it is in Spanish); and *Anegada*, or the 'Drowned Lands,'—this last is extremely flat and surrounded by reefs, making it very dangerous to mariners. In the old days, I believe, wrecking was there made a kind of fine art. As far as I can see, agriculture there is almost hopeless. *Virgen Gorda*, on the other hand, seems more hopeful as a field for the agriculturist, and miner, too, for that matter, as I believe several mineral ores are found there. Many romantic and interesting stories are told about the place, happenings of the old buccaneer days. Copper has been worked there since the early years of the seventeenth century. At present the chief industries of the place are fishing and charcoal-burning. Goats, cows, horses, &c., are also raised for the St. Thomas market. *Tortola*, the chief island of the group, and the seat of Government, is a rugged island about 14 or 15 miles long by some 5 or 6 miles broad, but the breadth is very variable. The hills in places rise to nearly 2,000 feet high, and the roads over them are extremely rugged, in fact only passable to native horses. The natives are fearless riders, and gallop over roads which shock the feelings of an Englishman.

"The chief town is Roadtown, what we in England would call a hamlet, chiefly a collection of ruined houses containing about 400 inhabitants, but showing abundant signs of former greatness. I am told that in the old days Roadtown rivalled St. Thomas itself. The staple industries here are stock-breeding, sugar and rum manufacture, fishing, charcoal-burning, &c. The natives are a very independent class of people, and will only work at comparatively high rates of pay; it is often remarked here that a native with a few acres of land is as independent as a man in England with £250 per annum. There is scarcely any circulation of money among them, and they work in gangs for food and rum."—*Kew Guild Journal*.

THE GARDEN

No. 1625.—VOL. LXIII.]

[JANUARY 10, 1903.

NEW HARDY FLOWERS OF 1902.

(Continued from page 2.)

LILLIUM BROWNII VAR. CHLORAS-TER.—In the size and form of the flowers this fine variety compares well with the typical Brownii. It is, however, quite distinct in colour, and possibly somewhat shorter in the trumpet. The yellowish tone of the inside of the flower and the much-reflexed character of the segments impart to it quite a character of its own. The plant is said to inhabit the mountain glens in sheltered, though not in shady places. A.M., September 23.

Lobelia syphilitica.—Of this useful and hardy species one or two crossbred forms were shown last year. These are Andrew Barlow, with flowers of a red-purple tone, and Purple King, a variety with large and showy rich purple flowers. These gained the A.M. on September 23.

Montbretia Geo. Davison.—This is a tall, strong-growing kind, with self yellow flowers on long spikes. In the larger and more widely open flowers there would appear much of the *Crocsmia* character. It is a showy kind. A.M., August 19.

Paeonia arborea Queen Alexandra.—A very large and handsome glistening white-flowered Paeony, the finest white tree variety known to us. In the slightly cupped or saucer-like form the broadly ovate, much imbricated petals display its fine qualities to advantage. A.M., May 28.

Papaver A. W. Chillery.—Briefly this may be described as a new shade of colour in the Oriental Poppies. These plants, however, are not of so much value for exhibition as for the garden, where the showy or gorgeous flowers are best seen; the colour is salmony pink, with blotches at the base. We would like to see a strain with these conspicuous blotches absent. A.M., May 28.

Primula viscosa Spring Beauty.—This is reputedly a cross between *Primula viscosa* and a garden *Auricula*. Of the immediate crossbred influence there is perhaps little doubt, though at the same time we note much resemblance to the *Auricula* in the flowers. These latter are rather more than an inch across, rich deep purple, with creamy centre. We believe this *Primula* rightly belongs to the group known as *P. intermedia*. It is a beautiful free-flowering and showy plant. A.M., April 8.

Senecio clivorum.—A vigorous species from

Central China, and one of the finds of Mr. Wilson. It is delightful for the wild garden, and is best described as a caulescent perennial or herbaceous plant with roundish peltate leaves, and producing freely on its 4-foot stems orange-coloured flower-heads about 4 inches across. A.M., August 19.

Saxifraga Guildford Seedling.—This is not merely a novelty but a welcome addition to the set to which it belongs, *i.e.*, the mossy section. It is believed to be a chance seedling from *Saxifraga Rhei*, and as no definite information was forthcoming concerning it, and as the introducer, who also was indeed the raiser, if unwittingly, is alas! no longer with us, we feel justified in placing the fact on record. Indeed, when we first saw the plant at Guildford Mr. Selve Leonard requested our opinion, at the same time remarking, "We know nothing about it, except that it occurred here as a chance seedling; in fact, we have nothing like it." The time of flowering, character of the rosettes, and branching of the inflorescence differs in no sense from *S. Rhei*, but in place of the pink spotted flower that of Guildford Seedling is wholly a crimson velvet self colour. This is the shade of plants grown in the open, those exhibited so far having been grown under glass. Though both Mr. Selve Leonard and ourselves regarded the variety as a chance seedling, there is no proof of it in the least, and of course there is just the same probability that it is a sport from *S. Rhei*. *Saxifrage* sports are, however, rare. It will in the near future prove one of the brightest flowers for the rock garden. A.M., May 6.

Thalictrum orientale.—This is perhaps one of the most useful of the Meadow Rue family; it is compact in growth, less than 2 feet high, and with leafage intermediate in size between that of *T. minus* and *T. aquilegifolium*; it has pure white plumes, and not only in the garden but in the cold house this plant should prove of value. A.M., May 28.

The following are also novelties among bulbous plants:—

Gladiolus Coronation.—A large well-formed flower, very striking and beautiful in colour. The ground colour is white suffused with delicate pink in the upper parts, while in the lower petals a huge blotch of crimson velvet nearly covers this portion. A remarkable contrast. A.M., August 19.

G. Empire.—This is a fine break. It contains in all probability both *Gandavensis* and it may be *Lemoinei* blood. In the upper parts the dominating colours are flesh and rose, while a

golden blotch with crimson-purple is seen in the lower half of a very striking flower. A.M., August 19.

Narcissus Peter Barr.—This is a beautiful flower and a great acquisition to the none too plentiful white trumpet Daffodils. The parents are *Monarch* and *Mme. de Graaff*. It is at once the largest and whitest of the white trumpet Daffodils. At present the entire stock is represented by only a few bulbs. F.C.C., April 8.

N. Sir Francis Drake.—Briefly this may be accepted as a large highly refined Emperor, no mean testimony to its fine qualities. A.M., April 8.

(To be continued.)

THE CANDLEBERRY GALE (MYRICA CERIFERA).

THOSE who care for the most delightful kind of aromatic fragrance and have a sandy or peaty soil should grow this North American shrub. No bruised leaf, not even of Myrtle itself, gives off a better scent. It is a pleasure to know of it in various parts of a garden so that a leaf for picking is never very far off.

The Candleberry Gale or Candleberry Myrtle, also called Bayberry, is one of the four shrubs of the genus *Myrica*; three are North American and one European, the Sweet Gale or Bog Myrtle of our own peaty undrained lands. Another of this genus of fragrant bushes is the Fern-leaved Gale or Sweet Fern (*Myrica (Comptonia) asplenifolia*), also a good plant for English gardens where there is peat and moisture.

I had always heard of the sweet-smelling candles made from the Candleberry Gale, and had a great curiosity to know what they were like and how they were made. I took the opportunity in the summer of questioning a charming visitor from the United States, whose description of candles of half-transparent olive-green wax, burning with a sweet smell, added much to my interest. Some months later this was followed by the kind gift of one of the pleasantest books that I have seen for many a long day, and that may be most heartily commended to readers of *THE GARDEN*, namely, Mrs. Alice Morse Earle's "Home Life in Colonial Days" (Macmillan). Herein, to my great delight, was a description of the use of the Bayberries as follows:—

"A natural and apparently inexhaustible material for candles was found in all the colonies in the waxy berries of the Bayberry bush, which grows in large quantities on our coasts. In the year 1748 a Swedish naturalist, Professor Kalm, came to America, and he wrote an account of the Bayberry wax, which I will quote in full:—

"There is a plant here from the berries of

which they make a kind of wax or tallow, and for that reason the Swedes call it the Tallow shrub. The English call the same tree the Candleberry tree or Bayberry bush. It grows abundantly in a wet soil, and seems to thrive particularly well in the neighbourhood of the sea. The berries look as if flour had been strewn on them. They are gathered late in autumn, being ripe about that time, and are thrown into a kettle or potful of boiling water. By this means their fat melts out, floats at the top of the water, and may be skimmed off into a vessel; with the skimming they go on till there is no tallow left. The tallow, as soon as it is congealed, looks like common tallow or wax, but has a dirty green colour. By being melted over and refined it acquires a fine and transparent green colour. This tallow is dearer than common tallow, but cheaper than wax. Candles of this do not easily bend nor melt in summer as common candles do. They burn better and slower, nor do they cause any smoke, but yield rather an agreeable smell when they are extinguished. In Carolina they not only make candles out of the wax of the berries but likewise sealing-wax."

Beverly, the historian of Virginia, wrote of the smell of burning Bayberry tallow:—

"If an accident puts a candle out it yields a pleasant fragrance to all that are in the room, inasmuch that nice people often put them out on purpose to have the incense of the expiring snuff." G. J.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

January 13—Royal Horticultural Society's committees meet at Drill Hall.

January 14.—East Anglian Horticultural Club Meeting.

January 22.—Gardeners' Royal Benevolent Institution Meeting and Election of Pensioners at Simpson's, Strand.

January 27.—Royal Horticultural Society's Meeting.

February 3.—National Amateur Gardeners' Association Meeting.

February 7.—Société Française d'Horticulture de Londres Meeting.

February 10.—Royal Horticultural Society's Meeting.

February 11.—East Anglian Horticultural Club Meeting.

February 13—Royal Gardeners' Orphan Fund Annual General Meeting, Cannon Street Hotel.

Grouping of trees and shrubs at Kew.—Much has been done at Kew in the judicious grouping of plants, and here is a living place of instruction open to all, where the best of plants may be seen, and, to a considerable degree, the best ways of using them in gardens.—*Trees and Shrubs for English Gardens.*

Poinsettia pulcherrima.—At Finsbury Park a very pretty show of the Poinsettia is to be seen in the conservatory at the present time. Being that way on business recently I walked into the house, and to my surprise saw what I consider a fine show at this dull season of the year. The plants vary in height from 1 foot to 7 feet. Some of the bracts measure fully 14 inches across. The gardener in charge of the house informed me there are over 350 plants. Some of them carry two bracts, making it appear as though there were more. Arranged as they are amongst the Palms and other foliage plants, they have a very pretty effect.—L. RICHARDS.

"The Garden" Almanac for 1903. We have received many letters expressing pleasure that so many fixtures for the present year have been

published. Mr. H. E. Archer, secretary of the Ipswich and East of England Horticultural Society, sends the dates of exhibitions for the present year, which arrived too late for insertion in the Almanac. They are as follows: Summer Show, Wednesday, July 15; Chrysanthemum Show, Tuesday and Wednesday, November 10 and 11.

Rainfall at Hampton Manor, Hampton-in-Arden, during 1902. Days on which rain fell: January 9, 2.09; February 9, 1.62; March 13, 1.38; April 11, 2.86; May 20, 2.11; June 15, 1.99; July 10, 1.58; August 22, 3.62; September 12, 1.62; October 17, 2.22; November 13, 1.98; December 16, 1.97. The highest maximum in the shade was on June 28 and July 14, 85°.—NEIL SINCLAIR.

Chrysanthemum Golden Gem.—This is the best late yellow Chrysanthemum I know, and is a good companion to Lady Canning, but it is much freer flowering. There are many so-called late varieties which often disappoint the grower, in that a large percentage of the growths become blind. Golden Gem is just the reverse, as nearly every shoot terminates with a bunch of bright yellow flowers which develop into a rich bronze with age. They are very effective under artificial light and of value for cutting; the flower stalks are long and slender. We always strike a large batch of this variety in June for flowering in 6-inch pots, and there is no difficulty in having a good supply during January and February.—E. HARRISS, *the Royal Gardens, Frogmore.*

Eranthemum pulchellum.—This old East Indian plant, one of our most useful greenhouse and conservatory plants, is now in full beauty. No blue flower at this season can compare with it. This is really one of the most accommodating of plants, and might be more largely grown to advantage. The culture of old plants is very simple, shaking out and repotting in the spring after flowering. A mixture of two parts loam, one of peat, with a little leaf-mould and sharp sand, will suit them well. As they can be grown in 4½-inch pots, they are useful for vases. The larger plants in 6-inch pots are, however, most productive of bloom. Cuttings of half ripened shoots, under a hand-glass, with bottom heat, root freely.—STEPHEN CASTLE.

The prettiest weed of the garden. The prettiest weed of the garden after all—and the sweetest, if you bruise the leaf of it—is the common Crane's-bill (*Geranium robertianum*). I find in an old family herbal the remark that "very few know it by the name of Crane's-bill, but every one knows a Geranium." That was printed in the days when every Pelargonium was a Geranium. Now and then our Crane's-bill will make some shady garden corner rosy, or it courts full sunshine hanging from the grey limestone of the rockery. The delicate markings of the small flowers seem as it were "put in" with a touch, and so elusive is the colour one knows not if to call it pink or rose-lilac. No highly cultivated florist's flower could be more alluring in its beauty. How many such indeed are cultivated up to so huge a doubleness and machine-made regularity that a point is reached where all true distinction and character are lost. The flower of many a persecuted wild garden weed, in comparison, seems, as one might say, "hand-made"; bears still in the lovely painting and shaping of its corolla the mark of the hand of God.—"E. V. B.," in *Royal Horticultural Society's Journal*.

A new Chinese Mock Orange (Philadelphus Delavayi).—The *Revue Horticole* for the 1st inst. gives a woodcut two-thirds of the natural size, with a full description by L. Henry, of this most interesting new hardy shrub, which is one of the many fine plants sent from China to the Paris Jardin des Plantes (or as it is now called Muséum de l'Histoire Naturelle) by the French missionary Abbé Delavay, whose name it bears. The seed was received in March, 1888, under the name of *Philadelphus coronarius*, but on comparison with the flowers and foliage of that plant it was found to be quite distinct from them, and well deserving of a distinct specific name. About forty plants came up and bloomed

for the first time in 1890. From the downy appearance of the foliage, the late M. Franchet suggested that its name should be *P. coronarius* var. *tomentosus*, but on further and more careful comparison and observation of the seedlings they were found to be altogether distinct from this variety, with purer white flowers and frimbriated and lobed petals instead of entire. Many of them also were found to have purplish stripes and blotches, with a differently formed calyx of a bronzy colour. Some of these seedlings were sent by M. Max Cornu, late director of the Muséum, to M. Lemoine of Nancy, who, after some years of cultivation and observation, has named one of them var. *Melanocalyx*, and who will doubtless soon offer plants in his annual list of new and interesting hardy shrubs. In the same number is also figured and described by M. J. Foussat another interesting new hardy hybrid shrub sent out by M. Lemoine last year, and named *Ecochorda Alberti macrantha*. It is a hybrid (raised by the sender out) between the well-known *E. grandiflora* (known to some as *Spiræa grandiflora* or Pearl bush) and the more recently introduced *E. Alberti*, one of the introductions of the late Dr. E. Regel of St. Petersburg, which I have always considered in every way inferior to *E. grandiflora*, and of little or no merit as an ornamental flowering shrub. The chief merits claimed for the new hybrid, and well shown in the woodcut, are a more erect habit of growth and greatly increased floriferousness; in fact, the bush is shown to be one mass of pure white flowers. I think it should be a great acquisition to our shrubberies, and I hope before long to see it bloom.—W. E. GUMBLETON.

Daphne indica.—Few greenhouse plants can compare with this *Daphne* in the delicious fragrance of its flowers. The grafting mania is doubtless answerable for a good deal of the neglect into which this *Daphne* has fallen, for plants so propagated are seldom if ever satisfactory, while there is a general tendency to grow it in a warmer structure than is necessary. It needs only a cool greenhouse, that is to say, much the same conditions as Azaleas, Camellias, and Rhododendrons delight in. This *Daphne* can be struck from cuttings of the half-ripened shoots put in very sandy peat, and either covered with a bell-glass or placed in a close propagating case. According to the "Kew Hand List," the correct name is *Daphne odora*, but in "The Dictionary of Gardening" the two are kept separate.—H. P.

New clerk to the Gardeners' Company.—At a meeting of the Court of the Gardeners' Company, held recently, at which the Lord Mayor, as Master, presided, Mr. E. A. Ebbelwhite, F.S.A., barrister-at-law, of the Middle Temple, was appointed Clerk to the Guild, in the room of the late Mr. R. Gofton-Salmond. There were ten candidates.

A new late-flowering Chrysanthemum (Mrs. Swinburne).—This is another of Mr. H. Weeks' successes with English-raised seedlings, and promises to be a distinct acquisition to the late-flowering Japanese varieties. The flowers are large and handsome, and have very long petals of medium width, gracefully curling and twisting, and incurving at the tips, building up a flower of elegant form and of splendid depth and substance. It may be described as a beautiful glossy white, and remains long in good condition. I have a bloom before me which has been cut about three weeks, and this surely is a point worthy of notice. The plants were not housed until October last, about which time the crown buds developed, from which the present bloom is a result. This proves its late-flowering characteristic. In the case of blooms required for the November show it would be necessary to stop the plants in the early days of May, securing the first buds subsequently developing. When grown on single stems in 6-inch pots the cuttings should be inserted early in March, the first buds forming in the apex of the shoot in this case being secured. This variety is the result of a cross between the beautiful snowy-white Miss Alice Byron and the late-flowering Mme. Cadbury, two Japanese of high quality. This variety is being sent out from Thrumpton Hall Gardens.—D. B. C.

Rosa wichuriana at Christmas.—The longer one grows this pretty single Rose the more one appreciates it. Its late flowering, though sometimes complained of when other Roses are in flower, is an advantage at other times. It was unusually late during the past year, but it has more than repaid one for the waiting by prolonging its blooms until after Christmas, though we had some sharp frosts at the beginning of December. Its pretty flowers do not seem altogether happy, nor have they so much of the delicious fragrance they generally possess, but they are welcome aids in maintaining the bridge of flowers which in a well-filled garden of hardy plants spans the gulf between autumn and spring.

—S. ARNOTT, *Carsethorn*, by *Dumfries*, N.B.

Brussels Sprout Cambridge Champion.—Though there is a large number of good strains of this useful winter vegetable bearing different names, this variety is by far the best that has come under my notice. It was raised by that enthusiastic Potato cultivator Mr. J. H. Ridgewell of Cambridge, and he must be congratulated on introducing such a fine novelty. Unfortunately, in nearly all strains only a small percentage of plants appear to come true, or at any rate a large number are often worthless as regards producing good firm Sprouts, but this difficulty to a very large extent (owing probably to very careful selection) has been surmounted, as the large majority of stems are laden with medium-sized perfectly firm Sprouts of splendid colour. The plants are of medium height. I am sending a few stems, being a fair sample of this variety.—E. BECKETT, *Aldenham House Gardens*. [An excellent variety, and all that Mr. Beckett has written of it.—Ed.]

The Linnæan Society—Admission of women.

—In consequence of the presentation of a memorial in favour of the admission of women to the Fellowship of the society the council issued a circular in March last inviting an expression of opinion on the part of the whole body of Fellows. The result has been that 301 Fellows have pronounced in favour of the proposal and 126 against it, whilst 313 Fellows gave no reply. The president and council feel that this expression of opinion is such as to justify further action, accordingly the matter will be considered at a special general meeting summoned for the purpose on the 15th inst. The president and council are advised that the existing charter gives no power to the society to admit women as Fellows. It will therefore be necessary to obtain a supplemental charter for this purpose, and a resolution to this effect will be moved at the special general meeting. It is proposed to take advantage of the opportunity thus offered to obtain modifications of the terms of the existing charter with reference to various other points. These are, however, little more than verbal changes, and will be fully explained at the meeting in question.

Yellow Turnips in winter.—Frequently, owing to several causes, the late winter supply of garden Turnips is not so good as could be wished, as some of the white varieties sown too early are coarse and flavourless, and if sown very late are not reliable. I would put in a plea for the yellow-fleshed varieties for winter supplies. Many object to their colour, but the flavour of such sorts as Sutton's Perfection and Dobbie's Golden Ball will be much liked if they are well grown and cooked carefully. The yellow Turnips are much more grown in the northern parts of the country, and I am not surprised, as the roots are much harder, they keep sound much longer, and the latter is a great gain. I have also noticed that the yellow Turnips are much more reliable in heavy soil than some of the white ones. The varieties I have noted are excellent in that way, and also have a dwarf top, thus requiring but a limited space, and for that reason are well adapted for garden culture. The flesh of Yellow Perfection is a paler yellow than the Globe, the roots are flatter, being admirably adapted for shallow soils or stony land, and the flavour is perfect.—G. W.

Mistletoe on the Sugar Maple.—Notes and articles on Mistletoe are plentiful, but

it is seldom one gets anything more interesting both from a historical and practical standpoint than the article on page 407 (December 13). The subject is a fascinating one, and, though so often treated upon, some new point is generally met in each communication. It is fairly plentiful here in the park and pleasure grounds. The trees it chiefly grows on are the Lime and Thorn, but, so far as an individual tree is concerned, a fine specimen of the Sugar Maple (*Acer saccharinum*) has the heaviest burden. There are half a dozen huge bunches at the top of the tree, and a great number of small pieces are springing out of the lower branches. In many cases these come out underneath the branch, and, as careful examination shows no incision on the top side, the theory of propagation by the simple dropping of the seed is untenable. I can only account for the fact that birds perch on the branches with portions of the berries, and in cleaning their beaks rub the seeds into a crevice in the bark on the lower side. There is a plentiful supply of berries this year, which at present are well retained, a remark, by the way, which does not apply to the Holly. Here also berries were plentiful, but during the recent spell of cold weather the pigeons completely cleared them. Birds larger than the mistle thrush do not seem to care about the berries of the Mistletoe. In a season like the present, however, when there is nothing in the shape of Nuts to satisfy the birds, any and all kinds of berries are hardly likely to remain long on tree or bush. E. BURRELL, *Claremont, Esher*.

Gardening in Morocco.—"I have been somewhat long in writing to tell you something of Morocco; but you understand how unsettled one always feels during the first three months amongst a new people and fresh surroundings, and consequently how distasteful is letter-writing. Moreover, it is as well to let first impressions mature before writing. I have been here three months. When I landed in Rabat in January I found the Court there, and had to wait until it moved up here. It took us ten days to come up. The weather was wet, and in consequence the rivers were flooded and the country was soft and swampy. There are no made roads and very few bridges, so that travelling is not lacking in adventure. The country through which we passed is almost entirely devoid of trees, and even here there are none with the exception of Olive and other fruit trees. Fez is, I think, the most picturesque town I have yet seen. It is situated at the mouth of a deep valley, through which flows the river Fez to join the river Sebou a little below the town. High mountains rise on either side, on the lower slopes of which stand Olive groves and orchards of Figs, Peaches, Plums, &c. The town is surrounded by a high wall, part of which is in ruins. As in all Moorish towns, the streets are narrow and dirty. The decoration of some of the mosques is very fine, particularly the mosaics wrought with little glazed tiles on the floors and walls. The climate is most agreeable. Of course it is rather warm just now (last week we had 99° in the shade), but we experience no violent changes. I am engaged in making a flower garden within the palace walls. The greater part is to be laid out in geometrical designs; the surroundings do not allow of much rustic or natural gardening. I have sixty gardeners and as many labourers as I want. The gardeners are men who have been working in the orchards and vegetable gardens around the town. They are not, however, a very intelligent set. Of course, horticulture and agriculture are carried on in the most primitive fashion. The ground is tilled with simple wooden ploughs drawn by oxen, the corn is cut with sickles which leave a foot of straw standing, and everything else is done in the same imperfect manner. It is interesting, however, and gives one an idea of how things were done in the far past. The Moors do not believe in change, and have preserved all the ways and customs of their ancestors."—T. W. BROWN, in *Ker Guild Journal*.

Flavour in dessert Apples.—Recently in an interview with a representative of a daily paper, Mr. Garcia, the well-known Covent Garden salesman, represented that Ribston

Pippin, "a variety which no other Apple has yet superseded, was dying out." Neither statement seems to be quite in accordance with facts. In the first place, Cox's Orange Pippin has been universally pronounced to be the finest flavoured Apple in cultivation, and has certainly softer and more palatable flesh than Ribston Pippin; and in the second place, so far from Ribston Pippin dying out, it is still largely grown in gardens as bush or espalier trees, and when on the Paradise stock is seldom troubled with canker. There can be no doubt that because of its tendency to canker the Ribston as an orchard tree is dying out. It is probable that the strong market bias which exists in favour of the old Pippin is due to its long and intimate connexion with the market just as King of the Pippins is an old favourite, but neither is so good in either quality of flesh or in flavour as is Cox's Orange Pippin. This variety is not a strong grower, and as a rule does well on the Crab stock, making handsome though not large fruitful standard trees. Probably were an equal sample of both Cox's and Ribston offered in the market the high reputation of the former for flavour would cause the higher price to be paid for it. Whilst we have so many handsome and free cropping dessert Apples we yet have but one Cox's. There have been numerous additions made to our list of this desirable section during the past few years, but not one with perhaps a single exception equal to our best dessert variety. That exception is of course Cox's progeny, Charles Ross. Of that handsome Apple, however, opinions as to its flavour must be reserved until it has been more widely grown. Of less recent introduction no doubt the best flavoured as well as most handsome variety is Allington Pippin, which is an Apple that will be found in a few years' time in almost every garden. Both that and Charles Ross should prove valuable allies to Cox's Orange. I have found even the famous Blenheim Pippin to be very moderately flavoured indeed, after partaking of Cox's. It is a popular, but all the same a somewhat overrated, Apple, as also is King of the Pippins, both good croppers and universally grown, yet quite second-rate. Six varieties that seem to be of the best flavour in their season are Kerry Pippin, James Grieve, Allington Pippin, Cox's Orange Pippin, Cockle Pippin, and Sturmer Pippin. A second half dozen may be Worcester Pearmain, Braddie's Nonpareil, King of the Pippins, Blenheim Pippin, Ribston Pippin, and Rosemary Russet. It is quite possible that these selections will be open to argument, but they may be hard to beat all the same.—A. D.

THE ROCK GARDEN.

THE ROCK GARDEN IN DECEMBER.

UNDOUBTEDLY this is the worst month in the whole year with regard to the rock garden. It is true that here and there Christmas Roses may appear, or that in some sheltered districts some belated flowers have managed to escape the frosts and are still lingering. Among shrubby plants *Erica carnea*, *E. codonodes*, *Laurustinus*, and *Arbutus* may even be opening new blossoms; but the fact remains, it is mid-winter, in spite of the mild weather we have lately experienced, and the principal display of beauty in the rock garden at this time of year must depend on the foliage and berries of an ornamental character rather than on flowers. Many such plants were mentioned in my notes on rock gardening in November, and to these I would like to add

Galax aphylla, which at this time of the year is most attractive on account of its leaves, which have turned a brilliant scarlet and are far more showy than the flowers were a few months ago. It succeeds best in moist peaty soil in a half-shady position.

Shortia galacifolia was also not mentioned in my notes for November. It is now very beautiful,

with its leaves veined and mottled with bright red bronze. Its flowers are delightful in early spring, but just now its leaves are quite as welcome, and make the plant doubly valuable on that account. A moist, shady position and peaty soil are best suited to its requirements.

WORK IN THE ROCK GARDEN IN JANUARY.

As the season has been very wet, additional attention will be required to ensure good drainage. In the case of choice alpine such as *Androsace helvetica*, *Petrocallis pyrenaica*, and others which have to be planted sideways, it cannot be too strongly emphasised that the tiny rosettes of such plants during winter must rest on stones and not on soil, where they would speedily decay. The stones absorb the over-abundant moisture, and thus prevent the plants' perishing. Where such plants are not planted into vertical crevices, but on only slightly sloping or even more or less level ground, it would be very advisable to push a few bits of broken sandstone or other porous material under the leaves and leave them there during the winter. The best protection for delicate alpine plants during winter is, of course, snow; but as there is rarely a supply of this material in this country, Fir branches are perhaps the best substitute, as described in my previous notes for November.

Where there is water in the rock garden, say in the shape of a small pond filled with Water Lilies, Arum Lilies, &c., many people go to the trouble of breaking the ice (if there is any) in hopes of thereby benefiting the water plants. I consider this quite unnecessary, as such plants are in a more or less dormant state at this season. Even Arum Lilies, which here in the West generally get cut down by frost below the water level, are none the worse for this, but make fresh shoots and bring forth fresh flowers the following season as if nothing had happened. Very much coddling and covering of rock plants generally is not to be recommended, as frequently mice or other vermin seek shelter under such covering and probably do more damage to the plants than the frost would have done.

Elmside, Exeter.

F. W. MEYER.

TREES AND SHRUBS.

A NOTE ON YEWS.

I HAVE a strong liking for Yews of all varieties, as they are of such an enduring character that, given a good soil to grow in, one can almost do anything with them. I often think what a grand sight future generations will enjoy on seeing some of the stronger growing golden Yews in the form of big trees. One of the most pleasant garden memories I have was of the golden Yews at Elvaston Castle, near Derby. This was in 1876; doubtless they have grown a lot since then. I often think it a pity golden Yews are not more freely used for hedges in suitable positions. On moist holding soils they grow fairly freely and transplant well, especially if mulched afterwards, though my experience goes to prove that Yews generally dislike manure in any form, especially in actual contact with their roots. A mixture of well-rotted grass and leaves is the best mulching for all conifers. I am led to make these remarks from noticing a small colony of the variety above mentioned in the new nursery of Messrs. Backhouse and Son, near York. It has the deepest shade of gold in its foliage of any of the golden Yews I know. Judging by its general appearance, I should say it is closely related to *Taxus adpressa* or *T. brevifolia*, hence is more adapted for the margins of shrubby borders or planting on rockwork, &c. As will be known to many of your readers, *Taxus adpressa* is a green variety, and by no means a strong grower under the most favourable circumstances. There is a very fine specimen in the grounds here, planted, I learn, about 1840, and yet it is not more than 12 feet in

height now, although its branches extend fully that distance from the stem all round.

Grimston, Tadcaster.

H. J. CLAYTON.

TRANSPLANTING LARGE TREES AND SHRUBS.

(Continued from page 7.)

LAST winter we found it necessary to transplant about forty young Elm trees which came in the line of several new roads at present being formed in Cathays Park, and a few details of how the tree-lifting machine is used, I enclose photographs taken of some trees removed in Cathays Park, may be of interest to your readers.

In the first place, the trees we have removed this winter were planted in Cathays Park twenty-seven years ago, and are now about 35 feet to 40 feet high, and are in all respects what may be described as ideal trees for shifting. It certainly would have greatly added to the chances of success had we been able to prepare the roots for removal by digging around them a year ago, but as it was impossible to do this we had just to make the best of it, and I do not think that even under these circumstances we shall have any losses.

When a tree has been selected for transplanting, the first thing is to dig out a circular trench 3 feet wide and about the same distance from the trunk, thus leaving a mass of earth about 7 feet in diameter. The trench is taken to a depth varying from 3 feet to 4 feet, according to the size of the tree about to be removed, and at a few inches from the bottom a hole is tunnelled through the centre of the root mass and a steel bar placed in with its ends projecting out about 5 inches or 6 inches. Underneath these ends, and at right angles to them, two other steel rails are placed, one at each side of the tree. These two rails are gradually worked underneath, and when they have a sufficient "grip" of it two or three strong Oak planks are placed across them, and also gradually worked under the ball of earth. When this has been done the tree is ready for lifting, and the machine is then placed in position. To do this it is necessary to take off the back wheels and bars and slide the rest of the frame across the trench on planks; the girders are again fixed to the wheels, the back bars bolted on, and the machine is ready for its work. The chains of the four pulleys are then lowered and fastened to the ends of each of the two steel rails which are supporting the central rail and the Oak planks—practically a platform upon which the tree is resting. Two or three men work each pulley, and the tree with a large mass of earth attached to it is gradually lifted on to the machine. It should be mentioned that the ball of soil is never loosened at the base before being lifted, as the leverage of the pulleys is quite sufficient to break it away from the bottom of the trench.

When the tree has been safely lifted and made secure, the next operation is to remove the machine from over the large hole that has thus been made. To accomplish this a pair of wooden balks (supported by a number of ordinary 3-inch deals) are laid across the hole in a direct line with the two wheels, and the machine is gradually levered over these by the aid of pinch bars and removed to firm ground. This may seem rather a slow method of locomotion, but it is certainly a very sure one, for so far we have had no accidents when crossing the hole in this way, although mishaps have taken place when horses have been used for the purpose. When the tree is of any great size, and when it has to be taken a distance, three or four powerful horses are required to drag the machine along. The illustrations show a tree which has just been lifted and taken over the hole, and the method of bridging over the latter is clearly shown in all its details. In replanting the tree the same method of bridging over the hole prepared for the reception of the roots is adopted as that just described, and when the tree is in the position desired the balks and planks are removed, the ball of earth lowered into the ground, and the machine taken from around the tree. The platform is taken from under the tree just in the reverse order to that in which it was

put in, first the central steel bar, then the side rails, and lastly the Oak planks. Good soil mixed with manure is then worked in among the roots and firmly trodden in the trench, and if dry the whole is well watered. This—with the exception of staying the tree with strong wire to prevent its being blown over—completes the whole operation, and if successfully carried out the tree will in the course of a few years look as if it had never been growing in any other situation.

It will be seen by the number of men required to work this machine that it is rather an expensive undertaking to remove trees of any great size, but when we take into consideration the number of years saved by being able to plant such trees the gain is well worth the expense.

To remove trees and shrubs which have only been planted about nine or ten years it is not necessary to have a lifting machine at all, for such plants can easily be removed on a bogie, with a ball of earth sufficiently large to ensure success. During the past few years I have found a small bogie 6 inches by 3 inches quite adequate for removing shrubs with soil weighing from 5 cwt. to 15 cwt. The method of using this vehicle for transplanting purposes is very simple. After digging around the shrub, and rolling and securing a piece of cocoanut matting about the ball of earth left with the roots, it is laid over on its side and the bogie worked underneath it. The ball of earth is then lifted on to the centre of the bogie, secured by ropes, dragged out of the hole, and may be taken any distance without fear of shaking soil off the roots. One of the great advantages of using a carriage of this description is that it can be taken across lawns without doing them the slightest harm provided a few planks are placed under the wheels.

W. W. PETTIGREW,

Superintendent, Parks and Open Spaces, Cardiff.

THE FLOWER GARDEN.

NOTES ON HOLLYHOCKS.

HOLLYHOCKS still maintain their place in the autumn garden. Their great variety of tint and the noble way in which they stand guard behind the lower plants in the herbaceous border give them a distinct charm. Added to this is the great advantage of their long period of flowering and the ease with which seedlings are raised; in fact, they seem to propagate themselves so certainly as almost to become perennials.

The dread disease has been absent from all Hollyhocks in this garden for several years, and I hope it is not going to be so prevalent in other districts as has been the case during recent years. The illustration shows one plant only. There are many such at the back of this border, which is partially shaded by Beech trees and backed by a 5-foot hedge of Privet. The plants are allowed to form several spikes instead of leaving merely one great steeple of bloom as is sometimes done. W. JESPER.

Beechwood, Menston-in-Wharfedale.

No plants surpass this in grandeur or are capable of making a more striking effect in the garden when properly treated. For hiding any ugly background, whether of a wall, an uninteresting shrubbery, or what not, for breaking up the monotony of the ordinary mixed border, for forming the centre or crown of a large permanent bed—and everything must be on a fairly large scale to show off the Hollyhock to perfection—for all these purposes the Hollyhock is without a rival, even the Delphinium not fulfilling quite the same purpose by reason of its beauty being over so early in the summer.

The Hollyhock (*Althea rosea*) originally came from China, but has been known in our gardens for at least 300 years. It was not till somewhere near the middle of the last century that florists, professional and others, really took the flower in hand, as it were, with the idea of improving it, when the originally semi-double flower was brought to its present state of perfection. It attained a great vogue thirty or forty years ago, about which time the Hollyhock fungus (*Puccinia malvacearum*) made its appearance with most deadly results, many of the leading growers losing the whole of their fine collections, and some of the finest varieties being lost to cultivation. This

Of course they have all the stateliness of the double varieties as well as their beautifully varied colours, and though of many flowers we feel that the single sorts are most to be desired from a purely natural point of view, yet it is the more general opinion that Hollyhocks are one of the exceptions, in company with Carnations, Balsams, and Stocks. Double Hollyhocks, too, have an advantage over the single varieties, which is often overlooked, namely, that the more perfectly double the flowers are the less the production of seed, and, consequently, the longer the duration of the flowers. It is possible to get quite 3 feet of a stem of double Hollyhock clothed with blossoms in

perfect condition at one time, but with the single varieties the lower blossoms are fading long before this length of expanded flowers is reached.

RAISING FROM SEED.

In starting to grow Hollyhocks it is better not to be tempted into buying plants of named sorts, as these have always been propagated by cuttings, and they may have the seeds of the disease in them already. A much better, and at the same time a more interesting way, is to buy a packet of the best seed from some firm which has a good collection. If it is a reliable firm the seed will have been saved from the finest double flowers only, and a very fair percentage may be expected to come double, in a very great diversity of colours, including some of the most beautiful shades. In this way the beginner will at least start free from disease. If the seed is sown in pans in a frame in March, and the seedlings pricked out as soon as they are big enough to handle comfortably—and this is very soon—into some very good and deeply dug soil, they will

develop amazingly, and by the autumn will have leaves as big as cheese plates. It is from such plants that exhibition blooms are obtained. When pricking out the plants, if it is intended that they shall bloom the first season where they are pricked out, they should be planted a foot apart each way. This is a good plan, as all that are not of the required standard of excellence can be then pulled up as soon as the first bloom opens, without causing any disfigurement to the garden, while the plants left will be only the very best sorts and in the proper state for flowering the next season; a two year old plant is at its best from the purely decorative point of view for the pro-

duction of strong spikes of large flowers. If when pricking out the plants it is intended to put them in their permanent positions in the autumn they may be placed 6 inches apart each way.

Great care is necessary when moving them, as they send out large roots in all directions, which for some distance possess but little fibre, and the consequence is that, however much care is used, the earth will sometimes completely fall away from the roots: this gives a check to the growth of the plant, and in fact weakens it for the coming season.

In planting Hollyhocks in their permanent positions it should be borne in mind that they are most gross feeders. To have them at their best the ground should be trenched 2 feet deep and plenty of well-rotted manure added, and this should be supplemented by a mulching of manure in dry weather, together with copious waterings of liquid manure. The last two things are desirable, but the first two are absolutely essential if fine spikes of bloom are to be secured. They will not do well in a dry soil, as the blooms on the upper parts of the spikes in such conditions simply dry up without opening, while if the soil is a very wet one the plants will probably all decay in the winter. A soil of medium dampness is the best, deeply dug so as to give an ample root run and retain moisture in dry weather.

The propagation of Hollyhocks is an important part of their culture, as when one gets plants of a very fine strain one wants to perpetuate that strain, and, moreover, they cannot be relied upon to do well more than two years, as they are so subject to rotting off in the winter. For this reason the plan recommended above of allowing seedlings to flower in the nursery the first season is a good one, as if they are removed to their permanent quarters in October there will be less risk of losing any by damping off in the winter than if allowed to bloom a second year in the same place. This applies to the choicer sorts, which it is presumed will be the only ones allowed to bloom a second year. The hardy single ones seen in cottage gardens will stand anything and will last for years. Another recommendation in favour of raising some new plants from seed every year is that old plants are more subject to the disease than young ones. In fact, when the fungus has once made its appearance in a garden it would be as well to let no plants bloom a second year, but to treat them as biennials and raise new plants from seed every spring. Of course an exception can always be made in favour of any exceptionally fine specimens. Some people lose more old plants in the winter than they need do because they cut them down too closely after flowering. When they are cut down so close that a cavity remains in the crown of the plants the rain and snow penetrating the cavity is almost sure to bring about their loss. The old flowering stems should be left a foot or two in length till the spring, when they can be removed altogether. Some growers recommend lifting all the plants it is desired to save at the end of October, and lay them in a trench close together in a warm position under a wall or hedge, where, in very severe weather, a little shelter can be given. The ground where they are to be planted in spring should then be well prepared, so that when the plants are put in it in March or April they will flower as well as if they had not been moved.

The method of propagating Hollyhocks is of a somewhat unusual character. A large flower-spike has usually some small side shoots which produce few or no flowers.

SINGLE HOLLYHOCKS AT BEECHWOOD, MENSTON-IN-WHARFEDALE.

disease will be dealt with later. Meanwhile it may be stated that the fungus is much less common now, with the result that the Hollyhock is increasing in popularity and new varieties are again being raised. With due care and the adoption of the methods of cultivation about to be described, the fungus need not have much terror for us, unless it happens that the situation or the soil is particularly favourable to it or we have a succession of seasons that favour its spread. Some recommend growing the single varieties, as they are so much less subject to the disease and do not require the care that is necessary for full success with the best double ones.

Those bearing no flowers may be taken off about the time the plants are coming into bloom and cut up into single joints, a clean cut being made through the stalk just under a leaf, the leaf being left entire. These cuttings should be dibbled in thickly in a frame, in a soil composed of gritty sand, loam, and leaf-mould in equal proportions, sprinkled occasionally with water which has been warmed in the sunshine and kept shaded from the hot sun. The leaf and the piece of ripened stem serve to nourish and develop a bud in the axil of the leaf, while roots will soon form on the large majority of the cuttings if they have been carefully put in. When they become well rooted they should be taken up and put in 3-inch pots and kept in a frame through the winter and planted out in the spring in properly prepared soil where they are to flower. Young plants reared in this way and at this season, which is generally July, make fine plants and give excellent flower-spikes the year following.

Another method of propagation is that of utilising the stems of the old plants after flowering. These may be cut down, beginning at the lower end of the length of stem removed from the old plant; joints may be cut off as described above, all the way up the stem as long as the wood is well ripened, and each joint having a bud will form a plant, the treatment being the same as for the cuttings taken on the other system. Of course these plants are late, and will not make such good flowering ones as are obtained by what may be called the early summer method, and the only advantage of it is that the supply of cuttings which can be obtained in this way is almost unlimited.

Yet another method of propagation is in the early spring. The old plants or stools will have a number of young shoots springing from them at this season, more than should be left to grow into flowering spikes, as no plant should be allowed to have more than four at the outside if fine blooms are wanted. Some of these shoots can be taken off and rooted in heat, when they will form good flowering plants the same season, though they will probably not flower till the old plants have finished, thus making a succession. The Hollyhock season may be much extended by rooting cuttings and transplanting at different times of the year, so that they may be had in bloom from July to October.

The staking of Hollyhocks is absolutely necessary, or a storm of wind and rain will send them all out of the perpendicular and lay many on the ground, after which they will never look so well again. It needs doing with judgment, so that the foliage of the stems hides the stakes as far as possible, and it should not be deferred till the plants are high, as nothing is thus gained, while loss may be the result. Stout stakes 4 feet to 5 feet high are necessary, and while robust stems should have two stakes put to them, or, if the plant has two very strong stems, three stakes should be put to the two, as the weight of the flower-spike is proportionately heavy, and when this is laden with wet and has to withstand a wind as well, a great deal of support is necessary to keep the stem in an upright position. A well-developed blossom, a great rosette, will hold water like a sponge.

As regards the Hollyhock fungus, not very much can be done. When a plant is obviously attacked by it the best way is to destroy it utterly to prevent the contamination spreading to the others, while any plants which show any signs of being attacked should, as a preventive, or possibly as a "stitch in time," be washed

with flowers of sulphur dissolved in soapy water, or rather mixed in soapy water, as the sulphur does not dissolve but has to be kept constantly stirred. This may destroy the fungus in its very early stages, but there is no hope for a plant when the fungus gets well established upon it. Red spider is sometimes a troublesome pest with Hollyhocks when hot dry weather sets in. It attacks the undersides of the leaves, and these should be syringed with a solution of soft soap to which some tobacco liquid has been added.

ALGER PETTS.

WALL GARDENING.

WALL GARDEN MAKING.

III.—DETAILS OF CONSTRUCTION.

IN the previous chapter on "Wall Garden Making" (see THE GARDEN of November 15, page 344) I have in a general way described various walls, without, however, going into details regarding construction. It may be considered a very simple thing to make a wall garden, but as its success must in every case depend on the care exercised during construction, it may be helpful to mention at least the most important practical points.

CONSTRUCTION OF DRY WALLS.

Dry walls (*i.e.*, walls which have their joints filled with soil instead of cement or mortar) are the most important for wall gardening. What pretty effects can be obtained by such structures was illustrated by the picture on page 267 in THE GARDEN of October 18, showing a fringe of beautiful Carnations on the top of the wall. I would now show by means of the accompanying rough sketches how such a wall is made. Sketch No. 1 shows a transverse section of just such a wall as the one above referred to. Roughly speaking, the largest stones are used at the bottom, and

NO. 1.

must rest on a firm foundation. Sometimes it may be advisable to let these bottom stones be partly buried in the ground to guard against the possible danger of a slip. All stones used in the construction of a dry wall are tilted backwards for the double purpose of giving greater strength to the structure, and of

allowing the rain water to soak down to the roots of the plants in the wall.

After the bottom layer of stones has been placed in such a way that these all lay firmly on their flattest surface, soil is put behind them and firmly rammed with a small stick or rammer. If any of the stones do not lay quite firmly, or do not tilt backwards sufficiently, this is remedied by small wedge-shaped ones being driven in firmly with a hammer until it is impossible to shake them without using great force. The bottom layer thus finished, it should be completely covered with good soil to a thickness of 2 inches or 3 inches. This soil is made to answer the purpose of mortar in ordinary walling, and

NO. 2.

into it the second layer of stones is deposited. The latter should not project out as far as the bottom layer, but should be set back in such a way as to leave a narrow ledge, which will be greatly to the benefit of the plants. Again soil is filled in and rammed behind the second layer of stones, and is also spread on the top of the same. In this way layer after layer is built up, not necessarily in straight lines, but varied according to the stones at disposal, or according to the plants to be used. In all dry walls stability is of the utmost importance. No matter how firmly the soil was rammed behind and between the stones, directly it has become well soaked with rain it will settle still more, and the stones must be so placed that this settling down does not affect their stability.

Whether the stones are of regular or irregular shape matters but little. Of greater importance is the necessity of varying the joints so that upright ones do not occur one directly above another, but are bridged over and "tied together" by the succeeding layer. Sometimes, too, particularly long stones are put, not lengthways, but crossways, so that when they have been weighted with soil they form a substantial tie between the outer surface of the wall and the bank of soil.

If the retaining wall was built at the bottom of a sloping piece of ground there would sometimes be a danger of an excessive quantity of water accumulating behind the stones before they had quite settled down. In such a case it not infrequently happens that the water-soaked soil behind the stones forces the whole wall outward and the structure tumbles down. To prevent such a calamity it would be well, where this danger exists, to insert

NO. 4.

into the wall a few drain pipes at intervals, say, a couple of yards apart. This would effectually prevent the accumulation of anything like a large quantity of water behind the stones.

Illustration No. 1 gives an idea of the arrangement of an ordinary retaining wall. It shows in sections how the stones tip back and how each layer of stones is set back a little further than the preceding one to allow for the better development of the plants. The sketch also shows (though, for the sake of clearness, in a somewhat exaggerated form) the soil between and behind the stones.

Illustration No. 2 hardly needs explanation. The sketch represents a dry wall with two faces for planting. The spaces behind and between the stones are filled with soil in precisely the same manner as explained by sketch No. 1, the only difference in construction being that both sides of the wall must be built up simultaneously. The higher the wall the broader, of course, must be its base. Walls like the one sketched in section No. 2 may be made very ornamental indeed, as they offer the additional advantage of different aspects, and consequently a greater variety of plants.

While on the subject of the actual construction of dry walls, I would again suggest that there should be no elaborate attempt at irregularity in building the walls. Let the wall be built without any pretensions, plain and simple, and not have the appearance of very inferior rockwork. A wall is the work of man; rockwork should look like the work of Nature, and therefore the wider the difference between the two the better.

PLANTING OPERATIONS DURING THE BUILDING OF A DRY WALL.

To the planting of dry walls I hope to devote a separate chapter or two, but while on the subject of actual wall building I should like to point out the enormous advantages gained by planting such a dry wall, not after it has been completed, but while building is in progress. This might, of course, not always be practical, especially if the idea of making a wall garden was an afterthought, and had its origin in the desire to turn an already existing wall to good account. But in the case of new work, where the wall is specially built for wall gardening, there would be no excuse for letting such an excellent opportunity for most effective planting pass by unheeded. I do not think I am exaggerating when I maintain that planting operations while the wall is being built are ten times easier, and more effective and satisfactory in every way, than planting a wall already finished. The reason is obvious. After a layer of soil has been spread on the top of the bottom layer of wall stones, quite a number

of plants may be spread out over this soil. After the roots are properly spread and extended they are slightly covered with a little more soil. This is gently depressed. A few tiny bits of stone are placed right and left of the roots (to prevent their being crushed by weight), the next layer of stones is placed in position and the planting is finished. If carried out during autumn it will in most cases be unnecessary to do any watering, as the late autumn and winter rains are almost sure to supply all that is needed in this direction. It must be admitted that nothing could be simpler than this method of planting. Besides being most easy to accomplish, it has the enormous advantage over planting after completion of the walls, that from the start the roots of the plants are introduced into the medium specially prepared for them, and it would be difficult, indeed almost impossible, to get them into a similar position after the wall is finished. In some cases the pressure of the stones above will reduce the space filled with soil and plants to a very narrow crevice, but this does not matter, since it is the very state of things that many mountain plants would revel in—for instance, Androsace, Aubrietia, Arabis, &c.

If plants in pots are used for planting, and there is some danger that if planted in the manner above described their roots would be unduly crushed, we have another way of ensuring their comfort, which I have tried to explain by the sketches 3, 4, and 5. Sketch No. 3 is supposed to represent an alpine plant (say, *Saxifraga longifolia*) with its pot removed and the roots

loosened ready for planting. In sketch No. 4 this same plant is represented as a circle in the centre of the diagram. This diagram, or, rather, longitudinal section, shows how by means of small stones placed on each side of the plant the pressure of the large stone above is made quite harmless. Sketch No. 5 shows the same plant as it would appear when seen on the surface of the wall. Now, it will be seen at a glance that the soil around such a plant can at no time be filled in and rammed so easily and so effectively as during the building of the wall.

Suggestions for the arranging and grouping of plants will follow in a later essay.

NO. 5.

THE WALL GARDEN IN WINTER.

WALL GARDENS, like rock gardens, have but little to make them attractive during the dullest months of the year beside plants which have handsome foliage or berries. These were mentioned in my notes on wall gardening in November, and need therefore not be repeated here, especially as there is practically nothing to add. Work in the wall garden at this season is very light. Plants or portions of plants showing signs of decay should be removed and the places they occupied might be raked out with a piece of wood or a chisel, but it would not be advisable to refill such crevices now while there is a constant danger from frost forcing the soil out and disturbing things generally.

The action of the frost might, however, be a help in the case of masonry walls which are to be adorned later on with plants between the joints of the stones. The frost has a tendency to crumble the mortar, especially in the case of work done only recently, and this would make it all the easier to rake the mortar out of such joints in the wall as would be sown or planted later in the season.

Elmside, Exeter.

F. W. MEYER.

THE INDOOR GARDEN.

STOVE PLANTS.

ALTHOUGH hot-house plants will never be so popular as are hardy plants, herbaceous perennials particularly, they will probably never be altogether neglected either, for they are so indispensable in many ways, even to those who have no real liking for them, while to the enthusiast they strongly appeal by reason of their brilliantly coloured flowers and foliage, fleeting in some cases though the former may be, their interesting variety of form and habit of growth, and even the difficulties of culture that some of them present. For the decoration of the dinner table and the adornment of the dwelling-house, many of them, especially those with highly-coloured and beautifully marked foliage, are invaluable.

It should not be difficult for anyone having the necessary hot-house at disposal to work up an enthusiasm for these plants, for some are unequalled for delicacy of form and markings and refined colouring. What, for instance, is more handsome than the velvety leaves of *Anthurium crystallinum*, many of the *Alocasias*, some of the *Dracaenas*, the foliage of the *Fittonias*, *Caladiums*, or more richly coloured than that of the *Crotons*. Again, what is brighter than the bracts of the *Poinsettia*, so valuable during the dark days of early winter; and the brilliant *Bignonias*, *Dipladenias*, gorgeous *Allamandas*, *Eranthemums*, *Bougainvilleas*, and a host of others that could be mentioned. I am afraid there is not the same interest evinced in the culture of stove plants as was the case some years ago. The best prizes at the leading exhibitions are always divided between a very few and invariably the same competitors. They are rarely commented upon in the gardening papers as compared with the amount of space taken up by notes upon other plants, and the literature of stove plants is sadly out of date. Some of our nurserymen who still extensively cultivate stove plants do good work by endeavouring to keep them to the front by exhibiting groups of them at the leading London and provincial shows.

There is but little doubt, I think, that stove foliage and flowering plants will in due time again become popular. They are creating a deal of interest among horticulturists, and I think those concerned with their culture should do all they can to stimulate a more general liking for them. Many of our most beautiful Ferns come under the category of stove plants, and they are certainly attracting attention now, so that it is to be hoped with their revival a fuller appreciation of stove plants in general will follow. Needless to say the house devoted to the culture of stove plants must be efficiently heated. The chief need of this is during winter, when it is necessary to prevent the

temperature falling below a certain point. In summer it is not difficult to maintain the proper heat in a stove house; little firing is required. In fact in a moderate winter hard firing is not necessary, because, of course, the temperature of the stove is then proportionately lower than was the case in summer, the plants are partially resting, and therefore must be kept as quiet as possible.

During the summer months the night temperature should be kept as nearly as possible at 73°, never below 70° or above 75°. In winter it need not be more than 63°, that is, in moderately cold weather, but even when the thermometer outside falls very low one should always endeavour to keep the temperature of the stove at not less than 60°. As the warmer weather of spring and early summer approaches the temperature should be gradually increased from 63° until the maximum of 73° is reached. In the same way, when autumn approaches, the temperature, from 73°, should gradually decline, until in midwinter it has reached the minimum of 63°. In genial weather, such as that of late spring or early summer, the thermometer may be allowed to reach 85° before air is admitted, and more air must be given as the sun gains power. In the height of summer the temperature of the stove will often become very high, reaching 100° or more, but with plenty of moisture in the atmosphere and proper ventilation no harm will result. A. P. H.

AN ARTIST'S NOTE-BOOK.

TAGETES PATULA NANA.

MANY are the varieties of the French Marigold, some of the best being aurea (orange-yellow), aurea nana, pulchra nana, ranunculoides (brown), nana (which is illustrated), pygmæa, and the still stronger form pygmæa lutea, which, as the name suggests, has yellow flowers. No other annuals are brighter in town gardens late in the year than the Orange and French Marigolds. Out of the many varieties, *T. patula nana* is one of the brightest. It is a very simple matter to raise seedlings in gentle warmth early in the year.

NOTES ON HARDY PLANTS

THE DIERAMAS.

ONE is pleased to see Mr. Mallett's appreciative and useful notice of the Dieramas in *THE GARDEN* of December 27 (page 440). It will draw attention to comparatively little-known but very attractive plants. While a number of botanists only recognise one species—*pulcherrimum*—as Mr. Mallett says, there are some of high authority who consider that *D. pendulum* is distinct, and when one finds Mr. J. G. Baker's authority thrown into the scale in favour of maintaining the species *pulcherrimum* and *pendulum* there is certainly good cause for others being a little inclined to support that view. Yet one's knowledge of the two in gardens makes one doubtful if it will be possible to retain the specific distinction. If there is to be only one, then *pendulum* must have the priority I believe.

From what I have seen of these Dieramas I am doubtful of the desirability of multiplying varietal names. Not only do imported corms differ considerably in the character of the flowers they give and in their general habit, but seedlings raised from home-grown plants vary widely in many respects. The most remarkable instance of this I have yet met with was in the lovely garden of

Messrs. Walpole at Mount Usher, County Wicklow, where there are many plants of Dierama raised from seed and largely self sown. From among these it would have been possible to select a number of forms as deserving of names as *atropurpureum*, and noticeable from the variety of shades, of size and form of flowers; they also differed greatly in their more or less pendulous habit. Regarding cultivation, I fear I cannot quite agree with what Mr. Mallett says, as from my experience in growing the Dieramas and from what I have seen of them in one part and another I believe that they are better when among stones or, at least, with fair-sized stones above their corms. Some years ago I discussed these plants with Mr. T. Smith, of Newry, who was of this opinion also, and at Mount Usher the greater number of the Dieramas were

THE DWARF FRENCH MARIGOLD (*TAGETES PATULA NANA*).
(From a drawing by H. G. Moon.)

in the Japanese garden, where they grew well among the stones. The best, however, were by the margin of a little rockwork pool, where they were even more vigorous than in a drier position.

This is quite opposed to one's preconceived ideas as to the proper place for cultivating the Dieramas, as the Vartry Glen, where Mount Usher lies, is not a dry place; but it is in accordance with my own experience, which is that the Dieramas appreciate rather more moisture than growers are in the habit of giving them. The tunics of the corms can certainly resist a good deal of drought, but that they like it is entirely a different matter. They will also stand a fair amount of frost. S. ARNOTT.

HELLEBORUS FETIDUS AND CAPER-SPURGE.

THE following interesting reference to these plants occurs in the paper on "Weeds," by "E. V. B." (the Hon. Mrs. Boyle), published in the *Journal of the Royal Horticultural Society*:—

"Another favourite is a handsome weed that stays with us in beauty from about the first week of December until put an end to by the hot suns of summer. Gardening and botanical authorities have named it for me *Helleborus fœtidus*. Yet except for a kind of pungent odour in the leaf when crushed, I can discover nothing to warrant the unpleasant name. Had I had the luck to be its godmother it should have been named something that meant green-flowered, or charming, or 'the plant with sad-coloured leaf.' As usual, it is next to impossible clearly to make it out in the gardening books, at least in those I have been able

to consult. Mostly these descriptions seem to read as though the authors had never beheld the plants they describe; and when there are illustrations the case is worse; they seem to be coloured to look pretty and—ex-

cept when photographed—are unnaturally twisted about so as to fit the page.

"*Helleborus fœtidus*, if thus it must be, seems to have been with us always, more or less. At least I cannot remember when it was not there. It grows only in one special bit of the garden, within the shady angle of an old brick wall. I do not know of the narrow boundary being ever overstepped in the course of these many years past, save once only when one individual seedling contrived to transfer itself from the shady to the sunny side of the old wall. Here it rejoices in the hot sun, with equal zest as formerly in the cool shade. Hellebore seems to be not particular about either aspect or soil, thriving, as it does with us, both in deep garden mould and in gravel. Last December the abundant blossoms of our Hellebore weed were conspicuously attractive, and thus they remained unchanged until the first days of April. Even then the light green panicle cymes, in such good contrast with the dark foliage, retain their beauty, while the flower quietly seeds itself away. Long before the Hellebore has failed, *Euphorbia* (*E. Lathyrus*, or *Caper Spurge*) begins to dot the borders here and there with the columnar grace of his tall stem. *Euphorbia* never comes in such numbers as to require much clearing away. It may not be a feeling of

admission that rivets attention to this curious weed; it is more perhaps the strange symmetry of the set of its leaves. An equal measure of parts is no unusual characteristic among plants, yet *Euphorbia* displays this exact symmetry in rather an uncommon degree. The leaves are said to point north, south, east, and west; and I believe it to be true—at least it is thus with the *Euphorbias* in my garden. They may make a mistake sometimes, but as a rule they know the points of the compass.

"What mysterious magnetism is it that moves these strange leaves? What secret stirring of the slow white sap?

"A fine plant of *Euphorbia* rises against one of our walls, and has attained already (May 13) a

height of 3½ feet, with an exceedingly massive stem. Downwards from the budding summit, where are seven buds instead of the usual four, the colour of the stem is all pure lilac bloom fading palely into green. The leaves—blunted at the end, and each one's centre broadly veined in dull white—show a kind of careless vigour. This great Euphorbia king seems scarcely to know what to do with his own immense vitality; and before long the firm smooth pillar will be spoilt by the branching out—Brussels Sprout-wise—of little sprigs all the way down. The bud bears in some degree the semblance of a serpent's head, and so the plant has been called 'Medusa' or 'Medusa's Head.' And also it is said that a dead plant will come to life again and bloom if placed in warm water. I have not tested the truth of this."

DAHLIA IMPERIALIS AND PRITCHARDIA FILIFERA.

It is much to be regretted that the magnificent Tree Dahlia, or *Dahlia imperialis*, flowers so late in the year that the daylight in England is not sufficient for its perfect development. Were it otherwise, no garden of any importance would be without it may be safely asserted, and I think the photograph here reproduced from one taken last November in the stately grounds of Mrs. Evans' fine Italian villa at Nice bears out this statement.

In combination with fine marble steps and

STILLROOMS AND GARDENS.

"Of Herbs and other country messes
Which the neat-handed Phillis dresses."

In these days of hurry and bustle the art of making simples and medicaments is almost forgotten. We buy our pot-pourri and our Lavender by weight, while Elderberry wine and jams made of Hips and Haws are nearly unknown.

I cannot remember the stillrooms of a bygone age, but I have vivid memories of an ideal storeroom in an old Kentish manor house, which was as much of a storing place for treasures of the garden as a repository for kitchen necessaries. This storeroom was a spacious one, and the pride of its owner; deep bay windows overlooked a bowling-green flanked by Cedar trees and a big Mulberry, propped up with stone slabs, for it had stood the winter storms of many centuries, since the days when Queen Elizabeth and Lord Leicester are said to have rested beneath. On the broad window-sills of the storeroom stood big beanpots full of Wallflowers from the terrace borders, or Bachelor's Buttons from the riverside. The windows were latticed with Wistaria that in early summer thrust impertinent purple blossoms into the room, and whose fragrance mingled with the faint sweet smell of herbs and spices within. Wide shelves ran round the room ranged with tall brown jars containing Raisins, Currants, Sugar, dried sticks of Cinnamon, and green Angelica. These were the delight of childish visitors to the storeroom, and baby fingers committed daring robberies.

I have a keen recollection of one corner of the room devoted to jams made of fruit from the kitchen garden; every sort was there, green Gooseberry, Kentish Cherry, Quince, and Crab Apple from the gnarled and bent old trees where the Mistletoe grew at the corner by the potting-shed.

Sometimes for a treat we were allowed to choose a pot for nursery tea, and found it hard to decide between the rival charms of Strawberry and Green-gage, or a "super" of golden Honey made by the bees, whose

doings in their row of hives caused us such interest. One morning bright eyes were seen peeping from an old egg box filled with shavings, and a nest of baby mice was found cosily ensconced, born in the midst of plenty.

I can smell now across the gulf of years the Lavender, Sage, and Thyme, picked from the herb garden and hanging in bundles from the wainscotted wall. A storeroom such as this was a constant source of interest to childish minds, lucky children who are brought up in the country, with country pleasures, and the joys of an "own garden." In early autumn Acorns were carefully collected and put into slender glasses, while ardent hopes were cherished of planting tiny trees in our little gardens, where they should some day grow into giant Oaks.

ADONIS AMURENSIS.

Now that we have entered upon the New Year those with whom early flowers are particular favourites will be looking forward to enjoying their treasures. The very fact that these flowers have few competitors in the garden when they bloom makes us appreciate their blossoms all the more. The Adonises are always welcome, and a bed of *A. vernalis*, the commonest of all, is a fine sight in its time, though hardly ever met with in any quantity except in a few hardy plant nurseries. Many of the devotees of hardy flowers prefer *A. pyrenaica*, but it comes at a time when we have a greater abundance of flowers to choose from, and is thus not in a way so valuable perhaps, beautiful as it undoubtedly is.

One of the most recently introduced of the family is *A. amurensis*, from the Amoor River district, and one which is said to have been a long time in cultivation in Far Eastern gardens. As we know it here it has pretty yellow flowers, but we are led to believe that there are also flowers with colours of various shades, passing, indeed, into scarlet. The curious thing is that these appear not yet to have been introduced into this country, while the yellow one has been here for a few years. As compared with *A. vernalis*, *A. amurensis* owes its attractions mainly to its earliness, for it will flower with us in February or March—a time when we are not overburdened with such things of beauty as this. It is slightly dwarfer in habit, and is, taking it as a whole, fairly distinct in its appearance.

The members of the genus *Adonis* are not among the flowers which require much coddling, and we can hardly expect a plant from the Amoor to be too fastidious in our gardens, though it may sometimes object to the wet winters we often experience. I find that the chief obstacles to its welfare are the slugs, which delight in cropping it, just as they do with its congeners. As an unailing preventive there is nothing to equal a zinc ring, notched at the top so as to give Mr. Slug a most uncomfortable time should he endeavour to scale the hateful barrier. The best position for *A. amurensis* is a south exposure at the base of a rocky or near the front of a border of good soil. A sandy loam is about the best for it, and, like many other plants, it likes an occasional top-dressing with soil. The *Adonis* family is an excellent one to grow in the cold house, as in this the flowers are protected from weather trials, and they can be studied with greater comfort than outdoors.

S. ARNOTT.

DAHLIA IMPERIALIS AND PRITCHARDIA FILIFERA IN A RIVIERA GARDEN.

balustrades, the bold trunk and broad fans of *Pritchardia filifera* make an ideal frame for the Lily-like beauty of the *Dahlia*, and produce an effect that can hardly be surpassed even in the tropics. To those who are obliged for health's sake to absent themselves from England, such beauties are indeed a solace and delight; and to the energetic tourist of modern days an excuse for a run into sunny lands in the months of November and December.

Pritchardia filifera withstands up to 10° of frost without flinching, so it would be worth planting in the south-west of England, where occasional protection could be given, but in a young state it hardly gives any idea of its real beauty when fully grown; hence its absence from English gardens.

E. H. WOODALL.

Alas! the Acorns nearly always came to grief, and often the mice ate them. Another joy was the keeping of bulbs in coloured glasses covered with charcoal and placing them in a darker corner of the storeroom, while we impatiently waited through the winter months until the shabby-looking bulbs put forth springing shoots of green. At last, one happy spring day, the green pyramids burst out into blossom, deep blue as a summer sky, pearly white, or glowing crimson.

How well I remember in hot July weather trays of Rose leaves drying on the window-sills to make pot-pourri. We used to help collect the Roses for it, and occasional sprays of White Star Jasmine and Verbena. The pot-pourri was eventually put into big oriental bowls, or blue china jars, and the Rose leaves smell as sweet as ever to-day, though it is not ten years but twenty since they were gathered.

In the still October weather, when the days of summer joys in the garden were numbered and leaves had turned a golden-brown, came the business of picking the Quinces and Medlars that grew on low hanging branches, within the reach of children mounted on a short ladder. The yellowy brown Quinces were carried triumphantly indoors, there to be converted into moulds of jelly and stored away on the storeroom shelves, while the Medlars slowly ripened, or rather rotted in straw on the ground. There was yet another autumn treat, which was to watch the beating of the Walnut trees, and to eagerly dive among the thickly fallen leaves for the Walnuts, some still encased in their juicy green husks, and some almost ripe in the polished brown shells.

I cannot end these memories of the dear old storeroom, which was so closely connected with a garden we less beloved, without mention of a Nutmeg tree, an unusual occupant of an English garden. No one knew how it came to be there, and the Nutmegs never ripened properly, but the tree was pretty enough, with its blood-red leaves and tiny scarlet nuts, Filbert-shaped, that smelt so strongly of spice that they almost drowned the scent of the other plants in the flower-bed. DOROTHY DEAN.

STILL (?) OCTOBER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—How pleasant it would be if we could borrow each other's eyes for a time; we should see new worlds—occasionally much better ones. Was it not Turner who answered a lady, who complained that she could never see a landscape as he painted it, "No, madam; don't you wish you could?"

Thus the phases of the varied year appeal to all of us in different ways. October's tempests are by some of us less heeded than its subtler beauties. My critic "S. W. F." has, perhaps, quoted me from memory, for his inverted commas enclose a sentence I did not write—"The charm of the tenth month is its stillness." I did not claim that. It would be exaggeration. After referring to the storms that sometimes rend October I continue a little further on: "But the rarer and more excellent charm of the tenth month is its stillness." This is what I said and what I think.

THE HOME OF ALPINE IRIS (I. VIRESCENS), VALAIS, SWITZERLAND.

As a Nature lover (which my critic is) he will, I am sure, admit the wonderful quietude that does at times pervade that changeful, flower-fading, leaf-painting month which provoked his "wry smile" as he contemplated the wreckage in his October garden.

Even here in breezy Norfolk, with salt winds blowing straight from the North Sea, the lovely stillness that belongs to late autumn and early winter has been a boon the year has not withheld. Some weeks ago, at a spot where four roads meet and the winds are generally rough, was witnessed a scene of deepest—almost of spiritual—calm. A farmstead in a group of trees, with sunset fires behind them, the whole scene mirrored in a pool between it and the road; not a breath upon the surface of the water, the reflection far more life-like than the reality. Even the smoke of the "keeping-room" chimney, as it puffed vigorously downwards, looked less like dreamland than its counterpart above. It was the one and only thing that was not motionless, and it seemed a wonder that it should not cause a ripple. Many times we had passed this way in summer, but never to see such utter peace and stillness as in this later month which heralds winter.

It is such scenes as this—who has not met with them?—that do most powerfully impress and colour our associations; they are, to our minds, among the best and most precious gifts of the shortened days, when "moths go, mists come, and frosts remain." F. A. B.

ROSE SHOWS OF THE FUTURE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I was very glad to notice in your report of the meeting of the National Rose Society that mention was made of the necessity for making the Temple show more attractive to the public than it is at present. It seems to me to be quite time the committee made an alteration in the staging of the exhibits. At the Temple show last year the only crowded tent was that where the trade exhibits and garden Roses were shown. The big tent, with its rows of "little graves," looked most desolate, and after four o'clock all interest in the exhibition seemed to me to have departed. The committee will, I hope, seriously take that fact to heart, and

give over the centre of the tents, not occupied with exhibits of garden varieties, to the trade for "display exhibits," say, for a medal, and have the show boxes arranged around the sides of the tents only. The trade growers would only be glad of a chance of putting up an exhibit of Roses, both growing and cut. At the Royal Horticultural Society's show, where the Roses are one of the chief attractions, the public see them growing and flowering, and if they can be exhibited in pots from under glass in May, why not from out of doors in July? How much Dorothy Perkins was admired when exhibited as a pot plant. The public get tired of seeing the same Roses in boxes time after time. They like variety as well as quality. Roses like Mme. Eugène Régal, Enchantress, Mme. Abel Chatenay, Camille de Rohan, and other beautiful varieties are never seen, yet they are admired at the Royal Horticultural Society's exhibition. People like to see baskets of Roses of medium size, those they can recognise by their own specimens growing at home, whether show varieties or not, as well as the beautiful "Paony flower" exhibition ones. It is to the public the society has to look to for its future. It must reciprocate. C. J. P.

AUTUMN RASPBERRIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It may interest you to hear that our autumn Raspberry crop, noted in a late issue of THE GARDEN, continued to ripen up to November 29, and in that month the yield was 1 lb. of fruit to each 9 feet, run of row. This was, of course, in addition to the crop in October, which was heavier, and to those gathered during the latter part of September.

NEW HYBRID ALPINE IRIS.

I SEND you photographs of my new early flowering Hybrid Irises. One variety, Bouquet, is pure white with slight grey tinge on the falls. This photograph was taken in February last from plants potted up in late autumn and placed in a greenhouse, where they made a gay

show, that was in advance of Daffodils and the majority of spring flowers under glass. The blooms last fully a week in perfection at this early period of the year, and where a few varieties are grown a succession of flowers is readily kept up for fully two months. They are quite easily grown and multiply quickly, so that a sufficient number of them for pulling up each season may soon be obtained. Plants which bloomed indoors in January and February were planted out in the open again in March and April, and by September new rhizomes had grown up to a flowering size. These can be picked out, as they always show a tuft or two of side leaves as well as the main central one. When this only is seen the plant should remain for another season's growth. They are not particular as to soil, but prefer a strong loamy one perhaps, fairly well drained, and for situation as much free air and sunshine as possible.

Photographs were obtained of single rhizomes which have five, and one or two of them six flower stems, each of which gave two flowers, so that the number of blooms actually produced by a comparatively small number of rhizomes was considerable, and when the great range and variety of colour—from purest of whites through light greys, blues, purples, clarets to red, rich yellow, bronze, pale and lemon yellow up to cream and ivory tints—is considered it must be admitted that the show they make is delightful. As with their shades so with their shapes, for the Iris flower has to be studied with the same discrimination and the same appreciation of the nice points of distinction that are given to the Rose so readily.

Finally the hardiness of these little mountain plants is a great point in their favour. No frost seems to hurt them, they will take to places where few other plants would thrive, say, in thin soil on windy borders, provided they have a fair amount of sunshine and no overshadowing from plants, trees, or weeds; then from year to year as spring comes they increase and bring out their wealth of colour.

Rohais, Guernsey.

W. I. CAPARNE.

THE FRUIT GARDEN.

STRAWBERRY CULTURE FOR MARKET.

EARLY Strawberries will almost always command a fair price, and when grown successfully prove a profitable crop. They are often grown on shelves in houses with other subjects. I have seen some good crops grown on shelves in vinerias, also in Tomato houses, but they require careful treatment, and when houses can be devoted entirely to their culture the ventilation and temperature can be much better regulated. The houses may be of any size, but should be well heated and have good ventilating arrangements. The stages should be as near the glass as convenience will allow.

It is of the first importance to have strong well matured plants to start with and to select good varieties. At the present time Royal Sovereign is a general favourite with market growers, but for very early work the old Keen's Seedling is sometimes grown. Vicomtesse Héricart de Thury is also a good early variety. Sir Joseph Paxton and President may also be recommended. The earliest runners possible should be secured. They may be rooted in 3-inch pots before taking them off the parent plants, or taken up after they have rooted in the ground. As soon as sufficiently established in the small pots they should be potted into their fruiting pots; these may be 6-inch or

7-inch ones. The compost should be prepared some time before it is required for use, good loam or stable manure, and before adding to the loam some soot should be well mixed with the manure; this will destroy worms or other insects. Some crushed bones or Thomson's manure may also be added.

If the soil is in good condition it will be impossible to pot the plants too firmly. The crown of the plants should be kept well down, but not buried. After potting they may be placed out in the open fully exposed to the sun. Some arrangement should be made to prevent worms penetrating the pots. Where the ground has been well prepared and has a good covering of ashes worms will not be troublesome. Regular attention to watering, and later on applications of liquid manure and soot, may be used freely for a time, but after they have completed their growth this should be withheld and water given sparingly; by keeping them dry they ripen off and mature their crowns better, and before we get heavy rains in the autumn the pots may be laid on their side. Store in cold pits before winter.

When starting them give a temperature of about 50° Fahr. with plenty of light and air, and with sun the temperature may go much higher, but too much heat, especially in dull weather, must be avoided. The most critical time is when the flowers begin to open. The house should be kept rather dry and air given freely, but do not let them become dry at the roots. After a good set of fruit is secured the later flowers may be taken off. Manure may be used until the fruits begin to colour. In growing for market a regular succession should be kept up rather than to have a large quantity in at one time. The very early crop generally commands the highest prices, but sometimes the later ones may prove equally as profitable.

In gathering and packing the less the fruits are handled the better. The best samples should be packed in single layers in punnets or shallow boxes with a leaf between each fruit. There are various methods of packing, the most recent improvement being the small square baskets, which may be packed together in boxes. With all fruit a little extra care in packing will be well repaid, but with none is it more essential than with Strawberries, and mixed samples never sell so well as those divided into two or three sizes. Strawberries should be fully ripe when gathered.

A. HEMSLEY.

THE RENEWAL OF OLD FRUIT TREES.

When reading a short paper before the Royal Horticultural Society last year I was challenged to give a few hints as to the renovation of old fruit

trees, which I will now endeavour to do. It frequently occurs that a halo of sentiment hangs around and envelops the old fruit trees of our gardens, dating perhaps from the days of youth, when it was a real pleasure to pick and eat a fruit (when the gardener was away), and to feel that by that unrighteous act one had added a mite to one's horticultural knowledge; for, as a member of the family, we felt we had rights in the fruits of the orchard and gardens which were not always recognised by the reigning chief. And as we grew up and came home—possibly to take the place of beloved parents—a certain fondness for the well-known old trees appealed to our minds, and we could not entirely yield to the gardener's suggestion that "them old trees wasn't no sort of use, and had better be made into faggots," and some fresh ones be purchased to put in their place. So it

NEW INTERMEDIATE IRIS (VARIETY IVORINE). SLIGHTLY REDUCED.

came to pass that, after a quiet talk, we assented to half measures and gave the old trees another trial, either by grafting some new varieties upon them, or by cutting away the old mossy and gnarled spurry boughs, and assisting them by a liberal stimulant at the roots, and so started them into new growth.

Now it is possible in many cases thus to renew aged trees; Pears are particularly amenable to treatment, Apples partly so; but worn-out Plums, Peaches, and, in fact, all stone fruits (except Cherries in orchards) are better destroyed at once, and replaced by new trees of the best varieties, using a liberal supply of fresh turfy loam to start them in. Under such treatment they will soon respond to the trouble bestowed on them and quickly fill up the vacancies.

Stone fruits will not endure that severe pruning which is necessary to renovation, being liable to "gum" on the strong shoots produced, or to "collar" at the junction of the new growth with the old stem, and thus blow out under the strain of heavy winds, or choke with gum and become useless. Cherries in orchards, however, never get beyond treatment, and to renovate them the trees should be gone over as soon as the crop is gathered, all the dead wood removed, and the boughs which are injured by breakage, or "splits," from contact with ladders, &c., at gathering time, or from the strain of an abnormal crop, be cut away. Then, if in pasture land, the long strands of grass, thistles, and weeds should be mown, and with the cuttings and prunings removed from the orchard and burnt. Sprinkle salt at 2wt. to the acre over the ground, and when a new growth of grass has set in turn in some ewe sheep and feed them with Oil-cake, Chaff, Oats, Peas, or Barley once a day; move the feeding troughs every other day to fresh positions, until the new grass is fed down as close as a Turkey carpet, and continue this treatment through the winter, giving more or less food to the sheep, according to the weather, naturally most in cold times. The manure of the sheep will gradually improve the grass sward and cause the Cherry rootlets to rise in March to the surface for the nourishment to be found there. An earlier crop of foliage will thus ensue, which will protect the young fruit from those severe frosts which often occur in May, and even in June. The fruit will be nourished by every shower that falls, and after it is gathered new growth will be stimulated and a store of vigour imparted to the trees for the following year's crop.

On light soils the land in Cherry orchards may be again dressed with salt or kainit, and on heavier soils a dressing of twenty bushels of soot or 5wt. of basic slag to the acre in February will be of infinite value to the trees as well as to the grass. The same system will also renew or invigorate Plum, Apple, and Pear orchards, but the boughs should be very severely thinned, the useless spurs removed, and the centre of the heads of the trees be kept clear and regulated.

In renewing old Pear trees trained on walls one system is to cut out every other lateral tier 6 inches from the main stem and start the shoots behind the cut to form new tiers. Afterwards, the remaining worm-out tiers can be served in the same way, and thus the tree will in time be entirely renewed with young wood. In cases where the variety is only second rate (as so many of the Pear trees are that were planted some fifty years back) the lateral shoots can be grafted 1 foot from the main stem, and in two years' time will begin to give a small crop. Supposing a tree of eight tiers of branches, as many different varieties of recognised merit can be grafted in, or the tree may be used for the testing of new varieties, and in this manner a crop can be relied on in three or even two years, the root vigour of these old trees being very powerful. If needed some stimulant, mulching lightly, forked in may be used to assist the new growth. Another plan which I have seen successfully carried out is to remove all the branches and main stem down to the lowest tier, and by this radical operation the formation of strong new shoots will be stimulated from this lowest tier, which can be encouraged to grow in an upright form at such regular distances as are desired.

In this way a crop is readily secured the second year, and it is a very good plan for varieties which, like Jargonelle when old, often fruit on the ends of the branches only, and for other varieties which form a mass of fruitless spurs.

As regards overgrown pyramids and bushes both of Pears and Apples in gardens, I should advise that all of poor or doubtful quality be at once dug up and destroyed, while those which are of good recognised varieties should be allowed to grow in a free and natural way, merely thinning out the superfluous inside shoots; they will thus soon produce freely on the branches of two or three years' growth.

In cases where Pears are on the Quince stock, and Apples on the Paradise, they are more easily dealt with, as the roots are closer to the stem;

and if a trench be made round each tree, the coarse roots removed, and the trench filled with fresh soil, the new rootlets formed will be so abundant that the tree can readily be lifted and removed the following October, and be either placed in a new position, according to size and vigour, or be regulated in their former positions and refreshed with new soil to work in. We prefer, however, to make an entirely new plantation with the old trees elsewhere, and to substitute (after a year's fallow or inter-crop) a fresh lot of trees altogether to fill up the ground thus left empty. This gives a chance of renewing the old stale soil, and also of introducing new or desired varieties.

Where, however, the garden is limited, only half of the old trees should be operated on in one season in order to lessen the chance of an entire failure in the supply; but the old removed trees will after a season's growth more than reward the operator for any trouble he has taken with them. So far as cordons on walls are concerned, we should prefer to replant entirely, remarking the borders at the same time, as new trees can be purchased in a forward state at a cheap rate, as severe measures frequently prove unsuccessful.

With old Peaches, Nectarines, and Apricots it is far best to destroy them outright and start with young trees. In all good gardens a reserve of young free trees is maintained, so that a gap can be filled at once by a vigorous, healthy subject of three to five years' growth, which itself is all the better for the check it receives in removal. In the Society's Journal, vol. xxv., page 363, a wonderful drawing is given of a large trained Pear tree which was so successfully renovated by rooting the lower branches that the main and original stem could be dispensed with. In other words, the tree first had one, then three sources of root nutrition, and finally two.

In all cases new soil should be introduced to the roots. Good sound turfy loam is better than heavily manured soil, and if stimulant be necessary it is best supplied as a top-dressing. There is yet another way of dealing with old overgrown pyramid trees. After two years of free growth, as before named, the resulting shoots can be tied into a frame and made to assume a set form; thus treated they fruit freely, and the branches being secured the fruit is not bruised by the winds. It should be mentioned that where large trees are headed back the new shoots are very strong, and must be duly nailed in or otherwise secured; and if a second lateral growth should be formed from the lower eyes it should be pinched at the third leaf to encourage fruit buds to form.

Very old Figs often get bare below and far too crowded at the top of the wall. These should have the large coarse boughs cut away at the base and the best of the resulting new shoots be nailed to the wall. It is a great mistake to let Figs carry too much wood, and they more often suffer from over-manuring than the reverse. In fact, where they root into the vegetable borders it is as well to make a trench 2 feet wide and 3 feet deep and fill this with broken bricks, porous stone, loam, and old mortar rubbish. The roots revel in this material, and the trees lay up good, hard, sound, fruitful wood.

Though the Grape scarcely comes under notice in this paper, old Vines can be safely cut back where the precaution of leading up one or two long rods from the base of the cane has been previously taken. But it must be borne in mind in such cases that the borders often get into a bad state or that the roots go searching for nourishment in positions too far from the surface, so that the wisest economy may be to make entirely new borders and start with fresh Vines. In a small garden half the viney should be taken in hand at a time, but where several vineries are in use one house can be renewed in a season.

All small fruits, such as Gooseberries, Currants, and Raspberries, so soon bear fruit that old unsightly bushes are best destroyed to make room for new ones. It may be as well to say that Strawberries are of but little use after three years, and new beds should be made annually, so as to keep up a regular series.

Where old trees are to be grafted, the stems should be prepared in February, and the new grafts be inserted by the end of March. As the shoots swell very rapidly, the junctions of scion and stock must be carefully watched, or the tying material may cut into the new growth, causing it to be a harbour for insects and making it liable to snap off, and so losing a season. The scions should be cut in February and be laid in the ground half their length deep in a shady place until wanted for use.—G. BUNYARD, in *Journal of the Royal Horticultural Society*.

THE KITCHEN GARDEN.

THE CROPS DURING 1902.

WITH HINTS ON THE BEST VARIETIES FOR THIS YEAR.

GENERALLY speaking the past season cannot be regarded as satisfactory so far as the production of first-class vegetables is concerned, especially on heavy retentive land and in cold low-lying districts. This to a great extent can be accounted for by the ungenial weather experienced in spring and the absence of sunshine during the greater part of the summer. At the same time the rainfall has by no means been excessive, for until the present date we have only had about 20 inches, and as we were about 3 inches below the average in 1901 we may expect a good fall yet.

POTATOES.—Unfortunately, in many places the crop has been almost a failure, and even where this is not so the quality is anything but first-class. I have seen large fields in good Potato-growing districts absolutely not worth lifting in some cases, owing to an attack of the commonly-known disease, but in many instances for quite another reason which I can in no way explain; neither have I been able to get from anyone else a satisfactory explanation. Instead of the shoots coming through the ground and growing strongly they came up miserably weak and absolutely refused to grow. I have observed this under all sorts of conditions, both in open fields, enclosed gardens, and even in frames. In our own case I am prepared to prove that the tubers were properly stored and started, and when planted appeared to be all one could desire, the tubers being firm and the shoots sturdy and healthy. Some kinds did well, while others, planted and treated precisely in the same way, position, and date, were worthless. On examination of the old sets at lifting time these were practically as sound as when planted. It would be interesting to hear, through the medium of THE GARDEN, other experiences and what this is attributed to. Among the varieties which have succeeded in this locality are Windsor Castle, unsurpassed for quality, but should be planted and lifted early; Syon House, also good; Up-to-Date, quite one of the very best still for field culture; Carltonian, a new variety, which was tried and received an award of merit at Chiswick in 1891, is of great promise, being very handsome in appearance, a good cropper of fine quality, and apparently not subject to disease. I believe this variety has a great future before it. For frame culture Sharpe's Victor is still one of the best; so also is Carter's New Ashleaf, quite distinct and a great cropper. It may be interesting here to note that the collection of Potatoes staged by Messrs. Dobbie and Co. of Rothesay in October at the Drill Hall was probably the finest lot ever seen, and was worthily awarded the Royal Horticultural Society's gold medal. I understood these were produced from the open field and not specially treated, so that I trust other growers in the Scotch districts may be equally fortunate.

PEAS.—On the whole this may be regarded as one of the best seasons on record, in spite of the fact that the early sowings were particularly late in bearing; but the mid-season and late kinds I have never seen better, if as good. Owing to the mild autumn little trouble was experienced in

finding good dishes of fresh green Peas up till the middle of November. At the fine Brighton Chrysanthemum Show, held on November 11 and 12, at which vegetables were well and largely shown, nearly every collection contained a dish of really first-class Peas, quite equal to what one sees in August. Varieties worth noting for pot and frame culture were Carter's Forcing, very fine; Early Morn is also good for growing under glass, but requires more room. This is also one of the best early kinds for outside cultivation, being very prolific and of fine flavour, a much improved form of Gradus, and probably a selection from this well-known kind. Daisy is hard to beat as a dwarf variety, and, strange to say, it was recognised as one of the best among the extensive trials made at Chiswick during the past season. Though this has been in commerce several years I have always regarded it as one of the best Peas sent out by Messrs. Carter and Co., a firm which has done much to improve this important vegetable. It has an excellent constitution, a point which should always be taken into consideration in Pea culture, is hardy, very prolific, and of the best quality. For second

others for forcing and outside culture. Ne Plus Ultra is also good, but the pods are much smaller and the yield not so great as the first-named. I grew seven varieties of Runners, all of which did well, the best being Sutton's Prizewinner, Carter's Jubilee, and Neal's Ne Plus Ultra, all good either for exhibition or for home supplies. Few vegetables appreciate good culture more than these.

CAULIFLOWERS.—It has been an ideal season for these; I never remember a better. We have had an unbroken supply from the first week in May till now, and I hope to keep it up till well into the New Year. We commenced with Veitch's Early Forcing and Carter's First Crop in 8-inch pots. Both did remarkably well, and, following these, Sutton's Magnum Bonum in pits, then Walcheren (a fine old variety) and Webb's Peerless on a south border, following with autumn-sown Autumn Giant. This variety is a true gardener's friend, and Messrs. Veitch and Sons are to be congratulated on introducing such a general favourite. By making frequent sowings little trouble will be found in maintaining a continuous succession from early July till the end of the year. The latest sowings should be lifted with good balls of earth

seasons. I hear from many sources that the large bulbs, owing to imperfect ripening, are keeping very badly, and the home-grown seed in many places is a complete failure. Ailsa Craig still holds its own, also Cranston's Excelsior, both fine for exhibition. Ne Plus Ultra, a cross between Ailsa Craig and Carter's Record, is larger, and keeps well, but lacks that fine quality seen in the two first-named.

CARROTS.—The stump-rooted early varieties proved to be excellent, but this cannot be said of the intermediate and long kinds in most places. These were badly attacked with wireworm, the colour poor, and the keeping qualities very unsatisfactory. During the whole season I scarcely saw a typical dish. For early forcing I have found nothing to equal Carter's Long Forcing, which makes but little top, quickly matures, and is of excellent quality. Veitch's Model and Sutton's Favourite are both excellent to succeed this, and fine for exhibition at the early shows. Webb's Prizewinner proved to be the best of the intermediate type. With us it is deep in colour, and the shape all that one can desire. The new variety (Carter's Blood Red) is probably the finest coloured variety in existence, but, unfortunately, its constitution is not of the best. This, however, should prove the forerunner of something worth having. In any case this variety should be included in all collections where good Carrots are valued.

CELERY.—The early sowings of this very important crop failed in many places. I have known instances where the entire plantings ran to seed, and in others a very large percentage bolted also. This cannot be attributed to sowing the seed too early, the same dates being relied on as in former years; the cause no doubt could be assigned to the check it received after planting. Fortunately the later sowings have proved to be good, making quick and excellent growth, which is most essential for crisp, well-flavoured Celery. Veitch's Early Rose and Sutton's Early Gem are excellent early varieties, and a good selection of Standard Bearer cannot be beaten as a red variety, either for exhibition or home use. Webb's Solid White is very good indeed, being very taking when well grown and blanched and the quality of the best. Late Celery, owing to the late growth it has made, will require protection should severe weather set in.

BETROOT has been a good crop, especially where not sown too early. I have met with nothing new which is in any way an improvement on the standard kinds. The globe varieties are excellent for frame culture.

PARSNIPS made a luxuriant growth and promised well, but lifted badly, especially on heavy sand. Like Carrots, these have been much below the average, having cankered badly, and specimen roots were rare. Carter's Maltese and Sutton's Tender and True were the best with us.

CABBAGE have been good all through. Coleworts I never saw better. Ellam's Dwarf Early is unsurpassed for all seasons or for any purpose.

LEKES have been fairly good, but late. The culture of these in the southern districts is yearly becoming better known, and few vegetables are more admired at our exhibitions when well shown. The Lyon and Webb's New Champion should not be missed by any exhibitor.

TOMATOES have proved a failure in the open many districts, but have done well under glass. There are now a host of varieties, differing only in name. Polegate and Perfection are among the best for any purpose, both of which are splendid in shape and of very fine quality.

TURNIPS.—I never remember a better season for these, the appearance of the bulbs and the cooking qualities having been all one could wish. The late September sowings will prove invaluable for spring use. No one should fail to grow Carter's Early Forcing in cold frames for its earliness. I regard this as one of the finest varieties ever

THE FAMOUS NEW PEA EDWIN BECKETT. (The photograph was taken in Aldenham Gardens, Elstree, late last June.)

earlies, Duke of Albany and Alderman are both excellent, did well, and are universally well known. The variety I raised and named after myself fully came up to my expectations, and I trust it will do as well with others as it does here. No doubt it will be within the reach of all during the coming season. Sutton's Prizewinner is also good, and deserves a place in every garden. The Gladstone has done remarkably well during the past season. It is a great bearer, of fine appearance, but somewhat overrated, in my opinion, as to quality. Veitch's Autocrat has not yet been superseded as a late kind. It is by far the most reliable variety I know, and succeeds well in nearly all districts. Webb's Masterpiece somewhat in the same way is also excellent, and did wonderfully well with us, the pods being slightly larger than Autocrat.

BROAD BEANS did well, and gave good supplies for a long season. Leviathan, Aquadulce, and the new Broad Green Windsor should all be grown.

FRENCH AND RUNNER BEANS.—I made a very extensive trial of these, and, though like Peas, were late coming into bearing, they gave excellent returns till quite late in the autumn. Canadian Wonder still keeps up its reputation as a French Bean, and when well grown is far ahead of all

and placed in cold frames on the approach of frost, when these will produce small pearly white heads, so well suited for the dining-room table.

BROCCOLI have done well, and if means have been taken to protect them good results should follow; in most localities it is necessary to layer these early in November, especially in 1902, as the growth is strong and sappy and not at all matured, and, should a severe winter be in store for us, these are sure to suffer seriously. Sutton's Michaelmas White and Veitch's Self-Protecting are both good early varieties, the first-named much resembling a Cauliflower. A true stock of the old Snow's is invaluable, also Leamington; and for latest supplies Veitch's Model and Sutton's Late Queen are hard to beat.

ONIONS.—Autumn-sown kinds did wonderfully well, seldom better, Carter's White Emperor being the best early white variety. Sutton's White Leviathan is also good, being larger, but later. A good strain of Red Tripoli is worth having, and is one of the best keepers. Spring-sown kinds have been far below the average in many places, a large percentage having run to seed, owing, no doubt, to the check received after planting, and the bulbs generally lacked size and that fine finish which has been so noticeable during the past three or four

introduced. If sown early in March it will be fit for use the first week in May, and the great advantage it possesses over all other early sorts that I am acquainted with is that it is not only of the finest quality but remains in good condition for a considerable time. Sutton's Snowball, Webb's Prizetaker, and Veitch's Red Globe should all be grown. The latter is especially valuable in hot, dry seasons when good Turnips are scarce.

VEGETABLE MARROWS.—I never remember these so poor as they were during the past season. Except early sowings grown in frames, these revel in a hot, dry season such as we experienced during 1900 and 1901. A splendid addition to these is Sutton's Perfection. I do not hesitate to say that this is the most perfect Vegetable Marrow for any purpose now in cultivation, and no vegetable grower should fail to procure this novelty.

EXHIBITING VEGETABLES.

I have been pleased to note a very marked improvement in the preparation and staging of our various kinds of vegetables at the principal exhibitions during the past year, but there is still a good deal to be learned. A well-arranged collection of vegetables is always admired. I am far from advocating the principle of arranging vegetables in designs and devices as is sometimes done. This is childish and absurd, and serves no useful purpose. I trust the proposed vegetable exhibition to be held next autumn by the Royal Horticultural Society will do much to set up a standard (which is badly needed) as to what should constitute high-class vegetables and the mode of arrangement.

In conclusion, I must congratulate both Messrs. Fyfe and Gibson on the two splendid exhibits they made at different dates in the Drill Hall, when each received the coveted award—a gold medal.

E. BECKETT.

Aldenham House Gardens, Elstree, Herts.

BOOKS.

Wild Fruits of the Country Side.*

This is a work of much charm, delightfully got up, well printed, and with thirty-six good coloured illustrations of fruits and foliage familiar to way-side and woodland. Such books add greatly to our knowledge of the trees and shrubs of the country side, and open the eyes of those who observe not the beauty of fruit and leaf, of berry and twig, when mellow autumn is clad in its ripest and richest colours. Tree and lowly hedgerow plant, Carrot and Parsnip have each a place in the book, and the text is as ample as almost all can desire, though the author would have rendered more helpful assistance by conveying more practical information as to the needs of the various subjects dealt with so pleasantly, but probably that would be considered outside the scope of the book. Here is the description of the Cuckoo-Pint (*Arum maculatum*), which will show the character of Mr. Hulme's text: "Our fourteenth illustration depicts the brilliant berries of the Cuckoo-Pint or wild Arum (the *Arum maculatum*). This plant, common enough almost everywhere in damp and shady hedgerows or under the shade of the trees in the copse, is curious in the way it presents itself to us under such an entirely different guise at different times of the year. In the spring we see its quaint inflorescence rising from the midst of its mass of foliage, then that all passes out of sight and is forgotten, and presently, when the autumn days come, we see the scarlet spikes, such as we have figured, rising amidst the low vegetation in their naked simplicity, the leaves, like the flowers, having disappeared months ago. The leaves are bright and shining, as though highly glazed or varnished, and are of arrow-head shape. They are of a deep green colour, blotched over with purple spots of various sizes. They are so acrid that they inflame and irritate the skin, and may even raise blisters. Bulliard, in his "Histoire des Plantes

Venemeuses," instances the case of three children who ate some of these berries. They were seized with horrible convulsions, their throats becoming so swollen that they were unable to swallow anything; two of them quickly died, while the third was saved with great difficulty. . . ." All the descriptions are somewhat minute and recall those of the same author in "Familiar Wild Flowers." We must mention also that the plates are by Mr. Hulme. The book is altogether excellent, and should command a large sale. It forms a volume in the Woburn Library of Natural History, edited by the Duke of Bedford, K.G.

GARDENING OF THE WEEK.

INDOOR GARDEN.

ANTHURIUMS of the andreaeanum and ferriense types that have not yet been repotted should be now taken in hand. Shake away carefully all the old soil and remove decayed roots with a knife. Plants that have become leggy should be cut down close to the surface of the soil, preserving all the aerial roots produced from the stems or rhizomes of the plants. As this section is almost epiphytal the compost most suitable is two parts good fibrous peat, with all the finer particles shaken out, one part light fibrous loam, the remaining portion to consist of rough hard charcoal, clean oyster shells broken up, and coarse silver sand. Fill the pots to one-third of their depth with large clean potsherds, which cover with a portion of the compost, then arrange the plant so that the crown of the stem or rhizome is slightly above the rim of the pot. Work the soil among the roots as firmly as possible, keeping them well up in the compost, and finish by having the surface slightly mounded above the rim of the pot. Those leggy plants cut off at the surface of the soil will require smaller pots in consequence of having fewer roots. When potted place the plants in a temperature ranging from 58° to 62° by night with a rise of 5° by day. Syringe the stems of the plants and amongst the pots twice daily, and keep the house moist, admitting air only by the bottom ventilators under the stages.

HIPPEASTRUMS.

A portion of the stock of these bulbs should now be started for early blooming. Select such bulbs as do not require repotting. Clean over the bulbs, removing all loose and dry scales and insects should there be any. Loosen the surface of the soil with a pointed stick and remove it, being careful not to injure the roots, and top-dress with three parts of good loam, some dry cow manure rubbed through a fine sieve one part, with a good admixture of charcoal, finely broken crocks, and silver sand; it should be rammed firmly. Place the bulbs in a temperature of 54° to 58° and in a bottom heat of 5° above that of the atmosphere. One soaking with tepid water will suffice until the flower-stems are 2 inches to 3 inches high and in advance of the foliage. Afterwards water with care, remembering that these bulbs require only a very moderate amount of moisture beyond what they get by the daily morning syringing.

GLORIOSA SUPERBA.

Place a few tubers of this stove climber in a bottom heat of 65°, giving sufficient water to moisten the soil about them with a view to producing a few early blooms, and where the atmosphere will register a temperature of 65° to 68°. Where house-decoration is required put in cuttings of *Pilea microphylla*, *Panicum*, the green and variegated forms; *Selaginella paniculata* in large 3-inch pots, twelve or more cuttings in each. Also break up old plants of *Isolepis gracilis*, *Carex elegantissima*, *Cyperus alternifolius*, and *C. a. variegatus*. These, broken up into small parts and potted in any light rich sandy soil and placed in a temperature of 60° with a close moist atmosphere, will quickly root and make good plants

for covering the surface soil of Palms and other plants which may have to be placed in corridors or rooms.

Wendover.

J. JACQUES.

FLOWER GARDEN.

WORK in the flower garden must now be regulated by the weather, but every opportunity should be taken advantage of and work pushed on with all possible speed. Bulbs not yet planted should have immediate attention. Any surplus stock of Hyacinths, Tulips, Crocus, &c., in fact, any of our early spring-flowering bulbs, may be used for planting under trees or on any barren spot in the vicinity of the flower garden. Now that work is not quite so pressing, time may be found to dig holes about a foot square, fill in with any good rich soil, and plant the bulbs forthwith. Many of the spots that admit of very little sunlight later on through the density of foliage may be made to look bright in the spring time. And, to my mind, nothing looks prettier than these bright-looking flowers showing their heads above the surrounding undergrowth of wild vegetation.

IRIS SUSIANA (THE MOURNING IRIS).

These planted early in autumn will now be pushing their leaves through the soil. A sharp look-out should be kept for slugs and snails. These, together with damp and moisture, are the most inveterate enemies of this plant. Nothing should be allowed to accumulate near the foliage that is in any way likely to cause damp. Finely sifted coal ashes, or clean cocoanut fibre, placed on the bed and round the collar of the plants is a capital safeguard against slugs. Many of the failures in the culture of this interesting subject may be traced to slugs and snails eating out the centres of the plants in the earliest stage of their growth. Any trouble that may be taken to prevent this will be amply repaid when the flowering season arrives.

EAST LOTHIAN STOCK.

This is one of our most useful plants for many purposes, and where Geraniums are not used for bedding, on account of the room necessary for storing them through the winter, Stocks may be grown to great advantage. I can now gather handfuls of flowers from plants in the open borders from seed sown last January. Sow the seed in boxes or pans from the middle to the end of the month. When sown place the seed in a gentle heat. A vinery which has been started about a month will do. Cover the boxes or pans with glass and shade with a piece of paper till the seedlings show; then put them where they will get plenty of light. Sift a little dry soil on them to prevent their damping off. As soon as they are large enough to handle prick them out singly into 3-inch pots; put them again into a warm house to give them a start, and they will soon make a little growth and begin to fill the pots with roots. They may then be put into a cold frame, which should be kept close for a few days and covered at night if the weather is frosty. After that air should be given on every suitable occasion. Gradually harden them off until they are ready for planting out, which should be early in May. The soil in which Stocks are planted should not be rich or wet, or that tends to make them grow strongly and not flower so well.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

KITCHEN GARDEN.

ONIONS AND LEEKS.

THESE should now be sown where large specimens are required for exhibition or for use in the kitchen. Even in gardens where no exhibiting is done, a few rows of these should be grown, as they are extremely useful for special dishes. Of Onions, that well-tried variety *Ailsa Craig* is hard to beat, and, although there are other excellent varieties of the pedigree Onion, I place faith in the above-named.

LEEKs

of the Lyon and Prize-taker varieties are the best for this sowing. The seed should be sown thinly

* "Wild Fruits of the Country Side." By F. Edward Hulme, F.L.S., F.S.A. Published by Messrs. Hutchinson and Co., 34, 35, and 36, Paternoster Row, London, E.C.

in boxes 4 inches or 5 inches deep, placing a layer of crocks concavely over the holes at the bottom. Over all should be placed a layer of rough fibrous loam with the particles of fine soil beaten out in order to prevent the soil running among and blocking the drainage. The compost should be put through a quarter of an inch sieve, and be composed of two parts loam to one each of leaf-soil and well decomposed, rather dry manure, adding a shovelful or two of soot and wood ashes and sufficient sand to make the whole porous. Make moderately firm with the hand and leave the surface quite level, when the seed may be sown and covered with fine soil. A fruit house that has been recently started will be a good place for the boxes of seed, taking the precaution to cover with sheets of glass to prevent holes being made through drip and to hasten germination. A sheet of brown paper laid on the glass will also assist in this way. As soon as the seedlings appear they must be brought near the roof glass to prevent slender growth, and they may be removed to a somewhat cooler structure until the plants are large enough to prick off into other boxes.

HOT-BEDS

may be made with stable manure and tree leaves in the framing ground or any sheltered part of the garden. They will be found of great value for forcing Asparagus, Carrots, Potatoes, Radishes, &c. Attend to the rehiring of the beds and covering of the glass during cold weather in order to maintain as equable a temperature as possible. The earliest batch of

PEAS

may now be sown in 3-inch pots or shallow trays and placed in a genial temperature to germinate. Where large quantities of early Peas are required in the open the latter method is the best, whilst for a few rows to precede these seeds sown in pots will be found to answer well. For providing a few very early dishes a batch may be sown in 3-inch pots, and be shifted into larger sizes as required and kept in glass houses or pits, but avoid the use of fire-heat as much as possible, bearing in mind the more natural the treatment accorded the better will be the results. Grow them freely and feed occasionally when the pots are filled with roots. Abundance of light is essential or the haulm will become drawn up. Those for planting out on a warm border should be removed to a cold frame or pit as soon as they attain 10 inches in height, and all the air given that the weather will allow, in order to harden them in readiness for planting out when the weather is fit. I have found the varieties Early Morn and Chelsea Gem excellent for first earlies. Five plump seeds, or at the most seven, will be enough for a 3-inch pot, and room should be left when sowing for an inch of top-dressing when the pots become filled with roots. The compost should consist largely of loam with some old Mushroom bed manure rubbed through a sieve and mixed in to enrich it. Watch must be kept for rats and mice, or they will quickly make short work of the seed or young plants.

Stoneleigh Abbey Gardens. H. T. MARTIN.

MISCELLANEOUS.

NOTES FROM SWANSWICK

IN a season like this—it is still raining—one must summon up all one's make-shifts and apply craft to that outwitting of the elements that spells two-thirds of success. Not to be grandiloquent, I mean that one must get the continuous planting that goes on where labour is short done somehow, and when the ground is like unboiled Christmas pudding, as it has been here ever since June, there seems to be only one way of getting over the difficulty, namely, by digging out a hole for each plant and filling up with dry soil from a reserve under cover. As we do not suffer much from frost it is

possible by this means to go on moving seedlings and dividing perennials whenever the weather permits all through the winter, but they could not possibly be inserted in the cold paste of the soil as it now is without such a precaution. There is always a pleasure in circumventing Nature's obstacles, and this the plants seem to share with us, judging by the way in which some seedling Polyanthuses and Aquilegias so treated have gone ahead. I suppose this is one of the gardener's happiest seasons. At any rate, if there is a greater pleasure than

MAKING UP SEED LISTS

I have not met it. The only drawback is the evident impossibility of dealing with more than, at the most, one-tenth of the seeds one wants, which always confronts the average individual. If money be plentiful, room probably is not, and at all events I never yet knew a gardener, amateur or "pro," who did not end, in some way or other, by getting more produce than he could use. I have just been making a considerable planting of

SCHIZOSTYLIS.

The corns (if corns they are, which I take it is the case, since they so strongly resemble Montbretias, though having fleshier roots, like those of the *Gladiolus*) came from Ireland, and are particularly fine. Apparently there is less market for this kind of thing in Erin's Isle, for whenever I answer an advertisement of any garden stuff that is at all uncommon and particularly cheap, the reply is certain to be from that quarter of the universe. The lady who sent this especial consignment tells me the *Schizostylis* absolutely refused to grow in a former garden she owned near Lancaster, but it flourishes—a fact evident from the size of the specimens received—at her present abode near Clogher, the soil of which is not stated.

WINTER MULCH FOR ROSES.

The desirability of a stable manure dressing as a winter mulch for Roses is in some quarters so authoritatively denied that I am trying the experiment of using burnt earth instead on some of the Rose beds, all of which are recently

planted. The appearance of this mulch is certainly in its favour, and as a good deal of vegetable refuse was burned with the soil it is of a very hardy texture, easily spread, clean, and workable. For beds about the front of the house it looks more seemly, too, than the untidy, if perhaps more valuable, manure mulch, which has been relegated to the remoter Rose beds. I have, in former years, tried leaving these altogether uncovered, with poor results so far as any newly-planted Roses were concerned.

PLANTS UNDER TREES.

For effect under trees there is a great deal of value in the large gold variegated-leaved *Periwinkle*, but I find it extremely difficult to start. Where the plain-leaved form, and even the little white-flowered *Vinca* that is comparatively rare, go away at once, the large-leaved ornamental one sulks for months, and frequently ends by dying. Once it gets under weigh it is as rampant as any. I also find it very difficult to push along *Clematis Flammula* in its early stage. This is good *Clematis* soil, and provided their roots and lower stems are in permanent shade and the tops in sun, any of them grow thoroughly well and fast from the first, with this solitary exception. With regard to *Tropæolum speciosum*, may I be pardoned for saying that I am firmly persuaded that, were it only an amiable and accommodating thing, *Tropæolum lobbianum fulgens*, which is generally perfectly willing to flourish anywhere, would be universally preferred as prettier and more ornamental in the same line; although, of course, the former scores by being, if it will consent to be anything, a perennial, while the small trouble of raising the latter must be annually undertaken.

M. L. W.

AN OLD-FASHIONED GARDEN.

THE accompanying illustration depicts a corner in a garden that has evidently been as it is for many years. The old espalier fruit trees, and the high edging of box, with standard Roses in between, Tomatoes grown in pots, providing shade for the greenhouse front, while Ivy covers the wall at the back, are in great contrast to the modern garden.

IN AN OLD-FASHIONED GARDEN NEAR LONDON.

The modern idea of introducing brilliantly-bedecked flower borders amongst the fruit trees has evidently not been heard of, or at least not thought highly of by the possessor of this quaint old garden. R. B.

THE LEMON AS AN INCOME PRODUCER IN CALIFORNIA.

IN starting a Lemon grove climate and soil are the two essentials. If too far from the coast it will be too hot; and, on the other hand, equal care must be taken to select a frostless location. The land must have a good fall so as to provide good drainage for cold air. Light loamy soil will produce the best results. If poorly watered or badly cared for no climatic conditions can ensure success here any more than anywhere else. The crop is gathered every six weeks perfectly green, all yellowing fruit being discarded, to be utilised as manure. A ring $2\frac{1}{2}$ inches in diameter is used, and all smaller fruit left to develop. At present things are being rushed on the ranches and at the various packing houses, so as to sell before Christmas; prices fall after then. While writing now, 75 cents per 100lb. is paid by the packer, who visits ranches drumming up trade. He assumes all expenses and risk once the crop is delivered to him. In some cases he does the picking, when of course the price paid is less. Ranchers pay 15 cents per hour to pickers, and provide boxes, which, when full, are taken to the packing-house, which is generally near a depot, and there a car is loaded. The freight cost of a car is about 300dols. Many growers hold their Lemons till warmer weather for higher prices. Stacking them in piles under a shed roofed, but wall-less, has been found to be the best mode of keeping them. A canvas covering is used, raising or lowering it according to the needs of the particular pile of fruit, which generally averages a car-load. One man handled 75 cars of Lemons so this year, holding them for five or six months, thus ensuring selling to the best advantages. Such a system best solves the problem of profitable Lemon growing. Given a plan by which a large crop can be harvested and held over till conditions change, the prolific Lemon must be an infallible income producer.

La Mesa, California.

C. MACQUARIE.

ROOM PLANTS.

THE interesting note by "T.," in response to my allusion to the destruction among Palms, suggests that those who mismanage them, while not wholly to blame for their deaths, because the raiser and seller had a good deal to say to it, frequently also kill a much hardier and more useful plant—the Aspidistra. Those who only see these things growing under miserable conditions in railway refreshment-rooms and such places—how often I have, for want of being able to give one of them the better help that under the circumstances was impossible, emptied a wineglassful of the stale drinking water offered on these attractive tables into the parched pot!—cannot form an idea of how beautiful they really are. Because the Aspidistra will stand bad usage it nearly always gets it apparently. I have some variegated plants grown in pans about 15 inches across and 7 inches or 8 inches deep, and always kept in rooms where, however, no gas is used, which are most admirable objects. They carry a very large number of leaves, and I fancy they do better in these pans than in pots; at all events, they are more convenient for house decoration. They are in loam, leaf-mould, and sand, and are given weak stable tank liquid manure once a week from April to October, in spite of which liberal treatment the variegation is consistent. They have to be repotted every two years.

M. L. W.

RECENT PLANT PORTRAITS.

THE first number of the *Revue Horticole* for January contains a portrait of *Lælio-Cattleya Yellow Prince*, raised by the well-known French orchidist M. Marou of Brunoy, and is the result of fertilising *Lælia xanthina* with the

pollen of *Cattleya gaskelliana*. It is a most beautiful clear yellow flower of medium size, with a tube clearly veined with rose colour. The seed was sown on May 2, 1896, and the first flower opened in November, 1899. It was first exhibited at Manchester, where it was also named and awarded a first-class certificate of merit.

The *Revue de l'Horticulture Belge* for January contains portraits of *Cattleya Mossie var. Sir Thomas Lipton*, a most beautiful pure white flower with brownish orange shading in the throat, and *Barosma lanceolata*, a pretty and free-blooming greenhouse shrubby plant from the Cape, with numerous small rosy white flowers.

The *Botanical Magazine* for January contains portraits of *Ruellia macrantha*, a native of Brazil, also known as *R. speciosa* and *Dipteracanthus macranthus*. This is an extremely well known ornament of our warm houses, with large tubular rose-coloured flowers. *Muscari paradoxa*, a native of Persia, also known as *M. pycnanthum*, *Bellavalia paradoxa*, *B. pseudo-muscari*, *Hyacinthus paradoxus*, and *Botryanthus paradoxus*. This is one of the largest flowered of its family, but dull in colour and of little beauty or more than botanical interest.

Chrysanthemum indicum, a native of China and Japan. This is a small flowered, bright yellow composite, with no less than sixteen synonyms. It is one of the parents of the garden *Chrysanthemum*.

Allium Ellisii, native of Khorasan. This is a handsome species with large heads of rose-coloured flowers with white centres. *Diervilla middendorffiana*, native of Mongolia, Manchuria, and Japan. This is also known as *Calyptrostigma*, *Wagneria*, and *Weigela middendorffiana*. It has pretty pale yellow flowers, with red veining on tip, but is, unfortunately, not hardy enough to withstand our winters.

W. E. GUMBLETON.

INSECT PESTS.

DESTRUCTION OF ANTS.

CARBON BISULPHIDE is the best remedy known for the destruction of ants, which are frequently a great nuisance to farmers and gardeners. With a little careful observation most of the common house ants, except the little red house ants, can usually be traced to their homes out of doors. The only effectual way of stopping the annoyance or injury from these insects is to destroy the queens living in the nests which they never leave.

Method of Treatment.—The treatment consists in making one or more holes in the nest with a stick, and pouring into each hole one or two ounces of carbon bisulphide. The hole may be closed immediately by stepping on it, or, as many writers suggest, the vapour may be exploded at the mouth of the hole with a match in order to drive the fumes deeper in the chamber. If the latter method is adopted the hole should be covered with fresh earth immediately after the explosion in order to put out the fire and confine the fumes. If this is not done a large portion of the gas will be burned and the efficiency of the treatment be lessened thereby. Right at this point an added word of caution must be given. After the explosion the vapour continues to burn with a colourless flame. It is therefore invisible, but its presence may be easily perceived by holding the hand over the opening or blowing into it. This point should be carefully noted, for if the operator, thinking the fire had ceased and desiring to make an examination of the insects doubly certain, should attempt to recharge the hole from a can or a bottle an explosion would surely follow, with possibly fatal results. Explosion does not appear to add to the efficacy of the treatment and is not at all necessary. If it is not attempted it may be well to cover the nest with a wet blanket, which will greatly aid in confining the fumes. If any considerable area is infested, as is often the case in lawns, the holes should not be more than $1\frac{1}{2}$ feet apart each

way, and after the close of the application the surface may be thoroughly watered, as the wet surface will add to the efficiency of the treatment by preventing the rapid diffusion of the fumes into the air.

OTHER SUBTERRANEAN USES.

The vapour of carbon bisulphide applied at the rates previously recommended is said to have a marked action against certain cryptogamic parasites of plants, though its influence in this direction does not appear to have been much studied. It is also said to be fatal to the nematode worms, which are frequently injurious. In greenhouses these would seem to be particularly susceptible to effective treatment. The vapour of carbon bisulphide is fatal to animal life of all forms if inhaled in sufficient quantity. Within recent years this chemical has come into quite extensive and successful use against a class of small mammals which are common nuisances, if not actual pests, in many parts of the country, and particularly in the West. To Professor E. W. Hilgard, of the University of California, is given the credit of being the first to employ this remedy against ground squirrels and gophers. It is a matter of common knowledge that this agent is by far the safest and most efficient known for the destruction of prairie dogs, gophers, pocket gophers, ground squirrels, wood chunks, moles, and other pests having similar burrowing habits. The subject is quite an extensive one, and as it is now being given consideration by the division of biological survey, and does not properly come within the province of the division of entomology, further comments here are unnecessary.—*From the Journal of the Royal Horticultural Society.*

THE CARNATION FLY.

This little fly (*Hylemyia nigrescens*), commonly known as the Carnation fly, is not, fortunately for growers, one of the very common pests that assail our favourite flower; but still it does appear, and when it does soon makes itself known, and gives the grower constant and daily employment. It is very much like the ordinary house fly, only smaller, but it has two pair of wings, the under and lesser ones are quite hidden when at rest under the upper ones. It was some time before I found that it had a second pair. It does not fly much, and so with careful watching can easily be caught while depositing its eggs on the leaves of the Carnation. It is usually found in April, but last year was later, and did not appear until early in June on a batch of seedlings I had planted out. The grub is the mischief doer, though the fly is the author originally, for if it did not lay its eggs on the leaves there would be no grub on our favourites to destroy them, so the fly is the foe to watch for in the first place.

Young seedlings are more likely to have this pest than large plants, and unless care is given the whole plant will soon be destroyed. They generally attack the main stem and eat out the heart of the plant, so destroying it. Sometimes only a leaf is injured, and if this is at once picked off the pest may not spread. Care must be taken in looking over the plant to see that the grub is not on any of the small side shoots, as I notice that if checked in the main stem and heart of the plant the tiny side shoots are attacked, and being small easily get overlooked. The grubs are about three-eighths of an inch long, whitish, with heads, but are legless. They feed on the pith of the stem.

There is, I believe, no cure or preventive, and the only thing is to watch closely, and as soon as the grub appears either to pick off the leaves or, better still, prick the tissue of the leaf with a needle and so dig the grub out. I have tried sprinkling the plants freely with soot. It is a good fertiliser and can do no harm, though I do not think it did much good. By careful watching and going over them once or twice every day I saved all my seedlings, and now have a splendid batch, some already showing flower, though sown only in February last.

M. MITCHELL.

School of Horticulture, Torquay.

THE GARDEN

No 1626.—VOL. LXIII.]

[JANUARY 17, 1903

NEW FRUITS OF 1902.

NEW fruits are few in number compared to flowers, and in a measure this is satisfactory, as the increase in the number of fruits serves no good purpose unless they are of sterling merit. Several interesting additions were made to the hardy fruits last year, and also awards given to others, the important ones being Grapes, Peaches, and Strawberries. Many difficulties surround the raiser anxious to produce the best results, as in the case of fruit a considerable time must elapse before the merits or demerits of the variety can be ascertained. Then it is not always possible to test them properly owing to unsuitable surroundings. Varieties that when first raised found scant favour, in later years become recognised as worthy of the highest award. During the past year a few new fruits have failed to pass the fruit committee of the Royal Horticultural Society, and recently the test has been made more difficult, though this committee has never been lavish with its awards. In the case of bush fruits and Strawberries there is a wide field for experiment, as these do not appear to retain their vitality so long as stone fruits. Mr. Seden has been most successful. Again we see the result of breeding from the Raspberry and the Blackberry. These fruits may become more valuable in the future, and form the basis of quite a new race.

In a way the raisers of new fruits in this country are less favoured than on the Continent, the climate is not always kind; still it is only fair to add that some of the best Peaches, Nectarines, Plums, and Cherries have been raised in this country. We have only to note the splendid work of the late Mr. Thomas Rivers and his successors to show what can be done under glass. In the case of new Grapes, some of the crosses made do not at first sight appear at all suitable, but time may prove their worth.

PEARS.

Only four Pears have been given awards, and one of these late in the previous year, but it is so good and distinct that it is included in this list. The first to receive an award was the new *General Wauchope*, a seedling from the well-known *Ne Plus Meuris* and the larger *Duchesse d'Angoulême*. The two varieties named are well known, being of Continental origin. *General Wauchope* is a valuable late Pear and a great gain, as the Pear season is so soon over. It was raised by that veteran fruit grower Mr. Charles Ross, and will certainly prove

valuable on account of its good quality. The fruit is of medium size, regular form, and has a yellowish green skin with small spots, whilst the flesh is soft and richly flavoured and free from grittiness; it is stated to crop freely. This received an award of merit late in December, 1901.

Winter Nelis, an old variety, that has been grown in this country for nearly a century, and now, though late in the day, is recognised as worthy of a first-class certificate. Why such an excellent fruit was never noticed it is difficult to say. Probably it was overlooked, but it certainly should have received this award at the time. In the interesting competitions for the Veitch flavour prizes *Winter Nelis* has held its own on several occasions. The fruits to which the award was given were shown by Messrs. Veitch of Chelsea, January 14, 1902.

Michaelmas Nelis.—Here is a distinct new fruit, and certainly thoroughly deserves the award of merit given. It was sent out by Messrs. Bunyard and Co., Maidstone, and is well named *Michaelmas*, as it is a beautiful fruit at that season. Of course late in September and early in October good Pears are plentiful, but the one in question is welcome on account of its first-rate quality; it is of medium size, very shapely, or what may be termed a true Pear shape, skin a light greenish colour and somewhat russety, flesh white, juicy, melting, and of delicious flavour.

Pear Grise de Chine.—This is stated to be a favourite Pear in Belgium, and was sent by Mr. H. H. Raschen, Sidcup, Kent: evidently it is not much known in this country. The fruits are of medium size, with deep eye, short stalk, and the skin a brownish yellow, covered with thick russet, and firm. The flavour is good, the flesh being melting and juicy and of excellent quality for the season. Award of merit, December 9, 1902.

APPLES

are less numerous than usual. A new variety given an award of merit late in December of last year must not be passed over: it is named

The Houlton, and was raised by Mr. Charles Ross of Welford, the parents being the well-known Cox's Orange Pippin and Peasgood's Nonsuch. The fruits are not unlike the Cox's Orange in size, a gain, in my opinion, as large dessert Apples are not required. They are also highly coloured and remarkably handsome. The flesh is rich, not unlike that of Cox's Orange Pippin, but softer: the fruit is in season in midwinter. A valuable dessert variety.

Edward's Coronation.—We are not quite sure if this new Apple has not been renamed King Edward: at any rate, it is a beautiful fruit, of medium size, dessert, not unlike a good Cox's Orange Pippin, but more oblong in shape, and of first-rate quality. The parentage is not stated, but the raiser, Mr. Princep of Buxted Park, Uckfield, states that

it is a splendid cropper, and it should become a standard variety as it is so good. It was given an award of merit, October 21, 1902.

Tamplin.—A very pretty dessert fruit of conical shape, very highly coloured, and striped with red on the sunny side. It is in season from October to December. Award of merit, Mr. Basham, Bassaleg, Monmouthshire, November 4, 1902.

Norfolk Beauty.—A very fine cooking Apple, large, and of excellent quality: it is a grand mid-season variety. This is described as a seedling from the well-known Warner's King and Dr. Harvey. The tree crops very freely. The flesh is white, with a clear yellow skin and slight red markings on the sunny side, with here and there a trace of russet. This was raised by Mr. Allan, Gunton Park Gardens, Norwich, and well deserved a first-class certificate, December 9, 1902.

GRAPE IMPERIAL BLACK.

A very fine late Grape. Tested with Black Alicante and Gros Colman it proved much better. It is described as a free setter, and it certainly will make a valuable market Grape. The bunch is large, also the berries, which are oval and dense black. The quality is very good, the flesh being pleasant and of good flavour. It is well adapted for late use, as it has a firm skin and keeps well. This was raised by Mr. Goodacre, The Gardens, Elvaston, Derby. Award of merit, November 4, 1902.

RASPBERRY NOVEMBER ABUNDANCE.

A distinct new Raspberry of great promise, the result of crossing the American Catawissa Blackberry with Superlative Raspberry. The cross is a decidedly good one in every way. The fruits are large, oval, and of excellent quality. It crops freely till cut down by frost, and is a very free grower. The fruits are dark red. Award of merit, November 4, 1902, Messrs. Veitch, Limited, Chelsea.

LANGLEY BULLACE.

A new fruit in the Plum family, and a cross between the Orleans Plum and the Farleigh Damson. It is a very late fruit of first-rate quality, and is also valuable for its free cropping. This is a gain to fruit growers, as it will prolong the season greatly. From Messrs. Veitch, Limited, Chelsea. Award of merit, November 4, 1902.

PEACHES.

Duke of York.—One new Peach came to the front in 1902, and was raised by Messrs. Rivers of Sawbridgeworth. It is stated to be as early as the Alexandra. If so it will be of great value, as the last-named drops its buds badly when hard forced. *Duke of York* was the result of crossing the Alexandra Peach with Early Rivers' Nectarine. It is of excellent flavour, above medium size, very handsome, and beautifully coloured. Award of merit, May 20, 1902.

STRAWBERRIES.

The Khedive.—A new fruit, under medium size, long, deep red, and of first-class flavour. It should be most valuable for preserving. It is the result of a cross between British Queen and Lord Suffield, and should be a great favourite where flavour is valued. Award of merit, Messrs. Veitch, Limited, Chelsea, July 22, 1902.

Givons' Late Prolific.—This is a very beautiful Strawberry, and a most valuable addition to the late varieties. It is the outcome of crossing Waterloo with Latest of All, and the result is excellent. Last year this variety was favourably noticed, and now it is even better. The fruits are bright red, of wedge shape, and delicious flavour. A most useful late variety. Raised by Mr. W. Peters, Givons Gardens, Leatherhead. First-class certificate, July 22, 1902.

MELONS

were not so plentiful as usual, at least the awards were not numerous, only two being given, one early and one late in the season. These fruits are always uncertain. Though good this year they may lack flavour from various causes when grown by different growers and under varying conditions.

President.—This is a scarlet fruit with a good depth of flesh and deeply netted. It is above medium size and of first-rate flavour. It is a cross between Royal Favourite and Westley Hall. Raised by Mr. W. Ingram, Westley House Gardens, Bury St. Edmunds. Award of merit, June 10, 1902.

The Peer.—A large and excellent Melon, with a bright skin and a great depth of flesh. It is of excellent flavour, and the lateness of the season at which it was shown should increase its value. It should be good for late supplies; the flesh is white and very solid, and it is an excellent keeping variety. It was raised by Mr. Goodacre, Elvaston Castle Gardens, Derby. Award of merit, October 7, 1902.

Other new fruits were shown but failed to secure an award. These will in several cases be staged again, many being of considerable merit.

NOTES ON RECENT NUMBERS.

PRUNUS PISSARDI AS A FRUIT (page 442 of the last volume and page 3 of the present).—This is now known as *P. cerasifera atropurpurea*. Some fruits were received a year and a half ago from the late Mr. G. F. Wilson with the advice to stew them. They are quite excellent cooked; in fact, they were thought by the recipient so desirable a cooking fruit that the following autumn some were plaited against a wall, to be trained and used as fruit trees.

Cactus Dahlias.—The note about these by "A. D." is much to the point. It is to be hoped that if the Royal Horticultural Society has a trial of Dahlias at Chiswick that it will include all the best of the broad-petalled decorative kinds that have of late been thrust aside in favour of those with the narrow twisted petals. These broad-petalled Dahlias are by far the most generally desirable for garden use. Such a trial would be highly instructive, especially if the various kinds were well shown at the Drill Hall.

A prize station garden (page 4).—Good gardening at railway stations—happily, so often seen—is a boon not only to the dwellers at the station, but also to the travelling public. There are especial facilities for good gardening at those stations that occur in cuttings or that

are on hill-sides. Banks may be beautifully clothed with flowery growths of free, rambling habit, such as the Rambling Roses, Clematis montana, Flammula, and the native Vitalba, Everlasting Pea, both pink and white Honey-suckle, double-flowered Bramble, Virginian Creeper, and Pyrus japonica. If there are already on the bank a few bushes of common Whitethorn or Blackthorn that some of these may grow over, so much the better, and a few common flowering shrubs, such as Guelder Rose and Ribes, cleverly grouped would add greatly to the effect. In such places it would not be necessary, perhaps not even desirable, that the whole bank should be trenched or dug. It would answer every need if parallel strips, taken diagonally up and down the bank, were prepared for planting, the strips being 3 feet wide and the grassy spaces left between them 5 feet or 6 feet. This will eventually be covered by the rambling plants. There is a beauty of trim gardening such as is most usual at railway stations, and also a beauty of free gardening. Banks lend themselves best to the free treatment. Planting on diagonal strips would in itself tend to lessen the formality that in such places would probably be undesirable, and if the bank is a steep one the rain would not wash and cut the dug earth into the straight up and down channels so often seen on the sides of cuttings. Even in the dug strips it might be as well to leave a foot-wide span of grass undisturbed here and there in their length. Even in the poorest soil or nearly pure sand there are shrubs and plants that will make a bank beautiful. The best of these would be *Cistus laurifolius*, Heaths, and Lavender Cotton.

G. J.

KEW NOTES.

INTERESTING PLANTS IN FLOWER.

Temperate House.†

ACACIA ACINACEA, *A. baileyana*, *A. dealbata*, *A. ovida*, *Acanthus montanus*, *Aloe platylepis*, *Cestrum elegans*, *C. fasciculatum*, *Olearia ramulosa*, and *Sparmannia africana*.

Palm House.

Brownea coccinea and *Hymenocallis caribæa*.

Orchid Houses.

Aerides Vandarum, *Angraecum distichum*, *A. eburneum*, *A. sesquipedale*, *Bulbophyllum Medusæ*, *Cypripedium chamberlainianum*, *C. Morganæ* and others, *Dendrobium atroviolaceum*, *D. aureum*, *D. bigibbum*, *D. Cassiope*, *D. euosmum*, *D. Johnsonæ*, *D. superbiens*, *Epidendrum calamarium*, *E. ciliare*, *E. evectum*, *E. fragrans*, *E. kewense*, *E. nutans*, *E. snbpurum*, *E. tovarense*, *E. Wallisii*, *Eria vitata*, *Eulophia saundersiana*, *Lælia albida*, *Masdevallia fulvescens*, *M. macnra*, *M. tovarensis*, *M. triangularis*, *M. ventricularia*, *Odontoglossum Inslayi*, *O. Pescatorei*, *Otochilus fusca*, *Polystachya Adansonie*, *Ponthieva petiolata*, *Restrepia maculata*, *Seraphya multiflora*, *Tainia penangiana*, and *Vanda amesiana*.

† *Range.*

Randia macrantha.

Rock Garden and Herbaceous Borders.

Adonis amurensis, *Colchicum Dieffierii*, *C. libanoticum*, *Crocus chrysanthus*, *C. Imperati*, *Galanthus eliciticus*, *G. plicatus*, *Helleborus caucasicus*, *H. odoros*, *H. orientalis*, *H. viridis* and others, *Iris Danfordiæ*, *I. filifolia*, *I. histrioides*, *I. stenophylla*, *I. unguicularis*, and *I. Vartani*.

Alpine House.

Colchicum hydrophilum, *Crocus* (collection of species), *Cyclamen Coum*, *C. ibericum*, *Galanthus caucasicus*, *G. Elwesii robustus præcox*, *G. plicatus*, *Iris alata*, *I. Haussknechti*, *I. Histrio*, *I. reticulata* var. *sopenensis*, *I. Tauri*, *Merendera caucasica*,

Narcissus Bulbocodium var. *monophylla*, and *Primula megasea-folia*. [This is quite a cold house, and very interesting just now.—Ed.]

Arboretum.

Chimonanthus fragrans var. *grandiflora*, *Erica carnea*, *E. mediterranea* var. *hybrida*, *Hamamelis arborea*, *H. mollis*, *Jasminum nudiflorum*, *Lonicera fragrantissima*, *L. Standishii*, and *Rhododendron dauricum*.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

January 22.—Gardeners' Royal Benevolent Institution Meeting and Election of Pensioners at Simpson's, Strand.

January 27.—Royal Horticultural Society's Meeting.

February 3.—National Amateur Gardeners' Association Meeting.

February 7.—Société Française d'Horticulture de Londres Meeting.

February 10.—Royal Horticultural Society's Meeting.

February 11.—East Anglian Horticultural Club Meeting.

February 13.—Royal Gardeners' Orphan Fund Annual General Meeting, Cannon Street Hotel.

Gardeners' Royal Benevolent Institution.—The friendly supper in connexion with this institution will take place, as usual, at Simpson's, 101, Strand (for the last time in the present building) on Thursday next, the 22nd inst., at 6 p.m., after the annual meeting. Mr. Alfred Watkins will preside. The charge for the supper is 7s. 6d.

Apple Sandringham in the North.

This season late Apples have been more valuable on account of the smaller crop of earlier varieties, and few late sorts are more valuable than the above, as with us in what may be termed a poor fruit soil it not only crops well, but has fruits of good size and quality. This variety has been distributed some years, though by some called new. It is a very fine fruit, not only for the kitchen, but may be made serviceable for the dessert when others fail late in the season. Our best fruits are produced on bush trees, and grown thus it is most prolific. The trees are hardy and do well in exposed places in the northern part of the country, the fruits keeping well into March. I have not grown it as a standard, but from its free-fruiting qualities I think it would do well. As a cordon it is very prolific. For the past few years the Sandriogham has become a favourite in small gardens on account of its free cropping. I saw some very small trees in the eastern counties bearing fine fruits and in quantity.—A. C. N.

A new Brussels Sprout (Cambridge Champion).

—At the late autumn exhibition of the Cambridge Horticultural Society I noticed very fine specimens of this vegetable both in the collections and single classes, and, as the Sprouts were so uniform in size and so solid, I made enquiries as to its origin. The raiser, Mr. J. H. Ridgewell, of the Gardens, Histon, a large vegetable grower, gave me particulars of this new variety, and I regret to say I have lost my note of its parentage. One parent I think was a local sort; at any rate, there can be no question as to its good qualities. There is an entire absence of coarseness, and this is a great gain, even for market purposes a medium-sized, solid Sprout being preferable to a large, open one. It is not a fair test to merely judge Brussels Sprouts by the gathered produce. One must see a quarter of growing plants, and certainly every plant of the new Cambridge Champion was true and may be classed as a medium grower, and the crop a very heavy one indeed. Mr. Ridgewell grows all vegetables remarkably well, and he is fortunate in having such a very fine addition to this class. The quality when cooked is of the best, and I do not think that any variety can surpass it for cropping and keeping.—G. WYTHES.

Stephanandra Tanakæ.—While we are enabled from time to time to read notes about the popular *Stephanandra flexuosa*, so far *S. Tanakæ* seems to have escaped notice, the reason probably being its recent introduction to English gardens. It is larger in every way than *S. flexuosa*, sending up long shoots annually from the base, requiring very little and careful pruning. After the leaves have fallen the stems assume a pleasing, warm, yellowish brown tint, which is so beautiful in winter. Its hardiness is practically assured, as it has withstood the sharp frosts of 1901 and the present season without the slightest protection. When *Stephanandra Tanakæ* is to be obtained in sufficient quantities for massing in such places as the woodland, then I think it will prove a desirable and welcome addition to British planters of choice shrubs. The clay soil here seems to suit it.—A. E. THATCHER, *Aldenham House Gardens, Elstree, Herts.*

Salvia Heerii.—Where cut flowers are required in quantity during winter, *Salvia Heerii* is indispensable. Its pretty little scarlet flowers are produced in abundance on long shoots, which are clothed with dark green Sage-like leaves. It is valuable in the making up of large glasses, as the shoots can be cut 2 feet or 3 feet long, and its foliage is of no mean importance for this purpose. It is essentially a plant for the amateur, as its cultural requirements are very simple. Plants struck in the spring should be planted out during the summer months. These will be excellent by October, when they should be lifted and potted and placed in a cool house. During the growing season a judicious thinning of the shoots will be necessary, as if allowed it will grow into a dense bush, and its true character and effect be lost.—E. HARRISS, *the Royal Gardens, Frogmore.*

A use for Apple tree prunings.—When Apple trees are being pruned it should be remembered what capital flower sticks the prunings will make; the best possible sticks for Carnations or any plants of smallish growth that must be supported. For pot plants they are only second in value to Hazel suckers. The Hazel is rather the better because of its quiet unobtrusive colour, a matter of great importance, in the sticks used for pot plants. The Apple twigs are blacker. But often in a private garden there are plenty of Apple prunings, while Hazel would have to be bought, and it is satisfactory to bring into good use something that would otherwise have to go to the burn-heap. The prunings naturally have a curved shape, but if while green they are pointed at the cut end and tied together with three ties and put to dry over the boiler in the stovehole they dry perfectly straight and are ready for use when they are wanted next summer.—G. J.

Browallia speciosa major.—There are few more continuous flowering subjects than this; indeed, it will maintain a succession of bloom till quite exhausted. It forms a freely branched plant of a sub-shrubby character, and is seen at its best in a warm greenhouse or intermediate structure. The flowers have a tube about an inch long, with a spreading mouth divided into five segments. When first expanded the colour is a rich violet-blue, the throat lighter, but the flowers pale afterwards. *Browallia speciosa major* is a native of Colombia, while an allied kind, *B. elata*, known sometimes as the Forget-me-not of the Andes, is often treated as a tender annual for greenhouse decoration. These *Browallias* are well known, at least by name, to many readers of THE GARDEN, but they are not often seen.—T.

Correa cardinalis.—The popular name of Fuchsia has been given to this *Correa* by settlers in Australia, of which continent it is a native, owing to the resemblance between its drooping tubular-shaped blossoms and some of the members of this popular genus. The *Correa*, however, needs very different culture, as it belongs to what are popularly called hard-wooded or New Holland plants, and therefore needs much the same treatment as the Heaths, *Epacris*, and such like subjects—that is to say, a peaty soil, firm potting, thorough drainage, careful watering, and a free circulation of air whenever possible. The genus *Correa*

contains several species, in some of which the flowers from their greenish white hue are not particularly showy, but in this species the body of the flower is bright scarlet, tipped with greenish white. It does not form so shapely a plant as some of the less attractive ones, hence it is often grafted on *Correa alba*, one of the strongest growers. The usual blooming season of *Correa cardinalis* is from the New Year onward through the spring months.

Eranthemum pulchellum.—Though this *Eranthemum* is well known it might with advantage be more often met with in gardens, for the flowers are of a delightful shade of blue, a colour little represented among indoor plants, added to which they appear in the depth of winter, and the plant itself is easily propagated and grown. True, the individual flowers do not last long, but a succession is kept up from each cone-shaped head for some time. It is an old plant in gardens, where it is generally known under the above name, but is now by botanists included in the genus *Dædalacanthus*, with the specific name of *nervosus*. The genus *Dædalacanthus* now contains, besides the above, *D. macrophyllus*, which was also formerly included in the genus *Eranthemum*, *D. parvum*, and *D. Wattii*, which have been shown several times within the last year or two at the meetings of the Royal Horticultural Society. All are of simple culture, the chief trouble being red spider, and then only if the atmosphere of the structure in which they are growing is kept too dry.—H. P.

Gardens for working men.—The Horticultural Society of Valenciennes, presided over for so many years by M. Weill-Mallez, has resolved to take the initiative in creating and organising gardens for working men under the following conditions: The extent of each garden shall be at least 250 square metres; they shall be placed at the disposition of families without rent of any kind; they may be taken away at any time from the holder, if need be, and they can in no case be ceded by the holder to another; they will be specially devoted to vegetable cultivation, to supply the needs of each family; any garden badly kept will be taken from the occupier. The reasons which have decided the society to undertake the initiative in this beneficent work are that the fatigue of the workshop and the mine may be forgotten in the wholesome and refreshing labour of the garden; and to counteract the habits resulting from the vice of alcoholism.—*Le Jardin.*

Clematis calycina.—Among the hardy *Clematis* this is conspicuous for its evergreen leaves and its flowers, which are borne in mid-winter. Though for several reasons it is very interesting and worth a place in gardens where large collections of shrubs are formed, it cannot be called everybody's plant, for there are a great many far more ornamental species. It is an extremely old plant, the date of its introduction into England being given as 1783. It is a native of the Balearic Islands, and was sent to Kew about the date previously mentioned by M. Thonin, from the island of Minorca. The branches are slender, 10 feet or 12 feet long, and twisted and twined together so as to form a large tangled mass. The leaves are usually ternate, the leaflets being deeply lobed and deep green. The flowers, which are borne from the end of November till February, are pendulous, greenish white, and 2 inches to 2½ inches across. When growing in the open the flowers do not make a very great show at any particular time, but when against a south wall flowers are produced more freely and the colour is much better. The latter method of culture appears to be the most suitable one. Another name under which this species is sometimes seen is *C. balearica*.

Hamamelis mollis.—During recent years much attention has been paid to the Witch Hazels on account of the bright display made by their flowers early in January. The number of species in cultivation is four, and three of these bloom in January, the other during late autumn. *H. virginica*, the common North American Witch Hazel, is the autumn-flowering species, the spring-flowering ones being *H. arborea* and *H. japonica*—with a variety of the latter called *zuccariniana*—

from Japan, and *H. mollis* from China. With the exception of the Chinese species all have been in cultivation for a considerable time. The one under notice, however, is still a new plant, having been put into commerce two or three years ago by Messrs. Veitch. It was discovered by Dr. Henry in the Hupch Province of Central China, where it is said to make a tree from 10 feet to 30 feet in height. Its most distinct character is its large oval leaves, which are covered with silky hairs. The flowers, in addition to opening earlier than those of the Japanese species, have wider petals, terminated with a slight hook, and are not so twisted as in other species. Up to the present it seems to grow well, but has the disadvantage of starting into growth early, and is apt to suffer through late spring frosts. The sharp frost experienced last May damaged this species considerably, other species escaping in a large measure. At the present time—the last day of December—many flowers are open, and should the weather keep mild the plants will be in full bloom shortly.—W. DALLIMORE.

The common Bracken.—My experience is that this common Fern grows strongest when beneath tall trees, the soil having been manured for generations by the falling leaves. Naturally the shade promotes a greater length of Bracken stems, but, all the same, evidently revealing in the shade and ample store of root food supplied by the decaying tree leaves. Sometimes the fronds are 6 feet to 7 feet high. What Bracken is on really poor, unfed soils can be seen in Bushey Park, where out in the open, with only deer to manure the ground, it is of miserably stunted growth, showing how poor and foodless the soil must be. We are too apt to overlook the wonderful part trees can play in the rendering unusually fertile what previously was very poor soil.

Chrysanthemum Framfield Pink.—My neighbour, Mr. Hayward, the Kingston florist, showed me, on the 3rd inst., a bunch of this singularly beautiful pink variety, which he had brought from market. The flowers were not at all big, happily, but just the size to suit floral decorators, and were on long stems. To me, amidst the abundance of whites, yellows, and bronzes seen almost on every hand even yet, this pink variety was indeed charming. It was not a washy colour, but a real rich mauve-pink, the colour being as good as could be seen on any pink variety in November. In contrast was a bunch of the same variety from another grower that were rubbish; hence it is evident that all cannot, or do not know how to, grow the plants for such late blooming. I am aware that the French claim the name of *Mme. Felix Perrin* for Framfield Pink, but the market growers at least have resolved that the English name is to stay.—A. DEAN.

Winter-flowering Geraniums.—At the Manchester Chrysanthemum show, which was held on November 20 last, Messrs. Cannell and Sons staged one of the finest collections of cut blooms that even this firm has ever exhibited. Even the bright-coloured Japanese Chrysanthemums looked dull beside the glowing Geraniums. What struck me so much was the wonderful depth of colouring of the flowers as well as the individual size of the petals. Thinking the names might act as a guide for cultivators in the future in selection I append those that struck me as being the most noteworthy, with a brief colour description: Princess of Wales, rosy cerise; Duke of Norfolk, magenta, suffused crimson with large white eye; Mrs. George Cadbury, salmon. Captain Holford produces extremely large trusses and blossoms. In colour it is soft crimson, the lower petals shaded with purple, the upper are suffused with bright orange. General French is a soft scarlet colour, shaded deeper at the base of each petal. During the winter season the colour is more intense; it is an extremely fine variety; President McKinley, warm rosy red in colour, with a conspicuous white eye; Lord Curzon, a rich magenta shade, the blooms are large, the petals beautifully formed; Mary Pelton, pale salmon, delicate and beautiful shade; The Sirdar, deep scarlet; Lady Roscoe, a delicate shade of

blush pink; King of Crimsons is quite one of the best of winter-flowering varieties of a glowing crimson colour; Lilacina Improved, soft lilac-pink; Nicholas II., crimson-scarlet, large; Chaucer, cerise; Lord Faer, clear rosy scarlet; Lord Roberts, purple, shaded magenta, with a large blotch of orange at the base of the two upper petals; Lady Tennyson, salmon, mottled towards outside of petals; and Winston Churchill, magenta-pink, white eye.—E. MOLYNEUX.

Daphne Mezereum grandiflorum. Though little known, this variety of the Mezereum is a very old one, for it is alluded to by Loudon as *Daphne Mezereum autumnale*. These two varietal names well express its most prominent characteristics, for the flowers are larger than those of the type, and borne during autumn. The season of blooming is, however, not limited to that period, for unlike the common Mezereum, whose flowers expand almost simultaneously, those of the variety *grandiflorum* are produced from November until early in the New Year, hence at no time is there a display equal to that yielded by the type, but appearing as they do throughout the winter they are most welcome. The flowers are much larger than those of the type, and of a richer purple, while, like it, they are deliciously scented. Of the other varieties of the Mezereum, the white-flowered form affords a pleasing variety, and it flowers at the usual time. It is some years since I met with the white variety with double blossoms, but I see it is still in the "Kew Hand List."—T.

TREES AND SHRUBS.

YELLOW-FLOWERED SHRUBS IN WINTER.

OUR hardy shrubs that bloom during the winter months those in which the flowers are of some shade of yellow are largely represented and particularly welcome, for this colour is very effective in dull weather, and little dimmed by heavy rains. First and foremost is the Winter Jasmine (*Jasminum nudiflorum*), which maintains a succession of its golden blossoms for a long time. It is usually treated as a wall plant, and in this way forms a delightful object. It receives a certain amount of protection from sharp frosts, which, though they injure the expanded blossoms, have little effect upon the unopened buds. It is also very beautiful as an outdoor shrub, all that is needed being to secure the principal branches to a good stout stake and allow the minor ones to grow at will. Though seldom seen in this way it flowers freely, and against a background of dark-leaved evergreens is very conspicuous. On large bold arrangements of rockwork the bright green twigs studded with their yellow blossoms are seen to great advantage when draping the surface of a rock or in a similar position. The garden lover has much to thank Robert Fortune for, as he was the means of introducing not only this Jasmine, but many other valuable shrubs. After this comes the Japanese forms of the Witch Hazel (*Hamamelis*), in all of which the quaintly shaped flowers are of some shade of yellow, while the Cornelian Cherry (*Cornus Mas*), which blooms usually in February, is, when at its best, thickly studded with little tufts of blossoms which are of the same hue. *Berberis japonica*, the first of the Ash Berberries to unfold its blossoms, often commences to flower soon after Christmas, while the better known and richer tinted *Berberis Aquifolium* will, unless the weather is very severe, begin to flower quite early in the New Year. *Forsythia suspensa*, too, which is one of the first of what may be regarded as early spring-flowering shrubs, has also yellow blossoms.

COLLETIA CRUCIATA.

THE receipt of some flowering sprays of this *Colletia* serves to direct attention to one of the most curious of all our hardy shrubs, and a plant

full of interest in every way. It is practically leafless, the entire specimen being as it were built up of large flattened triangular-shaped spines, arranged in opposite pairs, each pair being set crosswise to the next. These spines are deep green, so that a specimen is in the winter nearly as effective as an evergreen. The flowers, which are borne in little clusters from the lower portion of the spines, are small, urn-shaped, wax-like in texture, and greenish white in colour. Closely inspected they are pretty, but do not add much to the general effect of this singular shrub. It is a native of Uruguay, and is, beside the specific name of *cruciata*, also known by that of *biconensis*. On the ground of priority, however, *cruciata* is the correct name, while it has also the advantage of being very descriptive. A second form of *Colletia*, known as *C. horrida* or *spinosa*, is composed almost entirely of awl-shaped spines, and is quite as formidable as the preceding. This was long recognised as a perfectly distinct species from the other, but of late years many instances have been noted of branches of one kind being produced from specimens of the other, thus proving conclusively that they are but forms of one species. Such a marked case of dimorphism as this occurs in few plants. The *Colletias* are hardy in the South of England, but in most districts succeed best in a sheltered position. T.

A BEAUTIFUL HOLLY (ILEX LAURIFOLIA NOVA).

IN his interesting notes of good Hollies (page 444) Mr. Clark has not mentioned the above, which I regard as quite the best of all green Hollies. This Holly is, I believe, known on the continent as *Camelliaefolia*, but is altogether distinct from *laurifolia*, which Mr. Clark writes of as synonymous with *Camelliaefolia*, and this accords with Messrs. Clibran, who give "*I. laurifolia* = English *Camelliaefolia*" and "*I. laurifolia nova* = *Camelliaefolia* of continental growers." *I. laurifolia nova* is not to be met with in all nurseries, and there are probably very few plants of specimen size in the country, but its merits are beginning to make themselves known. It has very large leaves, not quite so broad as those of the variety generally known as *I. Shepherdii*, and some others, though 5 inches by 2 inches would be about the average size of the leaves on a well-grown plant. The leaves are generally spineless, except at the tips, but some have also spines on the edges. They are a very deep green, and the leaves take on sometimes a deep purple tinge during the winter and spring, almost the colouring frequently seen in the Mahonia. As a berried Holly it leaves nothing to be desired, for the berries are very large, plentifully borne, and persistent, while the habit of the plant is excellent, being dense and stiff.

Shipley Hall Gardens. J. C. TALLACK.

[This is an excellent Holly, the leaves large, very leathery, and rich green. We noticed it at Shipley Hall in the autumn, and thought how handsome it looked in the garden, and also in Messrs. Barrow and Sons' nurseries at Borrowash, near Derby. Mr. Tallack sends a few leaves to remind us of its value.—E.D.]

PROTECTING EVERGREENS.

THE severe cold weather which has frozen up the whole North and a portion of the South, too, brings us suddenly to the question of tying up evergreen and other trees and shrubs deemed not quite hardy. The shelter these subjects require is that which will protect them from sun and wind. Any of the evergreens growing where the requisites mentioned are already afforded them by some building or large evergreen trees will be evidence of what kind of protection they require. I have seen these evergreens in such positions come through the winter with not a leaf hurt, when others of their kindred not so favoured would not be able to show a perfect leaf. Keep steadily in mind that the sun and the wind are the enemies in winter; then what to do will suggest itself. A nice little specimen of the rare, in this country, *Photinia serrulata*, in my own

collection came through last winter in splendid condition when so sheltered. A house kept off the cold winds nicely, but the plant got the full afternoon sun when not sheltered. The shelter was given it by a leaning board from the house to the ground breaking the sun from it. Not a leaf suffered. The practice of wrapping up evergreens tightly in straw, so close and tight that air cannot easily penetrate the covering, is wrong. I have seen evergreens killed outright by this practice. Some such covering is all right; but put it on loosely enough to break the sun's rays and the wind, but not to make the foliage and the wood tender by confinement.

In situations where evergreens are well sheltered from cold winds, and, in consequence, from hard frost also, the sun in winter is not to be so greatly feared. Rhododendrons and Magnolias when so sheltered near a dwelling are not hurt by the sun, especially when the ground is moist; but 50 yards away without this shelter the risk of losing every leaf would have to be run.—JOSEPH MEEHAN, in *The Florists' Exchange*.

THE INDOOR GARDEN. NEW ANTHURIUMS.

ABOUT twenty-five years since the large-leaved *Anthurium* brightened the flower shows; *A. crystallinum* had appeared; *Caladium* introduced from Brazil by M. Bleu were grown everywhere; *Alocasias* came into vogue; and the *Philodendron* began to be generally grown. But in 1880 a new era was marked in the evolution of the Aroids by the appearance of *Anthurium andreanum*. Whilst some specialists were enriching their collections with a series of novelties obtained from A. scherzerianum, others showed the brilliant results of their efforts with *A. andreanum*, *A. carneum*, *A. ferriense*, *A. houletianum*, *A. Chantreieri*, and *A. Edwardii* were sent out in 1884. Afterwards, in 1888, *A. lawrenceanum* appeared.

The vigour of these plants, their rapid growth, their free flowering, and, above all, their success, prompted the continuance of the search for them. About 1891 *A. Goliath*, with large deep carmine-vermilion spathes, was much admired at the different exhibitions, as also were the spathes equally as large, but of a salmon colour, of *A. Baronne Chandon*, as well as those of a rounded form of *A. John Laing*. Hybridists especially sought to obtain a white-spated variety, and finally *A. andreanum album*, with spathes of pure white, was obtained in 1898.

For several years past, owing to the general cultivation of these plants, we have constantly witnessed new productions, larger, deeper coloured spathes, improvements in the form of the plant, &c., at the annual exhibitions. Such are *A. Fournieri* of M. le Dr. Fournier de Neuilly; *A. Monarque* of M. Page; and *A. Baron Seillière* of M. Bultel. There are also the magnificent productions of M. Jarry-Desloges and of M. Fournier of Marseilles, as well as those which were lately shown by M. Valvassori of Italy, at the exhibition of the Société Française. Since then notable improvements have been made in the *Anthurium*. In 1900 we were struck by the phenomena which the inflorescence of one of our sowings presented. From the first leaf this one was always much more vigorous than the others. Its elegant leaves were further developed and of a deeper colour. Its flowering appeared to us to be so original that we feared at first it was but an eccentricity, and we waited until several others appeared before having it described. *A. andreanum rhodochlorum* (for such is its name) offers to the amateur the advantages of a plant which is at the same time both decorative and peculiar. Moreover, it presents a new and curious type to hybridists. To this variety, which is of the first merit, we would add *A. Goliath*, *A. Charles Joly*, and *A. Baronne Chandon*.

Another novelty of which we wish to say a few words is the result of crossing *A. andreanum*

MARICA GRACILIS.

with *A. scherzerianum*. This plant takes after both parents. It has the habit and the foliage of *A. andreaum*, but it remains dwarf, and its leaves, which are thick and long, are much smaller; the spathes are heart-shaped; they are glossy like those of *A. scherzerianum* and of a crimson colour. The spadix is erect and long.

J. CHANTREIER, in *Le Jardin*.

GREENHOUSE "FLAGS."

The members of the genus *Marica*, to which the above-named term may well be applied, are by some authorities included in the genus *Iris*, while by others they are kept distinct. Even then the nomenclature is by no means uniform, for *Morea* and *Cypella* sometimes claim them. The general appearance of *Marica gracilis* is well shown in the accompanying illustration, its floriferous character being there very apparent. In colour the flowers are whitish, marked in the centre with blue. Other well-known species are *M. cerulea*, whose flowers are pale blue, with the small petals in the centre striped and barred with purple; and *M. northiana*, in which the flower is dotted with chocolate-brown.

Morea iridioides, from South Africa, is another pretty member of this class, in which the flowers are white, with a yellow blotch. The Wedding Flower of Lord Howe's Island (*Morea* or *Iris robinsoniana*) was the subject of many eulogistic notices previous to its flowering in this country, now about fifteen years ago. When it first bloomed in the succulent house at Kew there was a general feeling of disappointment, not from any lack of beauty—for it is really a handsome plant—but because it had been so overpraised that one was led to expect flowers even superior to the Japanese *Iris laevigata*, but those of the new comer turned out to be very much smaller. The culture of the different *Irids* above alluded to is not at all exacting, the principal consideration being to give copious supplies of water during the growing season, with a less quantity throughout the winter, but at no time must they be kept dry. When once established they will keep in health for years and flower well without repotting. In all of this class the individual flowers remain but a short time in perfection, but a continued succession is kept up from each scape, thus extending their season of blooming over a lengthened period.

No notice of these tender members of the *Iris* family would be complete without mention of *Iris chinensis*, also known as *I. japonica* and *I. fimbriata*. When good-sized masses are established in pots from 10 inches to 12 inches in diameter, they will, in the month of March, be laden with their beautiful pale blue flowers. This species (an old one in gardens) should not be disturbed at the roots more than is absolutely necessary. In summer it may be stood out of doors in a sunny spot, this being of great help in ripening the growth for the next season's display.

H. P.

TECOMA SMITHII.

FOR some time past this charming plant has added not a little to the beauty and brightness of the greenhouse. Its somewhat large pendulous orange-coloured flowers are arranged in a loose head at the end of the summer's shoots. Plants about 18 inches or so high are very pretty, and look particularly well if intermixed with such things as *Narcissi*, white *Bourvardias*, *Epacris*, &c., and having an undergrowth of green furnished by *Selaginella* in pots. *Tecoma Smithii* is well worth the attention of those interested in greenhouse plants, and should not be absent from the smallest collection. It is not difficult of culture, requiring but a cool house. Young plants may be raised either from seeds or cuttings inserted in early spring. When established in larger pots they should be allowed the full benefit of the sun, so that the growth made may be as strong and well matured as possible.

NOTES ON BEGONIA GLOIRE DE LORRAINE.

This plant can be most successfully grown in a temperature higher than that of a cool greenhouse. As soon as the plants show signs of exhaustion after flowering, and some will now be in this condition, they should have rather less water given to them, and should also be placed in a somewhat cooler house where the minimum night temperature does not fall below 53°. The old shoots should be shortened back considerably so as to induce the formation of young growths from their bases. With the advent of warmer and brighter weather these will not be slow to appear. When the shoots are about 3 inches long they

should be taken off and inserted singly in small pots in a compost of equal parts of loam, leaf-mould, and silver sand, the whole being passed through a sieve; then in a close propagating case the cuttings will soon root. When rooted they must be exposed to the usual conditions prevailing in the house. They will be ready for potting into 3-inch pots in about a fortnight; the compost should consist of loam and leaf-mould with sand added. In a few weeks' time, if the plantlets are placed in a warm moist house, they will be ready for transference to 5-inch pots, and in these they may be flowered well. In 6-inch pots larger plants would be obtained, but for most purposes those grown in the smaller size will be found generally useful.

It is astonishing for how long a time this *Begonia* will continue to produce flowers. Commencing in the autumn, it may be had in bloom throughout the winter. Those who had the pleasure of seeing the splendid specimens shown by Mr. Fleming, Wexham Park Gardens, Slough, at the November exhibition of the National Chrysanthemum Society will not need to be told what splendid decorative plants these *Begonias* make when well grown. Those exhibited by Mr. Fleming were grown in large pots—8-inch, I believe—and being masses of flower and the plants of perfect shape, of course made a grand display. Plants in smaller pots, however, if well grown, almost smother themselves with blossoms. Good winter-flowering plants are none too plentiful, so that such a valuable one as *Begonia Gloire de Lorraine* deserves all the attention that can be given to its culture.

It is essentially a plant that well repays careful treatment, the difference between a fine plant, symmetrical and well flowered, and a poor weakly yellow-leaved specimen, with flowers which might be counted without difficulty, is very considerable; the latter is not to be compared with the former.

A. P. H.

THE FLOWER GARDEN.

INCREASING DAHLIAS.

INTENDING propagators of the *Dahlia* from cuttings should now make a start. Tubers should be thoroughly looked over to see if any are inclined to rot, and if simply the tips of the tubers are decayed they can be cut back to where the root is healthy; but if badly rotten cut back to the collar. Be sure that no affected portion remains or it may still continue and eventually be the means of losing the entire root. If the roots have been at all damp dry them, not too much, but only enough to make them feel leathery and rough when handled. The tubers being ready, a place in the greenhouse must be decided upon where they can be placed to produce cuttings. A suitable arrangement is a temporary stand fixed near the hot-water pipes on which about 6 inches of soil is placed and the tubers bedded in, always leaving the collars or crowns well out of the soil so that the cuttings may be the more easily taken off. One need not trouble about the soil for the tubers so much as in the case of potting mould, but if some fairly good well-rotted material is at hand mix a good portion of ashes with it, and if available some leaf-mould also. If when the roots are bedded in it is in a moist condition no water need be given for some time. If the greenhouse is kept up to a temperature anywhere between 50° and 65° cuttings will soon be ready to take. They should be about 3 inches long and cut off close to the base, unless a large number of a sort are required, or only one or two eyes seem likely to push forth, in which cases leave the bottom joints of the cutting for other shoots to start from. Cuttings taken at an ordinary joint do not, however, strike so easily. The cuttings can be put in one on each side of a small pot in very sandy soil and placed in a shady part of the

house. They may be somewhat freely watered, and in about fourteen days will throw out their first roots. They can then soon be parted, potted on, and placed out in a frame. If not convenient to make a special place in which to put the tubers they can be bedded in pits or boxes, or even potted if small enough, or if the grower cares to use pots large enough to hold them. As is done in many cases, they may be started on a hot-bed, but the hot-bed method, however, has never found favour with us. It is too forcing, and for striking Dahlias is often a source of sad failure. We once made up a small hot-bed and placed thereon a very fine collection of double Dahlia cuttings, all looking well for a day or so, and we did not think to notice how the heat of the bed was progressing till one morning nearly the whole lot was killed, and eventually only one survived—a little wiry chap, "Burgundy" by name, who happened to be placed at one corner of the bed. Of course, once bitten twice shy; but hot-beds are uncertain for striking Dahlia cuttings.

It is not necessary, as so many seem to think, that the cuttings must be placed in a tremendous heat. No doubt a moderate heat is best for quick rooting, but as everyone cannot have a first-class house with hot-water pipes and everything of the best to maintain a great heat, the cuttings must be struck in a cooler temperature. There is also an idea that they must be enclosed in hand-lights or close frames. This also is very good if attainable, but they will strike, as before-mentioned, in the open house, though they may present a sorry spectacle for a few days through flagging so much, but soon recover from this, and should not be unduly watered in order to freshen them or the chances are they will at first look better and finally rot. The wiry cuttings keep stiff and fresh from first to last. P.

CAMPANULA RAINERI.

I HAVE more than once been asked to describe the habitat of *Campanula Raineri*, which grows so beautifully in the rocks in the mountains of North-Eastern Italy. I cannot do better than send a small photograph done in one of the first days of November in the Bergamasque Alps, near La Presohana, Italy. The rocks are dolomites, a kind of tuff or limestone. *Campanula Raineri* sometimes grows in places that are damp and shady, and sometimes facing the hottest sun, but always in narrow rock crevices, into which the roots penetrate, so that it is very difficult to get them out. The best means of bringing it into gardens is by seed or by cuttings of its many little shoots. Such cuttings do very well in a cold frame in August or September.

H. CORREYON.

Floraire, Chêne-Bourg, Geneva.

HEMEROCALLIS OR DAY LILIES.

THE *Hemerocallis*, a group of very hardy and easily-grown plants from South Europe and Japan, have received marked attention in recent years. The advent of *H. aurantiaca major*, a singularly fine plant from Japan, helped to direct attention to the many good qualities of other species. Many of the taller species are admirable plants, their soft, yet distinct colours, tall towering flower stems and tufted habit, combined with a faculty for growing in almost any damp soil and in any situation, fit them for producing floral displays calculated to be effective at a distance. The smaller species, a few of the new hybrids, and the double-flowered varieties of *H. fulva*, make excellent border plants of limited growth, whilst the little *H. minor* is worthy of a place on a moist rockery. The one characteristic that in some measure damps their popularity as garden plants is the short

length of time the flowers last in good condition, and with such plants as *H. Dumortieri* and *H. minor*, which are few-flowered, this is a great drawback, but with others (*H. flava*, *H. Thunbergii*, and the like) which produce quantities of flowers daily the brief life of individuals is a matter of little moment to those who value them as plants and as flowers for cutting. All are moisture-loving plants, and the one reason why *H. aurantiaca major* fails in so many gardens is just lack of moisture. They increase quickly—some need triennial splitting up to keep them within the circumscribed limits allotted to plants in small gardens—and it is this freedom of growth and quality of self-help that renders *Hemerocallis* so useful in all kinds of informal gardening on a large scale, where the plants can spread at will and show more of their graceful habit than would be possible in a crowded plant border. The best plant for all purposes is the canary-yellow

THE HOME OF CAMPANULA RAINERI.

H. flava (L.), a European species producing ample leaves in dense yet graceful tufts 2 feet high and 1 foot through, and numerous spikes towering high above the foliage, each bearing about a dozen canary-yellow flowers from 3 inches to 4 inches long and 3 inches across, with broad inner petals and lanceolate outer ones. The colour is very pure and distinct, and the flowers are of good shape. The plant is good alike for the "wild" garden, and would grace any position in the choice plant border; it has been known for years, and is a general favourite. It flowers from the beginning of June onwards.

H. Thunbergii (Hort. Kew).—A tall species producing dense tufts of linear leafage 2 feet high and 1 foot through, and stout, much-branched stems 4 feet high, bearing large quantities of pale sulphur-yellow flowers each 2 inches across and 3 inches long. The plant is more suitable for grouping in the garden than for border planting, as it is a very strong grower and free to flower, making a grand display of its sulphur-coloured flowers in July and August. There are several forms of this plant in cultivation, two of them having simple flower-spikes and larger flowers, but the much-branched type here described is far and away the best. In strong soils, and especially

when planted near water, this plant grows from 5 feet to 6 feet high, the flowers being borne tier upon tier in endless profusion and for a great length of time if the swelling capsules are occasionally removed. It is one of the parents of the hybrid *H. luteola*.

H. aurantiaca.—A plant scarcely known to the majority of British gardeners, though I have noticed a few clumps of it in various parts of the country, but without names or history. It makes growths of smaller size than the variety major, forming a clump 2 feet high and as much through. The spikes are 2 feet long, sub-erect, bearing from five to eight orange flowers 6 inches to 7 inches long and 6 inches across, raised just above the foliage. It is a better plant than *H. aurantiaca major* in light, dry soils; it is also freer in growth, but the inflorescences are not so large. The variety

H. major (Baker) is the finest plant of the genus.

The leaves are arranged in broad, distichous tufts, which never grow so dense that the distichous character of the plant is lost. The spikes flower in July—sometimes a few are produced early in the year, and many often appear late in September. They average 1½ feet to 2 feet in length, and are not raised high above the foliage, but are poised at an angle, bearing from five to ten flowers of a fine rich orange hue, the petals of which are exceptionally massive, spreading to the fullest extent so that the flowers span 8 inches across. The plants require to be established for a year before they produce flower-spikes, and if the site is dry they must have heavy and frequent waterings to develop growth to the fullest extent. The season 1902 has been an ideal one for this plant. Specimens three years established are sending up several spikes each, and even tiny pieces are producing one spike. It does not require manure or high feeding of any kind—simply moisture in plenty and a sunny position.

GEO. B. MALLETT.

(To be continued.)

CHRYSANTHEMUMS.

NEW AND PROMISING VARIETIES.

AS promised in my last notes, I append a list of new sorts for the benefit of those who are adding to their collections and have not had an opportunity of seeing them.

These are undoubted acquisitions, and should be secured by all who are anxious to possess the best novelties either for exhibition or home decoration. All are quite new or were rarely seen before the past season.

Mme. Paola Radaelli.—This is not quite new. It is a monster Japanese of great merit. The colour is a very pleasing pink, and it is grand either for staging on boards or in vases, and is equally good for grouping. This was finely shown both in London and Brighton.

Hon. Mrs. Acland.—A fine golden-yellow English-raised Japanese variety which will make a splendid exhibition flower. The florets are broad, slightly incurving, and quite distinct.

George Mileham.—A very distinct and pleasing Japanese, colour rosy crimson. A very telling and refined flower.

Mrs. A. R. Knight.—A fine yellow Japanese. The petals are long, tipped with red. The bloom is of fine build and very pleasing.

Miss Mildred Ware.—This, in my opinion, is the finest Japanese novelty of the season. In colour it much resembles *Lady Hanham*, which is probably one of its parents. The flowers are of immense size, quite full, very elegant, and should find a place in every collection.

George Penford.—This is a welcome and desirable new Japanese variety, just the colour which was sadly needed. The petals are a fine crimson,

PHYTEUMA COMOSUM (LIFE SIZE).

the reverse gold, and will unquestionably replace that famous variety which has so long held its own, E. Molyneux.

Florence Penford.—Lemon-yellow, a finely-formed incurved Japanese, good. The two last-

tors; the colour is a most pleasing yellow, the petals long and drooping and somewhat pointed, the quality being all that one can desire.

Cecil Cutts.—Incurved; colour deep rich yellow, very large; will make a fine back row flower.

Mrs. J. Seward.—A very pretty, large, and telling incurved variety; colour soft yellow, shaded towards the base into rose.

Madge Creagh.—A magnificent incurved variety; colour yellow and bronze, a grand addition to this section.

The King.—This is probably about the best of the new incurved kinds, very large, of splendid form, and distinct. It was finely shown at the National Chrysanthemum Society's November show by Mr. Higgs, the champion incurved grower.

Curri.—A fine addition to the early-flowering decorative varieties; golden-yellow and very free.

Gertie.—A medium-sized early variety; yellow, shaded rose, very telling.

Belle of Weybridge.—This is a charming decorative variety, and should become a general favourite in this section; colour a rich crimson-scarlet. Should be a good variety for table decoration, &c.

named varieties were raised by Mr. G. Penford of Leigh Park Gardens, Havant, and he is to be congratulated on placing such fine novelties before the public.

Miss Olive Miller.—A beautiful Japanese of great size and with broad petals, slightly incurving; colour silvery lilac, the reverse being very pleasing.

Mary Perkins.—A fine incurved Japanese, large, and very full; colour light yellow.

Henry Perkins.—A distinct Japanese of great size but a little loose, nevertheless a grand addition; colour dull crimson on a first crown bud, but much brighter on a second crown.

Countess of Arran.—A fine drooping Japanese. The petals are of great length; colour salmon-pink.

Edith Smith.—Japanese. Finely shown by the raiser, Mr. H. Perkins, in his first prize stand at the November National Chrysanthemum Society's exhibition; the colour is a pleasing creamy white, and the flower is very refined.

Viscountess Cranborne.—A Japanese of promise, and will prove of great value to exhibi-

Joseph Lowe.—A decorative variety of great promise, beautifully shown as grown in a pot at one of the meetings of the Royal Horticultural Society; colour rich golden-yellow.

Black Prince is a very pretty early-flowering variety; crimson, golden reverse, very effective.

Nellie Blake.—A seedling from Mme. Desgrange, which it much resembles in habit, the colour being a pleasing crimson; good.

Acquisition is an early-flowering Pompon variety; colour bright crimson-red, shaded plum, very distinct and pleasing. E. BECKETT.

THE PHYTEUMAS.

The genus *Phyteuma* is one of the most completely alpine of the family of the Campanulaceæ. It belongs essentially to the Asiatic-European flora, and more especially to that of the Mediterranean regions. It extends throughout the south-east of our Continent and Western Asia. Among the fifty-one

P. CONFUSUM (LIFE SIZE).

species recognised by the *Index Kewensis*, eighteen are special to Eastern Europe, the Caucasus and Asia Minor, one to Siberia, one to the

Himalayas, and one to Japan, which no doubt is of Siberian origin. One species is said to be American, from Chili, but it is possible that this may prove to belong to another genus, for it would be difficult to account for its presence in the Andes unless it were possibly by the agency which has carried several Arctic and European species to Terra del Fuego. It is true that the *Index Kewensis* also indicates another species in South Africa, but this again may prove to be a plant of doubtful identity.

De Candolle's *Prodromus*,* with the exception of the one Siberian species, gives only the European and Asiatic-Levantine plants, the

* *Prodromus*, Vol. VII., page 430.

P. HEMISPHERICUM (LIFE SIZE)

PHYTEUMA SCIEUCHZERI (LIFE SIZE).

other species having been described since its publication.

But although the *Index* gives but fifty-one species, there are many other forms and geographical varieties that it does not recognise, but that in the monographs of de Candolle and Boissier and the works of other botanists have been given specific rank. From the horticultural point of view, the one here chiefly

under consideration, there are many more *Phyteumas* than appear in the Kew list. But only twenty are in cultivation, or possibly twenty-five to include all that are found in botanical collections. The Oriental species are very little grown, the greater number of them not having been introduced; probably many of them are of difficult cultivation, for the seeds brought by the botanist Alboff from the Caucasus could not be grown here at Geneva in our *jardin alpin d'acclimatation*. Of these Eastern species, which belong to the special group *Podanthum*, two only appear to be known in our gardens, namely, *P. limonifolium* and *P. canescens*. It would, therefore, be desirable if my readers (English people having special facilities in these regions) could effect their introduction by means of seeds.

The genus *Phyteuma* is distinguished from *Campanula* by its tubular corolla, coherent at the top, and, towards the base, divided into five narrow separated straps, which form, as it were, a protective rampart around the ovary.

The curious conformation of the flower is designed to facilitate cross-fertilisation. Those who are interested in this question will find some extremely interesting details on the subject in Müller's fine work.* They are frequented by a large number of insects, Müller giving a list of thirty-one species for *Phyteuma hemisphaericum*, of forty-eight for *P. orbi-*

place in tufa, in which it appears to grow most willingly.

It is a handsome plant of strange aspect, with coarsely toothed leaves and large blue sessile flowers, closely pressed together in a compact umbel, pale lilac in the swollen base,

P. PAUCIFLORUM (LIFE SIZE).

and deep violet in the narrowed upper part. The bifurcated style is fine and drawn out beyond the flower to a length equalling that of the flower itself.

It blooms in June and July, and must have an absolutely horizontal position, that is to

culare, and of sixty-eight* for *P. Micheli*. One of the special characters for guidance in distinguishing the species is in the bracts at the base of the head or spike.

From the cultural point of view the *Phyteumas* may be divided into three categories—firstly, the mural species; secondly, the rock-loving; and, thirdly, those that succeed in the open ground.

In the first division there is but one, but it is an extremely characteristic plant, of more value than many others. This is the well-known

Phyteuma comosum (L.), only found in a wild state within a comparatively restricted area. This very remarkable plant, of which de Candolle, in his monograph, makes a section alone, grows in the fissures of the calcareous rocks which edge the lakes of Como and Garda and the rocks of Carinthia. In some places it comes to the actual water edge and can only be gathered from a boat. It grows really in the rock, thrusting its thick fleshy roots into the fissures, which they fill entirely. They could only be got out by means of a stone-mason's chisel and hammer; indeed, I doubt if it is possible ever to get them out with the roots unhurt. It may, however, be grown from seed, though not easily. We did well with them in the tufa wall of the *jardin alpin d'acclimatation* at Plainpalais, also here at Floraire, to which place we have recently removed the garden and all our collections. Here we have made it a special

P. HUMILE (LIFE SIZE)

* Müller, "Alpenblumen und ihre Befruchtung durch Insecten," page 406.

say, it must be planted in the joints of a wall or a piece of perpendicular rockwork. It likes to face either the rising or the setting sun, though in England it can very well bear a full southern exposure. It must have limestone. It is one of the handsomest rock plants, and one of those most rarely seen in gardens. Still it is not very difficult to grow, its only requirement being a fissure in limestone.

In the second division we have the species that grow in mountain rocks, generally dwarf, tufted plants. They are as follows:—

Phyteuma Curesia (Bic.).—From Corsica and the Western Alps. This is a *P. humile* still more thick-set, and is grown in the same way as its congener.

P. Charmeli (Vill.).—From the Alps of Dauphiny, the Pyrenees, and the Apennines: 6 inches to 12 inches high; root-stock thick and brittle, leaves soft, coarsely serrated: flowers dark blue in round heads. The bracts are linear-lanceolate, very gradually drawn out to a point, usually entire and ciliated, often longer than the flower-head. A rare plant in gardens, flowering in June and July.

P. confusum (Kern.).—From the granitic rocks of the Tyrol. A low, tufted plant; leaves long and grass-like, narrowing abruptly to a toothed tip; bracts of the flowers broadly ovate-lanceolate: flowers deep violet in a close head.

P. globulariaefolium (Sternb.).—From the Southern Alps; a form very near *P. pauciflorum*, from which it is distinguished by the leaves being widened in their upper part and toothed, and by the more globular flower-head.

P. hemisphericum (L.).—From the granitic Alps. A small plant with grass-like leaves, forming large tufts scarcely distinguishable from the grass; flowers violet-blue, in close heads, with ovate-lanceolate ciliated bracts at their base. It flowers from June to August. In cultivation it likes a dry place in full sun. In our garden we have a fine white-flowered variety that was found near Bourg St. Pierre.

P. humile (Schleich.).—From the high middle and Eastern Alps. A beautiful and rare species, with large violet-blue flowers in globular heads; bracts as wide and as long as the flower, sometimes even longer; leaves narrow and grass-like, but larger than those of *hemisphericum* and sparsely toothed. June.

P. pauciflorum (L.).—From the high Alps, throughout the whole chain from the Pyrenees to the Carpathians; the smallest and most tufted species of the genus. It forms a close, short turf and sometimes very large tufts; leaves entire, ovate-elliptical, obtuse and toothed at the tip: flowers few, violet-blue in spread-out heads, with ovate-orbicular bracts, which are shorter than the flowers. June.

P. serratum (Viv.).—From the mountains of Corsica. A small plant, dwarf and tufted;

leaves lanceolate, with widely spaced teeth; flowers violet-blue, in globular heads, with wide bracts expanded or reflexed. June and July.

P. Sieberi (Spreng.).—From the Southern Alps and the Apennines; leaves ovate-rounded, cordate-crenulate; flowers deep violet-blue, in globular heads, with ovate, coarsely toothed bracts. June and July.

P. Scheuchzeri (All.).—From the sunny granitic rocks of the Alps, the Pyrenees, and the Carpathians. A plant with slender flexible stems, relatively tall (4 inches to 16 inches); leaves ovate-elliptical, with serrated edges, the upper ones long and narrow; flowers deep

IRIS TINGITANA IN A PENZANCE GARDEN.

violet-blue, in rounded heads, furnished with long narrow bracts, either expanded, erect, or drooping, always longer than the flower. July and August.

All the species in this division require rocky fissures in full sun and dread damp; they need but little soil, and that only of leaf-mould and sand. It is desirable in winter to protect them from heavy rains by some kind of overhead shelter, but this only applies to damp regions, such as the centre and north of England.

Flourire, Geneva. HENRY CORREVEON.
(To be continued.)

NOTES ON HARDY PLANTS

IRIS TINGITANA.

RARELY met with in this country is the Tangiers Iris, though an exceedingly beautiful species, a fact that is doubtless chiefly due to the difficulty generally experienced in flowering it. Numerous queries appear from time to time in the columns of the gardening press asking for information as to its successful culture, and very rare are the notes recording its blooming in the British

Isles. At Ryde, in the Isle of Wight, the late Rev. H. Ewbank flowered it, but, I believe I am correct in stating, not annually, and in certain other favoured spots it blooms fairly satisfactorily. The best examples that have ever come under my notice I met with in a garden some two miles distant from Penzance in the last week of March, 1902. The plants were growing in deep porous soil at the foot of a wall facing east, and the group displayed seventeen flower spikes, averaging about 2 feet 6 inches in height. The foliage was exceptionally strong and the flower-stems stout, this vigour being presumably accounted for by the presence of a layer of manure a foot or so beneath the surface. The garden in which these Irises were growing is noted for the splendid specimens of the rarer *Narcissi* that it produces. The flower, which resembles that of a glorified Spanish Iris (*I. xiphoides*), to which this species is allied, is in strong examples, 6 inches across, and is pale blue, merging into purple-blue, with a spreading keel of golden-yellow. The leafage is grey-green in colour and deeply channelled, curving gracefully outward as in the English Iris (*I. xiphium*), but considerably exceeding the leaves of that species in length. *Iris tingitana* starts into growth in the autumn, and carrying its foliage through the winter is exposed to the full rigour of that inclement season. The plants, however, are rarely killed by the frost, but in most instances persistently refuse to flower, and where this is the case their culture from a decorative point of view is useless. The conditions most suitable to this Iris are a rich and porous soil, shelter and ample sunshine, the two latter being most easily provided by planting at the foot of a warm wall.

S. W. FITZHERBERT.

POLYGONUMS BY WATERSIDE.

YOUR illustration of the tall-growing *Polygonum sachalinense* by the waterside reminds me of the great value of *P. alpinum*, a much dwarfier and better plant I think for the same purpose. Unless the sheet of water is very large one does not want too many tall plants round it, but *P. alpinum*, which is not well known, meets the case well, as it is only about 4 feet high, is sweet scented, and bears a very long succession of flowers

quite until late autumn, *i.e.*, until cut by frost, the flowers, too, being very white and large individually for a Polygomm. *P. sachalinense* is too readily affected by spring frosts to be universally useful, as there are many places where it would certainly have its first growth cut off if planted by the waterside in a low-lying spot. I have not seen *P. alpinum* served in this way, possibly because it is later in growth.

J. C. TALLACK.

SOLIDAGO SHORTII.

THE *Solidagos* are generally regarded as commonplace, and more suitable for planting in the shrubbery than among our choicer perennials. Yet the above is a very beautiful plant, and will prove a distinct addition to the herbaceous border. It has a robust constitution and reaches a height of 5 feet, bearing large heads of golden-yellow flowers in gracefully drooping racemes, which are splendid for decoration in a cut state.

It is most desirable either for grouping or planting as isolated specimens, and retains its characteristic beauty after the flowers have faded. *S. Shortii* quickly increases, and when better known will be a general favourite with hardy plant lovers.

A. E. THATCHER.

Allenham House Gardens, Elstree, Herts.

COLCHICUM BISIGNANI.

HERE the unseasonable character of the greater part of 1902 appears to have affected the late-flowering bulbous plants more than I had anticipated, and, writing in the second week of January, I may mention that *Colchicum autumnale roseum plenum* is still in flower, as well as *C. Bisignani* of bulb dealers. All other varieties of *C. autumnale* have long ago gone to rest, but the variety *roseum plenum* of Messrs. Barr and Son always flowers longer than any other. I have before referred to *C. Bisignani* as being one of the latest to flower, and it is in perfect condition now, although flowers have appeared for some weeks. *C. a. roseum plenum* looks a little unhappy, but one cannot say this of *C. Bisignani*, though our weather must have proved very different from what this Meadow Saffron experiences in its native Italy. I call this plant *C. Bisignani* "of bulb dealers," as Mr. J. G. Baker in the *Journal of the Linnean Society* only gives *Bisignani* as a synonym of *C. Tenorii*, in which he is followed by the "*Index Kewensis*." I am of opinion, however, that the plant here is not in accordance with *C. Tenorii* as described by Mr. Baker as above. Its segments are more pointed than one would expect from the description of our eminent botanist. The nomenclature of the Meadow Saffrons in gardens is very confused still. This matters less if we can procure exactly the plant we want, and I think that *C. Bisignani* can be had in this way under its name. Its late-flowering habit is a distinct advantage, and when one can have it in mild winters flowering in the open and without any glass shelter from some time before Christmas until well into January we have surely a good thing. This and *Polygala Chamæbuxus purpurea* form the brightest bits of colour in the garden to-day, except, perhaps, the *Winter Aconite* and the *Winter Jasmine*. The colour is quite different, however, of course, and the bright purple of *C. Bisignani* is welcome in the rock garden, especially when the sky overhead is gloomy and heavy rains sweep over the garden. I have grown this *Colchicum* for several years now, and each winter it seems to become more appreciated.

GALANTHUS SPECIES FROM ALBANIA.

THERE appears a general tendency on the part of the autumn-flowering *Snowdrops* to gradually adapt themselves to the habits of their sister flowers when they have been in our gardens for some time. The "October" ones gradually postpone their flowering until they come in the end of December and render the name of "*Octobrensis*" applied to one species a decided misnomer. I shall not venture to assert that this is invariably the

case, but my experience on this point is supported by that of some of my correspondents. Some who think a *Snowdrop* before its wonted time an undesirable thing will not lament this habit, but many will do so. A few years ago, through the enterprise of Mr. Van Tubergen, of Haarlem, Holland, an importation of these autumn-flowering *Snowdrops* was secured from Albania, and disposed of under the name at the head of this note with the addition "probably *Octobrensis*." They proved to be more robust than the ordinary form of *Octobrensis* as previously known in this country, though he would be a bold man who would attempt to discriminate and give distinct names to these *Snowdrops*. This stock has turned out the most satisfactory of the earlier *Snowdrops*, with the exception (here, but not elsewhere) of *G. Elsæ*. It is now in flower, and was the first to bloom with the exception of some newly-imported bulbs of *G. cilicicus*. This Albanian *Snowdrop* has the characteristic mark of all these autumn *Snowdrops*—a distinct white line up the centre of the leaf.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

THE HORTICULTURAL HALL

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It would be interesting to learn what was the particular public competition which furnished your correspondent "Onlooker" with the experience upon which his letter to you has been founded.

As a matter of fact the conditions which are stated in an invitation to such a competition are by this time well settled and known, and are available, and no exceptional difficulties or complications can on that account possibly arise. But I observe that your correspondent qualifies his "difficulties" by suggesting that they are "quite beyond the control of the present committee," and he pleads the necessity for a committee "of exceptional strength." This is not perhaps very complimentary to "the present committee"—your correspondent's estimate of which may have been influenced by an examination of the plans before us; but surely his argument points rather to the strengthening of the committee, should that be found necessary, than to the abandonment of a course which alone seems possible to rescue the society from the *impasse* into which it has been led.

I know that many Fellows of the society will receive with a feeling akin to despair the intelligence that the terrible building proposed as the English Home of Horticulture is to be adopted as it has been presented to us. Rather than this let us have any reasonable expenditure of money, time, and patience. EXPERTO CREDE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—"Onlooker" is quite mistaken in supposing that there are any substantial difficulties in the way of public competition among architects when any public buildings are proposed. That any such difficulties exist is absolutely contrary to practical experience. There is no conceivable reason why the council of the Royal Horticultural Society should not have invited architects to submit sketch plans for their approval. In this way there would have been a splendid opportunity of securing plans for a building which would have done credit to the taste of the society. Horticulture may not be an art, but it has none the less many associations with Art, and I trust sincerely that those Fellows who value these associations will protest against the architectural outrage which the council propose to perpetrate in Vincent Square in the name of the society and in the name of horticulture. If the council carry out the plans now proposed they will not only convict themselves of Philistinism which would be disgraceful in a

jerry builder, but they will further show that they have not even considered the most elementary questions relating to the practical utility of the hall for the many and varied purposes for which they propose that it shall be used. Let us hope that even yet other architects may have the opportunity of submitting plans, and that the council may call in the assistance of some of the Fellows of the society, whose names are famous in the world of Art, to supply the taste which they so obviously lack. CATTLE POISONING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I have only just noticed the article under the above heading in your issue of December 13 last, and am sending an account of my experience, which, perhaps, may be of interest to your correspondent. A few years ago my employer purchased a pedigree shorthorn heifer for £36, and the animal, with several others, was turned into the park in which grew a number of English and evergreen Oaks, from which were falling great numbers of Acorns. Soon three of the animals developed symptoms of bad health, and one, the pedigree heifer, pined away and died. A "vet." being called in he pronounced it a case of Acorn poisoning. After that time a number of pigs were always turned in to eat up the Acorns before the cattle were allowed. Pigs take no harm, but, on the contrary, soon fatten and become fit for market.

THE USE OF CLIMBERS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I can sympathise with "Dundee Rambler," and therefore send the following particulars, which he will find to answer well. Some years ago I was requested to clothe many of the trees here with climbers, such as rambling *Roses*, *Clematis montana*, and such like, and I found this a very difficult matter, because, as "Dundee Rambler" points out, if a climber be planted near the base of a large tree it is starved during the summer months for want of moisture, and if planted at some distance from the stem of the tree it suffers in the same way, also looks out of place, and requires some kind of support to lead it up into the branches. It is useless placing good soil thinking thus to improve matters, as this will quickly be taken possession of by the roots of the tree which the creeper is required to clothe. To get over this difficulty I adopted the following plan: I procured some sound cement casks which were well hooped; I bored one hole in the bottom of each and placed over it about 2 inches of broken potsherds for drainage. The cask was then sunk at the foot of the tree to be clothed by the creeper, not only its full depth, but some 3 inches or 4 inches below the surface. It was then filled with thoroughly good soil, which was well rammed in. The creeper was planted and watered, and tied to the stem of the tree. Let me here give a word of caution. Plant only healthy strong plants, as well as suitable kinds. For this purpose true rambling sorts are needful, whether *Roses*, *Clematis*, or what not. It is useless to attempt to cover a tree with such kinds of *Roses*, for instance, as climbing *Captain Christy*, *Niphetos*, but use such as *Dundee Rambler*, *Bennett's Seedling*, *Aimée Vibert*, *Crimson Rambler*, *Aglaia*, *Reine Olga de Wurtemberg*, and those known to be hardy and of robust growth. *Clematis montana* is the best climber for this purpose, and certainly the most beautiful. It will take care of itself under the most trying circumstances. Try the common wood *Honeysuckle* and the wild *Clematis* or *Traveller's Joy* (*C. Vitalba*). The common white *Jasmine* is a good plant for the purpose and very delightful, because it will retain its foliage during mild winters, and its fragrance is delicious. It is more suitable for deciduous than for evergreens trees. The *Japan Vines* are most delightful for this purpose. *Vitis Coignetia* is perhaps the best. *Aristolochia Siphocampylus*

is also a suitable plant. One more word of caution. Do not suppose that these plants will require no attention. They certainly should have abundance of water for the first two years. After they have thoroughly established themselves and have reached the outside of the branches they may be left to take care of themselves, and it is astonishing how well they grow, as they derive considerable nourishment from the decayed leaves of the tree. If "Dundee Rambler" has old Holly trees or Austrian Pines to cover, by all means try Clematis montana. Close by where I write there is an Austrian Pine almost covered with this delightful plant, and before it could reach this tree it had to clamber over Laurels, Hollies, Box, and other large shrubs. In May and June it is a beautiful picture. Polygonum baldschuanicum is a promising plant for this purpose, and should be tried. I believe it will succeed almost in any position.

T. ARNOLD.

The Gardens, Cirencester House.

ORIGIN OF LILIUM HENRYI.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I have just received THE GARDEN of October 25, and as I always glance first at articles concerning Japanese plants, and especially those about Lilies, I read at once the article "Lilium Henryi" by Dr. Henry. This interesting article ends with the following sentence: "It would be a strange thing, but one not inherently impossible, if Lilium auratum were really a hybrid of Chinese origin, which has become wild in certain parts of Japan."

I have at various times intended to write about this theory, and now that so great an authority as Dr. Henry has written to you concerning it I wish to add a few words. It seems to me that no one who has seen Lilium auratum here in its native land can have any doubt that it is a distinct species, native of Japan, for it seems impossible that any hybrid introduced into Japan could spread over the country to such an extent as we find this Lily. It grows in the Nikko Mountains, the Hukon Mountains, in fact, on the mountains and hills almost all over the eastern and northern parts of the island of Nippon, the most central and largest of this island empire, unfortunately, however, no longer in such quantities as formerly, owing to the immense quantities exported, for the planting stock is simply taken from the native haunts of the Lily each year. Collectors do not trouble

to cultivate the bulbs either by scales or by seed. In support of this theory it may be mentioned that on those hillsides too steep for man to reach there the Lilies are still to be seen in masses, all of which leads one—who in the early years has seen the Lily growing there—to conclude that it is a native Japanese plant and doubtless a species.

The question is often also asked why the early travellers here did not mention L. auratum. The answer to this is, I think, that before Japan was opened to the world foreigners were only allowed to live on the small island of Deshima in Nagasaki Harbour, and all plants which they described and sent home came from that region. L. auratum does not grow there. Another reason is that the Lily was so common here that the Japanese botanists who helped Siebold and the other foreigners probably never regarded this flower as an important one. The Japanese to-day rarely plant it in their gardens, apparently caring very little for it.

Yokohama.

ALFRED UNGER.

MELONS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—On page 10 "A. P. H." gives a list of some twenty-one Melons—old and new—as of particular merit. Unfortunately, the list is far too long to meet the requirements of those who want to grow only two or three, and much too short to include all the good or generally esteemed good Melons in commerce. Were a complete list of these furnished no doubt it would extend to 100 varieties, all of which are by some one or other grower held to be the best. But in spite of the fact that we have all these varieties, and that it would seem that stocks not only can be kept true but remain of good constitution for fifty years at least, yet Melons put out as new are constantly being raised. No one can declare that during the past five years any one variety has been sent out that is any better than older ones, and it becomes increasingly difficult for anyone to assert in what respect they differ from old ones. These are facts in relation to Melons that cannot be contraverted. Why is it so? Has the Melon reached the end of its tether in the matter of flavour, appearance, or cropping? It is well we should face the question whether it is so or not, because so few grow many of the old and, at one time, well-known varieties now. There can be no doubt but that were some of them put

forward as new few would be able to say whether they were or not. We want varieties that can be relied upon to produce fruits of high-class flavour under all conditions. No grower in cutting even the most perfect fruit from any one variety can be absolutely assured that it will have good flavour. That is the defect in all Melons which raisers should seek to overcome. It is all very well to describe certain varieties as having exquisite flavour, but when cut, alas! how seldom is it found.

A. D.

THE KITCHEN GARDEN.

VEGETABLE MARROWS UNDER GLASS.

FEW kitchen garden crops are more remunerative or more highly appreciated than early Marrows, and it is surprising, considering how easily they are brought forward, that they are not more grown. Cold frames

and the mildest hot-beds will produce excellent fruit early in May, and if carefully attended to will give a continuous supply till the frost puts an end to them in autumn. Not only are the fruits extremely valuable at such an early date, but what is of far more importance is that when the frames are removed at the end of May the plants are in full bearing for some weeks before those sown and planted in the ordinary way; thus from a market point of view this is a great gain. The seed should be sown the last week in February singly in 3-inch pots. Some heat will be required to germinate the seeds, but if kept moderately dry they will do so in a temperature of 50° to 55°. The plants should be moved into 5-inch or 6-inch pots when large enough, using a light porous compost warmed to the temperature of the house in which they are growing. Well drain the pots, and press the soil only lightly about the roots. Grow near the glass so as to keep the growths sturdy.

A very mild hot-bed should be prepared and made ready by the first week in April. Use a compost of loam, leaf-soil, and road grit in equal proportions. See that this is well warmed, but not overheated, before planting. Give air carefully at first, but when the plants are well established this should be given much more freely, the lights being tilted in the opposite direction to which the wind is blowing, especially if it is in the north or east. Regulate the growths by pegging them down, syringe with tepid water, and shut up early in the afternoon. Cover the lights securely against frost. The plants will soon show fruit, the earliest of which should be fertilised precisely in the same way as Melons or Cucumbers. The lights should be entirely removed whenever the weather is sufficiently warm, and be replaced at night. Towards the end of May the frames can be removed altogether. Give a good mulching of soil similar to that in which they are planted, but add a little decayed manure or bone meal, and should the weather be dull and cold place a few uprights and supports on which the lights taken from the frames can rest—(see accompanying illustration)—when the whole of the growths can be easily protected with mats at night. The plants should be well supplied with mois-

VEGETABLE MARROWS UNDER GLASS IN ALDENHAM GARDENS.

ture and manure water towards the end of the summer, when they will be found as vigorous and fruitful as late-sown plants.

Suitable varieties, of course, should be grown. The following I have found admirable when so treated, all being very prolific and of excellent flavour: Moore's Cream, white; Prince Albert, green; Pen-y-byd, white; Improved Custard, white; and Sutton's Perfection, green, the latter a new variety of much merit.

Elstree.

EDWIN BECKETT.

FORCED LETTUCES IN FRAMES.

Few vegetables do better in frames than the Lettuce. Plants from seed sown in January give excellent heads in April and May, and at a season when choice salads are much appreciated. For years I advised sowing in early autumn for a spring supply, but at that date the varieties relied upon, viz., the Hardy Cabbage and Brown Cos, had to be sown some seven or eight months in advance to get a supply at the season named, and, as growers found out to their cost, few vegetables were less reliable. After severe winters very few plants were left, even with frame protection. My note more concerns what may be described as sowing in heat. I follow the market plan of sowing in the autumn, but this varies considerably from the old system, *i.e.*, to sow and get a plant large enough to lift into frames at the approach of frost. These were the plants that often failed to mature, their worst enemy being damp, and the plants decayed at the ground level often.

I follow the market system of sowing late in cold frames quite close to the glass, and keep the seedlings as hardy as possible from the start. It is necessary that the plants be free from drip, and if they get too large they fail to winter well. There is a possibility that after severe weather damping may ensue. Early in spring the plants are thinned out, each one being lifted carefully so that the roots are not broken, and the thinnings are planted out on a warm border. Those left—*i.e.*, the most important ones—are then kept a little closer and are usually ready in about six weeks or a little more from the time of thinning. By this system a great quantity of seedlings may be grown in a limited space and there is a certain crop, whereas such is not the case with earlier sowings or from open ground sowings in August for a spring supply.

When sowing in heat early in the year more heat is necessary, but even then excess means failure. In the Cos section I find Sutton's Intermediate, Heck's Hardy White, and the Bath or black seeded the best, but I think the Cabbage the most useful. Many prefer Cos to the Cabbage, but the plants take longer to mature. The best hardy Cabbage varieties are the old Hammersmith Hardy, Lee's Immense Hardy Green, Brown Dutch, and Sutton's Marvel.

I now come to what may be termed present sowings. Of late years this method of culture has become very popular, as many growers are unable to give frame room, say, from October to March, whereas a pan or box of seed sown in January or early February, the seedlings pricked out in a warm frame a month later will give good material in April or May, or, say, about three months from the time of sowing, that is if the seedlings are given warmth from the start. I have mentioned that seed may be sown in boxes, but of course it is not essential, as more space may be spared and the plants sown on a slight hot-bed and the seedlings thinned. Grown thus I have had much earlier produce, and it is an excellent plan when the demand is great for early salads. It is a simple matter to utilise the thinnings, as those placed in other frames give a succession. It is the seedlings that are not disturbed that turn in quickly. Of course when sown in boxes the transplanting causes a slight check, but with a warm root-run it is soon got over. There is one great point with this sowing, and that is to avoid crowding, as if the plants are sown like Mustard and Cress it is impossible to secure a strong seedling at the start. From the first, no matter where sown at this early

period of the year, the seedlings should always be near the glass and not over-watered.

The best results are obtained from movable frames placed over a good bed of leaves and warm litter, I mean the bed for planting out the seedlings. When grown with more heat from hot-water pipes the heat fluctuates, is also much drier, and a thin plant is the result. I use leaves largely, as they heat slowly and keep warm much longer. It is well to make the bed as firm as possible when placing the materials in bulk. For this sowing the earliest Lettuce is the small but valuable Commodore Nutt. Either under glass or in the open it is most valuable. Another very excellent Lettuce is Sutton's Golden Ball. This variety requires little room, is deliciously crisp and sweet, and a gem for frame culture. A little larger Lettuce and quite as valuable is Veitch's Golden Queen, a perfect frame Lettuce, makes a solid heart with few outer leaves, and is of very delicate flavour. I do not advise the Cos varieties for growing quickly, that is, for frames with bottom heat. The white-hearted varieties are the earliest, but they are not so reliable as the Cabbage; by growing the early varieties advised there will be few failures.

G. WYTHES.

THE FRUIT GARDEN.

CULTURE OF MELONS.

FOR the production of ripe Melons as early in the season as it is possible to obtain them fit for the table the best house is undoubtedly a low, narrow, lean-to structure, having a south-west aspect and provided with four rows of 4-inch hot-water pipes—two flows and two returns—placed in pairs one above the other and resting on brick piers close to the wall the entire length of the house. Improvised troughs, say, 6 feet long, 1 foot wide at the bottom, 15 inches deep, and the same width at the top being placed thereon for the reception of soil to grow the plants in. Pieces of wood 3 inches by 2 inches and 14 inches long should be placed across the pipes at intervals of 2 feet to rest the boxes on. Put 1½ inches deep of potsherds in the bottom, following with a covering of half-rotted leaves or thin turves, grass side down, so as to ensure perfect drainage.

The next best house for Melon culture is a low span-roofed one, from 12 feet to 15 feet wide, running from south-west to north-east, this being provided with three rows of 4-inch hot-water pipes fixed one above the other—two flows and one return—on either side close up to the walls the entire length of the house. Borders about 20 inches deep, 16 inches wide, and confined by a 4½-inch wall, each border being provided with a flow and return pipe for warming the soil, and thereby stimulating growth in root and branch. These pipes should be covered with 2 inches or 3 inches of brick rubble, followed by a layer of stable litter to prevent the rooting medium choking the drainage. In the absence of the brick-enclosed heated borders indicated above, excellent Melons may be, and are extensively, grown in suitable soil made into hillocks on the floors of low span-roofed houses, on either side the pathway the length of the individual structure at intervals of 2½ feet; the heaps are about 15 inches in diameter at the bases and 9 inches deep at the top for setting the plants in as soon as they have reached the desired size. As to the time of sowing seed from which to raise plants to produce ripe Melons the end of April or early in May, nothing is gained by sowing before the end of December or early in January. As to varieties, Blenheim Orange, scarlet flesh; Earl's Favourite, green flesh; and Hero of Lockinge, white flesh, may be mentioned as being thoroughly reliable varieties, yielding good crops of handsome-looking high quality fruits with great freedom under ordinary cultural treatment.

Sow the seed singly in 3-inch pots three parts filled with a mixture of lean soil and horse manure, in the proportion of three parts of the former to one of the latter, passed through a

half-inch meshed sieve, putting a piece of crock and a few half-rotted leaves or such like material in the bottom of each pot for drainage. When the young plants have made a couple of inches of growth, and the stems have become somewhat hard and firm, top-dress with some of the compost described above, being careful in doing so not to press the stems of the plants. Give the plants a position near the glass roof in order to promote a sturdy growth, watering with tepid water to settle the soil about the roots.

Plants intended for planting on mounds or ridges and training to wire trellises (fixed to the rafters some 12 inches or 15 inches from the roof glass) should be shifted into well-crooked 6-inch pots as soon as the roots have pushed through the soil, making the soil moderately firm in repotting. Put a small stick to each plant for support and return to the shelf or stage, transferring them to the ridges when they have reached the height of 15 inches or 18 inches, and before the roots become matted in the pots.

Plants intended for growing in frames placed on hot-beds or for training over the surface of beds in hot water pits, should be planted out when they have made two rough (perfect) leaves, the soil being made fairly firm about them in planting. This remark also applies to plants being set on mounds and ridges. A minimum night temperature of from 65° to 70°, according as the weather is cold or mild, should be maintained, rising 5° higher with fire-heat in the daytime under like weather conditions, and 10° to 15° with sun-heat.

The soil in which the Melon delights is loam, dug up fresh and used immediately, in preference to that which has been stacked for twelve or more months. Should this be lacking in fertility, add one-fourth of horse manure or well-rotted stable manure, free from worms, and should it be of a stiff, adhesive nature, the addition thereto of a barrow-load or two of lime rubble will be beneficial. In every case the soil should be in the house, pit, or frame sufficiently long to become warm.

In planting let the surface soil of the young plants be about level with the top of the troughs, placing sufficient soil around the roots to cover the latter to the depth of 1 inch or 2 inches; top-dress at short intervals as the roots push through the soil and until the intervening spaces are filled up. The plants should be moist at the roots when transplanted. The weather as well as the special conditions under which the several batches of plants are growing will in a great measure determine the question of when the plants should be watered. As the soil becomes permeated with a network of hungry roots more frequent and liberal applications of water at the roots will be necessary. In the case of plants growing in boxes applications of tepid diluted liquid manure should be given to the roots twice a week while heavy crops of fruit are developing and until the fruits begin to change colour.

Allow the plants trained on trellises to reach within two wires of the top before pinching the points out, the object being to obtain an even distribution of fruits. This can be accomplished by pinching out the first flowers that show on the laterals proceeding from the base of the plants. Side shoots will proceed from the base of each leaf-stalk as freely and regularly as on a pot Vine and for the entire length of the stems. Superfluous shoots should, however, be pinched at one joint from the main stem. Train the shoots forming the plants at about 15 inches from one another on either side, and when they have made two or three leaves stop them. When five or more flowers are open on a plant fertilise in the ordinary way about midday when the pollen is dry. Stop the fruit-bearing shoots at one joint beyond the fruit, and when it can be seen beyond doubt which fruits are going to swell remove all superfluous ones, leaving from five to seven on a plant. All flowers and needless growths should be persistently removed. When the plants are in flower, and, again, when the fruits are ripening, keep the house dry and give more air. When the fruits are fast developing the temperature may safely reach 100° with sun-heat, give plenty of moisture at closing time in the afternoon. When the fruits are the size of a

bantam's egg or thereabouts they should be supported by two cross-bands of raffia secured to the trellis.

H. W. WARD.

ORCHIDS.

HISTORY OF LÆLIA DIGBYANA, WITH AN ACCOUNT OF ITS HYBRIDS.

FIRST sent to England in 1846 from British Honduras by Mrs. MacDonnell to Mr. St. Vincent Digby, of Minterne, in Dorsetshire, there this extraordinary Orchid flowered in 1847 for the first time in cultivation. This was before the times of the great importers of Orchids, and when it would have been extremely difficult to obtain and bring home the colossal importations that we have had in England almost annually for the last thirty years. It is a curious fact that the habitat of this plant was only known to one man, with the exception of his workpeople, who, under his direction, collected the plants. This and *Cypripedium fairieanum* are the only two very notable Orchids that baffled all efforts at rediscovery, and now we know the habitat of *Lælia digbyana* only the *Cypripede* remains lost.

Importers have very diligently sought for the *Lælia* for more than twenty years, in fact, ever since the huge importation was sold in Stevens's Auction Rooms in King Street, Covent Garden, about twenty-five years ago; but all efforts to discover it failed, and the plant became once again very scarce in collections, and, while Orchid lovers were lamenting over the great scarcity of specimens in cultivation, another large importation was offered for sale by our Orchid auctioneers, the famous Protheroe and Morris firm of Cheapside. This is only a few years since. One day the writer was sitting in his office at work and an old gentleman was announced who wished to take an order for an importation of *Brassavola digbyana*, as he was going back home to the country where it grew. Here was a surprise. This turned out to be the man who had sent the importations to Stevens and Protheroe. I promptly told him that the last lot had flooded the market, and no plants were wanted for a few years to come at least. Then he gave me the whole history of the plant, which he had known for more than fifty years. His name is Mr. C. T. Hunter, and he it is who held the secret of the habitat of *Lælia digbyana* for all those long years, never knowing that the plant was being so much sought after. The first big importation was a loss to him, hence it was many years before he attempted another. I am at liberty to publish the information he gave me. Mr. Hunter says *Lælia digbyana* grows on tall trees which bound the River Hondo (the Rio Norte or Northern River) in British Honduras. This river forms the boundary between the northern portion of British Honduras and Mexico, and it is necessary to take a boat from Belize and proceed up this river, searching the lagoons and creeks, on the banks of which this plant is to be found. The Rio Hondo is at least 120 miles long.

Wherever there is great moisture bordering the banks of the river most of the trees support plants

of this Orchid, but they are only found in the densest shade and from 6 feet to 20 feet from the ground. The trees on which the plants grow are often 80 feet in height, so that the plants have as a rule quite 50 feet of dense foliage above them. It will thus be seen that this *Lælia* is a shade-loving one. All the best and finest developed specimens are found in the forks of the branches of the trees where there is an accumulation of humus, decaying leaves, and probably excrement from birds and small animals. In this compost, surrounded by great humidity, the plants flourish, and these are the long-bulbed finely-developed plants. The short-bulbed stunted plants are found in more exposed places, in situations where there is little to nourish them. In the growing season, which is our winter, the plants have a temperature of about 80° Fahr. by day, which falls to 65° at night, with a prodigious amount of moisture.

The reason probably why so many plants have died under the general treatment of *Cattleyas* in cultivation is owing to growers giving them too little heat and moisture in our winter. It is

digbyana grew in an arid country and probably on rocks in full sunlight, hence our failure in growing it as well as it might have been was put down to our want of sunlight in this country in the growing season, whereas the true reason is probably owing to our having grown it too cool and dry in winter. Heat and moisture the plant must have, and in plenty when growing if one is to succeed with it for a number of years, and improve the specimens year by year. We know now that this plant flourishes in its native habitat in the densest shade, and we also know that the rainfall for a great part of the year is prodigious, which, together with the nightly dews, produces a saturated atmosphere quite beyond our conception, and would incline any Orchid grower to suppose that the plants must rot under such excessively wet conditions. I may remark here that naturally there is a free circulation of air among the plants at all times, and oftentimes hurricanes, hence the natural conditions under which the plant is found are very different to the artificial treatment that we usually give.

The flower of this extraordinary Orchid somewhat resembles the head and face of the Marmoset monkey, and is of a buff-white or tawny colour, sometimes pure white; the labellum is abnormally developed and very heavily fringed, the exquisite filaments resembling filigree work. It has been largely used of late years in hybridising, and some really wonderful results have been achieved. It was a long time before the fertilisation of this plant was well understood, owing probably to the very long and unusual distance between the stigma and the ovary, the pollen threads possibly becoming partially absorbed before reaching the ovules. The exceedingly long beak-like form assumed by the apex of the ovary often exceeds 6 inches in length, whereas in the majority of the species with which *L. digbyana* has been crossed the ovary commences practically from the base of the column. This curious feature has been the chief cause of our Orchid authorities again separating the species under mention from *Lælia* and returning it to *Brassavola*, in which genus it was originally placed by Lindley.

There are hybrids of *Lælia digbyana* in which it has been used as a pollen parent, but up

to the present time there are no authentic records of progeny in which *L. digbyana* was the seed bearer.

A list is appended at the end of this note showing what fine hybrids have been obtained by the influence of this plant, every recorded hybrid of *Lælia digbyana* up to date will be found recorded here. I know that hybridists have plants that may be expected to flower in a short time, in which *L. digbyana* has been the mother plant, and the flowering of these is looked forward to with much interest to see what differences there may be in structure, colouring, and character of the plants.

LÆLIA DIGBYANA. (About three-quarters natural size.)

evident that unless a plant has the necessary growing conditions afforded it in the growing season it cannot possibly flourish long. In the winter in Britain most of our Orchid houses that contain plants which naturally make their growths at that season are kept too dry, in consequence of giving more fire-heat to keep up the necessary temperature. This excessive fire-heat dries the very life out of the Orchids, and, unless there is an ample command of heat, a careful and good grower knows it would not be wise to saturate his houses with moisture, but the *Lælia digbyana* needs heat and moisture for its development, and it needs it in Britain in winter when it is growing.

In the south of France, and also in Italy, this *Lælia* flourishes much better than in Britain, by reason of the necessary high temperature which it is possible to maintain in those countries in the plant's growing season. With a good circulation of air, the necessary moisture is very easily supplied by frequently hosing the floors and stages of the houses with water. I think it worth mentioning here that the opinion of the majority of orchidists has been that *Lælia*

GARDENING OF THE WEEK.

KITCHEN GARDEN.

WATCH must be kept on the Broccoli plants, and any that are forward should be protected either by heeling over to the north, or, better still, by lifting them with some soil attached to their roots and placing in pits or sheds. On light rich soils the growth made by Broccoli is generally gross, hence the greater necessity for proper protection than on heavy land where they make firmer growth. Although quite hardy, the

WINTER SPINACH

will repay for some kind of protection. A layer of Bracken worked among the plants with the hand is as good as anything; this protects the top growth as well as the roots and stems. Failing this some soil should be placed against the stems with a draw-hoe. This crop is generally one of the first to burst forth into new growth in spring, and it is then highly appreciated, as green vegetables are often scarce. The present is a good time for applying a heavy dressing of farmyard manure to the

ASPARAGUS BEDS

if not previously done. Old beds on well-drained soils will also be benefited by the application of the drainings from pig yards, for it will be found that the old matted roots are none too wet, in fact, on lifting some for forcing quite recently we found the soil about them dry.

SALADING.

Although much variety cannot be expected at this dull season, yet the demand should be met by making frequent sowings of Mustard and Cress, and if the supply of Lettuce or Endive wintered under glass is short, a box of Lettuce seed should now be sown. The plants may be used in the salad-bowl when about 2 inches or 3 inches high. If grown quickly these will be found very tender. Chicory is another useful addition to the salad-bowl in winter, and is easily forced by putting a few roots in a pot of soil every ten days and placing them in the Mushroom house or the cellar. Watercress grown in pots or pans and placed in pits or cool houses near the light should now provide welcome salad. If a flavouring of young Onions or Chervil is liked, then a little seed should be sown, and the seedlings raised in heat and drawn as required.

EARLY POTATOES

are sometimes grown in pots, and in such cases the haulm must be supported with sticks and the plants top-dressed with a mixture of loam and old Mushroom bed refuse. When the pots are full of roots weekly applications of liquid manure may be given with good results. To follow these, the main batch in pits or frames should now be planted. It is a good practice previously to lay out the tubers in boxes containing some rough leaf-soil, placing them in a Vinery or Peach house that is being forced. Rub off all sprouts with the exception of one or two of the strongest at the apex of the tuber. When planting retain as much of the soil adhering to the roots as possible, and plant carefully with a trowel. The soil should be at least 12 inches deep, and a hot-bed with a frame thereon in which Asparagus has been forced

answers well for Potatoes. Mona's Pride and Ashleaf are both excellent well-tried varieties for under glass culture.

Stonleigh Abbey Gardens. H. T. MARTIN.

INDOOR GARDEN.

PELARGONIUMS.

OLD cut-back plants of the large-flowered and show varieties that were repotted in November or early in December will require but very little water at the roots at this season, but when water is applied give sufficient to moisten the whole of the soil contained in the pot; see that the plants are so placed as to receive the maximum of light and sun. An occasional fumigation with tobacco in some form will keep the plants clear of aphids. Where large specimen plants are required the points should be taken out of the young shoots as soon as three clear joints can be left, and the old shoots be got into position to facilitate future training. A temperature of 40° to 44° should be maintained by night, with an increase of 5° by day. Zonal Pelargoniums for pot culture, if not yet cut back, should have attention in this respect as soon as they cease to bloom: place them in any light airy position where a temperature of 38° to 40° is assured, and water must be entirely withheld for a few weeks. Where required the points of the prunings may be used for cuttings if those three joints long can be secured. Insert these in well-drained 3-inch pots, filled firmly with sandy loam, with a little sifted leaf-soil added; if placed on a light shelf or stage, but not in a draughty position, they will quickly make roots.

AZALEA INDICA.

These plants will require fumigating to keep thrips in check. All large specimen and half-specimen plants should have the shoots cut loose from previous training. Some of the shoots will be found to have become weak and should be cut out, selecting younger and more vigorous wood to fill in. Thoroughly cleanse the plants of all insect pests. Old plants which have not been repotted for two years or more will benefit by a top-dressing of sound hard peat and sand with a little fine charcoal intermixed, first removing with a sharp pointed stick all surface soil that is not thoroughly permeated with fine fibrous roots. Then add 1 inch or 2 inches of the top-dressing material as required. It must be made firm. Water the soil thoroughly with a fine rose watering-can.

CAMELLIAS IN POTS OR TUBS.

Plants having finished blooming should be cleaned of scale by scrubbing the stems and stronger branches with an approved insecticide, afterwards carefully sponging the leaves; then place the plants in an inclined position and thoroughly syringe them with tepid water. Such plants as require it should be repotted in a compost of good sound loam and peat in equal parts, with an admixture of bone-meal and sand, an 8½-inch pot full of the former to a barrow-load of soil. Drain well, as Camellias require plenty of water at all times, and pot firmly; place the plants in a temperature of 50°, syringing them in the morning unless dull weather prevails. Next season's blooming depends entirely upon the attention given the plants during the next few months.

Look over the tubers and corms of such plants as Calla elliptica, Gloxinias, Caladiums, Tydas, Gesneras, &c., now stored under stages or in store sheds to see that they are not shrivelling by a too prolonged absence of moisture. Should such be the case, damp the material in which they are stored and replace them until required for starting.

Wendover.

JOHN JACQUES.

THE FRUIT GARDEN.

HARDY FRUIT TREES.

THE mild damp weather which has been so favourable for pruning and nailing will have held out inducements to many to postpone such work as top-dressing and mulching until walks and borders are in a better state for wheeling manure, &c.; but so important a work must not be long

delayed. Where Pear trees are grown on the Quince stock and the roots have not been disturbed, the annual top-dressing of good rich manure may be wheeled out on frosty mornings as soon as the nailing is finished. It is well known that the successful culture of Pears on the Quince stock greatly depends upon rich top-dressings. Exhausted soil may be removed to the vegetable quarters to make room for the new. After a few years heavy cropping puts an end to extension of growth, blossom buds only are formed, and as many people are quite unable to thin the fruits the annual removal of old spurs at pruning time should be practised.

MELONS.

Where early Melons are required and a light, well-heated pit is at command, a few seeds of some free-bearing early variety may be sown at once in small well-drained pots, two seeds in each. Plunge the pots in a bottom heat of 80°, which can be maintained by the aid of hot-water pipes running beneath the bed. The great drawback to Melon culture at this early season is want of light, a difficulty which may be diminished by keeping the young plants close to the clean glass, and by covering with bell-glasses rather than mats on cold nights. Immediately after the seeds are sown set about the preparation of suitable materials for making up the bed in which the plants are to be grown. Well fermented Oak leaves produce the best results, as the moist heat from decaying vegetable matter is more favourable to growth. Another important item in successful Melon culture is a good supply of strong loam from an old pasture, which should be cut some months before it is wanted for use and stacked in an open airy shed or in long narrow ridges out of doors, with some kind of covering for throwing off heavy rain and snow. If this is not at hand lose no time in securing enough for the season, and expose it to the air, as wet crude soil is sure to lead to disappointment if not to complete failure. As soon as the young plants have made two or three leaves beyond the seed leaves they will be ready for transference into 6-inch pots; for the compost use turfy loam previously warmed, the pots, drainage, and everything required should be previously warmed by bringing them into the house.

POT MORE FIRMLY

than before, as the Melon loves a firm-rooting medium. Loose soil is apt to hold too much moisture, and often causes plants to canker. In potting always keep the plants well elevated in the new pots, and endeavour to preserve the seed leaves intact as long as possible. Stake the plants as required, and when it is quite clear which of the two seedlings is taking the lead destroy the weaker. Pot on as often as required until the fruiting size is reached; 15-inch or 18-inch pots will produce the very finest Melons, and they should be stood on brick pedestals, well surrounded with fermenting leaves, occasionally turned over and fresh added as the bottom heat declines. The Melon enjoys a high, moist, day temperature, and the atmospheric moisture should be in proportion. For very early forcing we are still conservative enough to grow those two old varieties, Easton Castle (green flesh) and Blenheim Orange (scarlet flesh); whenever we have trusted to "Somebody's new" we have been disappointed.

WILLIAM CRUMP.

Madrishild Court Gardens.

FLOWER GARDEN.

CHIMONANTHUS FRAGRANS (WINTER SWEET).

AT this dull season of the year how much poorer our gardens would be without this sweet-smelling hardy Japanese shrub. It deserves a place in every garden where fragrant flowers are in demand, and lasts well during winter in the open air. If planted against a south wall and sheltered a little from the north and north-east winds, the flowers last from December to February. Nothing will stand cutting better than this; in fact, the more it is cut the better it flowers. It will thrive in almost any soil, but prefers a mixture of loam and old mortar rubbish. It may be procured from almost

any nurseryman and is usually kept in pots, and may be planted now with perfect safety.

PLANTS IN COLD FRAMES.

Plants that are wintered in cold frames should now be well looked after. It is astonishing how much can be accomplished by judicious management in this way. Plants struck early in the autumn and well exposed to the open air before being placed in the frames will now be in condition to withstand the cold. Some loose material, such as hay or straw, should be in readiness for covering in the event of severe frost, and some of the same material should be packed round the sides of the frames. When thick coverings over the glass become necessary the material should, if possible, be perfectly dry, and shaken on loosely, as the more loosely it lies the better it will be for keeping out frost. If over this material some light covering, such as strong oiled calico, can be thrown it will prevent cold winds penetrating and keep the hay or straw dry. When it becomes necessary, owing to severe and continuous frost, to keep the glass covered up for a few weeks at a time, great caution is necessary in uncovering and exposing the plants to light and air when the weather changes suddenly to a thaw. To uncover suddenly under such circumstances exposes them to such a reaction as would prove far more destructive than a degree or two of frost. All watering should be avoided beyond what is necessary. It is much better for the plants to droop a little than to have them in the least degree too wet. Give air on all favourable occasions, and close the frame early in the afternoon.

HERBACEOUS BORDERS.

Should the weather prove favourable these will need immediate attention. All the old foliage of Asters, Delphiniums, Galegas, &c., may be cut away; in fact, neatness in this department should be a golden rule. Be careful not to remove the leaves of any plant which needs such natural protection. One often sees the Hepatica and the German Iris almost stripped of their leaves just for the sake of neatness, and one scarcely knows which to be the more sorry for, the plant or those who make such mistakes. If the plants in the border were lifted and rearranged last year it will not be necessary to do so now, as once in three years is quite often enough. Many plants during the past season made extraordinary growth, and consequently impoverished the border proportionately. These should now have a good top-dressing of well-rotted manure. It can be wheeled on in frosty weather and spread evenly over the border, and will be ready for forking in later on. When the Hepaticas are well grown it would be well to place hand-lights over some of the clumps. This will cause them to flower at least a fortnight earlier than those unprotected, and thus prolong the flowering season.

Those who are fortunate enough to possess a stock of single white Hepatica should take great care of it; it is now rarely seen. T. B. FIELD.
Aswellthorpe Hall Gardens, Norwich.

EDITOR'S TABLE.

Mr. Burbidge sends from the Trinity College Botanic Gardens, Dublin, flowering specimens of a New Zealand shrub,

OLEARIA FOSTERI.

The flower is not showy but deliciously fragrant, especially in the evening or at night. The plant is quite hardy at Dublin. It is a feature in the garden of Mr. George Vaughan Hart, K.C., at Woodside, Howth, the promontory just outside Dublin Bay.

FLOWERS FROM DEVON.

I send you what an old botanical friend assures me is a great rarity—the ripe fruit of the major form of the common white Jasmine, which has matured this last autumn on the wall of this garden. The plant is on the east side, but its head is on the top of the wall.

Ficus repens grows and fruits abundantly on the wall of Collaton Church and Vicarage near Paignton. This is also rare, I believe. I have still in bloom *Solanum jasminoides*, *Roses*, *Diplacus*, *Clianthus puniceus*, *Aubrietia*, *Coronilla*, *Wall-flowers*, *Primulas* of sorts, *Abelia*, *Hepaticas*, *Forget-me-nots*, *Evergreen*, *Candytufts*, &c., bursting their flower-buds, also *Roman Narcissus*. C. M. B.

We shall illustrate the Jasmine fruit.

MISCELLANEOUS.

FRESH ROSES IN WINTER.

UPON the fore part of the head the gentlewomen wear a border of pearls, and all other from the highest to the lowest, commonly wear garlands of Roses which they call Crantzies. For they keepe Roses all the winter in little pots of earth, whereof they open one each Saturday at night and distribute the Roses among the women of the house, to the very kitchen maid; others keep them all in one pot, and weekly take as many Roses as they need, and cover the rest, keeping them fresh till next summer.

And the common sort mingle gilded Nutmegs with their Roses and make garlands thereof. Only women wear these garlands in winter, but in summer time men of the better sort wear them indoors, and men of the commoner sort wear them abroad. They keepe Roses all winter in this sort, they choose the closest and thickest buds of all kinds of Roses, but the Damaske Roses best keepe the smell; and other kindes the colour. Then they take a pot of earth and sprinkle some bay salt in the bottome, and lay these buds severally, not very close, one to the other, which done, they sprinkle the same, and wet all the buds with two little glasses of Rhenish wine and again sprinkle them with bay salt in greater quantity, yet such as it may not eat the leaves.

In like sort they put up each two rows of the buds till the pot be full, which they cover with wood or leade, so as no air can enter, and then lay it up in a cold cellar where no sun comes. When they take out the buds they dip them in luke-warm water, or put them in the oven when the bread is taken out, which makes the leaves open with the turning of the buds between two fingers; then they dip a feather in Rhenish wine and wipe the leaves therewith to refresh the colour, and some doe the like with rose-water to renew the smell. I observed women at Leipsig in like sorte to keepe Cherries all winter. They enclose Cherries in a glasse, so as no air can enter, and then fasten the glasse to some low shrub or bough of a tree, so as the glasse may hang in a brooke runing gently.—From "German's Apparell," in the "Itinerary of Fynes Moryson," 1617.

THE GARDENER PER SE.

SHOW me a man who, in his habit as he lives, is almost perfect in character, and I will venture my last half-crown upon it he is a gardener! The finest testimonial to the art that deserves far better than that of hook and line to be called "gentle," is that it has the most extraordinarily beneficial effect upon character, or possibly the sweetest characters are those with a natural bent towards gardening. Where do you find among the garden's true lovers the detestable jealousies, the fermenting acidities, the detraction, and the unwholesome rivalry

that other "fancies" seem inevitably to breed? If there exists a dog breeder who will take me round his kennels, tell me all his secrets, and help me along with half a dozen of his best puppies I will accept the dog line of business, but I have never met him. The stamp or coin collector may possibly make an exchange with me, but I somehow or other do not get the best or as a rule an even share in the transaction, and there is left a smart not conducive to continued or initiated friendship. Even the other amateur photographer does not write and tell me how he managed to improve upon me to such an extent as to win everything I went in for in our last competition; he will not, indeed, even disclose his latest favourite in developers. My rivals in the poultry world go so far in the opposite direction as to waylay my bantams and prune their feathery unmentionables on the way to exhibition; as for my rabbit friends—to sink to the lowest depths of "the fancy," for the innocent bunny, though quite as sporting as a fowl, has, since the reported defection of a certain Marchioness or something equally grand, no aristocratic

OLEARIA FOSTERI (HOOK F.). (Half natural size.)

supporters at all—they only ask for half a chance, either to convict me of illegitimate improvements deserving of the Society for Prevention of Cruelty to Animal's attention, or to execute them for me upon my exhibits.

Someone at the bird show squeezes my canary, which expires after a graceful interval sufficient to cast a shroud of mystery round the incident; wherever I go, in short, in emulous pursuit of glory among the ambitious of the animal world, I find someone able and willing to do me a bad turn, and those who want to help me are few and far between—though there *are* angels in all alleys. About gardening, however, there must be some charm that raises its lovers, and the more they love it the better they grow. The cleverer the gardener the kinder is he (or she), the more patient with ignorance, the readier in generosity. Looking back upon my greenest infancy of horticulture I see people who must have thought me what I was, the being a dog fancier most utterly despises, an utter novice, taking real trouble to help a complete stranger only known to them by pen and ink. From several well-known gardens came beautiful

assortments of well-chosen plants that meant time and personal trouble to the giver. I had only to put my difficulties in print and they were solved. Even the general run of garden advertisers, even those among them who appeal to the greenhorn, do not carry such sharp shears for his fleece as do the too knowing that lie in wait for the live stock or collecting beginner. Three or four times I have been handsomely cheated, but what is this out of hundreds of successful and agreeable transactions? One gentleman's profitable idea of *Pæony* "roots" evolved itself in chopping up a single sausage-shaped tuber into inch lengths and calling each "one root." Another was unable to perceive the difference between "plants" and "cuttings" in the case of mule Pinks, while two or three were afflicted with a strange inability to count twelve. But, taking it altogether, after many years' experience, I never now hesitate to send money for anything I see advertised by private persons in the way of plants, for the chances are all in favour of the perfect genuineness of the description given, and the quantities sent are almost always good, and in some cases so liberal as to confer a positive obligation upon the recipient.

One has not far to seek for the ideal gardener; at this instant I could name many well known to all THE GARDEN readers. By what appellation to describe him is, however, the puzzle. A man—but just as frequently a woman—who combines all the skill and knowledge of the professional, with the ardour and enthusiasm of the amateur, though this latter word has been so abused by association with the utterly ignorant that it no longer conveys the pure meaning of "one who gardens for love of gardening." The connoisseur of the garden world is still waiting to be adequately christened. Meanwhile, this appreciation, imperfect as it is, is dedicated to all those kind and clever folk whose words and ways remind us that the first of all gardens was an Eden. Adam in his time of innocence would doubtless have been patient even with the seeker after advice, who writes twice a month—always at a busy time—to say that he has not done what was suggested in reply to his last, as he thought the opposite course preferable, but the event having proved unfavourable—"the frost has killed them all"—would Mr. Philanthos kindly advise him what to do next? M. L. W.

CHARLOCK IN CORN CROPS IN 1902.

THE Charlock season of 1902, though cold and wet at times, did not appear to be unfavourable to the growth of the plant, for later in the year unsprayed fields of its golden flowers were visible from almost all points between Inverness and the south of England. Several farmers have suggested to me that a good time to spray the Charlock is when it is just coming into flower, or actually in flower, because they have succeeded admirably in destroying it at that stage by using a large quantity of copper per acre. This suggestion is not on sound principles. It is now thoroughly proved that the Charlock can be destroyed at any period of its growth by copper sulphate, and that whilst the plant is young and in soft fibre a smaller quantity will effect the purpose than when the plant is older. This has an important bearing on the economical side of the question. Fifty gallons of 3 per cent. solution favourably applied to young

CRASSULA COTYLEDON AND AGAVES IN SIR THOMAS HANBURY'S GARDEN NEAR MENTONE.

plants will destroy 95 per cent. of the weed in an average infested crop; in fact, it will destroy all except those few plants that are shaded by other leaves from the spray, and this quantity and strength will affect the Corn crops so slightly that an increased yield of Corn more than sufficient to pay all the expenses of spraying may with confidence be looked for. On the other hand, if the weed is sprayed when much older, more copper is required, and this gives a shock to the Corn plant which prevents the likelihood of any material increase in the yield, besides which it must be remembered that the older the weed the more it has robbed the soil and shaded the sun from the Corn. For successful working the chief points to remember are to have everything in readiness well beforehand and the labourer trained so that it is only necessary to give the order to start when the weather is fine. The material must be pure and correctly measured and the spray fine so as to cover every plant. Successful spraying should result in average increase in yield of Corn from 4 bushels to 6 bushels per acre, and the destruction of 95 per cent. of Charlock, but when the weed is in dense mats, one plant overlapping another, a smaller proportion will be killed, but the increased yield of Corn will be greater. The increased yield of Corn by the destruction of Charlock leaves a profit, after all the expenses of spraying have been defrayed, and the annual value of all Charlock-infested land will increase until the extermination of the weed is complete.—G. F. STRAWSON.

IN A LAND OF SUNSHINE.

EITHER by accident or design harmonious combinations may be frequently seen, and often the least studied detail is the most effective. The illustration here given is of a delightful little nook in the gardens of Sir Thomas Hanbury at La Mortola, the major portion being occupied by the old South African *Crassula Cotyledon*, known also as *Crassula arborescens*, which is thriving and flowering in a way unknown to us in this country, while equally at home and harmonising perfectly with it, are the new world representatives in the shape of several different Agaves. Such plants

as these, which are here usually confined in pots, are, when seen growing so luxuriantly out of doors, apt to arouse a feeling of dissatisfaction with one's attempt at their culture under glass.

THE ROSE GARDEN.

PEGGING DOWN ROSES.

MANY of our best garden Roses are materially improved by being pegged down, thereby blooming longer than those not so treated. The old-fashioned plan of pegging down the current season's shoots, simply cutting of the tops and the old growth, is done with advantage in many places. I saw several good examples of this work last season, and now the growth for pegging down is vigorous and bold. C.

NEW CONTINENTAL ROSES.

MR. PETER LAMBERT, of Trier (Germany), whose success as a raiser of new Roses has been considerable, intends distributing this year several pedigree seedlings. These he regards as very fine novelties. Two of these—Hybrid Teas—will be distributed this spring. Their names and the raiser's description may be of interest:—

Frau Lilla Rautenstrauß.—Buds long and erect, held up singly on long stems, colour coppery yellow; expanded flowers reddish yellow in the centre, tinted deeper on the outer petals, which are edged with creamy white, very sweetly scented; petals broad, round, and slightly reflexed. The plant is hardy, of bushy growth and branching habit, with thick, glossy leaves. (Caroline Testout × Goldquelle).

Gustav Grünerwald. Long-pointed, solitary buds of a yellowish red colour, held up on long stems; flowers well built, full, high-centred, and cup-shaped; colour bright carmine with yellowish centre, outer petals of a lighter shade; growth erect and sturdy; wood smooth, almost thornless; leaves of a dark glossy green. A first-rate Rose for exhibition or cutting. (Grossherzogin Victoria Melita × Janne Bicolor). A. R. G.

THE GARDEN

No. 1627.—VOL. LXIII.]

[JANUARY 24, 1903

NEW TREES AND SHRUBS OF 1902.

EXCLUSIVE of the one Tree Pæony and the Roses that have been dealt with previously in *THE GARDEN*, the hardy trees and shrubs to which either first-class certificates or awards of merit have been given by the floral committee of the Royal Horticultural Society during the year 1902 are eight in number, two only gaining the certificate. In 1894 the trees and shrubs thus recognised numbered thirty. Taking those of 1902 in alphabetical order they are as follows:—

Rhododendron (Azalea) rustica flore-plena Ramona.—The double-flowered forms of Ghent Rhododendrons (Azaleas) to which the term rustica has been applied have received many additions during recent years, one of the latest being Ramona, which at the Temple show received an award of merit. The well shaped flowers are of a creamy white tint, suffused with pink. It is a beautiful shrub and shown by those well-known growers Messrs. R. and G. Cuthbert, Southgate.

Buddleia variabilis veitchiana.—The typical *Buddleia variabilis* is a very beautiful member of an interesting genus. It is at present far from common, and is in Messrs. Veitch's catalogue included in the list of choice and new deciduous shrubs. As indicated by the specific name this *Buddleia* is decidedly variable, some forms being far more vigorous than others, while the flowers vary from pink to pale lilac, but always with an orange throat. An excellent coloured plate is given in *THE GARDEN* of June 17, 1899. The shrub itself is 5 feet to 8 feet high, clothed with lanceolate leaves, dark green above, and on the undersides with white felt-like substance. During winter the branches often die back, but young shoots are produced freely from the old wood, and they grow and flower the same season. The individual flowers are small, but borne in large terminal branching panicles, and a succession is kept up from July to autumn. This species is a native of Western China, and seeds of it were first sent to Europe by M. l'Abbe Soulié in 1893. Some of the plants raised therefrom flowered in the following year. The variety *veitchiana*, to which a first-class certificate was awarded on August 19, represents a very fine form, with rich lilac-coloured blossoms, which will doubtless be distributed in due course. Shown by Messrs. J. Veitch and Sons.

Ceanothus Indigo.—Many of the *Ceanothus* are remarkable for their beautiful blue flowers. Apart from the original species there are many garden forms, nearly all of which have been raised on the continent. The variety *Indigo* which received an award of merit on September 2 is, we think, the finest coloured form that has been shown, the clusters of blossoms being of

a rich indigo blue. It was raised in the extensive and well-known nurseries of MM. Barbier frères at Orleans, whose predecessor M. Transon achieved a world-wide reputation for select hardy shrubs. It was shown by Mrs. Burns (gardener, Mr. Fielder), North Myms Park.

Dimorphanthus mandshuricus argenteo-marginatus.—The typical form of this *Dimorphanthus* has been long known in this country as a large shrub or small tree, plentifully furnished with sharp prickles, while the large wide-spreading compound leaves are remarkable. Towards the end of the summer or in early autumn appear the small creamy white blossoms which are borne in large branching terminal panicles. If cut almost to the ground each winter, and a single shoot only allowed to develop in the spring, it looks quite subtropical, and is in this way quite as effective as *Ailantus glandulosa* and *Paulownia imperialis*, which are often grown in this way. The variety *argenteo-marginatus*, which received an award of merit on April 22, is a counterpart of the type, except that the leaflets are clearly margined with white. It was noticeable at several of the exhibitions last year, and will doubtless soon become generally distributed. The award of merit was given to Mr. Russell, The Nurseries, Richmond.

Fagus sylvatica Paul's gold-margined Beech.—This should prove an admirable contrast to the Copper Beech, as the leaves are of a bright green tint, broadly margined with yellow. Judging by the specimens exhibited on June 10, when an award of merit was given to it, this Beech does not look as if it would scorch by full exposure to the sun, which is the bane of many variegated leaved trees and shrubs. In August, however, one might form a better idea of its sun-resisting powers than in June. From Messrs. Paul and Son, Old Nurseries, Cheshunt.

Libocedrus macrolepis.—Decidedly the most interesting tree or shrub of the year, though whether it will prove suitable for our climate is at present open to conjecture. The opinion of Dr. Augustine Henry is that it is doubtful if it will prove hardy except in warm corners of south-west Ireland and in Cornwall. This *Libocedrus* was figured in *THE GARDEN*, page 183, last volume, and accompanying it was a most interesting and exhaustive article from Dr. Henry. He says: "There are now known eight species of *Libocedrus*, the geographical distribution of which is remarkable, showing that in early geological times the genus was widely spread; indeed, a fossil species has been found in the Isle of Sheppey. Two species now occur in Chili and Patagonia, two species inhabit New Zealand, one species is peculiar to New Guinea, and another to New Caledonia; one species occurs in Oregon and California, and another in China." This last named is *Libocedrus macrolepis*, for which Messrs. Veitch were awarded a first-class certificate on August 5. Concerning the origin of their plants, Dr. Henry says: "*Libocedrus*

macrolepis, Bentham, has recently been introduced into cultivation in England by Messrs. James Veitch and Sons, from seeds collected at Szemao, in Yunnan, by Mr. E. H. Wilson, when he was paying me a visit at that station in the autumn of 1899." In its native country it is said to attain the height of 100 feet, but as it is likely to require protection here we shall probably not often see it beyond the juvenile stage.

Rhododendron Lady Clementine Walsh.—A very pretty hybrid *Rhododendron* with fine well-shaped flowers borne in large trusses, and of a delightful shade of pink, marked with white. Award of merit June 24. From Messrs. John Waterer and Sons, Bagshot.

Thuja ellwangeriana pygmæa aurea.—A very pretty dwarf conifer of a golden hue, which thirty or forty years ago would have aroused a good deal of enthusiasm, but nowadays conifers do not occupy the position they once did in popular favour. *Thuja ellwangeriana* has been long known as a dwarf or undeveloped form of the American *Arbor-Vitæ* (*Thuja occidentalis*). The variety *pygmæa aurea*, to which an award of merit was given on September 2, forms a dense pyramidal bush of a pleasing rich yellow tint, suggesting at a little distance a golden *Retinospora*. Shown by Mr. Charles Turner, Royal Nurseries, Slough.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

January 27.—Royal Horticultural Society's Meeting.

February 3.—National Amateur Gardeners' Association Meeting.

February 7.—Société Française d'Horticulture de Londres Meeting.

February 10.—Royal Horticultural Society's Meeting.

February 11.—East Anglian Horticultural Club Meeting.

February 13.—Royal Gardeners' Orphan Fund Annual General Meeting, Cannon Street Hotel.

Royal Horticultural Society.—The next fruit and flower show of the above society will be held on Tuesday next in the Drill Hall, Buckingham Gate, Westminster, 1 to 4 p.m. A lecture on "The Cultivation of the Blue Nymphaea," will be given by Mr. James Hudson, V.M.H., at three o'clock. At a general meeting held on Tuesday, the 13th inst., ninety new Fellows were elected, amongst them being the Countess of Dudley, Lady Clayton East, Lady Brooke, Lieutenant-Colonel H. W. Apperley, and the Hon. Mrs. Bourke.

National Dahlia Society.—The schedule of prizes to be offered at the next annual exhibition of this society, to be held at the Drill Hall, Buckingham Gate, Westminster, on September 1 and 2, will include a new departure of considerable interest to exhibitors. As the result of a general subscription amongst members, three silver challenge cups will be offered for competition, namely, a ten guinea cup in the premier Cactus

Dahlia class for nurserymen (eighteen varieties, in bunches of six blooms each), a ten guinea cup in the premier Cactus Dahlia class for amateurs (nine varieties, in bunches of three blooms each), and a five guinea cup, in the premier class for show and fancy Dahlias, for amateurs (twenty-four blooms distinct). In addition to the above, Messrs. Dobbie and Co., Rothesay, will present a gold badge, value three guineas, for twenty-four blooms Cactus Dahlias, distinct varieties, for amateurs, the gift to be repeated at the two following exhibitions of the society in 1904 and 1905. The prize money in this class (class 24, which is altered from eighteen blooms to twenty-four) and in that for nine varieties, in bunches of three blooms, has been increased, and three new vase classes have been added. The annual report and schedule for 1903 will be issued to members in the course of the next few days.

Pea Edwin Beckett.—Seeing the illustration of this Pea on page 29 of THE GARDEN, I should like to add what a splendid variety it is. I had one row last season quite 30 yards long, grown on the exhibition system, and it was a grand sight to anyone interested in the cultivation of exhibition Peas. This variety is very free, of good colour, and excellent flavour. When exhibited without being touched by the hands, but cut off with scissors and placed in shallow boxes on Parsley, it cannot fail to attract the judge's attention. I exhibited it in the single class at Sandy last August, and in a keen competition, where many large varieties were shown, its fresh appearance and fine flavour easily placed it first.—J. BARSON, *Hinchbrook*.

Coleus thyrsoides at Feltham.—This beautiful winter-flowering plant is now flowering well at Messrs. Veitch and Sons' Feltham nursery. No doubt it will be seen again at the Drill Hall, but nowhere in London, even in the most favourable light the Metropolis can provide, will the long spikes of flowers show that beautiful blue tint which is seen in the clear light at Feltham. The plants are from 30 inches to 36 inches in height, each one finely leaved and carrying several spikes 7 inches to 8 inches long, the colour of which runs that of *Salvia patens* very hard. It certainly is for the time of year and for the conservatory the most beautiful blue-flowered plant we have. Plants can be propagated by cuttings or from seed, and seem to be just as easy to grow as are those of any *Coleus*. Happily the leafage is of a good green self. May it be spared from any crossing with the summer-foliaged section.—A. D.

It is obvious that Messrs. Veitch have speedily acquired a knowledge of the way to grow this fine plant. The splendid group at the Drill Hall on Tuesday, the 13th inst., both in numbers and development, made this clear to all. Of course it is a *Coleus*, and such things are not infrequently described as weedy, but *C. thyrsoides* is different. Doubtless the plants have been liberally grown during the season to attain such fine proportions. They were 4 feet high, and many would have been nearly as much through had the shoots been tied out to sticks. But if liberally grown, the plants, judging by their firm leaves, had been given also a season of warm dryness such as may be theirs possibly in a natural state. What Messrs. Veitch, with so much expert knowledge at command, have so promptly discovered, may now be followed by all good gardeners who care to grow to perfection the finest of all blue winter-flowering plants, as undoubtedly this *Coleus* is.—E. J., *Hampton Hill*.

Chrysanthemum Mlle. Therese Panckoucke.—This late-flowering Chrysanthemum was at one time highly esteemed for its large size and usefulness for late exhibitions. In some of the older catalogues, a year or two subsequent to its introduction from the Continent, it was "compared to a white Etoile de Lyon." Since that period, however, its real value has been fully appreciated. Like many Continental and other Chrysanthemums it was, for show purposes, lost sight of after a year or two, but during the interval a certain market grower ascertained its undoubted value for late market work and made the most of

his knowledge. At length its original name was discovered, with the result that stock was freely distributed, till at length many growers were sending in handsome bunches to market. The flowers are of a useful size, with long fairly broad florets, and of the purest white. A few days ago I saw a large house full of this one variety. The plants were between 5 feet and 6 feet high, and the flowers were from terminal buds. For cutting at Christmas and during succeeding weeks it is specially suited, good prices being obtained for the blooms.—D. B. CRANE.

Moschosma riparium.—Some charming examples of this comparatively new winter-flowering Labiate in Messrs. Veitch's nursery at Chelsea show well what a desirable plant it is for the greenhouse at this season, for it is quite unlike any of our old favourites that are usually grown for winter blooming. Out of flower the general aspect of the plant suggests a *Salvia*, with leaves about 2 inches long, deeply toothed at the margins. The individual flowers are small, but in large, erect, much-branched panicles, so that they make a good show. In colour they are white, with purplish anthers. It can be

propagated and grown as easily as a *Salvia*, so that we shall doubtless meet with it before long in most gardens where winter-flowering plants are in demand. It was, I believe, first introduced into the Royal Gardens, Kew, where *Coleus thyrsoides* also unfolded its charming blue flowers for

COREOPSIS TENUIFOLIA.

the first time, while to add to the coincidence both plants are natives of Africa, the *Moschosma* from the southern portion of the continent and the *Coleus* from the more central part. Both, too, belong to the order Labiate.—H. P.

Coreopsis tenuifolia.—The perennial *Coreopsis* are among the brightest of summer and autumn garden flowers. After the annuals are over they are still showy, bearing blooms until autumn. *C. tenuifolia*, of which we give an illustration, is one of the prettiest; it has very elegant foliage, and bears a profusion of golden-yellow flowers during late summer and early autumn.—T.

The Penzance Briars on Manetti stock.—An obliging Reigate correspondent, to whom I have previously been indebted on the subject of Roses, has written me regarding my note on the above. From his note I gather that Messrs. Keynes and Co. sent these out on the Manetti, and that plants my correspondent purchased from them in 1894 have flourished, including Lady Penzance. He thinks that the Manetti roots will by this time have perished, and that these Briars are now upon their own roots. On

the other hand, a friend to whom he gave a Lady Penzance in 1894, which has done well, has since purchased others from the best houses, but perhaps on the Briar, which have not flourished. It is not at all unlikely, as I have suspected, that the stock on which they are budded has a great deal to do with the matter. It is surely desirable that the subject should be cleared up in the horticultural press, so that those who have to purchase the Penzance Briars may be able to secure plants which will succeed.—S. ARNOTT.

Tomato Holmes' Supreme.—All who have grown this very fine Tomato must agree that the three marks awarded by the Royal Horticultural Society were never better bestowed, for after trial with the best varieties in cultivation last season it came out of the test with flying colours, and must indeed become a prime favourite either for market or private growers. For pot culture it is admirable, the growth being very stout, whilst the heavy short-jointed bunches of fruit—as many as eight or nine to the bunch—are as freely produced as anyone could wish. Not over large, they are just the right size, and of so perfect a shape as to find a ready sale.—A. B.

Obituary.—We much regret to learn that Christina, youngest daughter of Mr. John Forbes, Hawick, died on the 19th inst., in her twenty-first year. The funeral took place at Wilton Cemetery on Thursday, the 22nd inst. The many friends of Mr. Forbes will sympathise with him in his trouble.

An agricultural post wanted.—Mr. Rider Haggard, in his recently published book about "Rural England," strongly advocates "an agricultural post, to be worked as a branch of the present Post Office, and as nearly as proves practicable upon the lines of the existing Parcels Post." He recommends this and road traction as a means of competing with railway rates which entirely stifle all the small farmers' chances of success. Mr. Rider Haggard, in support of his plea, gives a practical illustration of the present difficulties: "The other day in my own garden I saw some hundreds of particularly fine Cos Lettuces which were beginning to go to seed. I told the gardener that he had better sell them, to which he replied that there was no local market, and that they would not pay to send away by train. If an agricultural post had existed those Lettuces might have been delivered on the following day in London, Lowestoft, or Yarmouth, where they would have fetched a good price. As it was, they rotted and were thrown to the pigs."

Late yellow Chrysanthemums.—Seeing that Mr. E. Harriss so greatly esteems Golden Gem as a late yellow sort (page 18), it would be interesting to know why he so regards this variety. Golden Gem bears quite small flowers at best, and with me was so extremely varied and inconstant that some years ago I discarded it altogether, after having grown it by the hundred for some years. Has Mr. Harriss tried Golden Dart or H. W. Rieman among the late yellows? I do not mention the first as a January bloomer, that is, not late in that month, though I believe Mr. G. Wythes at Syon, and Mr. Burrell of Claremont have both flowered it quite well in January. In any case, it is much better than Golden Gem, and beautiful when grown for home use. In respect to the other one named, I have some blooms now expanding that at the present rate of progress will take a fortnight to open fully, while in respect to colour it is among the finest of all yellows. This, like Golden Dart, is a naturally late yellow, a fact that should be kept in mind so as to avoid too late stopping. Where late stopping goes hand in hand with a rather late season there will most certainly be a larger proportion of flowerless shoots than one cares at all times to admit. The flowers of both the varieties named keep well, have long stems, and should, like all decorative sorts grown for their lateness, be on terminal buds. The stems of H. W. Rieman will be 2 feet 6 inches long, longer than the entire plant of Golden Gem so late struck as June. As the foliage is quite good, such blooms will be of value in tall vases especially.—E. JENKINS, *Hampton Hill*.

The "Orchid Review."—The January number of the *Orchid Review* commences the eleventh volume of this publication. Mr. Charles C. Hurst in a leading article makes the following remarks, with which we agree: "The single numbers as they arrive each month in their familiar covers are apparently a simple monthly review of Orchid lore, giving us the current news of the Orchid world, and all the new and up-to-date information that we require, both cultural and scientific. But when the December index number arrives, and we bind up the twelve single numbers into one volume, we begin to realise that the work is a permanent one of great value, with its accurate records of facts and critical observations, based upon patent and original research. Now that the single volume has grown into ten, the realisation of the permanent value of the work has also increased tenfold."

Kidderminster and District Horticultural Society.—The next lecture of this society will be given on February 12 by Mr. E. H. Maskey, head gardener to Peter Adam, Esq., Cairndhu, on "The Culture of Annuals." Arrangements for 1903: March 12, Mr. D. R. Dixon, "The Culture of Onions and Leeks"; April —, Excursion to Midland Daffodil Show; May 14, Mr. W. Allison, "Pansies and Violas"; June 13, Excursion to Arley Castle and Arboretum (by kind permission of R. Woodward, Esq.); July 18, Conference and show at The Elms, Blakebrook (by kind permission of Col. Goodwin); July —, Excursion to the Midland Carnation Society show at Birmingham; August 15, Excursion to Madresfield Court Gardens (by kind permission of Earl Beauchamp); September 10, Show, Mr. A. R. Goodwin, F.R.H.S., "Hints on Growing Tea Roses"; October 8, Show, Mr. H. Bulmer, "A Chat about Celery Growing"; November 12, Mr. J. Duncan Pearson, "Dutch Bulb Farms, and a Peep at some English Ones" (illustrated with lantern slides); December 10, Rev. G. F. Eyre, F.R.H.S., "My Vicarage Garden." N.B.—The meetings at the Masonic Hall will commence at 8 p.m.

Scottish Horticultural Association.—The annual statement of this flourishing society just to hand shows a membership of 1,160 and funds amounting to £978 12s. 3d. Financially the results of the Chrysanthemum show were even more satisfactory than anticipated, for though the expenditure amounted to the big total of £1,039 2s. 5d., the receipts were £1,130 10s. 11d. But the association exists primarily for the mutual improvement of its members in horticultural matters, monthly meetings being held at Edinburgh throughout the year, when papers are read and discussed and interesting plants and flowers exhibited. The syllabus of these meetings for the current year is a very strong one, the names of Messrs. F. W. Burbidge, M.A., Dublin; R. Dean, Ealing; R. Mair, the Scotch Gladiolus expert, Prestwick; Gibson, Danesfield Manor, Bucks; and Webster, Gordon Castle, being of the number. Mr. Peter Loney, 6, Coulton Street, Edinburgh, is the secretary, and the annual subscription is only half-a-crown.

American blight.—I was rather astonished the other day to find colonies of American blight established on the branches of Apple trees hitherto unaffected by that dread parasite. It is the more unaccountable as so far as could be discovered other affected trees, hitherto clean, had been treated during early autumn. It is most unsatisfactory that in so many cases bought in young trees develop American blight, but as the pest had been hardly seen on any of our trees for several years, it is all the more strange that it should have become all at once so prevalent this winter. Whether the affection is general or not I cannot say, but gardeners would be wise to look for the insect when tending their Apple trees for the season. While the leaves are on the trees I have always found washing with an emulsion of soapsuds and petroleum an efficient remedy; petroleum is both penetrating and deadly, and the woolly envelopment under which the insect exists is not easily penetrated by any ordinary insecticide. If colonies are noticed during summer they should

at once be destroyed before eggs are hatched, and probably the present visitation is largely due to a successful egg season on the part of the insect. Treatment at present will consist in syringing with an extra strong petroleum emulsion, thereafter cutting away portions of the bark underneath which the insect has effected a lodgment. Hot oil applied with a brush might be equally good in its results, but whatever the means taken they must be of a nature to reach the insect.—B.

"Kew Hand List of Trees and Shrubs."—A second edition of this invaluable work of reference has been published, the first edition of this list of trees and shrubs grown in the Kew Arboretum having been exhausted. It is now republished in one volume, after having been carefully revised and enlarged by the addition of the names of numerous species which have been added to the collection since the first edition was prepared. The number of hardy trees and shrubs now enumerated amounts to about 4,500.

Chrysanthemum Mme. Louise Leroy.—This variety has generally been regarded as a semi-early flowering one, but during the past season the plants have flowered much later than usual. Though the terminal buds were thinned out in the middle of September the flowers were not fully expanded until Christmas week. The plants were purposely kept in a cold house, and during the moist weather and an occasional spell of frost hot water was turned into the pipes. Not the slightest trace of damping is to be seen.—D. B. CRANE.

Early Tomatoes.—No Tomatoes are more appreciated than those of the first gathering, and no effort should be spared to obtain them as early in the year as possible. To have ripe fruits in March the plants which were raised last autumn should now be ready to be potted into the fruiting pots. But on no account should they be potted till well rooted and the first flowers can be seen. Nothing is gained by doing so; on the contrary, the plants will be encouraged to make a lot of useless growth before commencing to flower, which will considerably postpone the fruiting season, and potting space should be left for a top-dressing of some rich soil, when a good set of fruit is ensured. If possible the pots should be plunged in a bed of leaves of moderate warmth. This will greatly facilitate root action, which would otherwise be slow at this time of the year. Fertilising the flowers is a matter which should receive close attention. A simple and sure method is to secure a well-developed flower, shake the pollen on the finger (this can easily be done with the point of a budding knife), then fertilise each flower individually. A night temperature of 60° will suit the plants, and plenty of air should be admitted on all favourable occasions until a good set of fruit is secured; then the temperature may be increased. Frogmore Selected and Winter Beauty are two varieties which may be relied upon.—E. HARRISS.

Botanic Garden, Calcutta.—In the annual report for the year 1901-2 we read:—A severe storm visited the garden on November 26, 1901, and did much damage by uprooting a number of valuable trees and greatly disfiguring many that were not completely destroyed. With this exception the weather during the year was of a normal character and not unfavourable to vegetation. The investigation of the dye-yielding *Indigoferas*, noticed in the last annual report, has advanced considerably during the past year. The opportunity afforded by a visit to Europe was utilised in a careful comparison of examples of the *Indigoferas* cultivated in South-Eastern Asia with the authentic material preserved in the Herbaria of London and Geneva. The results have been in some cases unexpected. The belief that at the time of the early intercourse of Europe with India, there were two centres of Indigo export, if not of cultivation, has been confirmed. One of these centres was Surat, where the Indigo grown was a form of the Egyptian Indigo, *Indigofera articulata*, which still persists in various parts of India, notably, in Scinde and Rajputana, where even now this plant alone receives the name "Nil" applied in Tirhut and Bengal to quite a different species.

The other centre was Ceylon and the Coromandel Coast, where the Indigo was obtained from Indian Indigo, *Indigofera tinctoria*, the produce of which was even in these early times held in less esteem than Surat Indigo. It was recorded in the last annual report that during the excessive floods of September, 1900, this East African Indigo came by no harm when all the Indian and American kinds were practically destroyed. It has now to be recorded that in 1901 the experimental plots were attacked by an insect blight which destroyed all save a few plants of every Asiatic and American *Indigofera* under cultivation without affecting in the least this East African species. Among other economic operations for the year it may be noted that the efforts to extend the cultivation of *Paspalum dilatatum* have been continued, and that the difficulties regarding its cultivation in Bengal have been successfully overcome. These difficulties have not yet been surmounted in other provinces, and the reports that have been received from correspondents are somewhat conflicting. In Southern India it is found that the drought-resisting qualities claimed for this grass in Australia have not been over-estimated, but in Western and Northern India it is stated that though an excellent fodder grass where irrigation is available, it is as a drought-resisting species distinctly inferior to some well-known native grasses. The number of named specimens distributed from the Herbarium to other botanical establishments has been 8,500. The number of specimens received has been 8,749, the chief contributors being the director, Royal Gardens, Kew, 1,051 specimens; and the director, Royal Gardens, Berlin, 1,134 specimens. The number of plants distributed during the year was 35,134, slightly below the usual figure, the demand for Rhea having been very small. The number of plants received was 8,521; these include some very interesting contributions, the most notable of which are a small collection of authentically named *Sansevierias* (Bow String Hemp plants) from the director, Royal Gardens, Kew; 389 bulbous and tuberous plants from Uganda, presented by F. J. Spooner, Esq.; 305 Orchids of remarkable interest, presented by Rev. L. Cardon, S.J., Chota Nagpur; collections of a very interesting nature from Madagascar, presented by M. Em. Prud'homme and from Dar-es-Salaam, presented by Herr Stuhlmann. During the year 1,206 packets of seeds were received and 4,083 packets distributed.

Broccoli Superb Early White.—In December and January good Cauliflowers and Broccoli are very scarce in most parts of the kingdom, and any variety that is reliable is a great boon in private gardens where small heads of good white Cauliflower or Broccoli are in demand. For the past few seasons I have grown Sutton's Superb White largely for the supply at this season. During December and the early part of January it was very good indeed, and the heads, though not large, were much appreciated. This variety much resembles the old Snow's Winter White, but with me the Early White is much preferable to Snow's, as the plants are more reliable, hardier, and the heads are well protected by the foliage. I am aware, no matter what the variety is, that the Broccoli is not frost-proof, but if the Superb Winter White is planted sufficiently early in summer and when the heads are formed the plants are lifted and given protection at the approach of frost, a supply may be maintained for some time. This variety is one of the best to remain firm and good when housed after removal from its growing quarters. I have kept plants in frames from January to March, a period of the year when the supply is most irregular.—G. WYTHES.

Hibbertia dentata.—With two or three exceptions all the *Hibbertias* are natives of Australia, and though the genus is an extensive one, only about half-a-dozen species are in general cultivation. In habit they vary from a vigorous climber, as in *H. volubilis*, to the dense twiggy bush of *H. Readii*. The best of the entire genus for the garden is *H. dentata*, which has been more than once referred to in THE GARDEN, but it is such a delightful greenhouse climber throughout winter that its merits in this respect must be my excuse for again alluding to it. *Hibbertia dentata*

is excellent for clothing the rafter of a greenhouse, as it is a slender climber of moderate growth, while the oblong-shaped leaves are very handsome, being deep green in the adult stage, but when young are tinged with bronzy red. The flowers, which in general appearance suggest an affinity to a *Hypericum*, are from 1½ inches to 2 inches across, and bright yellow. In *H. volubilis* they have a most unpleasant odour, but this is quite wanting in *H. dentata*. This last strikes readily from cuttings of the young growing shoots put in sandy soil and kept in a close propagating case. They grow quickly when rooted, in proof of which mention may be made of some cuttings I put in at midsummer, which were potted off when well rooted and are now thriving plants from 15 inches to 2 feet long. The fact that this *Hibbertia* will often flower from December to May is also in its flavour.—H. P.

Senecio macroglossus.—The genus *Senecio* with its 800 or 900 species contains some forms remarkable for the way in which they mimic plants they are not in the least related to. That referred to by this note, *S. macroglossus*, is a puzzle to many, and though introduced from South Africa a little over twenty-five years ago it is little known in this country at least. It is a free-growing climber, just the thing for the roof of a warm greenhouse, and the evergreen leaves exactly mimic those of the Ivy, hence it is sometimes called German Ivy; why German I cannot say. Its handsome foliage is by no means the only claim to recognition, for the flowers are borne more or less throughout the greater part of the year, but are perhaps most appreciated during winter. The flowers are from 2½ inches to 3 inches in diameter, and composed of eight to ten ray florets of a pale yellow tint, the disc itself being more of a greenish tinge. Its rapid growth is greatly in its favour as a pretty summer climber out of doors; cuttings strike root readily, and the young plants make rapid progress. In South Africa it is said to clothe the trunks of lofty trees far more rapidly than our native Ivy does at home.—T.

THE FLOWER GARDEN.

BEAUTIFUL GARDEN LAWNS.

AT this season, when we are beginning to think of the lawn and turf generally, the following notes may be useful. The lawn has been well described as the heart of the garden, but it is frequently so carelessly made that the results are disappointing, and sometimes remaking is necessary.

From want of knowledge or care, and occasionally local or other reasons, many people, thinking that any rough preparation will secure them a good sward, merely trench and turf the ground; others think that turf will come of itself; but such people are often rudely disappointed, and therefore some instructions as to the best way of laying down turf, where the work has to be done from the beginning, and also for repairing it when out of order, may be useful to some readers.

FORMATION OF GOOD TURF.

Should the spot chosen be on heavy soil, such as clay, take the levels and fix them 16 feet apart around the outside of the piece intended for a lawn. Take some levels across the piece, then take 12 inches of the clay out below the levels. Should any of these 12 inches contain good soil, wheel that to the outside of the piece, removing all the clay to a place near and burning it into ballast. This can be done by using slack coal. Find the natural fall of the ground and place pegs 16 feet apart in lines from top to bottom the way it falls, then dig out the soil in the line of pegs with a draining tool, 12 inches deep at top end, bottom end 18 inches deep. This will give a fall of 6 inches. Then lay in 2-inch drain pipes, with at the bottom end a 3-inch pipe for a main to take the water that drains from the subsoil. See that this main is

taken to some outlet. Cover the pipes with 3 inches of burnt ballast, and spread 3 inches of burnt ballast all over the piece of ground. Dig the ground over 12 inches deep, at the same time mixing the 3 inches of burnt ballast with the clay, taking care not to disturb the pipes or dig below them. After treading all over firmly, place on the surface 2 inches of burnt ballast, filling to the level with loam mixed with the good soil you have laid on one side from the surface. If you have no good soil, fill up with loam mixed with coarse gravel, brick rubbish, and burnt ballast. Tread all over again as before, making it level with a spade, pressing in any lump or stone that appears level with the ground. No rake should be used. You have now 2 feet of trenched earth. Do not dig down deeper in one place than another. A stick cut 2 feet long by the worker's side is the best. He can, with the stick, test his depth from time to time. In laying the turf keep the joints of each piece half an inch apart. When it is all laid down, pat it gently all over with a turf beater. It is better to take up the turf that is a little higher than the rest and take out a little of the soil than to beat it down to the level. Then spread some burnt ballast, ashes from the burnt refuse of the garden, and the top 2 inches of soil from a wood, sifted through a half-inch mesh sieve and mixed well together, all over the grass. Move it about until all the joints in the grass are level. Wait for rain, then go over the lawn and take out all weeds. Give another dressing of the soil as before, adding to this a little road grit and old mortar. If no old mortar is available, slaked lime will answer. Move this about until all is level again. In the month of March or the first week in April, if the weather is fine, sow all over the lawn some of the best grass seed. Get some fine Thorn bushes, lace them together in the shape of a fan heavy enough for two men to drag about the lawn in various ways. Roll with a light roller. Keep off the lawn until the grass has grown 3 inches, then cut it with a scythe, and roll with a light roller the first season. When mowing with the machine is commenced see that the knives are not set too close to the ground.

Should the spot selected for a lawn not contain clay so much the better. Dig holes here and there 2 feet deep in the winter months. If no water appears at the bottom of the holes, this shows it will not want draining; if there is water, drain as on heavy soil. In trenching the ground, if the subsoil be bad, take 3 inches of this away, filling up to the level with good soil to which have been added half-inch crushed bones in the proportion of four tons to the acre, fine brick rubbish and ballast in the same proportions as for the heavy soil. Turf and treat as on heavy soil. If you have a good grass field, take the turf for your lawn, remove the top spit, replace with rough soil, and place 3 inches of the loam that has been dug out upon the rough soil you have put in, then sow, bush harrow, and lightly roll.

TREATMENT OF OLD LAWNS.

Weeds, Moss, and bare places on lawns show that they are worn out. To renew these take off the turf in rolls 3 feet long, 1 foot wide, and 1 inch thick. If the turf cannot be rolled, take 6 inches of the surface away, then trench 2 feet deep, keeping the good soil on the top as you proceed. Tread firmly all over, and fill up to the level with good soil; mix with the loam, burnt ballast, old brick rubbish, half-inch crushed bones, and road sidings or sweepings. Then turf and treat as in the case of new lawns. On old lawns there are very often handsome deciduous trees too close to which it would be dangerous to trench. To get grass to grow under these, take away 2 inches of the exhausted soil, replace with good, and sow thereon grass seed thickly. Rake the seed in gently, roll it lightly, and water when necessary. This may be repeated in the same way as often as the soil under the trees becomes bare. In some cases where turf is scarce, a roll of turf 3 feet long and 1 foot wide may be taken and cut in half lengthways. With this form the outlines of the bed which have been staked out previously, beat down to the level required, and bring up the inter-

vening spaces to the level of the turf with good soil. Make this firm, rake it level, and on this sow some good grass seed. Rake it over, roll lightly, and protect from birds where these are troublesome. Cut the grass when 6 inches high with a scythe and keep it well watered during the summer if the weather is dry. In this way a beautiful lawn may be had at little expense as compared with turfing it completely over.

LAWNS ON PEATY AND SANDY SOILS.

In some parts of Hampshire where peat and sand abound seeds are by far the best to use to form a good turf. Remove all peat from the site you want for a lawn, pile it on the outside of the work and cast plenty of water upon it. Then take out 2 inches or 3 inches of the dark sand that is under the peat, cast this also over the pile of peat. Take out 12 inches of the sand, dig all over 12 inches deep and tread it firmly. Get all the road scrapings and road trimmings you can with a little clay and stiff loam and cast upon the peat pile. Having got together the quantity you think will fill up to your level, then cut up small the peat you have in the pile and mix all well together, fill up to the level, tread firmly all over, then give a good coating of cow manure, turn this 3 inches under the surface, and tread firmly again. In the month of March sow thickly. Do not let the surface get dry the first summer, and cut the grass when 6 inches high with a scythe.

Attention should be paid to keeping all lawns free from weeds. Dress lawns once a year with one bushel of salt mixed with fourteen bushels of wood ashes not too much burnt. When you see the wood is consumed, spread the ashes abroad and cover with good soil. Break the charcoal small, mix all well together, do not sift, spread upon the lawn, and roll it in.

HEMEROCALLIS OR DAY LILIES.

(Continued from page 38.)

HEMEROCALLIS × *LUTEOLA* (*aurantiaca* major × *Thunbergi* and *vice versa*) embraces a very graceful lot of hybrids, with broad leaves midway between the two parents. The growth is tufted, 2 feet high and 2 feet through. The spikes are much branched, erect in growth, 4 feet in height, and bear on an average five to eight flowers on the summit of each branch. They are coloured a pure golden-yellow, and average 7 inches in length and 6 inches in width. The flowers have the elegant bearing of *H. flava*, but are much longer in the tube and altogether larger. The type of inflorescence varies somewhat, some leaning to *H. aurantiaca* major, others most resemble *H. Thunbergi* in the tall imposing stems and pale-coloured flowers. It was raised by Messrs. Wallace, of Colchester, and sent out in 1900, and simultaneously by a continental firm, who raised identical plants from the same parents. It is a splendid border plant, producing several spikes from one tuft, the long-tubed flowers of much substance, though not so large as *aurantiaca* major, mark a distinct advance on any others in purity of tint and elegant shape. It flowers in June, July, and sometimes in August.

H. Middendorfi makes a compact and dense tuft of narrow leafage 18 inches high, and produces quantities of spikes bearing deep orange flowers flushed on the outside with reddish brown, agreeing with those of *H. Thunbergi* in size, but arranged in a very close umbel of five each, and poised just above the mass of foliage. It is a good garden plant of neat habit and moderate growth, free flowering, but inferior to the hybrid *Anreole*. The flushing of colour on the outside of the flower varies in different seasons, being mainly dependent upon strong sunshine for proper and full development. It flowers in June and July.

H. Dumortieri (*rutilans* = *Sieboldi*) is a plant of still smaller growth, making graceful little tufts 1 foot high, and producing soft yellow-coloured flowers on spikes 1 foot to 1½ feet high in umbels of four and five. They average 2½ inches in length and width, and are heavily flushed with reddish brown on the outside of the outer segments, and they do not open to the fullest possible extent.

CAMPANULA FRAGILIS AT HOME.

(The plant is growing in a wall at Ravello, Italy, its native country. Each flower is over an inch across.)

and bear umbels of cupreous red flowers 4 inches across and of greater length, the petals of which are rather thin but very shapely, and the margins are crimped. The spikes are carried high above the foliage, and the plant is on this account of value for effective massing. It grows in all kinds of soil, but prefers a strong loam, whilst it reaches its greatest dimensions on the banks of a small stream or pond where the tips of the roots alone could reach the water. Its varieties are all fine plants for border planting, particularly *disticha* and its semi-double form; this latter is a plant bearing magnificent flowers, shaped like those of a double *Petunia* and coloured a variable shade of orange-crimson.

H. f. var. Kwanso fl. pl. fol. var. is a capital decorative plant, the leafage being quite as bold as that of *H. aurantiaca*, and pleasingly but irregularly variegated. In some specimens the variegation is *vittate*, in others *marginate*; in others, again, it is *parti-coloured*, one side of the leaf being green the other white. Its flowers are double and of a bronzy red tint, and they are much above the standard of the flowers of most garden plants which show a full and really good variegation. The Japanese use the flowers of *Hemerocallis* as a salad, and it is mainly

owing to this use that *aurantiaca* major found its way to British gardens. An English bulb merchant travelling in Japan had the flowers served to him as salad, and after—to use his own expression—partaking of the best salad he had eaten in his life he bargained with the host for the purchase of all the plants, which he found were growing among beds of *Iris Kämpferi*. There is a cultural detail in this latter sentence that speaks for itself—*Iris Kämpferi* being, as all the world knows, a water-loving plant. I can speak with some certainty of the value of *Hemerocallis* flowers as salad. I have eaten (judiciously) of the flowers of all the species, and they all taste alike, resembling Lettuce mainly, with a suspicion of salad oil and Endive, and more than a suspicion of Spring Onions, a complete salad, in fact, without the trouble of mixing.

GEO. B. MALLETT.

CAMPANULA FRAGILIS.

CAMPANULA FRAGILIS (Cyrill), syns. *C. Cavolini* (Ten.), *cochlearifolia* (Vahl. non Lam.), *crassifolia* (Nees) is a native of the southern Apennines and Sicily, where it grows in cracks of walls and rocks. Nyman assigns it to Dalmatia, but I think wrongly; at any rate, it seems extremely doubtful, for I have never seen a dried specimen from that region. It is not named in any flora of Austria that I have,

and the "Index Kewensis" confines it to Italy. It is a dwarf plant, with spreading, branching shoots that hang downwards; leaves dull green, thick—those of the base rounded, cordate, bluntly toothed, those of the stem small. As they ascend, they become reduced to simple ovate-lanceolate bracts; flowers large, wide open, from four to eight at the ends of the shoots; the corolla is expanded, over an inch across, and deeply divided into five even lobes. It is of a fine light blue colour, with a very long white style in the centre. It flowers from June to August. This plant is not quite hardy with us, requiring a winter shelter of cold frame or cold greenhouse. It likes a place in rock in full sun, but it can be very well grown in a pot like other cold greenhouse plants. Often in the windows of our small Swiss towns, or on the outside galleries of mountain chalets, one sees enormous tufts of *C. fragilis* grown as window plants or in hanging baskets. The many branches hanging over the pot hide it completely, and are covered with flowers for several months; indeed, the plant is one of the most popular among those that are grown for rooms. It can be grown from seed, and is also easily increased by cuttings and division.

C. fragilis var. *hirsuta* (A.D.C.) is the same as *C. Barrelieri* (Presl.); frequent in gardens. Dietrich, in the "Encyclopedie der Gartenkunst," describes a variety *grandiflora* of Van Houtte, which I have not yet seen. The illustration shows it growing wild.

Geneva.

HENRY CORREYON.

THE ROSE GARDEN.

BOLD EFFECTS WITH CLIMBING ROSES.

SOME years ago the following notes were written in THE GARDEN by that excellent rosarian, the late Mr. T. W. Girdlestone, and we reproduce them as likely to interest those who are unfortunately deprived of his invaluable advice:—

The making of effective Rose pillars and arches is simply a question of the selection of suitable varieties, and perhaps the best of all Roses for the purpose is the *sempervirens* *Félicité Perpétue*. This magnificent plant, which is capable of covering a large house in a few years, is absolutely hardy, grows with a vigour and freedom unparalleled, is practically evergreen, its handsome dark foliage making a fine background for its immense trusses of pure white flowers, each one of which is a perfect rosette, and it will grow and flower profusely in practically any soil or situation. A great arch covered with *Félicité Perpétue* is a beautiful sight in June, and indeed looks well at any time by reason of its abundant and persistent foliage, which clothes the plant to its very base, and no Rose is better adapted for covering the pillars of a verandah—a task it will accomplish in a single season—soon running along the edge, too, from pillar to pillar, and framing the whole structure in a wreath of foliage and snow-white blossom. If this or any other really vigorous Rose be planted to make an isolated Rose pillar it is a good plan, instead of the usual single pole, to put in three poles triangularly 4 feet apart and to plant the Rose in the middle; the tops of the poles should be inclined towards each other, but not allowed to meet, being held apart by cross pieces 1 foot or 18 inches long, making a small triangle at the summit. The height of the pillar must of course be regulated by circumstances and surroundings, but poles of from 10 feet to 12 feet out of the ground make an effective height.

Another Rose that makes a fine pillar is the beautiful Japanese species, *Rosa multiflora* (syn., *R. polyantha*). The flowers, though single and individually small, are nevertheless produced so abundantly and in such immense trusses that the

The pedicels are very short and are clasped and completely hidden by the short boat-shaped bracts. The leaves are linear, slender, and grass-like; the spikes are not erect, but stand out at several angles from the main growths, and the flowers are not raised above the foliage. It is a highly coloured and very neat little plant, well worthy of a place in the choice plant border. It flowers in June.

H. x Aureole (Hort. Wallace) is doubtless a hybrid between *Dumortieri* and *Middendorffii*, though sent from Japan to this country as a new species. It has linear-lanceolate leafage 1½ feet long in dense tufts above 1 foot through. The flowers are coloured a deep shade of orange-yellow, averaging 4½ inches in length and 4 inches in span, and they are arranged in umbels of five with large clasping bracts surmounting the stiffly erect spikes. The outer petals only are coloured a warm brown on the outside, the extreme margins being orange. It is a pretty and very free-flowering plant and a great improvement on its parents. It flowers in June.

H. minor (Mill.) = *H. graminea* (Hort.) is a very small plant bearing pale yellow flowers 1 inch across in umbels of three or five. The plant makes a neat tuft 6 inches high, and is better adapted for a position on a rockery, especially as it is fond of a light free soil and warm position. It flowers in July.

H. fulva is a distinct though very common plant, with sea-green leafage of varying height and rambling habit. The spikes are produced in July,

plant when in bloom appears a mass of white, and the flowers, moreover, are deliciously fragrant. The garden variety *grandiflora* is even more vigorous than the species, but is not so effective when in blossom, as, although the individual flowers are larger, they are not produced so freely nor in such large trusses.

The most valuable of the multifloras, however, for the making of Rose pillars or arches is the more recently imported *Crimson Rambler* (Turner), a variety that is likely to compel a revival of this mode of Rose growing, since everyone must needs grow it, and the plant, magnificent in the open, will not flourish against a wall. I have only seen one fine plant of it on a wall, and even in that case the plant was quite bare at the base and was only in good condition at the top, where it had got above the wall. In the open, however, the effect that can be produced by a single plant of this Rose must be seen to be believed. The variety grows with all the vigour of the species and produces similarly immense trusses, but of double crimson flowers, which last an unusually long time when fully expanded, so that the display, in addition to being most profuse, is also exceptionally prolonged. There is no other red Rose at all approaching *Crimson Rambler* in its qualities of vigour and freedom of flowering, and it is therefore the more valuable; for otherwise white and pink are the prevailing colours of the very vigorous and free Roses, amongst which, to obtain anything like a red, it was necessary formerly to go to the Boursalts — uninteresting plants with dreary flowers, which everyone may be strongly urged to avoid planting. [A true prophecy.—Ed.]

Most of the Ayrshires are fine climbing Roses, but some have insignificant-looking foliage, and some a not too pleasant fragrance. Alice Gray, however, which has white flowers, and Ruga, flesh-tinted, are both beautiful and valuable Roses, while the hybrid Musk, The Garland, with its nankeen buds expanding into pure white blossoms, is well worth growing if only to show how immense a Rose truss may be, for every truss of bloom is a posy in itself.

All the Roses so far mentioned are somewhat early flowering, being generally at their best in June, but there are some varieties of a species indigenous to the Western States of America, namely, *Rosa setigera* (formerly called *Rosa rubifolia*, a descriptive name, as the foliage strongly resembles that of the Blackberry, but now, happily, discarded, for it used to lead to confusion with *Rosa rubrifolia*, a very different species), which, in addition to being perfectly hardy and vigorous, are well worth growing on account of the lateness of their flowering—quite at the end of July. Perhaps the best of these Prairie Roses, as they are called in America, are Queen of the Prairies (pink) and Baltimore Belle (white), both having quite double flowers of good size. *Rosa Brunonis*, though, of course, single, is a species that should be grown where it can have plenty of room (it is immensely vigorous), for its great bunches of pure white flowers with their rich gold stamens are very beautiful and deliciously fragrant; and *Rosa macrantha*, with its large flesh-pink blossoms, should not be forgotten.

There are two new climbing Roses which seem likely to prove valuable additions: *Aglaiia*, with large bunches of canary-yellow flowers, and the Dawson Rose, with big bunches of bright pink flowers which show up finely against the dark green shining foliage; but it is as yet rather early to speak quite definitely about these.

In addition to the *Polyantha* Roses already enumerated there is a variety that was raised in France in the days before the species was renamed *Polyantha*, namely, *Laure Davoust*, which is a splendid climbing Rose, producing the characteristic great trusses of perfectly double soft pink flowers, which are also amongst the most sweetly scented Roses that we have. There are, of course, some valuable climbers among the Hybrid Teas and Noisettes, though not many that can be confidently recommended for hardiness as well as for vigour and freedom. Of the Dijon race I should only recommend *Bouquet d'Or*, which is beautiful in foliage as well as in flower. *Gloire de*

Dijon itself gets too bare and leafless at the base ever to be an attractive plant. *Aimée Vibert*, with its great bunches of pure white flowers, and *Ophirie*, with its unique coppery coloured clusters, are both charming and valuable for the lateness of their blooming, and William Allen Richardson may be considered indispensable.

It is to the Hybrid Teas that we must turn for reds, and though some of the older varieties are sadly murky in shade, there are a few bright ones, namely, *Reine Marie Henriette*, perhaps still the best; *Reine Olga de Wurtemberg*, richer in colour, but only semi-double, though with glorious foliage: *Longworth Rambler*, crimson, and very vigorous; and *Marie Lavalée*, only semi-double, but of the most delicious shade of bright rose-pink.

[Of course several varieties have been raised since Mr. Girdlestone's death, but those mentioned are excellent.—Ed.]

TREES AND SHRUBS.

PLANTING NEAR THE SEA.

SOME are afraid of planting near the sea, and no wonder, considering the bleak look of things and the cutting winds on land near to it; but that arises rather from our own fault in cutting down trees in the past, and also from the great area of arable land which has hitherto been thought more profitable than woodland, so that in many wind-swept places evidently people have begrudged a break of trees, which, by the way, might often be worth while having for the sake of saving the crops from the prevailing winds; indeed, this has to be done in some countries, and it is interesting to see how well groves of hardy evergreen trees which thrive in a country will break the force of the wind. Yet even in places where the few trees that are planted are cut sharp off by the sea wind above the walls, as in Anglesea, we may see how soon good planting will get over difficulties that seem insurmountable. By the use near the sea of small-leaved trees like the Tamarisks, Buckthorn, and small Willows, we very soon get a bit of shelter, and by backing these with the close-growing conifers like our common Juniper and some of the sea-loving Pines like *Pinaster*, and in mild districts the Californian Cypress and the Monterey Pine, we soon get shelter and companionship, so to say, for our trees, and 50 yards away we might walk in woods as stately as in any part of the country. Having got our shelter in this way, the culture of the hardy Pines of the northern world seems as easy by the sea as anywhere: indeed, more so, because if there is any one place where the rather more tender Pines of the north are grown well it is near the sea in places around our coast, where, if the soil is good, one has not to be so careful about the trees we select as we have to be in inland places.

We have always noticed the evergreen Oak taking the lead among trees near the sea, and it ought to be largely used; but as it is not very easily transplanted from nursery-bought plants, it is just as well to raise it on the place and plant it young. Even seeds might be scattered with some advantage in places we wish it to grow in, as it grows freely from seed. But perhaps it is more suited for shelter in groups on lawns and in parks than for planting in a broad wood, for which purpose we had perhaps better go to the larger trees.

In addition to the common evergreen trees of Europe, the Scotch Spruce and Silver Firs, &c., we have the noble Corsican Pine, which, from its habitat in Calabria and in Corsica, can have no objection to the sea. The Pines of the Pacific coast, too, are well used to its influences, and hence we see in our country good results from planting them near the sea, as, for example, *Menzies' Spruce* at Hunstanton, the Monterey Pine at Bicton, the Redwood in many places near the sea, and the Cedar of Lebanon at Goodwood. One good result of planting in such places is that we may use so many evergreen trees, from the

Holly to the Cedar, and so get a certain amount of warmth as well as shelter.

Though our country generally is not perhaps fitted for the growth of the Cork Oak, it is here and there in southern and sheltered parts on warm soils, as in certain parts of Devonshire and on the warm side of the Sussex Downs, seen in good condition. This Oak naturally inhabits the southern parts of Europe and the northern parts of Africa, and it is most interesting to know that it can attain the size of a stately tree in our own country. At Goodwood there is a striking specimen of the Cork Oak. The girth of the stem at 3 feet from the ground is 12 feet 9 inches, and without doubt the trees at Goodwood owe something of their health to their good neighbour, the sea.

SOME REMARKABLE BUDDHIST TREES.

NATURE has provided many wonderful trees, but human imagination has increased the number. Both combine, no doubt, to produce the most wonderful of all—the tree of species beyond identification; beyond conception, indeed. We are told that in the fourteenth century a great Buddhist reformer died at Kounboun, and from his hair, for reasons and by process unexplained, this tree arose. Though between 500 and 600 years old it was not more than 8 feet high, but, on the other hand, three men with arms outstretched could scarcely reach round the trunk. The branches spread like plumes of feathers, bushy and evergreen; scarcely any seem to have died from the beginning. It produces large red flowers extremely beautiful in summer. The wood has an exquisite scent like Cinnamon—at least, so wrote M. Huc in his book after he and some reverend companions had visited Kounboun. From this description botanists will, no doubt, recognise a new species. But here comes the marvel. Each leaf bears well-formed characters of the Thibetan alphabet, some in dark green on a lighter ground, some light on a darker ground. On one leaf they are at the apex, on another at the base or in the middle. Commonly a sentence is inscribed on the foliage of every twig, but sometimes the bark must be perused in order to make out the context, for this integument also bears its crop of literature. Moreover, if the bark be removed, upon the soft wood beneath appear young inscriptions, still incomplete—the “i's” are not dotted, as one may say, or the “t's” crossed, but, as seemed specially to M. Huc, when these inchoate sentences could be read, often they did not repeat those upon the bark removed; in fact, a new revelation was preparing underneath the old and out of sight. We have not the comfort of supposing that there was any misapprehension on this account. The travellers examined everything most closely, until, in fact, between awe and scientific curiosity, we are told that “the perspiration ran down our faces.” They even made a sketch, which appears in the first edition of M. Huc's work, showing the tree and the silver umbrella put over it by the Emperor Khaug Hi.

The Buddhists have another wonderful tree—in fact, they have several—but the one at Anmadhapura, Ceylon, possesses historic interest. If the record be true—that is, if the original stem has not been replaced by a seedling or a plant altogether new—it must be 2,145 years old. That a Bo-tree was set in this spot by a daughter of the famous King Asoka is certain. She and her brother inherited the paternal zeal for spreading the doctrines of Buddha throughout the world, and when the latter resolved to go to Ceylon as a missionary Princess Sanghambhatta accompanied him. With her she took a cutting of the Sacred Bo-tree, under which Buddha sought refuge from a storm. This was laid in the earth at Anmadhapura, and we are invited to believe that the noble trunk still flourishing there is the very same. Everyone will hope it is true. Sir Emerson Tennant was convinced, and he had special advantages for investigating the case. “Its age,” said he, “is a matter of record; its conservancy has been an object of solicitude to successive dynasties, and the story of its vicissitudes has been preserved

in a continuous series of chronicles among the most authentic that have been handed down to mankind." We only hope it is all true; any way, it is very refreshing
W. N. BROWN.

NATURAL GARDENING IN SURREY WILDS.

A NOTE ON FERNS.

It is interesting to notice that some of our most beautiful Ferns will not only grow but flourish under careful treatment in poor sandy soils, and on banks which in summer usually get terribly dry and unfit for moisture-loving Ferns.

A *Blechnum boreale* or Spicant (see illustration), which is now probably thirty years old, and which I have watched for twenty years, is still in excellent health and has gradually increased, and now measures 4 feet in diameter. The fronds are well formed, the bright green barren ones being about 2 feet long and 2½ inches in width, the erect spore-bearing fronds 26 inches or more high. This specimen has not been moved for twenty years. It is in shade, about 3 feet from a wall nearly 6 feet high covered with Ivy, and looking due east. It gets no drip, has this year been little damaged by the weather, and up to December 25 the tall fertile fronds only showed signs of decay, the others retaining their bright colour and shiny healthy appearance.

Few Ferns like being moved. A good place should be selected in the first instance, and the plant allowed to remain, care being taken that, if planted on dry banks, a hollow depression should be made behind the Fern to catch the water, and a small tunnel made with a narrow spade slanting downwards so as to conduct water towards and well below the roots.

The fronds of Ferns generally should not be pulled off in autumn or winter, and I am sure it is better to leave them alone, though they may look somewhat untidy in winter; but when the new fronds appear they have the advantage of growing through the moist and partly decayed old ones, and particularly in the case of this old *Blechnum*, they push their new fronds upwards in the spaces they find, and as they grow they take far more natural positions than if attempts are made to facilitate their emergence, and they certainly retain their healthy appearance for a longer time if thus treated, even in mid-winter or later, if in sheltered nooks.

The secret of getting good healthy, evenly-grown fronds of healthy colour and firm consistence, so that they may well stand the winds and cold weather of our springs as well as the heat of summer, is to take care to leave at least the lower part of the last year's fronds attached to the crown. By this means the young tender fronds will be well protected and kept moist, and are thus encouraged to make their steady gradual growth without interruption.

In the case of *Filix-mas* and all the Ferns with long spreading fronds the best plan to adopt is the following: As the fronds get soft and begin to decay in late autumn, collect them together in one hand, and with a slight twist draw them several times round the base of the plant as near the earth as possible, and then tuck in the ends so that they retain their

place all through the winter, leaving the new head in a pretty deep cup. The new fronds are thus well protected in early spring, and make their own way, one after the other, through any slight obstruction far better than they do if we attempt to help them. In many cases I have left a collection of the old stems still attached, forming a deep circular depression perhaps 5 inches or 6 inches deep, at the bottom of which may be just seen the new fronds making their appearance. This system I have now followed for several years, and have not yet discovered any objection to it. The decayed and decaying fragments near the growing young fronds do not obstruct their growth or cause them to die and rot. These observations apply only to a dry sandy soil, from which water drains away only too freely, and it is seldom that I find fragments of Ferns rotting or forming a nidus for the growth of mildew or low fungi and vicious bacteria. In very dry weather this plan may save the life of many a good Fern in very light and porous soil in gardens in the drier parts of Surrey and on Surrey hills.

January 10, 1903.

F. R. S.

RIVIERA NOTES.

THE other day in an old garden belonging to a friend I came across an archway completely covered with

CLEMATIS BALEARICA

of many years' growth, and in the very fullest flower imaginable. The difference between a weakly plant that thinly covers a trellis and has but a few thin flowers, and this solid canopy of finely cut foliage with countless milk-white bells, is so great that for the first time I realised the beauty of this old but not much grown plant. It is certainly as well worth planting as a Banksian Rose, and is about as hardy, save that it flowers in the winter months. The hum of the bees in its myriad bells was in itself a reminder of summer,

and the mass of flower overhead recalled the beauty of the Banksian Rose very curiously, for there is not the least real likeness save in colouring. A walk lined with tall purple Iris flowers and the first pale pink Almond blossom beyond added to the charm. Lemoine's new hybrid *Habrothamnus corollinus* is a decided gain; its colouring is brilliant, the flower heads large, and the habit vigorous, so that it is a desirable shrub for winter blooming, but nothing equals the brilliance of *Bignonia venusta* on a wall for January and February. The

SEEDLING FORMS OF IRIS STYLOSA

are very delightful this year. It is surprising how many shades of colour and size of bloom appear in a good batch of seedlings sown from seed of the white and magnifica forms. So far I have not seen one white reproduced by seed, but shades of pale grey are not uncommon, while deep purple striped forms also appear. They are not as beautiful to my eyes as the selfs, but they find favour with some folk, and the variety as a whole is really very taking.

COLEUS THYRSOIDEUS

is just hardy enough to struggle on through the winter and produce short and stunted spikes of its bright blue flowers, but *Moschosma riparium* promises to be much hardier, and will, I think, when grown to a good size prove a very useful winter-flowering plant here; its sprays of light grey, purple-anthered flowers are very decorative. There are now three varieties of the pretty *Lopezia miniata* that are to be seen—one lilac, one pink, and one very brilliant rose-red, with a touch of orange in it. For cutting in long sprays it is very ornamental among white flowers of more solid substance. The

CULT OF THE CYPRIPEDIUM

(must I say *Paphiopedium*?) is at last arriving on these shores, and I was much pleased to see how well the varieties of *insigne* and *leanum* will thrive in pots out of doors,

NATIVE HARD FERN (BLECHNUM SPICANT) IN A SURREY GARDEN.

edging groups of taller plants under the shade of trees or shrubs; but they do not thrive really well when planted out, as they require such deep shade and moisture to carry them through the summer, while in winter they prefer a drier and sunnier spot. They are now florists' flowers as in England, a proof of their popularity. The

VARIEGATED OLEANDER

is the green that suits them best, as the Crotons naturally will not grow out of doors here during the winter, and when cut it is difficult to tell a good spray of the golden variegated Oleander from a Croton spray.

Tropeolum lobbianum is flowering most profusely this winter. I have found that French gardeners destroyed it in summer, and until the plants are more than a year old they do not show their full beauty, but by dint of much persuasion the old plants have been allowed to remain, and consequently reach to a far greater height, with an increase both in flower and in general beauty.

The wild starry Anemones are now appear-

ROUND ABOUT A GARDEN.

THE PROCESSION OF THE BULBS.

WHEN the Snowdrops flower winter seems to have ended, because the Snowdrops are only the vanguard of a procession of blooms—Scilla, Chionodoxa, Crocus, Daffodil, Narcissus, Jonquil, Hyacinth, and Tulip—which march on in growing glory until May without a break in their ranks, and when it snows and freezes they merely "mark time" till it thaws again. You cannot draw any dividing line between the season of the white Snowdrop and that of the blue Scilla and yellow Crocus, and when the Crocus flowers you can already see the Daffodil buds. Even now all the bulbs are in evidence, standing like well-drilled squadrons with green blades all in line of companies thrust above the earth, and it would be absurd to call this winter when every square yard of the garden shows new springing growth from day to day.

WINTER PLAYS HIDE AND SEEK.

Besides, counting backwards from the Snow-

hard winters in plentiful crops of berries, and no winter at all to speak of afterwards. The wild geese have been coming to the East Coast, and the seagulls have been coming inland, year after year, in increasing numbers; but still the cycle of mild seasons continued. A little more scientific were those prophets who, noting that the northerly winds of summer were very cold, concluded that they must have blown over unusual amounts of ice in the northern seas, and deduced from this the prediction that north winds in winter would bring bitter cold. Perhaps they would have done so, but the winds of winter remained persistently in the south and west, blowing over no icebergs.

THE MOON AND THE WIND.

There is plenty of time for cold weather yet, however, and a third class of prophets tell us that the end of this month and the beginning of February will bring much frost and snow. The middle of February is to be warm, with snow at the end again. March is to be a trying month of varied weather, April typical, and May horribly inclement. June will be an indifferent month, and a common characteristic of all the five months will be thunderstorms. These predictions are based upon scientific grounds, and if they are not fulfilled it will be because the savants have made errors in their calculations. For this new science of the weather recognises that the inconstant wind is the governing factor, and that the wind is an air-wave, caused, like the tide of the sea, by the moon when she pulls in conjunction with the sun. The irregularity of the moon's movements, compared with those of the world, prevent the same cycle of weather from repeating itself except at such long intervals that no weather records exist as guides for us to-day; so the prophets have to search such records as exist for partial and temporary resemblances in the positions of sun, moon, and earth which may have occurred at shorter intervals. In time to come, no doubt, the weather for any month, week, or day of the future will be calculated as easily and more exactly than we reckon the tides to-day, and although this system of weather prophecy is still in its crawling infancy, it is an infant that deserves to be treated with respect, because one day it will rule the world's affairs.

GARDENING BY CERTAINTY.

Gardening will be a more exact science, too, then. We—or, rather, those who come after us—will know to a day when to sow seeds, when to prune Roses, when to stake Dahlias, and when to put out bedding plants. There will be no unpleasant weather surprises then, and week by week *THE GARDEN* will be able to tell its readers on what days to cover their glass houses against hail, and when it will be waste of labour to water the garden, because rain will fall. Thus our successors will be saved many unpleasant experiences, though they may be no happier for it. The glorious uncertainty of gardening, as of cricket, is a large part of its charm, and even the joy of very early blooms in midwinter is enhanced by the tantalising doubt whether frost and snow may not come and spoil it all to-morrow. What pleasure could one take in a great flush of fruit blossom if one knew that a devastating hailstorm was due next day? Thus every advantage has its drawbacks and every evil its

POLYGONUM COMPACTUM BY PATHSIDE.

ing, and the golden heads of the yellow Tazetta Narcissus are out where not nipped off for the market or gathered for the house. What a pity that a flower should be so fatally attractive! E. H. WOODALL.

POLYGONUM COMPACTUM.

THE illustration shows this species, at one time regarded as a variety of *P. cuspidatum*, happily placed. It is an excellent plant, not unruly, and not excessively "compact," but with a certain charm that comes from the somewhat rigid stem and wealth of upright masses of flowers. It is shown grouped with broad-leaved Saxifrage, and no edging, so to speak, is handsomer where a bold effect is desired. *P. cuspidatum* is better known than *P. compactum*, but no good gardener allows this graceful plant unlimited freedom, else it becomes a weed difficult to get rid of. In rough places or grouped by water *P. cuspidatum* is very welcome.

drops of to-day, through the Winter Aconites, which were yellow with hardy bloom on New Year's Day, and the early Irises which flowered in mid-December, while the Roses were still glorious on the walls, it is not easy in years like these to locate "winter" as a season anywhere. Yet it should have been, according to many weather prophets, a season of "exceptional severity," in preparation for which some of us took extra precautions with our tender shrubs. Rather ridiculous some of these have looked, swathed like mummies, while week succeeded week of weather milder than last May or even parts of June! No wonder that weather prophecies are falling into disrepute.

OLD WEATHER PROPHECIES.

But there are weather prophets and weather prophets. The old-fashioned kind who looked at large upon the face of Nature, and foretold therefrom her coming smiles and frowns have been proved to know nothing. For six years running we have had the familiar presage of

compensations; but that is no reason for neglecting such advantages as we possess. And among these the increasing accuracy of scientific weather predictions must be counted. In a work just published on "Natural Law in Terrestrial Phenomena," Mr. Hugh Clements, the weather prophet, is quoted as saying that, in one year, "Mr. Inskip, a gentleman farmer, living at Shefford, Beds., observing that I had forecasted a dry September, and noticing that I was correct up to July, planted Cauliflowers in abundance, knowing that in September they would meet with a remunerative and ready sale in Covent Garden—as they did!" E. K. R.

THE PHYTEUMAS.

(Continued from page 41.)

The third division embraces the species proper to pastures and woods, and therefore those that are easiest to grow in gardens. They are comprised in the following section:—

P. austriacum (Beck.).—From the Alps of Austria and the Tyrol. This species is distinguished from the type *orbiculare* by the basal leaves being longer than their petiole, by the upper leaves, which are ovate-lanceolate, and, above all, by the flower-bracts being carried erect (in *orbiculare* they are spread out or reflexed), usually longer than the flowers. May and June.

P. betonicifolium (Vill.).—From the Alps and the Pyrenees. A rather tall plant; leaves lanceolate and heart-shaped, carried on long petioles. Flower-stem nearly 20 inches in height; flower-spikes blue, short, and oval, lengthening towards the end of the flowering season; at their base are one or two narrow bracts. May to July.

P. canescens (W. K.).—From the Carpathians, Balkans, and the Caucasus. Whole plant of a grey-green colour. Leaves sessile, ovate-elliptical, crenate; flowers violet-lilac, in closespikes. June and July.

P. Halleri (All.).—From the Alps, Pyrenees, Carpathians, &c. A tall, stout plant, leaves ovate-orbicular, serrate-dentate, with stout flower-stems 2 feet to 2 feet 6 inches high; flowers very dark blue in a long, close spike, with two long drooping bracts. June and July.

P. limonifolium (Sibt. and Sm.).—From the mountain regions of Asia Minor. A tall plant with branching flower-stem 1 foot 8 inches to 2 feet 4 inches high; flowers pale blue, quite open, and arranged along the stalk so as to form a long, narrow spike. July to September.

P. Micheli (All.).—From the mountains of Southern Europe. An erect plant; leaves ovate-lanceolate or narrowed at the tips; flowers deep blue, in spikes that lengthen as the flowering season advances. June and July.

P. orbiculare (L.).—The most generally distributed species, for it is found in all mountain pastures throughout Europe and even in the East; 1 foot to 2 feet high; leaves ovate-elliptical, crenate; flowers very dark blue, in orbicular heads. May to July.

In the *jardin alpin d'acclimatation* we obtained a dwarf variety that comes well from seed. There is also a white variety, but it is very delicate.

P. scorzonrifolium (Vill.).—From the mountains of Central Europe. Leaves polymorphous; flowers pale lilac or blue, arranged in long narrow upright spikes. June and July.

P. spicatum (L.).—Forests of Central and Southern Europe. A shade-loving plant, frequenting woodland. Leaves ovate-elliptical, serrated, often with a brown blotch at the base; flowers white or blue in a close spike. May to July.

PHYTEUMA BETONICEFOLIUM (NATURAL SIZE).

All the kinds that thrive in the open ground require a soil rich in humus, such as a mixture of leaf-mould and loam, and for the last-named species a position in half sun or shade.

Phyteumas are not difficult to raise from seed, that is to say, they germinate quite freely, but they are apt to go off as young seedlings. They require great care at this time to counteract their inclination to rot off.

Floraire, Geneva. HENRY CORREYON.

PHYTEUMA SPICATUM.

(NATURAL SIZE.)

THE INDOOR GARDEN.

WINTER-FLOWERING CARNATIONS.

STILL wanting a more definite term is that group or section of Carnations known as "Winter-flowering" or "Tree." Any designation descriptive of the season, as also the flower, is fraught with considerable difficulty, and until some one provides a better name the above will doubtless answer for a few years yet, as it has also sufficed in the past. Any such designation, however, as winter-flowering must be open to sharp criticism when we find the border Carnation—and therefore summer-flowering—Germany in several lists of tree or winter-flowering varieties. There is no greater

mistake made, and none calculated to bring good true winter-flowering ones into disrepute, than the obvious swelling of the lists, instead of the endeavour to raise good and suitable sorts. But because a border Carnation now and again may give a few blooms in winter it is at once designated a "tree" or "winter-flowering," and this very often by known florists. It is a mistake, however. A good, naturally flowering winter Carnation is valuable in any collection of plants or in a private garden, and it is no gain to the reputation of a florist to foist on the gardening public a variety that may have in some accidental way produced a few blooms in winter. The most notorious border Carnation may at times so forget itself and do this, and the point is to endeavour not only to get the same variety to repeat the flowering, but even to induce the same plant or cuttings from it to do so. Such instances, therefore, of winter-flowering are the merest accident, and where a large number of plants are grown a few will produce a very late or a very early growth that happens to come into flower at a useful time. Such growths, however, are akin to latent or even retarded buds in other plants, differing in the essential item that it is not possible with certainty they will ever appear or be reproduced again.

These, therefore, are the so-called "winter-flowering" Carnations that all interested in the right article should expose or discourage. Not that there is much fear of imposition, for it is too well known how impossible it is to flower the border Carnation in the depth of winter. Late autumn blooms may appear occasionally, and early flowers from early layers, but if you want half-a-dozen blooms between December 1 and the end of February it will be quite easy to prove how useless is the attempt to obtain them; indeed, the experiment has been tried and failed utterly. A friend of mine anxious to obtain some really good winter-flowering sorts placed an order with a grower of new winter Carnations with a request for blooms at any time between the end of November and the beginning of March. After receiving nothing but very frail excuses instead of the blooms expected for two years my friend gave up in despair, and believed that I had originally told him, viz., that he would "never get them."

There are winter-flowering Carnations, however, and these are worthy every encouragement. No flowers are more serviceable. No flowering plant requires to be grown with greater care. No forcing by artificial heat will compensate for late propagation or other failures or drawbacks. To say that a plant should receive no check is quite another matter; indeed, it is only possible when the plants are grown at home. A few years ago I ordered a few hundred "rooted plants," that came to me perfectly packed and quite fresh. More than this I cannot say. Obviously long ago rooted and transferred to 5-inch pots the plants had awaited orders; they were either torn out of the pots just mentioned or were cut out in squares as with a knife. The fresh young plants gave one the latter impression. Needless to say all freshly formed root fibres had been ruined in the process; as a result two-thirds of the lot perished. My neighbour fared even worse. Hence my advice is, propagate at home or purchase small plants nicely established in 2½-inch or 3-inch pots. No harm attaches to the purchase of young freshly-rooted cuttings. When the points of the roots in a Carnation become broken there is delay naturally enough in the forming of lateral rootlets.

This is not desirous in the infancy of the Tree Carnation, nor does it in any way assist in the future development of the plant; indeed, it is a check that is hardly recoverable. Hence the greater need for home propagation or the purchase of young plants just established in small pots; the latter have much to commend them.

With regard to propagation at home this has great advantages over all others. A choice of cuttings selected from the healthiest plants is not the least of these; in fact, while a large number place their faith upon mixtures of soils and the temperature, in so far as these relate to successful propagation, they are to me of only secondary importance to the state of the cutting — its

freshness and moderate vigour, combined with cultivation in a cool airy house. What the Carnation cutting dislikes, and at this season especially, is too much top heat. Cuttings from plants grown in any airy structure with a temperature of 50° may be quickly rooted at this season on a brisk bottom heat in a low house without any top covering at all, such as hand-lights, bell-glasses, &c.; in fact, the cutting, as the growing plant prefers a comparatively cool condition overhead, and this should be combined with

PHYTEUMA HALLERI.

(NATURAL SIZE.)

(See page 57.)

moderate dryness. Where a bottom heat of not more than 70° is available make up a 3-inch bed of pure sand and insert the cuttings in this. One good watering and, during January, no more for nearly a week; then another good watering, and, if the cuttings are the firm, hardy ones I have in mind, three weeks will see the majority of them rooted.

Great stress is laid by some on the size of the cutting and where it is taken from. Given the conditions I have named I do not mind whether the cutting be 3 inches or 6 inches long, whether it comes from the ground level or from high on the old flower-stem. A cutting with a broad

base has a much greater chance than one with a narrow base. Not a few split the stems of the cuttings. It is not necessary, and those who do so hardly realise, I think, where the roots emerge from. New roots in the Carnation cutting, in the case of one cut to a joint, form immediately inside the epidermis, hence the greater opportunities of the cutting with broader base.

The only possible advantage of stem splitting would be in the case of a small cutting form in assisting to expose its greatest possible basal surface. It is important, I think, to realise the principle of rooting in such plants, and, to the careful, it cannot fail to be an unerring guide.

The other most important item in this matter of propagation is the material employed; any material having a tendency to lie cold is dangerous, as compared with material of comparative warmth. For example, soil compared with sand is cold, therefore bad. To make it better we add sand. The more sand we add the better it is, because warmth and moisture are more rapidly dispersed. It is in this way we come presently to sand alone, and there is nothing better. No material more quickly conduces to quick rooting. Warmth more quickly permeates the entire mass, and water is so rapidly dispersed that, as far as may be, an uniform warmth is maintained at the base of the cutting. These conditions combined are most favourable to quick rooting.

Hampton Hill.

E. JENKINS.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

THE NEGLECT OF WHITE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Under this heading in THE GARDEN of October 18 Mr. Kay Robinson deals with a subject which has for years occupied the thoughts of the present writer, and whilst in full agreement with what has been said, one may be permitted to add an additional point or two of some possible value. White lights up, increases the size, and accentuates the shape of the garden as no single or combination of colours can do. Nor is there anything to equal white in dull aspects and seasons. In order to give a true or artificial idea of distance place some strong white-foliaged or flowering plant in the most remote shade, and all the intervening space at once becomes animate and attractive. Where one is accustomed to walk in the garden in the late evening (and what true garden lover does not?) when all the bright colours are indistinguishable, save as black masses, the white flowers are prominent and pleasing as ever. Mr. Robinson does well to plead for a larger space for white, but it is to be hoped that neither he nor others will desire to see it confined to regular lines and figure work. To our thinking it is seen at its best when alone or forming patches and splashes amid rather sombre surroundings. Large white plants demand such a strong high background as the woodland border affords, whilst in the garden of dwarf plants proximity to coarse rather than delicate foliage shows up the white and improves the neighbouring colours.

Melbourne.

C. B. L.

CULTURE OF THE LENTEN ROSE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I have a dozen good clumps of the Lenten Rose on a south border in rather light and dry soil, but the flowers have not been so plentiful the last year or two, during which time the plants have been going back. They have been five or six years undisturbed, although top-dressed every spring. I am thinking of removing them to another part of the garden, and would like to know the best time to do this and the soil and situation most suitable for them.

J.
[Provided our estimate of the present condition

of your plants is correct, viz., that they are in a somewhat sick or weak condition at the moment and the present flowering of but little worth, we would most certainly take the plants in hand at once.

On the other hand, if the flowers are sufficiently good and plentiful to deserve it, it may be well to wait till flowering is over. By carefully regarding your letter, however, seeing the plants have been going back for a year or two, the wisest course will be to discard the flowers now for the sake of the future well-being of the plants, as it is quite clear that they have not only exhausted the soil, but that the annual top dressing fails to sustain the plants in your case. We would most certainly advise you to replant them, and in doing so to select a different aspect. "A south border" would, in the majority of cases, be too hot and dry in summer, and we imagine this has been so in the present instance, as five years are by no means an abnormally long time for these plants to remain in one position; indeed, well planted at the start, they should be now, after five years, splendid specimens. The treatment best calculated to make them a complete success is as follows: Select a partially sheltered position free from tree roots, where the plants would not feel the hottest sun and be likewise free from cutting winds in spring, the latter even more important than the former. A bed of soil at least 2 feet deep should be given and thoroughly enriched. These Lenten Roses often send their roots to a depth of 3 feet where opportunity offers, and should therefore be catered for accordingly. As your soil appears rather light, we would suggest a very liberal addition of well-decayed cow manure, working it well into the soil 18 inches from the surface, and if possible a few barrowfuls of rather heavy loam or clay to render the whole more holding. If this is not possible use the manure with a liberal hand, keeping it of course free from the roots and avoid burying it in solid lumps. This special depth of soil and preparation are always the more necessary where the soil becomes too dry in summer, an item to be avoided where these handsome plants are to be made a success.

In removing the plants these will be greatly benefited by division, and under no circumstances is it well to transplant large clumps intact. Clumps of the age you describe should make four and probably six good plants fully large enough to successfully transplant. Even if space is limited, we must still urge the division of the clumps, as the division may be replanted to form groups in sheltered spots on the side of the lawn or shrubbery. A capital implement to break up the plants is a small hand fork, thrusting the point of the prongs sideways into the clump and then wrenching it asunder. This is far better than a knife, which cuts and destroys many roots. In replanting do not for convenience sake shorten the roots unless there is disease or decay present, in which case the shortening becomes a necessity so far as the decay reaches. It will also be well to retain all the old foliage; even should this be shabby or disfigured, it is still of assistance in promoting root action, and when the young foliage springs forth the old will die a natural death.

Avoid huddling the roots in a mass in a small hole, and plant them straight down. Frequently these plants suffer through want of moisture in summer, and in the event of a dry season a few liberal soakings of moisture or liquid manure will be well repaid. Take care also with the freshly-planted subjects that they do not suffer from the same cause in the coming spring, but once they take to a well-prepared bed, as above suggested, these Lenten Roses will not readily turn back, and another year should see them fully recovered and flowering again.—Ed.]

WORKERS AMONGST THE FLOWERS.

MR. HENRY CANNELL.

AMONG the diligent horticultural workers whose labours extend over many years, Mr. Henry Cannell, of Swanley, is one of the best known, and his work is reflected in the gardens of the world through his successful efforts to raise new races and develop those already in existence. Mr. Cannell went to Swanley about thirty years ago, but before then his name was identified with many good new flowers which have now passed into the list of those familiar in garden and greenhouse. We wish to draw attention to Mr. Cannell's work now for the reason he has recently received the gold medal

MR. HENRY CANNELL, V.M.H.

of the Royal Horticultural Society (V.M.H.), together with Mr. Bennett-Poë and Mr. George Masseur. Those who remember the old days of the Royal Horticultural Society in the Chiswick Gardens and at South Kensington will recall with pleasure the brilliant groups shown by Mr. Cannell. It was at South Kensington that this diligent plantsman showed the Juarezi Dahlia, the forerunner of the beautiful Cactus group, which we treasure for their sumptuous colouring in the late summer days, and about this period Mr. Cannell showed the single variety Paragon, and encouraged in every way possible the single-flowered group which we now prize for their grace and usefulness in many forms of decoration. Well we remember the beautiful Fuchsias raised at Swanley, the Cinerarias, that broad-flowered crimson variety March Past, which was a great advance upon those then in existence, and

the large-flowered Chrysanthemums, of which Edwin Molyneux was introduced by this renowned florist.

It is interesting to know that Mr. Cannell comes from Swardstone, near Norwich, and obtained much of his practical knowledge in horticulture in the nursery of Messrs. Massey and Stewart near that city. This was in 1852. Then he ventured to London, and began in what were then the rural districts of Clapham and Brixton, quickly making his influence felt in the neighbourhood, and exhibiting with success at the shows held in the Regent's Park Gardens and at the Crystal Palace. Heaths and New Holland plants were the chief features of the exhibitions, and they were grown by Mr. Cannell with conspicuous skill, and Grape growing, in which he excelled, was also attracting much attention. In 1864 a move was made to Woolwich, and it was in that year this skilful grower took to the great international show at South Kensington the six specimen Fuchsias which made at that period no small stir in the world of flowers.

A great work has been accomplished at Swanley, and is being continued there, and on the sunny slopes at Eynsford, where Mr. Cannell established a seed farm many years ago. We remember with delight the houses of tuberous Begonias and immense masses in the open air, the Cannas, zonal Pelargoniums, and the many other flowers Mr. Cannell improved and cultivated with such marked success. The brightest exhibits in the Drill Hall at Westminster in winter have been the zonal Pelargonium flowers, and the work of raising new varieties and growing the plants have been undertaken with an enthusiasm that young men of the present day should emulate if they would succeed in the great business of life.

We might write more of the acres of China Asters, hardy flowers, vegetables, and fruits at Swanley and Eynsford, but as our readers know, we are not forgetful of the good things produced there and note them when occasion arises.

Mr. Cannell, though of advanced years, is a sturdy specimen of his race, and by unflagging industry and keen perception has done much towards advancing the horticultural industry in these isles.

BOOKS.

A famous book.*—The scope of this botanical book is thus stated in the author's preface: "It has been my endeavour to produce a book which shall supply to residents at Simla, interested in botany and acquainted with the rudiments of that science, the means of identifying the trees, shrubs, and herbs they see in their walks about the station roads and paths in the neighbouring valleys." . . . Sir Henry Collett, gallant soldier and careful botanist, whose military career of forty years began with the Indian Mutiny and included much distinguished service, did not live to see his book published. He left it in the care of Mr. W. Botting Hemsley, F.R.S., the keeper of the Herbarium, Kew, who had already read the whole of the manuscript and had supervised the making of the illustrations.

Mr. Hemsley has also written an important

* "Flora Simlensis." A handbook of the flowering plants of Simla and the neighbourhood. By the late Colonel Sir Henry Collett, K.C.B., F.L.S. With an Introduction by W. Botting Hemsley, F.R.S., F.L.S., Keeper of the Herbarium and Library, Royal Botanic Gardens, Kew. Published by W. Thacker and Co., 2, Creed Lane, E.C., and Thacker, Spink and Co., Calcutta and Simla.

introduction, embodying descriptions of the position, area, and climate of the district, a map with detailed explanation, tables of genera and species of the flora of Simla, with one of the related flora of the British Isles, lists of the trees and Ferns botanically classified, aspects of vegetation, a glossary—an important item in a book that is partly addressed to amateurs—and a bibliography. The book should be of much use and interest to the many residents at the favourite hill station. Some botanical study or training will enable the reader to profit by it all the more readily, though in the clear and plainly worded text, where none but the simplest botanical terms are used (all noted in the glossary), there is nothing that cannot be apprehended by any reader of ordinary education and intelligence. It would be well if army officers in general had their attention directed to botanical study; well both for science and for their own advantage. Active service must often take them to places where perhaps no botanical traveller has ever penetrated, and there must be numerous occasions on foreign service in out of the way places, in small, perhaps almost isolated commands, where an interest in plants and trees and Ferns may make the whole difference in a man's life; one who has a little botanical knowledge finding in the study of the vegetation about him a pursuit of inexhaustible interest, while another, who might be without such a resource, finding the same place, apart from his necessary duties, intolerably dull and wearisome. The book has a quantity of admirable illustrations in line, drawn by Miss Smith, partly from dried specimens and partly from growing plants in the Kew collection.

Sir William Thiselton-Dyer, Director of the Royal Gardens, Kew, in a sympathetic "In Memoriam," records his impression of this work, the progress of which he has watched with "sympathy and interest," and we quote the following words from his kindly review of a life of devotion to his country and the cause of science: "He spent his life strenuously and with distinction in the service of his country and in the interests of science, and the end came with the simple exhaustion of his physical powers. Almost his last enquiry was as to the progress of his book. This fortunately had been left in a state which enabled Mr. W. B. Hemsley, F.R.S., the keeper of the Herbarium, to see it through the press with little difficulty. I think Collett felt no real anxiety as to its fate. He hoped that it would stimulate an interest in a subject which he himself had found a pleasant recreation in the midst of official duties. Those who use it will speedily discover that it is no mere compilation, but the outcome of conscientious and independent work. Collett had the true scientific temperament. He had no respect for scientific authority, and distrusted text-books. He was never content without verifying the facts for himself. He described his plants fresh from the field, and at once entered in his note-books copious memoranda and excellent drawings, and these he constantly used in working up his material at Kew. At first sight there may seem something anomalous in a distinguished soldier devoting his years of retirement to botanical studies, still more perhaps in prosecuting them in the midst of his professional duties. As a matter of fact, the obligations of botanical science to the army are very great; it is sufficient to recall the names so familiar to botanists of the late General Munro, C.B.; of the late Colonel Grant, C.B., C.S.I.; and of Lieutenant-General Sir Richard Strachey, G.C.S.I. The flora of Tibet would be hardly known to us but for the collections made by military officers, of whom Captain Deasy, the late Captain Welby, and Captain Malcolm, D.S.O., may more particularly be mentioned. Nor is it easy to estimate the position our knowledge of the Indian flora would occupy without the labours of a long series of officers of the Indian Medical Department. And among Russian officers the name of General Przewalski will always stand out pre-eminent for his botanical work in Western Asia. The fact is that the qualities that make for success both in the soldier and the botanist are largely identical; they are quick observation and the power of rapidly drawing correct observations

from minute facts. When Collett discovered his giant Rose through his field-glass he was using his eyes and his reasoning powers precisely as he would have done in a military reconnaissance. . . . In many ways he reminded me of the late General Gordon." We have seldom reviewed a book with so much pleasure as "Flora Simlensis."

GARDENING OF THE WEEK.

THE FRUIT GARDEN.

STRAWBERRIES IN POTS.

WHEN the earliest plants begin to throw up their flower-stems place them in the lightest and most airy part of the house, where they can have plenty of warm air; this will prevent the leaf-stalks becoming drawn, and to favour fertilisation of the flowers when they begin to open. Let forcing be carried on by daylight, followed by complete rest at night, when the temperature may be allowed to fall to 40° in severe weather, and 45° or more if this can be done without having recourse to strong fire-heat. Syringe with warm water when the day temperature begins to rise, and again when it is sunny, shutting up the house early; damp the walls and other surfaces instead of overhead syringing when the flowers begin to open. Bring plants into the forcing pit fortnightly, the number of plants being regulated by the stock in reserve, and a light shallow pit may also be filled with such mid-season sorts as Sir Charles Napier, President, and Sir J. Paxton, these plants to be used as wanted. In a pit of this kind the Strawberry will make good progress, as it will emit fresh surface roots into the top-dressing, and develop before being taken into the forcing house. Late plants from which fruit is to be gathered in April and May must be fully exposed to the elements unless the weather is wet—when the lights can be tilted—or very severe, when a few Fern fronds may be spread over the crowns in preference to covering the glass with mats. If well plunged in leaves or tan, water will hardly be needed, but drought must be regarded as most inimical to the Strawberry from the day it is potted until its fruit is ripe.

CUCUMBERS.

Where provision has not been made for economising fire-heat by the use of good fermenting material and covering at night, it is more than probable that red spider, and possibly mildew, will have attacked the plants. For the destruction of the first, the best remedy is light cropping, good feeding, and regular syringing with a weak solution of soft soap and Gishurst compound or clear sulphur water. The second, unless the ventilation is imperfect, may be kept in check by use of dry sulphur applied to the foliage with a fine dredger, and syringed off again with warm water after an interval of twenty-four hours. If these troublesome pests do not quickly give way to the above treatment it may be due to a cold border, insufficient water, or an impure, stagnant atmosphere. In some places canker is very troublesome, and it frequently happens that the sudden collapse of the plant is the first intimation that anything is wrong. The usual remedy is quicklime and sulphur, which should be well rubbed into the parts affected, but prevention being better than cure a liberal admixture of old lime rubble, charcoal, and rough fibrous turf should be used in the compost; the stems of the plants should not be buried, and last, but not least, the admission of fresh air near the level of the bed will have a beneficial effect in purifying the atmosphere. It is of no use trying to force the plants too much; a minimum of 68°, with a rise of 10° to 15° from sun-heat by day will therefore be sufficient for the present: a slight increase may be made upon these figures as days increase in length and brightness. Let the bottom-heat range from 80° to 85°, add fresh, well worked Oak leaves and short stable manure to the beds as the heat declines. Give atmospheric moisture by filling the

evaporating pans with diluted liquid manure and damping all available spaces at short intervals in preference to direct syringing. Keep succession plants steadily progressing by the maintenance of heat and moisture. Avoid close stopping until the trellis is well covered with foliage, and regularly remove male and female blossoms until the time arrives for allowing the plants to carry fruit, but beware of over-cropping young plants.

Mudresfield Court.

W. CRUMP.

INDOOR GARDEN.

THE forcing of Roses in private establishments is, by lack of suitable convenience, often attended with only partial success. For early flowering I prefer plants grown in pots; these, kept dormant by a dry cold atmosphere since October, and not too dry at the roots, if pruned a week or two ago, may now be introduced to the forcing pit, plunged in a bed of leaves slightly fermenting, but not to exceed a temperature of 55°, will soon begin to make growth. Other forcing plants for successional blooming, such as *Azalea indica* in approved varieties, *A. mollis*, *Deutzias*, *Spiraeas*, *Staphylea colehica*, *Dicentra spectabilis*, *Solomon's Seal*, *Lilacs*, &c., should be placed in a forcing house periodically. Selected crowns of *Lily of the Valley*, twelve to eighteen crowns potted in a 5-inch pot, and plunged in a bottom heat of 60° to 65° in small enclosed cases in any stove or forcing house and allowed only a subdued light, come quickly into bloom. *Lilium longiflorum*, *Harrisii* and *thunbergianum* which force well should now be placed in a bottom heat of 55°, and as growth is made fumigate occasionally.

INCARVILLEA DELAVAYI

also claims attention as a forcing plant.

Ixoras recently pruned hard back should be cleaned of all scale by a thorough washing with soft soap dissolved in water, 4oz. to the gallon and a quarter of a pint of XL All added. Syringe the plants with tepid water one-hour after the washing. *Dipladenia amabilis*, *D. brearleyana*, and others may now be pruned back to one-third, or perhaps less, of last year's growth; clean the old wood of scale and keep the plants in the stove, but avoid undue excitement for a few weeks longer. *Dipladenias* will not withstand so low a temperature as *Allamandas*, *Clerodendrons*, and some other stove climbers. All occupants of stoves should be thoroughly cleaned before the re-potting season commences, so that there may be no delay in that important work. Old plants of *Euphorbia pulcherrima* that may be required for propagating should have the wood well matured before being stored away.

THYRSACANTHUS RUTILANS,

Euphorbia jacquiniæflora, *Justicias*, *Eranthemums*, and *Coleus thyrsoides* that have done blooming must be cut back to two or three joints of last year's growth, and well exposed to the light at the cooler end of the stove to induce them presently to make young growth for cuttings. *Centropogons* and *Reinwardtias* require similar treatment with a lower temperature.

FERNS.

Where the old fronds are not required for spores remove them. Also clear the old plants of damp and decaying fronds, giving them all the light possible. Young plants raised from spores must be kept clean and in a position near the glass until repotting is necessary. Prepare fresh soil of light loam, leaf-soil and peat, two parts of the first to one each of the latter, with a good admixture of coarse silver sand and charcoal, this stored in a warm shed or house will be in good condition for use when required.

SEEDS SHOULD BE SOWN

as soon as they arrive from the seedsman in any light, fine sandy soil of *Gloxinia*, *Tydea*, *Gesnera*, *Streptocarpus* (the *Achimeniflorus* varieties are very attractive), *Asparagus plumosus*, *A. Sprengeri*, *Begonia*, *Browallia*, *Celsia Arcturus*, *Canna*, *Clerodendron fallax*, *Cobæas*, *Cyperus*, *Exacum macranthum*, and *Myrsiphyllum*. These may be sown in 5-inch pots half filled with drainage, then

JASMINUM NITIDUM IN MESSRS. WILLIAM BULL AND SONS' NURSERY AT CHELSEA.

filled to within half an inch of the rim with soil, placing a little finely sifted on the surface; then press the whole down firmly with the base of another pot. After sowing, cover very lightly indeed with a little of the soil passed through a fine sieve; water gently through a fine rose, and place the pots on a shelf in the stove or propagating house, cover each pot with paper fitting lightly over the rim, which if kept damp will render any more watering of the soil unnecessary until the seeds germinate.

Wendover.

J. JAKES.

THE FLOWER GARDEN.

THE RANUNCULUS.

This flower has long been a favourite with those who take an interest in the flower garden. For effectiveness in beds the Turban varieties are to be preferred to the Persian varieties, but for compactness, symmetry, and individual beauty the latter

must be admitted to be better; they are rivalled by few other spring-flowering plants.

The time to plant must be regulated by the time they are required to bloom. In good seasons, and in dry and favourable situations, the middle of October will be found a good time to plant. If required to bloom in April and May the end of this month or early in the next will be found sufficiently early. To grow them to perfection the soil requires to be good, rich, and loamy. The soil should be trenched to a depth of 18 inches, and plenty of well-rotted manure mixed with the soil. Manure of a cool nature is best suited for the Ranunculus, and where the soil is light cow manure is preferable. The tubers should be planted about 6 inches apart each way, and covered to a depth of 2 inches; place them firmly in the ground with their claws downwards. It is a good plan to cover them with a little sand before levelling the soil over them. To protect from severe frost cover the bed over with litter or half-decayed leaves; this, of course,

must be removed as soon as the plants begin to come through the ground in spring. As they make their roots near the surface they are more liable than almost any other plant to suffer from drought in the spring months, and careful attention in the way of watering is necessary, or their blooming season will be very short.

THE HOLLYHOCK.

Those who wish to have this old-fashioned but favourite flower looking healthy and flowering well towards the end of summer should now sow some seed in gentle heat, and if grown on with careful regard to the fact that the plant is hardy and cannot well endure a strong heat, the seedlings may be planted out in May, and will bloom well the same season. Care should be taken to procure seed from a good healthy stock, and also from a strain that has the character of producing a large percentage of double flowers.

THE FUNKIA.

This group of liliaceous plants with their handsome foliage will need well looking after in gardens where snails abound. Leaf-mould or cocoon fibre placed round the crowns of the plants, with a little soot sprinkled over occasionally, will prevent the snails and slugs doing them harm. Some of the most distinct, such as *F. sieboldiana* and *variegata*, should only be grown in pots and wintered in frames, and here they will require well looking after, for if the snails find them out the owner will soon lose them.

THE CALCEOLARIA.

Where plants are wintered in cold pits and frames they will now require attention. Give air on all favourable occasions, remove decaying leaves, and keep them scrupulously clean. When the plants begin to grow pinch out the points with the finger and thumb; this should always be done in the early stages of their growth. If left to get 3 inches or 4 inches high before this is done the plants are never so satisfactory as we like to see them at planting time.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

NURSERY GARDENS.

MESSRS. WILLIAM BULL AND SONS, CHELSEA.

FOR many years the late Mr. William Bull had an almost world-wide reputation for new and rare plants and Orchids, and one is glad to see that there is no likelihood of this reputation being allowed to lapse. A visit to Messrs. Bull's establishment recently proved to us that new and rare plants are still cultivated there as largely and with the same skill as before, despite the unfavourable conditions which prevail at Chelsea; the various houses are full of stove and greenhouse flowering plants, Palms and Orchids in the best of health. At the present time there are few Orchids in flower of course, yet all of them have that dark rich green foliage that signifies good cultivation and promise an abundance of flowers.

Some few *Cypripediums* were, however, brave enough to open their flowers, and of these we noticed *C. lecanium giganteum*, Bull's variety, and other good varieties of *C. lecanium*, *C. pavonium*, *C. nitens*, *C. Swinburnei*, and *C. selligerum*. In the Cattleya house are numerous plants bearing seed pods, the result of careful and systematic hybridisation, each of which may contain the germ of some hybrid *Cattleya* or *Lelio-Cattleya* of startling beauty. The most disappointing period (disappointing because it is responsible for so many failures) has yet to be passed through, however. The greatest difficulty lies not in the propagation of Orchids nor in obtaining the seeds, but in raising and cultivating the seedlings. *Cymbidium elegans* and *C. Mastersii* were in bloom, and a number of *Odontoglossums*; the *Miltonias*, potted in the new and now much

recommended leaf-soil, were a picture of rude health.

The collection of stove plants contains many remarkable both for their brilliantly coloured and beautifully marked foliage and bright flowers. Among the former, *Dracæna Queen Victoria* is conspicuous; its drooping creamy yellow and green leaves are very handsome. This *Dracæna* has been awarded a first-class certificate by the Royal Horticultural Society. *Hydrangea speciosa nivalis*, whose white centred leaves, with broad green edges, are singularly attractive; *Deyenia elegans fastigiata*, with prettily variegated erect grass-like leaves; *Maranta picta*, *M. insignis*, two of the best of these old and worthy, yet neglected, stove plants; and *Nepytithis picturata*, which has beautifully marbled sagittate leaves, are others of much value. The collections of hot-house climbers and of economic plants in Messrs. William Bull's nursery are exceptionally comprehensive. There are probably few other establishments where the enthusiast could so well replenish his collection, should his Cocoa, Pepper, Tea, Coffee, or other plant of economic value be lost. In this Chelsea nursery they and many others are growing, one can hardly say in primitive luxuriance; but they are evidently quite at home and happy in their surroundings.

Ardisia primulæfolia is another plant that one cannot fail to notice: the green leaves form a pretty setting to the bright red berries, very pleasingly disposed in small bunches. *Epiphyllum delicatum* (given a first-class certificate in 1898 under the name of Princess) is a plant that should not be lost sight of. *Ceropegia Woodii*, of which a drawing was given in THE GARDEN last year, is a delightful little plant for growing in suspended pans. The long slender drooping stalks with their uniquely pretty grey leaves are most ornamental.

Ficus radicans variegata and *Ficus repens variegata* are valuable varieties of valuable species. Every one knows the value of *F. repens* for covering bare walls in warm houses, so that its variegated form is sure of a warm welcome. *Aralia trilobata* is a most distinct plant that should also be mentioned. Of course, in addition to those we have noted, there are hundreds of Palms, Ferns, and the better-known stove and greenhouse plants. Several pits are full of seedling Palms only a few

months old. There must be many thousands of these alone that before long will become marketable plants. These few remarks will serve to show how plants notoriously difficult of culture may be successfully grown within the metropolis.

THE FRUIT GARDEN.

HARDY FRUITS IN SEASON.

APPLE LANE'S PRINCE ALBERT.

FEW Apples are more useful than this. Although excellent for cooking at Christmas, it is even more valuable for dessert during April and May. This variety bears excellent crops of fruit in most parts of the country. In the North the fruits do not colour so well, but they are more acid and keep longer. The best fruits seem to be produced by bush and standard trees; the former must not be hard pruned. When grown as a standard there should be plenty of room between the branches, for owing to its heavy cropping the weight of fruit often makes the branches droop.

APPLE ADAMS' PEARMAN (NORFOLK PIPPIN).

I AM sending you a few specimens of this useful dessert Apple. This is one of the best varieties we have, and worthy of general cultivation. It does well in this neighbourhood, rarely failing to bear. Last season we had good crops of fruit, and although we had but little sun the fruits are of good colour and flavour. The tree is a free and healthy grower and easily distinguished from other varieties. It is an excellent bearer even when young, and succeeds well as an espalier, but as a standard it is very ornamental and has but few equals.

COX'S ORANGE PIPPIN.

We had good crops of this Apple last season; the colour is good (rather better than the flavour). Many of the market growers in this neighbourhood planted largely of this variety a

few years ago, but owing to its fickleness in bearing have ceased to do so, but those who have kept their trees were rewarded last season with an abundant crop of well-coloured fruit.

Ashwellthorpe, Norwich.

T. B. FIELD.

[Excellent fruits of two of the best winter Apples. As Mr. Field says, Cox's Orange Pippin is not first-rate in flavour, but the fruits of Adam's Pearmain were delicious.—Ed.]

APPLE LADY HENNIKER.

This variety is classed as a kitchen or dessert Apple, and if kept late in the year is very good for table. The fruits, though large, are very handsome. For cooking in the autumn I do not think we have any variety to surpass it. Another good point in its favour is its free growth; it makes a good bush, a handsome pyramid, or does well as a standard in a sheltered orchard, and the fruits, given cool storage, may be kept well into February, but it is at its best in December. The trees when grown in good land are of upright growth, and owing to the size of the fruits are soon injured by gales. I prefer what are termed dwarf standards or bush trees. I recently saw a splendid lot of fruits of this variety in heavy soil in an exposed position in the eastern parts of the country. Lady Henniker is a favourite exhibition Apple.

PEAR NOUVELLE FULVIE.

This is by no means a handsome fruit, as even the finest or best grown are somewhat uneven, and when quite ripe of a dull green colour on the shaded side. For many years I have relied upon this variety for February and March supplies. Last year the fruits were ripe much earlier (at Syon). Doubtless in the North they would be later, and the longer we can keep good fruits of the Pear the more useful they are. My reason for sending a note is on account of its usefulness for dessert at this season, and in most years it may be had good even later. Few Pears in winter are of better flavour; it is rich, with melting flesh, and is very juicy. I have never found Nonville Fulvie fail to crop. Doubtless that is on account of its late flowering. The tree makes a handsome pyramid, and in the northern and eastern counties is well worth wall space. It is advisable to allow the fruits to remain on the trees as late as possible, as if gathered early they do not keep well and shrivel badly.

PEAR BEURRE PERRAN.

There are few really good Pears at this season, so that any variety better than others is well worth noting. The above is not much grown, though it is only fair to add that I have seen it exhibited on several occasions earlier in the season during the last year or two, but of course at that date one could not tell what were its qualities. So far I have only small trees, but even these crop freely, and any Pear which crops well in a young state may be relied upon. With us this variety makes an excellent cordon. The flavour is delicious for a late Pear, and the fruits are juicy and rich. The tree grows freely and the fruits are in season from December to February. Last season the fruits were ripe a little earlier, but I remarked that was usual with most varieties last year. It recently received an award from the Royal Horticultural Society for its excellence as a winter Pear, and certainly it has proved worthy of the same. With regard to crop and quality I can only note its merits from a southerner's point of view, and in a light soil, anything but a good Pear soil, it is very good. It also keeps well.

G. WYTHES.

OLD ORCHARDS OF ENGLAND

THE old fruit orchards of this country present ample food for quiet reflection. The history of many of them is obscure, their origin unknown, but the hands that planted them did something for

APPLE LANE'S PRINCE ALBERT. (Three-quarter natural size.)

posterity, and the present generation is still reaping the benefit of the forethought and labour of those who have long since died. To many of the gnarled old trees in home orchards there is a sweet sentiment attached. Trust the average schoolboy for knowing which specimen produces the most palatable Apples, and in years to come when he revisits the scenes of his boyish frolics the old Apple tree presents itself in the light of a close acquaintance. If the old orchard should eventually become his, the associations of the ancient trees are precious, and this doubtless is why so many decrepit specimens remain.

But there is a practical side to the question as well. We reap the benefit now of the work our fathers did in planting orchards, and is it not our duty also to continue the work, so that future generations may live to bless us in their turn? We should not think too much about dwarfing stocks and quick returns in the shape of fruit in two or three years. Not that I would be disloyal to Paradise stocks and dwarf Apple trees; but they have their place in gardens and plantations, and should in no way affect the establishment of permanent orchards, that will not only be profitable to the planter if he adopts the right methods at the beginning and has patience to wait, but also to those who follow him.

We may learn something also from the varieties found in old orchards to guide us in the work of selection. I do not suppose there is an old orchard in the country but that contains certain favourite varieties. The reason is not far to seek, they are good ones; but the same orchards also contain other trees that have been bidding for favour for a lifetime, but have never found it. Why not? Because they are undeserving, being seedling forms, no doubt, inferior in size or quality, or both.

Do not be in too great a hurry to blame the planter for encumbering the ground all these years with worthless Apples amongst the good ones, because in all probability he had no first-class nursery to go to, and had to rely on seedlings for his stock. Remember also that some of our best Apples have been nothing more than chance seedlings, found in out-of-the-way orchards, and owe their origin entirely to Nature. We bless the old planter for the good Apples he has left behind him, and blame him for the presence of the poor ones. This is human nature all over, but instead of finding fault it is better for the present day planter to make the most of the improved facilities of the times and plant only varieties of proved merit. It has been said that we have too many varieties of Apples, but this is a matter of opinion. One thing is certain, however, we have far too many poor varieties, and if these could be done away with and be replaced at once with the best only, Apple growing would be a more profitable undertaking than it is. This is asking too much, however, because few men have the heart to do away with a tree, no matter how poor the variety is, so long as it bears, and until the inferior varieties, with which home orchards are studded, wear out in the ordinary course of Nature their presence will be felt. But in the future we may expect to get more good and less bad Apples, for no man nowadays who has any thought for his own interest, and that of those who follow him, would think of planting any but approved varieties.

INITIAL MISTAKES.

Many a man has set out to establish an orchard with the best intentions in the world, but has failed absolutely through some blunder at the outset. Perhaps he never considered the site, and planted the orchard just where he wanted it, instead of in the aspect where the trees would do well. Situation is obviously the first thing to consider, and it is wrong to expect fruit trees to grow and flourish in the face of every stinging east wind that blows, unless measures are adopted for providing some means of shelter. "Why don't they grow?" says the man who has spent time and money in planting standard trees, and after a few years is disappointed with the result. Ah! why not? Examine the ground. Perhaps it is water-logged and has no natural means of drainage. There is the cause at once, and the spending of a few pounds in labour and drain-pipes at the

beginning would have made all the difference between failure and success. There is nothing imaginary about such a case as this. It is a stubborn fact, and one need not travel far to find instances of both hopes and orchards wrecked through planting trees in cold undrained soil.

G. H. H.

(To be continued.)

THE KITCHEN GARDEN.

THE CABBAGE UNDER GLASS.

WHILE agriculture in England has been suffering from severe depression during the past twenty or thirty years, so much so that in the opinion of many agriculturists, under the present condition of free imports of cattle and grain from all parts of the world it can only escape further depression by the enactment of some law for its preservation, it is pleasant to reflect that one aspect of horticulture—market gardening—has made immense progress during this time, and that in the face of the same stern and ever-present competition. There is scarcely an article grown by our market gardeners that is not imported in immense and increasing quantities free from abroad, and at all seasons of the year. The increased development not only in the culture of fruits and vegetables, both under glass and out of doors, but also of cut flowers and plants for market, has been immense during this same time. Whether this is due to the greater energy and enterprise of the market grower, or to the greater demand for the produce of the soil in which he deals, we will not stay to consider, but the fact is patent that this aspect of gardening has grown from an insignificant industry into one of great importance and value to the nation.

As regards vegetables alone, it is not too much to say that at the present day hundreds of acres of land in this country are covered with glass and devoted to the cultivation of such vegetables as the following: Potatoes, Peas, Broad Beans, Runner Beans, French Beans, Vegetable Marrows, &c., with satisfactory results to the grower; but few I think are aware of the considerable area of glass-covered land which is devoted to the culture of the sometimes despised and lowly Cabbage in some districts around London. I have been intimately associated with the cultivation of the land for the past forty years, and certainly to me it was a surprise when, some few months ago, on visiting one of the large market gardens I came upon an immense number of glass houses covering a matter of five acres of land, and that land cropped with Cabbages! These houses were divided into ten sections, each section covering half an acre. The roofs were supported by iron rafters resting on pillars, the only bricks used were for the building of the outside walls, so that viewed from inside the whole scene presented to me an extraordinary appearance—a colony of sturdy little Cabbages snugly housed under glass!

The time of my visit was in the month of April, and then the Cabbages were turning in rapidly, beautiful, crisp, hard heads, with scarcely a "bolter" amongst them. They were marketed every day in large quantities. Those of us who know too well the dearth of good vegetables in gardens at that season of the year, after a prolonged and hard winter, do not need to be told of the value of

such a crop as this. The seeds were sown about August 20, and the young plants put out at the end of September, 15 inches apart each way. A narrow alley is left in the centre of each section for the purpose of watering, which is done by means of a hose attached to hydrants, the water being applied by boys at small cost. The houses (which are unheated) during summer yield heavy and remunerative crops of Tomatoes. Immediately the crop of Cabbages is cleared early in May the Tomatoes are planted, and they again turn out in September to make room for the former. It goes without saying that the ground is heavily manured and well cultivated, sometimes with the spade and sometimes with the plough. There is little or no expense attached to the culture of this crop in the way of labour, most of which is done by women.

OWEN THOMAS.

MUSHROOM GROWING IN GARDEN, FIELD, AND COTTAGE PLOT.

(Continued from page 13.)

MUSHROOM GROWING IN OPEN SHEDS.

The culture of the Mushroom in the open shed is had recourse to more in the private perhaps than in the market garden, with the object of securing crops in hot weather from the end of June to the end of September, when they cannot be well grown in the Mushroom house proper. Any outbuilding will do that has a roof over its walls, but preference should be given to that part which may face the north. Here let a bed be formed, exactly on the same lines as advised for the house (only it should be 12 inches deep), and spawned as directed, as soon as the conditions are favourable, the surface soiled, smoothed, and made firm. It must be covered over to the depth of 5 inches or 6 inches with the long littery straw shaken out of the manure when preparing for the Mushroom bed. I am presuming that every precaution has been taken in preparing the beds as directed for those in houses. In that case the grower need not trouble to examine the bed again at least for a month, unless he anticipates trouble from rats, mice, or other pests, against which, of course, the beds must be protected. In about a month, or five weeks at the latest, the straw covering may be removed and the bed given a good watering with warm water, as previously recommended, when the covering should again be placed on the bed as before. In about ten days or a fortnight after this the grower should be rewarded with a heavy and remunerative crop. When these beds are in full bearing pick the Mushrooms about three times a week. It is not desirable to uncover the beds more often than is absolutely necessary, as the fact of often having to remove the straw, however carefully the work may be carried out, is attended with more or less damage to the crop. The treatment for the second crop must be the same as that advised for beds in houses.

OUT OF DOOR BEDS.

This is the system most favoured and almost exclusively practised by our market gardeners in the suburbs of large cities where manure is plentiful, especially round London, and where large sums are said to reward the growers for their skill and labour.

By this method of culture it is possible to have Mushrooms every day in the year, and that without the protection of a building of any kind, and where the cultivator is expert in his business, and especially when he can couple with it the trade of spawn making this branch of market gardening is without doubt very remunerative. The out of door

FLOWER BORDER AND OLD SUNDIAL AT FYFIELD MANOR.

beds are formed in the shape of wedge-shaped ridges, and measure when built, rammed, and completed $2\frac{1}{2}$ feet wide at the base, the same in height, and the ridge 6 inches wide at the top. The material for these outside beds should have a larger proportion of short straw in its composition than advised for indoor beds, for the reason that the heat would be retained longer and also that rain would be more effectually thrown off during winter. As soon as the beds are formed in condition to receive the spawn insert this, taking care that the temperature is not above 82° and on the decline. These conditions being secured, the beds must be earthed up in a similar way to Potato clamping. When this operation is completed the bed should receive a good

watering with warm water and afterwards be beaten with the back of a spade until the surface is of a pasty consistency. This will conserve the heat of the bed much longer than if left rough. During warm summer months the amount of necessary covering will be comparatively small, and the best material to use is the straw shaken out of the Mushroom bed material. As winter advances a heavier covering will be necessary. Indeed, the condition of the weather must govern the amount of protecting material to be applied, and as long as this is sufficient to keep up a temperature of from 45° to 50° on the surface of the beds it is possible to have Mushrooms from these even in the coldest weather.

During winter these beds will require little or no water, but in spring and summer it must

be applied liberally two or three times a week. After the best of the first crop is over a good soaking of manure water from the cow or stable yard often works wonders in securing a good second and successional crops. In the spring and summer the grower must be on his guard against allowing these out of door beds to become dry, because once allowed to become so it is most difficult effectually to saturate them afterwards.

(To be continued.)

MISCELLANEOUS.

A WIND-SWEPT GARDEN.

IT was on the top of a Surrey hill, 800 feet above the sea-level, being the resting-place of rooks as they flew from valley to valley, the nesting-place of larks, and the happy hunting ground of hedgehogs. Instead of walls a double row of trees and shrubs had been planted round it. They made slow growth, and before they could give much protection the experiment was tried of growing Roses. Two large pens were made with hurdles, and four beds were dug in the enclosed turf. The natural soil consisted of a stiff yellow loam filled with flints. The flints were taken out and Rose bushes, chiefly French Roses and Austrian Briars, were planted. This was in the autumn, and all straggling shoots had to be cut back or the bushes would have been uprooted by the wind. The hurdles broke the force of the wind, and the bushes thrived and flowered well the next summer, and profusely the summer following, giving splendid flowers from the middle of June until late autumn.

Flowers were wanted in other parts of the garden where hurdles would have been unsightly. Bulbs such as Daffodils and Scillas and plants like Scabious grew well, but the more choice kinds were cut off by the wind until the following plans were adopted—to grow everything from seed without transplanting, and to sink the flower beds slightly below the level of the turf. Then the plants grew sturdy and the pure air made the flowers brilliant. A bed of Pansies looked like a mosaic of beautiful colours set in the grass, for all the flowers turned their faces to the sky, their stalks and leaves being hidden beneath the edge of the turf.

WINIFRED SPURLING.

APPLE PIE.

THE following lines on the antiquity of the Apple pie as a national dish, written about 1710, will probably be interesting to many readers, be they Apple growers or otherwise:—

“When first this infant Dish in Fashion came,
The Ingredients were but coarse, and rude the Frame;
As yet unpolished in the Modern Arts,
Our Fathers ate Brown Bread instead of Tarts;
Pyes were but indigested Lumps of Dough,
Till Time and just expense improved them so.
King Cole, as Ancient British Annals tell,
Renown'd for Fiddling and for Eating well;
Pippins in homely Cakes with Honey stewed;
Just as he Baked, the Proverb says, he Brewed.
Then greater Art succeeding Princes show'd,
And modell'd Paste into a neater mode;
Invention now grew lively, Palate nice,
And Sugar pointed out the way to Spice.
But here for Ages unimprov'd we stood,
And Apple Pye was still but homely Food;
When Godlike Edgar, of the Saxon Line,
Polite of Taste, and studious to Refine,
In the Desert perfuming Quinces cast,
And perfected with Cream and rich Repast.
Hence we proceed the outward Parts to trim,
With Crinckumcranks adorn the Polish'd Brim,
And each fresh Pye the pleas'd Spectator greets
With Virgin Fancies and with new Conceits.”

The writer proceeds to give instructions on the creation of an Apple pie, on the use of brown sugar, clove, and candied peel, on the conduct of the crust, and the choice of a baker; but these particulars would possess no interest for our readers, and are therefore not reproduced.

W. N. B.

THE GARDEN

No. 1628.—Vol. LXIII.]

[JANUARY 31, 1903.

THE HORTICULTURAL HALL.

IT is rumoured—though we have no authority for stating it as a fact—that the building committee have accepted the scheme that is so generally and deservedly condemned, because it has not money enough to do better. If this is the case it would explain the thoroughly cheap appearance of the design as to the Hall itself, though it would not account for the mean and undignified style in which the front is conceived. A building may be absolutely plain, a great deal plainer than the proposed façade, and yet may have some qualities of repose and dignity. Many a large warehouse, factory, or mill building, without an atom of ornament or any intentional thought of beauty on the part of the designer, has good qualities such as are here absolutely wanting.

We wish this money were for the establishment of the good garden in unpolluted air and soil that is so sorely needed. In a few years such a garden would probably become self-supporting, and meanwhile it would be doing splendid educational work—the *true work of the society*. The proposed building, so unattractive for various letting purposes, can never earn its keep, as a better one might do, and will burden the society for ever with the whole train of rates, taxes, and upkeep that would not be greater for a worthier building.

But as we have stated before the Hall has been decided upon, and therefore we support the council, though we hope it is not too late to determine upon a more worthy scheme. We notice that many who clamoured for the Hall, and apparently forced the hand of the council, have not given that substantial financial assistance one might be led to expect from their noisy demonstrations.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE annual general meeting and election of pensioners on January 22, once more brings this institution into prominence, and provides an opportunity of again recommending to our readers the beneficent work which it accomplishes, and of urging its claim for support. There are now 202 persons receiving pensions from its funds, and this represents an annual disbursement of some £3,500—a heavy liability. There were forty-six candidates for election last week, yet the funds of the institution would admit of seventeen only being elected.

The remaining twenty-nine were disappointed, doomed for another year to live in such distress as only dire poverty can occasion. All the forty-six candidates are known to be in needy circumstances, for each case is thoroughly examined by the committee before being placed upon the voting paper.

The apathy of the British gardener, so far as his support to this most deserving charitable institution is concerned, was strongly commented upon by Mr. Harry J. Veitch at the afternoon meeting, and by Mr. Alfred Watkins in the evening. Among the subscribers to the institution, which exists solely for the benefit of gardeners and their widows, the percentage of gardeners is very small. This is certainly not as it should be; even if he were actuated merely by selfishness, the British gardener might be expected to subscribe, for in old age he might confidently reckon upon receiving a pension of £20 a year. This institution, however, is not a self benefit society, but a benevolent one, and to all with a spark of kindly and charitable feeling in their hearts it will appeal as such. If gardeners throughout the United Kingdom (for, as Mr. Watkins aptly said, this institution knows neither creed nor country) would but do their duty towards the unfortunate members of their craft there would not now have to be recorded the sad news taught by the recent election, of the bitter disappointment of twenty-nine distressed gardeners and their widows, two of whom have had the same bitter experience six and seven times respectively. In this world all cannot be successful, so if gardeners will not subscribe in the cause of charity and benevolence, they should do so for themselves, if they are not short-sighted, that should they in their turn one day be losers in the battle of life they may not be altogether without some means of sustenance.

The very generous gift of Mr. N. N. Sherwood of five guineas to each of the unsuccessful candidates who were formerly subscribers, together with donations from the Victorian Era and the Good Samaritan Funds, will bring gladness and relief to the recipients during 1903, and were the gardeners of the country to subscribe as they are able that gladness and relief would still be greater. There is no excuse for those not giving who can afford small sums only, for as Mr. Peter Veitch told those present at the dinner the country auxiliaries are always very glad to receive small amounts.

Mr. Alfred Watkins outlined a scheme to increase the income of the institution that we think to be capable of much good. Briefly it is this: Head gardeners throughout the kingdom should endeavour to persuade the young men under their charge to give one penny each on certain days of the week, or once a week, as may seem best, to the institution, the money to be collected by the head gardener. This is quite a simple plan, yet if thoroughly

and systematically practised in gardens throughout Great Britain and Ireland, its results would prove of incalculable assistance to the Gardeners' Royal Benevolent Institution.

KEW NOTES.

INTERESTING PLANTS IN FLOWER.

Temperate House.

ACACIA ACINACEA, *A. baileyana*, *A. dealbata*, *A. linearis*, *Aloe platylepis*, *Cestrum elegans*, and *Senecio grandifolius*.

Palm House.

Brownea coccinea and *B. grandiceps*.

T Range.

Aphelandra nitens, *Dædalacanthus macrophyllus*, *D. nervosus*, *Eranthemum albitorum*, and *Erica melanthera*.

Orchid Houses.

Aerides Vandarum, *Broughtonia lilacina*, *Bulbophyllum neilgherrense*, *B. Pechei*, *Calanthe vestita* var. *Regnieri*, *Cypripedium callosum*, *C. Morgania*, *C. nigratum*, *C. politum*, *Dendrobium atrovio-laceum*, *D. aureum*, *D. burfordiense*, *D. Cassiope*, *D. Curtisii*, *D. dominianum*, *D. fytchianum*, *D. nobile*, *D. primuminum*, *D. Rolfei*, *D. speciosum*, *D. superbienis*, *Epidendrum calamaricum*, *E. ciliare*, *E. Endresii*, *E. fragrans*, *E. kewense*, *E. nocturnum*, *E. xanthinum*, *Gomezia Barkeri*, *Lalia virens*, *Masdevallia melanopus*, *Maxillaria variabilis* var. *lutea*, *Oncidium splendidum*, *Otocchilus fusca*, *Phaius Blumei*, *Platyclinis arachnites*, *Saccolabium bellinum*, *S. gemmatum*, *Satyrium odorum*, *Selenipedium calurum*, *S. porphyreum*, *S. Rœzii*, *Seraphyta multiflora*, *Sophronitis violacea*, *Tainia latifolia*, *T. penangiana*, and *Vanda amesiana*.

Succulent House.

Agave Sartorii and *Cotyledon fulgens*.

Greenhouse.

Among other things, *Centropogon lucyanus*, *Darwinia fuchsioides*, *Jasminum confusum*, *Moschosma riparium*, forced bulbs, forced shrubs, and other things.

Herbaceous Ground and Rockery.

Adonis amurensis, *Crocus chrysanthus* varieties, *C. Imperati*, *C. Korolkowi*, *C. reticulatus*, *C. vernus*, *Helleborus caucasicus*, *H. orientalis*, *H. o. var. roseus*, *H. viridis* var. *intermedius*, *H. v. var. purpurascens*, *Iris Danfordiae*, *I. histrioides*, *I. maricoides*, *I. stenophylla*, and *I. Tauri*.

Alpine House.

Adonis amurensis, *Colechicum hydrophilum*, *Cop-tis trifolia*, *Crocus* (various species), *Cyclamen Coum*, *C. ibericum*, *Galanthus caucasicus*, *G. Elwesii* var. *robustus*, *G. nivalis*, *G. plicatus*, *Iris*—in addition to the species in flower outdoors: *I. alata*, *I. Haussknechtii*, *I. Histrio*, *I. reticulata* var. *Krelagei*, *I. r. var. sphenensis*—*Merendera caucasica*, *Narcissus bulbocodium* var. *mono-phyllus*, and *Primula megaseefolia*.

Arboretum.

Chimonanthus fragrans var. *grandiflora*, *Erica carnea*, *E. mediterranea hybrida*, *Garrya elliptica*, *Lonicera fragrantissima*, and *L. Standishii*.

NEW PLANTS OF 1902.

FLORIST'S FLOWERS.

If we except the Cactus Dahlias, of which quite a number have received the award of merit during the past season, the novelties in the other chief groups of florist's flowers is not great. Roses, Begonias, and Carnations, however, are each represented. The following list includes the whole of the varieties honoured by the Royal Horticultural Society. "A.M." signifies "award of merit"; "F.C.C." "first-class certificate."

Auricula Firefly (alpine).—A flower of exceptional size and merit. The colour is maroon-crimson, with a centre of quite clear pale yellow. Evidently of vigorous and compact habit. A.M., April 8.

A. Rosy Morn (alpine).—The chief colour in this flower is rosy or cherry-red, which is again separated from the creamy yellow centre by a thin circle of purple. A.M., April 8.

A. Wm. Herwood (show var.).—A green-edged kind, the creamy paste surrounded by a ring of blackish purple. A.M., April 8. This trio of good Auriculas was contributed by Mr. James Douglas, Great Bookham, Surrey.

A. Alexandra (border).—Strictly we imagine this is a border variety, with its large yellow blossoms appearing in great freedom in quite large trusses. It is scarcely a florist's flower, but a very vigorous and good garden plant. From the Misses Hopkins, Knutsford, Cheshire. A.M., April 22.

Begonia Erquisite (tuberous-rooted).—A large, beautiful, and well-formed flower, which is double, of a fine clear salmon tone, white towards the centre, and prettily fringed at the margin of the undulated petals. From Messrs. Cannell, Swanley. A.M., June 10.

B. Masterpiece.—A well-named variety, certainly in the self colours. It is tuberous-rooted, with very large crimson flowers. A.M., June 24.

B. Miss Dorothy Hardwick.—A tuberous-rooted Begonia, with flowers of great size. The colour is a very beautiful and pleasing soft pink. A.M., June 24. This fine pair were from Messrs. Blackmore and Langdon, Bath.

B. Agatha compacta.—This is a dwarf, compact, and densely-flowered B. Gloire de Lorraine, with rich or rose-tinted pink blossoms. The sturdy plant is less than 1 foot high and very attractive. As indicated in the name it is a dwarf form of B. Agatha. F.C.C., November 18. From Messrs. Veitch and Co., Limited, Chelsea.

Bouvardia King of Scarlets.—A large, handsome novelty. The flowers are rich in colour, while the division of the corolla is distinctly broader than in other red-flowered kinds. The variety is of vigorous habit and very free. A.M., December 9. From Mr. Robson, Altrincham, Cheshire.

Carnation Viscount Kitchener.—Briefly this is a white ground fancy variety of the Tree or winter-flowering type. The flowers are large, of good form, the petals striped freely with reddish scarlet. A.M., November 18. From Messrs. William Cutbush and Sons, Highgate.

C. Duchess of Westminster (Malmaison type).—This is, we consider, one of the finest varieties ever exhibited. The colour is exceptionally good—a full pink, with salmon shades on the inner surface of the petals. To its fine colour we are pleased to notice a powerful fragrance. Certainly a promising addition to this set. A.M., May 20. From the Duke of Westminster, Eaton Hall, Cheshire (gardener, Mr. N. F. Barnes).

C. Lady Hermoine (border type).—We single this out among Carnations of good form as an advanced type of the broad-petalled class. This, combined with the uniformly large size of petals right to the centre, stamps it as one of the best. There is, however, no reason why so good a flower in form may not be transmitted to other border kinds in the near future. The colour is salmon-red or rose, the variety as vigorous as it is good. A.M., June 10. From Mr. Martin Smith, Hayes, Kent (gardener, Mr. Blick).

C. Lady Carrington (border type).—This is from the same raiser as the last, and, like it, of very fine form and large size, while the colour is a delicate pink. A.M., July 8.

C. Bookham White Clove.—Pure white, well-formed, Clove-scented, and free. A.M., August 5.

C. Cedric.—A finely-formed yellow ground kind of large size. The petals are strongly marked with red at the edges and again through the centre with the same colour. A.M., August 5. The above pair were from Mr. James Douglas, Great Bookham.

C. Duchess of Portland.—A very pretty and welcome shade of pink in a Tree or winter-flowering Carnation of good habit. The flower is of the soft or pale shade of pink and sweetly scented; the habit bushy. A.M., November 4. From Messrs. William Cutbush and Sons, Highgate.

C. Louis Botha (border).—A nearly pure white kind, very full and showy, the centre petals faintly striped with white. A.M., August 5. From Lady Ardilaun, Clontarf, Dublin (gardener, Mr. A. Campbell).

C. The Shah.—A yellow ground variety, lightly striped with bright scarlet; indeed, one of the most effective of its class we have yet seen. The flowers are large and handsome and very showy. A.M., August 19. From Mr. Martin Smith, Hayes, Kent.

(To be continued.)

OBITUARY.

HERMANN WENDLAND.

WE regret to learn of the death of this distinguished botanist, who, as many of our readers are aware, was Director of the Royal Gardens at Herrenhausen. The following article about the late Herr Wendland appeared in the "Kew Guild Journal" of 1900:—

"He was born in October, 1823, in Herrenhausen, where his father and grandfather preceded him as Director of the Gardens, and where he received his early training. He left his father to study under Professor Bartling in the Botanic Gardens at Göttingen and Dr. Schott at Schönbrunn, proceeding thence to Kew. Here he was employed nearly two years as a gardener, leaving in 1849 to return to Herrenhausen, where he worked as assistant until his father's death, which occurred in 1870, when the son was appointed Director. In 1857 he was sent on a botanical expedition into Guatemala and Central America, where he collected many new and interesting plants and introduced many by means of seeds, &c., afterwards distributing them from Herrenhausen. One of his best-known discoveries was *Anthurium scherzerianum*, which he found in Costa Rica, and which flowered at Kew in 1862, when a figure of it was published in the *Botanical Magazine*, t. 5319, where it is described as 'a very singular little plant.'

"Herr Wendland prepared and published in 1854 a list of the Palms cultivated in European collections. This was followed by researches amongst the plants of this difficult Order with so much zeal and activity that he soon became the

recognised first authority upon Palms. Sir Joseph Hooker acknowledges his indebtedness to Herr Wendland's monographs, &c., in the preparation of the *Genera Plantarum*. He has also made a specialty of the cultivation of Palms, the collection at Herrenhausen rivalling that at Kew. There has always been a ready interchange of living examples between the two establishments.

"Orchids have also been objects of special attention with Herr Wendland, the collection he has formed and cultivated with exceptional success for many years being described by his bosom friend, the late Professor Reichenbach, as by far the richest in botanical species that had ever been formed. Until within the last few years, Herr Wendland visited Kew annually, spending several days amongst the cultivated Palms, Orchids, &c., and endearing himself to the officials by his urbanity. His knowledge of tropical plants and their cultural requirements is exceptional, and his readiness to impart this knowledge to others made his visits profitable as well as enjoyable.

"In 1891 Herr Wendland celebrated his fiftieth year of professional work. He was present at the Ghent Quinquennial in 1898, and officiated as a judge."

MR. JOHN S. MURRAY.

MR. JOHN S. MURRAY, the well-known and highly-esteemed pioneer florist of Montreal, passed away on the 31st ult. Some years ago he suffered a stroke of paralysis, from which he never recovered, but he was able to be up and around the house in an invalid chair and to receive friends. He appeared to be in his usual health until the last day of his life, giving no warrant that the end was near. Born at Alyth, Forfarshire, Scotland, sixty-nine years ago, he came to Montreal in 1854, where he worked as a private gardener for about eight years. He then started, on a very small scale, in the flower business, and soon built up one of the best in the city, being thus the pioneer among the florists there. He was a quiet, home-loving gentleman, attentive to his business and highly esteemed by the trade, who sent floral tributes in abundance and attended his funeral.—*The American Florist*.

MR. GEORGE RAWLINGS.

WE are sorry to hear of the death of this famous Dahlia enthusiast, who passed away at Pen-y-Van, Whitebrook, Monmouth, at the ripe age of eighty-three. With his death we lose a florist of the old school, whose work among Dahlias at Romford, Essex, will long be remembered. Many of the most beautiful of the show varieties were raised by Mr. Rawlings.

NOTES FROM SWANSWICK.

WEEDS.

A MAN'S daily task of digging in these parts is a "lug." What that obscure measure may be I know not, but if it is the amount our gardener gets through in a day, it is not to be recommended as a standard. Not that he is lazy; a Somerset man is seldom coruscatingly brilliant in mind, and cannot, as a rule, be called quick in his movements, but a good specimen of him is always industrious and thorough. It is the weeds that kill! "Crazy" is about the worst. This is Somerset for the wild *Ranunculus*, and no matter how deep you bury this hateful weed it never dies, but sends up a long feeler, with a sucker at the end, to the surface. Arrived there, it does not take the Crazy long to run in all directions, after the manner of a Strawberry, but far more firmly anchored at all its stations. In our heavy land you cannot pull Crazy out with fingers, but must follow it down with forks, a good part of the way to Australia. "Withvine" (obviously "Withy vine" by rights) is another delight, known outside our centre of the universe as Bind-

weed, and, I believe, known equally well everywhere, and with equal affection regarded. When it cannot get up to the surface it writhes and wriggles, and the long corkscrew twists of it that come up when you remove soil that has been thrown up out of a trench, and thus buried the *Convolvulus* deeply, are truly interesting an object-lesson of the greater vitality in

auction. Those which were planted in the beds are all up and mostly in bloom (and I am bound to say the auction ones, at about one-third the price, are much the finer): but of those in the grass not a single one has so far appeared, even by a leaf-tip, although their several situations are sheltered and apparently all that could be desired.

Daffodils, planted at the same time are coming up well. Possibly the Snowdrop in grass shares the elusive habits of the Winter Aconite, which has also made no show at all, and therefore, from all accounts, may be confidently expected next year. Other bulbs are much too forward, and will probably pay heavy toll for their foolhardiness, for although we are exceedingly well sheltered by trees and shrubberies, and feel the frost comparatively little, we have already had three severe spells of it, each lasting over a week, and still have the dangerous month before us.

SIMPLE PROTECTION.

Happy is he that cutteth down a Fir tree at the beginning of winter. Nothing is more useful or more handy as protection for most tender things than a moderately-sized Spruce bough. There is a natural arch or spring in it which

enables it to be laid over sprouting Lilies or Irises, or almost any bulbs and corms that have growth above ground likely to be hurt, without crushing them. It, or they, can also be laid against a wall over small tender wall shrubs and the lower parts of creepers. It is astonishing what an amount of damage such a trifling precaution sometimes averts. I have a number of cuttings of different shrubby Veronicas for which no frame was available, and as they were a gift from a beautifully warm and well-known garden in Devonshire, they might be expected to resent hardship, especially as they were rooted rather late, yet up to the present I have been fortunate enough to keep every one. They are enclosed by a bank or wall about 15 inches high of sods, and covered with Fir boughs at all times, except those of sunshine and brightness, which are at present extremely infrequent.

There is a pond—or rather there was a pond

before its water supply partially failed—in this garden, and it is a spot at which I fear my native obstinacy has displayed itself very frequently. On only one solitary occasion have I taken any visitor down there without being advised, more or less authoritatively, to make its extensive banks—since the water shrank there is almost nothing but bank to the affair—into a fernery. It is bad taste, of course, but I think Ferns very uninteresting in comparison with flowering plants, and to give up some eighty square yards, with a grand bog in the centre, to a race with which I have little sympathy seems to me waste. The desirability of Ferns is apparently always suggested to casual beholders by half the area being in dense shade, but it will now no more be so, for we have sacrificed an enormous variegated Sycamore from among the surrounding belt of trees, chiefly Firs, which it was hustling out of all shape. The brittleness of this tree when cut is very remarkable, and seemingly consistent, for we have cut down two and lopped a third, and they all snapped, whether it was a trunk 2 feet in diameter or a branch not 6 inches across, with equally disconcerting suddenness, before the saw was half-way through. The giant, indeed, contrived to precipitate a man from the height of a sizable ladder, by playing this trick, which the workmen who did the felling refused to believe likely or possible, having in mind the different behaviour of the ordinary Sycamore, which seems about as tough as the average. The variegated form is an extremely handsome tree, but in this soil detestably self-assertive, and most efficient in keeping off all light from everything within a wide radius round its trunk.

There are very few worms and fewer slugs in this place, a fact possibly to some extent due to the large number of snail-slugs. The gardener when digging at this season turns these latter useful individuals up constantly, and since his enlightenment as to their meritorious place in the scheme of creation, carefully digs a hole and replaces each one, after an admiring scrutiny of its rather repulsive pink body, with the curious air of being petrified and the weird rudimentary shell adorning the back. The first time I came across one of these things, many years ago, it had an inch of earth-worm hanging out of its mouth, and waving about, which I concluded in my haste must be part of a most remarkably unpleasant anatomy.

I have made the usual resolutions. Only a few really good seeds, no annuals, no tender things to need several shifts and make work, and no leaving seedlings too long in the pans. I hope these will be kept, but from past experience cannot hope with much confidence, but one resolve, at any rate, is firm—no German seeds—at least, not knowingly. Some people will tell us that we get them whether or no, and pay half-a-crown instead of sixpence for them, but I do not believe it, so far as my small experience goes, and last year especially I bitterly regretted saving eighteenpences and putting good British sixpences into Teuton Palms, for none of the German seeds did well, while those I got from—I must not say who—but he is *very* expensive—gave splendid results. After all, between forty and fifty absolutely first-rate single Pyrethrum roseum plants, with flowers of pure colour and well diversified in shades, and blossoms nearly 3 inches across the same season, or thirty odd fine strong Carnations, promising to be all doubles, is not a bad return for thirty pence, though half-crowns have a nasty trick of being so few to the pound, compared with sixpences and shillings.

M. L. W.

PAPYRUS ANTIQUORUM AND A JAPANESE BRONZE IN THE GARDEN AT LA MORTOLA.

the thing that is least wanted. Somerset weeds in general are "trumpery." "The ground is full of trumpery," expresses a thoroughly neglected parterre, such as not even the most enthusiastic worker would wish to enter upon. "Chronic" is, I believe, now a slang word in high company; hereabouts it is used to describe such conduct as that of our two graceful young duck-damsels, who, with their great bills, spooned up the food that their attendant, who favours the fowls, would rather have seen go down the biddies' equally ravenous, but less capacious, maws. "They ducks is just chronic" means, so far as I can discover, that "they ducks" behaviour deserves the most scathing reproach Somersetese affords.

PROGRESS OF SPRING BULBS.

In the early autumn we planted some Snowdrops, partly in the grass and partly in borders. They were *G. Elwesii*, obtained from two sources—a local one and from a London

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

February 3.—National Amateur Gardeners' Association Meeting.

February 7.—Société Française d'Horticulture de Londres Meeting.

February 10.—Royal Horticultural Society's Annual Meeting, 3 p.m.; Horticultural Club's Annual Meeting, 5 p.m.; Annual Dinner, 6 p.m. (Hotel Windsor).

February 13.—Royal Gardeners' Orphan Fund Annual General Meeting, Cannon Street Hotel.

Horticultural lectures.—I observe in your report of the proceedings at the Horticultural Club on January 13. following on the reading of Mr. O. Thomas's paper, Mr. C. Pearson is stated to have said that in the experience of horticultural lecturers villages gave poor audiences and towns the greater ones. Oddly enough that is the reverse of my experience in Surrey, and I have during the past eleven years lectured in every part of the county, whether in populous districts or in small villages. Just now I am lecturing weekly in a very remote rural village close to Sussex, yet I have an average attendance of forty, and that is remarkably good for so small a place. It is so in other localities, whilst the towns always give the smallest attendances. That is in my mind only natural. Workers on land in Surrey are far from ignoring the benefits attached to cottage gardens or allotments. I can show some of both these in our county that worked by farm labourers would take a great deal of beating anywhere.

Calceolaria Burbidgei.—Mr. W. James has sent me from Woodside, Farnham Royal, a flowering branch of this very pretty hybrid *Calceolaria*, which Mr. Burbidge raised in the Dublin Botanic Gardens some years ago. Mr. James is surprised that a plant which blooms so persistently and freely through the winter in a temperate heat is not grown largely by gardeners for conservatory decoration. At Kew it does remarkably well, as there it reaches many feet in height. It does well in pots or planted out. No seed is produced, but the plant, which is fairly hard-wooded, will increase readily by means of cuttings. The flowers resemble those of *C. amplexicaulis*, but are of deeper colour. The parents were *C. fuchsifolia* and *C. Pavonii*. As in midwinter bright yellow flowers on tall shrubby plants are rare, this *Calceolaria* should be in great demand. It also blooms very freely in summer.—A. DEAN.

National Dahlia Society.—We notice the following changes in the 1903 programme of this society. The name of the Earl of Ilchester is added to the list of patrons, and that of Miss Willmott, V.M.H., to the list of patronesses. Mr. F. W. Sharpe has resigned his position as vice-president, and Mr. J. F. Hudson, M.A., has been elected in his place. Mr. Hudson thus retires from the position of hon. secretary, which he has so ably filled during the past six years, and Mr. P. W. Tulloch succeeds to the position. Mr. E. T. Cook has been elected to the vacant seat on the committee caused by Mr. Tulloch's appointment. The membership shows an increase of over 11 per cent., and the prize schedule for 1903 has been improved by the addition of four new prize trophies, as already notified. Negotiations are in progress for the holding of a special exhibition of Dahlias by this society at Manchester in September next, which it is hoped will shortly reach a satisfactory conclusion. Mr. P. W. Tulloch's address is Sterndale, New Church Road, Hove.

Acacia ovata.—A very pretty free-flowering *Acacia* has, under the above name, made its appearance in Covent Garden, and furnishes a pleasing variety to the forms usually grown. It is a free bushy plant, with the principal shoots of clean and straight growth, and clothed with small, roundish, ovate leaves of a deep green tint, and studded for the greater part of their length with a profusion of small yellow globular flower-heads. Not only do the individual

clusters remain fresh and bright for some time, but a continued succession is kept up, so that its flowering season extends over a lengthened period. While it is generally met with as *A. ovata*, it is, I believe, the same as *A. obliqua*, which is in its turn in the last supplement to the "Dictionary of Gardening" referred to as *A. rotundifolia*. Besides this, other species that may be successfully flowered in comparatively small pots are: *A. ornata*, *Drummondii*, *hastulata*, *platyptera*, and *pulchella*. They are all natives of Australia, and succeed in an ordinary greenhouse, but *A. Drummondii* and *A. platyptera* need rather more peat in the soil and more care in their culture than the others.—H. P.

Chrysanthemum Vivand Morel and its sports.—It only appears as yesterday when the above varieties were victorious in every direction, and when it was often freely expressed that the zenith of the *Chrysanthemum* had been reached and the day for new varieties was over. Few then could have realised that the advent of some of those now occupying the leading positions was so near at hand, and raisers were at the time advised to study quality and not quantity, with the result that we have had some decided acquisitions brought out, notably, W. R. Church, M. Louis Remy, and Mrs. G. Mileham as examples. Others will follow, but they must be only of the best. Much as one is grieved to part with old friends, such as the subject of this note, we must do so. For exhibition (other than as plants) it would almost appear as if their day were ended.—A. B.

Brussels Sprout Cambridge Champion.—I notice in Mr. Wythes' note on my new Brussels Sprout (Cambridge Champion) he says he lost his note and was unable to name the parentage of it. It was raised by crossing the Reading Exhibition with Sutton's Dwarf Gem, and by carefully selecting the best and firmest-buttoned ones for the last five years I have now got an ideal strain.—J. H. RIDGEWELL, *The Gardens, near Histon, Cambridge.*

Referring to the paragraph in your issue of the 17th inst., respecting Brussels Sprout Cambridge Champion, we beg to inform you that we have acquired the stock, and shall be pleased to supply it through the trade.—CHARLES SHARPE AND CO., *Slough.*

Exhibiting Carnation blooms.—All lovers of this beautiful and popular flower who have visited the recent meetings of the Royal Horticultural Society must have noticed the pleasing display made by Messrs. W. Cutbush and Son, of Highgate, owing principally to the graceful way in which they have arranged the flowers. Surely this is a step in the right direction, and the sooner this form of arranging cut flowers generally is adopted the better. There is nothing more unnatural than the way Carnations and many other cut flowers are exhibited at the present time. I am not aware who are the makers of the stands used by Messrs. Cutbush, but they are certainly neat and elegant. The colour is green, and the material used probably zinc, being sufficiently large at the mouth to hold several flowers and a suitable amount of foliage.—E. BECKETT.

Vegetables and frost.—The short severe spell of frost has proved the value of certain vegetables, and, of course, no matter what Cauliflower or Broccoli be grown, they are not hardy unless protected in some way. I find, however, that the plants with foliage well above the flower or head are greatly superior in this respect. The Kales, though a little soft owing to the wet growing season, are now most valuable, and will be in season for the next three months. Our system is to grow the Broccoli or Kales for the supply from now until May, and for this reason there are some really excellent varieties for flavour, such, for instance, as the finely curled Scotch Kale for present use, and the Arctic Curled for latest supplies. This latter is now getting better known for very late use, and I know of none so good for use at the late season named, as it is one of the last vegetables to run to seed in spring. I have found after a severe winter we have not lost one plant, and as this is in a moist low situation it shows how well it thrives. Doubtless its hardness is due to the low compact growth and short stems,

so that it is more readily protected. Another important point concerning the Kales is their good flavour even after severe frost, but the Kales are not always cooked as well as they deserve; after protracted frost they should be cooked in two lots of water, as this removes any disagreeable taste. For use from now to March or later the Savoy is at its best, not the large Drumhead type, but such kinds as Sutton's New Year and Perfection, which are invaluable at this season. The seed should be sown in May for July planting. No note would be complete without referring to the Winter Cabbage for present use, a vegetable often overlooked. I need not mention roots for use at this season, but I would briefly note the value of Celery grown for cooking for this purpose; the Solid White is splendid. Chicory also is a change from other vegetables when the sturdy new blanched growths are cooked. I fear the Spinach crop has been rather injured by frost owing to its tender growth; even in the south the frost was rather severe.

Sutton's Broccoli Superb Early White.—The very fine heads of Sutton's Superb Broccoli, staged at the last meeting of the Royal Horticultural Society, showed what a useful winter variety the above is, and no one can go far wrong when they select this one for the winter. I have grown it in Northumberland with great success in a garden much exposed, coming in at a season when it was most valuable. Comments were made regarding the size of the heads shown. Some were considered too large, but that is a good fault. It is an easy matter to cut the heads in a smaller state. At Alnwick Castle we never found it large, and the heads were perfect in shape and colour, and what is so important they last so long after they have been housed or protected. We have had them good for six weeks after being lifted and placed under shelter. The Winter White is much better than the old Snow's Winter White, which is not reliable. Doubtless the newer Early White is a better type of that old and at one time good variety, and a great boon to those who need choice vegetables in quantity.—G. WYTHES.

Greenhouse plants and the fog. As a rule, plants with firm, glossy leaves are much less injured than those whose foliage is thinner in texture and more or less hairy. Among the commonly grown plants of a shrubby texture may be mentioned the Azaleas, which suffer terribly, for the young leaves shrivel up as if burnt, while the mature ones drop wholesale, and frequently leave the bush nearly devoid of foliage. Even among the Indian Azaleas some varieties resist fog much better than others, one of the best in this respect being Mme. Van der Cruyssen, which is seldom affected to any extent, while another, Sigismund Rucker, is often killed outright. Both these kinds are very popular with the Belgian cultivators, and are sent here in considerable numbers, but the latter is useless in the London district. Greenhouse Rhododendrons that have originated from the intercrossing of *R. ciliatum*, *R. Edgeworthii*, and *R. formosum*, and which now constitute an extensive section of for the most part white-flowered varieties, all suffer somewhat, and frequently the flower-buds are killed, while on the other hand, the Javanese or tube-flowered section is quite indifferent to fog, for the members of it will even flower throughout the winter in the London district. The charming little *Rogiera*, *gratissima* suffers terribly, nearly as bad in fact as the *Bouvardias*, which are quite scorched up. Most of the different species of *Eucalyptus* suffer considerably, but none other to the same extent as *Eucalyptus citriodora*, which frequently loses every leaf and dies outright. If the foliage is kept clean, that pretty shrub *Thibaudia acuminata* does not seem to mind the fog, but there are very few plants that are not more or less affected by it. Soft-wooded plants of course suffer greatly, the members of the various sections of *Pelargoniums* often losing nearly all their leaves, while *Primulas*, *Cinerarias*, and other things look as if burnt, in addition to the foliage being blackened with soot. *Cyclamen* leaves are seldom affected, but the flowers quickly perish.

Rose Marquise Litta.—This is one of those good varieties that should never be absent from collections, the beautiful large cupped flower always commanding attention; indeed, it is difficult to find a better all-round variety. Speaking to a clever grower a short time ago I was assured that for autumn blooming it had few equals, some excellent blooms cut from the open late in November fully bearing out his remarks. So pleased is he with it that he has added more plants this season.—A. B.

Chrysanthemum Mabel Morgan. This beautiful flower is probably better known as a refined Japanese variety of exhibition standard, though rather late for the November shows, unless specially treated to a system of stopping and timing. Its colour may be described as pure rich butter-yellow, and its long petals develop very evenly and make an ideal Japanese reflexed bloom. For some few weeks past handsome bunches of this beautiful variety, grown freely for decorative uses, have been sent into the markets, and are fully appreciated because of their lovely colour and bright and pleasing character. Here, in the second week of January, are the Chrysanthemums to be seen in grand condition, and as long as raisers and distributors can add to the list good decorative sorts as the one under notice, so long will the Chrysanthemum continue to be popular.—D. B. C.

Clivia cyrtanthiflora.—This, which is better known in gardens under the generic name of *Imantophyllum*, is a supposed hybrid between the two species—*nobilis* and *miniata*. It is by no means equal to the last-named, which, under the title of *Imantophyllum miniatum*, is everybody's plant, and may be grown equally as well in the amateur's greenhouse as in more pretentious structures. *C. cyrtanthiflora* has, however, advantage over its better-known relative, and that is whereas the flowers of *C. miniata* do not expand until the spring, those of *C. cyrtanthiflora* are at their best quite early in the new year, even in a greenhouse temperature. Like all the members of the genus, the dark green strap-shaped leaves are decidedly ornamental, and the partially drooping flowers, which are in a crowded head, are smaller than those of *C. miniata*, and do not open so widely. In colour there is a certain amount of individual variation, but the usual tint is some shade of salmon-yellow.—H. P.

Bouvardia King of the Scarlets. By the kindness of Mr. J. Robson, Bowden Nurseries, Altrincham, I am in receipt of a fine truss of this beautiful Bouvardia, which shows well what an acquisition it is to winter-flowering plants and how well merited was the award given it at the Royal Horticultural Society's meeting on December 9 last. For many years now the position as the best scarlet-flowered Bouvardia has been held by the variety President Cleveland, which first came here from the United States fifteen or sixteen years ago, but it is now likely to be superseded to a great extent. The flowers of King of the Scarlets are larger than those of most Bouvardias, particularly in the width of the lobes, while the colour is a clear bright scarlet, with the tubes almost white. It is strange that the two Bouvardias just mentioned should have come to us from abroad, for while President Cleveland was sent from America, this newer form had a still longer journey, as it was raised in Sydney, New South Wales.—T.

Oxalis Ortgiesii.—In habit this species is quite distinct from the typical members of the genus. Its roots are fibrous, and its stout, erect, fleshy stem grows to a height of a foot or more; the trifoliate leaves are borne on long reddish stalks, and the leaflets are dark green above and purple beneath. The small yellow flowers, which are freely produced, are borne in dichotomous axillary cymes. With some this plant has fallen into disrepute, being characterised as "too weedy," but this weediness is chiefly due to its being kept in too high a temperature. The plants which now should be flowering grow best in the cool greenhouse; here they have a sturdy habit, and continue to flower for a long time. During the summer months this *Oxalis* may with advantage be grown

in a cold frame. Water must never be wholly withheld, but when the flowering period is over the plants should be kept on the dry side for a period of rest. Cuttings root readily in sandy soil; overpotting should be guarded against.

Yuccas in the rockery.—At this time of the year many rock gardens present a bare and uninviting appearance, due in a measure to the almost exclusive use of dwarf plants. To obviate this more use should be made of such plants as *Yuccas*. Their habit of growth is in keeping with a rockery, and no matter how freely they may grow they never wholly hide the rocks, and nothing can be finer than *Yuccas* when in flower. When planting it would be advisable to place the species and varieties with the habit of *Yucca filamentosa* and *Y. recurva* (*Y. gloriosa* var. *recurvifolia*) in the foreground, having such as the stiffer-leaved *Y. gloriosa* further back; passers by then will not be in danger of brushing against the sharp leaf points. Where it is sufficiently hardy the graceful *Cordyline australis* may with advantage be used similarly.—A. C. BARTLETT.

Garrya elliptica.—Very few Californian shrubs are really hardy in this country, except in the south-west counties and similarly favoured localities. This applies to the above shrub, for, although about London it succeeds in the open, it is usually seen in better condition when given the protection of a wall. In places where it thrives it is useful as an evergreen alone, being distinct from any other. Where it is required for its inflorescences, the male plant, which is by far the more common, should be obtained, for it is the yellowish green catkins of this that prove so attractive in midwinter. In the open it makes a bush 4 feet to 6 feet high and 3 feet to 4 feet through. When planted against a wall, however, it grows to a height of quite 12 feet and flowers very freely. Two large specimens existed a few years ago in the gardens at Wimbledon House. They had been planted at the foot of a wall and allowed to grow out from the wall in a free manner. These plants each winter flowered profusely, the catkins being from 6 inches to 9 inches long in large clusters.

The Camellia-leaved Holly.—A fine specimen of this Holly may be seen in the Holly collection near the temperate house at Kew. In this position, surrounded by many other varieties of *Ilex Aquifolium*, its superiority over a large number of other varieties is at once apparent. It has been known by two names, the correct one—*I. A. var. camelliifolia*—and *I. A. var. laurifolia longifolia*. It forms one of the most striking examples of the great variation in form of leaf to be found in the common Holly, for in no particular does it bear the slightest resemblance to the type. Among other varieties this may be easily recognised by its dense pyramidal habit and handsome very dark green leaves. The leaves measure from 5 inches to 6 inches in length, and the largest are upwards of 2½ inches wide. Many of the leaves are entirely destitute of spines, others have a small spine only at the apex, and others, again, have a few scattered spines on the margins. The berries are duller in colour and not so effective as those of the type, but are larger. Like many other Hollies it can be increased from cuttings, and also by budding on stocks of the type. For a year or two whilst young it appears to be rather tender, on account of commencing to grow rather early and so being damaged by late frosts. After three or four years, however, it will withstand as much hard weather as most of the other varieties.—W. DALLIMORE.

Tropæolum speciosum.—I note that most of your correspondents in writing of this plant insist that it should be planted where the direct rays of the sun cannot fall upon it. It may be conceded that the plant flourishes in such positions, but that they are not absolutely essential to its welfare I have had proof. Several years since when on a visit to Wales, and travelling from Dolgelly to Barmouth I rested at a small wayside tea garden for a few minutes. In that garden I saw a large patch of the *Tropæolum* growing in the open, quite away from any building and looking at a distance like a small planting of Scarlet Runners. This was in the month of August,

both flowers and fruit being abundant, though the latter predominated. So far as I can recollect the soil was loamy and cool. Subsequently I saw several plants in similar situations, in or near Dolgelly, where it seems to be common. If you have any correspondents in North Wales I think they will fully confirm my observations.—W. THOMPSON, Ipswich

A winter Viola.—There is just now, and, indeed, has been all the winter, in most profuse bloom two large beds of a creamy white *Viola* in some hardy plant grounds at Feltham, Middlesex. I have seen these beds several times during the winter, and having to pass them on a fairly fine day—the 9th inst.—could but stop to admire them. It was, indeed, a matter for comment that any bedding *Viola* out of many varieties there being grown should be literally a mass of bloom, just as though it were May rather than January. Surely there are many with gardens who would like to have this variety for winter flowering. I could not learn its name, as the grower did not seem to know. The flowers are self-coloured, but have a few dark rays. Perhaps some one may know it, and if so, will no doubt kindly state, so that readers of THE GARDEN may know what variety to ask for.—A. DEAN.

Acacia dealbata.—The finely divided leaves of this *Acacia* render it extremely ornamental at all seasons, but in planting it one thing to bear in mind is that it is of quite tree-like habit, and would therefore soon outgrow an ordinary greenhouse. It is a plant for a lofty structure, as it is of rapid growth, and when once it has obtained a considerable size is very free flowering. Along the shores of the Mediterranean it forms one of the most beautiful of flowering trees, its blooming branches being largely sent to this country and disposed of under the name *Mimosa*. This *Acacia* is the Silver Wattle of the Australian colonists, the name silver being derived from the whiteness of the leaves, but this is a feature in which respect individuals vary considerably, that is to say, when raised from seed, as if it is saved from the whitest form some of the progeny will be almost green. Beautiful as the foliage is in a pure atmosphere, it suffers very much in London during winter; indeed, a few days of heavy fog will cause nearly all the leaves to drop.—T.

THE FLOWER GARDEN.

NEW HARDY FLOWERS OF 1902.

(Continued from page 17.)

NARCISSUS INCOMPARABILIS TORCH.—A very showy flower. The segments are yellow and the crown a glowing red. A very vigorous and handsome form. A.M., April 8.

N. incomparabilis Primrose Phoenix.—This beautiful addition to the double incomparable *Daffodils* has so descriptive a name that further reference to it is almost needless. The colour is a full primrose tone and quite pleasing, and the bulb is said to grow well. A.M., April 22.

N. Queen Christina.—This is a fine bicolor of the *N. b. Victoria* class, but larger and with whiter segments to the perianth. A very handsome kind. A.M., April 22.

N. Duke of Wellington.—This is a rich golden-yellow flower, a splendid *Narcissus*, and very large. A.M., April 22.

N. Queen Emma.—A fine bicolor, especially with regard to the trumpet, the segments being those of *N. Horsfieldi* almost. A.M., April 22.

N. Warley Magna.—A very pure white *Ajax*, the cup well opened out and frilled. A.M., April 22.

N. Bettie Berkeley.—Nearly a bicolor Queen of Spain, with a lemon cup and white segments. A.M., April 22.

N. Glory of Noordijyk.—This is a bicolor of giant proportions, perhaps one of the largest yet seen. The crown is of exceptional size and the brim very widely expanded. A.M., April 22.

N. Cressett.—This is a seedling, such as may have arisen from crossing a Leedsii or Burbidgei with some good coloured single incomparabilis. The segments are very white and pure, and the crown richly coloured. A.M., April 22.

N. Incognita.—This is akin to the last-named kind, but quite distinct in colour; it has very long white segments to the perianth and orange crown. A.M., April 22.

N. Ada.—This belongs to *N. triandrus*, and has pure waxy white flowers; it is very beautiful. The flowers are usually three in a scape, and there is much character in the well-shouldered upper part of the crown. F.C.C., May 6.

N. Moon Ray.—This is possibly allied to *N. Ada*, and is larger but less meritorious. A.M., May 6.

N. Cecil Rhodes, a large pale flowered *N. Queen of Spain*, suggestive of the crossing of *N. triandrus* and a yellow *Ajax* kind. A.M., May 6.

N. Watch Fire.—A very beautiful Daffodil and quite distinct. The segments are buff or creamy buff, and the crown bright red, margined with orange. A.M., May 6.

Tulipa gesneriana lutea pallida.—This self Tulip is vigorous, and a good addition to existing kinds. Not only is it a shapely as well as showy flower, but is sweetly scented, reminding one of Violets. The stems are at least 2 feet high. It should prove of great value among the late-flowered Tulips. F.C.C., May 6.

Tulip Pride of Haarlem.—A Darwin Tulip, very showy, indeed of almost brilliant colour. It is, perhaps, one of the most valuable in the late May-flowering section of this genus. The colour is cerise-scarlet. A.M., May 28.

ASTERS OR MICHAELMAS DAISIES.

As showing the popularity of these plants quite a large number have been in the past season honoured by the award of merit, and we give them in detail in the hope of guiding those readers who in these things desire to be quite up to date. As the list is a rather long one, and not all of the sorts are novelties of the past year in the true sense, we give them as briefly as possible.

A. Novi Belgii Dorothy.—Excellent in habit, with a wonderful profusion of clear lavender coloured flowers. This should prove a fine border plant. Height 4 feet. A.M., September 24.

A. N. B. Celestial.—A vigorous seedling that occurred in the Society's Chiswick gardens. Flowers pale blue of good form. Height of plant 4½ feet. A.M., September 24.

A. N. B. Daisy Peters.—A seedling from Mrs. W. Peters, and possibly an improvement. Flowers pure white in great abundance. Height 3½ feet. A.M., September 24.

A. N. B. Top Sawyer.—One of the tallest and showiest of this group. Large flowers of good form and lilac-blue in colour. Height 5 feet. A.M., September 24.

A. N. B. F. W. Burbidge.—One of the most distinct in growth. Flowers well formed, of a rosy lilac tone; a great bloomer. Height 4½ feet. A.M., September 24.

A. N. B. Ariadne.—One of the best of mid-October varieties. Flowers, 1½ inches across and

fine pale blue. The plant is nearly pyramidal in habit when naturally grown. Height 5½ feet. A.M., October 13.

A. N. B. Calliope.—Showy, vigorous, and free; flowers pale mauve, 1½ inches across, the bushes densely laden with blossoms. Height 4½ feet. A.M., October 13.

A. N. B. Elsie Perry.—An excellent sort in every way. Flowers of medium size of a warm rose tint. Height 4½ feet, habit strong and branching. A.M., October 13.

A. N. B. Coombefishacre Brightness.—An improvement upon *Coombefishacre*, and remarkable for freedom of flowering. Height 4 feet. Flowers rosy pink of medium size. A.M., October 13.

A. Cordelia.—A cross-bred variety of some worth. The flowers are of the palest blue, very distinct, and pretty. The plant is very free flowering. 4 feet high. A.M., October 13.

A. vimineus Delight.—A charming sort, graceful, free, and beautiful. Habit nearly erect, 3 feet high, and decked with white rosy-eyed blossoms, each half an inch across. A.M., October 13.

A. vimineus perfecta.—A slender growing yet welcome Aster. Habit nearly erect and free, the flowers in their great abundance completely covering the plant. Colour white, suffused and tipped with pink, a dainty and pleasing sort. Height 3½ feet. A.M., September 24.

A. cordifolius magnificus.—Quite a typical Aster in growth, with the same great profusion of flowers. Height 4½ feet; colour lilac-blue, delicate, and pretty. A.M., September 24.

A. cordifolius elegans.—This is not a novelty of the year, but certainly one of the gems of this group. The plant is elegant in habit and flowering. The flowers are white and tinted with palest mauve, with the colour-changing disc so noticeable in these plants. These cordifolius sorts are very beautiful and free-flowering. Height 5 feet. A.M., October 13.

A. acris var. nanus.—This is not merely a dwarf form, but a late flowering form of *A. acris*, and as such a most welcome plant. Barely 16 inches high, with the same blue stary-petalled flowers, it is quite a good addition. At its best in mid-October. A.M., October 13.

A. levigatus.—This plant is well known to gardeners under the name of *A. longifolius formosus*, &c. It has a wealth of rosy pink flowers on plants of bushy habit and the growth is less than 2 feet high. It is a great favourite for pots and for market. A.M., September 24.

A. ericoides Ophir.—Not many of this group have received distinctive awards, and this is one of the best. The habit is the same as the type, and the pretty tinted pink blossoms expand quite a week before those of the species. Height 3½ feet. A.M., October 1.

A. ericoides Sensation.—Not a good name certainly for a small-flowered type; this has the same graceful habit and freedom, the same dainty yet larger blossoms, and purer than all others of its class. The flowers are freely set on elegant branching sprays. Height 3 feet. A.M., October 1.

A. Amellus bessarabicus.—No Aster is better known, and it seems strange to give an award after it has been in cultivation for so many years. Free and beautiful in flower and of erect branching habit, it is worthy of a place in all gardens. Flowers bluish purple and nearly 2 inches across. A good September flowering plant, 2 feet high. A.M., October 1.

N.B.—The dates of the awards in these plants will afford a clue to the time of flowering, the varieties in each case being at their best when the awards were made.

THE FLORIST'S TULIP.

On the 13th inst. a lecture on "The English Florist's Tulip," illustrated by coloured diagrams, was delivered by Mr. Richard Dean, V.M.H., before the Weybridge Horticultural Society, there being a good attendance of members. Commencing with a short reference to the history of the Tulip, the lecturer proceeded to say that *T. gesneriana* is generally believed to be the progenitor of the English florist's Tulips, and it was named after Conrad Gesner, who was described as the "Linnaeus of the sixteenth century," and who first made the Tulip known by a botanical description and drawing of the flower. Gesner records that "he first saw the Tulip in the beginning of April, 1599, at Ausburg, in the garden of the learned counsellor John Henry Herwart." It is scarcely known when the Tulip was introduced to Europe, but it appears certain it came to Germany, though by what means is not accurately shown; it is yet on record that the Dutch merchants and the rich citizens of Vienna, who were fond of flowers, sent to Constantinople at different times (the Tulip being a native of the East) for various renowned sorts. The first roots planted in England were, it is said, brought from Vienna in 1600 or thereabouts.

After a brief reference to the Tulipomania of 1634—1637, the lecturer proceeded to say that the bulb of the Tulip which produces the flower decays, its business in life being to put forth foliage and flower. Having done this it perishes, but propagates its kind by means of offsets; by the end of June or early in July they are ready for lifting, and they are better out of the ground till planting time than in it. While the bulb is placed away in a drawer till it is planted there is no suspended animation, the bulb undergoes change in size and shape, and is forming within itself all the elements of the future flower. It enjoys the dryness and coolness of the cabinet better than the summer rains if left in the ground; indeed, experience shows that the summer moisture has a prejudicial effect upon it.

Any good garden soil suits the Tulip, that which will grow Beans well will do; it can be helped by mixing with it some chopped up turf. Wet is more destructive to Tulips than frost, hence the soil in which they are planted should be well drained, and that is the reason why growers of choice varieties have their beds raised 12 inches or 18 inches above the ground level, and the bed is edged with wood, turf, &c. There is a further advantage—by so raising the beds the flowers are brought nearer the eye. The time to plant is generally the first or second week in November, but the middle of October is not too soon and the early part of December not too late. Once planted the bulbs are left to the action of all weathers, until the foliage begins to develop in early spring. All that show a second leaf may be expected to flower. From a single leaf, however vigorous it may be, no bloom can be expected that year. In Lancashire those producing a single leaf only are denominated "widows," and several causes might be assigned for failure—some inherent weakness probably. During the prevalence of sharp frost some protection of the leaves is necessary, bright sunshine falling upon frozen foliage is harmful, and rough winds blowing them about when frozen is equally injurious. A critical time is when the buds appear in the hollow formed by the leaves, and if the wet lodging here becomes frozen it may be permanently injured. The water can be liberated by opening the leaves. As the flower stems rise in April hailstorms sometimes happen, and if the bud be struck by a hailstone or the foliage wounded harm is done; the future flower is pretty certain to disclose a blemish in consequence.

By means of coloured diagrams, Mr. Dean traced the flower from seed, showing the peculiarity of the seedling Tulip to put forth a number of others lower down in the soil, and technically termed "droppers." This goes on for a few years, a single leaf only being developed, until the second leaf appears, and then it is known the seedling is about to bloom. Five and six years usually elapse before the seedling Tulip produces a flower. The seedlings when they bloom almost

invariably take on the self or breeder character, and they are differentiated into three sections—the bizarre breeder, with a yellow base; the byblem; and the rose, with white bases. The bizarre breeder is suffused with reddish or yellowish brown, dull red, or approaching mahogany; the byblem, with a lilac, slate and shaded tint of one of these; the rose (and many of the rose breeders are very beautiful) are suffused with pink, rose, or scarlet. In time, it may be in a year or two, or it may be in many years, these breeders, in no order of time, or rank, or age, break or rectify, but when they will break, and in what form they will break, no one knows; the breeder colour appears to be lifted off from the flower, and new and beautiful combinations appear. The flowers then either come feathered on the petal edges, with a flame of colour running up the centre of the petal, or the colour is laid on only round the petal edge; the former is a flamed, the latter a feathered flower. Bizarres break to black, red, or brown approaching red; byblemens to some shade of purple from light lilac to all but black; and roses, to rose-red or scarlet. Diagrams of flamed and feathered flowers were shown, and the curious changes which sometimes appear, illustrated.

The importance of shading from burning sunshine when in bloom was insisted upon. The mode of planting a bed and the method of arranging the bulbs according to height was also stated. A Lancashire Tulip exhibition was described, and in conclusion emphasis was laid upon the importance of maintaining the culture of and interest in such a remarkable flower, which was forty years ago much grown round London. A hearty vote of thanks was passed to Mr. Dean for his interesting address.

THE INDOOR GARDEN.

EUCHARIS AMAZONICA.

DECIDEDLY the most popular of all bulbous plants that require the temperature of a stove for their successful culture is *Eucharis amazonica*, for it is an universal favourite, being found in nearly every garden where accommodation exists for it. In addition it is grown by the houseful in some of the large nursery establishments that supply Covent Garden Market with choice flowers. By different modes of treatment a succession may be kept up throughout the entire year, and during the London season there is a great demand for the flowers, as there are few if any social functions, in which flowers are used, where the *Eucharis* does not figure prominently, and for bouquets, crosses, wreaths, and such purposes it is invaluable.

Concerning the early history of *Eucharis amazonica* it was introduced from the Amazon district of South America, and first flowered in this country in 1857, so that it has now been before the public for nearly fifty years. Though generally known by the specific name at the head of this note, it should according to the latest botanical classification be *Eucharis grandiflora*. There are several others that have had at one time or another a great deal said in their favour, and though they may suffer by comparison with the prince of the family, without it they would occupy a prominent position among bulbous flowering plants. The oldest member of the genus is

E. CANDIDA,

a native of New Grenada, from whence it was introduced in 1851. The leaves, which are smaller than those of *E. amazonica*, have not the prominent ribs of that species, while the flowers, which are borne in an erect umbel, have the segments reflexed in a very regular manner. This species had at one time a very poor reputation, as the least showy of all the

genus, viz., *E. subdentata*, somehow got generally distributed under the name of *E. candida*. Very large importations of the true species were, however, disposed of in this country in the early eighties, since when *E. candida* has been generally grown, but without ever threatening the position held by *E. amazonica*. Two species of botanical interest only are *E. subdentata*, just alluded to, and *E. hartwegiana*, both of which are better known by the generic name of *Caliphruria* than that of *Eucharis*. Compared with the others they are small growers and very shy flowering.

The above embrace all, I believe, that may be regarded as distinct species, though we have quite a long list of other names, some of which may be varietal forms, and others hybrids, either natural or artificial. Thus we have *Eucharis sanderiana*, *E. Mastersi*, *E. bakeriana*, *E. Lowi*, *E. Moorei*, and *E. Stevensi*, but it is simply impossible to say where one begins and the other ends, or indeed to select

EUCHARIS AMAZONICA IN THE GARDEN OF MR. BROOME, LLANDUDNO.
(From a photograph kindly sent by Mr. Broome.)

one from the other with any degree of confidence.

No notice of *Eucharis amazonica* would be complete without reference to a most remarkable hybrid in the production of which it has played a part. This is

URCEOCHARIS CLIBRANI,

which was first shown at a meeting of the Royal Horticultural Society in the summer of 1892 by the raisers, Messrs. Clibran of Altrincham, and announced as the product of *Eucharis amazonica*, crossed with *Urceolina aurea*. This last, which was introduced by Messrs. Veitch through their collector Richard Pearce, of tuberous *Begonia* fame, some time in the sixties, has drooping urn-shaped blossoms, colour bright yellow tipped with green. The flowers of the hybrid are in shape about midway between its parents, but the golden colour of the *Urceolina* is completely eliminated, the tint being that of the *Eucharis*. It readily conforms to cultivation, and is a beautiful and interesting plant.

H. P.

TREES AND SHRUBS FOR BRITISH GARDENS.

THE BARBERRIES.

(BERBERIS.)

PROBABLY between sixty and seventy species of Barberry are now known to botanists. They are found in the temperate parts of North and South America, in temperate Asia, and in Europe. The common species of Britain (*B. vulgaris*) is found wild in North Africa, but has possibly been introduced. They are shrubs, characterised throughout by having yellow wood and yellow flowers, and their beauty is such that scarcely a single species has been introduced which is not worth growing for its own intrinsic merits. A few occupy a place in the first rank of useful and ornamental shrubs. Some of the species, of

course, are so much alike that in gardens the genus may be quite adequately represented without growing more than half of them. The sorts that are indicated below by an asterisk may be taken as a selection of the best and most distinct, and as representing the genus in all its forms. There are evergreen and deciduous species, and others, which may be termed half evergreen, the persistence or otherwise of whose foliage depends on the severity of the winter.

One very distinct section of the Barberries requires special mention. This consists of the species that were formerly called "Mahonia," and were kept a genus apart from *Berberis*. Loudon called them the "Ash Barberries." They are chiefly distinguished from the rest of the genus by invariably having pinnate evergreen leaves. Although the leaflets are generally armed with stiff, spiny teeth on the margins, the branches of the Mahonias are not armed. In the true Barberries, however, the branches are often formidably armed with three, five, or seven-pronged spines, which spines are really metamorphosed compound

leaves. This matter, although interesting morphologically, need not be entered into now. A reversion of the spines to leaf-like organs, however, occasionally is seen. The Mahonia group is represented in North America and in temperate Asia.

As shrubs for the garden the Barberries have many recommendations. Nearly all of them are quite easy to grow in any soil that is not water-logged. On dry light soils they are especially useful. Some of the Mahonia group flower in late autumn and early spring, but all the true Barberries blossom between the end of March and the beginning of June. The flowers are either borne in racemes or they are solitary—rarely two or three together—on the stalk. This difference in the mode of inflorescence is worth noting, for species very similar in foliage can be distinguished by this means. Many of the Barberries are beautiful in the autumn for their abundant fruits, and a few for their autumnal tints.

All the true Barberries are best increased by means of seeds; the hybrids and varieties by cuttings or layers. Some of the Mahonia group, especially *B. Aquifolium*, can be propagated by division, but with them, too, seeds are preferable.

The Barberries have not been hybridised so much as one would expect. I know of but two hybrids—*B. Neuberti* and *B. stenophylla*.

EVERGREEN.

I.—North American.

**Aquifolium* (Mahonia), *Fremonti* (Mahonia), *nervosa* (Mahonia), and *repens* (Mahonia).

II.—South American.

**Buxifolia* (*dulcis*), **congestiflora*, *empetrifolia*, **Darwinii*, and *ilicifolia*.

III.—Asiatic.

Fortunei (Mahonia), **japonica* (Mahonia), *nepalensis* (Mahonia), **pruinosa*, and **wallichiana*.

IV.—Hybrids.

Neuberti and **stenophylla*.

DECIDUOUS.

V.—European and North African.

Aetnensis, *cretica*, and **vulgaris*.

VI.—North American.

Canadensis and *Fendleri*.

VII.—South American.

Actinacantha and *heterophylla*.

VIII.—Asiatic.

**Angulosa*, **aristata*, **concinna*, *diaphana*, **diptyophylla*, *heteropoda*, **Lycium*, *sibirica*, *Sieboldii*, **sinensis*, **Thunbergii*, **virescens*, and **vulgaris*.

I.—EVERGREEN SPECIES.

B. AQUIFOLIUM.

Introduced from Western North America in 1823, this shrub has since become one of the commonest and most useful of evergreens. It furnishes one of the many instances that show the advantages planters of the present day enjoy over their predecessors of sixty or eighty years ago. For some years after its introduction its price ranged from 5 guineas to 10 guineas per plant. Even in 1838 the price was 5s., although London in that year expressed his hope that they would in time cost only half-a-crown each. Plants can now be bought for 30s. per thousand, and they are frequently planted in large quantities for cover, undergrowth, &c. For such purposes it is unsurpassed, especially in shady positions. The lustrous dark green foliage of summer acquires a purplish tinge after frosts have set in, and where it is planted in good breadths

gives a rich and very charming effect. The leaves consist usually of nine or eleven leaflets, firm, or even somewhat hard in texture, and set with sharp teeth on the margin. It produces in the spring erect crowded clusters of bright yellow flowers, followed in due time by black roundish berries covered with a violet "bloom."

This plant can be increased by means of seeds or by division, but plants divided up require two years to become established. In a wild state it is spread widely over the western side of North America from the Nootka Sound southwards. Consequently it varies much. The following are some of the more distinct varieties:—

Var. fascicularis.—This differs from the ordinary *B. Aquifolium*, which is usually 2 feet to 4 feet high, in being of taller growth and in having narrower leaflets of a duller green. It is very free flowering, and is perhaps the best of all the forms of the species.

Var. murrayana is also handsome. It has dull green leaflets shorter and broader and more wavy at the margins than the preceding, also dwarfer in habit.

Var. rotundifolia (Hervei) has large, broad leaflets, and is one of the dwarfiest forms. Other varieties whose leaf characters are expressed in the name are *macrophylla*, *latifolia*, and *undulata nana*. It should, however, be said that in any large sowing of seeds young plants appear that differ from the type almost or quite as much as some of these named varieties.

B. BUXIFOLIA.

Of the true Barberries this is the first to flower in spring; it is generally in bloom by the beginning of April, and occasionally a few flowers are open in March. It is a South American species, and ranges from Chili southwards to the Magellan Straits. It was first raised in Messrs. Low's nursery at Clapton a little over seventy years ago. As the specific name implies, its leaves are deep green and Box-like, oblong, and rarely toothed. The flowers are solitary on stalks 1 inch long, and their profusion makes a bright display. They are of a pretty amber-yellow. There is a large mass of this Barberry near the Palm house at Kew, in which are plants 5 feet to 6 feet high. This is, perhaps, about as high as it grows. Like some other species, it is half evergreen, the retention of its leaves depending on the mildness or otherwise of the winter. Probably some of its forms are more deciduous than others. The dwarf one known as *var. nana* seems purely evergreen.

B. CONGESTIFLORA.

The only form of this remarkable Barberry in cultivation is that known as *var. lakeoides*, which was figured in the *Botanical Magazine*, t. 6770. It was introduced some forty years ago by Messrs. Veitch through their collector, Richard Pearce, and is a native of the mountains of Chili. It has been grown at the Coombe Wood nursery ever since its introduction, and has thus proved its perfect hardiness in the London district. It forms a bush some 6 feet or 7 feet high, and is quite distinct from any other Barberry. The leaves, 1 inch to 2 inches across, and of orbicular outline, are thick and leathery, and set with rigid teeth on the margin. Some of the leaves have no stalks, others have them $1\frac{1}{2}$ inches long. The foliage has very much the appearance of being cut in metal. In flower, however, it is exceedingly pretty, for it bears its blossoms in dense globose

clusters, and these clusters are very bounteously produced along the branches. The habit of the plant is loose and spreading, and the branches grow to a considerable length without forking. It is one of the rarest of Barberries in gardens, but is worth looking after by those who are interested in out-of-the-way plants.

B. DARWINII.

Of all the evergreen species of true Barberry in gardens, this is undoubtedly the most beautiful. Although not quite so hardy as one could wish in northern districts, I have never known it much injured by frost at Kew. It can bear low temperatures much better than full ex-

BERBERIS (MAHONIA) JAPONICA (REDUCED).
(The leaves are 12 inches to 18 inches long. See page 71.)

posure to keen north and east winds. It thrives to perfection in the south and west of England; still, in most gardens, sheltered places can be found to suit it admirably. It was first discovered in 1835 on the island of Chiloe (off Chili) by Charles Darwin, when on his famous voyage, as a naturalist, in the *Beagle*. But we owe its introduction to Messrs. Veitch, their collector, William Lobb, having sent it home from South Chili just over fifty years ago. It is beautiful, both as an evergreen shrub and as a flower-bearing one. The leaves are small but very abundant, and of a particularly dark and glossy green. When in bloom it is

unsurpassed by any of its class, except perhaps the hybrid *B. stenophylla*, raised from it. The flowers are borne in drooping racemes 1 inch to 2 inches long, and they are of a deep yellow tinged with orange. It is at its best in April and early May. The berries are round and deep purple, and the species can be easily increased by means of the seed they contain, also by cuttings.

Var. nana.—This, a dwarf, more spreading shrub than the type. I do not know its origin, but it has the appearance of being a seedling from *B. stenophylla*, which, raised from seed, often reverts to *B. Darwinii* or the other parent, *B. empetrifolia*.

B. EMPETRIFOLIA.

It is from being one of the parents of *B. stenophylla* that this species is chiefly known to British planters of trees and shrubs. It is itself a shrub of modest appearance, producing slender trailing branches. Possibly this habit is due to our soft, mild climate, for specimens gathered on the mountains of Chili show it to be much sturdier there than in gardens here. It is to this habit, modified by the stiffer one of *B. Darwinii*, however, that *B. stenophylla* owes its surpassing grace. Its leaves are narrow and made to appear still narrower by the margins being curled under. They are of a very dark green, and appear in tufts guarded by a triple spine. The flowers appear singly or in pairs at each tuft, and are golden-yellow. Quite distinct from all other Barberries, this little shrub is very well worth growing. Its dwarf, trailing habit adapts it more especially for the rock garden. It was originally discovered by Commerson, the noted South American traveller, but was first introduced by Messrs. Low of Clapton, through Anderson the collector.

B. FORTUNEA.

Although it is not one of the most ornamental or useful of the Mahonia group of Barberries, this is one of the most distinct. It is hardy at Kew and thrives there, although not so well as it does in milder districts. In Canon Ellacombe's garden at Bitton I have seen it very nicely in flower. It is easily distinguished from all other "Mahonias" by the shape of its leaflets. There are nearly always seven of these to a leaf, and they are of narrow, lanceolate form, varying from 2 inches to 4 inches in length, and from a quarter of an inch to three-quarters of an inch in width. They are dull green and armed with thin spiny teeth. The flowers are crowded on a narrow cylindrical spike 2 inches to 3 inches long, and commence to expand in October and November. Fortune first found this shrub in a nursery in Shanghai, and introduced it in 1846. In China it also flowers in autumn and grows 4 feet high.

B. FREMONTII.

Rather too tender to be of much value in the colder parts of the country, this species nevertheless deserves the notice of those whose gardens are situated in the south and southwest counties. In the milder parts of Surrey even I have seen it succeeding very well, but at Kew it has never established itself permanently in the open. It is a native of the South-West United States, often inhabiting the dry regions of Texas, Arizona, &c. In appearance it is one of the most distinct species in cultivation of the Mahonia group, the leaves being of a more glaucous hue than any other. The leaf consists of three, five, or seven small, spiny, Holly-like leaflets, and the flowers are borne in a loose panicle 2 inches to 3 inches long. Only small plants at present exist in this country, but in a wild state it is described as growing "3 feet to 15 feet high."

The fruit is remarkable in becoming dry and inflated when mature.

B. ILICIFOLIA.

First introduced to England from Terra del Fuego by Sir Joseph Hooker when he was attached to Sir James Ross's antarctic expedition, now nearly sixty years ago, this curious Barberry still remains one of the rarest species. It flowered at Kew as long ago as 1847. Said to be a straggling bush 8 feet high in its native country, it has seldom reached more than half that height in this. It has large Holly-like leaves armed with spiny teeth, obovate, leathery, and of a dark glossy green. The largest leaves are over 2 inches long. The flowers are produced in short, densely-flowered racemes, and are of a uniform orange-yellow. It is this arrangement that chiefly distinguishes it from *B. heterophylla*. *B. ilicifolia* occurs in Chili as well as Patagonia.

B. JAPONICA.

Introduced by Fortune fifty years ago from China, the identity of this species has ever since been an debatable matter. It was figured in the *Botanical Magazine* for 1855 twice—as *Berberis Bealei* and *Berberis Bealei platanifolia*; but Sir William Hooker pointed out at the time the probability of its being one of the many forms of *B. nepalensis*.

This it no doubt is from a strictly botanical point of view, but, horticulturally, the plant from China and Japan is distinct enough from the Nepalese one to justify the retention of both names. This is what has been done in the new edition of the Kew "List of Hardy Trees and Shrubs."

According to Fortune, it grows 10 feet high in China; near London I have seen it 6 feet or rather more high, and it is always very erect and sturdy in habit. The leaves are 1 foot to 1½ feet long, and have four to six pairs of leaflets measuring from 2 inches to 6 inches in length and about two-thirds as much in width. They are very spiny toothed, dark green and hard textured. The flowers are borne in a cluster of spikes at the end of the shoot, each spike 6 inches to 9 inches long. Seen at its best this is by far the most striking of the Mahonia group. The leaves are much larger than in any other species—a single leaflet has been known to measure 8 inches in length by 6 inches in breadth. It flowers early in the year, sometimes in February, and is hardy in fairly sheltered positions. It is a plant that requires great care in transplanting, and even then will often take a couple of years to

ROSE AGLAIA IN MR. GOODWIN'S GARDEN AT KIDDERMINSTER.

recover. Therefore a permanent position should be selected for it early.

Kew.

W. J. BEAN.

(To be continued.)

THE ROSE GARDEN.

NOTES ON RAMBLER ROSES.

DURING the last five or six years few Roses have received more attention than those known as "Ramblers," and, with the exception of *Crimson Rambler*, probably no other varieties have been so largely planted as the three hybrid multifloras, *Aglaia*, *Euphrosyne*, and *Thalia*. These are often described respectively as the yellow, pink, and white Ramblers, names which are perhaps somewhat misleading now that other improved varieties, such as *Electra*, *The Dawson*, *Psyche*, and *Dorothy Perkins* have made their appearance. I do not here intend to discuss the merits of the various varieties, except to add that after a four years' trial we have discarded both *Thalia* and *Euphrosyne* as not being quite worthy of a place in a garden where space is limited, and thus only room can be found for the best. The *Dawson* has proved itself immeasurably superior to *Euphrosyne* in every way, so also has *Psyche*, while *Dorothy Perkins*—really a *wichuriana*—

judging from the form in which it has been exhibited, seems likely to outstrip even these two varieties. As far as the multifloras go, we are really in want of a double white variety, with flowers as large, say, as those of *Psyche*. *Thalia* is only a slight improvement on *Polyantha simplex*, and although I should be the last to deny its prettiness, I prefer the old *Félicité Perpétue* for use on pillars and arches and as a companion to *Crimson Rambler*. One fault of the multifloras is their habit of making strong flowerless shoots before the time of flowering. These rise above the mass of bloom, and, to my mind, rather detract from the general effect. I remember pointing this out to Mr. H. E. Molyneux when he and I were admiring the wide-spreading bushes of *Rosa multiflora* at Kew during the latter end of June last year. The other drawback is that their foliage is shrivelled up by the first sharp frost, and is very unsightly until it falls. On the 7th ult., our exposed thermometer registered 18° (Fahrenheit) of frost, and, while the foliage of *Reine Olga de Wurtemberg*, *Longworth Rambler*, and others came through the ordeal without much harm, it quite spoiled the look of *Aglaiä*, *The Dawson*, and *Crimson Rambler*.

This is rather an important point for planters to remember, as if too much use is made of these multiflora varieties, arches and pergolas will present a rather ragged appearance during part of the year. Now that *Aglaiä* has got thoroughly established I am very pleased with it. The foliage alone is very beautiful and excellent for cutting to arrange with other Roses. The plant portrayed in the illustration is growing on a trellis pergola here in company with *Crimson Rambler*, *Mme. Berard*, and others, and was planted from a pot in 1898. The year following it did not attempt to flower, but grew very strongly. On December 12, 13, and 14, 1899, we registered from 28° to 33° of frost, and I found in the following spring that my plant of *Aglaiä* had had some of its wood *rather damaged*. However, it flowered fairly well in 1900, and since then has been a perfect mass of fragrant yellow blossoms each year, evoking a great deal of admiration.

The plant has made immense growth, and is so thorny that it would be just the variety to use if an impenetrable hedge were required. The cry now is for perpetual flowering Ramblers, and these, it seems to me, will only be obtained by introducing Tea blood. And if this be done, will not hardiness be sacrificed?

I am rather of the opinion—though many will no doubt differ from me—that a hard winter will cripple some of these newer Ramblers. The whole question of hardiness is one of extreme interest and importance to rosarians, and *THE GARDEN* will do a great service to planters in obtaining authentic information on the subject. The list of Roses recommended for trial in Sweden is a good one, but might be extended. *Crimson Rambler*, for instance,

might well be given a trial. I was looking through my old volumes of *THE GARDEN* quite recently in order to see if I could find any mention made as to the hardiness of *Rambler* Roses, and under the heading of "American Notes" (Vol. LV. page 299) came across the following remarks by Mr. W. H. Taplin of Philadelphia, U.S.A.: "Notwithstanding the fact that on two occasions during the past winter (1899) we had a temperature of 10° below zero, and the zero point was reached on several nights . . . rose-crimson Rambler has apparently survived the ordeal, and will doubtless give another fine display of bloom in the course of a couple of months." It would be a help if some of your American

petual Rose from amongst the class of summer-blooming climbing Roses. The clusters of bloom are exactly like those of *Thalia*, but the plant is not such a strong grower, though well adapted for pillars, arches, &c. During both summer and autumn it produces fresh shoots in great profusion, each bearing blossoms."

Kidderminster. ARTHUR R. GOODWIN.

ROSE ADMIRAL DEWEY.

WHAT a lovely new Hybrid Tea Rose this is, a sport from, and described as, a light blush *Caroline Testout*. With me here it comes a lovely creamy-white colour, very much after the style of *White Lady*, with the advantage of the strong growth of its parent. It has bloomed very freely throughout the summer and autumn, and as late as the 25th ult. I picked a really beautiful flower—one that would not have been despised even in July. It is a garden Rose of the first importance, and one that should be included in every collection.

Enfield.

C. P.

NOTES ON HARDY PLANTS.

THE BOLD MASSING OF HARDY FLOWERS.

A GLANCE at the illustration will show how a rough bank may be beautified with groups of hardy flowers. Those in the picture are chiefly German or Flag Irises, and so planted that hard lines are avoided by allowing the plants to spread over the path and break up a formal edge. The illustration explains itself.

IN THE ALPINE HOUSE AT KEW.

A FEW days ago, when the Gardens were hidden from view by a thick fog, we sought the little cold or alpine house in the "herbaceous" ground to enjoy the few spring flowers either open or expanding. One of the brightest of these was *Merendera caucasicum*. It is well known to alpine plant lovers as a charming little *Crocus*-like plant, which blooms in midwinter with the earliest *Snowdrops*, and continues to push up its pale pink-mauve flowers in all kinds of weather. It is worth growing in pots. The genus is closely related to *Colchicum* and *Bulbocodium*, but the flower segments are divided to the base, forming a cluster of slender filaments instead of a tube. Ten species are known, and they are natives of South Europe, North Africa, and the Orient. The flowers of all of them are either lilac or white, with bright green stamens. That here figured is probably the best for the garden. Although long known to collectors of choice bulbs, it is not found as often in gardens as its early-flowering habit and prettiness deserve.

Those who are interested in the *Muscari* should note *M. præcox* (illustrated). It is just the right kind of plant for the cold house.

BOLD MASSING OF IRISES AND OTHER FLOWERS BY PATH.

(From a photograph by Miss Willmott.)

correspondents could tell us about the behaviour of this Rose under still lower temperatures than this.

Mr. Peter Lambert of Trier, who of late years has raised so many good Roses, distributed in 1902 a new variety, which I have not yet had an opportunity of seeing, under the name of *Perpetual Thalia*. It is said to be the result of a cross between a seedling from *Thalia* and the well-known China Rose *Mme. Laurette Messimy*, and is described in Messrs. G. Paul and Son's catalogue as a fine novelty. The raiser's description is as follows: "At length we seem to have obtained a really per-

This Muscari was introduced to Kew in 1899 by M. Siehe of Mersina. Strictly speaking, it is not a Muscari but a Hyacinthus, and probably nothing more than a pigmy form of *H. azureus*, of which we know of several forms widely divergent from the type, the most striking, perhaps, being that named *H. azureus* var. *giganteus* by Mr. Baker, also one of M. Siehe's discoveries on Mount Muris, in Northern Cilicia, at an elevation of about 4,000 feet. The form is the other extreme in size to that here figured, the latter being 3 inches high, whilst the former is almost a foot. The typical *H. azureus* was first introduced into the Gardens in 1856, but it was not generally known until about fifteen years ago. It grows about 6 inches high, and has a conical raceme three-quarters of an inch wide of deep blue flowers. The plant here figured has a smaller raceme, and the colour of the flowers is light or Cambridge blue.

Of Saxifrages the beautiful *Saxifraga burseriana* major is almost too well known to describe. Its pure white flowers are very fresh and beautiful, and little tufts in pots are as enjoyable as anything one can well grow in the cold house.

The early Irises were in full beauty on January 17, and included

I. alata, *I. Histrio*, the beautiful light brownish *I. Haussknechtii*, *I. Tauri*, *I. reticulata sophonensis*, *I. histrioides*, and other plants in bloom were the *Merendera*, mentioned above, *Iberis gibraltaria*, *Cyclamen ibericum*, *Galanthus Elwesii robustus* and *Narcissus Bulbocodium* var. *monophylla*, with many things in bud.

We shall illustrate this house shortly and give dimensions. It is inexpensive, and through the spring one of the pleasantest spots in the Royal Gardens. Amateur gardeners can learn much from Kew, and those who care for their alpine flowers in winter, when to tramp about the garden is to court various ills, should add a structure of this kind to their plant houses.

IRIS TINGITANA.

THE illustration of the beautiful Tangiers Iris on page 41 of THE GARDEN is remarkable. To the account of it by Mr. S. W. Fitzherbert little remains to be said, and he rightly conjectures that the flowering of the species by the late Mr. Ewbank in his garden at Ryde was not an annual occurrence. I have had several conversations with the late Mr. Ewbank concerning his plants, and my general conviction was that whilst Ryde as a locality was generally suited to *Iris tingitana*, it yet lacked that amount of vigour more or less essential to a more successional flowering year after year. Doubtless the greater depth of soil in the instance before us may be responsible for much of the success, also the good dressing of manure and favoured climate. What would be doubly interesting now would be to know the behaviour of this self-same group of *Iris* in 1903. I put this

MUSCARI PRÆCOX.
(Flowers turquoise blue.)

point advisedly, as I believe that age and a fairly long period undisturbed in one spot has much to do with success, in conjunction always with that good depth of soil that permits of full development. In the garden at Ryde the plants were not sheltered by any wall, nor, if I rightly remember, was manure freely given. The late Mr. Ewbank's garden was essentially a sun garden; there was no shade and no shelter available naturally. Probably with a more liberal treatment a success far more permanent might have been recorded. Any definite information concerning this species should be of the greatest value, and there are many sunny and sheltered spots in gardens with high walls reflecting the heat that could be put to account in growing this fine *Iris*. The depth of soil can be managed. What is news to me is the apparent fact of this species being almost a gross-feeding plant, and, if this has not been given in the past, a valuable lesson in rare plant cultivation has been divulged by the publication of the illustration in question and by the valuable notes accompanying the same.

Hampton Hill. E. H. JENKINS.

FLOWERS OF IRIS RETICULATA.

AMONG all the notes which have appeared in your paper concerning *Iris reticulata*, I have not seen the durability of its blooms alluded to, and I should like to mention an experience of my own. On the morning of Boxing Day a blossom of *I. r.* var. *histrioides* was discovered to have opened outside in the night. Over this our gardener put a bell-glass, and it was only yesterday (January 20) that I noticed—in spite of the severe frost we have recently experienced—that this flower was showing signs of departing its rather long and much appreciated existence. The bulb came from Herr Max Leichtlin in the autumn along with various others, all of which are well above ground and promising to produce their flowers in the course of a few days should the weather remain open.

CLARA MYERS.
Dunningwell, Millom, via Carnforth.

ROUND ABOUT A GARDEN.

THE BULLFINCH PROBLEM.

THE glowing ruby of the bullfinch's breast, shining like a danger signal among the leafless branches of a fruit tree at this time of the year, raises the question of "birds in gardens" in its acutest shape. Except the kingfisher, we have no British bird so tropical in its hue as the bullfinch. It is a feature of the landscape, wherever it sits, and with plenty of confident bullfinches about your garden you have something, even in winter, which visitors will cordially admire. But there is another side of the question. Bullfinches eat buds, especially the buds of

MERENDERA CAUCASICA.

(In flower now in the cold house, Royal Gardens, Kew.)

fruit trees. One bullfinch in a day consumes, perhaps, a potential bushel of Pippins. If you have a dozen lovely, ruby-chested bullfinches in your small orchard every day during the winter and early spring, how many Apples will you get? And the bullfinch in a Gooseberry bush presents the same problem with another background.

THE "HOOP."

The bullfinch is bad enough on the East Coast, but in the South-West he is a plague. There gardeners speak of him as the "hoop"; and old church records show that churchwardens were authorised to pay rewards in money for the destruction of foxes, polecats, kites, and "hoops." In those days civilised man had not fought out his fight with Nature to a completely triumphant finish. He had not learned how, by legislative enactment, to compel all good birds to be common and all bad birds to be rare. We are now only tinkering at the job; and, meanwhile, a crimson-throated bullfinch in a garden remains

SAXIFRAGA BURSERIANA MAJOR.

a problem. If you like birds at all, you cannot help liking the bullfinch immensely; but he is such a shrewd thing among your buds that you cannot help setting a cage-trap for him. Then, as you might expect from a bird with such a bluff demeanour and so portly an expanse of red waistcoat, he confidently gets caught.

THE SALE OF GARDEN BIRDS.

What to do with a bullfinch, when caught, is the next question. There are few men, I fancy, who can wring the necks of bullfinches; and, as he is an engaging as well as a beautiful bird, and does not fight against captivity with the unreasoning fury of many wildlings, you can at first generally find a friend or a servant who would "like a bullfinch." If, however, you have a large area of garden to protect, in a bullfinch-infested neighbourhood, you soon come to the end of the small circle of persons who would like to have one of these birds. Yet in a London bird shop the average price of a bullfinch is, or was, five shillings; and it seems to me that, if a stall were opened in Covent Garden for the sale at "popular prices" of British birds trapped by gardeners in self defence, many a fruit grower might make more profit out of his bullfinches than the bushels of Apples which the birds, if they had not been caught, might have destroyed.

THE "CRUELTY" OF CAGING BIRDS.

Many people declaim against the "cruelty" of keeping British birds in cages, but I fancy that they must always be persons who in youth kept birds badly, and are now horrified by the recollection of the sufferings which they caused. A well cared-for cage-bird lives about six times as long as a wild bird. It becomes so fond of its owner and its surroundings that when the cage is thrown open it will not fly away. It suffers so little for want of a mate that if, pitying its solitude, you introduce a prospective mate, it thinks of nothing except banging her on the head at first for her impudence in daring to intrude into its private cage. One day I heard a skylark singing divinely in a cage in a butcher's shop. "Poor thing!" said a lady, "see how it quivers its wings! How it longs for liberty." "Longs for liberty, does it, ma'am?" said the butcher, and he opened the cage door wide. Out popped the lark and flew to a shelf, where it stood, with wings quivering, close to a tin box. The butcher, chuckling, took down the tin box and opening it picked out a mealworm, which he gave to the bird, who promptly flew off with it to his cage. Whenever custom was slack, the butcher explained, he was in the habit of feeding the lark with dainties, and when he was making up his accounts and too busy to attend to it, the bird would run all over the paper and peck at his pen.

SPARROWS AND CROCUSES.

But no one, alas! will give five shillings for a caged sparrow; and February is the month of the yellow Crocus, a flower which the sparrow annihilates in many gardens. The white Crocuses and the blue lie spares, but the yellow seem to suggest some greedy connexion of ideas, inasmuch that you may, from your bedroom window, see a sparrow go down a row of yellow Crocuses, nipping them off one after the other, but never seeming to get from them anything that was worth the trouble. Apart from this eccentricity the sparrow is not nearly such a nuisance in a garden as you might gather from articles in the newspapers. He is easily scared from seed-beds, and he has no taste for buds. You do not find him inside the Strawberry nets, and he leaves the fruit alone. All through the summer, indeed, he is busy

catching insects; and perhaps if we could strike a balance the credit on the garden account would be on the sparrow's side.

FLOWERS FOR NESTS.

The sparrow is worst at nest-building time. He often begins nesting operations absurdly early, when material is scarce. Then you may see him, calmly walking round the flower-beds and tugging at the seedlings to see which will "come up" easily, so that he can add them to the pile of rubbish with which he stuffs up the water-pipe and calls it a nest. I have seen a sparrow struggle up to the roof with a whole plant of *Nemophila*, bearing half-a-dozen blue blossoms, and then return to the flower-bed and tug at all the *Nemophila* plants in turn, to see if any of them were loose enough to "come up" in the same way. The starling, however, is worse than the sparrow in this respect. In some gardens it is quite impossible to keep any plant with woolly or silky leaves in spring, because the starlings pull them to pieces for nesting material. But when I come to the misdeeds of the starling in a garden I reach a new chapter.

E. K. R.

THE FRUIT GARDEN.

STRAWBERRY FORCING.

ASSUMING that the plants are thoroughly ripened and developed, the difficulties attending successful Strawberry forcing are very few, providing proper convenience is at command. Comparatively few gardens can boast of a Strawberry house, or any house that can be devoted to Strawberry culture alone. Where space is very limited I would advise deferring Strawberry forcing to a more favourable season, when the chances of failure will be considerably less. At this early date it is no easy matter to get a good percentage of plants to flower; but this difficulty may be lessened if a heated pit is available and the plants can be plunged in a bed of leaves of moderate warmth. In so doing, the roots are encouraged into action correspondingly with the leafage. To restrict leaf growth until the flower spikes are visible a little air should be admitted on top and bottom of the pit on all favourable occasions. It is the undue hastening of the plants into luxuriant growth that causes so many to become blind. As soon as the flower spikes can be seen the plants should be placed on a shelf as near the glass as possible in a house with a night temperature of 65° or 70°. This will encourage the flowers to throw up well above the foliage. Occasional waterings with liquid manure will help to strengthen the flowers at this period. When these are opening the house will, of course, be kept dry and airy to assist fertilisation. After this success will be practically certain.

E. HARRISS.

THE OLD ORCHARDS OF ENGLAND.

(Continued from page 63.)

If an orchard is to succeed the work from the beginning must be thorough. Look about and see if this is the case. Too often I am afraid it is not. Many people buy trees at what is presumably the cheapest, but eventually proves to be the dearest, market. They get specimens with weakly stems and stunted, ill-formed heads, and place them in the ground without a thought as to conditions and soil preparation. Depend upon it there could be no greater mistake, as results will show later on. A good tree is a cheap one, no matter if it costs half as much again as an inferior specimen, and if it is to be profitable it needs better treatment than a Blackthorn. I emphasise this because at the season of planting one sees the beginnings of orchard formation that can only end in disappointment, if not disaster. When

will people realise the error of planting standard trees in pasture and meadow land, and allowing the rank grass to grow up to the stems to choke and cripple the tree in its infancy? Will some contend that this is not a mistake? If so, I would ask them to visit some of the farms in Kent where orchards are formed on arable land, which is afterwards laid down to grass, and note how the trees establish themselves under these conditions. I am aware, of course, that it is not always convenient to plant orchard trees on arable land, but this does not prevent the grower from keeping the turf away from the stems of the trees for the first few years, until they are well established; the results will more than repay for the labour. Then there is the question of

VARIETIES AND THEIR PECULIARITIES.

Let the orchard planter remember that he is doing something for posterity, and act accordingly. I am aware that there are some districts in which almost any variety of Apple will grow; but there are few localities so favoured, and therefore careful selection is necessary. Some people, before planting, select their varieties by means of a book on the subject, the writer of which may be thoroughly practical, but perhaps his advice is founded on experience gained in a locality entirely different both as regards soil and general conditions. Others choose varieties from specimens of fruit on the shelves in the fruit room at the nursery where they buy the trees. Both methods are of a hit-and-miss character; they may turn out right or they may not, and a better course for the would-be planter to adopt is to note the varieties that do well in the district, and, if they are good ones, select these for the future orchard. I would say a word also with regard to habit of growth. Some Apples, such as Wellington, Blenheim Orange, and Bramley's Seedling, have a branching, spreading habit; others, such as Lord Derby, grow upright. To plant an orchard of spreading varieties entirely means overcrowding some day, whereas if these are planted in alternate rows with trees of upright habit the danger is avoided.

ESTABLISHING TREES.

My closing advice to anyone who may be planting standard trees with the view of establishing an orchard, is to think more of the tree at the beginning, and not to be over-anxious about fruit. Fruit will be sure to follow if the foundation is well laid by planting a good specimen in deeply-worked, well-drained soil. It may need a little manure at the time of planting or it may not, according to the fertility of the ground, but feed the tree afterwards. Even if it makes rather rank growth in its early stages, it will right itself in time; better have too much vigour than no growth at all. A standard tree needs no root pruning, but the branches must be looked after and be thinned and shortened so as to secure a symmetrical head of main shoots; these will be the limbs of the trees when it reaches maturity. Some standard tree will bear fruit at an early stage, but if they do so heavily the consequent strain has an effect on the production of wood, and there is no gain in the long run. It is during the first few years in the life of a standard that the pruner must use his knife in shortening. After that the pruning is nothing more than careful thinning of the branches, removing those that rub and cross each other, and keeping the shoots evenly dispersed so as to allow free penetration of light and air. This should be an annual operation, and it is only the neglect of it that results in the thickets of branches which are characteristic of many neglected orchards in this country to-day.

G. H. H.

GARDENS OF JAMAICA.

The skies are not always bright nor the trees green in our own favoured land. The snows of winter succeed the flowers of summer, and the landscape becomes black and bare, which a few months before was clothed with verdure and beauty.

But there are other lands where these changes are never seen, where the trees are always covered

with foliage, and even the flowers may be found at all seasons of the year. The arid heat may parch the grass and wither many of the green herbs, yet Nature is ever bright and fair, and the hills and valleys rejoice in the never-changing hue upon which the eye delights to rest.

Far away beyond the seas are some of those sunny regions. There are many of us who would gladly escape from the piercing winds and benumbing cold of our own winter, and for a time at least find a refuge in those bright and beautiful climes. But content we must be with all the blessings which we have at home; if we must have the frost and the cold we have at least the enjoyment of our own fireside. But if we cannot have our ramble in reality, we may at least have it in imagination. We may follow the traveller as he explores those distant lands, and, aided by his descriptions, seek with him to enjoy the beauties and the wonders of Nature.

Let our ramble be in the "green glades" of the "sunny West," where are grouped together these beautiful islands, many of which are among the colonies of our own Great Britain. The large steamers which now traverse the Atlantic will bear us away to the West Indies, among the Coconut avenues and Orange groves, where the fire-flies dance and the humming birds drink in the dew from the flowers as the bee sucks the honey in its wayward flight.

The wide ocean is passed. Borne on the surging billows we at last find ourselves among the West India Islands. As we approach Jamaica, the "Isle of Springs," we notice the Blue Mountain Peak towering aloft 8,000 feet above the level of the sea. Anon the port is reached and our ship casts her anchor in the smooth waters of the desired haven. We have done now with the briny sea and with the star-clad heavens. We care not for towns and villages, for the haunts of men and the abodes of the great. To the forests we will go, in the pleasant shade of the overhanging woods, and by the murmuring streams that leap down the mountain side. It is for these that we thirst, and among these that we long to wend our way; the pen shall bear away its trophies as a witness to the dear friends we have left in old England of our love and of our labours. This is the land of Coffee and Sugar.

THE COFFEE

grows at the loftiest elevations; the higher you ascend the finer are the plants and the better the fruit. But it is in the low flat countries that the Sugar-cane flourishes, and there you will see the fields waving to and fro with their feathered tops, and hear the sound of the mill at the time of the ingathering.

We are now making our way up the Port Royal Mountains. We have reached those steep and winding ascents where no vehicle can pass, and where we need the sure-footed mule to carry us in safety along the dizzy heights, so perpendicular and precipitous are they that we wonder how the feet of man could have scaled these sides, or the hand of man raised plants in such inaccessible places, for it is on the mountain sides that the Coffee plantations are raised. In other parts of the island where Coffee is cultivated the ground is not so steep, but here the fine quality of the Coffee must be the chief compensation to those who plant and gather in under such difficulties; but it is only in the mountain districts that the Coffee flourishes, and there at the time of blossom the sight is beautiful beyond description. The trees, which are all planted at regular intervals, have their dark green leaves mingled with the snow-white flowers. A strong and almost overpowering perfume is swept along by the soothing breeze, and the winding valleys and rugged hills seek in vain to hide from our view their precious stores. And when the advancing season turns the blossoms into the crimson fruit and the branches hang down with their rich burden, it seems to please the eye as much as the time of blossom.

It is very interesting to observe the process by which the Coffee is prepared for use. The purple berries are conveyed to the works, and by horse or water-power the pulp is removed in the pulping-

machine. After being carefully washed it is spread on terraces called Barbicues for the purpose of being dried. This being done the dried berries are placed in a mill, by means of which a fine thin skin with which they are covered is crushed. The next process is that of fanning; this serves to separate the berries from the skin or any other matter. When carefully picked and sorted the Coffee is ready to be used in the country or to be packed in casks for exportation.

But there are much higher points above. We should have to ascend to an elevation of nearly 5,000 feet more above the level of the sea in order to reach the Blue Mountain Peak. The scenery about these passes is truly grand and sublime. It is up hill and down dale for many a long mile. Here and there we have to pass roaring streams or gushing rivulets. Then the ascent becomes more trying and difficult till we reach the Abbey Green, one of the last settlements that is to be found below the Peak.

(To be continued.)

DRACÆNA VICTORIA.

This is a very fine *Dracæna* introduced from Brazil by the late Mr. William Bull of Chelsea, and first distributed in the spring of 1899. Previous to that, viz., in the autumn of 1898, it was awarded a first-class certificate by the Royal Horticultural Society. It is in the way of the now well-known *Dracæna Lindenii*, but instead of the leaves becoming greener with age, as that does, they retain their richness of colouring or become of even a deeper hue. The leaves are broad, firm in texture, and gracefully recurved, while the margins are wavy. The major portion is golden, with a central band of bright green, while narrower stripes of an intermediate tint also occur.

During a recent visit to the nursery at Chelsea some well-coloured plants of this *Dracæna* formed a particularly bright feature in the half light of a dull winter's day.

DRACÆNA VICTORIA. (Introduced by the late Mr. William Bull from Brazil.)

Botanically, it is a variety of *Dracaena fragrans*, but horticulturally is quite distinct, and is in every way a highly ornamental decorative plant.

It, of course, requires stove treatment, but its firm, massive foliage enables it to resist exposure to draughts better than many others. It may be pointed out that the true *Dracaenas*, to which this belongs, are few in number, for the innumerable hybrid forms with leaves more or less red or bronzy to which the name of *Dracaena* is in gardens always applied are really all varieties of *Cordyline terminalis*, which occurs plentifully throughout the South Sea Islands, and is also largely cultivated in the tropics as well as in a small state in this country.

ORCHIDS.

ODONTOGLOSSUM × WALTONIENSE.

THIS beautiful new hybrid Orchid was exhibited by W. Thompson, Esq., Walton Grange, Stone, Staffs (gardener, Mr. W. Stevens), at a meeting of the Royal Horticultural Society, held on January 13; it was then given a first-class certificate by the Orchid committee. It is a flower of charming form, and rich lemon-yellow colour. The sepals have slightly recurving edges; the petals are prettily crinkled. Upon the broad, long labellum, which is of a paler colour than the sepals and petals, is a large patch of chocolate-brown.

O. crispum and *O. polyxanthum* are the parents of this hybrid, which is undoubtedly one of the most remarkable *Odontoglossums* yet raised.

SLUGS! SNAILS! AND WOODLICE!

WILL not some sympathetic reader tell of an effective antidote or a means of getting rid of these pests? By so doing he will earn the undying gratitude of hundreds of enthusiasts. We watch and tend our plants the year round: when, joy, that little pet *Odonto*, which has been so carefully watched, has at last a spike showing! With what interest have we noted the various gradations of that plant since the time when its bulbs were little larger than a Pea. Each year they have increased in size, and now the reward is *apparently* in sight. Alas! it is only apparently, for one night a silent foe, unseen, comes and feeds on the succulent tender spike, regarding it as an excellent tit-bit. It is not often that the visitor, which in its path leaves a glistening slime, is of large dimensions. If these appear they are soon detected, but it is the small unseen sluggish mite who more than equals its larger ally in comparative voracity.

"Unseen, unheard, it sets to work
Upon our 'crispum' spike;
The cotton-wool it does not shirk,
But eats away all night.
Next morn our embryonic flower
A sorry sight appears;
Gradually the tip drops lower,
The sap exudes in tears."

Lettuce leaves, bran, and the other standard methods of catching all you see are not thoroughly effective. Is there no other remedy than *persevering search*, too much zeal in which often results in scorched leaves and disfigured patches on the foliage, owing to drip from the oil lantern?

I was once told that fumigation was certain death to woodlice, but after two successive nights of this killing treatment I found them still contentedly feeding on the *Dendrobium* roots. It is very interesting to see the young roots pushing from the base of the new growths in search of food, but with woodlice on a similar mission the case is different.

If some reader can tell of a better method than prowling about half the night, he will be a benefactor to hundreds of others, besides

AN ANXIOUS AMATEUR, in *The Orchid Review*.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

USES OF CLIMBERS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—If your correspondent "Dundee Rambler" would try planting his climbers in very slightly constructed wooden boxes sunk in the ground immediately at foot of the trees destined to serve as supports, I think he would succeed in getting the plants to make a very fair show in about two years. By the time the wooden box crumbles the roots of the climber are strong enough to take care of themselves. I have found the system to succeed in an old orchard consisting chiefly of Pear, Cherry, and Plum trees, where *Bignonia capreolata*, two kinds of *Smilax*, several kinds of *Clematis*, *Jasmine*, also *Banksia*, *Crimson Rambler*, *Carmine Pillar*, one or two *Boursault*, and a variety of *Noisette* Roses are all doing well against these old fruit trees, with the exception of the *Bignonia capreolata*, which is climbing a young and vigorous purple Maple, and nevertheless shows excellent growth.

France.

IDEALGESINSTER.

POINSETTIAS AND EUPHORBIA JACQUINLEFLORA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I have a few plants of the above. The bracts of the *Poinsettias* are about over, and the *Euphorbia* has likewise finished flowering. Would any propagator of these plants tell me how to treat them from now so as to get cuttings from them, and also how to strike them, as I understand they are not easy of propagation? The *Poinsettias* are single-stemmed plants.

A. E.

[Both the *Poinsettia* and *Euphorbia* are propagated from cuttings of the young shoots, but the treatment differs in some respects. The *Euphorbias* that have done flowering, though somewhat shabby, should have a good place in the stove assigned them, and be kept sufficiently moist to encourage the formation of new shoots, but an excess of moisture must be guarded against. Early in February, or at least during that month, the first batch of cuttings will be sufficiently advanced to be separated from the plant. When the young shoots are about 3 inches long they should be cut off close to the old stem and inserted in pots of light sandy soil, such as a mixture of loam, peat, and sand in equal parts. The cuttings may be put singly in small pots, or about half-a-dozen around the edge of a 4-inch pot. By this latter method they do not take up so much room in the propagating

case, and they can be potted off without any injury to the roots if carefully done. The cuttings must not be put in too deeply, otherwise they are liable to decay, or an excess of moisture will have the same effect. They should be inserted as soon as possible after being separated from the parent plant, otherwise they quickly flag. If placed in a close propagating case or under a bell-glass in a stove temperature they will not need any water for a few days. Under such treatment they will soon root, when they may be gradually hardened off. The old plants will give several crops of cuttings, and the early struck ones may after a time have their tops taken off for the same purpose. If possible, the propagating case in which these *Euphorbias* are struck should be given entirely up to them, as they will often need more air than is suitable for many other subjects, for, as above stated, too much water is likely to prove fatal, and surface moisture may be kept down by tilting the lights. The late-struck cuttings make the most effective plants when put three in a pot, as they will not need so much stopping in order to produce well-branched specimens. *Poinsettias* may now be placed under the stage in the coolest part of the stove or intermediate house and kept dry, just giving them an occasional watering to prevent them becoming parched up altogether. Generally they may be allowed to remain there till the end of March or even later, when they may be put up on the stage in a warm house and more water given. The result of this treatment is shown in the plants starting freely into growth, and when the young shoots are about 4 inches long they may be taken off as cuttings. These should be put singly into small pots, using the same soil as recommended for the *Euphorbia*. The cuttings must be taken off close to the old wood. They should then be placed in a close propagating case in the stove, where they will quickly root. *Poinsettia* cuttings are not so liable to damp off as those of the *Euphorbia*.—Ed.]

MELONS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—What your correspondent "A. D." says about new Melons not being better in flavour than

FLOWER OF ODONTOGLOSSUM WALTONIENSE (NATURAL SIZE).
(Given a first-class certificate, Royal Horticultural Society, January 13, 1903.)

old ones no one is likely to dispute, but as the raising of new varieties is so easily accomplished and their value can be readily proved, a continual stream of them will in consequence be forthcoming. These facts account for comparatively few varieties remaining popular for any length of time. Those who remember Turner's Scarlet Gem, which was largely grown upwards of thirty years ago, will agree with the opinion that Melons in recent years have not improved in flavour. This variety was deservedly followed by Read's Scarlet Flesh and Blenheim Orange. This last has for a long time been known as one of the most reliable varieties, approaching as it does under proper treatment your correspondent's ideal Melon, viz., one that "produces fruits of high flavour under all conditions." Weather, of course, has effect upon the flavour of Melons, though management has far greater. Owing to the improved houses we have much better facilities for producing highly flavoured fruits than our predecessors had, and there is no reasonable excuse for the presence of the many badly flavoured fruits that are commonly to be met with at summer shows.

The custom once often followed of unduly drying the soil when the fruit was nearing maturity is now wisely almost or entirely discontinued, for doubtless this has been the cause of many crops of fruit being flavourless. There is usually, however, no great difficulty in growing good-flavoured Melons, provided the best sorts are selected, though it must be confessed there is no absolute certainty, as "A. D." remarks, about it until a fruit is cut and tasted. It is easy to bring about failure by neglecting simple details.

T. COOMBER.

CUSTARD MARROW IMPROVED WHITE AND PRINCE ALBERT (TOP VARIETY).
(The photograph was taken in The Gardens, Aldenham House, Elstree, last summer.)

THE KITCHEN GARDEN.

THE BEST VEGETABLE MARROWS.

MOORE'S CREAM (white).—A very prolific trailing variety, medium-sized, good flavour, splendid for exhibition, and good for any purpose. It does remarkably well in large pots grown under glass in an intermediate temperature.

Pen-y-byd.—A white trailing variety, very free fruiting, nearly round in shape, quality of the best; good for frame or culture in the open.

Custard, Improved White.—This is extremely ornamental when growing, shows and sets its fruits freely, and when cooked quite young is very delicious. It bears very freely under glass, also in the open.

White Bush variety.—Produces long, shapely fruits, suitable for a limited space in the open.

Green Bush variety.—This differs from the above in colour only.

Prince Albert.—A true stock of this is the best trailing green long sort I am acquainted with; a fine exhibition and market Marrow.

Sutton's Perfection.—A new introduction of much merit, greatly resembling Pen-y-byd except in colour. It sets its fruits very freely, and is a splendid variety for forcing; good for any purpose.

E. BECKETT.

MUSHROOM GROWING IN GARDEN, FIELD, AND COTTAGE PLOT.

(Continued from page 64.)

THE ARTIFICIAL CULTIVATION OF THE MUSHROOM IN PASTURES.

THE only way that suggests itself to us in which this can be successfully carried out is

by digging holes in pastures which are well drained and the soil of not too heavy a texture, and inserting in these holes, which should be 12 inches deep and the same in width, as much manure (prepared in the same way as advised for beds) as will fill the hole to within 3 inches of the surface, leaving room to cover it over after the manure and spawn are inserted, with the turf 3 inches thick. The manure should be rammed into the hole as firmly as possible, and the spawn, a piece about 4 inches square, inserted at the same time, as there is no danger of this small quantity of manure overheating. Finish the work by placing the turf over the hole and treading the same with the feet as hard as possible. Should hot weather soon follow after this work is completed it is most likely the turf would be killed, and as it is not desirable that water should reach the spawn or the manure at this stage, cover each turf over with half a spadeful of mould. This will keep it moist and fresh until it has had time to strike fresh roots and begin to grow again, which it soon will do when it feels the influence of the manure. As regards the season of the year in which spawn should be inserted, any time during the month of May will answer well. Before this time the earth is too cold, and would have an injurious effect on the spawn; should the season be a late and cold one defer the work until the last week in May. Should the summer prove dry and hot give a good soaking of water towards the end of July, and with this and warm showers afterwards abundance of Mushrooms should result towards the end of August, through September, and well into October, and in due season for years afterwards.

HOW A COTTAGER CAN GROW HIS OWN MUSHROOMS.

The artizan or labourer can grow his own Mushrooms. That it is possible for the ordinary working man to become proficient in the work one may instance by quoting the experience of a man well known by repute to the present writer. He was a carpenter by

trade, always having a fondness for gardening. His health failed, and he was advised to follow an out-door occupation, and his fancy turned towards growing Mushrooms for market. He started in a small way by growing them on the same principle as that adopted by market gardeners. At first he attained to moderate but encouraging success, and went on little by little, until after a few years he became one of the largest and best known growers in the neighbourhood of London, supplying Covent Garden with many tons of Mushrooms in the course of the year, as well as having established a large and lucrative business as a spawn manufacturer. This illustration is given as showing that no special training is required to qualify for the work, though not with the idea that all carpenters should forsake the bench and become Mushroom growers. The workman who may decide to try his luck in this way should well study the details given as to the treatment and preparation of the manure, as on this operation more than any other depends the success or otherwise of his labour. He will find the out of door system in ridged beds one of the best ways in which he can start, and this he can practice in his small garden, and, failing this, in his back yard. Another excellent position to make up a bed is in a cellar or any underground unoccupied room, the conditions in a subterranean position of this sort suit the requirements of the Mushroom admirably. It is in the catacombs of Paris where most of that city's Mushrooms are grown. Failing any of these conveniences, a good way is to place manure in any odd boxes there may be to spare, placing them in corners of rooms in the house, the cellar or the attic, or any other intervening space which can be spared. The boxes should be 1 foot deep, and, after being filled with manure, placed in position, covered over with dry hay, finally nailing an old newspaper down over the box. If the time is spring or summer the boxes will need watering with warm water at the end of a month, and the covering relaid. On

examination again in about a fortnight's time the Mushrooms should be making their appearance and continue regularly for six or seven weeks or more. During the winter season in this rather damp position very little water will be required, and none should be given unless the surface of the soil should appear parched and dry. It must not be supposed that there is any offensive smell from these boxes; they are perfectly sweet and without odour. The boxes may be spawned and soiled over immediately they are filled, as with a small amount of manure like this there is no danger of overheating if the manure has been properly prepared.

(To be continued.)

GARDENING OF THE WEEK.

FRUIT GARDEN.

ABOUT VINES.

AMID-SEASON house containing several varieties may now be started, and pot Vines which were cut down for growing into fruiting canes may be brought forward by being placed on fermenting material. Give water sparingly, shake out and pot when they have made growths 2 inches in length, and plunge in a bottom heat of 70°. Put in the remainder of the "eyes," using small pots firmly filled with sandy loam, and have a hot-bed in a close pit ready for them by the first week in February. Fruiting pot Vines may be kept at a temperature of 60° to 65° by night and 10° higher through the day; give air at 70°. Having selected the bunches for the crop, stop the shoots at the third leaf beyond the bunch, and allow the first set of laterals to extend until every part of the trellis is covered but not crowded with foliage. Feed well with tepid liquid manure, and cover the roots with fresh surface dressing as often as the soil is washed away from them. Guard against sudden checks by the admission of cold air or by allowing the bottom heat to fall below 70° without adding fresh leaves. If the pots are standing on pedestals the whole mass may be turned to the bottom of the pit without disturbing the roots.

LATE PEACHES.

In the management of late Peaches all pruning should be performed as soon as the fruit is gathered, when the application of fire-heat for a few weeks will cause the blossom buds to develop and ripen the wood to the tips. Vigorous shoots on young trees may be tied in full length; but should there exist a doubt as to their ripeness the strongest shoots may be cut back to a triple bud, which always contains a shoot-producing bud in the centre, but the roots must be well supplied with water from the tanks, as the buds are now swelling and a short supply of water will prove fatal to the crop by causing the buds to drop prematurely. Give abundance of air by night and day, and to counteract the influence of mild weather remove all portable lights when the external temperature is above 40°. In cold, damp localities where the open-air Peach crop is uncertain large span-roofed houses of the most simple and inexpensive character, if judiciously planted with the best late sorts, will soon prove remunerative, as the demand for late Peaches is considerably on the increase, and, like late Grapes, pay better than those early forced. For this house such varieties are suitable as Barrington, Walburton Late Admirable, Gregory's Late, Prince of Wales, Sea Eagle (a fine free-bearing variety, which keeps a long time after it is gathered), the Nectarine Peach, and a few of the high-coloured mid-season sorts, including Bellegarde, Royal George, and Dymond. Nectarines being less valuable, a good yellow like Pitmaston or Pine Apple, Stanwick Elruge, and Albert Victor might suffice.

Madresfield Court.

WILLIAM CRUMP.

INDOOR GARDEN.

TREE CARNATIONS.

THE beginning of February is probably the best time for propagating these Carnations, therefore prepare a sufficient number of 3-inch pots, which drain thoroughly, and fill with light sandy soil pressed moderately firm and surfaced with silver sand. Water through a fine rose to render the soil and sand firm, take the strongest of the side shoots, those from 2 inches to 3 inches long make the best cuttings, strip off two or three leaves from the base and make a clean cut immediately under a joint; when so made insert eight or ten cuttings around the inside rim of a pot, water sufficiently to settle the sand, and plunge the pots in a small case where a bottom heat of 60° to 65° can be maintained. Admit just a little air into the case to dispel any excess of moisture, and wipe the inside of the glass once or twice a day to remove the moisture condensed there, and shade very lightly when necessary.

LILIUM AURATUM.

Recently imported bulbs should be cleaned preparatory to potting by removing any decayed or mouldy scales. For a compost I prefer equal parts of loam and peat with a little coarse charcoal, the whole made moderately open by adding coarse silver sand. Select pots of 6 inches or 8 inches diameter to suit the bulbs; these should be half filled with the soil made moderately firm, on which place the bulbs, and fill in around them until the bulbs are firmly secured, leaving one-third of the bulb above the soil, place the pots in a moderately dry atmosphere in a temperature of 50°; if plunged to the rim in clean leaves and a little fibre thrown over the bulbs they will not require water until the young roots appear. Young plants of

CYCLAMEN PERSICUM

raised from seed sown as soon as ripe, if not already pricked off, either singly into 2½-inch pots or into seed pans 2 inches apart, should now be attended to. Any light sandy soil with an addition of finely broken crocks suits them well. Place the young plants near the glass in a moist house and in a temperature of 60°.

Wendover.

JOHN JAQUES.

FLOWER GARDEN.

PRUNING SHRUBS.

THE proper management of the shrubbery requires quite as much skill and attention as the pruning of any other trees or plants. The object of pruning shrubs is generally to modify their form or reduce growth. Now is a good time to perform this operation before the rush of other work comes on. Neglected shrubberies are an eyesore, and nothing but grubbing up and replanting will be satisfactory. To avoid this, all dead, sickly, and misplaced branches should be removed. Shorten back to within a few inches of the roots any poor growths. In the case of many flowering shrubs other considerations must be kept in view, such as the natural habit and mode of flowering. Rhododendron branches should be thinned out when too crowded, but the terminal shoots should never be shortened, as it is at the points that the flowers are produced. The Weigela flowers upon the wood of the previous year. The trumpet Honeysuckle may be spurred to one or two eyes of the previous year's wood. If this plant is allowed to run wild, the wood soon becomes weakly and the flowers small in proportion.

ERANTHIS HYEMALIS.

Those who love the little Winter Aconite will now see it in its full beauty wherever it is grown in sheltered places. This little harbinger of spring competes with the Snowdrop for earliness. It is remarkably showy, producing its bright yellow flowers profusely, often in spite of frost and snow. It is one of those plants which, like the Crocus and Snowdrop, can be planted close to the edges of beds and left through the summer, in which way it thrives much better than when removed every year. By far its best use is for naturalisation in shady spots under trees and shrubs. Here it will

grow and flourish where not a vestige of anything else can be seen, and thus we may enjoy it without providing positions suited for rarer and more fastidious things or taking any trouble whatever about it. The end of May, or beginning of June is a good time to divide or replant, and if given some light sandy soil to start in it will soon establish itself and help to brighten up spots which have hitherto been uninteresting in the early year. I have often transplanted the Aconite when in full bloom, and if lifted carefully in clumps with the trowel or spade and planted firmly in nice light soil it will make a display at once and give no further trouble.

DAHLIAS.

These should now be examined, and if fresh and plump may be covered over again for a month, but if decay has set in the suspicious-looking tuber at least should be put into peat to promote growth, but when all goes well the 1st of March is early enough to place them in heat, except in the case of those which are to be increased as much as possible. These should be started early in February.

SWEET PEAS.

Where it is desirable to have these in flower early make a sowing now on a warm dry border. If sparrows and mice abound, the seed before planting should be coated with red lead or smeared with paraffin, neither of which will injure the seed, but will keep away depredators. Should the soil be wet and cold the seed should be sown in pots under glass or in strips of turf. Over-watering must be carefully avoided when the seed is germinating or the seedlings will go off wholesale. A cold frame is the best place in which to grow them until the weather will permit of planting out. They can then be protected by placing branches of Fir or Laurel by the sides of the rows.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

KITCHEN GARDEN.

TOMATOES.

ASSUMING that seed was sown in December or early in the present month for producing plants for fruiting under glass early in May, these should by now be making progress. It is a good practice to sow two or three seeds in the centre of small pots, and when an inch or so high thin out, leaving one strong seedling in each. Avoid giving the young Tomato plants the slightest check, and, on the other hand, do not force them unduly at this season. As the pots become filled with roots, transfer the plants into 3-inch or 4½-inch pots, and keep them near the roof-glass in a warm house or heated pit with a temperature of from 55° to 60°. Pot on or plant out in restricted borders as they gain strength, which they will do as the days lengthen. Another sowing should now be made for the main crop under glass. Earliest of All and Winter Beauty are excellent for early crops, whilst Ham Green, Frogmore Prolific, and a good type of Perfection are favourites for succession.

CARROTS.

Early Carrots are always in demand, and a portion of a pit or a frame should now be prepared for sowing the seed. Excellent Carrots for ordinary use in the kitchen can be grown in frames placed on a bed of stable litter and new tree leaves, but if roots are required for exhibiting then a deep pit with a hot-water pipe running round is best. For ordinary use make up the hot-bed and place the frame thereon, throwing in about 10 inches of good garden soil, and allow the whole to become settled for a few days before sowing the seed. Tread fairly firm and sow in drills 6 inches apart. When the young plants are 2 inches or 3 inches high thin out slightly at first, afterwards drawing others when fit to be used.

CUCUMBERS.

Sow seeds singly in 2½-inch pots and plunge in the propagating bed. Use light rich soil, and do not press this, but gently push in each seed half an inch below, giving the pot a smart tap on the potting bench to cover the seed with soil. Seeds sown now will make good plants for the

NATURAL GROUPING OF SHRUBS ON ROCKY GROUND.
(From "Trees and Shrubs for English Gardens.")

early crop of Cucumbers in heated pits or houses. As the young plants require repotting, this should be done in the structure in which they are growing, and the soil and pots must be quite warm.

BROAD BEANS AND PEAS

may now be sown on warm borders, and these will succeed those already sown in pots or boxes. Continue to make up succession Mushroom beds as required; none but the longest litter should be shaken out. We obtain much better produce and plenty of it by not removing too much of the rough material. Beds formed of manure alone are apt soon to become cold and wet. Make new plantations of Horse-radish where necessary, adopting the system of planting sets (as with Seakale). I prefer to have the sets 8 inches in length, whilst for Seakale 4 inches would suffice. The order for the required number of Pea and Bean sticks should be placed. These should be pointed ready for use when the men are unable to get upon the ground through hard frosts or much rain.

Stonleigh Abbey Gardens. H. T. MARTIN.

CHRYSANTHEMUMS.

PROPAGATION OF ALL SECTIONS.

This should be completed as soon as possible, though any late-flowering kinds and any which adapt themselves for midwinter blooming, and are generally termed decorative, may be rooted and will prove useful at a much later date. February struck plants, however, will prove far more satisfactory. There is not the slightest doubt as to these annually becoming more popular, for

beautiful as the large massive blooms are in November, they cannot compare for usefulness with those specially treated for midwinter flowering. Fortunately these do not require any great skill to produce them at their best. Looking at it from a financial point of view they are probably produced at less cost at that season than any other class of plants, and are as easily cultivated by the amateur as the professional gardener. For all kinds of cut flowers they are simply invaluable, and are equally indispensable for the conservatory or for arranging about the house as pot plants. The charm of these, especially when well grown with good healthy foliage, is to bloom them in as small pots as possible. Excellent results can be obtained in those 7 inches in diameter. We seldom grow ours in a larger size. We have for some years made these a special feature, and I have often advocated their value, and from the large amount of correspondence I have received respecting them I feel sure many others appreciate their worth.

THREE GRAND NEW VARIETIES

were brought before the Royal Horticultural Society's floral committee on the 13th inst., and each justly received an award of merit. All were beautifully fresh and distinct. Perhaps the best was a very fine sport from Niveum. The

flower is pure white, the florets being forked and fimbriated, the growth also quite distinct from its parent; a very pleasing variety. Harry Whately is a brick-red-coloured sport from the well-known Framfield Pink; good. Ruby Martin is light brown, of good size, and very free. All these are worthy of cultivation, and will prove acquisitions. Many of the single varieties when required to flower late are among the most beautiful, and few things can surpass them for table decoration when artistically arranged with suitable foliage. Good healthy cuttings of

EARLY-FLOWERING VARIETIES

cultivated in pots, such as Mme. Desgrange, its sports Mrs. Hawkins and G. Wermig, Source d'Or and its sport Lizzie Adcock should now be selected. The last two named are among the best for general purposes, each being very free, the colours pleasing, and their long, stiff flower-stalks render them most suitable either for arranging in large or small vases. They should be rooted singly in 2½-inch pots, and grown on freely till the time of flowering.

POMPON AND POMPON ANEMONES.

The true value of these can only be estimated when a good selection is made and care taken to procure them at their best. In my opinion insufficient encouragement is given to these at our Chrysanthemum exhibitions. If substantial prizes were offered for them either as groups in pots untrained or in long sprays shown in large vases it would do much to relieve the monotony

(now so sadly needed) instead of offering such miserable prizes for a few blooms shown on boards. These should also be rooted without delay singly in small pots.

Examine carefully the stock of those inserted last month and make good any failures or that do not appear to be growing freely. Freshly put in healthy cuttings are preferable to these, as they will invariably make the best plants. Immediately a sufficient stock is ensured the old stools should be destroyed, the pots and drainage well washed and placed away for future use.

SPECIMEN PLANTS.

Those intended to make large specimen plants will require careful and constant attention, as the earlier the growth the better will be the after results. These should be potted on as required, and the points of the growths pinched out when a sufficient length of clear stem is assured. To induce them to break freely the most suitable place is a shelf in a greenhouse quite close to the glass. Watch minutely for any traces of rust, mildew, or aphid on all cuttings and young plants, and take means to destroy either as soon as noticed.

SOCIETIES.

CROYDON AND DISTRICT HORTICULTURAL SOC. ETC.

ANNUAL DINNER.

THE third annual dinner and smoking concert of this flourishing society was held on the 14th inst., when some sixty members and friends sat down. Mr. J. J. Reid made a capital chairman. Mr. W. J. Simpson thanked Dr. Ridley for the two papers he had delivered to them during the year. Last year they had lost their worthy and energetic secretary, Mr. Gregory. He was sure, however, that they had gained in Mr. Boshier a secretary as worthy as any man they would find among their members. Mr. P. F. Bunyard proposed "The Chairman." During an interval in the programme the chairman said he had a very pleasant duty to perform, viz., to present Mr. Briscoe with the valuable work "Book of Gardening," for his essay on "Propagating." Mr. Briscoe's paper was one which any member of the society might be proud of. The following is a programme of meetings arranged for this year: February 3, "Garden Root Crops" (excluding the Potato), by Mr. T. Bunyard; February 17, "Peaches," by Mr. Alderman, The Gardens, Morden Hall; March 3, "Mushrooms," by Mr. W. Green, nurseryman, Sidcup; March 17, "Cucumbers," by Mr. A. C. Roffey, Church Road, Croydon; April 7, discussions; April 22 (Wednesday), exhibition of spring flowers, &c., at the Art Gallery, Park Lane, Croydon (further particulars will be announced); May 5, "Sweet Peas," by Mr. H. J. Jones, nurseryman, Lewisham; May 19, "Popular Horticulture," by Mr. W. Turney, Bonchurch, Handcroft Road, Croydon; June 16, "Heating and Ventilating of Horticultural Structures," by Mr. W. J. Simpson, 51, Windmill Road, Croydon. The honorary secretary is Mr. Harry Boshier, 62, High Street, Croydon.

The first lecture in the new year of this society's syllabus of meetings was held at the Sunflower Temperance Hotel, George Street, on Tuesday, the 20th inst., when the chairman, Mr. W. J. Simpson, introduced Mr. J. Deans, who gave a most interesting and appreciable paper on "Nature's Seed-sowing." The lecturer, in his opening remarks, referred to the well-known authorities on the subject, such as Darwin, Lubbock, &c., and their theories of the many ways which Nature has of distributing the seeds of plant life over the earth, attributing the methods of dispersing the seeds to four chief ways, viz., by water, winds, birds, and animals, and explaining the channels of each in detail, thereby showing the harmonious working of Nature and her subjects. The lecturer passed round different sorts of seeds, and these served to explain in a very clear manner the points which he raised in his discourse. A good discussion by members followed the reading of the paper, and on the proposition of the chairman, seconded by Dr. Brooks-Ridley, an unanimous vote of thanks was accorded the lecturer for the splendid way in which he dealt with his subject. Seven new members were elected.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

AT Simpson's, Strand, on Thursday, the 22nd inst., the annual general meeting of this institution was held. Mr. Harry J. Veitch in the chair. There were also present: Messrs. A. W. Suttoo, P. C. M. Veitch, A. Watkins, J. Hudson, G. Munro, O. Thomas, G. Paul, E. T. Cook, R. Dean, J. White (of Worcester), H. G. Cox, and others.

The minutes of the last general meeting having been read, the secretary read the following report and balance sheet:—

ANNUAL REPORT FOR 1902.

The committee have the pleasure to submit their annual report and statement of accounts, as audited, for the year 1902. They are thankful to be able again to congratulate the members and subscribers of the institution on its satisfactory condition, and the continued progress it has made, as evidenced by the increased benefits they have been able

to dispense to those who, through misfortune, declining years, and other causes, have been forced to seek its aid.

At the commencement of the year 190 persons—103 men and 87 widows—were each receiving £20 and £16 a year respectively, entailing an annual liability of £3,452. During the year seventeen of that number died—seven men and ten widows. Three of the men left widows, whose circumstances, after careful investigation, proved to be of such a nature as to warrant their being placed on the funds for the widow's pension of £16 a year, in accordance with the powers conferred on the committee under Rule III., 13, thus leaving at the close of the year 176 persons in receipt of permanent aid. The committee propose to increase this number by recommending for election this day fifteen candidates from a list of forty-six applicants, and also to ask the subscribers to confirm their action, graciously approved by their president, H.R.H. the Prince of Wales, in placing on the funds without election all those of the unsuccessful candidates—eleven in number—at the last election, who had previously been subscribers to the institution, to commemorate the coronation of their Majesties the King and Queen, patrons of the institution, and as a thank-offering for the recovery of the King from his Majesty's recent severe illness. The total number of pensioners, therefore, on the funds will be 202, twelve more than on the corresponding date last year, and the largest number at any period in the history of the institution. Whilst fully cognisant of the increased liability thus incurred, the committee feel they will have the practical sympathy and support of every friend and well-wisher of the charity in their forward policy of assisting more of the unfortunate people whose cases plead with such pathetic urgency, and they strongly appeal to all their friends not to relax their efforts on behalf of this old and well-tried work, which for sixty-four years has done so much for disabled and decayed horticulturists, or their widows, in their time of need.

The committee are glad to be able to report that the anniversary festival dinner, which was held in May last, under the presidency of his Grace the Duke of Marlborough, K.G., proved most successful, and they desire to place on record their very grateful thanks to his Grace for his able and convincing advocacy of the claims of the institution, which brought such a substantial addition to its funds. The committee also express most gladly their indebtedness to the stewards, collectors, donors of flowers, the horticultural press, and to other helpers, whose kind services and contributions were sincerely appreciated. They likewise gratefully acknowledge the services of the honorary secretaries of the several auxiliaries, which still continue to prove valuable adjuncts to the institution.

During the year the following amounts have been received:—Reading and District Auxiliary (hon. sec., Mr. H. G. Cox), £117; Worcester Auxiliary (hon. sec., Mr. Percy G. White), £110; Bristol and Bath Auxiliary (hon. sec., Mr. G. Harris), £79; Devon and Exeter Auxiliary (hon. sec., Mr. W. Mackay), £33; and Wolverhampton Auxiliary (hon. sec., Mr. R. Lowe), £20.

The committee have pleasure in reporting that in consequence of a large public meeting and concert at Liverpool, which was attended by the treasurer and the secretary, as a deputation, an auxiliary has been inaugurated in that city, which gives promise of being very successful, and likely, under the able honorary secretaryship of Mr. Waterman, to render substantial assistance to the institution.

To the gentlemen named above, and to other friends throughout the country who have helped forward the work, the committee tender their best thanks.

The Victorian Era Fund and the Good Samaritan Fund are still a source of incalculable benefit.

From the first-named fund £104 has been distributed amongst the unsuccessful candidates at the last election who had been subscribers, and £120 has been given from the latter fund to the remaining unsuccessful candidates who were not subscribers, and to other applicants as temporary help in their distress and need. This latter fund has been particularly useful in enabling the committee to assist cases of a very pressing nature, to which, had it not been for this fund, they must necessarily have had to turn a deaf ear. As the interest alone of the fund is available—unless special donations are given unconditionally—the committee's resources are limited, and they therefore again commend it to those who have the power to increase its usefulness.

With regard to the new rules which were adopted at the special meeting in January, 1902, the committee are hopeful that they will prove satisfactory in their working and to the advantage of the institution. On the whole, general approval has been expressed with the alterations, which were inevitable under the circumstances. A suggestion which has been made from several quarters to increase the number of votes at elections to annual subscribers of twenty years' standing and upwards is receiving the careful consideration of the committee.

Unfortunately, the committee have to deplore the loss by death of many valued friends and supporters during the past year. Amongst others who have thus passed away may be mentioned G. F. Wilson, Esq., of Weybridge, a vice-president; Mr. E. W. Cathie, of Simpson's, an old subscriber; and Thos. F. Peacock, Esq., of Gray's Inn, who for many years had acted as honorary solicitor to the institution, and whose services on many occasions will be gratefully remembered.

They are glad to be able to state that W. A. Bilney, Esq., of Fir Grange, Weybridge, and Temple Chambers, Temple Avenue, has kindly consented to take the place of Mr. Peacock and to help the charity by acting as its honorary solicitor.

In conclusion, the committee most earnestly ask for renewed effort on behalf of this national horticultural charity. After to-day's election there will be thirty-one applicants left on the list who are appealing for aid, and of this number several are totally blind. To help them an increased income is needed, and, whilst being thankful beyond measure for the generous support accorded to them in their work in the past, the committee plead most earnestly for further aid to enable them to extend the

benefits of the charity to those who are so much in need of them.

II. J. VEITCH, *Chairman*.

J. WILLARD.

Mr. Harry J. Veitch, in moving its adoption, said he thought the report a most satisfactory one. With the fifteen pensioners to be elected, there would be over two hundred on the books for the first time in the history of the institution. This will necessitate an annual disbursement of £3,500, so it is essential to do everything possible to increase the income. The Good Samaritan Fund and the Victorian Era Fund do a great deal of good every year. Most grateful letters have been received from those who have been benefited by them, and also from the ten "Coronation" pensioners. The institution said Mr. Veitch, is much indebted to the auxiliary societies for their most valuable help. The Liverpool auxiliary was now constituted and promised very well; special reference was made to the good work of the secretary, Mr. Waterman. A smoking concert was to be organised early this year. At the Holland House

show, Lord Ilchester very kindly threw open the grounds to visitors upon a small payment, the money received being given to the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund. The former received as its share £113. A similar plan was to be adopted this year by kind permission of Lord Ilchester, who has again consented to a show being held at Holland House. The new rules on the whole had been well received; some few letters had been sent asking for certain points to be explained. It was absolutely necessary, said Mr. Veitch, that the rules should be altered, on account of the increased number of those who under the old rules annually became eligible for election. There would, however, have had to be an election this year in any case, as for twenty-seven qualified subscribers there were but fifteen vacancies. It was felt that the old rules were unjust also to those who had subscribed, say, thirteen or fourteen years. Now all who apply for relief go to the election, but those who have subscribed the longest are given the most votes. He felt sure that the new rules would meet with approval. Mr. Veitch also referred to the loss the institution had sustained by the death of Mr. Peacock, their honorary solicitor. Mr. Bilney had very kindly offered to take the position. Mr. Veitch read a letter from Mr. N. N. Sherwood, saying how sorry he was to see that so many candidates could not be elected this year; to each of them he would give £5 as a thank-offering for recovery from his recent illness. Mr. Denning seconded the report, which was passed unanimously.

Mr. W. A. Sutton proposed that Mr. Harry J. Veitch be re-elected treasurer of the institution, and that the best thanks of this meeting be presented to him for his invaluable services, and testified to the very valuable work that Mr. Veitch had done and was still doing for the institution. The auxiliaries were the outcome of Mr. Veitch's suggestion, and he went down personally to help inaugurate them. The new rules had not lessened interest in the institution in the Reading district. Mr. G. Monro seconded the resolution, which was passed unanimously.

Mr. G. Monro proposed the re-election of Mr. G. J. Ingram as secretary, Mr. Denning seconding. This was carried without dissent. Mr. Ingram briefly thanked the meeting for his re-election.

Mr. R. Dean proposed that the retiring members of committee be re-elected. Mr. Mc Kerchar seconded this, which was carried.

Mr. J. Hudson proposed, and Mr. O. Thomas seconded, that the auditors be re-elected and thanked for their services. This was also carried.

Mr. Denning proposed the re-election of the arbitrators. Mr. P. C. M. Veitch seconded. Carried unanimously.

Mr. A. W. Sutton proposed that the action of the committee, graciously approved by the president (H.R.H. the Prince of Wales), in the placing on the funds the eleven unsuccessful candidates, formerly subscribers to the institution, to commemorate the Coronation of their Majesties the King and Queen, patrons, be and is hereby confirmed. Mr. Sutton was sure this step would have the hearty approval of the meeting. Mr. P. C. M. Veitch seconded, mentioning that all absent country committee members received notice of this. Passed unanimously.

Mr. O. Thomas proposed, and Mr. G. Paul seconded, that Messrs. E. G. Monro and Melady be appointed scrutineers of the ballot. Passed unanimously.

RESULT OF THE POLL.

(1) Jane Kent, 6,741; (2) Jane Temple, 4,216; (3) William Glasscock, 3,305; (4) Emma Honess, 3,195; (5) John Bates, 3,063; (6) William J. Stacey, 3,056; (7) Rachel Tegg, 3,046; (8) Charles Puzey, 3,015; (9) George E. Allis, 2,991; (10) Stephen Bracebridge, 2,968; (11) William Wall, 2,878; (12) William Darvel, 2,850; (13) Robert C. Alliston, 2,825; (14) James Level, 2,761; (15) Elizabeth Gower, 2,602. Mary A. Donnan (995) and John Price (426) were placed upon the funds by the committee.

THE FRIENDLY SUPPER.

The annual friendly supper was held at Simpson's in the evening and was well attended, about sixty persons being present. Mr. Alfred Watkins (of Messrs. Watkins and Simpson) presided. He was supported by Messrs. Harry J. Veitch, H. B. May, W. A. Bilney, P. C. M. Veitch, W. Baker, and Arnold Moss. Others present were: Messrs. George Monro, William Sherwood, Edward Sherwood, Anderson, Cuthbert, Morgan Veitch, Rudolph Barr, George Barr, Ingram (of Messrs. Wood and Ingram), J. F. McLeod, M. Gleason, George Paul, E. Monro, A. Monro, W. Ponpart, K. Drost, Joseph Rochford, Mc Kerchar, Moore, Glendenning, and W. Roupell.

After the loyal toasts were honoured, the chairman proposed "our Institution and its continued prosperity." Mr. Watkins said that the adequate support of our charities was a deep problem. As a rule, the few subscribe to charitable institutions and the many do not; the problem is to get hold of those who do not give, owing either to apathy, ignorance, or selfishness. Mr. Watkins mentioned the importance of widely advertising as an aid to increased subscriptions. He was afraid the widow's mite was not much thought of nowadays, at any rate few practised the principle it taught. As an instance of the lack of interest taken in charitable work, Mr. Watkins mentioned that in Twickenham, with a population of 22,000, there were but 200 subscribers to the local hospital; he was afraid it was the same everywhere. If we could only get sixpences and shillings for the Gardeners' Royal Benevolent Institution much good might be done. The chairman mentioned the method practised by commercial travellers for raising money for their schools and benevolent institutions, i.e., by collecting one penny from each person who dines in the hotel commercial room. He thought it would not be difficult for some similar plan to be followed in aid of the Gardeners' Royal Benevolent Institution. Under gardeners might give a penny or some other small sum, say, once a week or more often, and this might be collected by the head gardener. Gardeners do not subscribe to the institution as they should; they represent a very small proportion of the subscribers. It was very sad for applicants to have to try

several times before being placed on the funds, and this sadness could be mitigated if gardeners would support the institution more. Letters of regret at being absent were read from Mr. Peter Kay and Mr. J. Sweet (who sent five guineas to the Good Samaritan Fund). The chairman announced the generous gift from Mr. Sherwood (mentioned in our report of the meeting), and said it would be well if there were a few more men like Mr. Sherwood in the world. He coupled with the toast the name of Mr. Harry J. Veitch, to whom he said he might safely leave all statistics with regard to the institution.

Mr. Harry Veitch remarked that there were now on the books more pensioners than ever before, in all 202. He said that both the additional pensioners placed on the funds were very pitiable cases—one was from Ireland, the other from Clifton. As Mr. Watkins had said, the institution knows no country and no creed. Although there were so many unsuccessful candidates, owing to Mr. Sherwood's generous gift they would receive substantial help. They must take care, said Mr. Veitch, that the money paid from the sister funds with Mr. Sherwood's gift did not exceed the pension given to those elected. Both the Good Samaritan Fund and the Victorian Era Fund are doing a lot of good. Mr. Veitch mentioned that 95,000 votes were polled during the afternoon, each five votes representing £1. There were 335 spoilt votes in 49 papers. The speaker referred to the case of William Glasscock, who applied for relief some years ago. After his application, however, he got better, and wrote the committee to that effect, asking that if he fell ill again he might be reinstated. He had since re-applied, and as a result was elected to-day. He was allowed to count the votes he had when ill previously. Although those who subscribed to the institution have a better chance of being elected than non-subscribers, by reason of the votes allowed to them, Mr. Veitch said all must be helped, for this was a charitable, not a benefit institution.

Mr. Arnold Moss humorously proposed the health of the committee, honorary officers, and country friends, to which Mr. P. C. M. Veitch and Mr. W. A. Binley replied.

Mr. Veitch advocated the extension of the auxiliaries; he thought one might well be started at York. He mentioned that small subscriptions were accepted by their Exeter auxiliary.

Mr. Binley said he would do all that lay in his power to further the interests of the institution. He had taken a great interest in horticulture for many years. He said he always patronised nurserymen at home, and could not understand those who had gardens going abroad for their seeds and plants.

Mr. W. Poupard proposed the health of the chairman, and to Mr. H. E. May was entrusted "The Old Landmark; its pleasant recollections." Mr. George Monro replying.

Songs by Mr. W. Poupard, a recitation by Mr. Monro, jun., harp solos, and songs by other gentlemen added much to the pleasure of an enjoyable evening.

ROYAL HORTICULTURAL SOCIETY.

ALTHOUGH the weather on Tuesday last was exceptionally mild, the exhibition to the Drill Hall was the smallest held for some years. Orchids, again, were the greatest attraction, together with Messrs. Cannell's Chinese Primulas. A collection of Oranges from Messrs. T. Rivers and Son, Sawbridgeworth, was of much interest. Mr. James Hudson, of Gunnersbury, gave an interesting lecture on "The Blue Nymphæas."

ORCHID COMMITTEE.

Present: Harry J. Veitch, Esq. (chairman), Messrs. James O'Brien, de B. Crawshaw, Henry Little, R. Brooman-White, Frank A. Rehder, H. Ballantine, James Douglas, Edward Hill, John Cypber, W. A. Binley, W. H. Young, W. Boxall, H. A. Tracy, W. H. White, and J. Wilson Potter.

Messrs. Hugh Low and Co., Bush Hill Park Nurseries, Epsfeld, exhibited a small group of Orchids, including such choice plants as *Cynorchis Lowii*, *Cattleya Trianae* Lower, *C. T. Atalanta*, *C. T. Cleopatra*, several plants of *Laelia anceps* sandieriana, *C. perivaliana splendens* (with rich rose sepals and petals and a beautiful orange and purple lip), *Cypripedium aurantiacum*, *C. Charlesworthii lawrenceana*, &c. Vote of thanks.

Messrs. Sander and Sons, St. Albans, in an attractive lot of Orchids exhibited several well-flowered plants of *Phaius grandifolius* var. *porphyreus*, *P. Martine* var. (*P. Blumei* x *P. tuberculatus*), *P. Norman* var., *Cymbidium eburneum* (the lovely white, yellow-throated flowers powerfully scented), *Laelio-Cattleya novissima* (*C. gaskelliana* x *L. anceps*), *L.-C. Pallas*, *Cypripedium Lord Derby*, *C. tautianum* var. *miniatum*, *C. chamber-leeanum* var., *Odontoglossum apterum* var. *album*, *Epidendrum Endresio-Wallisii*, and the handsome *Zygopetalum Sanderi*, which obtained a first-class certificate and is described elsewhere. Silver Banksian medal.

J. Bradshaw, Esq., The Grange, Southgate (gardener, Mr. G. G. Whitelegge), showed several varieties of *Lycaste Skinneri*, viz., *L. S. Enchantress*, *L. S. Fairy*, *L. S. Lady Gladys*, and one unnamed; also a well-flowered plant of *Odontoglossum* x *Bradshawae*, which was given a first-class certificate.

J. Forster Alcock, Esq., Northchurch, sent *Cypripedium insigne* var.

Norman C. Cookson, Esq., showed a cut raceme of *Odontoglossum loochristyense* Oakwood var. (*O. crispum* var. x *O. triumphans*).

Jeremiah Coleman, Esq., Gattin Park, Surrey, exhibited *Dendrobium wiganianum* and *D. w. Gattin Park* var.

F. Westlesley, Esq., Westfield Common, near Woking, showed *Cypripedium Alice Wallace*, a lovely flower, the dorsal sepal, lip and petals being suffused with a rich vinous red; *C. Euryades* var. *Gilbertii*, *C. Miss Edith O'Reilly*, and flowers of *Cattleya perivaliana* Westfield var.

A cultural commendation was given to a plant of *Ipsaea speciosa*, an Orchid with few slender leaves and bright yellow flowers borne upon stalks almost or quite 3 feet high. The dorsal sepal forms a hood over the column, the petals are at

right angles to the lower sepals, so that while the full width of the former is seen, the edges only of the latter are visible as one looks straight at the flower. This and *Odontoglossum Edwardi*, bearing a fine raceme of flowers, were sent by Mr. Bennett-Poe.

A cultural commendation was given to Mr. C. Hill, gardener to the Right Hon. Lord Rothschild, Tring Park, Herts, for a splendid cut raceme of *Phalaenopsis schilleriana*. A raceme of *P. Stuartiana* was also shown by Mr. Hill.

CERTIFICATED ORCHIDS.

Zygopetalum Sanderi.—Undoubtedly the finest hybrid *Zygopetalum* yet raised. The parents are *Z. Perrenoudii* and *Z. Mackayi*. The sepals and petals, marked with blotches of chocolate colour upon a ground of pretty pea-green, are not in themselves remarkable, but the lip is very beautiful. The predominating colour is violet, though purple, especially towards the base of the lip, is also present. There are irregular white markings more pronounced in some flowers than others. From Messrs. Sander and Sons, St. Albans. First class certificate.

Odontoglossum Bradshawae.—A very handsome and striking flower, the result of crossing *O. harryanum* and *O. andersonianum*. The sepals and petals are long and of symmetrical form; their ground colour is pale yellow. Upon the basal portion of the sepals are blotches of red. The base of the petals is white. The flat, rather large, white lip is prettily marked with dull red in its upper half. Exhibited by J. Bradshaw, Esq., The Grange, Southgate (gardener, Mr. G. G. Whitelegge). First-class certificate.

Cypripedium x *J. Wilson Potter*.—The parents of this new hybrid *Cypripedium* are *C. harrisianum* superbum and *C. Charlesworthii*. The influence of the former is very marked, and especially in the colouring of the petals and lip. The latter parent has much modified the form of the flower. The dorsal sepal is veined with crimson upon a darker ground, and has a narrow margin of white, the petals and lip are deep crimson-red. Award of merit. Exhibited by J. Wilson Potter, Esq., Elmwood, Park Hill Road, Croydon (gardener, Mr. W. H. Young).

FLORAL COMMITTEE.

Present: W. Marshall, Esq. (chairman), Messrs. C. T. Drury, H. B. May, G. Nicholson, R. Dean, J. Hudson, W. Howe, G. Reuthe, C. R. Fielder, C. Dixon, J. A. Nix, Charles Jeffries, R. C. Nottcutt, R. W. Wallace, E. H. Jenkins, W. J. James, Charles Elick, and G. Paul.

Of really hardy things those from Messrs. Wallace and Co., Colchester, included the lovely *Adonis amurensis* with golden-yellow flowers; *Iris Tauri*, in many pretty shades; *I. Ilirio*, pale blue; and the darker *I. histrioides*, being very beautiful. In addition, Galanthus Whitall showed as many variations in leaf as in blossom, and with a small group of *Crocus biflorus* made up a most pleasing lot of these earliest flowers of the year.

A small collection of hardy rock plants from Mr. A. R. Upton, Guildford Hardy Plant Nursery, included *Anemone blanda*, the fine winter-foliaged perennial *Tellina grandiflora* that is worthy attention by reason of its fine bronzy foliage at this time; *Iris alata*, much stronger than usual; *Saxifraga bursariiana* major, *Erica mediterranea* hybrida, *Sedum spatulifolium*, and *Saxifraga valdensis*. *S. longifolia* and *Pulmonaria rosea* were also interesting.

Another group from Messrs. Barr and Sons, Covent Garden, included *Lenten* and *Christmas Roses*, *Iris Tauri*, pretty sprays of the *Winter Jasmine*, *Cyclamen Coum*, very dainty and bright, and with the white form pleasing at this dull time. *Galanthus Elwesii* in pans was plentiful and showy; the fragrant white *Mezereon* always acceptable and useful; *Narcissus minimus* is the pigmy of its race, and a pot was well filled with flowering plants. In the background large bowls were filled with the Chinese Sacred Lily, very showy and strongly scented. Bronze Flora medal.

Primulas of the *sinensis* type were largely shown by Messrs. Cannell and Sons, Swanley, and may be described as fully representative of their fine strain of these flowers. The plants were mostly in 5-inch pots, and carried fine trusses of bloom. Silver Flora medal.

Messrs. Hugh Low and Co., Bush Hill Park, N., had a showy group of forced things. *Azaleas* in variety and forced *Lilac* were very good, and equally so the forced standard plants of double *Prunus*. *Palms*, *Epacris* in variety, with the tall *Acacia longifolia* magnificent in the background, also assisted in the group. In the margin *Lilies* of the Valley and the beautiful *Funkia maculata* aurea also contributed to a most useful lot of material. Silver Banksian medal.

The new sport from *Niveus*, with forked petals, was again set up. It is named *Harry Whately*, and some fifteen medium size blooms were shown. Other *Chrysanthemums* at this meeting included a golden sport from Mrs. Fogg, *Winter Cheer*, a deep rose or amaranth pink, with long stems and perfectly fresh and good flowers; *Princess Beatrice*, pale pink; and Mr. Edward Lowe, white, are all sports from *Framfield Pink*. From Mr. J. E. Lowe, Shrewley Nursery, Warwick.

Chrysanthemum Christmas Glory, a deep chestnut-crimson, came from Mr. W. H. Dyer, Frimley, Surrey; this is a good and useful shade of colour.

Some fine *Hippeastrums* were sent by the Right Hon. Lord Rothschild, Tring Park, Herts (gardener, Mr. E. Hill). These were *Rufus*, a deep crimson of the finest form; *Prince of Orange*, orange-red, netted with salmon-orange; and *Eden Kop*, crimson-scarlet, with white feathered lines and pure white interior, a handsome and striking flower.

CERTIFICATED PLANT.

The following received an award of merit:—*Tritoma longicollis*.—A very beautiful winter-flowering species. Flowering at this season, it naturally requires cool greenhouse protection. The flowers are of a beautiful clear yellow, cylindrical in form, and very refined in character. The plant is evidently free-flowering, a moderate-sized plant producing the three handsome spikes shown on Tuesday last. The foliage is long, dark green, and strongly keeled. Exhibited by J. T. Bennett-Poe, Esq., Holmwood, Cheshunt (gardener, Mr. Downes).

FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. W. Balderson, T. W. Bates, George Woodward, Henry Esling, S. Mortimer, Alex. Dean, Horace J. Wright, H. Markham, C. G. A. Nix, J. Willard, F. L. Lane, Owen Thomas, A. H. Pearson, H. Somers Rivers, W. Poupard, and J. Jaques.

Mr. George Woodward, Barham Court Gardens, Maidstone, was given a cultural commendation for *Pear Passerane*. The fruits shown were very fine ones.

Messrs. T. Rivers and Son, Sawbridgeworth, Herts, were awarded a silver Knightian medal for a collection of Oranges. No less than eighteen varieties of these fruits were shown, ranging in colour from bright orange to very pale lemon. The small Tangerine was represented, and also the much smaller Myrtle-leaved, with fruits not so large as a Crab. Among the pale-coloured fruits were the *White Lemon*, *Grape fruit* and *Jaifa*, while *Excelsior*, *Bittencourt* and *St. Michael's* were perhaps the most handsome. The other varieties were *Botelha*, *Silver Egg*, *Dun-skinned St. Michael's*, *Achilles*, *Sustain*, *Maltese Blood*, *Thlicis*, *Dulcissima*, *White* and *Brown's*. This collection of Oranges and allied fruits created much interest.

Sutton's Superb Early White Broccoli was shown by Messrs. Sutton and Sons, Reading.

REDHILL AND REIGATE GARDENERS' ASSOCIATION.

THIS association held its fortnightly meeting at Mutton's Hotel on the 20th inst., Mr. Brund in the chair. After the usual business and election of new members, the names and winners of the society's certificates were announced. Mr. Brund gained one for a good dish of *Bramley's Seedling*, and Mr. Bone with an excellent dish of *Cox's Orange Pippin*. The chairman briefly introduced the lecturer, Mr. McLeod of Dover House, Rochester, who spoke about *Carnations*. Mr. McLeod was received with cheers. The lecturer dealt with his paper and subject in a very striking manner, clearly showing that he was a master at growing *Carnations*. He divided his subject under three heads, namely, the "Malmaison," the "Tree," and "Border" *Carnations*. Considerable discussion followed, and each point was answered by the lecturer as it occurred. The following took part in the discussion:—Messrs. Brund, Wells, Peters, Duncan, Herbert, Mould, and others. It may be taken for granted that those who grow *Carnations* will put in practice the many points the lecturer emphasised. The attendance was good, about ninety members being present. A hearty vote of thanks was accorded the lecturer, who briefly responded. This brought the meeting to a close.

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY. The annual report of this society is unavoidably held over until next week.

A NOTE ON CHRYSANTHEMUMS FOR CUTTING.

THE so-called decorative *Chrysanthemums* are those sent to market in boxes and in bunches. One has only to stroll through the flower market in the early morning to see to what extent the *Chrysanthemum* is grown for cutting, and it is remarkable to see the excellent way in which the flowers are offered for sale. In many instances they appear to be as fresh as when they were first cut. Later in the day the florists' shops in the City and West End of London are bright with a *Chrysanthemum* display. Only a year or two ago the number of varieties offered for sale in this way was very limited and the flowers poor in quality. A great change, however, has taken place, and now the quantity, quality, and colour of the blooms generally offered for sale leave nothing to be desired.

The season begins as early as August, sometimes earlier, and continues well into January and even February. Now in mid-January the selection of varieties will suit the taste of the most fastidious—yellows, whites, and pinks, and an occasional vase of crimson and bronze. The market growers, instead of flooding the market in November with one or two sorts, which was the case only a few years ago, are maintaining a display over a long period, with probably more profit to themselves and enhanced pleasure to those who ultimately purchase the flowers. The flowers now offered for sale are fresh and bright.

During the time the market growers have been progressing with the decorative *Chrysanthemums* private establishments generally have been at a standstill. Of course there are gardens where the smaller flowers are grown extensively, but not many. The market growers have shown us what can be done with well flowered *Chrysanthemums*, and the present time is opportune for acquiring a selection of suitable sorts for next season's display. The various *Chrysanthemum* societies might with advantage give a share of their support to the exhibition of blooms of small to medium size for decorative work.

D. B. CRANE.

Mr. E. H. Wilson (of Messrs. James Veitch and Sons, Limited, Chelsea) sailed again for the East yesterday (Friday), and we hope his journey will prove as good for British gardens as the last.

The Earl of Warwick will take the chair at the dinner of the Gardeners' Royal Benevolent Institution, to be held at the Hotel Metropole next summer.

A fine range of glass houses.—Few ranges of glass houses erected expressly for trade purposes enjoy so public, if exposed, a site as those recently built at great cost by Messrs. Sutton and Sons, the famous Reading seedsmen. Their well-known seed grounds, situated in the fork of land that adjoins the Great Western and South-Western Railways just above Reading, has been for many years familiar to all travellers on these great railways, and it is on the northern side of the seed ground that the new range has been erected. The old glass houses in the Portland Road nursery have become too small and space there is too cramped for the firm's purposes, hence the removal of the pot plant culture to the more elevated and open site in the seed farm, where, too, the light will be so much greater and the air so much purer. The range of houses has been built by Messrs. Duncan Tucker and Co., and no expense seems to have been spared to render them everything that could be desired. The northern side, which is parallel to the Great Western Railway, is straight. In the centre is a noble conservatory some 50 feet by 40 feet, lofty, and purposed to be a winter garden, reception hall, lecture room, or for other useful purposes. Behind that is a big potting house, then large seed stores, lavatories, private offices, stores for roots, bulbs, &c., and a packing shed, even a large dry store for pots is included. Returning to the conservatory a door on either side opens into a long glass corridor, from which radiate off southwards twelve long span houses, ranging from 12 feet to 14 feet wide, while in the front of these are large span pits, frames, &c., all of the best possible form, and built to furnish every convenience. Because of the corridors in question on the north side, the inclusion of the potting sheds, and all needful conveniences, it is at once easy and practicable for workers to reach every house or part of the great range without going outside into cold air. The southern doors of the houses alone open into the open air. Two large boiler houses have been erected south of the range, each being filled with two large Cornish or Trentham boilers, and even here some simple arrangements help to save labour in a remarkable degree. Most certainly in all these matters the motto of the firm is "Efficiency." Besides the provision of large tanks in each house there is a huge tank to receive the overflow from these, which again receive from the house roofs; no less than 45,000 gallons of water can thus be stored. For the supply of the boilers a big tank at the top of each boiler house is fed by the aid of a windmill pump which lifts the water from a well. Apart from the floral attractions the houses now afford, the range well merits inspection by all who contemplate the erection of similar houses.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

Names of plants.—H. D. R.—As far as we can make out the names of the specimens are as below, though it is in some cases impossible to say with absolute certainty, as the specimens were not very good: 1, Magnolia grandiflora; 2, Bambusa (probably atrea); 3, Epatorium odoratum; 4, Cassia glauca; 5, Tecoma capensis; 6, Eunonymus japonicus;

7, a Pittosporum. Of these the Magnolia, Bamboo, Eunonymus, and perhaps No. 7 will be hardy with you, the others requiring protection.

Poinsettia pulcherrima. Is the honey poisonous? (T.)—We have no personal knowledge of any injury caused by the honey that collects on the flowers of Poinsettia pulcherrima, but the order to which it belongs (Euphorbiaceae) contains so many members whose sap is poisonous that we should be at least inclined to view it with suspicion.

Acacia (W. N.)—In all probability your Acacia is A. arabica, but whether this is correct or not it will not prove hardy with you, as all the Acacias require a greenhouse. If you have no glass structure in which you can place the plants during winter you may keep them in a good light position in the dwelling-house, and in the summer they may be placed out of doors.

Planting fruit trees (S. C. J.)—Whilst it is invariably held that the planting of fruit trees is best done in the autumn, yet it is done in many places all the winter when the weather is open. Planting of any description should never be done when the ground is even but partially frozen or when it is saturated or heavy with wet. It is a bad practice to plant when the soil is very dry also, but in such cases it may be possible to water freely. In nurseries, where of course trees of any description can be lifted and replanted at once, planting often runs into April. That is needful when from a quarter all trees needed to be sent out have been taken and those left have then to be lifted and replanted more closely. Long transit in harsh windy weather is often harmful to trees, as the roots get much dried. Nurserymen should always send trees out with the roots well damped and covered; but if received dry it is best to soak them for an hour in water before planting. If you will take ordinary precautions, planting only in open weather and have at hand to throw in about the roots plenty of fine soil, you may safely plant till March.

White Jasmine (H. T.)—The fruit of this plant is black. We give a little illustration of it.

Large Onions (PASSION).—The fine exhibition Onions you mention cannot be obtained by what is known as ordinary garden culture. They are raised by sowing seed now, although some growers sow even earlier, in shallow pans thinly, putting them in a greenhouse or frame where there is gentle warmth and ample light. Growth follows in about twelve days, and in a month the seedlings are large enough to lift and dibble out 2 inches apart into shallow boxes of any convenient size. These should be filled with a mixture of loam, well-decayed leaf-soil, old hot-bed manure, and sand. In these boxes, kept near the glass so as to induce strong growth, the plants remain till early April, when they should be shifted into a cold frame to harden ready for planting out on to deeply-trenched and heavily-manured soil. At the end of the month the plants should be lifted from the boxes with a trowel, leaving a good ball of soil attached to each, and be put out into rows 18 inches apart, the plants being 12 inches apart in the rows.

Late or midwinter Pears (AMATEUR).—There are several very good late-ripening Pears that you can grow to have late-keeping fruits; but as a rule all do best on west walls, as it is needful that the fruits be of the best well-grown sample of the variety to induce late keeping. On walls also, if netted over to exclude birds, the fruits may hang quite late, and the longer the better do they keep. The varieties are Winter Nelis, one of the most delicious of late varieties, and may in some gardens be grown on a north wall; Josephine de Malines, a very nice Pear; Olivier des Serres, President Barrabé, often very fine; Easter Beurré, and Beurré Rance. Beyond being well grown, the fruits need to be stored thinly on shelves in a cool even temperature where at times free ventilation is given. If you cannot grow against a wall, then plant bush or pyramid trees worked on the Quince stock. Get planting done at once.

Flower beds (P. CALDCOTT).—We think the plants mentioned will do quite well for the central cross bed, and we know of no better blue Lobelia than Emperor William when grown from cuttings, not seeds, while the best yellow Calceolaria is floribunda grandiflora. This blooms most abundantly. For the four circular beds we think you will obtain a good effect by using Phlox Drummondii in some of its most most showy colours. Those of the pink, red, salmon, and carmine or crimson shades are particularly showy and bright. The Eschscholtzias in gold and rich or deep intense orange are also showy and profuse. We are somewhat handicapped in giving you a fuller reply or even

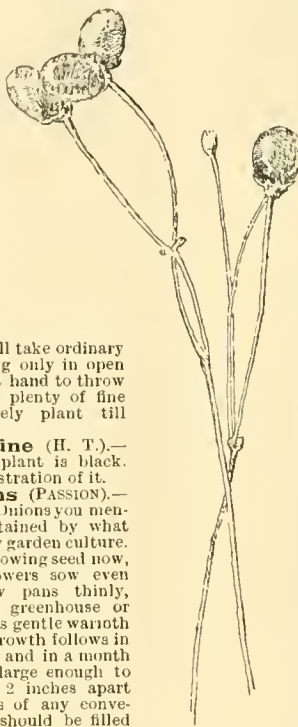

a more helpful one, as we have no information respecting your conveniences for raising plants. If you had convenience we should think a bed or two of the richly-coloured Celosias would make a fine display, or one of Zinnias, which, with the Phlox above named, would have to be raised under glass, e.g., a warm frame. The other group may be sown in the open bed.

Indian Rhododendron seedlings (E. I. T. M.).—In your favoured clime we should recommend planting out the seedlings of Rhododendron triflorum in April or May of this year. It will be far better to have the frame on the ground level than raised above it. To prepare the bed for the reception of the young plants take out the soil to a depth of about 15 inches, then place in the bottom 6 inches or so of drainage material, and complete the remainder of the bed with good soil, containing at least a liberal proportion of peat and sand. This must be broken up moderately fine (the rougher portions may be used for drainage) and pressed down firmly. When planted give a thorough watering through a fine rose to settle everything in its place. The after treatment will consist in the usual routine work, such as watering, giving air, weeding, and so on. If the frame is in an open spot, yet sheltered from the full rays of the sun, so much the better.

Herbaceous plants (N.).—We have not the least hesitation in recommending you to divide and replant almost the entire lot of plants; in fact, any that have not been divided and replanted for the past "six or seven years" could bear no comparison in their flowering with others that were replanted at least every three years or so. Had you anything but the substantial holding clay, not a few of the things mentioned would have been in a sorry plight long ago. What we now recommend is renovating the entire border as early as possible. We would go to work in the following manner: In any open weather in February lift all such things as Michaelmas Daisies, Ox-eye Daisy, Achillea, German Irises, Delphiniums, Sunflowers, Tritonias, or any other free-growing plants and heel them in for the time being. If in vigorous health we would not interfere with Spirea Arneus, Day Lilies, Oriental Poppies, Peonies, and Columbines, as these things re-establish themselves less quickly than the first set. Having laid the first batch in, you may now proceed to trench the border thoroughly, working up the soil for a depth of 2 feet at least, and putting in plenty of old manure and leaf-mould as the work proceeds. If the soil is very heavy work in road sweepings or grit to make the great mass of soil more friable. As the digging proceeds and you come near to the roots of Peonies—these in good stiff soil may go on for a score of years without replanting—Spirea Arneus, &c., a liberal supply of old manure, leaf-mould, and old mortar or grit may be worked in at 2 feet deep. Do not go too near these plants, for with the freshly moved soil and generally improved condition the outlying fibrous roots will quickly get into it. Throw up the soil of the borders rather roughly, and when completed give a surface dressing of air-sieved lime, say, one barrowful to every two rods of ground. The border may, when finished, be left alone for a month for the soil to pulverise, then before replanting lightly fork over the surface to prick in the lime. You may replant any time in March. In doing this do not make the common error of planting the old central and very hard clumps of such things as Michaelmas Daisies, but select instead from the outer circle of any clump some of the youngest and therefore the most vigorous of the stems. If you wish to make a fine display in the first season and so recompense yourself early, plant six or eight of these young pieces singly at about 9 inches apart or nearly so, and in such a way that a ground space of 2½ feet is occupied by the plants. These will grow together and form a group capable of yielding double the amount of good flowers usually seen on an old clump. Such a group will require 6 feet of head room to develop. We give you this instance that you may follow it throughout. When planting, modify it to suit the border and your own requirements. The same thing applies to the Irises, planting single crowns and several to form a group in place of the old-fashioned way of one large piece that often did not do what was expected of it. The Delphiniums may also be divided, though less severely, replanting such as have three good crowns each. If you follow this principle the border should be a showy one in due course. With respect to the Roses, a similar mode of treatment would doubtless greatly improve the plants. This should be done as early as possible, however. First carefully lift the plants, thoroughly trench the border, work in old mortar, grit, lime, leaf-mould, and manure quite freely, but do not apply the manure in bulk to the roots of the plants. It is possible that a slight root pruning may be necessary before replanting the Roses, and especially if there is an absence of much fibre and too many large roots. In replanting the Roses you may do the plants much good if you have a barrowful of grit or old mortar, old potting soil, leaf-mould, and manure at hand, placing a peck or so about the roots of each. This would probably greatly increase the number of fibrous roots which we imagine the plants are now in want of. Do not allow the Roses to remain out of the soil or get dry at the roots, but cover them till again required for planting. Surface mulching is useful where the beds are first well made for the plants, but no annual mulching can compensate for badly made beds, or for the poorly-rooted plants that invariably follow as a result of such work. The book you mention should be helpful, as also would "Roses for English Gardens."

ADVICE TO OUR READERS.

It is gratifying to find that readers of THE GARDEN take advantage of our offer of help in simple matters of advice. At the same time, any short editorial answer is not intended to be taken as exhausting the possible helpful answers. No one or two experiences can cover the whole range of horticultural practice, and answers from others bearing on the same question will always be welcomed as an additional assistance to the querist and to those whose perplexities may be of the same kind.

THE GARDEN

No. 1629.—Vol. LXIII.]

[FEBRUARY 7, 1903

ROYAL HORTICULTURAL SOCIETY'S ANNUAL REPORT.

THE report of the society for the past year is wholesome reading. Few societies, we think, are more popular than that devoted to horticulture, a fact accounted for by a widespread interest in gardening pursuits and by the subscribers getting full value for their subscriptions. Not only does the annual subscription entitle a Fellow to receive the increasingly valuable "Journal," but right of entry to the beautiful fortnightly displays in the Drill Hall at Westminster and to any other shows the society may hold during the year. It is therefore not surprising to learn that (to quote the words of the report) "the exact number of new Fellows elected in the past year has been 1,140," which is "a larger number of new Fellows than in any year since its establishment in 1804."

CHISWICK GARDENS.—Under the head of ordinary expenditure at Chiswick £1,953 has been spent on the general work and maintenance of the gardens, and including legal expenses. The receipts by sale of surplus produce amount to £373, making the net ordinary cost of the gardens £1,580."—[*Money well spent.*—Ed.]

TEMPLE SHOW.—By the continued kindness of the Treasurer and Benchers this was as successful as ever, and was visited by their Majesties the King and Queen. It is a matter of satisfaction to the council to find that this meeting is universally acknowledged to be the leading horticultural exhibition of this country."

THE HOLLAND PARK SHOW.—The best thanks of the society are due to the Earl of Ilchester for his kindness in allowing a great show of, and conference on, Roses to be held in his park at Holland House, Kensington, on June 24 and 25. Financially the show was not a conspicuous success owing to the fact of the King's serious illness taking place on the 24th, but from every other point of view it more than fulfilled expectations. The Fellows will be pleased to know that his lordship has consented to another show being held at Holland House in the ensuing year on June 25 and 26. Fellows are requested to inform their friends of this show so as to make it this year a financial as well as a floral success."

THE HALL.—Our readers will remember the discussions that have taken place as to the most fitting way to celebrate the centenary of the society, and in a leading article last week we expressed our views again as to the unworthy design for so important a building. At a meeting held on April 23, 1901, a resolution was carried

"That the proposed site is not the best means of celebrating the centenary of the society, and in

supporting this resolution Mr. H. J. Elwes, F.R.S., unconditionally offered £1,000 if a new Hall were substituted for a new garden as the celebration of the society's centenary. Mr. A. W. Sutton, V.M.H., and Mr. N. N. Sherwood, V.M.H., also offered £1,000 each, and Baron Schröder a day or two afterwards offered £5,000 if the new Hall were adopted."

We are pleased to know that the sum "subscribed up to the date of this report going to press is £22,000, which the council cannot but regard as a promising commencement. The total estimated cost of the new Hall and offices is £40,000, inclusive of furniture and equipment. While the council gratefully acknowledge, on behalf of the Fellows, the response they have already received to their appeal, they feel confident that there are very many Fellows, amateur and professional, who will desire to recognise the great and continuous advantages they receive from the society by liberally supporting the new Hall fund.

"The council are aware that the plans and elevation they have placed before the Fellows have been criticised. They desire to point out that they have purposely restricted expenditure on external ornamentation in order to provide satisfactory internal accommodation; and that the architect has to comply with the restrictions and limitations necessary to meet the requirements of the ground landlords, the County Council, and other authorities." [*It is not a question of external ornamentation, but of simplicity and dignity. As we wrote last week: "Many a large warehouse, factory, or mill building, without an atom of ornament or any intentional thought of beauty on the part of the designer, has good qualities such as are here absolutely wanting."*—Ed.]

A NEW GARDEN.—One gratifying paragraph in the report is the following:—

"The council desire to assure the Fellows that the provision of a new garden has by no means been lost sight of. The society's lawyers are in correspondence with those of the Duke of Devonshire, and negotiations for the surrender of the Chiswick lease are in progress, and they hope that these, when completed, will materially facilitate the acquisition of the new garden."

The past year has been marked by strenuous work and that keen desire to help forward the horticultural industry and love for gardening to which we must surely attribute the remarkable increase in membership.

The past year is a record one in many ways, and every well-wisher of the society will hope that the desire of the secretary to double the number of Fellows before March, 1904, may be fulfilled.

As the provisions of the New Charter require that three vacancies shall be created in the council every year, the council have decided that one vacancy having occurred already by the resignation of Mr. J. T. Bennett-Poë, V.M.H., the other two vacancies shall be created by the resignation of Mr. William

Marshall and the Rev. H. A. Berners. The vacancies are filled by the Right Hon. Lord Redesdale and the Hon. John Boscawen, and Mr. Marshall, who is reappointed.

The vice-presidents nominated are: The Right Hon. Joseph Chamberlain, M.P., the Right Hon. the Earl of Ducie, the Right Hon. Lord Rothschild, Sir Frederick Wigan, Bart., and Sir John D. T. Llewelyn, Bart.

The annual meeting takes place on Tuesday next at 3 p.m. It is seldom that a society can offer a report that records such sound progress during the year financially and, as shown by the excellent "Journal," in horticultural work.

NOTES ON RECENT NUMBERS.

GARDENS FOR WORKING MEN (page 35).—Next to the ownership of a piece of ground there can be nothing better for a working man than to have the use of such a piece as he can cultivate. Many owners of property in and adjoining country towns and large villages have already done good work in providing allotments, but much remains to be done. It is a work of the highest national importance as well as a boon to the individual and his family.

Greenhouse Flags (page 37).—The short article with this heading refers to the Iris family, but the heading itself brought to mind another kind of greenhouse flag, namely, stone paving, and the way so many greenhouses and conservatories are spoilt by being floored with many-coloured tiles. They are doubtless used with the best intention, namely, that of making the place look pretty and well cared for. But it should be remembered that in such places the beautiful effect should come from the flowers and foliage and not from the flooring, and that when the paving is made prominent the flower effect must in great measure be lost. Nothing is better than plain stone flags; their quiet grey colour is most becoming to all flowers and foliage. In the same way some gardeners spread the benches of their stove houses with bright gravel; it looks very neat and clean in itself, but the plants look better on a ground of coal ashes, when nothing that is bright or catching to the eye comes into competition with the leaf and bloom of the pot plants.

Horticultural Club (page viii., January 17).—It is to be hoped that the substance of the discussion on "Wasted Opportunities in Fruit Growing in English Villages," brought forward by Mr. Owen Thomas, may be put into shape and printed in THE GARDEN. It has often occurred to the writer of these notes that it would be an excellent thing to have in country districts small experimental gardens, where the best kinds of produce and methods of cultivation could be shown. Such gardens should

be under the charge of a thoroughly competent gardener, and should be open to the public at all times, except Sundays, before three o'clock. They should provide young Cabbage and Lettuce plants and permanent roots to cottagers at nominal prices, and should sell general produce to local retailers at market rates. The gardener and others who could help would give information and instruction on week-day evenings. Such a scheme might be amplified in several ways to the very great benefit of a large neighbourhood. If a lecture room could be added to the gardener's house, and lecturers invited or engaged, valuable instruction could be given on winter evenings. The gardeners of the neighbourhood would probably find it an attractive meeting place on Sunday afternoons, the only time in the week when they have comfortable leisure and have their minds free from the more pressing needs of their business. Such a garden would probably become incorporated with the interests of any local gardeners' society, and would immensely strengthen it. It is a matter well worth the attention of those who have the means and the good will to do useful work in country places.

Penzance Briars on Manetti stock (page 50). THE GARDEN has always preached a vigorous protest on the subject of needless grafting. It is, indeed, no wonder if the rampant Penzance Briars, children on one side at least of a wild British stock, should rebel at being grown on the foreign Manetti. These Briars should *always* be on their own roots, and indeed many, if not all, garden Roses. It is, no doubt, one of the many evils that are owing to the pressure of trade competition; growers find they must graft to get stock enough in the easiest and cheapest way; and the customer suffers. It would be well if customers could insist on knowing what they were buying, and that it should be made binding on nurserymen to state distinctly in their catalogues whether a plant is grafted or not and *on what*. Grafted and own-root plants might be differently priced. It is clearly not right that the customer should pay for a Penzance Briar and find that for two years he has an unhappy weakling Briar, and that, finally, he has a flourishing plant of Manetti.

Yuccas in the rockery (page 69).—Mr. Bartlett draws attention in his excellent note to one of the commonest faults in rock gardens, namely, the want of a few bolder plants in prominent portions of the structure. Scale must, of course, be considered, but for a fairly large rock garden, as he says, nothing is finer than the Yuccas, with their distinct forms and massive spikes of bloom. It is also important that the upper or crowning portions of rock gardens should, in almost all cases, have some plants of shrubby and permanent character. In gardens too small to admit the larger Yuccas there will always be space for *Y. flaccida*, or the one commonly grown as *filamentosa*, while a crowning growth of alpine Rhododendron, or one of the neat *Andromedas*, gives that comforting impression of permanence and good winter clothing that is so often wanting in the ordinary rock garden. G. J.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

February 7.—Société Française d'Horticulture de Londres Meeting.

February 10.—Royal Horticultural Society—Meeting of Committees, 12 a.m.; Annual General Meeting, 3 p.m.; Horticultural Club—Annual

Meeting, 5 p.m., and Annual Dinner at 6 p.m. at the Hotel Windsor, Victoria Street.

February 11.—East Anglian Horticultural Club Meeting.

February 13.—Royal Gardeners' Orphan Fund Annual General Meeting, Cannon Street Hotel, 3 p.m.

Horticultural Club.—The annual meeting will take place on Tuesday next in the Club Room, Hotel Windsor, at 5 p.m., and the annual dinner at 6 p.m.

Royal Horticultural Society.—The next meeting of the committees of this society will take place on Tuesday next, the 10th inst., in the Drill Hall, Buckingham Gate, S.W. The annual general meeting of the Fellows of the society will also be held in the Drill Hall at 3 p.m. on the same date. At a general meeting held on Tuesday, the 27th ult., forty-eight new Fellows were elected, among them being the Countess Fitzwilliam and Baron de Teissier, making a total of 138 elected since the beginning of the present year.

Geo. Monro, Limited.—As has been already announced, the business established by Mr. Geo. Monro in 1871, and carried on by him alone since 1873, has been converted into a private company. An interesting and tastefully-produced booklet, a souvenir of this important occasion, has been privately circulated. From it we learn that Mr. Geo. Monro is governing director, and Messrs. Edwin Geo. Monro (who has been in the business for nearly twelve years), Geo. Monro, jun. (manager of the flower department for eleven years), Bertrand J. Monro (salesman for eight and a-half years), Alex. James Monro (accountant for thirteen years), all sons of Mr. Geo. Monro, and Mr. Chas. Cole, salesman in the fruit department, for twenty years associated with the business, are directors. Geo. Monro, Limited, have ten premises altogether, most of which are in the neighbourhood of Covent Garden, one is in the Scilly Isles, another in Guernsey, and one in Manchester. The booklet, descriptive of this important business, which disposes of immense quantities of fruit and flowers in the course of a year, is illustrated by portraits of Mr. Geo. Monro and the other directors, as well as by views of the places of business.

The Royal Gardeners' Orphan Fund.—The annual general meeting of the subscribers to this fund will be held at the Cannon Street Hotel, London, E.C., on Friday next, for the purpose of receiving the report of the committee and statement of accounts for the past year; to elect officers for the ensuing year; to elect twenty-four children to the benefits of the fund, by special resolution; to alter Rule xiii. by inserting in line 7, after the words fourteen years: "but the committee may at their discretion in exceptional circumstances extend the usual allowance for a further period not exceeding two years. Further"; and to transact such other business as may arise. The chair will be taken at 4 p.m. The fifteenth annual dinner in aid of the charity will take place at the Hotel Cecil, Strand, W.C., on Tuesday, May 5 next, under the presidency of the Right Hon. the Earl Carrington. The secretary will be glad to receive the names of any gentlemen who may desire to act as stewards or to be present on this occasion, and will be pleased to furnish any information that may be required with reference thereto.

A great fruit and vegetable show at Chiswick.—It is proposed to hold a great show of fruits and vegetables in the Chiswick gardens on September 29, 30, and October 1 next. The secretaries' announcement is as follows: "The great autumn show of British-grown hardy fruits, which the society has held for several years past at the Crystal Palace, has become as much a thing to be regularly looked for by fruit growers as the show at the Temple in May is looked for by growers of flowers. A very strong desire has, however, been expressed that vegetables should also find a place at this show, and the council have acceded to this request, only stipulating that they absolutely refuse to accept any prizes (or money offered for prizes) which are accompanied with the restriction that the seeds from which the vege-

tables have been grown have been procured from any one specified firm. The council are of opinion that growers should be at perfect liberty to procure what seeds and whence they please. The authorities of the Crystal Palace having always strictly prohibited the introduction of vegetables at this show, it has been decided to hold it this year at Chiswick, which is nearer to London, and more quickly accessible therefrom. It is calculated that such a show, with prizes for both fruits and vegetables, cannot be held under an expenditure of £350 to £400. If, therefore, the show is to take place, it will be necessary for all who are interested (and who is not?) in the encouragement of the growth of good fruits and vegetables *within* the United Kingdom, instead of depending so much on external and foreign supplies, to combine in raising a sum of at least half the amount of money required." Cheques and postal orders should be made payable to the secretary or crossed London and County Bank.

THE VIOLET.

A VIOLET in the meadow grew,
A lovely flower of purple hue,
So modest and so shy.
There came a shepherdess that way,
With tripping step and spirit gay;
She sang as she passed by.

"Oh," thought the Violet, "if I were
The finest flower earth e'er did bear,
For just one moment's space!
My love would stoop and gather me,
And on my beauty look with glee,
And press me to her face!"

Ah, but alas! the maid passed by,
And did not hear the Violet's cry—
It lay her foot beneath!
All crushed, it sank to earth, yet cried:
"I still rejoice, for I have died
Through her!—O welcome death!"

* * * * *
Crushed 'neath her foot, it gladly died—and yet
She never even said—"Poor Violet!"

SYDNEY HESSELRIGGE.

—(Translation of the words of a song of Mozart's.)

Sale of poisonous compounds.—Mr. T. G. Dobbs, secretary of the Traders in Poisons or Poisonous Compounds for Technical or Trade Purposes Protection Society, writes: "It may interest many of your readers to know that it is in contemplation to effect a change in the law as to the sale of poisons, which, while safeguarding the public interest, will meet the convenience of large numbers of persons who make use of poisonous compounds for agricultural, horticultural, trade, and technical purposes. Hitherto the law, although it has not always been strictly observed, has required that such compounds should be sold only by properly qualified chemists, but it would be manifestly more convenient that articles such as sheep dips, insecticides, disinfectants, and articles used for photographic purposes should be readily obtainable from agricultural agents, nurserymen, seedsmen, ironmongers, and oil and colourmen, as well as chemists, the former having more practical knowledge of the uses for which these articles are required. It is understood that the departmental committee on poisons will report to the Privy Council and to Parliament in favour of an alteration in the law, and that the Government will shortly bring in a Bill amending the Pharmacy Act on the lines suggested by the poisons committee providing for the sale by licensed traders, in properly labelled and sealed bottles or packages, of articles already described as supplied by manufacturers or wholesale dealers. The pharmacists are certain to endeavour to retain their present privilege; it is for the traders who favour a change in the law to take care that the proposed alteration is made thoroughly effective in their own interests. The time is now ripe, therefore, for concerted action to be taken by the traders affected; and we, on behalf of the Traders in Poisons Compounds, &c., Protection Society shall be greatly obliged if they will at once communicate with us, so that arrangements may be made for deputations to wait upon the members of Parliament for all constituencies, claiming their support of the Bill." The address of the secretary is 24, Sansome Street, Worcester, and the treasurer is Mr. G. H. Richards, 234, Borough High Street, London, S.E.

Sutton's Superb Early White Broccoli.—The fruit and vegetable committee at the Drill Hall, on the 13th inst., before whom this fine early Broccoli was shown, expressed a desire to see other heads, the plant being sent just as it was pulled and untrimmed. One object of such requirement was to see what leaf protection was furnished to the heads, a very important matter with mid-season Broccoli, and a further reason was that smaller heads might be seen, as those sent, besides being hard-trimmed, were too large, a fault very easily remedied by the grower. Really the heads sent were as large as are those of Autumn Giant Cauliflowers in October. Gardeners at the table said the samples were too large, and they wished to see heads small and less exposed to the light. In spite of the size, however, heads cooked later proved to be soft, mild, and delicious, much more resembling Cauliflower than Broccoli. The variety is not only fine but wonderfully early, and if quite hardy should prove to be a valuable addition to winter Broccoli.—A. DEAN.

Late Chrysanthemums.—As a slight addition to the note on page 50 I may mention that Golden Dart has been grown here since its introduction, and is a useful late variety, good flowers being nearly always available until the end of January. The flowers are not more than about 6 inches across, and of good substance and colour. Golden Gate is another good late yellow variety. With reference to the matter which led to Mr. Jenkins' note, I should say it is impossible to draw a hard and fast line as to the varieties that should be grown in private places. It is a question of individual tastes, and as a rule this depends upon particular shades and their adaptability for certain lights and situations, which is probably the reason for the retention of Golden Gem in quantity at Frogmore. Personally, until very recently I had to grow more Source d'Or and Tuxedo than any other varieties, as in their respective seasons nothing was so much liked when cut.

Chimonanthus fragrans flowers. Notes on the Winter Sweet are numerous every year, but there is one feature I have not seen recorded—viz., the long-retained vitality of the flowers after their removal from the tree. When gathering the sprays that prompted the editorial note on page 2, I placed a few in a small vase in the fruit room, at the same time putting another beside the vase on the board. There was no difference as to the retention of vitality between the flowers in water and those simply on the board. At the end of a fortnight the latter were perfectly fresh and the colour of the petals was quite natural. The scent, however, disappeared after about a week. A comparison, by the way, touching this sustained vitality between the type and the variety known as Grandiflorus is altogether in favour of the latter, as the petals of the older form collapse within a week.—E. BURRELL, *Esher*.

Veitch Memorial Fund.—At a meeting of the trustees held on the 27th ult., it was decided to offer to the Royal Horticultural Society two medals and prizes of £5 each for competition at the Chiswick show, to be held on September 29 and two following days; one medal and prize to be awarded to fruit, and one medal and prize to vegetables. It was also decided to offer the Birmingham and Midland Counties Fruit and Horticultural Society a medal and prize of £5 to be awarded to fruit; also to Mr. Holland of Clay Cross, Derbyshire, a silver medal in recognition of his long and faithful services to horticulture extending over a period of sixty years as secretary of the Clay Cross Horticultural Society. It was further resolved to contribute the sum of fifty guineas towards the fund being raised by the Royal Horticultural Society for the erection of a new hall and offices.

Cercis Siliquastrum.—In the early part of this year much was written regarding this, commonly known as the Judas Tree. In some papers it was said to be very rare; it is, however, nothing of the kind, and all lovers of shrubs have known and planted it for many years past. About the time those notes appeared I was visiting one or two gardens in the neighbourhood of Yeovil,

Coker Court amongst them, and here I saw the finest specimen of this tree that I ever came across. It was about 18 feet high by 18 feet wide, growing in standard form. At the time of my visit it was full of bloom, its handsome leaves and rosy purple flowers made a lovely sight beside a fine tree of *Pyrus Malus floribunda* in blossom. Grouped in front, fringing the turf, was *Weigela rosea nivea*, a pure white variety. At the back of these were Laurels and other evergreen shrubs acting as a background. This group of shrubs in flower was charming from its simplicity and naturalness. A few days before I saw another good bush of the *Cercis* at Melbury, Lord Ilchester's fine Dorset seat. This garden contains many fine trees and shrubs. Planters should make a note of the Judas Tree and the others named above.—J. CROOK, *Chard*.

THE INDOOR GARDEN.

CAMELLIAS.

I SUPPOSE the growing taste for flowers of a light and graceful character, small and apparently insignificant as many of them are, is answerable for the decline of the *Camellia*, a decline noticeable in the scant favour accorded it in private gardens and in the low market price, as it is hardly at any time a saleable flower. There is, however, a refined beauty in many varieties very attractive to those prepared to recognise beauty in almost every flower; and certainly the long season of cutting afforded by *Camellias* is a very useful feature, especially in those gardens where there is little opportunity of supplying forced flowers in quantity. With just enough fire-heat to keep out frost, I start cutting at the end of November and continue until about the middle of April, or as long as the flowers are required. It varies a little with the season, a hot summer with plenty of sun or one dull and damp making all the difference in the development of the buds; but this would represent the average duration of the flowering season. The exact time that the plants have been in their present quarters is not easily determined, the largest probably close on one hundred years, and as the flowers show no deterioration either in quality or quantity, it must be granted that there are very few greenhouse plants that wear so well. The dimensions of the house do not admit of the plants attaining a great size either in height or width, 15 feet by 8 feet being the maximum, and severe annual pruning is necessary to keep them within bounds. They have, however, developed some fine stems, the largest being 3 feet in circumference. One of these unnamed is evidently the variety figured in Mrs. London's book as *japonica Pomponia*, and may be best described as loose Anemone-flowered, a bit erratic in shape, and still more so in colour. In the latter respect the variation has seldom been more pronounced than during the present season, some flowers nearly a pure white, others a pale pink throughout, others white with a pale pink tinge after Lady Hume's Blush, and yet others with a white ground more or less splashed or veined with pink. This is the earliest variety I have. Some splendid blooms are now available of the old *Donckelaari* and *Conspicua*, the contrast between the bright yellow-tipped stamens and the parti-coloured or pink flowers being very fine. *Conspicua* throws the larger flowers, but the petal markings of *Donckelaari* are exceptionally delicate and beautiful. The former is seldom found in England. I believe our plant was brought from the garden of Bonaparte's birth-place in Corsica. Two old varieties that hold their own for button-holes are *Lady Hume's Blush* and *Cup of Beauty*. The groundwork of the latter is pure white with occasionally a very thin pink streak. This, although tiny in size, is very clear and well defined; the flower is comparatively small, retaining its cup-like character to the end. Other sorts in the beds are *Alba plena*, as large a plant as *Pomponia*, *Marchioness of Exeter*, *Woodsi*, *Chandleri*, and a dark scarlet under the name of *Rubens*.

The *Camellias* in question are quite a contradiction to the theory sometimes put forward that a certain amount of open-air treatment is essential to the proper development of flower-buds. Not only have they been under cover all through their career, but the house is also poorly ventilated. It is a span with a brick wall at back, high front sashes, and a very flat-pitched roof. Of the back portion of the roof none of the lights are movable, and in front only one in three, ventilation being mainly supplied by means of the front sashes, as well as in summer by the opening of all doors. For some time I used no shading of any form, but, finding that the young growth was apt to scald a little owing to the hot sun striking on leaves that had been damped by rain driving through the open sashes, I have for the last few seasons shaded a little, as the young growth was well started. With the end of flowering a considerable amount of pruning is always necessary, especially at the top of the house and to the wall of foliage facing the front sashes. I like to get the pruning over as soon as possible, because if front growth has to be cut away it naturally means relying on back wood to furnish another season's display, and consequently this should get all possible benefit of light and air. Varieties differ considerably in the amount of flower-buds annually furnished, some only just about enough to get a fair display all over the plants, whilst in others they are produced in great profusion, necessitating a lot of disbudding. *Alba plena*, *Pomponia*, and *Woodsi* are the most prolific in this respect, from five to nine buds often showing on pieces of wood not more than 4 inches in length. In such cases I generally leave one terminal bud and another towards the base of the shoot, a succession of flowers being thereby secured. Watering is regulated by the seasons—in summer once a week, in spring and autumn once a fortnight, and in winter once in three weeks, care being taken, whether the operation is performed frequently or at wider intervals, always to give a thorough soaking. Cow manure is the only stimulant used, the invariable practice being, so soon as the flower-buds show signs of plumping up, to get a couple of loads from the park and cover the beds all over with the same rather over an inch thick. I used to put this on in early summer, in May, directly after pruning and tying in where finished, but discontinued it until later in the year, finding that the earlier surface-dressing had a tendency to promote rank growth, and that flower-buds under such circumstances were but sparingly produced. E.

THE FLOWER GARDEN.

THE TREE MALLOWS.

(LAVATERAS.)

PROBABLY there are about two dozen species of *Lavatera* known, the majority of which are natives of the Mediterranean region and Western Europe. One species is found in Australia, whilst others occur wild in the Canary Islands and in Central Asia. Under cultivation in English gardens two species only can be said to be of importance, one of which, however, may be classed amongst the most beautiful and showy of the hardy annuals we possess. This is *L. trimestris*. The genus belongs to the Mallow family, and is nearly allied to *Malva*, from which it differs chiefly in the lobing of the outer envelopes of the flower. The name was given by Linnaeus in honour of two naturalists (brothers) called Lavater, who lived in Zurich during the eighteenth century.

L. trimestris.—This is the best and the commonest of *Lavateras* in gardens. It is an annual, and is a native of Southern France, Spain, Morocco, and most of the countries that surround the Mediterranean Sea. It was first introduced to Britain in 1633, and is certainly one of the showiest of hardy annual plants, and grows about 3 feet high. The leaves towards the base of the stem are larger and more rounded than those towards the top, where they become narrow, pointed, and lobed.

The flowers are each 3 inches to 3½ inches in diameter, and in the typical plant are of a bright rose colour with a patch of maroon in the centre. In the variety *alba* they are pure white. The flowering season extends from July to September. The flowers are charming for indoor use; the greater part of the stem, with its open and unexpanded blossoms, should be cut and arranged in vases, &c., in which the blooms will continue to open and remain in full beauty for several days. The plant is worth growing in a reserve plot for this purpose alone. The seed, which can be purchased for a few pence from any seedsman, may be sown in March or early April on the border where the plants are desired to grow and flower, thinning them out when an inch or two high. Like most of the Mallow family, the plants like a deeply-dug and well-enriched soil. The variety *malvaformis*, discovered by the late Mr. John Ball at Reraya, in Morocco, has smaller flowers of a pale purple colour.

L. arborea (the Tree Mallow, or Sea Mallow).—This is a shrubby species abundant near the sea in various parts of South-Western Europe and in the British Isles. It has been gathered wild in the south-west of England, in Ireland, and on the Bass Rock in the Firth of Forth, always near the sea. Inland, in the latitude of London, it is not hardy, but in the gardens (often cottage gardens) near the coasts of Cornwall and Devon it is very often to be seen. Under cultivation and grown in rich, deep soil it reaches 6 feet to 10 feet in height, and has thick succulent shoots bearing large, soft, and many-lobed leaves. The flowers are each 2 inches to 3 inches across and pale purple. A more showy and attractive plant than the type is the var. *variegata*, a form sent out many years ago and given a first-class certificate by the Royal Horticultural Society. It is, unfortunately, no hardier than the green-leaved plant, and requires protection in winter, but it is a striking plant when well grown and in full vigour, the leaves being splashed with large, irregular patches of white. It is worth growing in an unheated or cool greenhouse, can be propagated from cuttings, while it comes fairly true from seed.

The two following are in cultivation (as are also several others), but it is chiefly in botanical collections that they are to be found:—

L. Olbia (the Tree Lavatera).—A native of the south of France, and especially common in Provence, where it is known as *Lavatière d'Hyères*, and whence it was introduced to Britain in 1570. It is now naturalised in some of the warmer parts of this country. It is naturally of shrubby appearance, growing from 2 feet to 6 feet high, with five-lobed leaves of the usual soft texture and reddish-purple flowers, each measuring 2½ inches across and produced from July to October. The variety *hispidia* is a more woolly form, a native of Barbary.

L. thuringiaca.—A hardy perennial that was in cultivation in Britain in 1732 and mentioned by Philip Miller in his Dictionary, but not of sufficient merit to be generally cultivated in these days. It grows wild in Scandinavia, Germany, the region of the Danube, Asia Minor, and Siberia. The stems are annual and bear their purple flowers during July and August.

R. T.

THE BEST TUFTED PANSIES.

(In reply to "Q.")

WITH so many really first-rate tufted Pansies (Violas) now in general cultivation, it is not easy to make a selection of a limited number. Tufted Pansies can never be regarded other than bedding flowers, and to see them at their best they should be grouped in colours of one variety at intervals in the hardy border or planted in masses by themselves. Some of the dwarfer and more compact sorts make a pretty edging to a large border, and this in the distance is very pleasing. The miniature-flowered type so charmingly represented by the late Dr. Stuart's rayless white, named *Violetta*, is excellent for edgings to beds and borders. I wish more attention were given to this smaller type of flower. Of those now generally

catalogued almost the whole of them are sweet-scented. The following selections will no doubt meet the requirements of most readers of THE GARDEN:—

SIX RAYLESS SORTS.

Melampus.—A pretty rayless Pansy with an almost circular flower, deep rich yellow in colour. Each one is on a stout, erect footstalk, well above the compact and robust growth. A free-flowering variety.

La Vierge.—This is another pretty circular rayless flower. It blooms freely, and is pure white with an orange eye. It is of excellent habit.

Blanche, *syn. White Empress*.—There is considerable doubt as to which is the proper name, and the same variety is frequently met with as often under one name as the other. The flowers are large, of good form and substance, and the colour may be described as pale creamy white, with a yellow eye. Good habit, robust growth, and free flowering.

Blue Gown.—If a good stock can be obtained, this variety is excellent. The flowers are of medium size, and appear freely on a perfect tufted habit. It is another of the late Dr. Stuart's gems. The colour is pale blue, tinted mauve, with a yellow eye, giving a pretty finish.

King of the Blues.—There is no better blue Pansy in cultivation than this. The flowers are not large and produced freely. The colour is deep blue, with rich yellow eye; good compact habit. Unfortunately, the stock is difficult to obtain, so few specialists possessing it.

Leda.—This finds many admirers. The flowers belong to the edged type, are large, creamy white, neatly margined pale purple-blue. Habit dwarf and tufted.

TWELVE RAYLESS SORTS.

In addition to the six sorts already described, the following will complete the selection of twelve varieties:—

Floricele.—This is a beautiful rayless variety, and one of the most distinct. The flowers are of somewhat oval shape, beautifully finished. Colour bluish lilac, and borne well above the procumbent growth.

Rosea Pallida.—Another handsome bedding Pansy, with charming rosy lilac flowers; the growth is most dainty, dwarf, and compact.

Queenie.—This is a pretty flower with a creamy white ground, edged and streaked with pale lavender. When massed in the border the effect is very pleasing. Each flower is borne on a good length of footstalk, which stands well above the tufted growth.

Deronshire Cream.—A very profuse flowering Pansy; the flowers are not over large, but appear persistently and profusely. The colour is rich cream; good habit.

Sweet Lavender.—This is a distinct lavender-coloured self introduced in 1893. The flowers are of good size and produced freely. Although its habit is not so good as some it is worth a place in a small collection. It blooms very early in spring.

Pembroke.—One of the best of the rayless yellow varieties. The yellow colouring is rich and deeper on the lower petal, the growth vigorous, and in the late season somewhat coarse.

FOUR MINIATURE FLOWERED RAYLESS SORTS.

For alpine gardens these small-flowered Violas are very suitable:—

Violetta.—The original type, and without a doubt the best of all. The fragrant flowers are about 1½ inches to 1¾ inches across, and are produced on long flower-stalks. The growth is dwarf and compact; free-flowering.

Forget-me-not.—A really dainty little flower, white ground and rayless, prettily edged with bluish lavender. The plant grows freely, and has a perfect habit; it is also a profuse flowering variety.

Pigmy.—As a plant for a narrow margin to a large bed or border this excels. It is of good growth, and blooms freely and persistently; colour deep purple-blue, with neat yellow rayless eye.

Robin.—This is a most distinct variety, of very dwarf and compact growth; colour rosy blush. It remains in flower for many months.

Highbate, N.

D. B. CRANE.

ALPINE SHRUBS IN THE ROCK GARDEN.

LINNEA BOREALIS.—This charming little shrubby plant, a representative of the once numerous Arctic flora of Great Britain, is one of the most handsome of this class. It is a creeping evergreen, with small, roundish, slightly crenate leaves and pendulous bell-shaped flowers, either white or rose tinted, and usually sweetly scented. The European form has bright green leaves, sparingly hairy and slender smooth wood, while the American form is more hairy and the colour of the leaves is not so green. The former is the more handsome of the two. *L. borealis* is easily grown in peaty soil, fairly moist, and shady at the north side of the rock garden. It is also well adapted for pot culture as well as for the wild garden.

Helianthemum (Rock Cistus).—A genus of pretty shrubs, of which one or two species are quite common in Great Britain. The most common is *H. vulgare*. This is found quite close to London in meadows and wastes. They are all dwarf, either creeping or erect-growing shrubs, and are almost evergreen, with small oval or roundish leaves, and usually large, showy, invariably brightly coloured flowers. In the various species there are many garden forms of different shades of colouring, pure white to yellow, red-purple and orange flowers often spotted single and double, and the leaves are often in the erect-growing kinds silvery or lanate. The garden forms are usually much freer than the wild species, but each flower only lasts about a day. The forms of *Helianthemum* are very numerous, and as all are worth growing I shall not enumerate them. They are, however, difficult to transplant, and it is therefore advisable to plant only pot-growing sorts, which should not be too large and quite young, as these will always be the most satisfactory. They grow best in exposed, dry, sunny situations in poor stony soil.

Euonymus radicans, the now recognised typical species, is an evergreen of very close and creeping growth, with small, roundish, dark green leaves. It is useful for fairly moist, sunny, or shady positions in any kind of soil. It is apparently still rare, and is not so well known as it deserves, especially as the variegated large-leaved form known under the name of *E. radicans* fol. var. is not so pretty.

Betula nana.—A pretty little shrub often seen as the last plant of the tree order near the eternal snow of the high Alps, also in Northern Europe, in Norway and Sweden, and occasionally on the mountains of Scotland. It rarely grows over 1 foot to 1½ feet high, and has roundish, light green leaves, netted beneath, and is deciduous, like *Betula alba* and allied species.

B. pubescens is another dwarf form, growing mostly in boggy soil; also a high alpine.

Cytisus Arduini.—This is of dwarf, creeping growth, with small ovate hirsute leaves and rather large yellow flowers. A fine plant for the sunny part of the rockery or front row of the herbaceous border.

Genista dalmatia most resembles a small *Ulex*, of dwarf, erect growth, with small, ovate leaves, and pretty yellow flowers. When well grown it is undoubtedly one of the most handsome of flowering shrubs. *Genista pilosa* fl.-pl. is a well-known plant, of close creeping growth, and double yellow flowers.

Vaccinium Vitis-Idaea.—A dwarf evergreen, from 6 inches to 12 inches high. The leaves are obovate, smooth, bright green, and rather larger than most of the other kinds. The handsome flowers are bell-shaped, white or rose-coloured, and later in the year the shrubs are covered with bright or dark red berries.

V. Oxycoccus.—A bog plant with almost filiform stems and small, ovate, acute leaves and red berries; edible, especially when preserved. Another and larger form is *V. macrocarpon*. All these *Vaccinium* grow best in peaty soil.

Gaultheria procumbens is one of the best and most beautiful of dwarf evergreen shrubs. It scarcely grows over 6 inches in height, and has ovate or obovate thick leathery leaves, at first deep green, later in the year purple. The flowers are white or rose-coloured, urceolate or bell-shaped, and during the autumn and winter the plants are covered with large coral-red berries formed out of the persistent calyx. The berries have a strong spicy scent. This species grows best in peaty soil or leaf-mould in the shade of trees on the north side of the rockery, and as the plant is of fairly rapid growth it soon forms large masses.

G. myrtifolia is much rarer and comparatively little known. The small leaves are heart-shaped, hirsute, and the flowers are white. It is of slow and dwarf growth. Grows best in shady, sheltered places in peaty and fairly moist soil.

G. Shallon in poor, exposed positions grows only about 9 inches to 1 foot in height, but in Cornwall I have seen it often 4 feet and 5 feet high. The leaves are ovate, rather large, and evergreen, as in the former. The flowers are bell-shaped, white or flesh coloured.

Pinus.—Of these there are several dwarf-growing kinds, also of the abies, and in fact of most of the coniferæ. Of late years a number of dwarf forms have been introduced, which are very acceptable for the rock garden and its surroundings.

Veronicas.—The shrubby kinds have become very numerous since the introduction of the many alpine species from New Zealand. The best of them are probably *V. epacrioides*, *V. Hectorsi*, *V. cœrulea glauca*, *V. pimeleoides*, and *V. buxifolia*, and all of these have proved to be quite hardy in Great Britain.

Ononis fruticosa.—A pretty leguminous plant growing about a foot in height. It produces nearly through the whole of the summer an abundance of rosy flowers. *O. rotundifolia* is similar, but much commoner than the former.

Potentilla dahurica is probably a form of the well-known shrubby *P. fruticosa*, but very dwarf and creeping. G. REUTHE.

THE ROCK GARDEN.

ROCK GARDEN-MAKING.

VI.—PROBLEMS IN ROCK-BUILDING.

IN previous chapters I have already given general hints and suggestions in rock-building, when the stones used were of the *igneous* or unstratified class. By way of explanation I gave also examples from Nature's own work illustrating the natural disposition of such rocks (see THE GARDEN of January 3, pages 7 and 8), and in the issue of December 27 of last year a small rock garden was illustrated during various stages of the work. I will now give another example, viz., a case in which the circumstances were peculiar.

The reasons for constructing rock gardens are various, and probably in no two cases quite alike. One lover of plants has become enraptured with the gems of the mountain plants and desires to found a home in his garden for the flowers he loves; another, perhaps, has a fascination for rock shrubs, and constructs a rock garden specially adapted for showing his favourites to the best advantage; still another is fond of picturesque scenery, and introduces into his garden bold rocks surrounded by broken, irregular ground. But sometimes it may so happen that the ground which is to be laid out as a garden is of so peculiar a nature that its partial transformation into a rock garden is not only the best and most effective way out of a difficulty, but also the most economical. Such is the case here illustrated. The accompanying illustration repre-

sents a view in the gardens of Mr. E. Hain, M.P., as laid out a few years ago by Messrs. R. Veitch and Son, of Exeter, at Trelozhan, St. Ives, Cornwall.

When the handsome mansion was erected the few acres of ground surrounding it were simply a desolate waste, being, in fact, the site of an ancient mine. There were boulders of granite and "blue elvin" partly scattered over the ground and partly buried under mining *débris*. But apparently the greatest obstacle to the making of a garden was the huge piles of mining rubble from which the ore had been extracted, and which consisted of broken stones averaging about the size of a man's fist. Many thousands of tons of this mining rubbish or waste had been deposited on the ground. The main ridge was about 120 feet long and 20 feet to 25 feet high, forming an angle of 40° to 45°. To cart away this huge mass in order to give the garden the usual orthodox level appearance would have involved an enormous expense without gaining any other effect than that of formality. Why not turn the whole ridge into

in and out, going sometimes above and sometimes below the level of the less steep adjoining ground. This trench proved of the utmost importance. Into it large and small stones were placed, and around and between the stones soil was filled in and firmly rammed. This gave a firm foundation. Without such precaution any stones or soil placed on the steep bank would have been slipping away continually.

In the illustration, on the left side in the foreground, some of these foundation stones, irregularly placed, may be plainly seen. The illustration also shows how the "rocks" are broken up at intervals, leaving between them large and small spaces covered, not with stones, but with green sward or with various plants. But although on the surface scarcely any stones are visible in such spaces, there had to be a connexion underground, especially in the steepest parts, where, starting from the firm foundation above referred to, it was necessary to place stone upon stone for the sake of support, in order to allow much larger stones

HEAP OF MINING RUBBLE MADE INTO A ROCK GARDEN AT TRELOZHAN, ST. IVES, CORNWALL.

a rock garden? The suggestion was accepted and carried out. The result is shown by the illustration, which, however, was prepared from a photograph taken some time ago, and now, since the plants have grown up and have hidden some of the defects, the effect is more pleasing and more natural. As in other gardens cases may exist where it might be desirable to treat unsightly ridges of rubbish in a similar way, it may not be amiss to give here a brief description as to how the transformation was effected in the present case.

As the ridge of small waste stones had been left just as in days gone by the miners had tipped them from their trucks, it was naturally very steep, and on being disturbed this rubble would shift and roll down the steep incline. It was necessary, therefore, to remedy this. In the first place, the rubbish was spread out in some parts while left untouched in others, so as to effect as much variety as possible under the circumstances.

In other portions recesses were dug out in order to increase the irregularity. At the bottom of the steepest parts of the incline a trench was dug out, not straight, but winding

in the higher parts to protrude more prominently. Only when the firm support of such large stones was properly secured could the smaller stones between the bolder groups be covered with soil, &c. Where the rubble had been spread, so as to be less steep, holes were dug out here and there for large single stones and sloping trenches on a higher level, where it was intended to combine the stones into groups to resemble massive rock.

As the stones used for the construction of this rock garden were those found in other parts of the same ground, namely, granite and "blue elvin," which are both of the unstratified kind, anything like regular layers or strata were carefully avoided. In the centre of the picture are some rocky steps, facilitating access from the lower to the higher parts of the ground. But even these steps were kept as irregular as possible, so as to give the idea of naturally scattered pieces of rock rather than that of a staircase. Between the steps *Thymus lanuginosus*, *Veronica rupestris*, *Sedum spurium*, *Thymus Serpyllum albus*, *Erinus alpinus*, and many others have been planted with good effect.

Among rock shrubs which adorn this rock garden may be mentioned many shrubby Veronicas, including *Veronica carnosula* and *V. buxifolia*. These have done remarkably well, as have also the many kinds of *Helianthemum* or Rock Cistus, for which the comparatively dry exposed slope seems well adapted. *Rhododendron ferrugineum* and *R. hirsutum* have also done fairly well. Of other rock plants which have here given very satisfactory results, I may mention various Thrifts, *Dianthus*, and *Plumbago*, also *Statice*, *Artemisia stelleriana* with its long silvery shoots, and the prostrate *Acena ovalifolia* have formed a dense covering. Of *Mesenbryanthemum*, the quick-growing *M. edule* has covered the bare southern slopes, while *M. uncinatum* adorns the more rocky portions. That this rockery is also full of *Arabis*, *Aubrietias*, *Alyssum*, and other spring flowers goes without saying.

Since the photograph was taken many good things have been added to the plants, and visitors never suspect that the same spot was only a few years ago a heap of mining rubble piled into a ridge.

Elmside, Exeter. F. W. MEYER.
(To be continued.)

NOTES ON HARDY PLANTS

CAMPANULA LACTIFLORA

ONE of the most interesting of the whole family is this beautiful Bell-flower, and, as the illustration suggests, produces sheafs of flowers, white, except in the variety *cerulea*, of which the colour is soft sky-blue. A group of it was formerly in the cottage garden of the late Mr. G. F. Wilson at Weybridge. It is quickly raised from seed, and in fairly light soil soon becomes established. V.

VIRGINIAN CREEPER *v.* IVY.

THE use and abuse of Ivy for covering walls has been often discussed by the antiquary and the gardener from their own distinct points of view. An old Ivy-clad ruin has undoubtedly many charms, but for the archaeologist, who has the happiness of being able to combine both the picturesque and the antique, there is always the thought that beneath Nature's dense clothing there is, in all probability, some choice architectural decoration of a past age which is not only hidden from sight, but whose destruction has been going on for years, perhaps to be finally and irretrievably lost beyond recovery should the Ivy at any time be forcibly removed, for in the process of tearing down its tightly clinging stems much destruction is caused to stone and brick surfaces.

The planting of Ivy on plain brick surfaces under conditions where such brick buildings are eyesores has much to commend it, but even then choice should be made of such varieties of Ivy as to produce the best effect, without too great prominence or overloading.

There are far too many illustrations in the country of valuable buildings and priceless relics of past ages that have become a prey to the Ivy, such, for instance, as the church of the Holy Cross, Winchester, thus seeming to fulfil the words of Dickens that "the stateliest building man can raise is the Ivy's food at last." That this, however, need not be so has been forcibly shown of late in a most useful and interesting paper on "The Preservation of Ancient Buildings," read before the Architectural Association by Mr. W. D. Caröe in April last. The value of this paper is so important that its contents should be known outside the circle for which it was originally written, for it appeals more or less to all who have anything to do with plants, especially in relation to buildings.

With these important bearings in mind I think no apology is needed in drawing attention to Mr. Caröe's paper and in reproducing some of its most salient facts from the garden point of view; for though we personally most cordially support the author in almost every word he says on "Restoration, Reparation, Preservation, Protection," there is much that especially concerns the gardener and horticulturist. On the subject of the preservation of ruins as ruins, Mr. Caröe thus writes on the destruction of Ivy: "Quite apart from the destructive qualities of Ivy, the entire concealment of architecture by an evergreen growth is merely the rendering of it valueless. It might as well be a rough brick wall, and any beauty such a combination possesses belongs to the Ivy and not to the architecture. One is reminded of the seer of Brantwood's words: 'The artist who looks to the stem of the Ivy, instead of the shaft of the pillar, is carrying out in more daring freedom the debased sculptor's choice of the hair instead of the countenance.' For the artist you may substitute the general lover of the picturesque and of antiquity, who is horrified when the parasitical growth has to give way to the exposure and preservation of its victims."

Mr. Caröe's recommendation of a substitute for the Ivy will, in most cases, if not in all, be endorsed by the gentlemen whose co-operation he invites. "Of course," he says, "in the early days, after Ivy destruction, your building looks bare and unclad, but take heart and counsel; Nature has provided a most happy substitute, which is as harmless as it is beautiful. You may plant *Ampelopsis Veitchii* to any extent, the lovely light-hearted and fickle, but always tender sister of the stern and solemn Ivy. After two or three years of patient tending and watching, the growth of a plant which has tested and likes its situation is almost phenomenal. You have the daintiness of the spring leaves, the richness of the summer green, and the glory of the autumn sunsets; and when the glory has departed all your architecture is revealed again, with the tender stems only adding texture to the walls. At the highly interesting church of Westwell, near Ashford, in Kent, a church where the thirteenth century groining is done in concrete, this creeper has been permitted to grow over the window glass, which it loves to do. The glass is fortunately transparent. The effect is more beautiful than any modern glass painter has ever conceived, and the contrast between Nature's handiwork in glass painting and that of man in the east window, which alone is dight with unhappy saints, is striking indeed."

Here, then, is a suggestion from a man who happily combines a love of nature with a perfect

CAMPANULA LACTIFLORA AT MOUNT USHER, IRELAND.

knowledge of his craft, and we await with some interest the development of a more general adoption of his suggestion. I may perhaps here say that in a remarkable church built by him at Exeter—St. David's—the planting of *Ampelopsis* has been carried out under his direction by Messrs. R. Veitch and Son of that city, the results of which as the plants spread will no doubt be fully realised. For the covering of a west window, where the effects of the setting sun would have full play, the *Ampelopsis* (*Vitis*) is desirable. The contrast to Ivy is forcibly shown in the east window of the parish church of the village of Lymstone, where it has been allowed to grow over the wire netting on the outside of the window, the side divisions of which are almost totally obscured by the thick growth of both stems and foliage of the Ivy, producing complete opacity, which would be obviated by the planting of *Ampelopsis*, besides improving the effect of the coloured glass by toning.

Such, then, are some of the advantages of planting *A. Veitchii* over ecclesiastical and other buildings possessing architectural features, an illustration of the happy results that might often accrue from a more general co-operation between architect and horticulturist.

With regard to the difficulties that often occur in getting rid of Ivy from a building, Mr. Caröe says: "The thick stems should be cut at about 3 feet distances and dressed with corrosive sublimate or any strong destructive chemical. The Ivy must not be torn down from the face of the wall until it has lost its power of clinging, and

should then be most carefully removed by the aid of scaffolding, and, what is still more important, the aid of tender-handed and careful workmen. Great Ivy stems are frequently found growing in the very centre of the walls, disturbing the core and pressing out the ashlar. There is no other course but to take out a stone or more and destroy it by removing all that can be reached and killing the remainder. Again, perhaps, great dead Ivy stems will have to be dealt with which have wrapped themselves round the ruin, and can hardly be displaced without disturbance of its stones. These cases are sometimes most difficult to meet, and can only be met by an ample use of scaffolding and shoring. I have known cases where the removal of the Ivy means necessarily the destruction of a small feature, such as a pillar. In that case alone, the parasite must be allowed to stay and continue to sustain its victim until its life is lived. JOHN R. JACKSON.

Claremont, Lympstone, South Devon.
P.S.—*Ampelopsis Veitchii* is *Vitis inconstans*.

THE ROSE GARDEN.

THE LARGEST ANNA OLIVIER ROSE TREE IN ENGLAND.

REPRESENTED in the illustration is the largest plant in England of the beautiful Tea Rose Anna Olivier. It is really a dwarf variety, but has developed to a large size, measuring 19 feet long by 13 feet high. This Rose is an excellent wall plant, not a fast grower, but is always in bloom.

ROSE SOLEIL D'OR.

ONE of the most interesting Roses in this garden last year was M. J. Pernet-Ducher's Hybrid Briar Soleil d'Or. While one cannot claim that the expanded flower is anything but flat, the shades of colouring are so rich and distinct that this variety will be most useful for grouping in the garden. My plant has grown well, and seems as if it will form quite a large bush with age. The disastrous frost of May 14, which sadly injured most Roses, did not affect this variety at all; and the flower buds, which were then quite advanced, passed safely through the ordeal and produced splendid blooms at the end of June. I noticed that each day they seemed to vary slightly in colour—at one time a deep orange and at another a blending of orange-yellow and nasturtium-red. It is to be hoped that M. Pernet-Ducher will devote further attention to this class of Rose and give us other distinct shades of colouring.

ARTHUR GOODWIN.

The Elms, Kidderminster.

NEW PLANTS OF 1902.

FLORISTS' FLOWERS.

(Continued from page 66.)

CHRYSANTHEMUM FRUTESCENS CORONATION.—This is a sport from one of the white-flowered forms generally known as Marguerites or Paris Daisy. It takes the form of an Anemone crowned centre, and with the large and pure florets forming the ray makes a very distinct feature. A.M., June 10. Shown by Messrs. Ward Brothers, Southgate, but the stock has since passed, we believe, into the hands of Messrs. Cutbush and Sons, of Highgate.

C. Carrie.—A very beautiful early-flowering or border sort, of dwarf habit, and very free. The flowers are yellow and slightly drooping. A Japanese variety. A.M., September 23.

C. Gertie.—A showy and free-flowering decorative border variety. The predominant colours are rose and buff, and possibly bronze, which make an effective combination. A.M., September 23. The above pair are from Messrs. W. Wells and Co., Limited, Earlswood, Redhill.

C. Joseph Lowe.—This is a handsome free-flowering decorative yellow variety. Every shoot on the plant had a good flower, and the free manner of breaking into growth was very striking. Plant 4 feet high and carrying fully a score of well-formed blossoms. A.M., October 7. From Mr. J. Shawyer, Hounslow.

C. S. T. Wright.—This is one of the grandest flowers in the rich crimsons that we have yet seen. The colour is rich and intense, the broad petals and the large size of the blooms only adding to the general effect of this fine addition. A.M., November 4. From Messrs. Wells and Co., Limited, Redhill.

C. Harry Shrimpton.—A very fine novelty. It is a Japanese Chrysanthemum of the largest size, and a well-built flower withal. The chief colour is golden-yellow, the flower being copiously covered with red or chestnut-red. A.M., November 4.

C. Mrs. J. Seward.—A golden incurved of good size. The variety is of the incurved Japanese type, not the true incurved form of a few years ago. The flower, however, is solidly built, and the plant very dwarf in habit. A.M., November 4. These two novelties were from Mr. W. Seward, Hanwell.

C. Leila Filkins (Japanese).—A large and refined flower of great beauty. The colour is a soft silvery rose and most pleasing. In general appearance it may be regarded as a refined and improved Vivian Morel. A.M., November 18.

C. F. S. Vallis.—This is also a Japanese. It is of the self yellow class, soft in tone, the florets gracefully drooping and otherwise prettily arranged. The flower is of the largest type. A.M., November 18. This excellent pair of novelties came from Messrs. Wells and Co., Limited, Earlsfield, Redhill.

C. Belle of Weybridge.—A large decorative

variety that by some may be called single. It is, however, not purely single-flowered, as the flower-head has a second row of florets. It is a good and showy sort withal, and the bright crimson-red colour renders it most attractive. A.M., November 18. From G. Ferguson, Esq., Weybridge.

C. Miss E. Seward.—A fine incurved flower of a rich golden-yellow, an approach, indeed, to that of the old Jardin des Plantes which has not been surpassed. The flower is of good proportions. A.M., November 18. From Mr. W. Seward, Hanwell.

Dahlia F. A. Wellesley (Cactus).—A very handsome flower in which the dominant tone is a rich and bright carmine, the sides of the florets revealing a touch of ruby crimson. A.M., August 19. From Mr. H. Shoosmith, Woking.

D. Minnie West (Cactus).—A charming flower of the brightest primrose-yellow, each floret strongly tipped with white, a beautiful combination of colours. A.M., September 23. From Mr. J. T. West, Brentwood.

D. F. W. Balding (Cactus).—A fine and showy flower. The colour is gold with shading of amber, the latter inserted, so to speak, in the inner parts of the flower. A.M., September 23.

D. H. J. Jones (Cactus).—Soft yellow or full primrose tone, the florets much tipped with white. A very pretty variety. A.M., September 23.

D. Raymond Parkes (Cactus).—A showy flower of rich crimson colouring. A.M., September 23.

D. Etna (Cactus).—Not the colour one would expect by the name. Etna is a rosy lilac and buff with twisted florets. When such a class exists this may be a "Fancy" Cactus. A.M., September 23.

D. Vesuvius (Cactus).—A showy and effective sort, the flowers yellow, striped and freckled with crimson. This will be in the same category as the last. A.M., September 23.

D. F. H. Chapman (Cactus).—A striking and richly coloured variety; the flowers are

ROSE ANNA OLIVIER (THE LARGEST PLANT IN ENGLAND OF THIS VARIETY) IN MR. PRINCE'S ROSE NURSEY NEAR OXFORD.

orange-scarlet underlaid with yellow. A.M., September 23.

D. Mabel Tulloch (Cactus).—A bright and pretty variety, in which the chief colour is rosy peach with buff centre. A.M., September 23.

D. Eva (Cactus).—This is a neat and well-formed flower of the purest white save for a delicate primrose centre. A.M., September 23. This formidable set of eight Dablias from one raiser on a single occasion is proof of great enthusiasm. The exhibitors and raisers were Messrs. J. Stredwick and Son, Silverhill, St. Leonards-on-Sea.

(To be continued.)

AN ARTIST'S NOTE-BOOK.

KNIPHOFIA LONGICOLLIS.

THIS is one of the many excellent garden plants that we owe to the enterprise of Herr Max Leichtlin. He obtained it from Natal, and in distributing it, in 1894, he described it as a probably hardy species, with tall spikes of yellow flowers, produced late in the year. It flowered first with him at Baden-Baden in 1893, when it was named and described by Mr. Baker. It flowered next with Mr. Gumbleton at Queens-town in February, 1897, when a drawing of it was made and published in the *Botanical*

KNIPHOFIA LONGICOLLIS.

FLOWERS PALE YELLOW.

Magazine, t. 7623. At Kew it was first tried in the open, where it grew freely and pushed up stout flower-scapes, too late, however, to escape destruction from cold. The following year the plants were lifted and taken into the temperate house to flower, when its merits were fully revealed. It is now represented in the Himalayan section of that house by several large clumps.

Imagine a *Kniphofia* with all the vigour of growth and leaf characters of *K. aloides* (*Uvaria*), which, in a house where it receives slight protection, bears tall stout scapes of clear canary yellow flowers (not green-yellow, as shown in the *Botanical Magazine*), and which is at its best in midwinter for at least two months. It might be grown out of doors all summer and brought into a conservatory in October to flower. In the favoured counties, such as South Devon and Cornwall, it would no doubt be perfectly happy in the open air. Mr. Veitch might do worse than devote a big border to a few hundreds of it in his Exeter nursery. This *Kniphofia* was shown before the Royal Horticultural Society on January 27, by Mr. J. T. Bennett-Poë, and then obtained an award of merit.

SCHOOLBOYS AS GARDENERS.

THE BRITISH ORPHAN ASYLUM, SLOUGH.

IT occurred to me that, while much is written at the present day on the subject of horticulture as carried on by adults, it might yet be interesting to some of the readers of *THE GARDEN* to hear what is happening amongst the younger generation. While hesitating, a visit from a representative of *THE GARDEN* settled the matter, and I have now been asked to write a short account of gardening amongst schoolboys.

Some eight years ago there was, at the back of our premises, a rough mound, covered with Couch-grass, Bindweed, Horseradish, and almost every other enemy to successful gardening. This was the site our boys chose for their new undertaking, and, by dint of much perseverance and hard work, they have brought it to its present state, rendering it in the season, one of the prettiest and tidiest spots in our spacious grounds.

This result, of course, has been achieved only by constant progress, and, as our boys have to leave at fifteen, those who first started the project have long since been earning their own living; but these pioneers of our school gardening have left behind them an enthusiasm which has stimulated their successors.

The first step to be taken was to declare war against the Couch, Bindweed, &c., and this was carried on so resolutely, that at the end of two seasons these enemies were completely vanquished. Then small plots were marked off, tile edgings put down, gravel paths laid, and the once unsightly piece of ground was converted into thirty-six miniature gardens. These were then allotted to their respective owners, who were allowed to keep them as long as they remained at the school.

In a large institution, where cricket, football, fives, &c. are the chief pastimes, and where an excellent carpenter's shop exists, it might naturally be supposed that

BOYS LAYERING CARNATIONS IN THE SCHOOL GARDEN, BRITISH ORPHAN ASYLUM, SLOUGH.

there would be a good percentage of boys who would not care to take up horticulture. This, however, was not the case, and the applications were so numerous that it became necessary to put each garden under the joint ownership of two boys, so that, out of one hundred boys, seventy-two had now expressed their intention of taking up horticulture as a recreation. Nor was this a momentary craze only. At the present time there are just as many "gardening boys" as there were at the beginning.

The site chosen for this work being of a very irregular shape, it is impossible to get a photograph to represent the whole. The accompanying illustrations (taken last July) give two views. (1) a lower part of the gardens, (2) a portion of the middle, showing the steps of the first rockery, and boys above layering Carnations. During the next three years it was found that certain of the gardens, on a steep slope facing south, were not satisfactory, and a new scheme was formed, viz., to convert the slope into two levels with a rockery between. Two years ago this was accordingly taken in hand and occupied most of the winter months. It was finished by the following May. Four new gardens were made on the lower level, and the rockery planted with various kinds of bulbs and rock plants, including Saxifrages (about twelve different), (E. nothera, Campanula, Helianthemum, Achillea, Veronica, Erodium, Thalictrum, Heuchera, and many others.

The far end of this bank was specially prepared for a small fernery, in which has now been planted a very good selection of hardy Ferns. At the beginning of last season there still remained a portion of the gardens which, by reason of the shade, had defied all attempts to grow a general collection of plants such as had been done in more favourable

positions. This, then, was the next undertaking, and proved to be the most gigantic work of all.

The idea of converting it into another fernery was formed by a small batch of boys who were remaining at the school during the Easter vacation of last year. The plan was at once put into execution, and before the main portion of the school returned from their holidays a very good start had been made. At first it was begun in a moderate way, but as the work went on the idea grew, and it was

not till the middle of July that it was actually finished.

The proprietors of the extensive brick-fields in this neighbourhood very kindly supplied all the burrs gratis. From measurements made since it has been computed that between 700 and 800 wheelbarrow-loads of soil were removed to a spot outside the gardens, while seventy wheelbarrow-loads of gravel and 140 of burrs were wheeled in. I mention this to show the amount of energy it is possible for boys to display when their hearts are in their work. This new rockery will be planted next March with Ferns on one side and shade-loving rock plants on the other; and as soon as funds will allow an artificial pond is to be made in one of the recesses, in which to grow different kinds of Water Lilies and other aquatic plants, which a friend has kindly promised to give when the pond is finished.

As the name of the school implies, the boys are all orphans, and therefore have only a very limited supply of pocket money. Still, it is their wish to buy (if they cannot raise) every plant they grow, and they have therefore drawn up a list of special prices arranged to suit their means. Of necessity they are unable to pay

the prices charged by nurserymen, so they have devised a system by which the cost of everything is considerably reduced. In the first place they have been greatly encouraged by many nurserymen (whose names, I fear, I may not mention here), and especially one firm in the immediate neighbourhood which supplies them with all the plants they require at half the catalogue price. Then, again, many amateurs have from time to time sent presents of plants. These are all sold, and the proceeds put to the credit side of the garden account, a

FLOWER BEDS IN THE LOWER PART OF THE SCHOOL GARDEN.

method which enables them still further to reduce the price of other plants that it may be necessary to buy. For instance, the cost of a certain plant at the nurseries is 9d.; this they get, at half price, for 4½d. It is brought here and sold again at the special price of 2d., thus being a loss of 2½d. to the garden fund; but the presents of plants, on the other hand, having been sold at a profit, generally balance the losses, and so the result is found to work out satisfactorily in the end.

A few prizes are given every season by kind friends for the best gardens; also one for the names of plants (correctly spelt), and another for the meanings of botanical names. Mr. Arthur Turner of Slough has very kindly judged them twice a year (in the spring and summer) ever since they were started, and the work of the boys has been greatly encouraged by occasional visits of experienced men from his nurseries.

Let me conclude by saying that if any of your readers are ever in the neighbourhood and would care to see the gardens, which I have endeavoured to describe, it will afford the boys, or any of the authorities, the greatest pleasure to show them what juvenile enthusiasm and industry can accomplish.

A FRIEND OF THE BOYS.

TREES AND SHRUBS FOR BRITISH GARDENS.

THE BARBERRIES.

(Continued from page 73.)

B. NEPALENSIS.

UNDER *B. japonica* I have alluded to the relationship between these two plants. It is simply the very old problem as to whether there are two species or one. Compared with *B. japonica*, this Himalayan plant has longer leaves, which carry more numerous leaflets, sometimes as many as twelve pairs (in *B. japonica* they average four or five), and they are narrower in form and more membranous in texture. According to Sir Joseph Hooker it inhabits the Temperate Himalaya at 4,000 feet to 8,000 feet elevation. In those regions it is occasionally 20 feet high, and the flower racemes as much as 12 inches long. It is not so hardy as *B. japonica*, and is better adapted for Devon and Cornwall than the more northerly districts.

B. NERVOSA (SYN. *B. GLUMACEA*).

A dwarf evergreen, whose leaves are composed of eleven to fifteen leaflets, very firm in texture, and deep green. The flowers are borne on racemes much longer than those of *B. Aquifolium* (they are 8 inches, or even more, long), and are fully open in April. The most distinctive character of the species, however, is to be seen in the veining of the leaf. Three or five

prominent veins start from the base of the leaflet and run lengthwise, and the leaf-stalk is very distinctly jointed where each pair of leaflets is attached. The species is a native of Western North America, and was introduced in 1822. It is quite hardy, and thrives in shady spots. It is not very common, however, and does not increase so fast as *B. Aquifolium*.

B. NEUBERTI.

Of the two hybrid Barberries that exist in gardens—this and *B. stenophylla*—the latter is far superior as a plant for gardens. *B. Neuberti* is, however, of exceptional interest in regard to its origin, uniting as it does the two sections of the genus. It was raised from seeds of *B. (Mahonia) Aquifolium* fertilised by *B. vulgaris*. It appeared in the once famous nursery at Bolwiller in France in 1850, and was first noticed there by M. A. N. Baumann. Its

BERBERIS (MAHONIA) NEPALENSIS.

leaves show almost every intermediate stage between the pinnate ones of *B. Aquifolium* and the simple obovate ones of *B. vulgaris*. They follow the former in being evergreen, but have none of its handsome dark green glossiness. This hybrid must rank as a curiosity more than anything else, especially as it rarely flowers.

B. FRUINOSA.

In the near future we may look to the

enrichment of our gardens by numerous trees and shrubs from Western and Central China. Of these, this Barberry is a forerunner, having been introduced to France from Yunnan by Delavay the missionary in 1894. At Kew it is represented by several plants, none as yet more than 4 feet high. It grows well, however, and promises to be one of the largest in the genus—somewhat in the way of *B. aristata*. Its foliage has hitherto remained on the plants throughout the winter, so they may be described as evergreens. But the species has not yet experienced a very severe winter here. The leaves are arranged in the usual rosettes, are thick, leathery, and shining, oval-oblong, 1 inch to 2½ inches long, and armed with widely separated spiny teeth. The flowers are of a citron-yellow, and borne singly (or sometimes in twos or threes) on stalks springing from the leaf-axils. This arrangement is, of course, very different from the racemose one of *B. aristata* and *B. Lycium*, which two species it seems likely to most resemble in habit. The berries are black, but covered with the very abundant plum-coloured bloom to which the specific name refers. This new species commences to flower at the end of April.

B. REPENS.

The dwarfest of the Barberries of the *Mahonia* section, this species ought to be useful in positions where a low, close, evergreen covering for the ground is desired. But it still remains one of the rarest of the *Mahonia* group, although introduced to English gardens from the inland slopes of the Rocky Mountains at least seventy years ago. It has but few divisions of the leaf—usually five or seven—which are dull green, ovate, from 1 inch to 2 inches long, and armed with numerous spiny teeth at the margin. It produces its clustered short racemes of rich yellow flowers in April and May. Although perfectly hardy it does not ripen seed freely in this country, hence probably its scarcity.

B. STENOPHYLLA.

I do not think there is any doubt but that this is the most beautiful and valuable of all the Barberries. It is not a species, however, but a hybrid, and first appeared in the nurseries of Messrs. Fisher, Holmes and Co. of Handsworth, near Sheffield, about forty years ago. Its parents are *B. Darwinii* and *B. empetrifolia*. To the latter it is, of course, superior in every way; and compared with *B. Darwinii* it is certainly hardier, grows with greater freedom in all situations, and is much more graceful. Growing about 8 feet to 10 feet high, and more in diameter, it forms a dense bush of interlacing branches, from the central mass of which each summer it sends out slender arching shoots 2 feet or more long. These shoots the following April and May are wreathed from end to end with corymbs of beautiful golden-yellow blossom. The leaves are narrow with revolute margins, and resemble those of *B. empetrifolia*, but are larger. It is perfectly evergreen, and soon makes an impenetrable thicket. For forming masses in open spots in semi-wooded grounds it is admirably adapted, and when once established requires no attention at all. In Mr. Chambers' garden near Haslemere it has been put to charming use as a hedge plant, being cut back immediately after flowering. It ripens seeds freely, but plants raised from them rarely come quite true. Most frequently they revert to *B. Darwinii*, and I have seen seedling-raised plants scarcely distinguishable from that species. Mr. T. Smith, of Newry, has raised and named some of the most distinct, and B.

reflexa is one of them; but *B. stenophylla* is quite easily raised from cuttings.

It should be mentioned that there is a wild *Berberis*, a native of China, named *B. stenophylla* by Mr. Hance. This is not in cultivation so far as I know, but is said to be allied to the Himalayan *B. wallichiana*. Of course, it has nothing to do with the *B. stenophylla*, which owes its origin to purely Chilean species.

Kew.

W. J. BEAN.

(To be continued.)

LILIUM AURATUM VAR. MACRANTHUM.

The flowers shown are from two bulbs planted in February, 1898. They were planted 1 foot deep in sandy soil, and on the top of the bulbs 3 inches of sand, then the same depth of well rotted manure, after this some leaf-mould, and then filled up with manure. During the time of growth water was given twice a week with liquid manure. The bulbs have not been disturbed since planting, and they are mulched every November. Each year they have thrown up fresh stems. Last year (1902) some of these were 7 feet high.

THE GARDEN IN THE SHADE.

Of gardens in the shade one hears but little. Possibly it is because gardens which have the advantage of sunshine are generally considered to be the more satisfactory, and demand less care and forethought in their arrangement. The modern amateur gardener is not widely different from the rest of his fellow men, and therefore is apt to expend his energy in tending and improving that part of his garden which gives the best return with the least possible outlay. As a natural consequence the garden in the shade suffers more or less from neglect. Yet by following such a practice countless opportunities of relieving the monotony of, and imparting a new interest to, the garden are lost.

For their beauty and interest gardens are dependent to a very great extent upon the weather. Should the spring be cold and sharp frosts prevail, the early buds and blossoms of flowering trees and shrubs will be injured, and should the fates be unkind enough to provide a summer without the refreshing showers so essential to the good looks of the garden, then one's favourite flowers will wither and fade without having developed their highest beauty. If, on the other hand, the summer should prove dull and sunless, the plants will lack vigour and the flowers will be colourless. Again, as was the case last year, the rainfall may be altogether exceptional, and one may look in vain for flowers, and watch with astonishment the abnormal stature to which the plants attain. The inexperienced will probably congratulate himself upon such splendid growth, and look forward in due time to an abnormal harvest of flowers also. His disappointment will be great indeed when the long, overgrown, and immature shoots produce but a handful of half-developed flowers just in time to be cut down by the first frosts of autumn.

Such, then, are some of the effects of the vagaries of the weather upon the common or garden form of garden, and it is in its comparative indifference to the elements that the garden in the shade proves its claim to notice. To a very great extent the late spring frosts are unable to injure its occupants. Plants growing in the shade will naturally start into growth later than those exposed to the

LILIUM AURATUM VAR. MACRANTHUM FROM TWO BULBS PLANTED IN FEBRUARY, 1898.
(From a photograph sent by Mrs. Earle.)

stimulating influence of the sun, and in all probability by the time they are vulnerable spring frosts will be past. But even supposing plants in a shaded garden to have been caught by frost, they still enjoy another advantage, and that a material one, over their *confrères* in the ordinary sun-exposed garden. Plants frozen during the night suffer much more serious damage if the following day is bright and sunny, for the action of the sun upon frost-bitten foliage brings about disastrous results. The fact of the frost disappearing gradually from plants in the shade minimises to a great extent the harm that is possible, nay, probable, when the frost is quickly dispelled by the sun.

Should the summer prove sunless, what matters it, for is it not always sunless in the garden in the shade? Its inmates grow and flourish entirely unconcerned as to whether the day be sunny or not, and the possessor of such a garden goes on his way rejoicing, not alternately cursing and blessing the weather as it happens to disappoint or fulfil his expectations. During the hottest of hot summers the plants in the shady garden cause their owner no inconvenience, no unusual care and labour, yet they flourish as well as ever. 'Tis then that one has cause to be thankful: one's treasured plants look one in the face, and are just as bright and fresh after their owner's return from a month's holiday as upon the day of his departure. In the sunny garden of one's neighbour many plants have succumbed through want of water, some are ripening seeds instead of bearing flowers, while the more rampant growers have smothered the weaker ones. In the garden in the shade more equable conditions prevail, and the weak and the strong grow together in perfect harmony. Although it can hardly be claimed for the shaded garden that it has advantages over the ordinary garden in a wet season, it at least has the satisfaction of being equally well off; while it is true that the soil

in the sun-exposed garden would dry more quickly, it is equally certain that less rain would fall in the shaded garden by reason of the foliage of the trees above.

Gardens in the shade may be either natural or artificial. The majority are natural, a small minority representing those artificially made, and this is chiefly due to the fact that their possibilities are not realised. What then are the possibilities of the garden in the shade? Briefly they are these. There can be grown at least one family of plants (and that one of the most beautiful, most extensive, and most neglected), which cannot successfully be grown in the sunny garden, namely, Ferns. Those plants which thrive best in the shade are of quiet colouring, and provide a most welcome and refreshing change from the garish and brilliant colours of beds and borders filled with herbaceous flowers. No gardener can be altogether delighted that seeks to please by means of bright colours alone, contrast as well as harmony is essential. As has been explained, plants growing in shady gardens are less affected by changeable weather than those in gardens more exposed, and they require a very modest amount of care and attention. What a delightful garden could be made of Ferns alone, their variety, beauty of form and even shades of green are never ending!

To mention just a few of the plants that occur to me as being suitable for the garden in the shade, there are the *Berberis*s, several of them most lovely flowering shrubs, *Rhododendrons*, *Camellias*, *Aucubas*, *Dog Wood*, *Cotoneaster*, *St. John's Wort*, *Ivies*, *Butcher's Broom*, *Periwinkles*, and *Snowberry*, nearly all of which are evergreen; of flowers one might name *Blue Bells*, *Primroses*, *Violets*, *Forget-me-nots*, *Anemones*, *Hyacinths*, *Daffodils*, *Scillas*, *Cyclamen*, *Evening Primroses*, *Lilies of the Valley*, *Liliums*, and *British Orchids*. With these plants the garden in the shade might make a start, after a time others would probably suggest themselves. A. P. H.

MISCELLANEOUS.

GRAFTING THE VINE.

WHERE many varieties of Grapes are grown in one house it often happens a few years after the Vines have been planted that the grower is disappointed with one or more of the varieties, and wishes them changed for more desirable sorts. To the mind of the inexperienced this change presents a serious if not an impossible problem, short of destroying the Vine and planting another in its place, which would not be satisfactory in many ways, besides entailing a delay of some years before a return of fruit could be obtained from the newly-planted Vines. There are two ways by which this change can be accomplished without destroying the Vine you wish to get rid of; indeed, the Vine to be discarded is requisitioned into service. The one is by a term known as "bottle grafting" and the other by "inarching." The former is accomplished by grafting the wood of the new variety on the stem of the Vine you wish to discard, and is carried out in the following way: About a foot above the base of the Vine a slice should be cut out from its side, 3 inches long, and deep enough to cut into the wood below the bark. Have ready a shoot from the variety you wish to grow; it should be about a foot long, in fact, a shoot which is cut off at pruning time in the usual way. If this shoot is too long it should be shortened by cutting off the end, and care should be observed to cut to a good sound bud. Below the second bud from the top of the shoot cut a slice off the side the same length and depth as from the stem, bring the two cut pieces together, taking care that they fit into one another exactly, and with pieces of raffia, tie the two together securely, using plenty of raffia, so that no part of the grafted stem is exposed to the air. The shoot grafted should be long enough to admit of a length of 6 inches or 7 inches hanging below the graft, in order that it may be inserted in a bottle of water, in which it must be kept during the first season's growth, and the water occasionally changed.

The best time to carry out this work is about a month before the Vines are started into growth, and the graft should not be interfered with in any way whatever until towards the end of June, when it should be looked to in case, through the swelling of the grafted parts, the raffia may be cutting into the bark; before the matting is

loosened three other ties should be made around the grafted part, one at each end and one at the middle to make the grafts secure. If this is omitted and the grafts separated, then all labour is lost. Therefore take care that the grafts are made secure before the original matting is taken away. If the work has been well and properly carried out as directed the grafting will have been successful, and the joining of the scion and stem securely and permanently accomplished.

Should the three ties last made be found to have cut into the bark then three other ties should be applied before these are taken away, as you are not sure the graft will not separate from the stem until the parts have become hardened in the autumn. One only of the top buds of the grafted shoot should be allowed to grow, and in course of the season if the grafting is successful it will have made a long shoot, which in winter should be cut back to 12 inches or longer, according to its strength. That part of the shoot inserted in the bottle of water must be cut away at the time of pruning, close to the grafted part, as the water is no longer of any use. As the grafted shoot increases in strength and size, so must the Vine to be discarded be cut away to make room for it, until in two or three years the new variety will take the place of the old.

The other operation, namely, "inarching," is of a similar nature, only it is carried out in summer, when two green shoots are grafted together in the same way as directed for bottle grafting. In this case the variety you wish to substitute for the one you are doing away with should be grown in a pot, and as soon as the young Vine has produced a shoot large enough this should be grafted on to a similar green shoot of the Vine to be discarded. This should be selected from a position as near the base of the stem as possible. This is an excellent way of finding out expeditiously the value of a new Grape, as by inarching a shoot one year it is possible to obtain fruit the next, whereas if the new Vine were planted out in the ordinary way it would at least take two years. A. P. H.

A REMINDER—THE NEW HORTICULTURAL HALL.

"AND a Man shall ever see that when Ages grow to Civility and Elegance, Men come to Build Stately sooner than to Garden Finely; as if Gardening were the Greater Perfection. I do hold it in the Royall Ordering of Gardens there ought to be Gardens for all the Months in the

Year; In which severally Things of Beautie may be there in Season."

There are some of us who may think it would have been better to "garden finely" than to build at all. But, since we are to build for man's sake, let it be to build "stately" and not vulgarly, but in a manner worthy of the things of beauty that it is hoped will be found there in all the months of the year.

THE WRITER OF "IN A TUSCAN GARDEN."

THE KITCHEN GARDEN.

NEGLECTED VEGETABLES.

ARTICHOKES.

OF Artichokes there are three distinct kinds—the Globe, the Jerusalem, and the Chinese. The Globe is quite different to the others, and requires special consideration. It is not largely grown and varies greatly in quality, the finest forms being those which produce large succulent heads. The plants are at times grown from seed, but it is unwise to rely upon seedlings, as they are usually poor spiny productions of little value; it is better to propagate by suckers when a good strain has been secured. The Globe Artichoke also is not hardy in severe winters, the plants frequently dying even when well protected, but much depends upon the locality, the growth in some districts being stronger than in others. Whether hardy or otherwise make a new plantation every three or four years, as the old stools exhaust the soil and the heads dwindle in size as the plants age.

The Jerusalem Artichoke is tuberous and generally placed in any out of the way corner, and there remains for many years, but by giving a change of soil and selecting the seed carefully much better tubers are obtained.

The Chinese Artichoke is an excellent vegetable, but the small size of the tubers is against a wide popularity.

GLOBE ARTICHOKE.—Ample space is necessary for this Artichoke, a distance of 4 feet between the rows being none too much, and half that distance from plant to plant. The suckers should be placed three together, as a clump gives a better return. Trench the land deeply, manure heavily, and prepare some time in advance of planting. In heavy land it will be advisable to incorporate lighter soil or burnt refuse with the soil, also to take care that the plot is well drained. April is a good month to plant, and in dry seasons give water freely with liquid manure and salt dressings in showery weather from June to September. Guano and salt form one of the best foods for older plants not recently manured. Give protection in the late autumn, and after the old growths are cut away place some fine ashes over the roots, and pack dry Bracken or litter round the young growths, as these supply heads for the following May. In cold or wet soils detach a few suckers from the finest forms and place in boxes or frames for the next spring planting. When seed is sown sow it under glass in pots or in rows in April, but it is a mistake to raise plants in this way. Globe Artichokes yield from May till September, and it is well to cut the heads and place them in water when full grown, as if left too long they harden and lose flavour.

JERUSALEM ARTICHOKE.—This Artichoke will grow in any soil, but is most successful in a deep, well manured friable loam and open situation. We enjoy it in winter as a change from Potatoes, and since Messrs. Sutton introduced the smoother white tuber, which has fewer eyes, and is of better flavour than the older types, the Jerusalem Artichoke is regarded with greater favour. It is profitable for the reason that though it

JERUSALEM ARTICHOSES.

needs considerable space the crop is in proportion. Many object to this root when served in the same way as Potatoes, but there is no need to do this. There are quite a dozen methods of cooking, and few roots are better for soups and gravies. It should be remembered that once the plant is grown it will reappear from the smallest portion of root, and doubtless that is one reason why the seeds are not given new quarters so often as they deserve. It is an easy matter, however, to clear the soil if care is taken when digging. Always purchase or save good seed, trusting nothing that will not give shapely roots, and change the stock when disease is probable or the plants fail to crop well. February and March are the best months to plant. There must be a space of 3 feet between the rows and 12 inches between the sets. More room may be given if available, and planting may also be done much earlier. Cover the sets with 6 inches of soil and leave the tubers in their growing quarters, digging them up as required or clamp them in the same way as Potatoes are frequently treated; they are best when not housed in a warm store, but kept as cool as possible.

CHINESE ARTICHOKE (*Stachys tuberosa*).—Owing to the small size of the curiously crinkled tubers this has not become so popular as it deserves. It needs good land and a little more attention to culture than the Jerusalem Artichoke. The tubers are small, white, with a clear skin, and produced freely. Overcrowding is a mistake. It does well in a light, freely manured loam, with the sets in rows 2 feet apart and 6 inches between the seed. The tubers are much finer when there is no lack of moisture. It is a good plan to mulch between the rows in dry years. The tubers are ready for use early in the autumn, and though not suitable where quantities are needed this little root makes a good vegetable for game and *entrées*.

MUSHROOM GROWING IN GARDEN, FIELD, AND COTTAGE PLOT.

(Continued from page 78.)

MANUFACTURE OF SPAWN.

This is now practically a lost art among private gardeners, Chatsworth, so far as I know, being the only private garden where the article is manufactured. Better crops of Mushrooms have never been obtained than from the home-made article, one of the reasons for this being that the spawn is fresh and not kept over from the previous season.

The work of making the spawn is a very simple matter, and once the details are understood a handy and careful labourer can manage the work splendidly. Quantities, of course, will be decided by the amount of spawn required and the principle of making is the same for large or small lots.

Take a barrow-load of cow manure, the same of horse manure, and the same of mould or garden soil. Mix the whole well together, and by watering bring the material to a consistency of dough. Have ready moulds made of any rough bits of wood 9 inches long, 6 inches wide, and 2 inches deep. Place the material on the potting bench or some other convenient place and commence to fill the moulds. This is done by placing the mould on the bench and when full making the contents as hard as possible, and finishing the brick off level with the edge of the mould. Have ready in the middle of an airy shed a shelf placed in such a position that the air can circulate round it from all sides. On this place the mould sideways (not

GLOBE ARTICHOSES.

flat). You will require to have the same number of moulds as the number of bricks you intend making (once made they will last for years). When the moulds are all filled and placed in the shed to dry they will require no further attention for, say, ten days or a fortnight, by which time they will have attained such consistency, dryness, and toughness as to be in a condition to bear puncturing; make five shallow holes in each, one at each corner and one in the middle, ready to receive the spawn. Upon the quality of the spawn will depend almost entirely the success of the operation. Under proper conditions the vitality of spawn may be preserved for a number of years. The length of time depends on the temperature and dryness of the atmosphere in which it is kept. The mycelium of the Mushroom is of so sensitive a nature that, once exposed to over moist or too warm an atmosphere, it commences to grow and spread, after which its efficacy for producing satisfactory crops is all but destroyed. Spawn therefore to be satisfactory must not be more than a year old, and should be kept in a dry store room, where the temperature in winter ranges from 45° to 50° Fahr.; in summer it should be kept as cool as possible. To find out the quality of the spawn break up the brick into four or five pieces, and if it is permeated with a network of the most minute thread-like veins nearly of the colour of flour you may be satisfied that the spawn is all right; if, on the contrary, those thread-like veins are swollen and spreading more or less about, you may conclude that fermentation has taken place at some time to the detriment of the spawn. Sometimes only a part of the brick may be affected, the other portion being good. In any case doubtful spawn must not be used in impregnating the new bricks. Shallow holes having been made in the bricks as advised, a lump of spawn must now be placed in holes about 2 inches wide by 1 inch deep, well pressed in and sealed over with some of the material left from forming the bricks. As soon as this sealing material is sufficiently dry, which will be in the course of three or four days, the bricks should be turned out of the mould, and built up on

the top of one another sideways and crossways, leaving small spaces between for air to permeate the whole heap. The heap may be built up of any size, according to the number of bricks one has to deal with, but 4 feet square and about 5 feet high is a convenient size. They should be stacked in a fairly warm room and covered over with a quantity of littery straw or mats; these in the course of a few days will generate more or less heat, which is, of course, required, in order to induce the spawn to run and permeate the brick. This it will do in the course of nine or ten days, when the covering may be taken off, the bricks allowed to dry and harden, then they may be stored in their proper quarters until wanted for use.

A thermometer should be placed in the heap and carefully watched, and the heat should range from 60° to 65°. The bricks must not be exposed to this heat an hour longer than is necessary for the filling of the brick with mycelium.* Spawn may be manufactured at any time of the year, but the best time is September, when the spores naturally run out of doors in our fields.

O. THOMAS.

BOOKS.

The Amateur's Greenhouse.†—This is a book for the amateur gardener, and takes the place of the late Mr. Shirley Hibberd's "Amateur's Greenhouse and Conservatory." The author is Mr. T. W. Sanders, F.L.S., who has had the good sense to come down to the level of the many thousands of amateurs and others whose gardens and means are small. Greenhouse construction is fully dealt with, and special information for the erection of both large and small greenhouses is clearly defined. Numerous plans and illustrations, showing the forms of glass structures best suited to plant life, should simplify the work of those who desire to erect their own glass houses. Chapters are devoted to such important considerations as "Site and Position," "Mode of Construction," "Greenhouse Heating," and the much-voiced question of "What Constitutes a Tenant's Fixture." "Greenhouse Management" is a very

* This can be ascertained by breaking up a brick or two.
 † "The Amateur's Greenhouse." By T. W. Sanders, F.L.S., F.R.H.S. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London, E.C. Price 5s.

important feature in this work. The arrangement of the plants for effect is carefully considered, and words of wisdom given respecting "overcrowding." Mr. Sanders writes: "One of the greatest mistakes made by novices in greenhouse management is that of overcrowding the house with an assemblage of plants that differ largely in cultural requirements. Some of these probably require a low, and others a high temperature; others, again, a dry or a moist atmosphere. It is impossible to grow plants needing such divergent conditions of culture together successfully in one house. Nor is it wise to crowd too many plants together. Each plant requires its proper share of light and air, and unless it obtains these essentials weakly growth will be the inevitable result. . . . The man who succeeds in the management of a greenhouse is he who grows one or two classes of plants only, and gives each plenty of room to develop." The above quotation is characteristic of the advice given throughout the book. About thirty pages are devoted to greenhouse pests. Each pest is described in such a way that the merest novice cannot fail to understand what is intended, and the remedies in each case follow the description. Popular greenhouse plants, arranged in alphabetical order, and covering no less than 277 pages, are fully described. The species are also described, and their culture and methods of propagation each dealt with in turn. Owners of small greenhouses should find a store house of information in this book. It is, however, badly printed.—D.

GARDENING OF THE WEEK.

FLOWER GARDEN.

DIGGING SHRUBBERIES.

IN many gardens this operation is done very carelessly. All interference with the roots should be carefully avoided. Newly-planted shrubberies may be carefully gone over, and all vacant ground turned up and exposed to the light and air, as this will sweeten and pulverise the soil, give it a neat appearance, and at the same time encourage root action to the newly-planted shrubs. In all established shrubberies the better practice is to top-dress the soil over the roots with some rich compost, or, if a vigorous growth is desired, give a good dressing of rotten manure. All decaying leaves and other vegetable matter which accumulates under them should be annually raked up and carried to a convenient spot to decompose, and if afterwards mixed with soil and manure may be used as a top-dressing with advantage. If shrubberies are neglected they soon become unsightly, even injurious to the health of those who live near them.

AMARYLLIS BELLADONNA (BELLADONNA LILY).

This is much admired for its soft colouring and effective display in the garden, with its tall robust stem and large trumpet-shaped flowers. It is one of the most interesting of all our autumn-flowering bulbous plants. The flowers vary from pale blush to dark red, and are produced after the leaves have died off. They will now be pushing through the soil and will need slight protection. It is well to remember that in all bulbs the leaves are the means by which the roots are brought to maturity, and as the bloom is the result of this maturity care must be taken that nothing interferes with their proper development. This beautiful Lily does well if planted 10 inches or 12 inches deep in good soil under a south wall, and hardly ever fails to bloom if the young leaves are protected in early spring. Any light material such as dry straw, Moss, or a few Laurel branches placed in front of them I have often found sufficient to keep them from all harm. I never find snails or slugs attack them. Their only enemies are shallow planting and damp and frost in early spring.

CAMPANULA CARPATICA (CARPATHIAN BELL-FLOWER).

This little blue Campanula is one of the most useful hardy edging plants we have. It grows

about a foot high, is easily propagated either by division of the roots in spring or by seeds, from which it comes perfectly true. Now is the best time to sow the seed. If sown in a temperature of 55° or 60° it will soon germinate, and when large enough to handle prick off the seedlings into boxes and keep in heat for a few days till they begin to grow freely, then turn them into a cold frame and plant out early in May in rich soil. This plant lasts a long time in bloom on heavy rich soils, but in hot situations and on light soils is apt to succumb before autumn. If watered occasionally in dry weather it will greatly prolong its flowering season. This is a very useful plant for those who have no glass as it is perfectly hardy and easily increased.

T. B. FIELD.
Ashwellthorpe Hall Gardens, Norwich.

INDOOR GARDEN.

MALMAISON AND BORDER CARNATIONS.

YOUNG plants from the latest layers will now be ready for their final shift into 6-inch or 7-inch pots, according to their vigour. Prepare a compost of three parts good fibrous loam, with all the finer particles shaken out, one part fibrous peat, with a good admixture of rough charcoal and coarse silver sand. Also add one 6-inch potful of Clay's Fertilizer to each barrowload of soil, drain the pots thoroughly, and pot firmly, using a thin stick to work the soil round the lower part of the roots. Avoid injury to the young roots when removing the crocks. These plants do best on raised stages where the air can circulate freely among them; damp the house slightly about 9 a.m. on clear fine mornings. Plants previously potted should by this time have rooted through the soil, in which case a very light dressing of Bentley's Carnation manure may be sprinkled on the surface soil of each pot. Each plant should now have the assistance of a small stick, to which tie the young plants very loosely. Remove all foliage that exhibits traces of disease and ventilate the house freely; in very damp or foggy weather have a little fire-heat in the pipes.

HERBACEOUS CALCEOLARIAS

should now be placed in their flowering pots. Avoid as far as possible using very large pots, those of 7 inches or 8 inches in diameter should be ample for the largest plants when grown singly. A compost containing a rather large proportion of humus suits the Calceolaria, consequently leaf-soil or dry horse or cow manure rubbed through a fine sieve may be used to the extent of one-fourth of the whole soil. If the loam is a little heavy add extra coarse sand and finely broken crocks or oyster shells. Before potting remove all decayed leaves and fumigate for the destruction of aphids. Keep the plants in a temperature of 40° or 45° by night. A cold pit or frame sufficiently protected suits them well, in any case avoid fire-heat if possible.

LILiums, GLADIOLI IN POTS,

and other bulbous plants now plunged in cold frames require occasional inspection, and as growth progresses inure them to the light gradually. Introduce a batch of Gloxinia tubers to the stove or forcing house, selecting those which have already started. Where the tubers have been stored in boxes and slightly covered with fibre they can be easily examined. A light, rich soil suits Gloxinias, and for the first potting I consider it unnecessary to add any manure. Start them in a minimum temperature of 60° in a moist atmosphere, and as the young growth progresses dust them with Tobacco powder to prevent the injurious effects of thrips or mite.

Wendover.

J. JAKES.

KITCHEN GARDEN.

SEAKALE.

CONTINUE to introduce the crowns into the Mushroom house or other forcing structure according to the demand. Slow forcing in the open for a later supply may be resorted to, and the present time is opportune for covering over the crowns. The material I find best is that from a spent Mushroom

bed. This is placed over the crowns in the form of a ridge 15 inches deep, and the gentle warmth imparted by this material will ensure the production of fine, clean, well blanched Seakale for use throughout March and part of April; then the produce from the forcing house is either exhausted or has deteriorated in quality. At that time good vegetables will be none too plentiful, and a good dish of Seakale daily will be much appreciated.

GARLIC AND SHALLOTS

may now be planted, choosing a warm sunny border that has been dug and manured. I prefer to have these on the herb border, but where large quantities are grown this is seldom possible. The largest cloves only of the Garlic should be planted, and these may be dibbled in rows 10 inches apart and 15 inches from row to row, covering the cloves with 3 inches of soil. Shallots should not be entirely buried; a slight impression may be made with the hand and the bulbs pressed into it.

RHUBARB.

Large quantities of forced Rhubarb will be wanted at this time owing to the scarcity of Apples in most districts. Some of the old crowns may now be covered with pots, tubs, or boxes, and these should be covered with stable litter to exclude light and provide warmth. The Rhubarb will grow slowly, and will succeed that forced in the Mushroom house.

SEEDS TO BE SOWN UNDER GLASS

are Lettuce of the Golden Queen type (and if pricked out into other boxes as soon as large enough to handle they will make useful plants to succeed those raised last August), Brussels Sprouts for very early pickings, and early white Celery. The sowing of all seeds in the open should be deferred for a few days, though every preparation should be made in order that when the weather is favourable and the ground suitable there may be no delay. Proceed with digging and trenching as fast as the weather will allow. Plots for the main crop Onions and Parsnips should be the first completed. Examine the stores of

CARROTS, POTATOES, BEET, ONIONS, &c.,

removing all that show the least signs of decay. Potato tubers for seed purposes should be laid out thinly on shelves or trays in a cool structure from which frost is excluded. If covered for protection from frost they must be exposed on every favourable opportunity to ensure the sprouts being strong and green. If time can be spared it is a good practice to rub off all these with the exception of one or two of the strongest at the apex of the tuber. Maintain a supply of

TARRAGON AND MINT

by inserting rooted pieces from the old plants, 2 inches apart, in pans or pots filled with old potting soil, and place them in a warm house. This is a much more satisfactory method than lifting the old plants.

Stonleigh Abbey Gardens.

H. T. MARTIN.

THE FRUIT GARDEN.

PRUNING AND MANURING IN ORCHARDS.

THE pruning of all fruit trees should be completed before the sap is in motion, if we except Nuts, which are usually left until the tiny little female blossoms can be discerned. A Kentish Filbert or Cob Nut bush looks almost as bare as a vine when pruned, yet the crops gathered testify to the soundness of the practice. In counties in which Filberts are allowed to grow on the extension system the fruit is neither so numerous nor so fine. All young Apple, Pear, Plum, or Damson trees are now having their strong leaders cut back; the trees require strength of branch to carry a crop, and the only way this can be secured in the case of young trees is to prune the erect shoots to at least one-third of their length. We have ample proof of what the result is when this is neglected. The trees grow upwards instead of filling out laterally; the first crop bears them down so much that the limbs have to be supported, or they inevitably get broken off, and nothing is gained as regards quantity or quality of fruit.

If the rampant erect shoots are checked in their upward career the weakly undergrowth comes into bearing far more quickly and the fruits are finer. Market gardeners look to quality as much as quantity, and if pruning did not pay they would not do it. One sieve of good high-priced fruit is worth two or three of seconds, and the expenses of transit and commission are the same in each case. Manuring is done also on a liberal scale; where are the orchards attached to private gardens that are supplied with manure at the rate at which they are by market growers?

A GARDEN HALF STARVED

is bad enough, but a starved orchard is worse; it can yield nothing. If we would but take that old advice—viz., "I will dig about it and manure it, and look for fruit another year," we might find that the seasons were improving, at least as regards fruitfulness. Some growers have had plenty of fruit, even in bad seasons, some none; moderate pruning and more than moderate manuring is the secret in the case of those who are successful.

PEACH AND NECTARINE TREES

on south walls are, of course, detached, pruned, and securely supported by means of stakes and ties some distance away from the walls, and in this position they must remain until we have a change in the weather. In the absence of frost a little extra care in washing the walls and trees to free them from the larvæ of insects will be well repaid. For stone fruit trees, after they are nailed in, a barrel of soap-suds from the laundry, with 2lb. or 3lb. of sulphur and a like quantity of soft soap added, will make an inexpensive wash, which may be applied freely without fear of injury to the most tender buds.

GOOSEBERRIES.

If these have not been pruned the sooner they are done the better, as a crowded state induces early growth and pruning checks it. An idea prevails that birds are not so likely to spoil an unpruned tree, but it matters little whether the tree is pruned or unpruned if a pair of bullfinches find their way into it. The safest and best way is to prune and dress with a mixture of soot and lime reduced to the consistency of cream, and passed through a fine sieve to admit of its being taken up and discharged by an old syringe. If time admits, trees and orchards should be thinned out and divested of moss which may have gathered on the stems and branches by scraping with a piece of hoop iron. When this has been done, wash with the composition recommended for Gooseberries and top-dress the roots with fresh soil, road scrapings, or rotten manure.

Madresfield Court.

W. CRUMP.

ORCHIDS.

SELENIPEDIUMS.

AMONG these there are many of the autumn and winter-blooming plants that may now be repotted should this be necessary. The majority need attention in this way more frequently than many of the Cypripediums, as many have a tendency to grow direct out of the compost, and as the roots of this class of Orchids seldom thrive so well when exposed the plants will in most cases need repotting every other year to bring the base of the young growths down near the compost. To do this the plants must often be divided up, otherwise the back growths would be too deeply buried in the compost. Selenipediums generally are not so fastidious as some Orchids in the matter of root disturbance, for if repotted in the usual way in equal proportions of good fibrous peat and sphagnum moss, it is only a short time before they become well rooted, though there are exceptions.

Selenipedium caudatum, for instance, does not yield to cultivation so readily as its allied species and hybrids. It needs very careful handling to keep it in perfect health. When dividing the plants sever the rhizome, leaving two growths either way. Each piece may be potted up singly, or numerous leads may be placed together to form specimen plants. The back growths should be

placed together in the same manner or potted up singly. Either way they soon produce young growths and make good healthy plants. If one desires to make as many plants as possible it is quite safe to divide the plants, leaving but one growth each way, providing each piece has a few roots attached, or the leading growth is about to emit roots. After repotting water rather sparingly until the roots have taken to the new material. These require the same treatment generally as the warm-growing Cypripediums, with the exception of overhead syringing, which must be strictly modified, for the young growths are liable to damp off if water lodges in them.

MILTONIAS.

Such plants as *M. Bluntii*, *M. candida*, *M. Clowesii*, *M. cuneata*, *M. flavescens*, *M. Regnelii*, and *M. spectabilis* are beginning to grow, and as new roots push from the base of the young growths when but a few inches long it is then that any necessary repotting or top-dressing should be done. Use pots or pans half filled with crocks or Fern roots. Either will do, as the plants are principally surface rooters. Free the plants from all old worn-out compost, and repot in good fibrous peat and sphagnum moss in equal parts. Press the same moderately firm, keep the base of the plant level or a little below the rim of the pot, water sparingly until the new roots have taken to the fresh compost and the growths further advanced. Grow the plants at the coolest part of the stove or the Cattleya house, and syringe among the pots on bright days.

DENDROBIUMS.

Many of these are now pushing out their flower-buds and will require more heat to properly develop their flowers. A temperature of 65° by night and 70° by day should be maintained. The plants will also need more water at the roots; apply it when the plants have become properly dry, as too much would cause the young growths to damp off. The atmosphere should be kept moderately moist until many of the flowers have expanded. Then it is best to have less moisture in the atmosphere until the flowers are taken from the plants or they will not last their usual time.

PLATYCLINIS GLUMACEA.

This is an elegant species, its graceful drooping spikes of greenish white fragrant flowers being very attractive. When in bloom they should be suspended where they may show their beauty in the most effective manner. The plants after a long season of rest are producing new growths, and will need more heat and moisture both at the root and in the atmosphere. They should now be placed in the stove or the warmest part of the Cattleya house, and as the growths develop the plant must not be allowed to become dry at the roots until growth has finished. Any necessary repotting should be done when new roots issue from the base of the growths.

SHADING.

This should now be had in readiness, for in houses where a maximum amount of light is obtained many

tender subjects, such as *Phalenopsis*, *Cypripediums*, *Zygopetalums* of the *Bollea* section, *Odontoglossums*, *Masdevallias*, &c., will now require shading on bright days for a short time.

F. W. THURGOOD.

Roslyn Gardens, Stamford Hill, London, N.

ORCHIDS.

CALADENIA CARNEA ALBA.

AUSTRALIA contributes little to the usual British Orchid house. A few *Dendrobium*s and other genera, together with numbers of terrestrial Orchids, make up this portion of its flora. Many possess considerable beauty, but in most cases this is overshadowed by uncertainty of results obtained under cultivation. The ground Orchids are usually small and fragile, generally with bulbous roots. Few of them have been grown in this country, but now that many people appreciate small alpine plants perhaps Orchid growers may take up small things like these. The *Caladenias* are very pretty. Give them light soil, putting a dozen or so plants in a pot, and water freely during the growing period, hardly any is required when the leaves turn yellow and disappear for a season.

The photograph represents *Caladenia carnea*

CALADENIA CARNEA ALBA.

alba, and was taken last year. The plants were imported early in 1897, and have since then flowered well every year in the Cattleya house. Another beautiful species is *Caladenia cerulea*, a counterpart of the preceding, but with lovely blue blossoms. These species usually flower during winter, and remain in perfection for weeks, so that they are far from being curiosities only.

DAVID S. FISH.

NURSERY GARDENS.

MESSRS. SUTTON'S CHINESE PRIMULAS.

THIRTEEN thousand Primulas, all in 5-inch pots, and every one in the respective forty varieties so exactly alike its neighbour in plant as pot is to pot. It is a surprising flower show, one of which even the great firm of Sutton and Sons may be proud, and they have shown many big things in their time. Such was the sight which greeted the eyes of the numerous representatives of the horticultural press who met at the Reading seed grounds and in the superb new range of glass houses that now forms so conspicuous an object from the adjoining railways on the 23rd ult. Apart altogether from the singular excellence of cultivation shown in the presentation of this great number of plants, all from seed sown last July, in their fine even condition of growth and bloom, there was the evidence perhaps most remarkable of all of what has been evolved out of the Chinese Primrose since its introduction here in all its native simplicity and plainness. Every plant is from seed, and every one is grown to produce seed, for the demands on the firm's stock are enormous. There are several sections in certain diverse habits or characters, yet in most there is duplication of colouring in the flowers. Thus there are of both palmate leaf and of Fern leaf many varieties, singles and doubles, and florally, though not in foliage, reproductions of each other. Even with these sections there are those having pale green leaves and stalks as there are others having dark leafage and stalks.

Farther off there are the huge flowered giant single forms in several colours, and some ten or twelve varieties, the blooms generally as large as crown pieces and finely fimbriated. There is also the stellata strain, or by some called pyramidal, in several colours. Another, not least, the doubles, or as commonly called, to distinguish them from the non-seeding doubles, semi-doubles. It is therefore not difficult to understand how the forty varieties, all distinct, are made up, and even now new ones are constantly cropping up because the work of intercrossing varieties to produce novelties goes on unceasingly.

One of the most remarkable and beautiful of the more recent introductions is named The Duchess. There is of this singularly beautiful variety from 800 to 900 plants in one huge group, and so fine throughout, every one being in equal bloom, that, while the quality is of the very best, not two flowers differ in form or colouring. It presents, indeed, a marvellous break, and has also even produced a double form as well. Round the eye of each flower is a band of rich reddish crimson, and the ground of the outer margin being of silvery peach, shading to pale lilac. All flowers are of good size and form, and charmingly fringed. A brilliant comparison to this is *Crimson King*, which has, too, a band of deep maroon round the eye, the ground being of blood crimson. This in the full light at Reading is indeed a glorious variety. Of whites there are several. *Royal White* has full pure blooms of good size over dark foliage, and is a capital companion plant to *The Pearl*, which has pale green foliage, and also to the fine selection of the moss curled-leaf form of *alba magnifica*. *Snowdrift* is a beautiful Fern-leaved variety.

Very lovely also is the Fern leaf *Rosy Queen*, flowers pale pink or flesh white, whilst deeper and a singularly lovely form is *Reading Pink*, which seen in bulk has a splendid effect. A glorious rosy red is *Brilliant Rose*, the flowers having clear lemon eyes that add so much to their beauty. How charming, too, are the blues. There is first a very pallid blue, well named *Cambridge*, and then there is a fine selection known as the *Reading Blue*, which is much richer in colour, and even now, though only in process of selection, is a much deeper blue; indeed, the richest blue tint we have yet seen in the *Primula*. But it is possible only to mention a few of the large quantities. There are so many others, and, not least, some of striking colour in new clothes that must, a year or two hence, be seen in considerable bulk. The giant forms are all that it is possible to desire in size, substance, form, and beauty of flower. Most of these are rather late, but plenty were open, and the quality was seen to be of the very finest conceivable. In the stellata section it is interesting to see a blue is being introduced. The most effective, whether as pot plants or for picking from for table decorations, are *Ruby* (a real rich scarlet), *White Queen Star*, *Mont Blanc Star* (both white, yet diverse in form), and *Carmine Star*. Great care has been exercised to retain in these stellata forms the free-flowering and pyramidal habit which has made them such favourites for winter use. The doubles are indeed glorious, and are yearly being increased. Singularly beautiful were the *Double White*, so free and pure in colour; *Double Scarlet*, giving intense rich colour in great profusion of bloom; *Double Blue*, giving, because of the greater abundance of petals, very effective colour; *Double Pink*, really lovely, so pleasing and so refined is its colouration; also a beautiful *Carnation-flaked* variety in great quantity, most delightful to have. These are not all, as the *Double Duchess* and some others evidence. It is a singularly attractive section, and must grow into popularity yearly. It is not possible to close a brief notice of this wonderful *Primula* show without paying to the growers of these myriads of plants the compliment of saying that they have done their work splendidly, and none other would have done it better.

OBITUARY.

MR. RUSSELL HALLACK.

FOR some time past South African affairs—from politics down to botany—have been among the dominant topics, and the interest with which they are invested has certainly not been diminished by the trip made by Mr. Chamberlain, whose penchant for Orchids is so well known, while in a minor way the letters from the Cape which have been published in *THE GARDEN* have also directed attention to Cape flowers. Most tourists from the Cape are greatly interested in Kew Gardens and the North Gallery. Among the places visited by the famous floral artist was Port Elizabeth, and many of her admirers will remember that in her work, "The Recollections of a Happy Life," she mentioned that she, like all other travellers interested in flowers, called upon Mr. Hallack, who, in addition to taking a prominent and active part in public affairs and different useful institutions, devoted considerable time and study to botany, which was one of his great hobbies. He made a special excursion with Miss North to Van Staadens, which abounds not only in flowers but in rambles, scrambles, and drives; a well-known charming spot and a place of great natural beauty.

In this locality, full of scenic attractions, Miss North both painted and described many of the beautiful flowers of the Cape. Her excursion in this part of the colony is described with much enthusiasm, and the well-known gallery is embellished with several specimens from that favoured locality, where there are many of the most famous wild flowers in South Africa. The grand blue patches of *Agapanthus*, well known in cultivation,

evidently took her fancy. She also painted one of the *Harveyas* (root parasites), many of the species of which are very showy and gorgeous, but they, unfortunately, are never likely to be introduced into England. As president of the Eastern Province Naturalists' Society, Mr. Hallack took a most active interest in his favourite study—botany. Few people are absolutely without some interest in flowers, and he soon kindled the enthusiasm of members for a science, his knowledge of which was by no means small. It invariably formed the subject of his frequent addresses. As a companion he was one of the most delightful of men; in fact, he was of a stamp not quite as plentiful as Blackberries.

Few men were better read than Mr. Hallack in an age when books are many, and the leisure to read them increasingly scanty. Those who had the honour of his friendship breathed the refining air of taste, knowledge, and goodness. He had a great natural gift of memory, and he was, as the French aptly say, a *grand charmeur* in conversation. There were few circles of society where he was not welcome, and he will have a most enduring hold upon the hearts of many friends not only in this colony but also in England. The news of his death which has just taken place will touch a chord of thoughtful sadness among all those who knew the Cape and its beautiful wild flowers. Like most men of his years he found the multiplying gaps around him one of the chief trials of old age.

In the Cape where the sun shines gloriously forth in the manner of Italy the flowers have more gorgeous tints than in many countries. Now that the war is over it is to be hoped that botany like the other sciences may exert some slight influence in binding together the English and the Dutch—the two different races of the Cape, and both of them are proverbially fond of flowers.

MR. WILLIAM WILDER.

THIS well-known inhabitant of Slough, who had been at the Royal Nursery, Slough, all his lifetime, died there on the 28th ult., aged 64. He was one of three brothers who were at one time in the employ of Mr. Turner. Going to the nursery on leaving school he was placed in the seed shop, and rose in time to be head shopman, in which capacity he died. He was well known and highly respected at Slough, and a trusted and industrious servant. For the space of forty-four years he had been a chorister in the parish church. In sending the notice of his death Mr. Harry Turner states: "We shall soon have lost all our old hands."

MISS ARNOTT.

WE much regret to learn that Harriet Mary, daughter of Mr. Samuel Arnett, Rosedene, Carsethorn, by Dumfries, N.B., died on Thursday, the 29th ult. The many friends of Mr. Arnett will be sorry to hear of his loss.

MR. L. G. KING.

WE much regret to announce the death of Mr. L. G. King, of the firm of Messrs. John K. King and Sons (seedsmen to His Majesty the King), of Coggeshall, Essex, and Reading, Berks, who passed away peacefully at Matlock on the 30th ult., at the early age of thirty-five years. The deceased gentleman took an active and practical interest in the business. He was much esteemed in the neighbourhood of Coggeshall, where he resided, and was highly respected on Mark Lane and other markets by all who had business transactions with him. As an employer he was kind and considerate, and his death is deeply regretted by all who were under him. In athletics, Mr. L. G. King took a keen interest. He was a good cricketer, and as a football player will be remembered as being at one time a prominent member of the Essex County Eleven. The greatest sympathy has been shown to his widow and other relations, who are held in the highest esteem throughout the whole of the Eastern Counties.

THE GARDEN

No. 1630.—Vol. LXIII.]

[FEBRUARY 14, 1903.]

ROYAL HORTICULTURAL SOCIETY'S ANNUAL MEETING.

THE annual meeting in one of the upper rooms of the Drill Hall, Westminster, was one of the largest held in connexion with the society.

We gave last week a *resumé* of the report, and a full account of Tuesday's proceedings will be found on another page. The meeting was presided over by Sir Trevor Lawrence, the president, who spoke of various items in the report, the two principal points being the new Hall and the Chiswick gardens.

With reference to the Hall, we presume from the remarks made that the plans are definitely settled upon, but we strongly object to the view adopted by the president when declaring that he never knew a building that pleased everyone. The structure that is to be is utterly without architectural charm, and the general opinion is that it is unsuitable pictorially as a temple for all that is beautiful in the world of flowers. Our earnest hope, however, is that the sum of about £22,000 still required will be quickly forthcoming, and that the thousands who have not yet subscribed will do so, so that the building now begun may be ready for the opening ceremony next year.

Mr. Elwes, in opposing the report, mentioned that the council had not taken the Fellows into their confidence, either with regard to the plans or the disposal of the lease of the Chiswick gardens. We venture to think that if the plans had been hung in the Drill Hall for some time previously and objections carefully considered, the Fellows would have thought better of the council; but a great work has been begun, and we hope it will be carried to a successful conclusion. Our hope is that the society will not in the near future suffer from a surfeit of bills in the shape of taxes, rates, and the general burden of maintaining a large establishment.

Mr. Elwes asked the chairman whether the council had power to dispose of the lease of the Chiswick gardens, and he said that such was the case; and, further, we understand that it has been practically parted with for the sum of £5,000, which will be devoted to a new garden elsewhere. We understood that the surplus funds of the society, amounting to about £1,600, may be devoured by the new Hall, but we think this will rest with the

Fellows. If they wish to avoid this undesirable proceeding they must subscribe to the building fund.

A garden is necessary to the society's existence. Thousands of Fellows would at once stop their subscription if the society were without a garden. An honourable institution would practically cease to exist, and become of value merely for its Hall and the flowers to be seen there by those who live in London or the neighbourhood.

The chairman alluded to the expense of maintaining Chiswick; but what is the society for but to possess a garden for holding trials and as a means of distributing seeds and plants? Some may consider the plant distribution somewhat farcical, but many Fellows who have never seen a London show and are therefore quite indifferent about a new building, regard this part of the society's work as of great interest and importance.

As the days of the Chiswick gardens are numbered, we take the following from this year's report of the society. The council here speak for themselves:—

"The society's gardens were first established at Chiswick in 1822, and since that time have been looked upon as a leading and important help to horticulture. The new plants discovered by Reeves, Potts, Damper Parks, and Fortune in China and in the East Indies; by Don on the West Coast of Africa, South America, and the West Indies; by Forbes at the Cape of Good Hope and the Zambesi region; by Douglas in North America; and by Hartweg in Central America, were all first grown at or introduced to Chiswick, and from thence afterwards distributed over the British Islands and the continent.

"The council being anxious to make the gardens (as far as the funds at their command will allow) a school of practical and scientific horticulture, and of increased value and interest to the Fellows, have given careful attention to their present condition. The gardens are devoted (1) to the cultivation of all such fruits, vegetables, stove, greenhouse, and hardy plants and flowers as are found to be most generally useful or ornamental; (2) to the trial of new sorts side by side with established varieties; (3) to the hybridisation of plants and the raising of new varieties; (4) to experiments in the culture and treatment of those plants which possess a floral or decorative as distinguished from a merely scientific value and interest. To these may be added (5) the trial of such horticultural appliances and materials as may from time to time be submitted.

"The cultivation, trial, &c., of fruits have always been considered as of the utmost importance, and happily forms one of the most valuable features of the gardens. There is an almost unique collection of the best varieties of fruits, and it is intended to maintain and extend it by the trial of such novelties as the raisers may be good enough to bestow on the society.

"The cultivation of Grapes is conducted on a large scale, and the great conservatory, 180 feet by 30 feet and 26 feet in height (one of the largest and noblest structures devoted to Grapes in this country), affords at all seasons ready examples of, and instruction in, successful Grape culture, which might be of service to many of the Fellows; and when the fruit is ripe is an object of the greatest possible beauty. House No. 14 has been planted with Muscats, and is similarly useful and instructive.

"House No. 5, which is devoted to Peaches trained on the back wall, has also been furnished with bush trees in front of them, and their culture will, it is hoped, prove extremely interesting to many Fellows.

"Two of the largest houses—Nos. 2 and 6—are devoted to the cultivation of Figs in pots, forming, without doubt, the finest and most varied collection of Figs to be found in this or any country, and will well repay the attention of all lovers of this particular fruit.

"A collection of standard and typical varieties of different vegetables will again be grown (as far as space permits) for comparison with new varieties, both to assist the committee in recommending their awards and for the general information of the Fellows. Besides this general collection, specially exhaustive trials of certain classes of vegetables are made every few years in rotation, and descriptive reports given.

"The Floral department includes plants and flowers of a distinctly decorative garden character, whether for cultivation under glass or out of doors. A few classes only can be illustrated each year. The collections of Cannas, Phloxes, Herbaceous Peonies, Iris, Perennial Asters, Ivies, Early and Late Chrysanthemums, Cape and Zonal Pelargoniums are very extensive. A large number of Carnations have been planted. Hybrid Tea and China Roses, and Cactus Dahlias, as well as other subjects, will receive special attention this year.

"The officials of the society will give any information and render every assistance in their power to all Fellows. Anyone wishing to study any particular branch of gardening operations, or to make any special observations on different subjects, should make direct application to the secretary, 117, Victoria Street, Westminster."

One or two speakers alluded to the grounds of the Royal Botanic Society as a likely refuge for the new garden. Amalgamation with that society, which is in debt and devotes its beautiful gardens to amusements, is impossible. The council are happily entirely opposed to such a course.

Special allusion was made to the value of the Journal. We believe the remarkable increase in the list of Fellows is in no small measure due to this excellent production. It is a famous work, and the greatest credit is due to Mr. Wilks for his diligence in maintaining its usefulness. It is a record valuable to the present generation, and will be more so to lovers of gardening, practical and scientific in the future.

NOTES ON LILIES.

LILIES IN POTS.

SEVERAL Lilies are justly valued for pot culture, and, grown under these conditions, they are useful for various decorations. As this treatment admits of ready removal from one place to another, Lilies can, when grown in pots, be taken into the conservatory or the dwelling-house just as the blossoms are on the point of expanding, hence they impart quite a new feature and a pleasing variety to the plants then in bloom. In the large floral nurseries two species are grown in immense numbers in pots; *L. longiflorum*—of which we derive our supplies principally from Japan, but also from Holland, Bermuda, and South Africa. The second species is *L. speciosum*, vast numbers of which reach here from Japan, and a lesser number from Holland. Other species that may be also grown in pots, but of which only a limited number are so treated compared with the preceding, are *L. auratum*, *Brownii*, *croceum*, *elegans* or *thunbergianum*, *Hansoni*, *Henryi*, *Krameri*, *odorum*, *rubellum*, *testaceum*, *tigrinum splendens*, and *umbellatum* or *davuricum*.

L. speciosum roseum makes a grand effect for conservatory decoration in late summer and early autumn, that is just as most summer-flowering subjects are on the wane and before the advent of the *Chrysanthemum*, is a great point in favour of this Lily and its varieties. Single bulbs of *L. speciosum* may be grown in the market cultivator's favourite—the 5-inch pot—but for the largest pots 6 inches and 7 inches in diameter will not be too big. Effective masses may also be formed in large pots or tubs by increasing the number of bulbs. A cold frame where they are just protected from sharp frosts, and that also serves as a shelter from very heavy rains, is the place for them, and as soon as the spring frosts are over they may be stood in the open ground. There they can be allowed to remain till the earliest buds are on the point of expanding, when, if taken indoors, they will continue to open without a check. This Lily possesses two valuable advantages over several other sorts—firstly, the plants are during the growing season rarely, if ever, troubled by insect pests; and, secondly, the flowers have not that all-powerful perfume that greatly limits the use of others in confined places.

One thing especially to bear in mind in the case of *L. speciosum* is that it is a vigorous stem-rooter, hence in potting ample space should be left for a good top-dressing at a time when it is most useful, that is, just as the young roots are ready to take possession of it at once. As the pots get full of roots a little weak liquid manure occasionally will be of service. Of the numerous varieties all the following are good: *L. album* (of the Dutch), white when fully expanded, but with the outside of the buds as well as the stems and leaf-stalk brownish; *Kratzeri*, sometimes sent here from Japan as *album*, flowers white, centre tinged with green, while the buds and leaf-stalks are also green; *album novum*, much like the last, but the flowers are more massive,

while the anthers are bright yellow instead of the chocolate-tinted ones of *Kratzeri*; *roseum*, white, tinged with rose; *rubrum*, of a somewhat deeper tint; *Melpomene* (from Japan), the deepest tinted of all, the petals being bright carmine-crimson, edged with white; and *rubrum superbum*, from Japan, a larger and finer flower than the Dutch *rubrum*. *Lilium speciosum* is of all Lilies one of the most amenable to permanent pot culture, for it may be kept in health and flowered year after year provided the bulbs are repotted when they die down in the autumn. In carrying this out remove as much of the old soil as can be done without injuring the roots.

Lilium longiflorum.—The bulbs of the variety *Harrisii* of this Lily reach here in August, and if potted and brought on in a greenhouse temperature they flower in early spring. Those from Japan and Holland which arrive later may be potted and grown under glass to give a succession to the pre-

shelter in the unfolding leaves and may cause a good deal of damage before they are detected. Of the other Lilies above alluded to, *L. croceum*, *L. elegans* or *thunbergianum* and its varieties, and *L. umbellatum* or *davuricum* all belong to the upright-flowered section, that bloom for the greater part in June, and, except a few varieties of *L. elegans*, the flowers of nearly all of them are of some shade of orange-red. After potting these only need protection from actual frost. *L. auratum* thrives best where its roots are cool and moist, with the tops just protected from direct sunshine. *L. Brownii*, its near ally *L. odorum*, with *Hansoni*, *Henryi*, *Krameri*, and *rubellum* may be treated as recommended for the latest batch of *L. longiflorum*, while *L. testaceum* and *L. tigrinum splendens* simply need a little protection from sharp frosts.

RETARDED BULBS.

Of late years a system of retarding Lily bulbs has been tried with such success that

THE ENTRANCE TO THE KITCHEN GARDEN AT MALSHANGER.

A lesson to those who consider this part of a garden unworthy of being made beautiful and interesting.

ceding, while if they are potted and placed in a cold frame protected only from absolute frost, and stood out in the open as soon as this can be safely done, they will flower about midsummer. The bulbs being smaller than those of *L. speciosum*, a 5-inch pot is large enough for all, while three of medium size may be grouped in a 6-inch pot. One particular advantage in growing *L. longiflorum* in pots is that owing to heavy rains, which usually occur at about its flowering period, the pollen is washed over the flower and destroys its spotless purity, but if the plants are in pots they can be taken under cover just as the buds are expanding, and the trouble is thus obviated. *Lilium longiflorum* is, when under glass, liable to aphides or green fly, but they may be kept down by regular fumigation, or, better still, vaporising. A little tobacco powder dusted in the apices is also helpful. This caution is particularly necessary, as the insects will

immense numbers are now so treated, and a considerable amount of capital has been sunk in the enterprise. It consists in storing the bulbs in refrigerators so that they are kept quite dormant till removed, when they start into growth without a check. The splendid flowers of *L. longiflorum* and *L. speciosum* that were so noticeable in the florists' shops of London in December were all the produce of retarded bulbs, and would even if planted out of doors at the proper season have flowered in July and August respectively. Such a sight as this would a few years ago have startled everyone, but this system of retarding bids fair to revolutionise plant growing in general, for it is questionable where it will stop. Dealers talk glibly of millions in connexion with Lily of the Valley that have been treated in this way, while *Lilacs*, *Azalea mollis*, *Spiræas*, and *Lilium auratum*, as well as *Seakale*, may all be obtained in a retarded state. H. P.

KEW NOTES.

INTERESTING PLANTS IN FLOWER.

Temperate House.

ACACIA ACINACEA, *A. juniperina*, *A. obliqua*, *Barosma fetidissima*, *Cestrum elegans*, *C. fasciculatum*, *Lissanthe strigosa*, *Melaleuca densa*, and *Senecio Petasites*.

Palm House.

Brownea grandiceps.

† *Range.*

Hemantus Lindenii, *Pitcairnia corallina*, and *P. darblayana*.

Succulent House.

Agave Sartorii, *Aloe ciliaris*, *A. insignis*, and *Protea cynaroides*.

Orchid Houses.

Acridis Vandarum, *Brassavola grandiflora*, *Broughtonia lilacina*, *Bulbophyllum neilgherrense*, *Cymbidium hookerianum*, *C. lowianum*, *Cynorchis compacta*, *Dendrobium burfordiense*, *D. Curtisii*, *D. dominianum*, *D. eudocharis*, *D. Euryalus*, *D. fytchianum*, *D. Madonna*, *D. nobile*, *D. n. Cooksoni*, *D. primulinum*, *D. sarmentosum*, *D. splendissimum*, *D. wardiano-japonicum*, *Epidendrum calamarium*, *E. stanfordianum*, *E. Wallisii*, *E. xanthinum*, *Eulophia saundersiana*, *Lælia harpophylla*, *Odontoglossum andersonianum*, *O. a. var. ruckerianum*, *O. cariniferum*, *O. Rossii majus*, *Oncidium batemanianum*, *O. splendidum*, *Ornithidium coccineum*, *Phaius assamicum* × *P. Marthe*, *P. tuberculosus*, *Platyclinis arachnites*, *Satyrium odorum*, *Tainia penangiana*, *Trias picta*, and *Vanda amesiana*.

Greenhouse.

Forced shrubs and bulbs, *Primula sinensis*, and various *Ericas* are the principal things in flower. *Rhododendron præcox* and *Wistaria sinensis* are specially noteworthy.

Alpine House.

Anemone blanda, *Bulbocodium vernum*, *Colchicum hydrophyllum*, *Coptis orientalis*, *C. trifolia*, *Crocus* (collection of species), *Corydalis rutæfolia*, *Cyclamen Coum*, *C. ibericum*, *Eranthis cilicica*, *Hyacinthus azureus var. robustus*, *Ionopsidium acaule*, *Iris* (collection of species), *Merendera caucasica*, *Orchis longibracteata*, *Primula megasæfolia*, and *Scoliopus Bigelovii*.

Rock Garden and Herbaceous Ground.

Adonis amurensis, *Galanthus* (collection of species), *Iberis gibraltaria*, *Iris lanfordiæ*, *I. Histrio*, *I. histrioides*, *I. reticulata*, *I. r. Krelagei*, *I. stenophylla*, *I. Tauri*, *Leucojum vernum*, and *Narcissus minor var. minimus*.

Arboretum.

Cornus Mas, *Daphne Mezereum*, *Erica carnea*, *E. lusitanica*, *E. mediterranea var. hybrida*, *Garrya elliptica*, *Nuttallia cerasiformis*, *Prunus davidiana*, *P. d. var. alba*, *P. triloba var. Petzoldii*, *Rhododendron præcox*, and *R. nobleanum*.

NOTES OF THE WEEK.

National Rose Society.—The exhibition of Roses on July 15 next in St. Andrew's Hall, Glasgow, promises to be of exceptional interest. We are pleased to find the society holding an exhibition in Scotland.

A note on Lenten Roses.—These are very peculiar in their liking, for I have a plant in the sunniest and driest part of my garden, and it is in splendid health year after year. Another clump now in the shade is not half so beautiful. They were put there ten years ago and have never been disturbed since.—L. CUENOD, *Fevry*.

Fragrance of the larger Christmas Rose.—Is it generally known that the flowers of *Helleborus niger maximus* (syn. *altifolius*) are sweetly scented? I have not seen anything to that effect in descriptions or on notes on the plant, neither have I noticed the fact

before this winter, when several plants flowering here were unmistakably strongly scented. The scent very much resembles that of *Daphne indica*, at the same time suggesting sweet Violets. Perhaps some of your numerous correspondents on the subject of hardy plants may have had a similar experience.—E. HORTON, *Harthorn Cottage, Park Road, Hale, Altrincham*.

Increased popularity of Bananas. In round figures the consumption of Bananas during the past two years—*i.e.*, since Mr. Chamberlain's effort to aid Jamaica—has risen from 1,500,000 to 3,500,000 bunches per annum, which speaks eloquently for the growing popularity of this fruit.—ELDERS AND FYFFES, Limited, 9 to 12, Bow Street, Covent Garden.

Retirement of Mr. Browne of Hyde Park.—Mr. W. Browne, after thirty years' service, is retiring on a Civil Service pension from the superintendentship of the Royal Central Parks, London. We hope Mr. Browne will enjoy for many years a life of repose after the onerous duties connected with the management of the Central Parks, and Hyde Park in particular. The flower planting of Hyde Park has been much criticised, but the general opinion is that Mr. Browne has accomplished much good work. We have enjoyed and learned much from the beautiful grouping in spring and summer. Mr. Browne was one of the first, we believe, to use the large specimen *Heliotrope*, *Fuchsias*, and other plants which English gardeners had almost forgotten, and all who know the London parks will remember with pleasure the beautiful effects gained by the right use of a few things.

A seedling from La France Rose.—It is well known that the *Rose La France* does not seed freely; nevertheless, M. Dienemann of Klein-Furra (Thuringia) writes to the *Rosen-Zeitung* that he once obtained a ripe fruit on a specimen of this variety. M. Dienemann sowed the three seeds, however, and obtained from them three plants. The first soon bloomed, but it had single flowers. The second produced flowers analogous to those of the variety, Mme. Julie Weidmann, but still paler. The third acted in a peculiar manner; it developed considerably in height, but did not blossom. M. Dienemann then grafted it upon other stocks, but had to wait a long time before obtaining a flower. The shoots produced many buds, but as soon as these had reached a certain size they withered and fell. At length, during a spell of dry and warm weather, a bud opened into flower. "The flower," says M. Dienemann, "was unique both in form and colour." Nevertheless the grower abandoned the plant because of its difficulty in flowering. Still this important fact remains—namely, that it is not absolutely impossible to obtain seeds from *Rose La France*.—*Revue Horticole*.

Spring flowers at Hampton Court. It was interesting on a fine sunny day in the first week of February to note in these gardens in charming bloom those now all too rare hardy plants, the single and double red Hepaticas. The Winter Aconite was likewise blooming profusely as a sort of carpet to a shrub bed; also that the double *Arabis* was as precocious to flower as the single one. Many of the myriads of *Polyanthuses* put out in the autumn in beds were showing flowers, and, indeed, had been most of the winter. Many of the early-blooming Heaths were also in charming flower, and of shrubs both the red and white forms of *Daphne Mezereum* were full of bloom, the white especially, in clumps of several bushes being most effective. I could but notice how remarkably fresh and nice the Wallflowers were in the beds, a condition no doubt materially due to the provision of wind-breaks about the plants and round the beds, formed of branches of Yew, which had kept quite green. In a few weeks these famous gardens will be very attractive with spring flowers, and it will be possible for Londoners to reach them from Hammersmith or Shepherd's Bush per electric tram, thus seeing *en route* a large portion of the Thames valley. I confess to having a desire to see at Hampton Court some of the back beds devoted to special flowering shrubs, such as *Forsythias*, *Ribes*, *Azaleas*, *Philadelphuses*,

Berberis, *Viburnums*, *Ceanothus*, *Rhus Cotinus*, *Hydrangeas*, *Brooms*, *Deutzias*, and other similar suitable representatives of beautiful hardy shrubs. No doubt in public gardens such as those at Hampton Court much has to be considered; but it is equally important that the public taste be educated to appreciate the beautiful in gardening material. Even now in what are regarded as good private gardens, the best flowering shrubs and trees also are very indifferently represented.—A. D.

Ardisia crenata.—The above, according to the "Kew Hand List," is the correct name of the plant so long grown in gardens as *Ardisia crenulata* and *A. crispa*. A generation or two ago it was far more popular than it is now, but why it has been allowed to drop out so far in favour is hard to say, as its brilliant scarlet-coloured berries form an attractive feature at this season of the year. This fact is well illustrated just now in the † range at Kew, where there is a small group consisting of half a dozen plants or so, each about 18 inches high, and all profusely berried. The rich green of the prettily crisped foliage is also another notable feature. There is besides these a specimen of the variety *alba*, with rather larger berries than those of the type, and of an ivory-white tint. The leafage of this last is, as a rule, not so rich in colour as the red berried form. This *Ardisia* is a native of China, and in this country needs a warm greenhouse or intermediate temperature. I have seen a variety with variegated leaves, but was rather surprised to read the following in a catalogue of one of the principal nursery firms in Japan: "More than twenty varieties of variegation are known, either marginal, speckled, or striped." Of the smaller-growing *Ardisia japonica*, which is rarely seen in this country, the just named catalogue also mentions twenty variegated leaved forms.—H. P.

Alcohol in Agaves.—M. R. Roland-Gosselin points out in the "Bulletin de la Société Centrale d'Agriculture, &c." of Nice, the value of certain Agaves for the production of alcohol, of which the industrial use is becoming daily of more importance. We think it will be interesting to quote the essential passages of this article. "In Mexico (the country of nearly all the Agaves) an alcohol of variable quality, from which brandies are made, is produced in great quantities under the name of 'Mezcal.' The plant which furnishes this alcohol is a variety of medium height of *Agave rigida*. It is true that from its size it is not likely to yield an abundant supply; but if good quality can be obtained the quantity is considered of secondary importance. It is not the same, however, with some large varieties of *Agave salmiana*, whose thick and fleshy leaves, full of juice, yield from the same plant more than a ton of matter to be distilled, without counting the stems, &c., which are capable of doubling the weight. The late M. Madinier some twelve years ago introduced from the high lands a variety called in Mexico 'Maguey verdé,' which is remarkable in this respect, and which is specially cultivated with the object of producing alcohol. I cultivate this plant here. It has not yet produced a flower-spike, but it presents all the appearances (except the colour, which is very peculiar) of *A. salmiana*. Instead of the characteristic dark green, which has caused *A. salmiana* to be described by the synonym of *A. atrovirens*, 'Maguey verdé' has leaves of grass almost Spinach green. Making the alcohol is very simple. The leaves, methodically cut as they are wanted, are placed in a crushing machine, which reduces them to a thick pulp, sufficiently aqueous in the large varieties to be submitted to distillation without further moistening. The American Agave can also be used, but its yield, it appears, is not sufficiently remunerative. It is important to make trial only of those Agaves recognised in Mexico as meritorious, either for yielding the best quality or for the greatest quantity of alcohol. Preference should be given to the latter for experiments in the district of Nice, where so much unused land would suit this culture. The Agave may become the Beet-root of the littoral."—*Revue Horticole*.

Tomato Veitch's Golden Jubilee. It is surprising that this splendid variety does not find more general favour. For some reason or another yellow varieties are not so popular as the red ones. We find this to be so, not only at our horticultural exhibitions, but also with the general public. I cannot help thinking that prejudice must have something to do with this, as no variety is of better quality both for flavour and solidity of flesh, and when well ripened it has a most pleasing appearance. It is also very prolific. I believe I am right in saying this was a sport from one of the best-known red varieties, and where Tomatoes are appreciated in a raw state this should most certainly be grown. I should like to see yellow varieties receive more encouragement at our exhibitions.—E. BECKETT.

Blackberries in a Peach house.—In the gardens of A. Coates, Esq., Woodside House, Paisley, under the care of Mr. Hogg, there are in a Peach house two plants which at first look like vigorous Crimson Rambler Roses, but are really the Wilson Junior Bramble. One of the plants has about eight shoots from 8 feet to 14 feet long trained up the back wall of the house, the rods being about 12 inches apart. The wood is well ripened, and, under such conditions, must produce splendid fruits. Anyone fond of Blackberrying could do it at home if they would devote a little space and care to this splendid Bramble.—SPECTATOR.

Bulbous Irises at Kew.—In the alpine house at Kew one may always feel certain of seeing some little gems at this season, the various bulbous forms of Iris being conspicuous; but these beautiful plants are not limited to the glass structures, as on the last day of January they formed one of the brightest features of the outdoor garden. Nestling at the foot of a wall in the herbaceous ground was a representative collection of these charming forms, not singly, but in most cases a little clump or colony of each served to brighten up a winter's day. One of the showiest of all was the comparatively new *I. Tauri*, the flowers of which are of a rich reddish purple colour, though some might prefer the smaller bright yellow flowers of *I. Danfordiae*, known also as *I. Bornmulleri*. A clump of this is conspicuous, more especially in dull weather. The pretty pale blue *I. Vartani* that usually flowers earlier in the winter was in bloom, and furnished a distinct shade of colour among these little gems. *I. stenophylla*, which by the way is more frequently known as *I. Heldreichii*, was beautifully in flower, the colour being a kind of purplish blue, with dark velvety blotches on the outer petals. *I. Histrio*, with its light blue mottled flowers, was also represented, as well as the allied *I. histrioides*, the blooms of which are of a deeper colour, but mottled as in the preceding. That distinct form of the Netted Iris (*I. reticulata Krolagei*) had just unfolded the first of its claret-purple flowers. Under glass most of the forms above mentioned were represented, and in addition were some delightful masses of the Algerian Iris (*I. alata*), whose comparatively large flowers are of a bright purplish lilac colour. This, one of the oldest of the section, was first introduced so long ago as 1801. Most of the forms of these bulbous Irises are by no means expensive to purchase, but it is difficult in many gardens to establish them permanently.—H. P.

Gardening at Exeter.—There are but few cities or county towns that can compare with Exeter in the interest taken by its inhabitants or by its local press in furthering the knowledge of the natural beauties of the city or county, or by encouraging the people to protect places and native plants from destruction, that have either historical or scientific interest attached to them. The Exeter folk are naturally proud of their public garden at Northernhay, where, notwithstanding its elevated position above the railway, flowering plants are always in a forward condition and mostly ahead of the season. It is therefore interesting to note, on the authority of the *Devon and Exeter Gazette*, that Kew has recently lent a helping hand to this western city. A writer in our provincial contemporary says: "Northernhay, I

am glad to see, is receiving attention. Some specimen shrubs have been given to the council by the authorities at Kew. I hope that only just so many will be used on Northernhay as are really desirable. I am not sure that the slope in front of the castle has been improved by the bushes planted there. The graceful sweep of turf laid with an artistic eye, and broken only by the rock, needed nothing to add to its effect." As a further illustration that the true principles of gardening are encouraged and practically demonstrated the same paper contains a notice of a meeting of the Devon and Exeter Gardeners' Association—a flourishing institution—where Mr. S. Radley, of Messrs. R. Veitch and Son's nurseries, opened a "demonstration of the various methods of preparing cuttings." The value of the instruction so given and obtained is thus set forth in the report: "The senior members, with specimens provided for the purpose, showed the juniors of the gardening craft how they prepared cuttings of the various kinds of plants, and gave their reasons for adopting the methods they preferred, for there are many. Surely no better mode of mutual improvement in their art could be practised than this, and the large number of members present was proof of their appreciation. Societies working in the practical and friendly manner in which the members of this particular association do, must assuredly do good, and should be encouraged. The committee have been happy and fortunate in their selection of subjects, and the infinite variety provided has had the beneficial effect of sustaining the interest of the members and furthering the aims with which they first set out."

Stuartia pentagyna.—This, the so-called American Camellia, is one of the most beautiful of all North American shrubs as well as one of the most rare, and has been much sought after for many years, being sparingly offered at times by a very few nurserymen in America and Europe. *Stuartia pentagyna* is the only American representative of the Tea and Camellia family which can be grown in the latitude of New England, and a few very fine clumps are now growing in the vicinity of Boston. It flourishes and flowers to perfection in the Arnold Arboretum, Jamaica Plain, Boston. It is an erect shrub, 10 feet or 12 feet high, well foliaged, and with large axillary flowers, 3 inches or 4 inches across, with white creamy petals, deeply crenulated on the margins, and resembling those of some of the single Camellias. Altogether it is one of the finest of all shrubs for single or mass planting and thrives in damp situations as well as in drier garden soil. *Stuartia pentagyna* is worthy a place in the smallest and most carefully selected gardens, and we take the greatest pleasure in being able to offer this rare and beautiful shrub to our customers.—H. P. KELSEY, *Boston, Mass.*

Weather prognostics.—It will indeed be delightful when, as your correspondent "E. K. R." prophesies in your issue of the 24th ult., it is possible to predict what the weather will be on a given day with as much certainty as we can the tides, so that we shall be able to know on what day a hailstorm may be expected, or what day will be hot and fine. What a change will be made in our lives! No more flower shows ruined, or garden parties marred; no more hats or ladies dresses spoiled by unforeseen storms, or pleasure trips taken in unsuitable weather. Surely then the millennium will not be far off. Unfortunately, however, it is not easy to see on what grounds "E. K. R." builds his hopes. What are the irregularities of the moon's movements that he alludes to? If they are apparent in the changes of the atmosphere they should be more in evidence in the tides, which can be calculated for many years in advance, and do not show any aberrations from their usual course. No doubt there is a tide in the air just as there is in water or any other fluid, but owing to the greater rarity of the air the attraction of the sun and moon does not have so much effect upon it as it does on a denser fluid, but such tides as there are must be as regular and as frequent as those in water. Even in the finest and most settled weather I have never heard that any meteorologist has been able to detect them.

If "the wind is an air wave caused like the tide of the sea when she pulls in conjunction with the sun," why does it blow as it often does for several days in the same direction? It should ebb and flow like the sea. "E. K. R." gives certain predictions for the first six months of this year, and then says: "They are based upon scientific grounds, but if they are not fulfilled it will be because the savants have made errors in their calculations." Is not this begging the question? I do not for a moment imagine that we know all about meteorology. Most undoubtedly we do not, but that the cyclones which come to us from the Atlantic Ocean, or the thunderstorms that sometimes develop with so little warning, will ever be shown to have the same regular periods as the tides, I cannot for a moment believe to be possible. It would be most useful to all gardeners to study the weather. By watching the form of the clouds and the direction in which they move, and the rise or fall of the barometer, frosts and gales can generally be foretold a few hours beforehand by these simple observations, and everybody knows what that means in a garden.—G. S. S.

Cypripedium spectabile.—This is the handsomest and one of the rarest of all hardy Orchids, and is really more known and cultivated in England and Ireland than in America, where alone it is native. The broadly ovate sepals and petals are pure white, while the large inflated pouch is a beautiful soft rich rose colour. It is a strong grower, often reaching 3 feet in height, the stems being leafy and the leaves profusely furnished with soft white downy hairs. In places where the soil is not naturally peat or rich vegetable matter, this fine plant will succeed admirably in the prepared Rhododendron bed, but in any case it should be planted deep, as the roots are then cool and moist during the hot weather and do not suffer from frost in winter. The Moccasin Flower is an admirable bog plant, will succeed fairly well in any shrub border affording shade, and is an excellent pot plant.—HARLAN P. KELSEY, *Boston, Mass.*

Chrysanthemum rust.—This is now most prevalent; there are few growers who have not had to contend with it. It may be worth while asking cultivators to give their experience of its origin in their own gardens and how they treat plants when badly affected. We grow many varieties principally for cut flowers, and have been troubled with rust more or less for five years. It attacks some varieties more severely than others, and some of our old favourites have become so weak as to be hardly worth keeping—for instance, *W. H. Lincoln*, *Peter the Great*, *Florence Percy*, *Tokio*, and *Cullingfordii*. Nothing could have been more vigorous than these were some years ago. Last year I obtained cuttings from five or six different places—from Jersey among others. Even this did not ensure freedom from rust. We find the best way to keep it down is to syringe the plants occasionally with soot water and with Abol insecticide. Nothing keeps them quite free from rust, however, so I regard this as having come to stay. It occurred to me that feeding the plants, and as soon as the flowers are over cutting down the stems close to the pot, may have something to do with the question. Has any grower tried to obtain stock from plants which have not been fed and whose stems are not cut?—J. CROOK.

Specimen Frankoas.—*Frankoa ramosa* is well known as an extremely graceful and useful plant for the greenhouse, and it is also useful to associate with other flowering plants in the formation of outside groups in various positions where colour is required. When the stocks of large Pelargoniums, Hydrangeas, and things of similar character are overhauled, it is a good plan to transfer a few Frankoas to 12-inch pots, selecting good stout plants that are carrying from half a dozen to a dozen breaks. Soil that will suit the Pelargonium will do well for them, and after potting they can be staked out to the edges of the pot to allow plenty of space for the individual spikes of flowers. Plants of this description look charming standing up well above a groundwork of scarlet or crimson Pelargoniums or pink Hydrangeas.—E. BURRELL.

Dendrobium wardianum in Glasgow.—The way to grow the charming *Dendrobium wardianum* has certainly been demonstrated in a very practical manner by Mr. McIver at Camp Hill Gardens, Queen's Park, Glasgow. Plants imported four years ago have now pseudo-bulbs from 2 feet to over 3 feet long; but it is not the length which strikes one so much as the thickness of the bulbs, the nodes bristling with buds. *Dendrobium nobile* is also especially good, with thick bulbs of good length, well furnished with healthy leaves, and at the same time full of flower-buds. Mr. Whitton, Superintendent of the Parks and Gardens of Glasgow, is convinced that less heat and more air have brought about these excellent results.—SPECTATOR.

Chrysanthemum Golden Gem.

On page 50 Mr. Jenkins asks why I so favourably regard Golden Gem as a late-flowering variety. I can assure him Golden Gem has been grown here for many years without the least sign of the defects he mentions in his note. We have never tried H. W. Rieman, but Golden Dart certainly cannot take its place if we are unable to depend upon its flowering in January. At this date (January 29) Golden Gem is at its best, and it is likely to give a good supply of flowers well into February. I did not mean to infer that the whole batch of this variety was struck in June. We grow from 600 to 700, many of which are already planted. The plants which are struck in June are grown especially for grouping, for which purpose they are invaluable where groups have to be made in limited space. Lady Canning, too, makes charming little plants when grown in this way, and I have noticed that these late-struck plants have a much smaller percentage of blind shoots; but good strong cuttings must be obtained to ensure success. The flowers of Golden Gem are not so large as some varieties, but I fail to see that impairs in any way its value for ordinary decorations.—E. HARRISS, *Royal Gardens, Frogmore.*

TREES AND SHRUBS.

JAMESIA AMERICANA.

A PRETTY dwarf shrub is this, and we are pleased to show a small bed of it in the Botanic Gardens at Edinburgh. It is just the shrub for a lawn, though one rarely sees the *Jamesia* in gardens. It is the only species of the family, was first introduced into England in 1865, and blooms in early summer, every shoot bearing clusters of white flowers, which are individually about half an inch across. It grows usually between 2 feet and 3 feet in height, is of bushy growth, and produces a wealth of neat, whitish Raspberry-like leaves.

SHRUBBERIES.

THAT most charming production "Trees and Shrubs for English Gardens" cannot fail to draw still further attention to the wealth of beauty which is lost by the neglect of trees and shrubs. Most striking of all is the fact that in spite of the general improvement in gardens little is discernible in shrubberies—still the old jumbled up muddle which Mr. Robinson laments in "The English Flower Garden." During the last few years it has fallen to my lot to have to deal with a shrubbery mainly composed of Laurels, Privet, Snowberry, and Lilacs, all much overgrown and neglected. Renovation was out of the question; in fact, nothing was possible except to make a clean sweep of everything. The Lilacs were scraggy and a mass of suckers, the Laurels were in complete decay, while Snowberry in our

JAMESIA AMERICANA IN FLOWER IN THE BOTANIC GARDENS, EDINBURGH.

light sandy soil is an almost ineradicable pest, so that we decided to choose its room in preference to its company. In this district Holly, Yew, and Box are our mainstays among the evergreens, and these we have made most use of. When once established—rather a difficulty when the solid sandstone rock crops up at a depth of 4 feet, and above this is at least a foot of coarse gravel!—they grow well, and benefit greatly by an annual mulch of leaf-mould and burnt garden refuse. But even with this attention many deciduous shrubs fail, and sooner or later one has to fall in line with Nature, and remember that on poor and hungry soils it is simply courting failure to plant promiscuously subjects which one may happen to have seen succeeding in more fertile districts. In a hot and dry season the ravages of drought are soon apparent, and do what one may losses are inevitable. Perhaps the following (necessarily restricted) list of the deciduous shrubs, which really are a success on the shallow soil of this district may be helpful to some readers: Almonds, *Berberis vulgaris* and its varieties, *Buddleia globosa*, *Colutea arborescens*, whose good qualities are ignored around here; *Cornus*, some varieties do fairly well; Hawthorns, very well; *Cydonia japonica* and its varieties, Gorse and Brooms, *Deutzia crenata*, most excellent, even in the shade of large trees; *Halesia tetraptera*, very good; *Hypericums*, *Kerria*, Lilacs, very well; *Lonicera* (shrub Honeysuckles), of which *tatarica* makes a lovely hedge, and *Morrowi* is one of the most beautiful of May-flowering shrubs; *Philadelphus*, *Prunus Pissardi*, and the wild Sloe, Crabs, *Rhus Cotinus* and *typhina*, flowering Currants, Elders, *Spartium junceum*, most *Spiraeas*, *Viburnum Lantana* and *Opulus*, and *Weigelas*.

Returning to the subject of evergreens, I was very pleased to read the appreciative note on Yews by Mr. Clayton (page 20), and am in full agreement with him as to the beauty of the Golden Yews at Elvaston. Unfortunately, there is such a preponderance of evergreen trees and shrubs at Elvaston that the general effect (to my mind) is not so pleasing as it would have been had more of the deciduous trees and shrubs been given a place. This overuse of evergreens has since been explained to me when reading "The British Winter Garden: being a Practical Treatise on Evergreens; showing their general utility in the

Formation of Garden and Landscape Scenery, and their mode of Propagating, Planting, and Removal, from 1 foot to 50 feet in height, as practised at Elvaston Castle. By William Barron, Head Gardener." In this little work Mr. Barron states at page 11 that "nothing is so common as to see close to our mansions such commonplace things as Elms, Ashes, Sycamores, Poplars, or any other rubbish that the nearest provincial nursery may happen to be overstocked with; all stuck in to produce either immediate or lasting effect! The immediate effects I shall not describe, but some of the lasting ones are these—a continual litter of decayed leaves during that period of the year when our gardens are expected to look their best; and an assemblage of leafless stems without either beauty of form or outline, and affording neither shelter nor protection from bleak winds for seven months in the year; a want of protection in winter and early spring; the absence of colour (being without leaves) during the same period; the constant litter from falling leaves during the late summer and autumn months; and the unwholesome effluvia arising from decaying leaves in autumn and winter, form insuperable objections to deciduous trees being planted, or indifferent and uninteresting ones remaining, wherever grounds are intended to be well kept, or where snugness and neatness are expected. All deciduous trees, then, should be so disposed as to secure the greatest possible advantage from their beauty; but should never be allowed to occupy the space of such as will be both more useful and ornamental in a shorter space of time. I must be honest to confess that had I a place of my own to lay out I should infinitely prefer planting it *exclusively* with *evergreens* wherever beauty or shelter was my motive for planting." And so on, with the result that the carrying out of these ideas has made the Elvaston arboretum of too sombre a character, and the contrasting harmony which might have been produced by the use of a liberal proportion of the best deciduous trees and shrubs is sacrificed.

Unlike the Box, the Yew nowadays seems to have lost its commercial importance. It was at one time in great request for bows; and Caesar tells us that it was very plentiful in Central Europe, but that it was so esteemed by turners and carvers that whole districts were stripped of it. Frequently one sees splendid specimens of the Yew

in churchyards, and there is a remarkable example in the little churchyard of Stanford Bishop, not far from Worcester, whose girth at 6 feet from the ground is no less than 24 feet.

In a recent number of *Chambers's Journal* a writer gives an interesting account of the manufacture of the rosary or chaplet. The Pyrenees are noted for the Box trees that clothe the lower slopes in a mantle of picturesque green. There are also numerous very rapid streams, or *gaves*, as they are called, which, fed by the glaciers in the higher ranges, fling their brawling torrents down every ravine and valley. Man has hastened to take advantage of the combination, and often in most unfrequented and unexpected places you come across the homely mill-dam and roughly built sawmill which, worked by water-power, converts the neighbouring Box trees into chaplets. Every little Pyrenean village, however small, is sure to be the centre of a *commune* or parish owning extensive forest and pasturage rights on the wild mountain slopes around it. Once yearly, on a Sunday, its mayor and councillors solemnly assemble in the little *Mairie* and put up for sale these rights, the bidders being, of course, only the inhabitants of the commune. The Box trees fit for cutting are an important item. After a spirited competition, much helped by good wine, the sale is over, and he who has bought the Box trees is alternately congratulated and chafed by his friends, and he wonders what on earth made him do it, and whether or no he will make anything out of his purchase. However, in due course he cuts a load and conveys the ugly, whitey brown sticks to the sawmill and sells them to the chaplet makers. At the sawmill they are sawn up into small pieces, and after being turned, polished, and dyed, finally emerge as *perles* (beads) on a rosary. And thus in its majestic Pyrenean home is the humble Box tree converted into the many-coloured chaplet, and sent broadcast over the land.

At the beginning of these notes I referred to the lack of interest in the shrubbery. As a child one used to love the dark labyrinths and secret caverns formed by Yew and Laurel as being safe retreats where "grown-ups" with clothes to spoil would not dare to penetrate. It is the same now as then. Most people leave the shrubbery severely alone, and children alone enjoy its cool recesses. I do not plead for the old-fashioned shrubbery—dark, dark, and depressing—but for the shrubbery beautiful through which it is ever a joy to wander at all seasons, and where one does not meet barriers of gloomy Laurel at every turn. Its airy paths are bestrewn with wild Thyme and wood plants, Daffodils wave their heads in its sheltered hollows, Foxgloves rear symmetrical spires of bloom, and the Evening Primrose gleams in the summer twilight.

Worcestershire.

ARTHUR R. GOODWIN.

LORD CAREW'S IRISH GARDEN.

THE first impression received by the visitor to Castle Boro is its high keeping, for though the spick and span appearance which characterises so many show places is happily absent, there is from lodge gate to kitchen garden a well-kept look, bearing silent testimony to the tastes of the owner and his able lieutenant, Mr. John McLennan.

TREES

are one of the most striking features of Castle Boro, the Beech being especially fine, and close to the drive is a huge circle of giant specimens, their branches being so thickly interlaced overhead that the strong sun of a hot July afternoon can hardly penetrate to the cool depths beneath. The memorial trees are of great interest. The Prince of Wales and the Duke of Clarence each planted a Chestnut while on a visit to Castle Boro in 1891. The latter now possesses a certain melancholy attraction, as it is believed to be the last tree planted by His Royal Highness. A Cupressus

macrocarpa is labelled as being planted in 1894 by the Duc d'Aosta, and the Comte de Turin chose an *Abies nordmanniana* to commemorate his visit in 1895. The wedding tree of Lord and Lady Carew is a splendid specimen of *Pinus insignis*, planted in 1888, and Mr. H. M. Stanley's Copper Beech thrives apace. The original

CASTLE BORO

was built about 1550, and is now little more than a picturesque ruin, though the help of a ladder and a considerable scramble will enable you, if you are fortunate enough to get permission from the present Lord Carew, to see the room in which many of his ancestors were born, and which is still in a fair state of preservation. The present house, a comparatively modern building, stands on high ground in the centre of the park, well above the Killigney, a tributary of the Boro river, and bordered as far as one can see by clumps of Nile Lilies. The approach from the river to the house is by terraced ground. Stonework and steps are all of Irish granite, and were built in the time of the famine to provide work for the starving population. A slight irregularity in the outline of one is shown in the work of these unskilled labourers. On the second terrace—one on each side of the steps—are two *Fleur de Lys* in box, fully 150 feet long, planted by the second Baron Carew. The collection of

HARDY FLOWERS,

both rare and well known, is very large. *Lupinus* of every shade, from Cambridge blue to royal purple, rear their stately spikes in the background, while *Galega officinalis*, or Goat's Rue, is seen in many shades, and the dainty sprays of lilac blossoms are useful for cutting. Of the varieties of *Spiræas* there is no end; *Morina longifolia*, with its Thistle-like foliage and wealth of pink blossoms, and some tiny bushes of *Weigela* are loaded with dark red flowers, forming a pleasant contrast to the pale pink variety which is better known; *Boussingaultia baselloides*, a very fine creeper, not nearly so much grown as its merits deserve, is being propagated for ultimate removal to the position which suits it best, namely, a dry or sandy bank; and *Buddleia globosa*, a mass of orange flower balls, is flourishing as though the County Wexford and not Chili were its natural habitat.

RANGES OF HOUSES

devoted to flowers, fruit, and foliage of all descriptions next claim attention. In the vineries, huge bunches of Hamburgs and the infinitely-to-be-preferred Muscat are ripening in a carefully regulated temperature, in another Peaches are colouring, while Melons are growing in an underground stove, the heat of which makes one give a gasp of relief on getting outside. Geraniums of every shade make one house a blaze of colour, trusses of blossom the size of a dinner plate being the rule and not the exception. A specially beautiful one, *Lady Anne Wilson*, is flame-coloured, with laced edges of delicate pink. From this house you enter a grotto. From roof to floor the rockwork is a mass of Ferns, *Selaginellas*, and small varieties of *Begonias*, forming a beautiful picture. In fact, one is often at a loss for words to express the beauties of these gardens, and photographs give no idea of the lovely colouring. Another grotto, much larger, is treated in the same way as the one before described, has Ferns of a more delicate character, growing in such luxuriance that shows how thoroughly this natural method of growing suits them, and

the walls of the Palm house are similarly planted, but here *Begonia Rex* is used in far greater number and variety. The fame of the Castle Boro collection of this *Begonia* is well known, being probably the largest private one in existence.

Lord Carew will soon have to pay the penalty of the successful cultivation of Palms, namely, sacrifice his Palms or raise the roof of the house, for though it is now an imposing structure of at least 50 feet, the trees have grown so that the great umbrella leaves are within a very short distance of the roof.

Carnations are filling another house with perfume. Yellow, peach, pink, flame, scarlet, and the old-fashioned dark red clove make up a fragrant bunch, though many new varieties of colour are not wanting, notably a large pink striped and splashed with warm heliotrope, though with this typically old-world flower it is in most cases the well known kinds which are most liked, and let us hope the day of that monstrosity the green Carnation is over.

ROSES

are everywhere, standards, bushes, and climbers, and in the nursery garden many of the less known kinds are being grown on probation as it were till they are proved worthy of a more important position. I am told the yellow Banksian flourishes in this kindly soil, and wonder that more people who can do not grow this charmingly fragrant Rose. Bunches of its dainty blossoms mixed with Scarlet Rambler give a most effective combination of colour, and for the hiding of an unsightly bit of wall where it need neither be disturbed nor pruned there is no more delicate screen. Yellow Banksians always take me back to an old Elizabethan manor house in the heart of the English shires, where they fought for the supremacy with everything else planted against the garden front of the house. They scented the morning room through the windows, looked in at the bedrooms, and waved great bunches of blossom triumphantly from the chimney stacks; but, alas! someone one day used the word old-fashioned, and the owner, all unworthy to be the possessor of so much beauty, had them pruned and reduced to reasonable proportions. The Roses naturally resented this, and now their place knows them no more.

A *Yucca* on the lawn is signing its own death warrant by showing flower, and spikes of creamy blossoms are half coming out, though still partly cased in their red-brown outer sheaths. A particularly fine specimen of the Lebanon Cedar is in close proximity to a huge Oak, affording a fine contrast and most grateful shade, and if I were asked for a suggestion where to spend a nice long happy day in the country I can think of no pleasanter spot than a secluded corner of this garden. Fortunately, many are able to enjoy this, for permission is liberally granted to residents in the surrounding districts to picnic in the park and visit the glass houses and gardens. One is glad to hear this permission is not abused, for in only too many cases acts of wanton mischief have forced the owners of beautiful places to close them to all but a favoured few.

In the kitchen garden flowers occur in odd corners, and fine hedges of Sweet Peas promise quantities of bloom. Espaliers of great age are loaded with fruit, and Jerusalem Artichokes with many heads and Poppy-like foliage strike an ornamental note amongst the more homely Cabbage and Onion beds.

But time is flying, and even an enthusiast has some conscience which gives uncomfortable qualms at having monopolised the undivided

attention of Lord Carew, his gardener and forester, and likewise his steward, who have devoted themselves for a whole afternoon to pointing out all the spots and objects of interest in and about Castle Boro.

Wexford.

B.

THE FLOWER GARDEN.

NOTES ON THE GENUS ERODIUM.

ON the whole the Erodiums do not receive quite the attention they deserve from lovers of hardy plants. Provided they are given a sunny position and well drained calcareous soil all the dwarf species may be successfully grown in the rock garden, and are especially suitable for

cuttings refuse to root, and division is sometimes impossible and always a hazardous method of propagation, it is scarcely likely to become a common plant in gardens. However, I would most strongly recommend it to all who appreciate alpine gems as a plant for the choice rock garden or for a sunny chink in a wall.

E. supracanum is another member of the family which is rarely seen and certainly ought to be included amongst the choicer rock plants. The foliage is silvery, but not so beautiful as that of the first-named plant, while the flowers are of a peculiar greyish white colour, marked with coloured veins. It is much more amenable to cultivation than *E. chrysanthum*, and ripens seed which readily germinates.

E. trichomanefolium (syn. *cheilanthifolium*) is a lovely little plant with very finely cut dark green foliage. This species will bloom into winter, and a patch of it in full bloom on a sunny bank in the rock garden will prove attractive for a long period. The flowers are

deep flesh colour with darker veins. It is a native of Mount Lebanon.

E. guttatum is one of the showiest species and a free grower of easy culture. It can be easily distinguished by the almost pure white petals, the larger of which are heavily blotched with dark lilac-purple.

E. chamaedryoides (syn. *Reichardi*) is a tiny species from the Balearic Islands. I have it doing well here at the edge of a bed of Tea Roses in moist loamy (made) soil, where it forms quite a carpet with its mass of heart-shaped miniature leaves, flecked here and there with little white flowers that are delicately veined. I see that in "Nicholson's Dictionary" it is said to be half hardy, but it proves to be quite hardy here. Of the tall growing

E. Manescavi I need say but little, as it appears to be known to most hardy plant lovers.

A group of half-a-dozen plants in the mixed border will produce a striking effect during the whole summer and autumn, more especially if the plants are prevented from setting seed.

E. micradenum hails from the Pyrenees, and is quite distinct from the other species, owing to the dark blotches on the two upper petals, the remainder of the flower being white, tinted flesh colour and veined with purple. It is a free grower, and forms handsome tufts if given a sunny position in any well-drained soil. All the species to which I have so far referred can generally be found mentioned in the lists of those nurserymen who make a speciality of choice rock plants. It seems

remarkable that although hardy plants generally have of late years received a great deal of attention, and the world is being ransacked for novelties, many good plants—swept away from gardens by the disastrous bedding craze—have not been reintroduced. The subject of the illustration,

E. pelargoniflorum, which was introduced to this country many years ago, is a case in point. Anyone who has a dry arid soil such as we have in this neighbourhood knows what a trouble it is to persuade many of the best herbaceous plants even to exist—much less to grow satisfactorily. Thus one is always pleased to add a fresh name to the list of plants which prefer such a soil, and *E. pelargoniflorum* can certainly be included in this list, as I find it succeeds far better with me than in the garden of a friend on heavier soil. Finding that this species is so little known to hardy plant growers, I have been at considerable pains to ascertain its history, and will relate what little I have been able to gather about it. Those who have access to the *Botanical Magazine* will find it figured in the volume for 1860 (t. 5206), accompanied by a description of its specific character by Boissier, and the following note, which reveals the fact that even a staid and scientific work such as this was influenced by the then prevailing tyranny of "bedding-out" gardening: "*Erodium pelargoniflorum*, from the collection of W. Wilson Saunders, Esq., Hillfield, Reigate, where the shelves of a very cool, airy greenhouse were enlivened by its sparkling blossoms. In the days when the Geraniaceæ were cultivated extensively as botanical objects, this would have been very much prized; but that time is gone by, and their place is taken by the General Tom Thumb, the Golden Chain, and others, which render our flower-beds in summer objects of such universal admiration. The present is a recently-discovered species, by Heldreich, of the *Erodium* genus, in Anatolia, growing on shady rocks and among caves between Karaman and Ermenek, at an elevation of 3,000 feet above the level of the sea. It may therefore be expected to succeed in the open air in summer, but at its period of rest in the winter the roots will require protection."

From another source I learn that Boissier discovered this plant about forty years ago amongst shady rocks on Mount Ghelipel (Taurus Mountains) close by Ermenek. I first made its acquaintance a few years ago when a small seedling plant of it was sent to me under the name of *Erodium pelargonifolium*. Not knowing its origin, and suspecting its hardiness, I planted it out at the end of May against the foot of a south wall and amongst some pieces of sandstone rock. Here it grew into a large plant, but did not attempt to flower, and as it was still making growth in the following November I decided not to disturb it, but to give protection if needful. This, however, was not accorded, and in spite of our exposed thermometer that winter registering 23° (Fahr.) of frost, the plant remained perfectly evergreen, and only suffered the loss of some of its leaves. The first blossoms expanded during the last week of March—although the flower-buds were visible in February—while the photograph, from which the illustration was prepared, was taken early in May, and the plant continued to bloom on and off right into the late autumn. This species is in fact extraordinarily free blooming—more so in fact than any other member of the genus with which I am so far acquainted. The inflorescence consists of eight to ten flowers, which are white, blotched with purple spots at the base, and veined with five branch-

ERODIUM PELARGONIFLORUM AT FOOT OF WALL.

planting on steep banks and in crevices of old walls. They cannot be considered the best of plants for a cold, wet, or stiff soil, as they are prone to damp off during the winter months—at least I have heard this complaint made against them. On the shallow sandy soil of this garden all the species I have tried grow admirably, and most of them bloom profusely the summer through. Undoubtedly the daintiest member of the family is

E. chrysanthum (L'Hérit), which hails from the mountains of Greece. It forms a tuft of bright silvery Fern-like leaves and bears numerous small light yellow flowers. Nothing will induce it to seed in this garden, and as

FASCIATED LILY (*L. SPECIOSUM*).

ing lines extending to the edge of the petals, and as a rule not more than five blossoms are expanded at once on an individual cyme. The leaves are radical, and borne on long stalks covered with silky hairs, while in shape they are ovate-cordate, rather sharply toothed. The upper surface is shiny, and remarkable on account of its stickiness, while the underneath surface is furnished with rough hairs. The rhizome is scaly and pink in colour, going almost woody with age. In spite of the fact that it is classed as a perennial it should rather be considered a monocarpic or biennial plant, although my original plant has produced a crop of seed and is still (January, 1903) alive. Seed, in fact, forms an easy method of propagation, and should be sown in a cool frame as soon as gathered, while cuttings, if given cool treatment, will soon root and form good plants.

E. hymenodes (a species from Mount Atlas of little garden value) appears to be its nearest ally, but it is in every way superior to this. *Erodium pelargoniflorum* can be summed up as a most beautiful and desirable hardy plant, and one that in the near future is bound to become popular, and I see no reason why by crossing it with *E. Manescavi* and other species it should not be possible to obtain some valuable results. As far as I am able to ascertain the only hybrid *Erodiums* at present obtainable are *Erodium pelargoniflorum* × *E. hymenodes*, and *E. macradenum* × *E. trichomanefolium*. As with many other families of hardy plants a burden of synonyms surrounds this genus, and it is not an easy matter for an amateur to avoid pitfalls when attempting to unravel the diversities of nomenclature.

In addition to the species mentioned already there are many others, and I append a list of just those which occur to me:—

Erodium carviifolium.—Mountains of Central Spain.

E. chium.—Mediterranean region.

E. cicutum.—Mediterranean region.

E. corsicum.

E. daucoides.—Spain.

E. gruinum.—South Europe.

E. maluchoides.—Mediterranean region.

E. macrophyllum (biennial).—California.

E. romanum.—Described in Robinson's "Hardy Flowers" as a perennial, but is only biennial here.

E. Salzmanni.—South Spain.

E. Semenovi.—Central Asia. I have not seen this species, but have lately obtained seed of it from Thompson and Morgan, Ipswich.

E. serotinum.—Caucasus.

E. sibthorpiannum.—Orient. I have obtained a plant under this name, but am not certain whether it is true.

E. tmoleum.—Asia Minor.

Some of these I already possess, others I have noticed in various botanic and private gardens, or seen mentioned in books. No doubt amongst them are plants of little garden interest, but the main object of these notes is to promote if possible a discussion, and thus help to sift out the species of the most garden value.

Worcestershire. A. GOODWIN.

FASCIATION IN LILIES.

(Extract from a Letter.)

SPEAKING of this, I turned up the word in Nicholson's "Dictionary of Gardening" (Supplement), where this passage occurs: "Recently some interesting experiments have been conducted by M. L. Geneau de Lamarrière with the object of producing fasciation in the stems and inflorescences of plants. . . . It was found that mutilations practised upon the principal stems and branches favoured the formation and development of dormant abnormal buds, and thus gave rise to branches and inflorescences more or less fasciated. Mutilation of the principal axes, then, we are told, is a cause of teratological growths; an indirect cause, certainly, but none the less effectual." Just as this particular group of *Lilium speciosum*, some ten shoots, were breaking through the ground this early spring (1902) my pigeons badly broke them while sunning themselves on them. I had to put sticks to stop them lying there. Four were broken quite off and five threw up fasciated stems.

Dawlish, Devon.

A. BAYLTON.

HARDINESS OF THE FINER EARLY-FLOWERING CHRYSANTHEMUMS.

The variable weather so far experienced during the winter has put to the test the hardy qualities of the early-flowering Chrysanthemums. For years they have been regarded as needing some protection during winter, but this does not apply to many of the better sorts. The less robust kinds are usually lifted and placed in cold frames or other equally cool and suitable quarters before winter. Some may wonder why such care is taken to perpetuate these weaker sorts when there are so many vigorous ones in commerce. The reason why the less hardy Chrysanthemums are grown is because they have some characteristic trait which will continue to be appreciated until something better comes along. Lyon and its beautiful sport Alice Butcher are instances. Well-grown plants of these two varieties are among the handsomest and best of the early-flowering Pompon Chrysanthemums, and until plants with flowers of equal

merit and with a constitution of a more robust kind are introduced these two varieties will be generally cultivated. The display made by these two sorts fully justifies one in continuing their cultivation. Plants of this type just now present a sorry spectacle, and those who have been so unwise as to leave them in their beds and borders run considerable risk of losing them altogether. The newer race of plants which may be said to have been introduced with the distribution of Mme. Marie Masse, a very excellent, free-flowering Japanese kind of a lilac-mauve colour, promises to completely eclipse all others. This variety is represented by plants of robust growth capable of withstanding the ill-effects of our most severe winter. This plant has been introduced some years now, and has sported in a very remarkable way. The first sport was a creamy white flower, and this was distributed under the name of Ralph Curtis. About the same time there appeared in the garden of a southern market grower a beautiful chestnut-bronze sport from the same variety, and so quickly was stock available that the latter sport was distributed in the succeeding spring as Crimson Marie Masse. In the following season there was still another sport of a salmon-cerise colour. This beautiful variety was sent out under the name of Rabbie Burns. A really good rich bright yellow early-flowering Japanese variety was much needed, and two seasons ago this was forthcoming in a beautiful sport from Crimson Marie Masse and named Horace Martin. This lovely yellow sort has completed a valuable and interesting quintette of members of the Mme. Marie Masse family of Chrysanthemums. This family represents all that is required of these plants for outdoor culture. In the course of a season's growth they assume quite large proportions, bearing in the greatest profusion flowers on a useful length of stalk, and this without disbudding. Most important of all, the plant develops quite a large number of basal sucker-like shoots, which extend far from the main stem of the plant and provide sufficient stock to satisfy the heaviest demands made upon it. These plants appear to stand well the most rigorous weather of our English climate when many other highly-regarded ones fail. For this reason the future of the early-flowering Chrysanthemums seems to depend largely on further sports from these excellent varieties, and also from seedlings which result from crosses made with them by the hybridiser. There is already evidence that certain trade specialists are keenly alive to the excellent attributes of the Mme. Marie Masse family of plants, for there is now a good list of seedlings which include the progeny of this race of plants. During the past season it has been my pleasure to carefully inspect many of these varieties; some are now two seasons old. The range of colours was considerably extended, and the beauty of the majority of the flowers proves most conclusively that the near future has much in store for admirers of these early autumn flowers.

Highgate, N.

D. B. CRANE.

THE ROSE GARDEN.

ROSES WITH BEAUTIFUL WOOD.

OF the various groups of Roses none can furnish us with species whose wood is more ornamental than that of *R. cinnamomea*. In the case of *R. blanda* the purplish crimson of the wood just now is most showy, and I am rather surprised that this plant has not been utilised more for its attractive colouring in winter. In comparison to the bark of the Dogwood, *R. blanda* is not quite so bright, but when it is remembered that there are flowers also, even if somewhat insignificant, it has a claim on our regard and should be more frequently planted. *R. cinnamomea* with its brownish red wood is a species of much beauty in winter. *R. alpina* must not be omitted, for some of its vigorous

growing varieties have very beautifully coloured wood, notably Amadis and Morletti.

R. acicularis, too, is not to be despised, and there may be others of the group known to botanists that would come within the scope of my present remarks. I do not include R. rugosa and its varieties, though these are very distinct, their greyish wood and numerous prickles in many instances being most attractive, even when denuded of all foliage. Where the species and varieties alluded to are planted only for their decorative value in winter, I would advise hard pruning each spring of some, if not all, of the growths, for undoubtedly the most brilliant colour is obtained on one-year growths. I believe there is a great future for this group of R. cinnamomea, and anticipate that hybridists will get some elegant shrub Roses from it by judicious blending with other types.

MERVEILLE DE LYON AND CRIMSON RAMBLER.

I AM not sure that we always obtain the best possible effect from our plantations of Roses. Contrast of colour and habit is not thought out so much as it might be. A very beautiful arrangement, and one I can commend to all who seek a fine display in July, is to plant a few pillar Roses of Crimson Rambler in a good large bed, at the same time providing a groundwork of white by freely planting that fine Rose Merveille de Lyon. The stiff and regular growths of the latter give it a pronounced decorative value, every flower standing erect on the rigid stems. As soon as the Crimson Ramblers have attained their third year a magnificent bed of blossom will be the result. I know of no better way of displaying the gorgeous beauty of the Crimson Rambler, the white of Merveille de Lyon accentuating yet toning down the gorgeous Rambler. Should this seem a long time to wait, the Ramblers could be planted from pots, and the plants then grow away without hindrance.

Although we cannot claim for the Hybrid Perpetuals the continuous flowering habit of the Tea-scented, there can be no doubt about their effectiveness when at their best, and Merveille de Lyon, though scentless, is one of the most valuable. The bold white flowers when slightly flushed with delicate pink are superb.

EDGINGS TO ROSE-BEDS.

SOMETHING depends upon circumstances whether edgings to Rose-beds should be of flowers or leaves. If the paths of the rosary are gravel, I imagine foliage would be more welcome than blossom. But supposing the two can be had well together, then surely this would be the most suitable. Of all the varieties contained in the Rose family, the wichurianas are the best for the purpose named. Of this rapidly increasing group the varieties Evergreen Gem and Jersey Beauty are most commendable for edgings. As a foliage plant, whether as a trailer on the ground, or over an archway, or as a pendulous standard, Evergreen Gem is the best. If used for edging few plants would be required, for they make in one season growths of 4 feet to 5 feet in length. I would advise that some supports be given to the growths, such as galvanised hoops, so that they may be kept away from the ground, and yet answer the purpose of supplying an edging to the Rose-beds. Subsequent treatment would mainly consist in cutting away the old growths and tying down the new, and by so doing a pretty boundary of foliage would always be present. If it is desired to provide for flowers as well, then one or more of the older growths must be retained; but, as I

said before, if there were no flowers at all, this sort and Jersey Beauty would be worth growing for their foliage alone. The latter is worthy of special commendation for its blossoms. It possesses the simple beauty of a Cherokee Rose, with a hardiness and general adaptability to our climate that this lovely species does not possess. I hope hybridisers will raise more of the single wichurianas. They are extremely beautiful. If one has an odd bit of terrace wall to cover these are just the thing. They will tumble over a 4 feet wall and hang down the other side with a gracefulness peculiarly their own, and that makes a refreshing variation from Ivy and such like things.

PHILOMEL.

NOTES ON HARDY PLANTS

ÆTHIONEMA DIASTROPHIS.

I N the nurseries of Messrs. Robert Veitch and Son, at Exeter, the plant here illustrated was photographed, where it has grown freely and flowered abundantly. It is a native of the mountains of Armenia. It was planted at Exeter about five years ago, and has now developed into a very handsome specimen. It is not truly herbaceous but shrubby, and loses all its leaves in winter, and during that time of the year it looks to be simply a small bush formed of apparently dry and leafless branches; but in the summer season it is a perfect gem for the rock garden. It is not to be reckoned among the minutest gems of the mountain flora, for it will form a bush some 20 inches to 24 inches in diameter and 10 inches high, but it is so unlike anything else, and above all so free-flowering, that it is worthy a place in the rock garden. The leaves are linear in shape and somewhat glaucous. The flowers are borne in large round terminal racemes 2 inches to 2½ inches in diameter, densely crowded, and of a pleasing pale rosy lilac colour. The flowering season is from June to August, but frequently it will flower

a second time during autumn. The plant which I photographed has never been protected in any way, and seems of the easiest possible cultivation. Here at Exeter it is growing in somewhat heavy loam, which has received an admixture of limestone chippings. It has never suffered in any way, and I have known its flowers to last from six to eight weeks.

Elmside, Exeter.

F. W. MEYER.

MIDWINTER FLOWERS IN SOUTHPORT.

"And spring comes slowly up the way,
And paints the laughing soil."

WE were very forcibly reminded of these beautiful lines of Coleridge, as we looked into the eyes of the first Primrose which greeted us with such delight upon the first day in the new year, and which has even stood without flinching the cold of the late severe frosts. The flowers that bloom in the spring are always looked upon with pleasure and delight even to the casual observer. The advance guards of the grand pageantry of spring and the beautiful summer days are already here, and we welcome them with joyful hearts, reminding us, as they do, of the sure returning of the long summer days.

Even before the year had passed away we had a few Primroses in our gardens at the foot of some limestone rockwork, where they had been planted with a purpose in a sheltered position so that they might have a chance of blooming at a very early period in the year; but we did not expect them to put on their bridal garments so soon.

The Primrose, this little first one, is essentially the flower of our youth—the irresistible Primrose, which has so often led us into forbidden ground. The Primrose was not the only flower to cheer us with the advent of the glad new year. A little distance away, upon the same piece of rockwork, was a sister plant, the Polyanthus. These two, along with the Christmas Roses, have been flowering all through the keen frosty weather, and now, under a more genial sky, they are again lifting up their heads in joy and gladness as if to greet the glorious sunshine which is bathing the world with light.

ÆTHIONEMA DIASTROPHIS GROWING ON ROCKWORK IN THE NURSERIES OF MESSRS. ROBERT VEITCH AND SON, EXETER.

As the days advance they are being joined with a noble company of midwinter flowers. These include the beautiful Siberian *Adonis amurensis*, which has bravely held up its golden flowers to keen frosty air.

Another and still rarer *Adonis*, hailing from the Japanese Alps, is *Adonis Naderkato*. What the meaning of this singular Japanese name is I cannot say. The plant was received here from a friend in Japan. It is, however, entirely new to this country, and not even in cultivation in the Western Hemisphere. The flowers are a beautiful orange-lemon colour. We have still another hardy plant in flower—the beautiful Chinese *Jasminum nudiflorum*, which for eight weeks has been covered with its charming lemon-coloured flowers.

At the present time we have some Himalayan Primroses and Saxifrages pushing up their flower-stems, with the petals opening to the response of the genial sunshine and the greater amount of light which is now experienced with the advancing length of days.

CAMPANULA PORTENSCHLAGIANA MAJOR.

CAMPANULA PORTENSCHLAGIANA is "as old as the hills," but it is only during recent years that the variety here illustrated was introduced. The photograph is of a plant in Messrs. Robert Veitch and Son's nursery, Exeter, where the plant has been growing in an exposed position for about eight or ten years. As the name implies, the plant is larger in all its parts than the well-known type. It also seems more robust. At Exeter its large deep blue flowers form a pleasing contrast to the white flint rock on which the plant has become established, spreading about 3 feet. It must rank among those rock plants which may be described as being very beautiful without requiring a lot of extra attention or special treatment of any kind. My experience is that it will grow anywhere, and is not at all par-

at such moments, and the gardens where everything has been swept away to make room for grass lawns and Palm groups afford no protection to anything but the plants directly underneath the Palm shade. The blue Fern-leaved

CHINESE PRIMULAS are excellent in any such shelter, and mark a distinct advance towards the really sky-blue Primula we all long for. Each year there comes some fresh development, so perhaps the true blue will arrive ere long. Meanwhile this Fern-leaved variety and a new rich red, which deepens rather than fades in the sunshine, are the two best varieties this season.

EUPATORIUM PURPURI seems the nearest approach to the much-desired white *Ageratum* I have yet seen. It has been a surprise to me, as one associates the name of Purpus with strictly American and alpine plants, and this plant, which has all the effect of an *Ageratum*, certainly cannot have sprung from such surroundings. Some day I hope to hear its "whence and how." It seems as if the earliest forms of

ANEMONE BLANDA were of the deepest blue; those now out are so deeply dark blue they might pass for a distinct variety, while those large "Scythian" forms, which bloom much later, are sky blue and pure white, or white tipped with sky blue, perhaps the loveliest of all; but they flower so late that *A. apennina* is then flowering, so these early forms are the most welcome as winter flowers after all. This is not the season for

ROSES in any great quantity; the December crop is exhausted, and the florists' shops are being supplied with forced blooms, so I was glad to see a strong plant of that delightful yellow Tea *M. Georges Schwartz* with several good blooms and buds on it that had not suffered at all from the two or three frosty nights I mentioned. Out here I think it is a most promising winter Rose, as its habit is like *Safrano*, and its colour and quality infinitely richer and better. Were I a market gardener I should most certainly make a large plantation of it, and as an amateur I shall equally desire a good lot of it for winter-cut flowers. There are few varieties that do equally well in England and out here, and this is another example, as in England *M. Georges Schwartz* has the reputation of being a weakly grower. Any Rose I think that does exceedingly well in England is less good here, and *vice versa*, so we feel pleased when a good Rose falls to our share in winter.

IRISES are flowering well this winter, but the *Reticulata* group seem less desirable here than in the north. The beautiful *Iris tingitana* is in big bud and demands much manure and moisture. Planted on a dry bank, where I first placed it, it did not thrive or flower, but when a friend advised me to plant it in a moister spot, and put a good spadeful or two of manure under each group, it grew away strongly the next autumn and is now promising well for flower.

The clumps of *Iris stylosa magnifica*, major, or whatever the fine large and high coloured form may be named, are one mass of bloom, solid patches of colour, while the old and inferior variety goes too much to leaf, and is of comparatively little value save for its drooping leaves, which are useful as an edging to shrubs.

EDWARD H. WOODALL.
[Mr. Woodall's reference to *Iris tingitana* is instructive.—Ed.]

CAMPANULA PORTENSCHLAGIANA MAJOR.

The Snowdrop has put in an appearance along with the rest of the midwinter flowers.

"Already now the Snowdrop does appear,
The first pale blossom of the unripened year;
As Flora's breath, by some transforming power,
Had changed an icicle into a flower.
Its name and hue the scentless plant retains,
And winter lingers in its icy veins."

This little harbinger, along with the Primrose, bears the palm of captivating elegance, and must be looked upon as one of the universal favourites of the infant spring. Besides the plants in flower already mentioned, we have the little single blue and red *Hepatica* unfolding their sweet charms. A few Pansies have managed to keep in flower in sheltered places, besides some beautiful *Arbutus*, better known as the Killarney trees, comprising such as the *Arbutus Unedo*, *A. Croomii*, and *A. Andrachne*. These have all been in flower since last October, beautiful alike both in foliage and their wax-like flowers. Last, but not least, is the charming little *Erica carnea*, a most beautiful little Heather hailing from the Pyrenees and south-eastern Europe. This is a very fair record for this season of the year, and bears ample testimony to the bright and genial climate of Southport.

Kew, Southport.

W. H. STANSFIELD.

tical as to soil. Its bright green leaves are ornamental even in the depth of winter; its flowers appear in abundance from June to August, and very frequently there is a second display of blooms as late as September and October.

Elmside, Exeter.

F. W. MEYER.

RIVIERA NOTES.

PSADIA GLUTINOSA, an elegant shrub belonging to the great *Senecio* or *Groundsel* family, is new to me this winter. Though it has no ray petals, yet the closely-packed heads of yellow capitules are quite showy, and the shining, slender, pointed leaves attract attention by their distinctiveness. It is decidedly hardier than many members of the family, for the week of frosty nights which we lately endured has left no mark on it, while shrubs like *Wigandias* and *Daturas* are injured unless they have some protecting spray overhead. The value of the Olive's silvery shade is untold

AN ARTIST'S NOTE-BOOK.

CLIANTHUS PUNICEUS.

FLOWER OF GLORY, Glory Pea, and Parrot's Bill, the common names under which this plant is known, suggest beautiful and curiously-shaped flowers, the former two names referring to brilliant colouring, while the latter name is given on account of a fancied resemblance between the shape of the flower and a parrot's bill. It is a New Zealand shrub, and is said to have been first discovered by Sir Joseph Banks in 1769, though it was not introduced to British gardens until 1831. In the article accompanying the figure

Floriculture Cabinet for 1835, and three guineas appears to have been the price asked for plants.

From the time of its introduction until the present it has held its own among other garden plants, and particularly in the warmer counties it is an extremely useful plant for clothing walls and trellises, and even for the open border. In less favoured localities it has to be grown in a sunny greenhouse, but even in Scotland good plants are noticeable from time to time on warm walls out of doors. Whether grown indoors or out, against walls, trellises, on a roof, or as a bush, it is a very desirable plant, the rich red flowers, upwards of 3 inches in length, which are freely borne in dense axillary racemes, being extremely showy, while the bright green pinnate leaves are light

NEW PLANTS OF 1902.

(Continued from page 92.)

DAHLIA MANXMAN (Cactus).—A very showy variety, the chief colour of which is a flame-red, and the base of florets light orange. The handsome flowers are well set up on good stalks. A.M., September 23. From Mr. S. Mortimer, Swiss Nursery, Farnham.

D. Lucifer (Cactus).—This is a brilliantly coloured flower of good form. The dominant tone is salmon-orange with reddish crimson centre; flower very large and showy. A.M., September 23. From Mr. P. Tulloch, Hove, Brighton.

D. Clarence Webb (Cactus).—A distinct flower of orange and fawn, the outer florets strongly incurving to the centre. A very

CLIANTHUS PUNICEUS. (About three-quarters natural size. From a drawing by Miss I. M. Charters.)

in the *Botanical Magazine*, t. 3584, it is stated that seeds were sent by Mr. Richard Davis, Missionary Catechist in New Zealand, to the Rev. John Noble Coleman, 5, Terrace, Ryde, Isle of Wight, in the autumn of 1831, and the plants produced from these seeds flowered during the spring and early summer of 1833.

From the first it was marked as an extremely useful garden plant, but was more often recommended for outdoor than indoor culture. Plants were given by Mr. Coleman to Mr. Leveson-Gower of Titsey, near Godstone, and these two gentlemen experimented with various kinds of soil, finding eventually that soil of a peaty nature suited it best. Messrs. Young, nurserymen, of Epsom, appear to have been the first people to advertise it for sale, mention being made of it in the

and pretty. It can be readily increased by means of seed or cuttings, which quickly make good-sized plants. On walls out of doors it grows 9 feet or 10 feet high and from 12 feet to 18 feet across. When planted outside it should be protected by mats or straw in severe weather.

The specimen from which the figure here given was taken is growing outside in a Devonshire garden; the flowers in the figure are represented rather less than natural size. Several varieties have from time to time been noted, of which *magnificus* (with darker flowers than the type) and *albus* (with white blossoms) are the best known. The latter plant does not appear to flower so freely as the type, and is not so showy; it is, however, useful, as it makes a good contrast to the type.

W. DALLIMORE.

beautiful and well-filled flower. A.M., September 23.

D. Miss J. Cherry (Cactus).—A pretty shade of cerise-red, in which there is an infusion of yellow. A.M., September 23.

D. Coronation (Cactus).—A very bright flower, yet not of the largest size. The brilliant scarlet-crimson, however, is sure to attract, while the moderately sized blossoms would render it extremely welcome in the garden. A.M., September 23. The three last-named all came from Messrs. Keynes, Williams, and Co., Salisbury.

D. Albion (Cactus).—This is a pure white of good size and the best form, the florets spreading out in a rather horizontal way and attracting much attention. It is a first-class novelty. A.M., September 23. From Messrs. J. Burrell and Co., nurserymen, Cambridge.

D. Winsome (Cactus).—Prettily formed flowers of a creamy white, they are moderately large, full, and with cupped or incurving florets. A.M., September 23. From Hobbies and Co., Limited, Dereham.

D. Mrs. W. Treseder (show).—On the pale ground the florets are edged somewhat deeply with rose-carmine; a solid, high-centred flower of capital form. A.M., September 23. From Mr. H. T. West, Brentwood.

D. A. M. Burnie (show).—A flower of excellent form, good in petal, and well built to the centre; the colour is buff with orange, and is deeper in tone at the base. A.M., September 23. From Mr. St. P. Harriss, Hill House, Orpington.

D. Rosea (Pompon).—A prettily formed flower of a nearly rose self tone, close, and compact. A.M., September 23. From Messrs. Keynes, Williams, and Co., Salisbury.

D. Serita (single).—A flower of beautiful form and petal of fine substance; the colour is crimson with magenta shading, with a deep crimson zone around the central disc. A.M., September 23.

D. Snowdrop (single).—Excellent in form and of medium size, this nearly pure white sort should prove a distinct gain. There is a shading of yellow surrounding the disc which in older flowers may be less pronounced. A.M., September 23. From Messrs. J. Cheal and Sons, Crawley.

Hippeastrum Sir Christopher Wren.—A beautifully formed flower with stout, well-imbriicated segments and of rich crimson tone; a bold and handsome variety. A.M., March 25. From Captain Holford, Westonbirt, Gloucestershire.

H. Nysa.—A very striking, if not exceptionally large, flower. The colour is of the deepest and most intense crimson; it is one of the finest of crimson selfs; the segments are much imbricated. A.M., April 8.

H. Sylvanus.—This is one of the netted class, the well-formed segments being of a clear scarlet colour, strongly and clearly reticulated with white. The effect is very good. A.M., April 8.

H. Mrs. Bilney.—A beautiful flower; scarlet, much chequered with white. A.M., April 22.

H. General Buller.—A fine flower of rich orange-scarlet shade, tempered in its dazzling brilliancy by a pale greenish band in the centre of each petal. The variety has short and broad petals, and with recurving tips. A.M., April 22.

H. Queen Alexandra.—This is another of the chequered flowered sorts, less so than the others already noted. The petal is good and of quite firm substance. A.M., April 22. The above five meritorious varieties are from Messrs. J. Veitch and Sons, Limited, Chelsea.

Nymphaea stellata W. Stone.—The most distinct feature in this is the colour, which is violet-blue shaded with purple, and golden centre; attractive. The stout stem keeps the flower head well out of the water as in all this group. F.C.C., May 28.

N. Mrs. Ward.—This is virtually a rose-coloured variety of *N. stellata*, with the pointed petals and general character of that group clearly seen. A.M., September 2. From Leopold de Rothschild, Esq., Gunnersbury House, Acton (Mr. J. Hudson, gardener).

Pelargonium Colonel Baden-Powell.—An addition to the Ivy-leaved section. The flowers are large and freely produced. The colour is blush or flesh pink, occasionally striped carmine. A.M., May 6. From Mr. Charles Turner, Slough.

Pea Dorothy Eckford.—This is the white Sweet Pea that has caused some controversy as to its name, and the above, we believe, is the result. It is a very fine variety, and to say it is the best white to date is to convey no small tribute to its qualities. A.M., September 2. From Hobbies, Limited, East Dereham, Norfolk.

Primula obconica semi-plena.—This is probably the forerunner of a really double-flowered variety, which may or may not be an improvement. Hitherto variations in colour and size only have appeared, and some of these are very beautiful. The new comer in the present instance is of the same shade as the typical species, with an extra arrangement of petals. A.M., December 9. From Sir Trevor Lawrence, Bart., Burford, Dorking (gardener, Mr. Bain).

Rose Peace.—A sweetly-scented Tea Rose of a creamy tone throughout. The variety is wonderfully free flowering, and has much of the habit of *G. Nabonnand*. A.M., September 2. From Mr. G. W. Piper, Uckfield, Sussex.

R. sulphurea.—Also a Tea Rose, and, as the name implies, the flowers are of a sulphur yellow tone; very free, and exceptionally good as a decorative Rose. A.M., September 23.

R. Mme. Antoine Marie.—This also belongs to the Tea and decorative classes. The creamy white tone with its suffusion of rose on the outer petals gives it a distinct charm. It is very beautiful. A.M., September 23.

R. Field Marshal.—A climbing monthly Rose of considerable vigour and freedom. Flowers large, full, and rich crimson. To climbing Roses this should prove a good addition. A.M., July 22. From Messrs. W. Paul and Son, Waltham Cross.

R. Frau Karl Druschki (H.P.).—A large imposing white—nearly pure white—variety, and sweetly scented. The expanded blossoms are very large, and attract the attention of all. This fine sort should be extremely popular in the garden and for exhibition. A.M., July 8. From Messrs. F. Cant and Co., Colchester.

R. Ben Cant (H.P.).—This is a decided gain to the crimsons of the Hybrid Perpetual class. Its huge size and fine proportions generally are among the main features of this handsome Rose. The size, texture of petal, good form, and fine fragrance are its great attractions. A.M., July 22. From Messrs. B. R. Cant and Co., Colchester.

R. Dorothy Perkins.—A very beautiful hybrid of the wichuriana class, with pink flowers nearly or quite 2 inches across and rather light in the centre. The glossy foliage is distinctly pleasing, and closely approaches to evergreen in this section. A very charming variety. A.M., May 20. From Mr. E. Potten, Cranbrook, Kent.

NOTES FROM SWANSWICK.

HAVING had my economic hopes as regards *Prunus Pissardi* somewhat dashed, I now want to know what may be expected of

Diospyros Lotus and *Eleagnus edulis* planted in good soil under a sunny wall, south-east aspect, but more south than east. The latter, I believe, ought to be in poor soil, but perhaps its being close to a path may do as well. The Persimmon is against a buttress that gets well baked in summer. On reperusal of the last Royal Horticultural Society budget, I see a complaint that

SAXIFRAGE SEED

is troublesome about germinating. Two years ago I sowed a packet of mixed mossy Saxi-

frage. Every seed seemed to "arrive," and that without undue delay, but there was no variety, all the resultant plants being exactly alike, and closely resembling *S. ajugifolia*. My horticultural life, which has only been a serious one for between ten and fifteen years, has not been nearly long enough for me to learn Saxifrages, especially as I wish to be *au fait* of Campanulas first, so I only advance this latter statement—*re S. ajugifolia*—very tentatively. Anyway, it is not material, the issue being that the seed germinated speedily and well under no specially favourable condition, merely sown in a box in a shady cold frame in March. However, the encrusted section may be meant: these I have never tried, but I have sown *Sempervivums* without result—foreign seed. Seeds, by the way, are, or ought to be, the refuge of the ambitious but impecunious gardener, and yet it generally seems as if just the people who cannot afford to buy new and good plants in any quantity are those who set least store by culture from seed. They refuse to take any interest in beautiful things like *Gerbera Jamesoni*, blue Primroses, blue Polyanthus, *Incarvilleas*, choice Carnations, *Romneya Coulteri*, and *Eremuri*, on the score of impossible expense, because they cannot get plants all ready grown for twopence apiece; yet they will not see how heavily they could score from the economic point of view by growing dozens of each for the paltry price of seeds. To be sure these people generally are the unlucky ones who keep hide-bound single-handed gardeners. I remember a long succession of these in the gardens of my youth, each one more invincibly ensconced in his own practice than the last. None of them ever read anything, and the only way to induce them to try new and grow new or improved flowers was to show them something someone else's factotum had produced—a difficult thing to do, since the said individuals were mostly on the same lines with themselves.

GARDEN JOURNALS.

Of course, there were not so many garden papers then, and some of our gardeners could not read, while the literature of the day was perhaps above the heads of those who could. But even in the present day it is curious how little a certain class of working man—and usually the valuable, industrious, country-loving class that gives by far the best service—grasps or retains from reading. From a week's evening perusal, very solemnly undertaken, and asserted to be thorough, of three "easy" garden papers, our particular treasure does not, at any rate, carry away one single *name*, whatever else may be imprinted on his mind, and I have never discovered that the smallest result of a practical kind followed his painstaking perusals.

Such village traditions of garden practice, frequently of a highly mischievous nature, as that which ordains that on transplanting Leeks you are to cut off their leaves and expect stumps to go ahead faster than perfect plants, are much too firmly imbedded to be shaken, either by the written word, or by the example of our unmutilated ranks, thrusting twice as lustily as those of our cottage neighbours, though not at all more favoured in the matter of manure and soil. You hear terrible prophecies of the evil to come to the young folk of the working-classes from their habit of reading fictional rubbish, but if it only flows over their minds as superficially as garden literature does over those of rusticity, it will not leave many stains. From the internal evidence they themselves offer it would appear

that the smaller garden papers are circulated almost entirely among townfolk, and this bears out most completely what was remarked upon as Mr. Pearson's experience at a recent discussion of the Horticultural Club.

M. L. W.

ORCHIDS.

LÆLIA ANCEPS SANDERIANA.

OUR note was taken of the plant which has been grown in the collection of Sir John Edwards-Moss, Bart., Thamesfield, Henley-on-Thames. It has been in Sir John's collection for several years, and improves annually. This season it carried six fine spikes of flowers, and is one of the finest varieties of *L. a. sanderiana*, being large in size, of grand form, and good substance. It is a much showier plant than *L. a. Dawsoni* and much freer in growth. It is true the petals have not the beautiful rhomboid form and breadth of *L. a. Dawsoni*, but more flowers are borne on the spike and on longer and thicker stems, and the flower-spikes are produced more freely.

Botanically it is not distinct from *Dawsoni*, but for horticultural purposes it is quite superior. For this and many other of the finest varieties of the white anceps we are indebted to the zeal of the firm of Messrs. Sander and Sons, of St. Albans. *Lælia anceps sanderiana* was found by the collectors of the firm on the Pacific coast and *L. a. Dawsoni* at Orizaba and Cordoba, on the Atlantic side. For six months in the growing season these *Lælias* are subjected to torrents of rain daily for several consecutive hours. Besides this the plants are thoroughly wet all the night through—every night; but in the early morning the wind blows fresh and sharp from the snow-capped peaks of the Cordilleras, when the greater part of the moisture which has been upon them all night dries up like the heaviest of heavy dews, and the scorching sun following soon dries up every vestige of moisture from the leaves and bulbs. Daily drenching storms, daily fresh morning breezes, daily hot blazing sun—these are the conditions under which *Lælia anceps sanderiana* flourishes in its native habitat.

Probably these plants are taking in food day and night in the growing season. The air is no doubt impregnated with ammonia and other plant food. The manure of birds and animals and many decaying substances no doubt provide food for aerial plants in great abundance. If we could only give Orchids under cultivation the sunlight and heat that they get, for instance, in a country like Mexico, we could supply the moisture, and we should be astonished with the results obtained.

ARGUTUS.

PERISTERIA ELATA.

VERY few Orchids now in cultivation possess such a fascination for the general public as the Dove Orchid, introduced from Panama in 1826. Its long, handsome green leaves, which under good cultivation are from 2½ feet to 3 feet long, and the strong flower-stems, bearing waxy dove-like flowers deliciously scented, should encourage many to take it in hand. Either a stove or Orchid house will do equally well for its accommodation. In dealing with its culture it may at once be said that it is

strong and fleshy rooted, and delights in a good compost with plenty of water when in active growth.

Although September is the best time for potting, those who have not already done this should now lose no time. For the largest bulbs one in a 7-inch pot will be found quite enough, usually three bulbs will be sufficient for a 9-inch pot; ample drainage is most essential. The soil I have used with success consists of two parts fibrous peat, one part fibrous loam with all loose particles shaken out, some soft red sandstone broken fairly small, and coarse silver sand, mixing all well together. Over the drainage place a thin layer of sphagnum moss, then the rougher compost, until the pot is almost filled. Fix the bulbs into position, securing each with a neat stake and surface with a little sphagnum moss. A few lumps of the compost should then be placed among the roots, and a little sphagnum.

With the exception of an occasional slight syringing, no water will be required until growth commences, when the supply can be gradually increased and weak liquid manure given once a week. When active growth has ceased less water

LÆLIA ANCEPS VAR. SANDERIANA IN THE COLLECTION OF SIR JOHN EDWARDS-MOSS, BART.

should be given, and dry off until the flower spikes are well advanced, then a little water may be given with advantage. If the plants are kept in a moderately warm temperature the flowers will keep well for several weeks. The pseudo-bulbs are often attacked with the black spot, which I have found is often caused by insufficient drainage, too close a compost, or deep potting. White scale often infests the leaves, but this can be easily removed by careful sponging with soapy water, taking care not to damage the leaves. A. B.

PROPAGATING DENDROBIUMS.

AT this time of the year Dendrobiums are easily increased by means of older growths, provided they are plump. These should be cut into lengths of about 6 inches and laid in a receptacle filled with sphagnum moss in a temperature of 60° to 65°. When signs of growth are apparent the shoots should be removed to a close case, where a temperature of 70° to 75° is maintained. As soon as they have started rooting the young plants may be transferred into very small Orchid pots, using only live sphagnum moss as a rooting medium. All the Dendrobiums cannot be increased

by this method, but among those that usually do well may be mentioned *D. nobile* and its variety *nobilius*, *D. wardianum* and its variety *Lowii*, *D. thyrsoflorum* and *densiflorum*, and numerous others.

J. DENSMAN.

THE LATE MR. GEORGE RAWLINGS.

A GREAT DAHLIA RAISER.

THIS well-known Dahlia specialist and one of my oldest floricultural friends, whose death was recorded in THE GARDEN recently, left Romford some years ago, where he had established himself in business as a Dahlia specialist, and went to Monmouth to end his days, his sons succeeding him in his business. To the last he maintained his interest in the Dahlia. I had an occasional letter from him in reference to the flower, to the improvement of which he gave the best years of his life. He remained a subscriber to the National Dahlia Society. He lies in Llandogo Churchyard, by the side of his wife, whom he had outlived eleven years.

In 1851 George Rawlings was living in the Globe Road, Bethnal Green, and had already commenced work as a raiser of Dahlias. It is possible to conjecture that Bethnal Green was then a semi-country district, and there were several florists in that neighbourhood at that time. The National Floricultural Society was formed in 1851, and held its first meeting in April of that year. George Rawlings was one of the 207 original members of the society, and with Mr. William Paul of Waltham Cross were the two remaining members of this roll of worthies. In August, 1851, he obtained from the National Floricultural Society a label of commendation for Dahlia *Dr. Tramp-ton*, a pale ground show variety edged with purple; in the following month, through being shown in improved character, it was awarded a first-class certificate of merit; and it received the same award at other London Dahlia exhibitions, as several were held in the metropolis in those days. Other new varieties shown by Mr. Rawlings that year were *Sir F. Thesiger*, which received a certificate of merit in 1852; this was a popular lilac self; *Louisa Glenny*, deep yellow; *Defiance*, blush white; *Rose of England*, rosy purple, &c. *Lilac King*, a lilac self, which subsequently became a very popular exhibition variety, gained a certificate that year or the year following. Many were engaged in raising seedling Dahlias in the early fifties. Rapid improvement was being made, and no flower unless of extraordinary quality could hope to maintain a supremacy for more than two or three years. At the outset of his career as a raiser, Mr. Rawlings set before himself a high ideal flower, and strove to reach it, and he selected from among his seedlings nothing but what he considered to be of the best character.

In course of time the growth of London, the formation of new neighbourhoods, and the erection of works and factories, compelled Mr. Rawlings to go farther afield—to Romford, and while there he prosecuted his work as a raiser with great vigour, and produced seedling after seedling of great merit. Several of his raising occupy a high position in selected lists of the present day. Mention may be made of *Arthur Coocek*, *Clara*, *George Gordon*, *George Rawlings*, *Harrison Weir*, *Harry Turner*, *John Bennett*, *J. T. West*, *Mr. G. Harris*, *Mr. Glasscock*, *Mrs. Glasscock*, *Mrs. Shirley Hibberd*, *Queen of the Belgians*, still one of the very best light varieties; *R. T. Rawlings*, a superb yellow self; *Shirley Hibberd*, *T. J. Saltmarsh*, *Thomas S. Ware*, *William Dodds*, and *William Rawlings*. All the foregoing are approved present-day exhibition varieties, and some of them are high up in the Dahlia analysis prepared by Mr. E. Mawley, and published in the recently issued annual report of the National Dahlia Society. All these show that fine quality of

outline, petal, and centre which is so characteristic of Mr. Rawlings' seedlings. Most of them will rank as exhibition varieties for some years to come. One fancy variety raised by Mr. Rawlings, Mrs. N. Halls, scarlet, tipped with white, is also a popular exhibition flower.

Such is the record of a long and useful life. Mr. Rawlings had outlived many of his earlier contemporaries, still there are many lovers of the Dahlia about the country who will learn of his recent death with regret. His son William was with him at the end. R. DEAN.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

MELONS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—On page 43 a very interesting note is sent by "A. D." referring to an earlier article on page 10 by "A. P. H." My remarks will be brief, though I crave a little space to support "A. P. H." as, though his list was a long one, it was sent doubtless to show special sorts from various raisers. I am unable to support "A. D.'s" theory that little progress has been made of late years, but does this not apply to all other fruits? Take Grapes, for instance. Has any new Grape been raised equal to the Muscat of Alexandria, or a new Peach of better flavour than the oldest varieties, such as Royal George? I admit we have had no lack of awards for Apples and Pears during the past ten years, but are the fruits superior to Doyenné du Comice Pear or Cox's Orange Apple? We do not hear the same objections made to the introduction of other new fruits in the same way as are made to Melons. Probably "A. D." knows that Melons do not keep true so long as one could wish, as the flowers are so soon fertilised by bees. A large grower such as Mr. Mortimer of Farnham would tell us that even he is at times deceived, and that a Melon grown under the best possible conditions may not when cut be equal to expectations, though the greatest care has been taken in the parentage and culture.

To sum up briefly, Melons are not reliable. I have, when judging large classes at flower shows, dreaded the Melon competition, many being bad, and at times none really worth a first prize. I have before me a list of Melons grown twenty-five years ago, which is not a long period when we think of the age of other standard fruits. I find very few of the old kinds are grown at the present time, and this shows the need of "A. P. H.'s" list, some of which will doubtless drop out in time; but those that remain will have served a good purpose. I can assure "A. D." that most growers endeavour to get fruits of the best flavour, and because all are not so I would ask him also to note that all Melons are not well grown. Some are badly cultivated, and others fed too highly. Personally, I am loth to condemn good intentions, but I am not adverse to consigning a new Melon I have raised to the rubbish heap if I find it is of inferior quality. A Melon should not be condemned because someone grows it badly; some Melons are also wretched growers, and many fail to set freely. This "A. D." overlooks. The plant should be of good habit and the fruits of the right quality. S. H. B.

MAKING A ROSEMARY HEDGE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—A member of our horticultural society wants some instructions as to the best way of making a Rosemary hedge to divide a flower garden. Would you publish a short article on this subject in THE GARDEN, please? A.

[Given good bushy plants, such as may be obtained from some nurseries, the making of a Rosemary hedge is a simple matter. The Rosemary succeeds best in a warm, deep, well-drained loam, which should be thoroughly dug, but unless

it is very poor no manure will be needed. The plants should be put 18 inches apart in the row, that is if they are sturdy little bushes. This planting must be carried out with as little delay as possible, and if it is followed by a dry period two or three good waterings will be of value. Then, in the latter half of April the hedge must be gone over, and any shoots that have a straggling tendency shortened, but the plants must not be cut back hard. Preserve the natural beauty of the Rosemary as much as possible. A slight pruning each spring is all the after treatment that will be needed if the hedge is in a sunny position, but if shaded there is more likelihood of the plants growing tall and getting bare at the base, in which case the spring pruning must be more severe.

If the intention is not to purchase plants, but to propagate from a few bushes that may be available for the purpose, a different way will be needed, and, of course, a longer time will elapse before the hedge reaches a good size. The best time of the year to put in cuttings of Rosemary is during the summer months. A length of 6 inches is very suitable for the cuttings, which should have the leaves cut off the basal half, and be then inserted in a shady border and covered with a handlight. In this way they will be well rooted by autumn, when they can be planted out. Should the spot for the prospective hedge be an open one they may be permanently planted at from 9 inches to 12 inches apart, according to the vigour of the plants. In the spring just pinch out the tops of the shoots in order to ensure a bushy habit of growth. If the spot selected for the hedge is so situated that the little plants will be overshadowed by larger neighbours, the better way will be to plant the rooted cuttings out in an open space for a year before they are permanently planted.—ED.]

CHRYSANTHEMUMS FOR CUTTING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Mr. D. B. Crane's note on "Chrysanthemums for Cutting" on page 83 of THE GARDEN is most opportune. The value of these plants cannot be overrated. The Kent County Chrysanthemum Society have an open class in their schedule for four vases of decorative Chrysanthemums, four distinct varieties, three sprays (not disbudded) of one colour in each vase, to show not more than 18 inches of stem above vase, any foliage. It is a most attractive class, especially with the lady visitors, and helps to break up the monotony of the boards.

Lee.

GEO. D. JUDGE.

THE FRUIT GARDEN.

OUTDOOR TOMATOES.

FOR a great number of years the cultivation of this fruit in warm positions on walls out of doors has been successfully practised in British gardens, and little need be said on this aspect of the question as the subject is well understood, but the practice of growing it in the open quarter of the garden and the field is of more recent date and is as yet of restricted dimensions, but when better understood and more suitable and hardier varieties have been introduced this aspect of its culture opens out a very interesting and profitable field for the development of the industry. It is important to bear in mind that the Tomato plant when planted outside occupies the ground but for a very short time—say from early June to the beginning of October, only some four months—so that every condition likely to favour rapid growth and maturity must be taken advantage of. The first, and one of the most important of these, is the position and quality of the land, which should be of a warm and dry nature and fully exposed to the sun. (It is useless to attempt their culture on heavy, cold land.) The ground should be well trenched and heavily manured (which should be well decayed) in the course of the previous winter and spring. It is futile to

expect a heavy and well-ripened crop from poor land, and this has been one of the chief causes of failure in the past. Having satisfied ourselves that the condition of the land is in every way suitable, our next duty will be to see that the plants are in the best possible condition for planting when the time arrives for this operation to be carried out early in June. More depends on this than on anything else, as if our plants are weak and poor at this season there is no time for them to recuperate and to bear a good crop of fruit as well before the season is over. Therefore, let the grower make up his mind that before he can expect to succeed he must be prepared to have his young plants well grown, healthy, and sturdy, and not less than 1½ feet or 2 feet high, and with several bunches of fruit already set on the stem at the time of planting. In order to do this, if they are to be grown on a large scale, it is imperative to possess a goodly number of cold frames or pits with a covering of glass, so as to enable us to grow and prepare the plants for planting. The seeds should be sown at the end of March in pans or boxes and placed in a warm frame near the glass. If the grower does not possess a frame or house which is artificially heated, he should make a small hotbed on which to place the frame. This will afford excellent and ample provision in the way of heat to raise the young plants in.

As soon as they are large enough to handle they should be potted singly into 3-inch pots, placed back in the warm frame, and kept there until they are well rooted, which will be in about a fortnight, when they may be removed into a cool frame and given a little more room. They should still be kept warm even in the cold frame by giving but little air for some time and closing early in the afternoon, running the temperature up to 70° or 75° for a few hours, and covering the frame with mats or some other material at night. When the plants are about 5 inches high and have filled their pots with roots, they should be potted into 6-inch pots in soil composed of ordinary loam three parts and one part of some light manure passed through a three-quarter inch sieve, with a sprinkling of lime and soot. They must now be given more room in order to make them strong and sturdy. For the first week after this second potting they should be kept fairly warm until the roots have taken hold of the new soil, when more air must be admitted and the plants grown as hardily as possible, but never subjecting them to a temperature below 40°. Towards the end of April and through the month of May the lights may be taken off the frames altogether each day for a few hours when the weather is warm and bright. Towards the end of May the plants should be showing flower, and if the frames are wanted for some other purpose temporary cover should be provided in some sheltered place out of doors. This may be furnished by driving stakes into the ground at distances of 6 feet apart and tying mats to these to form sides, and for a covering a lath should be nailed to the top of the stake crossways in the way of a rafter, on which mats could be placed at night.

Caution must be exercised not to plant in the open quarters too soon, as the Tomato is a tender plant, and one exposure to a frosty night would throw them back and cripple them for the season. Therefore do not be in a hurry to plant out too soon. From June 10 to 16 I have found to be the best time. They should be planted in rows 2 feet apart, and the same distance from plant to plant. The work should be done when the ground is in a suitable condition for planting, neither too wet nor too dry, and the ground round the ball of the plant should be made firm by treading after planting. Stout stakes about 4½ feet high should be provided, to which the plants should be secured as they develop; from 3 feet to 4 feet is as long as it is advisable to let the stem grow, as there will be no time to set and ripen the fruit which may form after the stem has attained this height. Therefore the stem should be stopped at about 4 feet. The side shoots or laterals should be cut out close to the stem as they appear, so that the whole energy of the plant may be utilised for the benefit of the fruit. A good watering must be

given the plants after planting, and the precaution should be taken to have the roots sufficiently moist at the time of planting, or it will be difficult to moisten them thoroughly afterwards.

Should the weather prove dry immediately after planting, the plants should receive occasional waterings until such time as they have rooted into the soil. When this is the case a mulching of short manure should be placed round the roots, then the crop will give little further trouble for some time, except that the ground must be kept free from weeds by hoeing, the laterals stopped, and occasional waterings given should the weather be exceptionally dry. It will take 10,890 plants to plant an imperial acre at 2 feet apart, and if the season proves favourable, and all has gone on well, each plant should yield 3lb. of ripe fruit at a low estimate, and the price for it should average 2d., the best would be 3d. or more. This would give a return of £272 per acre, giving at least a clear £100 profit after all expenses were paid. I do not know of another crop capable of extracting so rich a return from the land in so short a time.

A. P. H.

THE KITCHEN GARDEN.

EXHIBITION VEGETABLES

MANY who have read the interesting series of articles by Mr. Beckett in THE GARDEN of last year will be interested in the accompanying illustration, which represents a group specially taken in the Aldenham Gardens of certain varieties. It needs no explanation. Gardeners and others interested in vegetables should read that series, and as in the coming autumn an exhibition and conference are to take place at Chiswick Mr. Beckett's advice should prove of considerable value to intending exhibitors.

NEW VEGETABLES OF 1902.

THE list of new vegetables is necessarily a small one, as even under the best conditions the same progress is not made with what may be termed a limited class, as in the case of flowers. Another point is that the new vegetables are only new varieties, but at the same time some of these add greatly to the interest taken in this department of horticulture. Doubtless the coming year will show greater progress than the past, as we are to have either a congress or series of meetings (prizes also) in the Royal Horticultural Society's Gardens at Chiswick in the early autumn months, and I welcome this announcement, as, though I have no authority for my statement, I have during the past months, in conversation with a well-known horticulturist, been told that we are to have trials at Chiswick in addition, and certainly these are always interesting and of educational value. Our thanks are largely due to the editor of THE GARDEN, who regularly gives vegetables a fair space and much encouragement. There is yet ample room for new vegetables. I wish we had harder Cauliflower or Broccoli, but we cannot expect too much when we find its parentage and country so different to our own. Again, what a boon would be a hardy Lettuce! Yet how can we expect it when the tenderness of the leaf is its greatest value. We may yet get these vegetables by selection or crossing. We see what

has been done during the past quarter of a century as regards Peas. Wonderful progress has been made both with respect to quality and quantity, and the same result has taken place with Potatoes. Magnum Bonum is now less grown than formerly, but what a revolution it created in the matter of cropping! I well remember having this by the side of one of its parents some twenty years or more ago, and the Victoria gave one peck to a hundredweight from the Magnum, and this progress has continued. There are splendid varieties, both as regards crop and freedom from disease. These are only a few instances of the progress made, and we can safely add that we have now finer stocks of other vegetables also.

CUCUMBER BRITISH KING.

This excellent Cucumber, staged at the Temple show by Mr. S. Mortimer, Rowledge, Farnham, was the result of a cross between Sensation and Famous, both very fine varieties and of good flavour. This is a long, very dark green, handsome fruit, having minute black spines, and stated to be enormously prolific. It should certainly be a favourite market variety. This new Cucumber is now the property of Messrs. Sutton, Reading, and has been renamed by them Satisfaction. Award of merit, May 28, 1902.

NEW POTATOES.

New Century.—This is a valuable early Potato, and most valuable to follow the very early Ashleafs. It is a white Kidney of very handsome shape, with few eyes, and of splendid table quality. A good cropper and dwarf growth. From Messrs. Dicksons, Chester. Award of merit, August 14, 1902.

Northumbria.—A very handsome white round tuber of splendid table quality, the parents being Syon House Prolific and Sutton's Seedling. A very good mid-season variety with us, with moderate haulm; keeps well, and is valuable for use between the early and late sorts. From Mr. G. Wythes, V.M.H., Syon House, Brentford. Award of merit, August 14, 1902.

Victoria Improved.—An excellent round variety, white skin, and of splendid quality, evidently a late variety, as when lifted in August it was immature. A very good cropper, and free from disease. From Messrs. Sharpe, Sleaford. Award of merit, December 5, 1902.

Scammell's Seedling.—A white, flattish round, and evidently a mid-season variety. It was of excellent flavour and a good cropper; free from disease. Award of merit, September 12, 1902.

It is only fair to add that there were several other promising varieties at the December trial for cooking, notably Alderman and Springfield. From Messrs. Dobbie. These just missed an award, and will be tried again next year.

NEW RHUBARB.

Sutton's Crimson.—This is a variety from abroad, and it differs greatly from our well-known sorts, as it grows readily without forcing, being fit for use early in the autumn. Not a large grower, but of a beautiful crimson colour and of good quality. From Messrs. Sutton and Sons, Reading. Award of merit, November 4, 1902.

Veitch's Christmas.—Evidently a similar Rhubarb to the last-named. Messrs. Veitch, Limited, Chelsea. Award of merit, November 4, 1902.

G. W.

GARDENING OF THE WEEK.

FLOWER GARDEN.

NEW LAWNS.

WHERE these are in contemplation the present is a good time to begin work. Before attempting to lay down turf or sow grass seeds the ground should be well trenched. There should be no hesitation in this respect, for if the ground is only dug to the depth of a few inches the turf during a dry summer would not preserve its freshness without constant watering. The difference in the aspect of a lawn prepared on trenched ground and that on ground merely dug up during

A COLLECTION OF EXHIBITION VEGETABLES.

the summer and after several years is most striking. The surface soil should, of course, be kept on the top and thoroughly pulverised and levelled evenly throughout. Provision ought to be made for carrying off storm waters and subsoil soakage, or in very wet weather the water would remain upon the lawns, injure them, and keep them damp for a long time. Before the turf is laid the surface should be rolled evenly with a moderately heavy roller. The same should be done whether the lawn is to be sown or turfed. However carefully lawns may at first be made they will not present a good appearance unless systematically mown and at times dressed with fine soil and rolled. In the course of several years the soil becomes impoverished, and it will be found necessary to dress with a fertiliser. Bone-dust and fine dry soil would be found a most effective means of renovating lawns. The best time to spread it is in early spring.

VERBENA VENOSA.

One seldom meets with this old favourite. When it does well it is one of the best plants we have for large beds. Seed should now be sown. I find it is a good plan to steep the seed for several days before sowing and never let it become dry afterwards. Sow the seed on an even surface of loam, leaf-mould, and sand in equal proportions and very slightly covered. After watering cover the pan or box with glass to prevent evaporation, and shade from the sun till the seed vegetates and the young seedlings appear; the seed is sometimes very irregular in its germination. Care should therefore be taken to prick off into rich soil the young plants as soon as they possess two rough leaves. Keep them in heat until they meet in the box or pan, then put them into a cool house near the glass.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

KITCHEN GARDEN.

GENERAL work in this department will be regulated to a great extent by the state of the weather and the ground. If sufficiently open and the ground fairly dry, seed sowing may be commenced, beginning with

PARSNIPS.

To grow clean, shapely roots of these the soil must be deeply dug or trenched some time before the seed is sown. This crop may well follow Celery, for the constant moving to a great depth of the soil for earthing purposes suits admirably for Parsnips and Long Carrots, which penetrate to a great depth. Such a plot will contain sufficient manure for these roots, and all that is necessary is to dig deeply, and during the operation distribute the manure from the old Celery trench evenly over the whole area. Excellent roots may be grown on such a plot without boring, but if exhibition roots are wanted holes should be bored with an iron bar to a depth of 3 feet or more and filled with fine sandy soil at a distance of 14 inches from each other in the row, and 18 inches from row to row. Press a small pinch of seed into the soil and cover it an inch deep.

SPINACH

of the round leaved variety may be sown on a warm south border; the produce from this will succeed the winter crop. I prefer to leave the early crops of summer Spinach unthinned, or if thinned at all do it but lightly, the plant being then cut clean off at the ground level instead of gathering the leaves singly.

TURNIPS

of the early Milan type may now be sown in a similar position for providing early dishes, as may also some seed of Horn Carrots to follow those grown in frames.

JERUSALEM ARTICHOKE

may be planted at any time now, and although these require and amply repay good culture, yet they are not a crop one cares to have in the kitchen garden proper unless to form a screen to an unsightly part of the garden. Outside the garden walls is best for these tall-growing plants if the soil is not too impoverished. The rows

may be 3 feet apart and the tubers placed 4 inches below the surface at 14 inches from each other. We invariably plant the sets as the digging is done, as Potatoes are planted in some localities. Sutton's White variety has superseded the older Purple. Cabbage beds should now be examined, and any plants that are not healthy pulled up and replaced with others from the reserve bed. Stir the surface of the beds with a Dutch hoe, but if earth was drawn against the stems for protection do not remove it; and if, on the other hand, this has not been done, it should now receive attention. Winter Spinach should also have the surface soil stirred in like manner after first removing any protecting material that may have been placed about the plants.

Stonleigh Abbey Gardens.

H. T. MARTIN.

INDOOR GARDEN.

EUPHORBIA JACQUINLEFLORA FULGENS.

In propagating this plant from cuttings it is necessary to take into consideration that they are succulents, and better results will be obtained by allowing the old plants to become dry at the roots for a few days prior to taking the cuttings. If possible take these with a bit of old wood at the base (what is generally termed a heel), insert them in very sandy porous soil six cuttings inside the rim of a 3-inch or 4-inch pot. Three or four of these pots may be placed in a seed pan of 6 inches or 7 inches in diameter, which place on a dry shelf in a stove or propagating house and cover with a bell-glass with a piece of paper or tiffany for shade; in such a position they root more freely than in a close moist frame.

RICHARDIA ELLIOTTIANA.

R. Pentlandii and their varieties intended for early blooming should now be brought into a temperature of 55°. Remove a little of the old surface soil and replace with fresh, rather light soil, and give one good watering. As many of the old roots from these tubers are perennial and dislike being disturbed now, I prefer to defer the repotting until after the plants have bloomed. These magnificent Richardias are deserving of all care and attention. I find they require an intermediate temperature, and are satisfied with much less water at the root than *R. aethiopica*.

EUCHARIS AMAZONICA

as grown in pots is frequently found in a more or less unsatisfactory condition. Where an entire house is devoted to their cultivation it is a much simpler matter to keep them well than where only a dozen or two plants are required and have frequently to be moved from house to house. I am convinced that submitting them to a low temperature for any length of time, or exposing them to a strong sun with insufficient moisture, are responsible for the condition in which they are often seen. Where narrow borders alongside paths in stove or other hot house, if partly under the side stages and near hot-water pipes, can be given up to them, so much the better, and the bulbs be there planted out in any light fibrous soil, they will simply luxuriate and flower profusely.

FUCHSIAS.

Old plants that have been stored away for the winter, and which are required for conservatory decoration during early summer, should now be placed in an intermediate house and pruned back to two or three buds at the base of last year's wood. Where the plants are old remove the loose bark from the stems and see that the plants are thoroughly cleared of all insect pests. Whatever means may be employed to effect this purpose avoid using too strong a wash. When the buds become active the plants may be repotted; replace the plants in pots one or two sizes smaller, using a rich light compost of loam and leaf-soil with one-eighth dry cow manure rubbed through a fine sieve and some sand and rough charcoal. Place the plants in a temperature of 50° by night, with an advance of 5° during the day, syringe them twice daily, and keep free from aphids by fumigation. Young plants struck from cuttings in September or October will now require a larger pot, and

must be exposed to as much light as possible. Pot Roses recently started should now be freely syringed on clear days, raising the day temperature 5°.

Wendover.

JOHN JAUQUES.

THE FRUIT GARDEN.

FIGS.

THROUGH the favourable weather early trees have made considerable progress, and many of the most forward Figs have reached a size which will not increase until the flowering process is complete, but this apparent standstill need not cause alarm. Hard forcing will not help them. If the weather continues favourable a steady night temperature of 60°, with a rise of 10° by day, and 5° more after shutting up, will be quite high enough for a considerable time, but in the event of a change to wintry weather 5° lower will form a safe working standard. Figs as a rule do best in shallow well-drained borders, therefore keep the roots well supplied with tepid liquid and guano water alternately, as the Fig when in growth is a gross feeder, and soon resents a falling off in quantity or quality. Be careful to keep the young growths and foliage firm and stout by means of liberal ventilation, and clean by a vigorous use of the syringe, particularly when the house is closed for the day, with plenty of solar heat. Guard against overcrowding by pinching side shoots to form spurs, and remove weakly growths entirely where there is not room for full development of the foliage and exposure of the fruit when it begins to ripen. Repeat former directions in the management of the succession house, always bearing in mind that a steady supply of heat, air, and moisture, combined with liberal feeding to well ripened trees which are not overcropped, are important points in the production of high class fruit. Get trees in late houses pruned or thinned, washed, and tied in as opportunities occur, as the time is near at hand when many matters will require prompt attention.

MELONS.

To maintain a steady supply of Melons throughout the season another sowing should at once be made to succeed the first batch now coming into rough leaf. If the bed intended for these is not ready give them a small shift and replunge in bottom heat near the glass. In the meantime prepare the fruiting pots and plunge them where they are to remain until the fruit is ripe. Prepare the soil (stiff calcareous loam, which has been stacked for some months in an open shed) by breaking it up with the hand. Place it loosely in the pots, to admit of the heat passing freely through it, then ram firmly and turn out the young plants before they become potbound. If the soil is poor add a 6-inch potful of bone-dust, or twice the quantity of dry rotten cow manure to a bushel of loam. Mix thoroughly some time before it is wanted, and see that a few of the roughest lumps are placed over the drainage. Give water sparingly until the roots reach the sides of the pots, and defer feeding until the fruit begins to swell, when the highest culture that can be given will be needful. Sow Blenheim Orange now for the main crops.

GRAPE ROOM.

Keep the room dark, dry, and well ventilated. A temperature from 40° to 50° is quite high enough for Lady Downe's, still the best and most profitable kind for keeping, until Black Hamburgh is ripe; and as the above figures can be maintained without the aid of fire-heat, all that is needed is just sufficient warmth on fine mornings to expel moisture.

WILLIAM CRUMP.

Madresfield Court Gardens.

CHRYSANTHEMUMS.

CUTTINGS.

THOSE propagated with the object of producing large flowers, whether they have been rooted singly in 2½-inch pots or in any other way, will now need shifting into other sizes. The majority should be sufficiently advanced to be placed into 3½-inch pots, but overpotting at this and all other stages

should be strictly avoided, consequently at every potting two or three different sized pots must be in readiness. As this potting will play an important part as to the future of the plants hardly too much care can be exercised with regard to details, and in the case of the weaker plants 3-inch pots will be amply large enough and far preferable to the larger size.

COMPOST.

Prepare this a few days before required and turn it every other day. The mixture should consist of three parts good fibrous loam, one part leaf-soil, one part half decayed horse manure, a liberal quantity of coarse silver sand, with a small amount of wood ashes, fine charcoal, and bone-meal, all thoroughly mixed before it is used. Warm this to the same temperature as that in which the plants are growing. The pots and drainage should be quite clean, and any new pots soaked and dried before using. Provide ample drainage to allow the water to pass away freely, and place over the crock some fibre taken from the loam. Heap with all the soil removed. Before beginning make quite sure that the soil is in a suitable condition, being neither too wet or dry, also carefully examine the plants and water any that are at all dry a few hours before turning out. Pot moderately firm, and see that each is carefully labelled.

The position which the plants are to occupy will of course depend upon circumstances, but an ideal place is a light pit facing south with a flow and return hot-water pipe through it, which can be used only as required. The less fire-heat the plants receive after now the better. The growths should be kept as close to the glass as possible. Place the plants upon a bed of finely sifted cinder ashes. Frequently damp over, but keep close to induce them to overcome the slight check as soon as possible, after which give air freely when the weather will permit. Strive to build up the growths in as sturdy and as natural a way as possible, and immediately the plants begin to make new growth thin them well out so that they do not suffer from overcrowding. It will be well while the plants are under glass to assign one or two lights to the more weakly and late-struck plants, where these can be nursed along more easily than if mixed about among the more robust and general collection. Watch minutely for any traces of aphid, rust, or mildew, and allow neither to gain the upper hand. Where any collection is free from rust every endeavour should be made to keep them so, as there are few so fortunate. Isolate any which are procured from other sources, and make quite certain that these are perfectly clean before bringing them into contact with the clean collection. Far better to destroy choice kinds than to contaminate a clean lot. Only those who have suffered from this pest can form any conception as to the trouble it occasions to hold it in check, especially in some seasons. E. BECKETT.

Aldenham House Gardens, Elstree, Herts.

EDITOR'S TABLE.

JASMINUM NUDIFLORUM.

"A Town Gardener" sends a beautiful bunch of the winter-flowering Jasmine (*Jasminum nudiflorum*), which, he says, "is flowering gaily in a garden not three miles from Charing Cross." We can well believe this. It is a Jasmine for the town garden, and makes a cheery picture for many weeks in the dulllest season of the year as far as a London suburb is concerned.

CHINESE PRIMULAS.

Messrs. William Bull and Sons, Chelsea, send us a selection of their Chinese Primula flowers, and among the many beautiful colours and pretty forms we have made note of the following: *Alba oculata-lutea*, large, fringed white, with bright yellow centre; *Brilliant*, a variety with fringed flowers of bright crimson-magenta, lemon-yellow eye; *Comet*, carmine-crimson, with yellow throat; *Countess*, blush pink, fringed; *Imperial Blue*, a beautiful lilac-coloured flower, large, and elegantly

fringed. *Mont Blanc* has splendid snow-white flowers, while *Ruby Queen* is a brilliant crimson-magenta fringed variety. The red and white strains of *P. sinensis fimbriata* are also very attractive. Among the double-flowered varieties, the best undoubtedly is *Bull's Blushing Beauty*, a new Primula, with large blooms of a lovely shade of blush pink; *Fulgens fl.-pl.*, one of the best deep-coloured doubles; *alba fl.-pl.* and *rubra fl.-pl.*, both good types of double flowers.

GARRYA ELLIPTICA.

I see in *THE GARDEN* of the 31st ult., a note headed the above, and I think it may be of interest to your readers to know that we have here a very fine plant of *Garrya elliptica*, the dimensions of which are: Height, 13 feet; depth through, 12 feet; circumference, 66 feet; length of catkins, now, 6½ inches, not yet fully developed. The plant stands out at the corner of a small plantation nowhere near a wall, in strong yellow loam, in a western aspect. It appears perfectly hardy, never having suffered in the severest winters, and a little later on the catkins will be fully 9 inches or 10 inches long. It is a very handsome bush and attracts much notice. I enclose a small spray. This plant was

LITHOSPERMUM PROSTRATUM.
(Gathered a few days ago.)

put in about thirty years ago.—*JANET PEEL, Hampton-in-Arden, Warwickshire.*

[We always welcome the beautiful *Garrya elliptica* upon our table, and it is interesting to know of so fine a plant.—*Ed.*]

LITHOSPERMUM PROSTRATUM.

Mr. Field sends from Ashwellthorpe Gardens, near Norwich, flowers of this beautiful blue trailer, of which we have made a much reduced illustration. It is interesting, of course, at this season, as the shoots sent were full of buds and flowers.

SEEDLING HELLEBORES FROM MR. ARCHER-HIND.

We have received from Coombefishacre House, Newton Abbot, a few of Mr. Archer-Hind's seedling Hellebores, which are now beginning to be very pretty in his garden. The flowers are of beautiful shape and varied colourings, some almost pure white, others delicately spotted, and a few of warm plum shades. The following are extracts from a letter from Mr. Archer-Hind in *THE GARDEN* of February last: "I really know of none more readily and easily amenable to treatment by amateurs; none more certain to show good results from careful selection within certain limits. You know beforehand how to adapt the

crossing to the production of new colour in a good shape, or new shape in a good colour, as well as how to improve the general habit of growth. As to the value of the flowers for their hardiness, time of blooming, and variety of colour, both at home and abroad, they have been the admiration of first-rate authorities. The display of really well-arranged jars or bowls of suitable colours and forms has excited constant admiration, the more so that even a very few years ago they were new to people in general. . . . Everyone knows that when the stalks are split up (and the further the better) Hellebore flowers will keep good and fresh for a week or even ten days."

MISCELLANEOUS.

MOLES.

MOLES are lauded by entomologists for the service which they render to agriculture by daily destroying a large number of cockchafer grubs, wire-worms, and earth-worms. This, however, does not prevent them from being regarded as formidable enemies to the gardener, with whose work they interfere, not by cutting the roots of his plants, but by lifting them out of their position when they are excavating their underground runs. If they confined themselves to burrowing only in the quarters in which large vegetables are grown, we think many gardeners would say nothing against them. But they follow the gardener whenever he sows any seed or sets out any valuable, carefully-grown plants. When he begins to water his seed-beds, flower-beds, and decorative plots of bedding-out subjects, immediately the moles tunnel their runs in all directions in the soil. And yet, they are only in search of earth-worms, which form the principal part of their food, and which are found in large numbers in any part of the soil which has been watered.

It is impossible for a gardener who cares anything about his work to regard with indifference the displacing of his plants and the frustration of his labour. He sets traps, and when a mole is caught he is well pleased. Often, indeed, owners of gardens will pay 25 centimes (2½d.) to professional mole-catchers for every mole they catch, to encourage them in their work of destroying them. What is needed, then, is some means of keeping away moles from select parts of the garden and banishing them to wooded parts, where they might burrow undisturbed and be useful without injuring anything. Last year we made use of an insecticide which proved very serviceable in banishing moles. Early in July we had a tennis ground made in a moist meadow, close to a river. Every day this ground, which was naturally very flat, was made perfectly level, but every succeeding morning we found it literally turned up into mole-hills. One would have said that all the moles in the neighbourhood had made the place their rendezvous. After two days' cogitation on the subject, we resolved to pour some petroleum into their runs, which we effected by opening the runs under the mole-hills and pouring in about one-third of a pint of petroleum at each opening. We then levelled the mole-hills over the openings. A second application of petroleum was necessary, after which we had no more mole-hills, and to this day the tennis ground has been quite free from them. If gardeners try this plan they will certainly be well pleased with the results.—*Revue Horticole.*

READING "THE GARDEN."

In an ordinary way I read, mark, learn, and inwardly digest the weekly numbers of *THE GARDEN* with commendable regularity, especially the "marking" noting in the weekly index (to be transferred later on to the half-yearly one) such things as I may wish to refer to at some future period, and entering in a note-book any special fads and fancies. But this autumn, being much engaged in other ways, I had neither time nor acuity to spare for this literature, and so deferred

the weekly readings till the end of the year, when I had leisure to take THE GARDEN of four months in sequence. But, on the whole, I find there is much to be said for this way of reading—you get question and answer together, and in many ways one seems to get a more thorough grasp of a subject than when taken in small doses. Take the papers on

SELECTIONS OF ROSES

for instance. These have been specially helpful, as I am just about to plant some climbers near trees—certainly, reading the various lists together has made it much easier to come to a decision than if weekly memoranda had had to be made. The correspondent who suggests "drain-pipes" draws a Michael Angelo statue to his own hook—one feels so small never to have thought of drain-pipes in this connexion. Will anyone who has tried the Afghanistan Rose *Eae* give their opinion of its wants and merits or demerits as the case may be? I noted it some two (?) years ago when mentioned in an account of the late Canon Swaynes' garden in the pages of THE GARDEN, but have never seen it in any catalogue till the other day, when I found it in Smith's of Newry.

The only fault to be found with THE GARDEN is that it distinctly breeds discontent—shall we say a *divine* discontent?—in people living out of England, not only of the stately homes with their thirty-eight gardeners and incomes to correspond, but of the general atmosphere of culture and intelligence on gardening matters which prevails at home; there is nothing like it elsewhere, least of all in Italy.

Some years ago I tried hard to get the right name of the big-leaved Mahonia; familiarly, it was a Mahonia, and that was sufficient. One morning I sent a spray of it to the Horticultural Gardens, and, as luck would have it, an Englishman was there who at once wrote down on his card for my gardener "Berbi. japonica." Reading in the issue of December 6 on the very interesting description of the two—Berberis, as they are there called, japonica and nepalensis—I began to have a hazy idea that I had seen it somewhere stated, on the authority of the "Kew Hand List," that these two species were synonymous, and, had I been reading the paper in the usual weekly fashion, would probably never have bothered the Editor with an enquiry as to whether this was really so or if I had dreamt it—when, lo! by waiting to peruse the issue of December 20 I find that for once my memory has not misled me. I happen to have several fine specimens of these Mahonias, and, notwithstanding a discouraging warning in THE GARDEN some little time back that they were very impatient of removal, we have lifted them this autumn, as they had quite outgrown their position, and as all such operations are done in this country on the most unscientific principles I await the result with some anxiety.

TUSCAN.

[An important description of the Barberries, by Mr. Bean, of Kew, is now appearing in THE GARDEN.—ED.]

YAMS AND SWEET POTATOES.

A SHORT time ago the fruit and vegetable committee of the Royal Horticultural Society had an exhibit of the above vegetables before them, and naturally they created much interest. Their preparation is an art. Of course, they may be cooked simply like a Potato. In tropical countries the Sweet Potato is often baked and roasted, and after the outer skin has been removed the tubers are mashed and mixed with butter, but I have heard that it takes some time to get accustomed to the taste of the Sweet Potato. In South Africa these roots do splendidly, but I have been told that the flavour is not equal to a Barbadoes tuber; the latter are drier. A great trade is done in these roots in the Colonies, and they are now being imported to this country by Messrs. Pink of Portsmouth, and will doubtless be welcomed by those who have resided in India and the warmer countries. As their price is not great they should become better known. It is only fair to state that the Sweet Potato cannot be grown with any success

in this country: the soil is not warm enough. It requires a porous, warm soil, and grows rapidly. A friend in the Colonies writes that he prefers the Yam and Sweet Potato before the kinds at home, and the same opinion is held in the East Indies. There the Sweet Potato is a general article of food. The Yam requires a rich, porous soil, and is much grown in hot countries. The roots of the Chinese Yam go down to a great depth. These have been grown in this country, but with little success.

G. WYTHES.

RECENT PLANT PORTRAITS.

THE *Botanical Magazine* for February contains portraits of

Sanseria grandis, a native of Tropical Africa. This is a handsome plant received from Cuba, where it is known as Cow's-tongue from the shape of its ornamental foliage, which produces a fine white silky fibre of extraordinary strength, far exceeding any other. A few strands of it are sufficient to hang a man. It has a long spike of white flowers, and bloomed in the temperate house at Kew in July of 1901 and 1902.

Impatiens Balfourii.—Native of North-western Himalayas; a pretty Balsam with large rosy white flowers.

Acidanthera candida.—Native of East Tropical Africa; a most beautiful bulbous plant with large, pure white flowers.

Astilbe Davidii.—Native of China. This is a very handsome form of *A. chinensis*, with flower-spikes reaching to a height of 6 feet. It was raised from seed sent to Messrs. Veitch by their collector, Mr. Wilson.

Rhododendron brachycarpum.—Native of Japan. This is a beautiful plant with delicate pale yellow flowers. Seed of this was received from the St. Petersburg Botanic Garden in 1895, and bloomed in the open air in 1902.

The February number of the *Revue de l'Horticulture Belge* figures

Cymbidium tracyanum.—This is a fine and distinct form of *C. lowianum*, amongst a lot of which bought at a sale it came to Mr. H. A. Tracy, after whom it was accordingly named. It is a very handsome Orchid.

Strobilanthes unisophyllus (syn. *Goldfussia angustifolia*).—This is a very pretty and free-blooming ornament of our warm greenhouses, but is much better known under its second name. Its flowers are tubular and of a pleasing shade of purple-lilac.

W. E. GUMBLETON.

BOOKS.

The Journal of the Royal Horticultural Society, December, 1902.—

The Journal of the society just issued contains the papers and other matters relating to the Rose conference held at Holland House last year. It is worth purchasing by those who are not Fellows (Fellows are fortunate in getting it free), although the price is 10s., but the Journal has become one of the most important publications of the time through the efforts of the Editor, who is also the secretary of the society. The contents are remarkably varied, and comprise the papers read before the society during the latter part of last year. "Fungoid Pests of the Garden" is continued by Dr. M. C. Cooke, M.A., V.M.H., and a valuable series this is with its many illustrations, coloured or otherwise. The disease of the Carnation is specially treated by Professor Potter, and "Trees and Shrubs," with many illustrations, by the Right Hon. the Earl of Annesley. The Rev. Professor Henslow and Professor Debono discourse upon the "Botanical Garden at Malta," and the lectures given by Mr. Henslow at Chiswick are also reproduced. These must be very helpful to young gardeners and students. The following articles are practical: "Small Fruits in Private Gardens," by Mr. James Smith, V.M.H.; "Hardy Fruit in Yorkshire," by Mr. A. Gaunt; "The Gooseberry Mildew in Europe," by Mr. Ernest S.

Salmon, F.L.S.; "Mendel's Theory and Orchid Hybrids," by Captain Hurst, F.L.S.; "Fruit Trees in Pots," by Mr. T. Alfred Rivers; "Horticulture in Egypt," by Mr. Lionel Sandars, with the instructive reports on Tomatoes, Michaelmas Daisies, Phloxes, Potatoes, dwarf and Runner Beans, &c., at Chiswick; and "Commonplace Notes," by the secretary and superintendent. The many illustrations, for the most part excellently reproduced, add to the interest of the volume. We have often congratulated the Editor (the Rev. W. Wilks) upon the way the Journal is managed. We do so again, more heartily than before; it is a great success, and a most helpful guide to the thousands of Fellows that have joined the society in recent years. The yearly volumes bound up are books for every country house library, and appeal also to the practical gardener.

OBITUARY.

MR. JOHN DICK.

MR. JOHN DICK died at Philadelphia, on the 13th ult., in his eighty-ninth year. Mr. Dick was born in Edinburgh, Scotland, in 1814. He came to this country in 1834, with no capital, but a sturdy constitution and a determination to succeed in his chosen calling. He first obtained employment with Andrew Dryberg. After several years he went into partnership with James Ritchie, his brother-in-law, at America and Oxford streets, where they were quite successful. In 1850 he bought a plot of ground and erected greenhouses at Fifty-second and Woodland Avenue, where by careful management he built up a large business, making a specialty of hard-wooded greenhouse plants, such as Camellias, Daphnes, and so forth. He retired from active business about fifteen years ago.

MR. FRED L. HARRIS.

MR. FRED L. HARRIS, former gardener at the H. H. Hunnewell estate, died at his home in Wellesley, Mass., on Sunday, the 11th ult., aged eighty years. Thus passes away the "grand old gardener," best beloved in his profession in America. He stood for all that was noble and manly in American horticulture; a shining example to the young gardener, his record is an encouragement and incentive to ambitious industry. Such men are an honour to any calling and an inspiration to their fellows. The far-famed estate by Lake Waban, the most beautiful example of landscape gardening art on this continent, which under his guidance and art was transformed from an unadorned waste, is an enduring monument to his ability in his profession.—*The American Florist*.

CAPTAIN ALFRED TORRENS.

CAPTAIN TORRENS, who died suddenly recently at his residence, Baston Manor, was perhaps one of the best known men in the horticultural world. He was greatly loved in the parish where he spent many happy years, at Hayes in Kent. I happened to be in the neighbourhood the day after his death, and there was hardly a person who did not know of the sad event and express sorrow and regret. Captain Torrens was one of the most generous, kind-hearted, and sympathetic of men, both in his official capacity as a J.P., and as an employer. His manly figure, kindly sympathetic face and cheery words will be sadly missed by friends and neighbours.

Captain Torrens, who was seventy-one years old when he died, carried his age well, and the soldier and officer could easily be discerned in his tall and erect figure. He was the son of the late Colonel Robert Torrens, C.B., who served as Quartermaster-General under Lord Wellington at Waterloo. He was educated at Harrow, serving later in the 66th Regiment, retiring in 1867 with the rank of Captain. The same year he married the sister of the late Sir Edward Scott, Bart., of Sundridge Park. He first lived at West Wickham and removed later to Baston Manor at Hayes, Kent. Captain

Torrens was a great traveller, and he made a trip round the world in company with Mrs. Torrens; but his favourite journeys were always to Canada, and in fact when I met him only a few months ago he mentioned to me that he intended to go there again shortly, and promised to bring me several rare plants from that country. I became first acquainted with Captain Torrens at one of the flower shows at the Crystal Palace in 1894, when I was attracted by a splendid specimen of the charming Japanese *Schizocodon soldanelloides* and *Shortia uniflora*, never again seen in such perfection. Although at the time quite a stranger, Captain Torrens invited me to Baston Manor, and when I went he presented me with a plant of the *Schizocodon*. Since then I have received many invitations, which I have never refused, as the garden, though not large, contains one of the best kept rockeries and one of the choicest collections of alpinists in the county. Captain Torrens was one of the most successful growers of Japanese Tree Paeonies. He was one of the most enthusiastic of lovers of hardy plants.

G. REUTHE.

[We well remember Captain Torrens, and first made his acquaintance at the Crystal Palace show referred to by our correspondent. He reintroduced the beautiful *Schizocodon*, which was shown by him at a meeting of the Royal Horticultural Society in the Drill Hall, when it received a first-class certificate.—Ed.]

MR. P. S. PETERSON.

MR. P. S. PETERSON, the Chicago nurseryman, who died of pneumonia on Monday morning, was one of the city's early settlers. He came to America from Sweden in 1851, and after following his profession in the Eastern States a few years, supplementing the training he had received in Europe, established his business in Chicago in 1856, and remained at the head of it until his death. Probably no one citizen has done more towards beautifying Chicago than he. The countless trees and shrubs that grace the parks, boulevards, and private grounds were to a large extent sprouted at the Peterson nursery. These and the 500 acre nursery and the private park of twelve acres form an enduring monument to the art and industry of Mr. Peterson. Though not a politician, Mr. Peterson served as a trustee of Jefferson many years, and most of the good roads and bridges in that district are due to his efforts. Peterson Avenue, which was named after him, he opened for a distance of three miles at his own expense. As a philanthropist his name is known from one end of Sweden to the other. Mr. Peterson was for many years a member of the Union League and Germania clubs, and of horticultural societies at home and abroad. In 1894 he was made a Knight of Vasa by the King of Sweden.—*American Daily Paper*.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

ORCHID COMMITTEE.

PRESENT: Harry J. Veitch, Esq. (chairman), Messrs. James O'Brien, de B. Crawshaw, H. Ballantine, Norman C. Cookson, Walter Cobb, W. F. Biney, E. Hill, Francis Wellesley, H. T. Pitt, J. Wilson Potter, H. A. Tracy, H. J. Chapman, T. W. Bond, A. McLean, M. Gleeson, J. W. Odell, W. Boxall, W. H. Young, F. J. Thorne, F. W. Ashton, W. H. White, H. Little, and J. G. Fowler.

In the group of Orchids shown by Messrs. Sander and Sons, St. Albans, Phaius were largely represented. The plants were carrying splendid racemes of flowers, were the picture of good health, and growing in leaf-soft in comparatively small pots. Other remarkable plants were *Odontoglossum wilckeanum* var. *illuminatum*, bearing seventeen flowers on one raceme; *O. w.* var. *Rex*, with sixteen flowers, also on one raceme; *O. harrayo-crispum* var., *Cypripedium Illione*, *C. illustre*, *Pleurothallis Roezlii*, *Tetramera bicolor*, &c. Silver-gilt Flora medal.

Messrs. James Veitch and Sons, Limited, Chelsea, in a small and choice collection showed *Platyclinis* (*Dendrobium latifolia*, *Laelio-Cattleya Lucilise* (*C. dowiana* × *L. elegans*), *Calanthe gigas*, *Dendrobium Scylla* (*D. japonicum* × *D. Cybele*), *D. Ainsworthii sulphureum* (a large flower with pale sulphur-coloured sepals and petals and purple lip, edged with white), *Cypripedium Eurycles*, *zuttatum*, *C. Leonidas albidum*, *C. lathamianum*, and others. Silver Flora medal.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, N., exhibited a group of Orchids, among which we noticed *Dendrobium Boxalli* (very well flowered), *D. brymerianum*, *D. rubens grandiflorum*, *D. wardianum* Lowii, *Cypripedium Olivia* (*C. toussim* × *C. niveum*), a very charming flower; *C. Leonidas*, *C. Eurycles*, *C. Chapmanii*, several beautiful *Lycastes*, notably *L. Skioneiri* *Glaflator*, *L. S. Enchantress*, several *Odontoglossums*, *Cymbidium traceyanum*, *Cattleya Triane*, and other choice Orchids. Silver Flora medal.

Captain Holford, C.I.E., Westonbirt, Tetbury (Orchid grower, Mr. Alexander), contributed several very choice Orchids, notably *Lycaste Mary Gratrix* (a rich rose buff), *Laelio-Cattleya Afterglow* (with beautiful yellow sepals and petals and brick-red lip), *Miltonia bleuana grandiflora*, *Odontoglossum crispum* (splendidly flowered), *O. loochristiense* Lord Howick, *O. Adriane* Countess of Morley, and others. Silver Flora medal.

The Orchids from Jeremiah Colman, Esq., Gatton Park, Reigate (gardener, Mr. W. P. Bound), comprised plants of *Laelia anceps* in several beautiful varieties. The choicest was *L. a. wadonensis*, with sepals and petals and the base of the lip pure white, with a yellow throat marked with faint purple. There were also *L. a. hilliana* *rosefeldense*,

tenebrosa × *C. anrea*, *C. Triane delicata*, *Odontoglossum harrayo-triumphans*, and *Cypripedium Hera* var. *Madeline*. Vote of thanks.

Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gardener, Mr. W. H. Young), sent *Cypripedium chamberlainianum* × *C. concolor*, *Odontoglossum Ruckeri* × *triumphans* was shown by Messrs. Stanley, Ashton and Co., Southgate, N.

Mr. H. A. Tracy, Orchid Nursery, Twickenham, sent *Cypripedium villosum* var. *anreum*.

F. Wellesley, Esq., Westfield Common, Woking (gardener, Mr. J. Gilbert), showed *Cattleya choecensis*, Westfield var., *C. wellsiana magnifica* (a large flower, with rich purple lip), and *Cypripedium Eurycles* × *Charlesworthii*.

W. Sampson, Esq., Walton Grange, Stone, Staffordshire (gardener, Mr. W. Stevens), sent a cut raceme of *Odontoglossum harrayo-crispum* *The Queen*, heavily marked with chocolate colour upon a very pale green ground.

Mr. James Douglas, Edenside, Great Bookham, sent a cut raceme of a white *Laelia* (? *L. anceps Stella*); the flowers were very fine. Mr. Douglas also sent *L. anceps percivaliana*.

Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne, showed *Phaios-Calanthe* × *Ruby*, and an unnamed hybrid.

H. Whately, Esq., Kenilworth, sent *Cypripedium aureum virginalis*, *C. Leonidas*, and other *Cypripediums*.

From W. M. Appleton, Esq., Tyn-y-Coed, Weston-super-Mare, were sent *Cypripedium Lady Roberts* (*C. harrisianum superbum* × *C. niveum*), *Cattleya Triane* (Appleton var.), and *Cypripedium lanthe superbum* (*C. harrisianum anpernum* × *C. venustum*).

A flower of *L.-C. luminosa* (*L. tenebrosa* × *C. anrea Rossita*) was shown by M. L. Fournier, Marseilles, France. The flower was somewhat faded, its petals and sepals were rich apricot-buff, and the large prominent lip crimson-purple.

CERTIFICATED ORCHIDS.

Dendrobium Wigauu xanthochilum.—A beautiful and dainty flower, of a uniform pale buff colour, except for a dark crimson-brown blotch bordered by yellow in the throat. The flowers are not large, the petals are somewhat twisted, and the base of the lip recurves slightly. The plant shown was splendidly flowered, the numerous closely placed blooms making a pretty display. From Sir Trevor Lawrence, Bart., Burford Lodge, Dorking (Orchid grower, Mr. W. H. White).

Odontoglossum wilckeanum var. *Rex*.—A very fine *Odontoglossum*, with petals and sepals tapering at base and apex, heavily blotched with chocolate-red upon a dull yellow ground. The sepals are more heavily marked than the petals, and are almost wholly coloured. The lip is blotched with shining brown and marked with yellow below the column. From Messrs. Sander and Sons, St. Albans. Award of merit.

Odontoglossum loochristiense Lord Howick. A very handsome flower, rich yellow being the predominating colour. Sepals and petals are almost wholly yellow, the former having a few blotches of chocolate-red, the latter scarcely any. It is not the marking of this flower, however, but the ground colour, which is a clear good yellow, that makes it so striking. Shown by Captain Holford, Westonbirt, Tetbury, Gloucester (Orchid grower, Mr. Alexander).

Cypripedium Minos Young's var.—A very pretty flower with a large broad dorsal sepal marked with irregular lines of purple upon a white ground, except around the centre, which is green. The petals are drooping and reach to just below the lip, they and the lip are shining brown. From R. Briggs-Bury, Esq., Bank House, Acreington (gardener, Mr. J. Wilkinson). Award of merit.

Odontoglossum crispum Cooksonii.—This new *Odontoglossum*, obtained among others in an importation, created a great deal of interest and attracted much attention. The flower is large, the sepals and petals broad, with slightly fringed edges. Both sepals and petals are marked with blotches of rich ruby-brown, so regularly as to form a circular band of this colour, leaving a white centre and white edges. The lip is small and insignificant, tapering towards the lower end, and with a blotch of pale ruby-brown. It is altogether a striking flower, symmetrical, and of good colour. Exhibited by Norman C. Cookson, Esq., Wylam-on-Tyne (gardener, Mr. H. J. Chapman), and given a gold medal and a first-class certificate.

Laelio-Cattleya wellsiana magnifica.—Exhibited by F. Wellesley, Esq., Westfield, Woking (gardener, Mr. Gilbert). Award of merit.

FLORAL COMMITTEE.

Present: W. Marshall, Esq. (chairman), Messrs. George Nicholson, R. Dean, John Green, Amos Perry, J. F. McLeod, James Hudson, J. Jennings, G. Reuthe, W. Howe, C. R. Fielder, Charles Dixon, C. G. Salter, W. Bain, Charles Jeffries, Herbert J. Cutbush, R. W. Wallace, W. Cuthbertson, R. Wilson Ker, W. P. Thomson, E. H. Jenkins, W. J. James, Harry Turner, and George Paul.

Messrs. William Bull and Sons, Chelsea, set up a large group of Palms that included several species of *Livistonia*, *Thrinax*, *Phoenix*, *Cocos*, *Kentia Pritchardii*, *Areca*, and the like. Indeed, all the best-known species were fully represented in a large array of plants. Most of the plants were of the useful size, others again were large towering examples suited to elaborate decoration. Among smaller and dainty kinds *Thrinax elegans* was very beautiful, and a perfect plant for table work. Silver-gilt Banksian medal.

Mr. John Russell, Richmond, and white *Mezereon*, *Prinus triloba*, *Eurya latifolia variegata*, *Ivies*, *Berberis*, *Picea*

THE LATE CAPTAIN TORRENS.

L. a. sanderiana, and *L. a. Stella*, all having pure white sepals and petals, the lips being variously coloured. *Dendrobium wigauuianum*, several varieties of *D. nobile*, *D. Aspasia*, *D. Ainsworthii Colmanii*, *D. Cybele giganteum*, *D. Rainbow* and others, *Masdevallia courtauldiana*, and *M. tovarensis* were also very good. Silver Flora medal.

H. T. Pitt, Esq., Rosslyn Gardens, Stamford Hill, N. (gardener, Mr. F. W. Thurgood), showed a very varied group of Orchids, several pans of *Celogyne cristata*, *Cypripediums* of sorts, *Dendrobium atroviolaceum*, *Phaleopsis*, *Cattleyas*, *Maxillaria luteo-alba*, *Eulophia pulchra*, *Laelio-Cattleya Sunray*, *Bulbophyllum raufianum*, and others. Silver Flora medal.

Sir Trevor Lawrence, Bart., Burford, Dorking (Orchid grower, Mr. W. H. White), showed a small group of *Dendrobiums* well-flowered and of much beauty. Most conspicuous was *D. Wigauu xanthochilum* (which obtained a first-class certificate), *D. xanthocentrum pallens* (with orange blotched lip), *D. Juno*, *D. splendissimum grandiflorum*, *D. pallens*, *D. xanthocentrum*, and *D. chrysoideus* (the lip having a very dark crimson central blotch surrounded by orange-yellow) were also good. *Sophroneites rossiteriana* (with orange-yellow flowers), *Sophroneites Psyche* (the flower vermilion), *Laelio-Cattleya Sunray*, *L.-C. Adolphus*, and *L.-C. Mrs. M. Gratrix* (a large flower, rich ochre) were also included. Cultural commendations were given to *Epidendrum polybulbon* and *E. p. luteo-alba* A botanical certificate was granted to *Bulbophyllum Suavisimum*. Silver Flora medal.

Messrs. Charlesworth and Co., Heaton, Bradford, Yorkshire, showed *Miltonia bleuana*, *M. Warszewiczii*, *Cattleya Adonis superba* (*C. Mossia* × *C. gigas*), a lovely flower, with deep lilac coloured sepals and petals, and a rich purple fringed lip, *Laelio-Cattleya Sunray* (*L. cinnabarina* × *C. superba*), the lip an intense crimson; *L.-C. luminosa* (*L.*

THE GARDEN

No. 1631.—VOL. LXIII.]

[FEBRUARY 21, 1903

ROSE EXHIBITIONS OF THE FUTURE.

WE have received an interesting letter about the Rose exhibitions of the future, and it is time societies in general mended their dull ways of repeating each year the methods of the preceding one until many a flower becomes wearisome and commonplace. A Rose exhibition should be beautiful and instructive. It should show those who are planting Roses in bountiful masses over pergola and in pleasure ground something of the effect certain varieties are likely to give in the garden. This is impossible from the methods adopted by committees of the present day.

The success of flower exhibitions in the future will depend upon good taste and a knowledge of what the general public requires. When the ways of a generation ago are forgotten we shall hear less of small or no balances and forsaken tents. The show of the Royal Horticultural Society in the grounds of Holland Park last year was almost perfect as a representation of British-grown flowers and plants beautifully grouped and displayed.

The show bloom, of course, must have its place. A prize flower of Maman Cochet, A. K. Williams, or whatever the variety may be, is in itself a thing of beauty, but to sacrifice the show to the big bloom is to bereft it of those features which appeal most strongly to the visitor who seeks to know the flowers most suitable for the border, bed, pergola, or fence. The classes for "garden Roses," for so long a feature of every Rose prize schedule, are insufficient. They teach little, and remind one too often of a nosegay in which the flora of a county is jammed into one unhappy and unwholesome-looking bunch.

As flower shows have enjoyed many years of public appreciation, it behoves those responsible for drawing up schedules to take heed of a widespread desire not only for greater taste in setting out the flowers, but for information about the varieties there displayed.

The report of the National Rose Society for last year is convincing proof of the need for reform. We are pleased to know that the subscribers have increased greatly. They are chiefly rosarians quite unconcerned about prize-winning, but simply eager to have Roses everywhere; they seek the show for new friends that will bring joy to their pleasure grounds and woodlands.

As all Rose schedules for the present year are compiled, we cannot look for any change this year, but we begin these articles in the hope that the subject so interesting to the vast majority of gardeners may be thoroughly discussed. We append the letter referred to.

"Signs are not wanting that we are on the eve of a new departure in Rose exhibitions, and in the opinion of all who have the interest of the Rose at heart anything that will tend to display it to the best advantage, and also to provide an interesting exhibition for the general public to view will be warmly welcomed. I quite agree with the remarks of your correspondent 'C. J. P.' in a recent issue of *THE GARDEN*. It is time the National Rose Society bestirred itself and catered for the public taste. And what is the public taste? Not the show bloom only. The great majority of visitors would much prefer to see a display of Roses of such kinds as they can grow themselves free from the artificial appearance of the overdressed show flower. Therefore, to fall in with popular taste the display classes should be in the majority instead of in the minority. And not only that, but provision should be made so that they may be viewed with comfort. To encourage the trade exhibitors to bring groups of Roses worthy of our country should be the aim of the National Rose Society. Hitherto it seems to have been their aim to exclude such groups, for the space allotted has been ridiculously inadequate. To carry out the decorative designs as they should be done the society must provide suitable decorative "greenery" in the shape of Palms, &c., and not only so but exhibitors should be enabled to prepare the day before the show. Only those who have had to do this work know the importance of preparing well in advance.

"It is a simple matter to place the flowers in water if the vessels are arranged previously; but the Rose is so fleeting a flower that it must be kept cool and under cover till the last possible moment. This day before preparation brings up the subject of place.

"A more miserable place than the Temple to hold a summer Rose show I cannot conceive. There are no beautiful cool retreats if the day be hot; nothing whatever for the visitors but to submit to the torture of stifling tents or glaring sun outside. One sighs for the days of the Crystal Palace again or of South Kensington. Surely other places are available besides these Temple Gardens! Why not Holland House or Regent's Park? The latter would be an ideal place. Let the various large firms put up a tent of their own in these grounds beneath the shade of trees. The wandering from one tent to another would alone be a delightful pastime for the visitors, to say nothing of the large tent where the boxes could be arranged. The small growers need not be alarmed that their exhibits would

pass unnoticed, for here in these capacious grounds room could be found for all. Obviously if a show of such dimensions could be arranged it would be a simple matter to extend it to two days. The great objection to a two days' show has hitherto been the unrepresentable appearance of the flowers on the second day, but the bad condition of the flowers has been caused more by the heat of the tents than anything else.

"I know it will be said that these displays do not encourage good cultivation. But if there is a modicum of truth in this (which I do not admit), I would rather encourage the more extended cultivation of this beautiful flower for the purposes of decorating the garden than solely for the show box. I love a show bloom as much as the most ardent exhibitor, but a handful of the exquisite Mme. Abel Chatenay appeals to me more than a perfect specimen of a Mildred Grant."

We believe entirely in the general remarks of our correspondent. Holland Park, it must not be forgotten, belongs to the Earl of Ilchester who has kindly allowed the use of the beautiful and restful grounds this year to the Royal Horticultural Society, and also that the Temple Gardens are central. The question of position is not, however, the object of this discussion. It is the show itself that is in need of reformation.

JAPANESE PLUMS.

So much interest was shown by those present at the annual meeting of the Horticultural Club recently in the Japanese Plums on the tables that we reproduce an article written by Mr. Watson in *THE GARDEN*, April 5, 1902, page 221, about these fruits. Mr. Watson kindly drew our attention to the fruits, of which we then gave an illustration and now reproduce. Mr. Pickstone, who formerly had control of Mr. Cecil Rhodes' fruit plantations, was present on that occasion and referred to the fruits. Their condition was due to perfect packing and cold storage. It seemed almost impossible to believe that fruits so fresh and good in colour, as if gathered the day before from a tree in an English orchard, could have matured in South Africa. At the March meeting of the club Mr. Pickstone has promised to read a paper upon commercial fruit growing at the Cape, a subject of much interest and importance.

"Fruits of these Plums are now to be seen in the fruiterers' shops. They are from South Africa, where a praiseworthy effort is being made to grow fruit for export to England and other European countries at a time when it should find ready acceptance. It is to be feared that the ridiculously high prices asked by dealers in this country for these Plums—from 6s. to 10s. per dozen—will throttle this effort of the enterprising cultivator

in South Africa, which really deserves every encouragement.

"Japanese Plums have been brought into notice by our American cousins, who grow them largely. Their history is told by Professor L. H. Bailey, of Ithaca, New York, in a *Bulletin* published in 1894 by the University of Ithaca, from which the following is taken:—

"In 1870 Mr. Hough, of Vacaville, California, secured several Plum trees from Japan through Mr. Bridges, a United States Consul in that country, at a cost of 10dols. each. These trees soon passed into the hands of the late John Kelsey, of Berkeley, California, who obtained the first ripe fruit in 1876 or 1877. Mr. Kelsey became convinced of the value of this Plum for general cultivation, and its propagation on an extensive scale was begun in 1883 by W. P. Hammon and Co., of Oakland, who afterwards named it in memory of Mr. Kelsey, and who made large sales in the planting season of 1884. Subsequently, other parties, particularly Luther Burbank, of Santa Rosa, California, made importations of Plum trees from Japan, and have disseminated the varieties widely. For the past four or five years these Plums have awakened more interest throughout the country than any other new or recent type of fruits; and it has been found, contrary to the early opinion, that many of them are adapted to the Northern States. Whilst they are often inferior in quality to the best garden Plums (*P. domestica*), they possess various desirable characteristics which the others do not, particularly great vigour and productiveness of tree, comparative freedom from disease, great beauty and long-keeping qualities, and the best of them compare well in quality with the common Plums."

"I had often heard of the merits of these new Plums from American horticulturists when visiting Kew, including Mr. Bailey, and, although I was assured by English fruit growers that they were of no value in this country, I included a chapter on them in the new edition of 'Thompson's Gardeners' Assistant,' vol. iv., page 162, with figures of four varieties and descriptions of thirteen. When they were first tried in the United States they were condemned on account of the tenderness of the tree and the poor quality of the fruit. It is clear that the evidence was insufficient, and, luckily, it was not considered conclusive. Probably we shall find the objections against them in this country equally unfounded.

"The fruits now offered for sale in this country have much to recommend them. They are large, handsome, distinct in form, and, although lacking the quality of a first-rate English Plum in September, it must be remembered that the fruit has undergone a long sea voyage and the numerous disadvantages attendant on a passage through the tropics for a fruit of this character. The reports from the United States are highly favourable. 'The best of them are nearly equal to the best of the European kinds'; 'they are less seriously attacked by insects and fungi than the common Plums are'; 'they have long-keeping qualities.'

"The origin of Japanese Plums appears to be from a Chinese species of *Prunus* named triflora, by Roxburgh, from a specimen found in Calcutta Gardens over seventy years ago. It is characterised by having three flower-buds at each node, whereas *P. domestica* has only one, rarely two. The fruit of the Japanese Plums is globular, or more often conical, and with a deep depression at the base and a very prominent suture, the flesh clinging to or free from the smooth or lightly pitted scarcely winged pit.

"The varieties recommended by Bailey are Abundance, Kelsey, Burbank, Chabot, Satsūma, Red June, Lutts, and Engre. They are catalogued by the leading fruit tree dealers in the United States."

THE KELSEY OR JAPANESE PLUM (NATURAL SIZE).
(The fruits created much interest at the annual meeting of the Horticultural Club recently.)

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

February 24.—Meeting of the committees of the Royal Horticultural Society, Drill Hall, Buckingham Gate, S.W.

March 2.—Société Française d'Horticulture Meeting.

March 3.—Meeting of National Amateur Gardeners' Association.

March 9.—Annual General Meeting of the United Horticultural Benefit and Provident Society, Caledonian Hotel, Strand, at 8 p.m.

March 11.—East Anglian Horticultural Club Meeting.

Royal Horticultural Society.—Surplus funds.—An error occurs in THE GARDEN of last week, page 101. The surplus funds of the society amount to £16,000, not £1,600 as there mentioned.

The mild weather.—The mildness of the weather during the last fortnight has been remarkable. During this period, day and night, the temperature has not fallen below 45°. The result may well be imagined—fruit tree buds are swelling fast. As a matter of fact I notice one or two trees actually showing the young foliage. Roses are growing on apace, whilst shrubs generally, if the mild weather continues, will be a mass of greenery. The result will obviously be a failure of the fruit crop, as we are almost certain to experience sharp frosts during March. Although mild weather is welcomed by many, yet to the gardener and farmer sharp frosts and general cold weather for a time would surely have a better reception.—J. DENMAN, *Stroud, Gloucestershire.*

The mildness of the season is illustrated in a surpassingly beautiful manner in my garden, where an Almond is fast advancing to full flower. It is the only one I have, and the fact that it is sheltered no doubt accounts for its being a few days in advance of many in the surrounding neighbourhood.—H. W.

Visiting Mr. Ernest Mannington at Eaglesden, Benenden, Cranbrook, a week or so ago I saw decided evidences of the exceptional earliness of the season in the Black Currant quarters. Many of the plants had quite burst the upper buds—in

some cases the leaves were unfolding—and all the buds were nearly fully swelled up. This does not promise well for this season's crop, as late frosts of any severity are bound to do immense damage. By the way this is one of the few places in which of late years I have seen no traces of the dreaded big bud.—H.

Forthcoming fruit and vegetable show at Chiswick (September 29, 30, and October 1).—A desire has been expressed in several quarters that some idea of the vegetable schedule should be put forth at once. It will include classes for

a.	Single dishes of all sorts of vegetables.	
b.	Collection of vegetables (trade only) 100 sq. ft.	
	" " (amateurs) 50 "	
	" " " 24 "	
	" Pumpkins and Gourds (open) 50 "	
	" 18 vars. Potatoes (trade).	
	" 12 " " (amateurs).	
c.	3 dishes of Peas, distinct	"
	6 " Round Potatoes	"
	6 " Kidney "	"
	3 " " "	"
	3 " Round "	"
	4 " Tomatoes, distinct	"
	2 " " "	"
	9 vars. salad plants in basket	"

Royal Horticultural Society.—The next fruit and flower show of the above society will be held on Tuesday next in the Drill Hall, Buckingham Gate, Westminster, 1—4 p.m. A lecture "On the Use of Ether and Chloroform in the Forcing of Shrubs" will be given by M. Emile Lemoine. At a general meeting held on Tuesday, the 10th inst., eighty-two new Fellows were elected, amongst them being the Duke of Leeds, Viscountess Morpeth, Sir William Vincent, Bart., Sir Gilbert Greenall, Bart., Sir Harold Pelly, Bart., Lady Brownlow, Lady Evelyn Cotterell, and Lady Evelyn James, making a total of 220 elected since the beginning of the year. The society's annual examination in the principles and practice of horticulture will be held on Wednesday, April 22. Full particulars may be obtained by sending a stamped and directed envelope to the society's offices, 117, Victoria Street, London, S.W. The questions set at all the previous examinations are now published, price 1s. complete.

A pretty picture.—During a sunny afternoon recently at Kew a very pretty picture arrested my attention. It was a tree some 12 feet to 15 feet high of the Washington Thorn (*Crataegus cordata*), profusely laden with its small but bright red berries, which from my standpoint had as a background a tree of the Stone Pine (*Pinus Pinea*). From the dense head of the Pine the neighbouring Thorn stood out like a bright red cloud, particularly when lit up by the declining rays of the sun. The Washington Thorn is one of those species of *Crataegus* that might be more often planted than it is, as it is neat and distinct, while it is the last of the Thorns to flower, the period of blooming often extending well into July, added to which the berries are freely borne, and when ripe are brighter in colour than those of most species. The smooth glossy green leaves are, as suggested by the name, somewhat heart-shaped, but are cut up at the margins. This Thorn was introduced in 1738 from the United States, but is said to be less common there than it was formerly.

Azalea obtusa.—Botanically this is a form of *Azalea indica*, or, to be correct, *Rhododendron indicum*, for all the plants known in gardens as *Azaleas* are now included in the genus *Rhododendron*. To the lover of huge flowers this has little to commend it, for the flowers of the *Azalea* are comparatively small, but it forms naturally a sturdy freely branched bush. In size they are larger than those of the well known *Azalea amena*, but not much, while the colour is a bright salmon-red. There is a variety *alba* in which the flowers are white, though the majority of them are this, for there is generally a tendency to revert to the normal form, as is shown by the occasional production of red or parti-coloured flowers. In a warm greenhouse *A. obtusa* may be had in flower by Christmas or soon after, this being a point in its favour, as very few forms of *A. indica* will bloom so soon unless they are severely forced. The half ripened shoots of *A. obtusa* strike root readily if taken as cuttings, inserted in well-drained pots of sandy peat, and placed in a close propagating case in an intermediate temperature. By this means neat little bushes can be obtained, which are far more pleasing than if grafted on a naked stem, in which fashion our Belgian friends are so fond of treating all *Azaleas*. As illustrating this I have seen the pretty little spreading *Azalea balsamiflora* from the continent mounted up in this manner, and its individuality completely destroyed.—T.

Tabernamontana coronaria flore-pleno.—Though some publications give summer as the natural flowering period of this *Tabernamontana*, it is not limited to that season, for some examples of it are now blooming freely, and are much appreciated. It is a fairly well-known stove shrub, bearing a considerable resemblance to a *Gardenia*, while the flowers are much like those of a double-flowered *Nerium* or *Oleander*; indeed, the single form has been known as *Nerium coronarium*. This was introduced in 1770 from India, of which region it is supposed to be a native; at all events, it is generally cultivated there. Both the single and double-flowered forms are well worth growing, and when in good condition the deep green shining leaves serve admirably as a setting to the white blossoms. When once large specimens are established in good-sized pots they will remain in condition for years without repotting, provided they are given weak liquid manure and soot water during the growing season. Though usually regarded as a stove plant, this *Tabernamontana* will flourish in an intermediate temperature, and if planted out it will make considerable growth and yield a corresponding number of flowers. Mealy bug delights in this *Tabernamontana*, hence every care must be taken to prevent the pests gaining possession of the plants.

Senecio grandifolius.—The *Senecio* genus is an extremely variable one, for among the many species that it contains are small weeds, showy greenhouse plants (some of which are quite succulent), free-growing climbers, and sturdy, almost tree-like kinds. To this latter section belongs that at the head of this note, which will reach a height of 10 feet to 12 feet, with the lower

portion of the stout stem quite woody in texture. The leaves from whence the specific name of *grandifolius* is derived are oblong, and in vigorous examples over a foot in length. The plant is from this point of view alone well worth growing, but it also possesses another claim to our notice, for the upper portion branches out and each branch bears a large, flattened, closely-packed corymb of yellow blossoms. These corymbs are as a rule borne closely together, so that the whole forms one large, terminal head. As the earlier blossoms often commence to expand before Christmas and a succession is kept up till spring is well advanced, its flowering period is by no means a limited one. By curtailing its rooting space this *Senecio* may be flowered when from 3 feet to 4 feet high, but it then lacks the dignity of a full-grown specimen. For many years it has at this season formed an attractive feature at Kew, both in the temperate house and in No. 4 greenhouse, but elsewhere it is rarely seen. A native of Mexico, it needs the protection of a greenhouse in this country. Beside the specific name of *grandifolius* it is also known as *Senecio* (*ghiesbreghtii*).—H. P.

A note from Worcestershire.—Despite the fact that Wm. Howitt, in his "Book of the Seasons" depicts this month as "the most cheerless in the year," in a mild season such as this it is full of interest to anyone who grows (and who does not?) the early flowers which are the harbingers of spring. Since January 17 we have had no frost worth speaking of, and now each day fresh heralds arrive to announce Nature's reanimation. *Corydalis kolpakowskyana*, *Narcissus minimus*, and *N. obvallaris* made their first appearance above ground the first day of the new year. The *Corydalis* was in bloom by January 25, and amongst others were the noble *Galanthus Imperati Atkinsii*, *Cyclamen Coum*, blue *Primroses*, and *Daphne Mezereum* and its variety *album*. To-day (February 6) *Saxifraga burseriana major* is covered with opening buds, and the new *Saxifraga Griesbachii*, which promises to be a great addition to the early-flowering *Saxifragas*, is sending up two spikes of bloom and should be in beauty by the end of the month. One of the most beautiful hardy flowers now in bloom is *Anemone (Hepatica) angulosa atro-cerulea*, raised some years ago by Mr. Wm. Horsman, who is in charge of Messrs. R. Smith and Co.'s extensive collection of hardy plants. The flowers (of which I send a few) are a rich purple-blue, considerably darker than those of *Angulosa*, and also much larger, while it differs still further by the leaflets just under the flower being brown, and the stamens darker and bolder. We have planted thousands of *Snowdrops* beneath Beech and other deciduous trees, and they are now very beautiful.—ARTHUR R. GOODWIN, *Kidderminster*. [The *Hepatica* sent (*atro-cerulea*) has flowers of intense blue, a very beautiful flower.—En.]

"Indian Planting and Gardening."—This flourishing journal, published at Calcutta, and devoted to the interests of economic plants and ornamental gardening, has appeared in a new form, in which the gardening is prefaced by the planting section. The title of the journal is now as above, previously it was "Indian Gardening and Planting." Although the position of the horticultural matter has been changed, this is not less than usual, neither has it lost in interest.

Flowers from France.—During the past few days tremendous quantities of these have been arriving, and considering that there is a good supply of English cut flowers they have been making very fair prices. Two thousand baskets reached Charing Cross on the 9th inst., the largest consignment ever known. The demand for cut flowers for table and room decoration has increased by leaps and bounds in London and the large English towns. Our own growers can to a great extent meet this demand during the summer and autumn, but during the often too sunless winter and hither early spring they can but partially do so. At the present time there are nearly 9,000 flower farmers in the Department of the Alpes Maritimes, and the capital invested is estimated at upwards of £2,000,000 sterling. During the busy season from 2,000 to 2,600 baskets

a day are despatched, weighing from about 100 to 130 tons. Paris alone receives 25,000,000 Rose blooms yearly from the Riviera, and from 70,000,000 to 80,000,000 Carnations. Violets are not so easily reckoned, a bunch of the large, highly-scented *Parma* Violets containing fewer individual blooms than one of the smaller varieties. But if we take only 25 as an average number in each market bunch, it would give the total of 2,000,000,000 blooms every season.

A prize for garden Cactus Dahlias.—At a recent meeting of the committee of the National Dahlia Society Mr. A. Dean complained that without asking for permission, his usual prize of 10s. 6d. had been inserted in the schedule as last year. He did not intend to give it, for his regard for Cactus Dahlias as show flowers was much less than was his interest in them as garden flowers. For that reason he proposed to offer the amount as a special prize for the variety of Cactus Dahlia grown for trial at Chiswick this year, which was declared by the committee of inspection to be the best for garden decoration. It is well to draw attention here with regard to this trial that only varieties sent out during the past five years will be received, and only two plants of each variety.

Horticulture at the St. Louis, U.S.A. Exhibition, 1904.—There will be a splendid conservatory for the reception of exotic and other decorative, ornamental, and useful plants, including those of the greatest size. This will constitute a portion of the home of horticulture, which is to cost about £41,500. The frontage is arranged for 800 feet, and the depth will be 400 feet. The aim is to make in this palace of fruit, foliage, and flowers a complete display of the gardening world. The exhibit is open to appliances and methods of pomology, viticulture, floriculture, and arboriculture; and in addition to tools of every description for gardeners and nurserymen, this includes greenhouses, aquariums, garden architecture, plans, models, pictures, and literature dealing with the subject. As to the vine, it is such an important branch of horticulture that the idea is to make viticulture a separate group. For historical and decorative purposes the schedule includes casts and models of fruits in wax and plaster. Arrangements have been made for a display of ornamental standard trees and shrubs, plants for the park or garden, herbaceous plants, such as Dahlias, *Chrysanthemums*, mosses, and baskets of flowers. Further, it is part of the plan to show the working results of forced culture, including specimens from as many different countries as possible, of forced vegetables and fruit, varieties of plants, cultivated for ornamental purposes, plants for houses of moderate and extreme temperatures. Seeds and plants for gardens and nurseries are included—*i.e.*, collections of vegetable seeds and young trees, whether seedlings or grafted. Another group in the department will be devoted to ornamental trees and shrubs, fruit trees, the vine, and small fruits, while, with the idea of presenting the full scope of the profession of gardening, methods of propagating, planting, training, and pruning, as in use for any member of the species, will form a part.

Giant Snapdragons.—Those who have only contented themselves with naturalising the common forms of *Antirrhinum* in odd nooks and corners, or grown the so-called dwarf bedding type, have no conception of the splendid display that may be made by massing varieties of *Antirrhinum majus* (the giant Snapdragon). I was prepared for some good results when starting their culture, but the growth made far exceeded my expectations. Many of the first spikes were nearly 6 feet in height, and these being promptly removed with the first appearance of seed there was a second display almost equal to the first. Plants can be purchased if this is deemed advisable, but quite as good results are obtainable from seed if the latter is purchased from a firm making a speciality of hardy flowers. Named varieties with a description of colour are available, and 90 per cent. of the seedlings come true. Sow in June in boxes, and as soon as the seedlings can be handled prick out

in frames in soil that should be rather heavy to ensure short stocky growth. Keep through the winter in frames and plant in spring in prepared beds. I write prepared advisedly, because although any sort of soil may do for the common Snapdragon, this is not applicable to the forms under notice. I should recommend bastard trenching and a liberal addition from a heap of stiff road sidings. Two things are imperative in the after culture, viz., the early removal of the first spike to ensure the second display, and also staking to prevent the breaking down of spikes; these are brittle, and without support will be snapped off with the first high wind.—E. BURRELL, *Claremont Gardens, Esher.*

TREES AND SHRUBS FOR BRITISH GARDENS.

THE BARBERRIES.

(Continued from page 95.)

B. WALLICHIANA.

AMONG dwarf evergreens this Barberry deserves a high place. It is quite hardy and flowers freely, yet it is by no means commonly used. Originally discovered by Dr. Wallich in Nepal, it was introduced in the late "forties" by Sir Joseph Hooker, also by Thomas Lobb for Messrs. Veitch. It grows from 3 feet to 5 feet high in this country, but is said to become twice as high as that in the Himalaya. It produces a dense thicket of erect shoots, which branch towards the top and bear an abundance of very dark green leaves of lanceolate outline and armed with slender teeth. In one form of the species the leaves are of a striking glaucous white beneath. The flowers, of a pale but bright yellow, are produced singly on the stalks, but a cluster of them proceeds from each tuft of leaves. The fruit is narrow, long, and black.

Var. latifolia.—This has long been in cultivation, but has been figuring for some time

as a new plant under the name of *Berberis Knightii*. It differs from the ordinary *B. wallichiana* in being of taller, more robust habit (it is 5 feet high at Kew) and in having larger leaves.

Var. microcarpa is a smaller-fruited form from the Khasia Hills. Where a dwarf hardy evergreen is needed that will not require pruning to keep it dwarf, planters might give this species a trial. It can easily be increased by seed, also by division.

II.—DECIDUOUS SPECIES.

B. ACTINACANTHA.

In foliage this species is very distinct. Its leaves vary in shape, some being roundish ovate, others somewhat heart-shaped; they also vary in size from a quarter of an inch to 1½ inches in length. They are borne in rosettes along the branches, each rosette springing from a five-lobed spine. As was remarked in the introductory part of this paper, the spines on Barberries are really modified leaves. *B. actinacantha* proves this, for the spines, on young plants especially, often revert to a semi- or wholly-leafy state, and become palmate leaves. It is this character that gives the species so distinct an aspect among garden Barberries. The shrub grows about 3 feet or 4 feet high, and bears its flowers singly on the stalks, a cluster of which springs from each leaf-rosette. They are deep yellow, and have a sweet fragrance. The species is common in a wild state, and has often been introduced from the mountains of Chili. Still it remains rare. It first flowered in the Chiswick Gardens in 1845.

B. ÆTENSIS.

This seems to be no more than a mountain form of *B. vulgaris*. In habit it is dwarf and stunted, and grows about 2 feet high. The leaves are often very small, quarter of an inch to half an inch long, and the flowers are in dense racemes 1 inch to 2 inches in length. The fruit is red, and also small, but in other respects resembles that of *B. vulgaris*. This shrub,

which flowers in May, and is then very pretty, is suitable for a rock garden.

B. ANGULOSA.

Although discovered early in the last century in Kumaon, and afterwards by Sir Joseph Hooker during his Himalayan travels between fifty and sixty years ago, this distinct Barberry has never become common. It is, however, perfectly hardy, and thrives very well indeed at Kew. It is a dense but graceful bush, 3 feet to 5 feet high, very luxuriantly furnished with dark green leaves borne in clusters at each joint on the stem, which is armed with three or five-branched spines. The leaf is 1 inch to 1½ inches long, and obovate. The flowers are produced one (or, very rarely, two) on each stalk, and, for a Barberry, are large—half an inch to two-thirds of an inch in diameter—and of a pale golden-yellow. The species is ornamental in autumn both for its large berries, which are scarlet, and for its foliage, which dies off in rich yellow and red shades.

B. ARISTATA.

On the whole this is, I consider, the most useful of all the Himalayan Barberries. A strong and very robust grower, it is not very particular as to soil or position, and is perfectly hardy. It is an excellent shrub for establishing as an isolated specimen on a lawn. Growing 8 feet or more high and sending out its long shoots in an arching manner, the lower ones touching the ground, it ultimately forms a large, somewhat hemispherical mass 15 feet across. It is deciduous, but young vigorous plants, or young sucker growths, will retain the foliage through the winter. It is a variable plant, and possibly more than one species are grown under the name. The following is a description of the common form, and what may be regarded as typical: Leaf 1½ inches to 4 inches long (various sizes being borne in each cluster), and varying in outline from oblong to obovate; the margins are toothed, and each leaf cluster is guarded by a single or triple spine. Flowers bright yellow, and loosely borne on the terminal part of the pendent branching racemes. These racemes are frequently 5 inches or 6 inches long, and very bountifully produced. The species flowers in the latter half of May, and will then hold its own with almost any of the numerous shrubs in flower. The fruits are very free and handsome, being covered with a blue-white bloom. The bark of the young branches is grey.

Var. floribunda is recognised by botanists, being distinguished by its smaller leaves and longer-stalked flowers.

Var. integrifolia is the name given to a form whose leaves are without teeth.

B. CANADENSIS (AMERICAN BAR-BERRY).

There are only two species of the true Barberries found in North America; the rest belong to the Mahonia group. *B. canadensis* is one, *B. Fendleri* from the Rocky Mountains the other. In spite of its name, however, *B. canadensis* is not Canadian; it is confined to the Alleghany Mountains, and commonly inhabits the banks of mountain streams from Virginia southwards. As an ornamental shrub it is, perhaps, scarcely so handsome as *B. vulgaris*, which it much resembles. It is, in fact, the

A JAPAN VINE (*VITIS THUNBERGII*) AT NARROW WATER, COUNTY DOWN.

American representative of the vulgaris section, and differs from the common Barberry in the following points: The flowers are smaller, and are borne in more corymb-like racemes; the fruit is shorter, almost globose.

Except as a shrub of geographical interest, *B. canadensis* need not be grown. It is, of course, very pretty, but *B. vulgaris* may be said to fulfil better all the purposes to which it may be put.

B. CONCINNA.

Of the Himalayan Barberries this is the dwarfest; it is also one of the most distinct, because of the intense blue-white colour of the under surface of its leaves. It is a bush of neat habit, 2 feet to 3 feet high, its leaves being half an inch to three-quarters of an inch long, obovate, and armed with (proportionately) long, spiny teeth; the upper surface is deep green, and, when a branch is inverted, surprisingly in contrast with the vividly glaucous under surface. A slender, three-parted spine guards the base of each leaf-cluster. The flowers are deep yellow, solitary (or sometimes in pairs), on slender, thread-like stalks over 1 inch long. The fruits are half an inch long, and bright red. This distinct and pretty little shrub is not common in gardens. It is a native of the Sikkim Himalaya at 12,000 feet to 13,000 feet altitude, often in company with *B. angulosa*.

B. CRETICA.

This is a low, sometimes prostrate shrub, found on the mountains of Crete and other islands of the Mediterranean Sea. It is probably a close ally of *B. vulgaris*, but smaller in all its parts. The largest of its leaves are about the size of those of the common Box; the leaf clusters are closely set on the branches, and as each cluster is guarded by a strong triple spine the plant is rather formidably armed. The flowers are borne in a short, few-flowered raceme. The species is perhaps best suited for the rock garden, being a densely-branched scrubby bush. It has been in cultivation in England for about 150 years, but the true plant is rare.

B. DIAPHANA.

Of this new and rare Barberry not much is known in this country. There is a plant 4 feet or 5 feet high at Kew, but it has not yet flowered. It is a native of North-West China, where it grows 10 feet high. Its leaves are obovate, variable in size, the largest $1\frac{1}{2}$ inches to 2 inches long. Each leaf cluster is guarded by a triple spine, the branches of which are frequently 1 inch to $1\frac{1}{2}$ inches long, and being of a pale reddish brown form quite a feature at this season when the plant is leafless. The flowers are borne singly, or rarely in pairs, on their stalks. The berry appears to be the most noteworthy part of the plant; it is of oval or ovate form with the apex twisted over, and of a beautiful pellucid, opal-like colour. It is to this transparent character that the name *diaphana* refers.

B. DICTYOPHYLLA.

One of the numerous plants introduced from Yunnan in recent years, this is also the newest of garden Barberries. It has flowered at Kew twice, and promises to be a useful addition to hardy shrubs. It was discovered in Yunnan in 1886 by the Abbé Delavay, reaching culti-

THE ROCK GARDEN AT NARROW WATER, WARRENPOINT, COUNTY DOWN, IRELAND.

vation by way of France. Its most distinctive characters are its long, slender, arching branches, and its small leaves very glaucous white on the under surface. It flowers early in May, producing its blossoms singly or in pairs from the centre of a rosette of leaves; as these rosettes occur at intervals of less than half an inch, the bush then makes a very pretty display. The flowers are yellow, but of a paler shade than is found in, perhaps, any other cultivated Barberry. The leaves average half an inch in length, are stalkless, obovate, and armed with four or five spiny teeth. Each rosette of leaves springs from the axil of a triple spine. The berries are roundish and bright red. The plant at Kew—the first introduced to this country—is at present 3 feet high, but, growing quickly, promises to become ultimately at least twice as high. Among the older Barberries the nearest ally to this is the Himalayan *B. angulosa*, already described, but I think the Yunnan plant superior.

B. FENDLERI.

As has already been remarked under *B. canadensis*, this is one of the two species that represent the true Barberries in North America so far as is known at present. It is a native of New Mexico and has only been collected in the mountains near Santa Fé. It is rare even there. It was figured in *Garden and Forest* in 1888, where it is described as having shining green leaves; stems and branches purplish and shining as if varnished; flowers borne in racemes 1 inch to 2 inches long, and as large as those of *B. vulgaris*.

B. HETEROPHYLLA.

Of this curious and rare Barberry there is a good specimen at Kew about 3 feet high, which is almost as high as it gets to be. Its leaves are of two kinds, some being rounded at the apex and without teeth on the margins, whilst others end in a sharp point and are like little Holly leaves in shape and tootling. They vary also in size, but the largest ones are under $1\frac{1}{2}$ inches in length. From the base of each

leaf comes a single flower of a yellowish orange colour, and with the sepal and petals so incurved as to make each flower a little ball. The plant was discovered by Commerson in the Straits of Magellan, and is also found in other parts of Patagonia and Chili. Its Holly-like leaves give it a resemblance to *B. ilicifolia*, also from the Straits of Magellan, but this latter is easily distinguished from *B. heterophylla* by bearing its flowers in racemes.

Kew.

W. J. BEAN.

(To be continued.)

AN IRISH GARDEN.

NARROW WATER, WARRENPOINT, COUNTY DOWN, IRELAND.

SEND you some photographs which were taken in the gardens here last September, some of which I hope you will be able to reproduce in THE GARDEN. The rock garden was begun in 1883, and has been added to considerably from time to time since. The *Dracenas* (*Cordyline australis*) ripen seed nearly every year, from which any number of young plants have been grown. The height of the *Dracena* on page 128 is 26 feet.

There are also two fine specimens of *Chamærops Fortunei*, which have been planted out for many years, and have proved perfectly hardy here; they are each about 12 feet high, with leaves to the ground. The *Gunnera manicata* was planted from a 7-inch pot in March, 1885. Its measurements last summer were: Height 13 feet 6 inches, circumference 85 feet, and one leaf that I measured was 11 feet across. It is the same plant of which there is an engraving in "The English Flower Garden," but it is very much larger now than it was at the time Mr. Robinson's photograph was taken. *Vitis Thunbergii* is a fine plant, too; besides covering a part of the garden wall, it

ASPIDIUM (POLYSTICHUM) MUNITUM AT NARROW WATER.

has spread into a 'Portugal' Laurel as well, against the dark foliage of which its brilliant leaves look lovely in the autumn. I have the Beech Fern (*Polypodium Phegopteris*) on a bank; the mass is about 6 feet square. I have also a fine specimen of the American Holly Fern (*Polystichum munitum*), which I am very proud of. I had it measured recently, there are 189 fronds; the plant is 4 feet 9 inches high and 9 feet through. *Woodwardia radicans* and *Dicksonia antarctica* are both hardy here.

R. HALL.

Narrow Water, County Down, Ireland.

THE ROSE GARDEN.

A BRILLIANT PILLAR ROSE.

WITH so many Rambler Roses available one is apt to overlook the merits of older varieties. There is one especially that I think should be preserved, and that is the Hybrid Chinese *Fulgens*. It does not, of course, compare with *Crimson Rambler*, but its brilliant crimson flowers are very lovely, and are endowed with that neat cupped form peculiar to a number of these old Roses. Its fine willowy growth and glistening foliage of a rich colour when in the young state makes this Rose an ideal one for pillars. The variety is one of the hardiest we possess, and should be more frequently planted in smoky and crowded districts.

FAST-GROWING ROSES FOR ARCHES AND PILLARS.

A SERIES of Rose arches spanning a broad walk or running parallel with it seems to me a more worthy method of displaying many of the beautiful fast-growing varieties than when such are planted to run upon a pergola roof. As Miss Jekyll well remarked in her lecture upon pergolas,

Roses can obtain plenty of air and light and clamber more conveniently when trained as pillars or arches if the continuous pergola is modified by erecting a series of arches instead. Such an arrangement is surely more in harmony with the modern Rose garden. The Ayrshire and evergreen Roses are never more beautiful than when drooping over in a veritable tangle of blossom some pillar, arch, or bower. We all know what may be accomplished with the delightful *Félicité Perpétue* when thus apparently neglected, but there are many others of the same tribe if not quite as beautiful, yet are as well worthy of being planted. To name a few there is the delicate tinted *Alice Gray*, the snowy white *Bennett's Seedling*, the almost Tea-like *Queen of the Belgians* (whose slender growths and pretty foliage contrast so well with the flowers), the blush-white *Ruga*, or the expansive and profusely flowered *Virginian Rambler*, which to my mind is one of the prettiest. Then there is vigorous *Flora*, with its neat little blossoms most beautifully fashioned, and *Myriantbes Renoncule*, too good to omit. All these are really fast-growing, and should be given rather lofty or wide arches. It is a matter of individual taste whether two kinds are planted on one arch. My own inclination is for one only, unless it were to plant an autumn-flowering variety with a summer one, in which case good contrasts should be selected. It would be a good plan to plant a moderate grower that blossoms freely to clothe the base of these arches—for instance, *Griess* an *Teplitz*, *Gloire des Rosomanes*, *Bardou Job*, *Laurette Messimy*, *Armosa*, *Sombreuil*, &c., which would make these arches more interesting in autumn.

Of the Multiflora or Rambler Roses planters have a rich selection to choose from, and it looks as though the variety would soon exceed the opportunities available whereby they can be utilised. These Multiflora Roses possess one great advantage over other classes, and that is the wonderful persistence with which the flowers remain upon the plant. I am sanguine enough to believe that a race of autumn-blooming Multifloras will be an accomplished fact before long. Already there is a *Perpetual Thalia*, and it is commended as being a good acquisition. The want of a perpetual character to the Rambling

Roses has been rather a disadvantage, because flowerless arches are not very picturesque. Already planters are promised an improvement upon *Crimson Rambler* in the American novelty *Philadelphia Rambler*, but some of these American novelties have an unhappy propensity of turning out identical with kinds already in commerce, although I am bound to say that in *Dorothy Perkins* we have a gem among fast-growing Roses. I quite expect to see this Rose in as great demand as *Crimson Rambler*, as the soft colour must tend to relieve the latter of a garish hue so inseparable from the variety.

A very charming variety of the Multiflora group is *Waltham Rambler*. It has been well shown, and its large but elegant trusses of Apple blossom-like flowers, combined with great vigour of growth, will be welcomed by all who desire to obtain quick effects from their Rambler Roses. For a very lofty arch, or for a position where a dense mass of growth is desired, *Aglaia* is the one best suited from the pale or nearly white varieties of *R. multiflora*. For an ordinary arch or pillar I should prefer *Electra*, as it is freer in blooming. No matter how this Rose is grown, whether upright or running over the ground, it is a delightful object, and has the merit of flowering on the one year old wood which cannot be said of *Aglaia*.

What a splendid arch Rose is *Claire Jacquier* if given a little shelter from cutting winds. It quickly forms a veritable bower. I would strongly recommend this Rose for a sheltered garden. There are other good Ramblers, such as *Queen Alexandra*, *Psyche*, *Helene*, *Reine Olga de Wurtemberg*, *Mme. A. Carrière*, &c., all of which deserve to be planted, if not on arches then as towering pillars.

I am not sure that we have exhausted all the means whereby we may display these fast-growing Roses to the best advantage. Those who have had to do with this class of Rose know how desirable it is to have a durable support for them, and were it not for the temporary unsightliness whilst the plants were growing I should advocate brick pillars, say about 6 feet to 7 feet high. When the Roses had reached the top, just allow them to grow in their own way, and there would be a delightful column of blossom, all too fleeting perhaps, but very beautiful whilst it lasted. In a modified form old tree stumps answer the purpose. I always admire the pretty arrangement that is made at Kew with the *Dawson Rose*; the roots are in good soil and the growths run in and out of some large tree stumps. What interesting objects would be the newer *Wichuriana* Roses planted after this fashion. It is absurd to restrict them to the procumbent habit of the type when they are so eminently suited for more artistic arrangement.

With all these fast-growing Roses the more their long and slender growths are allowed to droop naturally after reaching a certain height the more artistic will be the effect when in bloom, and we are much indebted to Miss Jekyll for popularising what she has happily termed the "Fountain Roses," a habit of growth strictly in accordance with Nature. Perhaps I might say a word or two as to the treatment of these fast-growing Roses after planting. Doubtless the best plan is to cut them back rather severely the first season. This applies more especially to plants from the open ground. When those fine long pot-grown plants with shoots 6 feet to 10 feet long are planted in spring their growths may be retained their entire length, and of course some bloom will be obtained, although meagre compared to their future beauty.

PHILOMEL.

NOTES FROM BADEN-BADEN.

Crocus Atticus purple to white, and *Crocus Alexandri* are now very pretty; the latter is pure white, streaked, flushed, and painted violet on the outside.

The free-flowering variety *Iris bakeriana* Norma is in full beauty; the flowers are larger, deeper, and brighter in colour than those of the type. The white variety of *Iris histrioides* has been as beautiful as before, but it increases very slowly.

Has any one ever seen *Lilium speciosum* roseum? It appears that this variety has entirely disappeared. I saw it in 1842, and was struck with its wonderful uniform rose colour about the same as in *L. rubellum*.

Most seeds of *Lilium* when sown in autumn after they are ripe germinate the next spring or summer; with *L. polyphyllum* I found that seed will remain dormant for eighteen months.

In THE GARDEN of the 10th ult. there is a description of *Thalictrum orientale* which is not quite correct. It is a very small species, only about 3 inches to 4 inches high, with elegant adiantum-like foliage and comparatively large purplish rose flowers; it always has been and still is a very rare plant.

Baden-Baden.

MAX LEICHTLIN.

CHRYSANTHEMUMS.

THE MOST PROMISING NOVELTIES OF 1902.

FOR the introduction of a large number of good novelties, and those chiefly in the Japanese section, the past season cannot be regarded as a remarkable one. The National Chrysanthemum Society's floral committee has adopted a new method of awarding its certificates, and any novelty thus honoured may be regarded as a good addition.

Every grower who is an exhibitor knows full well the importance of acquiring the best and most promising novelties as they come along, if leading prizes are to be won in the succeeding flowering season. The varieties described below have points of merit quite new in many respects, and each one has come under my own observation. In all cases where the letters "F.C.C., N.C.S." are mentioned they denote the fact that a first-class certificate of the National Chrysanthemum Society has been awarded to the variety under notice; "A.M., R.H.S.," denotes an award of merit of the Royal Horticultural Society.

JAPANESE VARIETIES.

George Penford.—One of the best novelties of the past season. The flowers are very large, both deep and broad, having long and broad strap-like florets of splendid substance. The florets curl prettily at the ends, sometimes revealing the rich golden reverse, which, contrasted with the deep crimson colouring of the flower, considerably enhances its beauty. When finished the flower is a weighty one for exhibition. F.C.C., N.C.S., October 27, 1902.

George Milham.—This is a large spreading flower of considerable promise, and will assist materially in enriching the displays in succeeding years. The florets, which are fairly broad, are also long and gracefully reflexed; they are also slightly curled and incurved at the ends, in this way revealing the pale bronze reverse. The colour is a rich and deep shade of rosy crimson. This plant has the reputation of being easily grown. F.C.C., N.C.S., November 17, 1902.

F. S. Vallis.—A Continental introduction of high quality. In some stages of growth the flowers remind one of G. J. Warren (the yellow *Mme. Carnot*), and this opinion was freely expressed. As the season advanced, however, the flower proved entirely distinct from all others;

the colour is a lovely soft sulphur-yellow, with long, narrow, drooping florets, building a bloom of reflexed Japanese form, and of exceptionally neat and even finish. A.M., R.H.S., November 18, 1902.

Miss Mildred Ware.—This is a Lady Hanham-coloured seedling from the popular Japanese variety *Mme. Carnot*, but, unlike the parent plant, of easy culture. Grown in the orthodox manner, or on single stems in 6-inch or 7-inch pots, it is a great success. The flowers are very large, with long reflexing and drooping florets of medium width, and with a pale golden reverse. There is little doubt the blooms of this variety will oust many old and popular exhibition sorts. F.C.C., N.C.S., October 27, 1902.

Miss Olive Miller.—When I saw this beautiful flower in the raiser's garden its superb finish and pleasing colour greatly impressed me. The colour is a distinct shade of pale rosy pink on a silvery white ground. Florets long and fairly broad, grooved and curling, and incurving at the ends, making a very full and deep flower. Later buds develop flowers of richer colour. Cuttings inserted in January gave excellent results from a natural break and first crown bud selection. Nine-inch pot; height, 4 feet. The plant will carry five good blooms. F.C.C., N.C.S., October 27, 1902.

Henry Perkins.—This is a very large flower, with exceptionally long and broad florets, which reflex and build up a flower of great breadth and depth. I have seen flowers of this variety measuring over 13 inches broad and 8 inches deep. First crown buds develop blooms of a reddish crimson colour on a deep yellow ground, and with a golden-bronze reverse. A second crown bud selection produces flowers of a rich crimson colour. Certificated in the provinces.

Mme. Paoli Raduelli.—This superb example of the incurved Japanese type, though not absolutely new, has been so well and also so consistently exhibited, and on each occasion in first-rate condition, that its Continental raiser may be justly proud of its origin. For its size, both in depth and breadth, without being in the least coarse, it is invaluable for exhibition. The florets are very long and fairly broad, neatly curling and incurving at the ends. Colour, pale rosy blush, tinted yellow in the centre. F.C.C., N.C.S., October 20, 1902.

Viscountess Cranbourne.—One of the most distinct Japanese blooms, having fairly long and broad florets of good substance twisting and intermingling

very prettily, and building an exhibition bloom of good size. The colour is one of its best features, and this may be described as absolutely the best rich canary-yellow flower of its kind. At the great November show of the National Chrysanthemum Society it scored many successes. The blooms are quite self-coloured.

Beauty of Leigh.—This is an immense incurved Japanese, developing flowers of wonderful depth and breadth, also of splendid substance. The florets are broad, and, as the bloom finishes, those in the centre reflex, revealing the rich canary-yellow colour. The reverse is a paler shade of the same colour. F.C.C., N.C.S., December 2, 1902.

Mr. T. W. Pockett.—A deep canary-yellow flower of even form, and one of the largest and best of the newer introductions. Florets long and rather narrow, neatly reflexing and building a bloom of drooping form and of great depth. A.M., R.H.S.

D. B. CRANE.

(To be continued.)

NOTES ON HARDY PLANTS

CROCUS HYEMALIS.

NOW that the winter-flowering *Crocus hyemalis* is procurable in quantity at a more moderate price than was the case a short time ago, a much greater use might be made of it than hitherto, either in the rock garden, the alpine house, or the cold frame. It is, of course, a small-sized *Crocus*, and there are some who prefer a brighter coloured flower, for its little blossoms are white, and do not make a bright patch of colour on a sunny day when a sprinkling of snow still lies on the ground. Yet these same flowers are very charming, either when open or in the bud stage among the grassy leaves which appear with the flowers.

More than once the flowers here have never opened, and have been so much injured by the wet seasons that they became like dirty white tissue paper. This would point to the desirability of protecting the flowers with a bell-glass or something of the kind, or of flowering this *Crocus* in a house or frame. This is not always convenient, and when grown in the open one prefers to have such things without covering. Last autumn I

GUNNERA MANICATA AT NARROW WATER, COUNTY DOWN.

succeeded in securing corns from a new quarter to me, and the flowers from this stock have proved to have more resisting properties than any I have had before. This is a decided gain, and a clump was in flower nearly all through January.

It appears rather singular that all the plants of *Crocus hyemalis* which are in cultivation in Great Britain and Ireland of which I have heard have the black anthers which Mr. Maw, in his "Monograph of the Genus *Crocus*," speaks of as being the distinguishing feature of the variety *Foxii*, though they have not the colouring on the exterior of the outer segments shown in the illustration of this variety in Maw's plate (No. xliii.). Were it not that that authority describes the anthers of the typical plant as orange, and gives a coloured illustration showing this colour, one might have concluded that all the plants of *C. hyemalis* had black anthers. These black anthers add greatly to the beauty of the flower when open, and, along with the fine brass wire-like divisions of the style, make a pleasant picture on a sunny winter day. *Crocus hyemalis* often flowers with us in December, but the sunless summer and autumn of last year have retarded many things ordinarily earlier than they are this season. It comes from Palestine and the borders of Syria, and in Mr. Maw's arrangement is included in the division *Nudiflori* and the section *Fibro-Membranacei*. It is a *Crocus* of modest beauty, endearing itself to us greatly by coming at a time when hardy flowers of any kind are highly appreciated.

COLCHICUM RITCHII.

THOSE who desire a little bright colour in the garden in the dullest months of the year will do well to plant the pretty little *Colchicum Ritchii*. It is really, according to Mr. J. G. Baker, a form of the rather variable *C. montanum*; but apart from the botanical distinction at the base of the filaments, which is of little account from the gardener's point of view, it is distinct from other varieties of *S. montanum* in form and colour. When in bud it is a remarkably prettily formed Meadow Saffron, while the colouring is a very pretty purple-rose. It does not resemble in form or habit the common *C. autumnale*, and the shortness of its tube renders it better able to withstand bad weather. It came into bloom here late in December, and lasted all through January—in a somewhat unpleasant month—without any protection from weather vicissitudes. Now it looks as if it would last all this month. *C. Ritchii* has been here for two or three years. For association with the Snowdrop, the Winter Aconite, the earliest Irises, the Hellebores, or the few early Crocuses it is invaluable. It gives much the same tint as *Bulbocodium vernum*, but appears to be slug-proof, which is not the case with that useful, though cheap, early flower, and it is of a much more pleasing form. I do not know the habitat of this form of *C. montanum*, which is a very widely distributed species, but it came to me from Newry I believe.

Carsehorn, by Dumfries, N.B. S. ARNOTT.

DAVIDIA INVOLUCRATA.

HERE is another beautiful tree for our ornamental collections, almost a fruit tree, since its fruit is eaten when it is ripe. A species quite new to horticulture is no mean introduction. We owe

this new plant to M. Maurice de Vilmorin. Here is its history:—

In 1871 Baillon, when studying the plants collected in China by Abbé Armand David, created the genus *Davidia* in honour of that learned naturalist, to whom science and civilisation are indebted for so many introductions, and described the first under the name of *D. involucrata*. The plant was discovered in Eastern Thibet. Eleven years later, in 1882, a new species appeared, which had been discovered in the same region by Abbé David, and this time named by himself *Davidia tibetana*. These two species belong to the small and curious family of Hamamelidæ, which has already given us *Hamamelis*, *Fothergilla*, *Corylopsis*, *Parrotia*, *Liquidambar*, &c. They had attracted the attention of M. Maurice

The notes which M. de Vilmorin sent to me deserve to be reproduced in their entirety: "The seeds were sown in three places—at Barres, in the open land, in the shade of a tree; at Verrières, in the open land, and in pots in strata; and in the garden at Reuilly after several months stratification in a cellar. In September, 1898, the results of the three sowings were equally unfavourable. At Reuilly and Verrières the kernels had rotted in the earth. At Barres my gardener, having taken some up from the earth, gave me the same news, which sorrowfully I entered in my journal. Nevertheless, in June, 1899, two years after the sowing, I had the joy of seeing a plant in the line of sowing at Barres. At the beginning of September I photographed the young plant, which was then from 15 centimetres to 20 centimetres high, and I received from London in the course of the autumn a few words from Dr. M. T. Masters, who had kindly compared this photograph with the plants in Kew herbarium. He agreed as to their similarity. I had besides for reference some badly formed fruits which had not been sown. During the winter of 1899-1900 the young plant which was left in its place was protected by a glass frame banked up with leaves at the sides. The same thing was done during the two following winters, though it is probable that on account of their mildness this precaution was unnecessary, still with so rare a plant it was worth while. In 1901 four cuttings and a layer were taken. Two of the cuttings perished in the pots. Of the two others one was sent to the museum and the other to Kew. The layer will be sent to M. Sargent."

¶ I saw at Barres in last July the parent stem of these *Davidia*. It measured 1.60m. in height, with erect branches somewhat spindle-shaped, and with foliage resembling that of the Lime tree. The leaves exhale an odour unlike that of the leaves of the common Fig tree; they appear to dread the full heat of the sun. This tree will therefore require a climate which is not too hot. Let us hope, however, that it will be in this respect less exacting than the *Cercidiphyllum*.

M. A. Fanchet, in his "Plantæ Davidianæ," while stating that the tree blossoms in April in the forests of Moupine, where it was first discovered in 1869, adds that he found it near the house of refuge constructed by missionaries to hide their Chinese converts during the times of persecution. He thinks that its culture could be attempted with success in France, and that we should admire its beautiful and curious white bracts. We now possess this horticultural novelty,

thanks to the perseverance shown by M. Vilmorin, and his rights of priority in introducing the living specimen ought to be recorded in good time, and this is what we are doing. No doubt steps will now be taken to procure more packages of the seed, and we shall soon be able to possess in our parks and gardens another beautiful plant from that Far East, so full of surprises.

ED. ANDRE, in the *Revue Horticole*.

ROUND ABOUT A GARDEN.

THE QUESTION OF BIRDS.

IN my last wandering the sight of a ruby-chested bullfinch glowing like an electric lamp in one of the Gooseberry bushes—by the way,

CORDYLINAE AUSTRALIS IN AN IRISH GARDEN. (See page 125.)

de Vilmorin, who pointed them out to travellers in those countries, and more especially to the missionary R. P. Farges, to whom he gave the most detailed instructions.

Success attended these efforts. In June, 1897, M. de Vilmorin received the first parcel containing the fruit of *Davidia involucrata* sent from Se Tchuen. Another package sent from Thibet reached him in 1898. In the first parcel, out of thirty-seven seeds one only germinated. From the second, containing three seeds, nothing came. The altitude, 1,400 metres, ought by analogy to correspond, according to the belief of M. de Vilmorin, to a minimum winter temperature of from 12° to 15° centigrade. The second parcel, which came from Eastern Thibet, was originally from Sou Kia Ouan. The Chinese name of the tree was Sin-Ko-Chou.

we had some Gooseberry blossom fully open on January 1 this year—started me off upon the general effect of birds in gardens. This, of course, led straight to the sparrow among the yellow Crocuses; and the sparrow suggested the starling. But there I stopped, because the starling in a garden needs a chapter to himself. Not that he is wholly bad by any means. His character is rather like his plumage, speckled all over with spots of misdoing, but glossed with many shining virtues. And it is worth while looking at the gloss upon the starling, as he parades about the turf on a sunny spring morning, in order to see what kind of starling he is, whether an English starling, a Siberian starling, or an intermediate starling.

STARLINGS OF SORTS.

For ornithologists recognise three kinds of starlings, as above, by the seemingly trivial character of the gloss upon the head feathers. If the head has a rich green gloss the bird is an English starling; if it is all glossed with purple, Siberian; and if partly purple and partly green, intermediate. Formerly the purple-headed starling was supposed to be found only in the east of Europe, the green-headed one in the west, and the purple and green in the middle, as was natural. But in late years, at any rate, the two foreign kinds have multiplied in England, and on the East Coast the intermediate starling seems the commonest, while the Siberian is no rarer than the English. It is rather curious that the old English pheasant, whose head and neck are all green like those of the English starling, should similarly be giving place to a later importation whose neck is two-coloured.

“AUDI ALTERAM PARTEM!”

One advantage of this immigration of alien starlings, apart from the innumerable multitudes of grubs which they devour, is that, when we hear fruit growers complaining that Cherries and starlings cannot flourish in the same county, we can put all the blame upon the foreigner, in the same way that the newspapers justly quote the increasing criminality of London as evidence of the evil consequences of the alien invasion. But when all is said that can be said on the subject of starlings and fruit, and when you have exhausted your indignation at the sight of the starling pulling up your seedlings for nest material, you must admit that there is another side to the account. To talk of the glossy beauty of the starling as an ornament to a garden, or to appraise his rippling music, never wholly silent in any month of the year, as an equivalent for solid fruit might seem idle sentiment; but watch the starlings on your

lawn. They are full of business of some sort. They walk about, brisk and alert, gleaming like beetles when the sun shines upon them, and in every few inches they probe the ground with their bills at likely spots—likely spots for what?

THE STARLING'S WORK.

They are not poking holes in your ground for mischief. The stress of the struggle for existence leaves no room for idle play to the “lower” orders of creation, and love of mischief is a luxury reserved by Nature for men and monkeys. The starling would not affect your lawn if he got nothing by it, and he is probably more useful there than either blackbird or thrush. These hunt chiefly for worms, which they seem to hear moving near the surface of the ground; but the starling has not this gift, and the comparatively harmless earthworm suffers little from his ministrations. His victims are the wireworm, the chafer grub, and the pestilent “leather-jacket,” the root-devouring product of the daddy-long-legs. As you can track the tunnel of a mole by poking the ground with your walking-stick, so the starling, probing the ground with its bill under every tuft of grass, discovers the hollow caves in which these pests are hidden. Indeed, I think it may fairly be said that the starling is the most useful bird known to horticulture. Whenever you see a starling upon the ground (except in February, when he is hunting around for nesting material) you may be quite sure that he is doing good.

THE CHAFER GRUB.

A gardener who turns over his ground once a year may think that he can dispense with the starling's services; but I have before me a letter from a North Country nurseryman, enclosing a sample of grubs which he digs up in large numbers every winter at a depth varying from 12 inches to 20 inches. He wants to know what the grubs are, and it is evident from their abundance in his ground that the starlings are not given free play, because they are cockchafer grubs, the starling's favourite food. The bird cannot, of course, find them when they are buried from 12 inches to 20 inches underground; but that is their

winter depth. In summer these fat vermin come close to the surface, and are easily discovered by the starling's probing bill. Books which deal with farm and garden pests will give you half-a-dozen chemical recipes for extirpating the chafer grub; but there is no recipe equal to the encouragement of birds, especially the starling.

BIRDS AND CURRANTS.

A rather striking instance of the utility of birds in gardens came under my notice last summer. I like birds so much and Currants so little that we get a small crop indeed of that fruit, whereas a neighbour who grows his Currant bushes inside bird-proof netting has had splendid supplies. Last year, however, a curious thing happened. His Currant bushes, while still laden with a magnificent crop of ruby fruit, began suddenly to drop their leaves. On some, which had not fully ripened their fruit, the berries shrivelled also. Going to investigate this phenomenon, I cut off some of the dead branches and found, as I expected, that the pith had been tunnelled out by the caterpillars of the Currant clear-wing moth. This little moth is very good to eat, from the birds' point of view, as is shown by his having assumed the appearance of a wasp, with clear wings and gold-banded body, for the purpose of protection. Inside the wire netting, however, he is completely safe, and we see the result of the exclusion of birds in the death of the Currant bushes. E. K. R.

THE INDOOR GARDEN.

FLOWERING SHRUBS UNDER GLASS AT KEW.

A JUDICIOUS selection of hardy shrubs for flowering prematurely under glass is valuable where a floral display has to be kept up at all seasons; it is well shown at the present time in No. 4 greenhouse at Kew, for this class contributes no small share towards the embellishment of that structure. Perhaps the most beautiful item of all is a group of the little

Japanese Plum (*Prunus japonica flore-pleno*), which, by the way, is far more often met with under the name of *Cerasus japonica* or *sinensis*. It is a small-growing shrub, with slender ascending branches, which are packed for a considerable portion of their length with comparatively large double pure white blossoms. There is a form in which the flowers have a pinkish tinge, but this feature is more noticeable when the plants are in the open ground than under glass. It may be grown altogether in pots, and plunged outside during summer. In this way it can be flowered year after year. The flowers are more

THE HOUSE AND FLOWER GARDEN AT NARROW WATER. (See page 125.)

lasting than those of many other hardy shrubs so treated.

Azalea mollis, or *sinensis*, also contributes its share to the floral display, the warm terra-cotta tint of some individuals being totally distinct from that of any other occupants of the structure. It is one of the most popular of shrubs for forcing, and well merits the favour with which it is generally regarded. A dwarf form of

Azalea indica, principally known as *Azalea obtusa*, bears its little bright red flowers in great profusion. It is nearly related to *A. amœna*, and, like that well-known kind, can be had in flower early in the year with but little trouble.

Rhododendron Prince Camille de Rohan, one of the early-flowering hybrids belonging to the same section as the well-known variety *nobleanum*, is very noticeable, the habit of the plant being dwarf and free, while the flowers are of a blush white tint, with the upper segment freely dotted with crimson. That delightful hybrid

Rhododendron prince is quite safe under glass from sharp frosts and cutting winds, which often play havoc with the flowers early in the spring when they expand in the open ground.

Malus floribunda is also well represented at Kew; indeed, it is in general demand as a shrub for forcing.

A decidedly pretty effect is produced by the drooping clusters of *Wistaria sinensis*, which has only of late years been employed for flowering under glass. The plants subjected to this treatment are usually grown as small standards, in which shape the flowers are seen to great advantage, and for grouping purposes they are invaluable. Though the Chinese *Wistaria* is the only form used for forcing, the Japanese *W. multi-juga*, with its excessively long and slender racemes, should give equally good results. H. P.

BROWALLIA ELATA.

BADLY grown and drawn plants of this species are not very attractive, but nice sturdy specimens in 6-inch pots grown for winter flowering are among the prettiest of greenhouse plants just now. They are useful for conservatory or house decoration, and the little deep blue flowers are elegant when cut. The culture depends entirely upon timely attention and care, and it is one of the best amateurs' plants in cultivation. Seeds are offered by most nurserymen, and these may be sown at midsummer for early winter flowering, a later sowing being made for successful plants. Sow thinly in pots or pans, just covering the seeds with fine sandy soil in a greenhouse or frame. If the pans of soil are well soaked with water before sowing and afterwards covered, no more water will in most cases be required until the plants appear. Shade them for a few days, baring them as quickly as possible to induce nearly full exposure to sunlight. Prick them off 2 inches apart when large enough to handle, and eventually pot singly into 3-inch pots. The roots are rather easily damaged, but if carefully handled will take no harm. When established give air on every possible occasion and dew the plants over with the syringe twice daily. Never close the frame entirely until the nights are getting cold in September, by which time the plants will be in their flowering pots. A sound fibrous loam mixed with leaf-mould and peat in equal proportions is the best compost, but, as a rule, one has to make the best of what is to hand. Drain the pots well and make the soil moderately firm, replace the plants in the frame and keep a little closer for a few days. If kept well up to the light from the first and never crowded either in the pots or against each other, it is possible to obtain nice shapely plants without stopping, nor will the flower-buds appear if always kept growing freely. Rather than let them get drawn, the points of the shoots may be taken out once or twice. The frame should never be closed just as the plants are syringed, as this causes the drawing up complained of. If space allows, the plants should be housed in a light, sunny greenhouse in October or grown in pits where a little warmth may be turned on at night to allow of ventilation. This will harden

the stems and make the plants more free-flowering. After housing, a little weak soot water may be given at intervals, this helping to keep that dark glossy green tint in the foliage that is so much admired. Dryness at the root must be avoided while in flower, or this will cause the blossoms to drop. There is a white and also a blue variety of *B. elata*, but the latter is, I think, the more popular, as it is a favourite colour, while the white is not exactly pure.

ALLAMANDAS.

It can hardly be urged against the Allamandas that they are neglected by most cultivators of stove plants, neither can it be denied that they might with advantage be much more largely grown than is the case. There is, of course, something to be said for the statement one often hears that the flowers are so soon over. They have no lasting properties it is true, but the critics forget a most important feature of the Allamanda, perhaps the best, namely, its profuse and continued flowering. What is lost in the fleeting beauty of the individual flower is more than compensated for by the profuseness with which they are produced and the long season over which this is continued. Add to this the fact that the Allamanda is, when properly treated, a quick and most successful grower, and that the more it grows the more it flowers (growth is not made at the expense of flowering as with some plants), it cannot be gainsaid that it has many points to recommend it to the possessor of a warm glass house. The Allamanda is properly a stove climber; it is, however, to a considerable extent grown as a specimen plant in pots, and figures largely at the most important exhibitions in the classes for trained specimen plants.

Its chief value, however, so far as the general cultivator is concerned, is as a handsome flowering roof climber, and during the summer months but few plants present a more gorgeous picture. It is seen to the best advantage when the principal shoots are tied to the trellis, which should be 9 inches or 12 inches below the roof, and minor ones are allowed to grow as they will. This remark also applies to many other climbers, both greenhouse and stove. Half the charm of this class of plants is lost if all their shoots are tightly attached to the trellis.

The Allamanda may either be grown in pots or tubs or be planted out, but the latter method in my opinion is not to be recommended. If a large pot or tub is provided there will be sufficient accommodation, for the roots and stimulants can also be much better applied to plants with their roots thus under control, and Allamandas benefit greatly by the application of manure. They are vigorous growers and gross feeders. During winter the plants are at rest, and having them in pots or tubs the condition of the soil about the roots can be exactly known, whereas when planted out one never knows where the roots get to. When the plants can be removed from one house to another, as may be done when they are in pots, it is advisable to place them in a cooler house during winter. The flowers are produced upon the current year's shoots, therefore in early spring it is necessary to prune back the old wood to within two or three nodes of the base, so that the remaining buds may produce vigorous shoots during the next summer, for the stronger they are the better they will flower.

Repotting or top-dressing only perhaps in the case of large plants should be done early in the year, just as the buds are bursting. The Allamanda enjoys a rich loamy soil, loam with river sand and a good proportion of dried cow manure makes a suitable compost. An abundance of water is required during summer. Propagation is best effected by means of cuttings, preferably taken from the young shoots that push in spring when the old wood is pruned. These root readily if placed in small pots filled with sandy soil and plunged in bottom heat in the stove and covered with a handlight. When rooted they must be repotted, not using manure in the soil until the

second move. As the plants develop, if required to cover the roof only, the shoot must be allowed to grow the required height undisturbed and then stopped so as to produce lateral shoots, which must also in turn have their points pinched out. By this means the roof will quickly be covered when the plant is established. If it is desired to cover a low trellis then the apex of the young plant must be removed when it is about 9 inches or so high, so as to make it branch near the base. The best Allamandas are *A. nobilis*, *A. Schottii*, *A. S. var. Hendersonii*, and *A. Chelsonii*, all of somewhat similar shades of yellow. A. P. H.

EUCHARIS AMAZONICA.

I SEND you a photograph of a house of *Eucharis amazonica* in flower on the 10th ult. They occupy one side of a low span-roofed house 70 feet by 13 feet. A few years ago the same plants got into a very unhealthy condition entirely through bad management. Several gardeners who then saw them said that *Eucharis* mite was the cause of it, and advised me to throw all the plants away and obtain a fresh and healthy stock, but as I never thought that mite was the cause of the disease I gave them different treatment, with the result that I soon restored them to their present vigour. I first shook the bulbs out of the soil they were then in and repotted them into smaller pots, using good turfy loam mixed with best white sand, and placed them in a moist atmosphere of from 60° to 70° of heat, using water sparingly until they were well established in their pots. I have never watered them except with manure water, and never water them until the plants really require it. A moist atmosphere is maintained at all times.

ROBERT FEATHERSTONE.

St. Ann's Nursery, Kirkstall, Leeds.

GARDENING OF THE WEEK.

KITCHEN GARDEN.

ROOT crops remaining in the ground will now require lifting and storing in sand or dry earth, for if left longer where grown they will recommence growth to the detriment of flavour. These comprise Parsnips, Jerusalem Artichokes, and Turnips. Horseradish may also be lifted, and sticks thick enough for present kitchen use laid in a spare piece of ground. The thinner ones may be transplanted to a well-enriched and deeply-dug plot of ground in the outside garden.

ONIONS.

Young plants raised from seed sown under glass last month should by now be large enough for pricking off into boxes filled with well-prepared soil. Precisely the same soil may be made up for these as recommended for sowing the seed in, but it should be passed through a coarser sieve. Three inches apart each way should be allowed between the plants. Replace in a light part of a started viney until well established, when they may be removed to pits or frames. Aim at keeping the young plants sturdy by admitting air on all favourable occasions and by elevating the boxes so that the plants are within 2 inches or 3 inches of the roof glass.

The main crop of Onions may be sown at this date, provided the weather is favourable and the ground in a friable condition. Land for Onions cannot well be made too firm by treading and rolling. White Spanish is a good quick-growing variety for first use after the Tripoli is over, while Veitch's Main Crop and James' Keeping are hard to beat for general and late use. The Tripoli Onions may now be transplanted to a fresh piece of ground, or they may be slightly thinned and remain where sown.

PEAS AND BROAD BEANS.

The demand for first and second early crops are usually great, and some seed should be sown about once in ten days to ensure an unbroken supply. Of Peas, Criterion, May Queen, and Gradus are good for present sowing, while a good type of Long-pod or Green Windsor Beans should be chosen. Peas and Beans that were sown in pots or boxes under glass for providing early dishes may, if well hardened, be transplanted to the border prepared for them. The site should be a warm sheltered one, and when planted they should be moulded up and protected with branches of evergreens.

CAULIFLOWER WALCHEREN

may be sown thinly in a frame, preparing this in the following manner: Throw in some fermenting leaves and stable litter and tread it well; place thereon 4 inches of fairly rich garden soil, bringing this up to within 6 inches of the lights. Tread lightly and rake level, then sow the seeds broadcast. Brussels Sprouts for the main crop, and Lettuce to succeed those raised last autumn, may

but from laterals and side growths. There must not be too much pruning, merely thinning out of dead wood and a slight shortening of long strong shoots. All the most weakly-looking twigs will in due time be covered with clusters of blossom. No flower garden, however small, should be without its Banksian Roses.

ROSES IN BEDS.

Where H.P. Roses are grown in quantity and farmyard manure is used in the soil now is the best time to dig or fork it in. This ought to be thoroughly decomposed or it will do more harm than good. If this cannot be had it will be better left on as a mulch and dug in next autumn. If no digging is practised the soil should be well loosened with the hoe. This will do away with the weeds that have grown since October.

Those who have a warm wall and a dry situation are strongly advised to plant Fortune's Yellow. It is a strong-growing Noisette. The flowers are only semi-double and of a loose and irregular form, but they are very beautiful, of a lovely colour—yellow, flaked with carmine—and the fine loose petals are of charming texture. It

should not be allowed to get dry either winter or summer. More plants are lost through drought than from any other cause. T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

INDOOR GARDEN.

STREPTOCARPUS.

FOR early flowering a portion of the old plants may now be brought into an intermediate temperature. These plants are very useful to the decorator; they are, however, somewhat subject to mealy bug, and require careful cleaning before being started. Put the plants on a shelf and fumigate them strongly with XL All three or four times in the course of a fortnight; this will eradicate the pest.

CALADIUMS.

Bring into a stove temperature a few dozen tubers of the older approved varieties, which will give colour and variety to the warmer show houses early in the season, reserving the choicer sorts for the more important display required later on. In starting the tubers place them in shallow boxes on a layer of fibre, lightly covering them; keep the fibre moist by using the syringe. As soon as any growth appears expose it to the full light. The tubers may be potted after the young leaves are 6 inches or more long, but before the roots become entangled; use a light rich compost, and place them in a hot, moist house. As the spring advances a light shading with tiffany fertilizer is necessary.

CLIMBERS FOR THE STOVE

if not already attended to should at once receive attention. *Allamanda nobilis* and *A. Schottii* when planted out in a restricted border and allowed to ramble under the roof of a hot house, produce a charming effect. Unless it is desirable to cover the roof at once, as in the case of a recently-planted house, this *Allamanda* should be pruned back to three joints of last season's wood and tied in thickly under the roof, and 12 inches to 18 inches from the glass. *A. Williamsii* when grown in pots of 6 inches or 8 inches in diameter make choice plants for room or table decoration. It may be pruned to one or two joints of last year's wood. The plants should now be partly shaken out of the soil, at the same time shortening some of the stronger roots and repotting into the same sized pots, using only the rough fibrous parts of loam, with sand and charcoal and a little Clay's fertilizer.

Place the plants in a stove and give very little water until growth commences.

CLERODENDRON BALFOURI

as a pot plant will require pruning to three or four joints, and when potting use a lighter soil than for the *Allamandas*. The *Dipladenias* are less robust than either of those named above, and should be shortened back to the well ripened wood only. Most of these appear to prefer a compost of fibrous peat, with sufficient sand and charcoal to keep it open. *D. boliviensis* alone doing well in equal parts of loam and peat. *D. sanderiana* has proved a somewhat difficult plant to manage unless it be kept in very small pots.

ARISTOLOCHIA GIGAS.

This extraordinary plant requires pruning into the ripened wood, and it is advisable to put in cuttings of young wood occasionally, as the plants are liable to go off suddenly. It requires a moderate amount of roof space as it is vigorous. *A. elegans* produces interesting little flowers, is well adapted for small houses, and requires a much lighter soil.

CISSUS DISCOLOR.

This old plant makes a most effective covering for a stove house roof. Old plants that have been kept comparatively dry during the winter should now have all the soft unripened wood cut away and be repotted, after removing a portion of the old soil, in a compost of equal parts peat and loam,

HOUSE OF EUCHARIS AMAZONICA IN THE NURSERY OF MR. ROBERT FEATHERSTONE, KIRKSTALL, LEEDS.

also be sown in the same frame, to be pricked off on a warm border in the open when large enough.

PARSLEY.

Some of this should be sown now to ensure a supply to follow that wintered in frames or in the open. In all establishments there is a great demand for Parsley, and means should be taken to provide abundance throughout the year.

Stoneleigh Abbey Gardens. H. T. MARTIN.

FLOWER GARDEN.

ROSES.

If trained on south walls will now need pruning. Begin by taking out all dead and weakly wood, then consider which shoots are required for laying in, giving preference to the ripest rather than to the strongest. All gross shoots should be clean cut out and only the medium-sized ones left. These should be thinned, if necessary, and moderately spurred back. In the case of the *Maréchal Niel*, the *Noisettes*, and the *Gloire de Dijon*, if space can be given, it is best to lay in some of the strong shoots at least three parts of their length, and unless additional light is wanted these strong shoots should never be trained upright, as that is likely to lead to more wood and fewer flowers. The *Banksian Roses* need special treatment; strong wood should not be encouraged. The flowers will not proceed from strong shoots of the year,

is very early, quite one of the first *Roses* to be gathered out of doors, and blooms with me in May. Although it is sometimes cut a little with the early frost, I have gathered flowers from the same plant annually for the past twenty years.

SALVIA PATENS.

This is perhaps the most intense blue flowering plant we have. On good soils it is one of the most desirable plants for large beds and mixed borders we have. In lines mixed with yellows or whites it looks exceedingly well. Seed sown now in heat and grown on will make good plants by the middle of May, and where the tuberous roots have been wintered like *Dahlias* they may now be started in heat and will soon make plenty of cuttings, which strike freely.

LOBELIA CARDINALIS.

This grand plant should not be lost sight of. Roots that were taken up in the autumn and have been wintered in frames will now be making a move. Take off the suckers as soon as they can be removed with something like a heel to them, pot in small pots singly, and plunge in a gentle bottom heat. Use a light compost, with leaf-mould, loam, and silver sand added. When the plants have taken root shift them into 4-inch pots, keep them for a little while in a moist atmosphere, then gradually harden off. When the pots are filled with roots give plenty of water. This plant

with a liberal addition of sand and charcoal. Seedling plants as soon as large enough to handle must be pricked off, six or eight round the inside rim of a 3-inch pot.
J. JAGUES.

THE FRUIT GARDEN.

STRAWBERRIES IN POTS.

UNTIL we have a change to brighter weather great patience must be practised in the management of plants now coming forward. If they occupy shelves near the glass keep the latter clean, and avoid overcrowding towards their progress to the flowering stage. When in flower give more air, or remove them to a light, airy house, where they can be regularly watered and sufficient atmospheric moisture given to prevent the flowers suffering from bright sunshine. Give gentle fire-heat to admit of a free circulation of air by day and night, thin out weak flowers, and fertilise with a camel's hair pencil when the pollen becomes light and plentiful. Strawberries under artificial treatment are very impatient of a high temperature until the fruit is set. A minimum of 45°, with a rise of 10° by day, will be quite sufficient, but when fairly set and removed to a Pine stove to swell off there will be little danger in giving them too much heat, moisture, and stimulating food. They must not, however, be allowed to remain in this position if flavour is to be the test of skill in forcing. When quite swollen and partially coloured they should be removed to a warm, airy house, where exposure to light and the gradual withholding of water from the roots will greatly improve the quality of the fruit. As days increase in length and brightness successional crops may be brought on faster by closing for a few hours with sun-heat, and give moisture from the syringe, but air must be again admitted at night, when the temperature may range from 45° to 50° when external conditions are favourable. Where light shallow pits are at command use them as feeders to the forcing pit by placing 1 foot or 2 feet of fermenting leaves over the bottom and keeping them filled up with plants from the general stock.

CUCUMBERS.

It is difficult to conceive a better winter for Cucumbers than this has been, and good fruit through the latter part of February and March should be plentiful. Overcropping must be avoided, as checks of all kinds, particularly from overloading, make many houses barren at a time when good fruit is in daily demand. As the days increase in length a little more heat may be given, especially if it comes from the sun, but no great change need be made through the night, as hard firing brings many ill. Keep the evaporating pans regularly filled with stimulating liquid, top-dress the roots with fresh compost, and bathe the foliage and stems with warm soft water whenever the house can be run up to 80° or more with sun-heat. Young plants in small pots intended for training over a trellis in the Cucumber house may be shifted on from time to time if the bed is not ready, but one shift from the seed-pot to a hill is always best. It is better to throw plants away and fall back upon later sowings than trust to them when they become potbound and often infested with spider before the points reach the trellis. When young plants intended for pits and frames have made two rough leaves, pinch out the points and keep them close to the glass until the hills are ready for them. If the manure has been well worked and placed in the pits, make it firm and level on the surface, put clumps of turf grass side downwards across the centre to prevent the roots from striking into the manure, and upon these form a long, narrow ridge or small cones of light rich soil. Introduce a bottom heat thermometer, and when a steady heat of 80° to 85° has been secured cover the remainder of the bed with clumps of turf and plant out in the usual way.
Madresfield Court. WILLIAM CRUMP.

ORCHIDS.

EULOPHIA PALLENS.

THE genus *Eulophia* embraces a large number of species, but few are grown. The above species is

very interesting and distinct, and may be classed with those Orchids generally termed "botanical." It has round, pointed, and slightly furrowed pseudo-bulbs, surmounted by four or more grassy green leaves 2 inches across and about 1 foot long. The erect spikes which spring from the base of the bulbs are 3 feet long, and bear from thirty to forty flowers, which are about an inch across, having the sepals and shorter petals a very pale green, faintly tinged with purple, the bilobed lip and spur united being half an inch long, the base and lobes of the lip white, bearded in the centre; spur pale green. This species requires a shaded position in the stove Orchid house, and should be given a plentiful supply of water when growing. It has a long season of rest, and during that time requires very little water to keep the bulbs plump and healthy. Repotting should be done when new roots issue from the base of the growths; equal proportions of peat and sphagnum moss form a suitable compost. Pots or pans may be used, and drainage must be ample. The foliage when young and tender is quickly disfigured by thrip. Propagation is effected by dividing the pseudo-bulbs in the same way as recommended for other bulbous Orchids.

EULOPHIA PULCHRA.

This species may be classed with, and is a suitable companion to, the above, and one full of interest to lovers of "Botanical" Orchids. It has dark green pseudo-bulbs about 3 inches long bearing pale green leaves. The flowers are half an inch across, twelve or more being borne on erect spikes that issue from the base of the bulbs; the narrow sepals are white suffused with green, and faintly lined with pale purple; the shorter and broader petals are of the same colour heavily lined with purple. The bilobed apical part of the lip is creamy white, the basal part and side lobes being lined with purple. Both species, owing to their greater length of spike, are very useful, and form quite conspicuous subjects when arranged in groups among other more gorgeous and showy Orchids. This species requires the same cultural treatment and thrives under the same conditions as that recommended for *Eulophia pallens*. Both species bloom at this season.

DENDROBIUM VICTORIA REGINA.

This species, though by no means showy, is nevertheless very distinct, and owing to the colour of its flowers being rare among *Dendrobiums* it is quite a curiosity. It is dwarf in habit, the bulbs seldom growing more than a foot long; the flowers, which are about an inch across, are produced from the nodes of the bulbs in autumn; the basal halves of the sepals, petals, and lip are whitish, the outer portions purplish blue. Though it is a native of the Philippines, it grows and flowers well here in the cool intermediate house fixed to pieces of Fern stems, the lower end of the latter being placed in a pot, made firm with crocks, and the intervening space filled with

sphagnum moss. It is neither deciduous nor does it need such a dry and decided period of rest as many of the *Dendrobiums*, but it should be given plenty of water when growing, and must not be allowed to shrivel for want of it when resting. During the summer months it should be freely syringed overhead twice or three times on bright days, and occasionally sponged with some insecticide to prevent insect pest.

F. W. THURGOOD.

Roslyn Gardens, Stamford Hill, London, N.

THE FRUIT GARDEN

APPLE ALLINGTON PIPPIN

THE intrinsic merit of this recently-introduced dessert variety of Apple has forced it well into public favour. The case of this Apple is an excellent illustration of the fact that once a really good thing, whether fruit or flower, is exhibited before the committees of the Royal Horticultural Society its merits are at once recognised by an award. Apple Allington Pippin has received a first-class certificate. The fruit is of medium size, bluntly conical in shape, and of distinctly handsome appearance. On the shady side it is cream-coloured; on the sunny side suffused with rosy pink, giving it an attractive and pleasing appearance. It is a popular variety for market. Its flavour is sweet and pleasant, but not of the first order. Its cropping quality is excellent; the tree seldom fails to bear.

APPLE ALLINGTON PIPPIN (NATURAL SIZE).

This variety has the additional advantage of bearing fruit on quite young trees; indeed, so precocious is Allington Pippin in this respect that thinning the fruit must be resorted to, or the young tree's growth will be crippled.

OWEN THOMAS.

GRAPES FOR MARKET.

DURING the past few years Grape growing for market has greatly increased, and consequently the prices realised are not so high as formerly. It is now possible to get really good Grapes at almost any time of the year at a moderate cost. Yet it is still a profitable industry, for though the prices are lower the cost of production is also much less than formerly. In the first place vineries are built on more economic principles, and the large growers do everything in a systematic way, from the construction of the houses down to the smallest details.

It is in the neighbourhood of Worthing, in Sussex, and north of London that the greatest progress has been made. The construction of the houses in these two districts varies considerably. Those in Sussex are built more substantially than those north of London. This is perhaps owing to the high winds on the South Coast necessitating stronger structures. Messrs. Rochford may be regarded as the pioneers of modern Grape growing. The lightly constructed houses are in blocks of from twelve and more, all connected by broad gutters of Pine wood, supported by brick pillars or wooden uprights on cement or concrete base. Each house is about 28 feet or 30 feet wide. If ground can be secured where there is a good depth of loam a considerable saving will be effected in making the Vine borders. Deep trenching and the addition of crushed bones and other manures is all that is necessary. Good drainage is essential. Generally speaking the large growers give less attention to border making than formerly; they also crop the Vines earlier. Under these conditions the Vines do not last so long, especially those grown for very late crops.

The late crops are generally the most profitable, but it requires some care to keep the Grapes in good condition. The houses must be as nearly watertight as possible. If it is intended to keep Grapes after the new year the houses should be covered outside with canvas and the inside borders covered with dry straw. Of course this is not done until the Grapes are thoroughly ripe.

VARIETIES.

Gros Colman is the most popular market Grape we have, and it is also the most profitable. When well finished the colour is good, the berries large and handsome, and the bunches of good shape. This is grown for autumn and winter. The greatest difficulty with this Grape is to colour it well. Plenty of air night and day with as much fire-heat as possible from the time the berries begin to colour until they are ripe is most important. Alicante, which makes large, handsome bunches, and almost invariably colours well, is another good market Grape, and for early forcing the Black Hamburg of course takes first place. The Muscats, though they give more trouble, are profitable when well finished.

PACKING.

This is very important, for in most cases the Grapes have to travel some distance to market, and their appearance is an important feature. The bunches are usually cut with a portion of the lateral, which may be left about 2 inches long. Small berries or any that give the bunches a bad appearance should be cut out. Various sorts of baskets are used, but those most generally approved of are known as "baby baskets." In the place of wadding the soft wood shavings, "wood-wool" as they are called, are used. With a little of this in the baskets covered with soft paper the finest bunches may be laid round the baskets and fixed by the stem to the basket rim. The bunches must be kept quite close together so that they cannot move about while travelling. About 12lb. are an average weight for each

ODONTOGLOSSUM CRISPUM COOKSONIÆ (NATURAL SIZE).

(Shown by Mr. Norman C. Cookson, Oakwood, Wylam-on-Tyne, at the last meeting of the Royal Horticultural Society, when it was given a gold medal and a first-class certificate.)

basket. The exact weight is given with each basket, and the baby baskets are then put in flat pads or hampers. Many growers use the ordinary cross-handle baskets. These have no lids, but are simply papered over. In this way the Grapes travel long distances and reach their destination in perfect condition. Most Grapes grown for market are disposed of through commission agents; in fact, the fruit trade generally is in the hands of the established salesmen at the various market centres. Some of our best Grapes now go to America and find a good market there. A few years ago a good trade was started in France, but the heavy duties now imposed (I believe it is about 1s. 3d. per lb.) have practically closed the French markets to English Grapes.

A. HEMSLEY.

ORCHIDS.

ODONTOGLOSSUM CRISPUM COOKSONIÆ.

OBTAINED among others in an importation this new Odontoglossum created a great deal of interest and attracted much attention when shown by Mr. Norman C. Cookson, Oakwood, Wylam-on-Tyne, Northumberland, before the Royal Horticultural Society on the 10th inst. The flower is large, the sepals and petals broad, with slightly fringed edges. Both sepals and petals are marked with blotches of rich ruby-brown, so regularly as to form a circular band of this colour, leaving a white centre and white edges. The lip is small and insignificant, tapering towards the lower end, and with a blotch of pale ruby-brown. It is altogether a striking flower, symmetrical, and of good

colour. This Odontoglossum obtained the rare honour of being awarded a gold medal and a first-class certificate.

ORCHIDS AT GLEBELANDS.

PREVIOUSLY the collection of Orchids formed by J. Gurney Fowler, Esq., at South Woodford, has been noted in this journal, and a second visit paid in the last week of January served to emphasise the first impression made by the general well-being of the plants, which, though so near London, bid fair to form one of the choicest and most comprehensive collections of the day. The keen interest and enthusiasm of Mr. Fowler are evident throughout the whole collection. The following plants, seen by the writer on the occasion of this second visit, may be mentioned, the more so as at this dull season of the year, in spite of the choice varieties collected here, there is naturally not the show of flowers which would be seen at a more favourable season.

In the Cattleya house, a large structure devoted to both species and hybrids, are two well grown plants of Lælio-Cattleya Pallas, the one a fine variety carrying four of its richly coloured flowers on a spike, the other rightly bearing the varietal name of *superba*. The parents *Lælia crispa* and *Cattleya dowiana* are well represented in this hybrid both in shape and colouring. The deep purple lip of *L. crispa* acquires in this hybrid a rich crimson tint from the *dowiana* parent, while the throat is netted and lined with orange and gold. Fault alone can be found with the sepals and petals, which, deep rose in colour, are so strongly undulated at the edges as to appear narrower than they really are, a defect, it may be said, which is remedied to a great extent in the form *superba*.

Lælio-Cattleya Macnabiana, a pretty hybrid between *Cattleya Skinneri* and *Lælia cinnabarina*, gives the requisite touch of brightness to the house, from its clear colouring of chrome-yellow flamed with orange. Though as a rule wanting in

size, much could be said in favour of hybrids from *L. cinnabarina*. The elegant spray-like form of the inflorescences and the freedom with which they are produced are considerable advantages, and they are most amenable to culture, while the dominant yellow shade of their flowers renders them conspicuous wherever grown.

Dendrobiums are a strong feature in this collection. The pure white *D. nobile* is represented by sturdy well-grown plants, while the commoner species annually yield their full quota of bloom. At the present time, though quantities have been cut, some grand plants of *Dendrobium wardianum giganteum* are each bearing as many as 200 flowers and upwards, a magnificent sight only equalled by their utility where cut flowers are required.

A charming form known as *D. wardianum* Fowleri is present here, the sepals being marked similarly to the petals of the well known *D. nobile* Cooksonii. In flower is an exceedingly well-grown specimen of *Dendrobium aureum* (heterocarpum). The soft primrose-yellow shades of the sepals and petals are enhanced by the velvet-like markings on the labellum. Unlike the majority of Dendrobiums the species, apart from its floral beauty, would be worth growing on account of the delicate fragrance of the flowers.

In the same house, planted out in a bed of peat, moss, and rough crocks is a batch of *Epidendrum radicans*. That the position and culture given suit the plants is evident from the rampant way in which they grow, and the strength, size, brilliancy, and quantity of the scarlet umbels of flowers. In three or four houses, as best suits their requirements, are to be seen collections of *Cypripediums*, all of which are doing well. A splendid form of *Cypripedium Boxalli atratum* claimed attention, the deep purple-black colouring in the dorsal sepal suffusing the entire surface, save for a white tip and narrow border. A very handsome hybrid between *C. insigne* and *C. chamberlainianum*, and named in compliment to Mr. Fowler's sister, was also in flower, and though the cross has been repeated in other collections this form still stands pre-eminent in contour, and the clear colouring of the bright rose-purple pouch, and the clear white, cream-yellow and deep chocolate spotting of the upper sepal. It was given an award of merit by the Royal Horticultural Society in 1899.

C. Olivia, a reputed cross between *tonsum* and *concolor*, is one of the most delicately beautiful hybrids imaginable, with flowers nearly as large as those of the *tonsum* parent, soft ivory white, daintily tinged with blush rose diffused in varying intensity. The parents, however, are evidently wrongly recorded, and for the future *niveum* should be written in the place of *concolor*, which later, though a pleasing enough species, could never when crossed with *tonsum* yield a product with such white and rose flowers. In fact, Robinson, who raised *Olivia* in America, told a friend of the writer that he was sure the parents were *niveum* and *tonsum*, and any expert looking at the flower must come to that conclusion. By what error or for what purpose it has been recorded as a *concolor* cross it is difficult to understand. Certainly the raiser invariably spoke of his seedling as being between *tonsum* and *niveum*.

In the *Odontoglossum* house two fine specimens of *Odontoglossum harrivano-crispum* caught the eye, both handsome forms with well-developed arching spikes. Attractive as *Odontoglossum crispum* is, it is a question if this hybrid does not excel both its parents, excepting the finest and most valuable varieties of *crispum*. It is certainly superior to *O. harrivanum*. The flowers are produced in greater numbers and in taller spikes, while, as in the examples now quoted, the colouring on the petals is almost wine-purple, contrasting vividly with the marble-like whiteness of the apical area of the lip, a feature derived from the *harrivanum* parent.

ARGUTUS.

Flowering plants for honey.—For gardens: *Salvias* (Sage) in varieties, *Wistaria*, *Lupins*, *Crocus*, *Thyme*, and other herbs; *Mignonette*, *Sunflowers*.—*Indian Planting and Gardening*

MISCELLANEOUS.

SUNSHINE OR SHADE FOR FLOWERS.

AS all plants are not alike in their requirements as to sunshine and light, it naturally follows that the plants grown should be adapted to the particular place in which they are kept. Those liking a little sunshine, such as the *Begonia*, *Fuchsia*, and *Calla*, are satisfied with an eastern exposure, where they get the benefit of the sun early in the morning. The *Geranium*, *Carnation*, *Rose*, *Heliotrope*, and, in fact, the majority of flowering plants, which must have plenty of sunshine in order to fully develop their colours, find no other exposure so satisfactory as that afforded by a south window. A western window answers very well for many plants in winter, when the sun is not strong, but it is a poor place for them in summer, unless something can be done to greatly modify the intensity of the afternoon heat. Northern windows are not adapted to flowering plants, but shade-loving plants can be grown in them very satisfactorily. It will therefore be seen that all the windows of a house can be utilised for plant growing, provided we are careful in our selections and adapt the plant to the window it is to grow in.

It is safe to say that, as a general rule, light-coloured flowers are best adapted to windows having an eastern outlook. But there are many exceptions, and the only way to make absolutely sure of the best exposure to give a plant is to experiment with it, and thus find out what conditions of light it does best in. If we were asked to give a list of plants adapted to the several exposures mentioned, it would be something like this: For eastern windows—*Fuchsias*, *Begonias*, *Callas*, *Chinese Primroses*, *Primula obconica*, *Azaleas*, *Plumbago*, *Stevias*, *Lobelias*, and all kinds of bulbous plants. For southern windows—*Geraniums*, *Roses*, *Chrysanthemums*, *Carnations*, *Lantanas*, *Oxalis*, *Oleanders*, *Abutilons*, *Hibiscus*, *Marguerites*, and most of the plants having richly coloured foliage. For western windows—bright leaved plants and a few of the more "accommodating" plants like the *Geranium*, provided the effect of too strong sunshine is modified somewhat. For northern windows—*Ferns*, *Araucarias*, *English Ivies*, *Palms*, *Aspidistra*, *Ficuses*, and *Selaginellas*. *Roman Hyacinths*, *Primula obconica* and *Chinese Primroses* will often bloom well in sunless windows.

But the above lists are subject to great modification, because the florist who has "the knack" of flower-growing will contrive to so control conditions that he can grow almost any plant in almost any exposure. The sun can be tempered by shades and screens. Heat can be regulated, and water used in quantities to fit the losses by evaporation which will be different in different exposures. These things can not be put down on paper in such a manner as to make them plain to the reader, but they will come to the amateur florist by personal work among the flowers he grows.

We read a great deal about shade-loving plants. Now, "shade-loving" is a comparative term. It does not mean actual shade, in the sense ordinarily given the word, but it means an absence of sunshine. A *Fern* is called a shade-loving plant, but it will do just as well at a south window, if we keep it out of the sunshine, as it would in a window at which no sunshine enters. It is so with all plants not fond of sunshine. All the shade they need is exclusion from it, not, as so many suppose, a place in which light is so toned down that dimness results. A place may be shady in the sense that it is without sunshine, and yet it may be very light. And this is the kind of shade that shade-loving plants require.

If you are going to build a greenhouse on a small scale, like a lean-to, by all means, if possible, have the roof of it slope to the south. If you cannot do this, have it slope to the east. But never have the slope to the west or the north, for one will give you so much sunshine that your plants will be scorched by it, and the other will

give you none at all in winter. If you can have one with a roof having two slopes—one to the east and one to the south—by all means have it, as this will give you an ideal exposure, as it combines the advantages of early morning and midday sunshine, and nearly all kinds of plants can be so arranged that they will get just the amount of sun they need.

If you are going to build a greenhouse with an even-span roof—that is, the roof the same on both sides—let it run north and south. Do not make the mistake of having the building so high that the glass of the roof is several feet above the plants under it. The nearer you can get them to the glass the better it will be for them. In summer, the west side of an even-span roof can be covered with thin cloth or washed with a mixture of lime, or something similar, that will obstruct the free entrance of the rays of the hot afternoon sun.—*Canadian Horticulturist*.

PLANT LISTS AND GUIDES ON SALE AT KEW.

MR. WATSON, Curator of the Royal Gardens, Kew, writes: "I shall be much obliged if you will kindly publish in your paper the enclosed list of plant lists and guides on sale at the Royal Botanic Gardens, Kew. Many applicants for them omit to send the cost of postage, no doubt because in the press notices only the net prices of the lists are stated." The following is the list:—

Key Plan and Index to the Royal Botanic Gardens, Kew. Fifth edition. 1900. Price 2d.; post free, 2½d.

Official Guide to the Museums of Economic Botany. No. 2: Monocotyledons and Cryptogams. 1894. Price 4d.; post free, 5d.

Official Guide to the Museums of Economic Botany. No. 3: Timbers. Second edition, revised and augmented. 1893. Price 3d.; post free, 4d.

Official Guide to the North Gallery. Fifth edition, revised and augmented. 1892. Price 4d.; post free, 5½d.

Hand List of Trees and Shrubs grown in Arboretum (excluding Coniferae). Second edition. 1902. Price 1s. 3d.; post free, inland, 1s. 7d.; foreign and colonial, 1s. 10d. Part II. (first edition): Gamopetalae to Monocotyledons. 1896. Price 1s.; post free, 1s. 2½d.

Hand List of Ferns and Fern Allies cultivated in the Royal Gardens. 1895. Price 6d.; post free, 7½d.

Hand List of Herbaceous Plants cultivated in the Royal Gardens. Second edition. 1902. Price 1s. 9d.; post free, inland, 2s. 2d.; foreign and colonial, 2s. 6d. Cloth boards, price 2s. 6d.; post free, inland, 2s. 11d.; foreign and colonial, 3s. 3d.

Hand List of Orchids cultivated in the Royal Gardens. 1896. Price 6d.; post free, 8d.

Hand List of Tender Monocotyledons cultivated in the Royal Gardens. 1897. Price 9d.; post free, 11½d.

Hand Lists of Orchids and Tender Monocotyledons in one volume. Cloth boards. Price 2s.; post free, 2s. 4½d.

Hand List of Tender Dicotyledons cultivated in the Royal Gardens. 1899. Price 2s. 6d.; post free, inland, 2s. 10d.; foreign and colonial, 2s. 11d. Cloth boards. Price 3s.; post free, inland, 3s. 4d.; foreign and colonial, 3s. 5d.

Myecologic Flora of the Royal Gardens, Kew. 1897. Price 4d.; post free, 5d.

[We have frequently recommended these most helpful handbooks to our readers. They are valuable to all who are really interested in their gardens.—Ed.]

BEGONIA SOCOTRANA.

In the headlong rush for the newer *Begonia* (Gloire de Lorraine and its sports, this old but extremely useful *Begonia* is apt to be overlooked, but we are loth to discard old and well-proved friends. This species comes in in January after the other has become stale. This year it again shows its superior claims to utility and refreshing beauty. Being tuberous and easily grown, it does not take up valuable space through the crowded spring

months like *B. Gloire de Lorraine* does, as the pots, after proper drying off, may be laid on their sides away from the light, but in a warm temperature, until August, when the tubers should be shaken out and repotted according to their sizes, given generous treatment and abundance of atmospheric moisture. The leaves are very ornamental and the flower spikes are long and thrown well up above the foliage, consequently better for cutting purposes than those of *B. Gloire de Lorraine*. The newer race of scarlet winter-flowering varieties, such as *L'ideal*, *Mrs. Heal*, *Winter Cheer*, and others will, when their constitution is restored from hard propagation, become grand acquisitions to winter-flowering plants.

W. CRUMP.

CORRESPONDENCE.

ROSE CRIMSON RAMBLER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Referring to the issue of the 24th ult., pages 53-54, in the reprinted notes on climbing Roses, from the pen of the late Mr. Girdlestone, I see (page 54) the following: "I have only seen one fine plant of it (*Crimson Rambler*) on a wall, &c." As I have come across similar statements in the gardening papers during the past year or two, I thought it might interest amateurs to know that *Crimson Rambler* has found a happy haunt on the walls of my house here in Yorkshire, and has flowered profusely each season since it became established. I planted three of them—two on the south wall and one on the west wall of the house—just five years ago. One of the former flowered well in the second season, all three in the third season, and the last two summers we had a splendid show of bloom on two of them. As to growth, they have all climbed to the level of the roof-spout, and each puts out about one strong new shoot from the base each year. I have never cut them back, but I give them a little attention in this way. About three times each summer I hoe the top soil about their roots, then give each a half bucket of water, followed by a half bucket of strong manure water, and after the flowering season I turn the hose-pipe on to wash the spider webs, &c., from the stems and twigs against the wall. In the autumn I give a little manure at the roots. Their success on my house is no argument in favour of their use on walls in preference to trellis work; on the contrary, they are to be seen in perfection on trellis work in the garden of a neighbour of mine.

WALTER JESPER.

Berchwood, Menston-in-Wharfedale.

PROLIFEROUS (?) ARMERIA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—At the beginning of last December a gardener drawing attention to what looked like small plants springing from among the withered flower-heads of an *Armeria*, I carried this head home and placed it on the surface of a pot in an alpine house, sprinkling a little sandy soil over it and sinking the flower-head a little in the pot. I now see unmistakable leaves showing. Is this a common occurrence in this class of plant? I can find no account of it in Kerner and Oliver.

A. C. BARTHOLOMEW.

[It is impossible to determine whether this is a true case of proliferation, such as occurs in the inflorescence of *Agaves*, *Fourcroya*, and *Allium*, or not, since it does not transpire that the growth or apparent growth perceived in December among the withered flower-heads has remained green, and that the leaves at present showing after layering are a continuance of that growth. If this latter were the case, proliferation may be assumed; but if not it is more than probable that the new growth is simply the product of germinating seeds which would naturally have been present at the base of a matured inflorescence. In the *Agaves*, &c., mentioned, it is a frequent occurrence for proliferous buds to be formed in conjunction with the seed

capsules, and it is of course possible that a similar phenomenon should occur in the corymbiferous heads of *Armeria*, but in that case the embryo plants should remain in evidence from the outset under culture.—ED.]

EDITOR'S TABLE.

A NEW HEPATICA.

Mr. Goodwin sends a few flowers of a beautiful new *Hepatica* named *atro-cerulea*. It is a form of

THE NEW SAXIFRAGA GRIESBACHII.
(Drawn from a small plant sent by Mr. Smith, of Newry, and slightly reduced; the flowers are crimson.)

Anemone (Hepatica) angulosa, and is of beautiful colouring, an intense blue-purple, and very welcome at this time. It is just the plant for the cold or alpine house. Our correspondent writes: "I have sent you a few blooms of a new *Hepatica* raised by Horsman, of Messrs. R. Smith and Co., of Worcester. Horsman is quietly working to improve various hardy flowers."

SAXIFRAGA GRIESBACHII.

Mr. Smith, Daisy Hill Nursery, Newry, sends a plant in flower of this charming *Saxifraga*, which received a first-class certificate at the meeting of the Royal Horticultural Society on the 10th inst. We had a drawing made of it, and lovers of alpinists, especially those who have a cold house for the early-flowering ones, will treasure this gem. It is, as recorded in *THE GARDEN* of last week, page 120, "quite a new species, and from a new district, being found in Albania and Macedonia. Briefly described, it is not unlike a small *S. longifolia*; reminds one also of *S. calyciflora (media)*. It is the latter species that the new plant most closely resembles generally and in the flowering in particular. The peduncles are 4 inches or 5 inches long, purplish in colour, and densely hirsute, these appendages being likewise tinged occasionally with the same colour as the stems. The inflorescence is paniculate or racemose in outline, and freely furnished with short obovate decidedly green-tipped leaves. The flowers are small and numerous, purplish crimson in colour. The plant is obviously a good grower and free bloomer." Mr. Smith writes: "As you see it is one of the most charming of early February flowers." This is quite true.

HEATHS FROM EXETER.

Messrs. R. Veitch and Co., of Exeter, send a welcome boxful of Heaths, which include *E. arborea*, *E. codonodes* (now known as *E. lusitanica*), *E. mediterranea glauca*, *E. carnea*, and a form intermediate between *E. arborea* and *E. lusitanica*, probably a hybrid. The Heaths, though amongst the most beautiful of all shrubs, are amongst the most neglected, in spite of moorlands purpled with their colouring. The native species, too, remind one of those from other lands. This boxful of flowers from Exeter is a reminder of their beauty in winter, and we are pleased that Messrs. Veitch are devoting special attention to the family. The following descriptions of the hardy Heaths sent occur in "Trees and Shrubs for English Gardens":—
E. arborea.—This is the most remarkable of all

the hardy Heaths; it grows to quite a small tree. In the Isle of Wight, and doubtless elsewhere, it has been known to grow 30 feet high, with a trunk 39 inches in circumference. It is found in considerable abundance along the Mediterranean coast region between Genoa and Marseilles, the wood being used in the manufacture of the so-called Briar pipes, Briar being a corruption of the French wood *Bruyere*. All the Heaths flower with great freedom, but none more so than *E. arborea* and its near ally *E. lusitanica*. The flowers are almost globular and nearly white; they are quite small individually, but produced so abundantly that the plants are smothered with them from March to May. Mr. Bean

says: "My experience of this species is that it is hardier and thrives altogether better in the London district than *E. lusitanica*, a species for which it is often grown. It ripens seed every year almost, and can thus be readily increased in a natural way. The young wood is densely covered with short hairs, and the leaves are closely packed in whorls of three.

E. lusitanica (syn. codonodes).—Many will not recognise the name *lusitanica* as applied to the well-known *E. codonodes*, but *lusitanica* is really an older designation. This Heath, as its name implies, comes from Portugal; it is also a native of Spain, and is often confounded with *E. arborea*. Briefly, they differ in the following respects: The flowers of *E. lusitanica* are longer and more bell-shaped than the globular ones of *E. arborea*; the foliage of *E. lusitanica* is a rather pale green, and has a rather more plumose look, the individual leaf being longer and more slender; the young wood, although downy, is not so hairy as in *E. arborea*. The remarkable abundance of flowers, a feature of *E. arborea*, is quite as apparent as in this species; their colouring is a faintly pink-tinged white. Mr. Bean writes (and this is the Heath we refer to as probably a hybrid): "From Messrs. R. Veitch and Sons, of Exeter, who are taking a special interest in these tree Heaths. Kew has lately received a form intermediate between *E. arborea* and *E. lusitanica*—probably it is a hybrid. *E. lusitanica* does not apparently grow so large as *E. arborea*, but it is recorded to have reached 12 feet in height in Sussex. Farther west in Dorsetshire, it grows luxuriantly, and is certainly one of the loveliest of evergreen than can be grown even in that favoured county. Seeds afford the best means of propagation.

E. mediterranea glauca.—Messrs. R. Veitch also sent this beautiful variety, which has quite bluish foliage and a wealth of lilac tinted flowers.

E. carnea.—How welcome this is, a bright crimson mass, upon our table. Of all the dwarf Heaths more can be said in favour of *E. carnea* than of any other species. It is not only absolutely hardy, but it flowers with astonishing freedom at a time of year when flowers are particularly cherished. Its flowering of course somewhat depends upon the weather, but frequently one may see its bright rosy bells almost as soon as January comes in. By the

ERICA LUSITANICA (CODONODES).
(Three parts nat. size.)

end of February the entire plant is a mass of beautiful colour, and for two or three months longer they retain their freshness no matter what weather may occur. No free flowering is this Heath that its flowers literally cover it. *E. carnea* is one of those plants (and there are many of them) which, although perfectly well known and quite common, are still not used in gardens so freely as they ought to be. The majority of all early-flowering plants bear flowers that are either white or yellow, so that the rosy red colouring of this *Erica* makes a welcome change. However freely it might be planted it would never become wearisome or out of place, for its tints, though bright and warm, are not harsh.

SOCIETIES.

EAST ANGLIAN HORTICULTURAL CLUB. ANNUAL REPORT.

THE committee have much pleasure in presenting their report of the club's proceedings for the year ended November 29, 1902, together with a statement of accounts for the same period, which they trust will meet with general approval.

It is with great satisfaction that they are able again to report a progressive and successful year, which, unlike many of its predecessors, has happily been unclouded by the death of any member. One of the notable features of the year is the substantial manner in which the club has again maintained its rate of numerical growth, and when it is remembered that each succeeding year renders this achievement increasingly difficult, the extent of the new enrolments will be justly appreciated.

The financial position shows an advance corresponding with the numerical rise, and from the returns which follow it will be observed that the various departments have maintained a healthy activity, in most instances showing busier and bolder results than previous records.

The monthly gatherings have been characterised by uniformly good attendances, a respectful and orderly demeanour in debate, and a general attentiveness to the various proceedings. The committee fully recognise that the reputation of the club is largely dependent upon the character of these gatherings, and in view, therefore, of their great value as an advertising medium, they realise the importance of maintaining and, if possible, of enhancing the attractiveness and usefulness for which the meetings have hitherto been noted.

SYLLABUS FOR 1903.

March 11, "The Cultivation of Strawberries under Glass," prize competition (confined to single-handed gardeners); "How to Keep a Garden Gay from April to October," Mr. J. C. Abel; April 8, "The Narcissus and Its Cultivation," with illustrations, Mr. George Daniels, 48, College Road, Norwich; the best descriptive paper and specimens of the Primrose family, prize competition (limited to members of botanical section); May 15, "The Cultivation of the Grape, under Glass and Outside," prize competition (open to all members); June 10, "Originality: A Talk on Garden Notions, Old and New," Mr. Edward Peake (botanical lecturer); July 8, a discourse upon herbaceous plants, with examples, Mr. George Davison, The Gardens, Westwick House; August 12, "British Ferns found in Norfolk," Mr. J. Powley, F.R.H.S. (president); "Our Bird and Insect Allies," Mr. H. B. Dobbie, Pine Banks Gardens, Thorpe; September 9, "Fruit Growing for Cottagers and those with Small Holdings, giving Best Sorts to Grow," prize competition (open to all members); October 14, "Violet Culture, and How to Obtain the Longest Supply," prize competition (confined to single-handed gardeners); "My Experience in Grafting and Budding," Mr. E. Yeomans, Gunn's Court, St. Giles Street; November 11, "A Chat about Gardening in the Present Age," Mr. J. Clayton, 12, Royal Arcade, Norwich; December 9, no papers; annual meeting.

At the February meeting of this club, presided over by Mr. J. Powley, supported by Mr. T. B. Field in the vice-chair, nearly 100 members attended to hear Mr. F. W. Shrivell, F.L.S., give his interesting discourse upon "Chemical and other Manures." He (Mr. Shrivell) had brought with him a series of photographic views depicting the growths at the Experimental Farm, Tonbridge, which by the aid of a strong lantern were well thrown upon the sheet. A capital discussion followed, and a hearty vote of thanks was accorded to Mr. Shrivell for coming to East Anglia once more. The exhibition tables were well filled in the monthly competitive classes, and some fine products were noticeable. Mr. R. Abel had a typical plant of white Cyclamen. Forced bulbous plants, as exhibited by Mr. W. Rush, the Fernery Gardens, Thorpe, were very choice. Mr. F. Williams, gardener to Mrs. Louis J. Tillet, Old Catton, had a pretty arrangement in the class for bonquet of flowers. In the non-competitive class, a charming exhibit was placed on the table by Mr. George Davison, Westwick House Gardens, consisting of fine sprays of that somewhat rare shrub *Andromeda japonica*. This was much admired for its pendulous sprays of Heather-like blossoms. Mr. Davison also had blooms of the floribunda type and sprays of *Rhododendron precox*, all these being cut from the open. A fine solid silver bowl was presented to the club as a challenge bowl by Mrs. Louis Tillet, Old Catton. The committee have arranged a series of three competitions in the year and added further prizes, the highest points in this competition for the year to hold the bowl. If won by the same member twice it becomes his absolute property.

SHERBORNE GARDENERS' SOCIETY.

AT the ordinary monthly meeting held in St. John's Hall recently, Mr. J. Dean (president) in the chair, a very interesting paper on "Winter Flowers" was read by Mr. J. Crook, of Forde Abbey Gardens. He urged all gardeners to use their best efforts towards the production of blooms for the winter months, as the contrast between them and the summer time was so marked. In the prize competition there were no less than thirty entries. The prizes were awarded as follows: Brussels Sprouts—First, Mr. Barrett (gardener to Mr. Blake); second, Mr. Lane (gardener to Mr. E. B. Dingley). Beets—First, Mr. P. Thorn (gardener to Mr. R. Boden); second, Mr. Bishop (gardener to Dr. Williams). Celery—First, Mr. Crabb (gardener to Mr. Binnie Clarke, Digby Hotel); second, Mr. G. Leeding (gardener to Mr. Clayton, Bradford Abbas). Amateur section—Brussels Sprouts—First, Mr. Voisey; second, Mr. J. Evans. Beets—First, Mr. E. Hann; second, Mr. Evans. Celery—First, Mr. Hann; second, Mr. Voisey.

CARDIFF CHRYSANTHEMUM SOCIETY.

THE sixteenth annual meeting was held at the Grand Hotel on Friday, the 6th inst., the President (Councillor J. W. Courtris, J.P.) in the chair. Mr. H. B. Crouch (honorary treasurer) gave his report on the balance sheet, which showed an increase on the year's working, with a balance of £3 13s. in hand. The chairman gave his report upon the year's work of the society. After going into various details, he reported that this year there would be offered for competition three valuable cups and several medals given by local gentlemen. A pleasing compliment was paid the officials who had just completed the work of the past year with greater success than had hitherto been done in the past. The following were re-elected: President, Councillor J. W. Courtris, J.P.; the whole of the vice-presidents with the names of the two following gentlemen added, Messrs. A. T. Hill and Medhurst; chairman, Mr. John Julian; vice-chairman, Mr. Thomas Malpass; honorary treasurer, Mr. H. B. Crouch; honorary secretary, Mr. Harry Gillett; also Messrs. E. Molyneux, G. Adams, and H. Bartram have consented to act as judges again this year. The whole of the general committee were re-elected, and the name of Mr. J. Montney added. A strong executive committee were elected from this body to deal with the schedule at once.

WOOLTON GARDENERS' SOCIETY.

A MEETING of the above society was held recently at the Mechanics Institute, when there was a full attendance of members. Mr. R. Todd was voted to the chair, and introduced Mr. F. Ker, Aigburth Nurseries, to read a paper on "Hardy Plants and Bulbs for Early Forcing."

The lecturer considered about the middle of December a convenient time for forced blooms to take the place of the Chrysanthemum. The most useful for early work were the Van Thol Tulips, Paper-white Narcissi, and the common Daffodils. The Tulips succeeded best under the stage with some surfacing of litter or moss. These could be followed by *Azalea mollis*, A. Daviesii, A. indica, Lilacs of certain sorts, the earlier *Rhododendrons*, *Dentzia gracilis*, *Spiræas*, *Lily of the Valley*, *Lilium Harrisii*, and *Roses*, especially *Tea* and *Hybrid Teas*. The most approved temperatures and treatment were given in each case. Retarded plants also received some attention from the lecturer as contributing variety. A good discussion ensued, in which the chairman, Messrs. R. G. Waterman, T. Carling, G. Haigh, J. McCall, Jos. Stoney, and others took part. In addition to the plants and bulbs mentioned by the lecturer, the following were recommended as useful: Scarlet and white Thorns, *Clematis* in variety, *Laburnums*, pyramids or standards, *Magnolias*, and many herbaceous plants.

Mr. Jos. Stoney showed a well-grown *Odontoglossum crispum* of good form, and Mr. G. Haigh showed examples of the *Chrysanthemum rust*, fortunately for the district a pest not very well known. The thanks of the meeting were tendered for these exhibits. A cordial vote of thanks to the lecturer and chairman terminated an enjoyable meeting.

CROYDON HORTICULTURAL SOCIETY.

A MOST enjoyable and instructive evening was spent with this society at their rooms, Sunflower Temperance Hotel, on Tuesday week, when the subject "Peaches" formed the nucleus of Mr. Alderman's (The Gardens, Morden Hall) paper. Mr. Alderman talked about the introduction to this country of the Peach. In detail he discoursed on the life of the Peach tree from the time of propagating till its establishment as an old veteran in the greenhouse and on the walls of the garden, mentioning some trees under his own care which were over twenty years old. In the lecturer's opinion the Plum and Almond stocks were the best suited for grafting upon, and he emphasised the advisability of using good open, sandy soil, not too rich; for growing them successfully under glass, lean-to houses were best. From October to November he considered the best time for planting, although as late as February or March would be found suitable. In training trees the fan shape was considered to be best, leaving the centre of the tree well open, as this would eventually fill up when active growth took place. Disbudding should be done gradually, allowing a week's time between each operation, keeping the shoots regularly tied, and allowing exposure to sun and air. The thinning of fruit should be done at intervals, leaving a square foot of space from each fruit for exhibition purposes, and where a general crop is required 8 inches to 9 inches was sufficient. The application of a good mulch of short manure on the border, with the occasional addition of a little artificial manure, when fruits were well formed, would be beneficial. The troubles of insect pests were treated of, and the lecturer had always found the application of clear soot water applied with the syringe to be one of the best preventives. Some of the best varieties to be grown were

named by the lecturer. The discussion which followed was assisted by several members, and the chairman, Mr. W. J. Simpson, in proposing a hearty vote of thanks to Mr. Alderman for the paper, fully expressed the unanimous appreciation of the members for the lucid and practical manner with which the lecturer had dealt with his subject, and this was endorsed by Mr. M. E. Mills.

BATTERSEA, CLAPHAM, AND WANDSWORTH AMATEUR CHRYSANTHEMUM AND HORTICULTURAL SOCIETY.

UNDER most auspicious circumstances the annual dinner of this society took place on Saturday, the 7th inst., at Stanley's Restaurant, Lavender Hill, S.W. In the absence through illness of the president, Mr. F. J. Coppin, the chair was taken by the treasurer, Mr. W. J. Stringer, who was supported by Messrs. H. J. Jones, J. T. Berridge, D. B. Crane, G. T. Nines (hon. sec.), A. B. Freeman, and ladies and gentlemen to the number of about eighty. Mr. D. B. Crane, in proposing "the Ladies," congratulated the society on their innovation in asking the ladies to dine with them this year. He referred to the interest taken in our gardens by ladies, and their willingness at all times to assist their husbands to achieve success. That the artistic skill of the ladies in arranging flowers might be encouraged, Mr. Crane appealed for special classes for them. Mr. H. J. Jones responded. The chairman, in an enthusiastic speech, proposed "the Society." He justified its existence by the excellent work that was being accomplished, and asked that the members should continue to work with the same spirit which they had done during the past year. This was responded to in a very clever speech by the hon. secretary (Mr. Nines), to whom the society is greatly indebted for much hard work. Mr. H. J. Jones gave the toast "the Officers," to which the secretary replied. "Presidents, past and present" and "the Visitors" were both toasted with the same enthusiasm as that with which the previous toasts had been received, and the company broke up at a late hour. An excellent series of monthly meetings and lectures for 1903 and 1904 are in course of preparation, and several well-known horticulturists have promised their services. The society is financially sound, and there is the promise of a distinct accession of members in the near future.

LIVERPOOL HORTICULTURAL ASSOCIATION.

THE twenty-fourth annual meeting was held on Saturday the 31st ult., at the society's office, Liverpool, Mr. T. Foster, chairman of committee, in the chair. The report read by the secretary gave evidence of a useful year's work, spring and autumn exhibitions had been held which fully upheld the high merit of Liverpool shows. A cordial vote of thanks was tendered to the donors of special prizes, including Messrs. Thos. Davies and Co., John Cowan and Co., H. Middlehurst, W. Rowlands, R. Pinnington, and H. Sadler. The lectures delivered throughout the session were of a practical nature, and the thanks tendered to Messrs. Jos. Stoney, F. Ker, C. Paul, and J. Hathaway were well deserved.

The statement of accounts showed that a satisfactory financial year had been experienced, showing a gain for the year of £45 1s. 5d. The chief items include balance brought forward, £208 2s. 9d.; subscriptions, £337 14s. 9d.; advertisements and bank interest, £20 7s. 11d.; spring show, £35 9s. 9d.; autumn show, £167 15s. 11d.; total, £767 11s. 1d. Disbursements: General, £88 4s. 10d.; prizes, spring show, £73 9s.; autumn show, £154 4s. 1d. Expenses: Spring show, £80 0s. 10d.; autumn, £118 8s. 2d.; total, £514 16s. 11d. Balance, £253 4s. 2d. The usual donations of £3 and £2 were given to the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund.

The election of officers gave evidence of satisfactory results, the following being re-elected to their respective positions:—President, the Right Hon. the Lord Mayor of Liverpool; hon. treasurer, Mr. William Fletcher Rogers; sub-treasurer, Mr. G. Blackmore; auditors, Messrs. Harwood, Banner and Son and R. G. Waterman; secretary, Mr. H. Sadler, 7, Victoria Street, Liverpool.

The thanks of the meeting were tendered to Mr. Foster for his services in the chair.

The members met at the society's office on Saturday last for the purpose of hearing a lecture by Mr. C. Paul, Botanic Gardens, Manchester, on "Stove and Greenhouse Flowering Plants for Exhibition." Mr. T. Foster occupied the chair, and, in introducing the lecturer, stated he was one who could speak from practical experience, having been in the forefront of exhibitors at the past famous shows of Manchester. The lecturer referred to the changed times of gardening, comparing the giant specimens of the past with the smaller plants of to-day. In asking whether this was the fault of the gardener, he thought distinctly no. He believed that there were more good gardeners at the present day than twenty years ago. There were more difficulties to contend with now, such for instance as a dearth of good peat and loam, and water free from chemicals. The chief species were mentioned with concise notes as to their management, the form of house (span roof was recommended), the temperature, compost, potting, watering, syringing, shading, training, &c., all were treated clearly.

As usual the discussion which followed brought out many practical questions which were ably answered by the lecturer. At the conclusion a cordial vote of thanks was heartily passed to Mr. Paul for his excellent lecture and to Mr. Foster for presiding.

WISEBECH AND DISTRICT DAFFODIL SOCIETY.

THE annual exhibition will be held in the Public Hall, Wisbech, in April. Daffodils, Hyacinths, Tulips, and other spring flowers will be shown. For the best collection of Narcissi, not less than twenty distinct varieties, the ladies' silver challenge cup, value £10 10s., is offered in addition to cash prizes. Full particulars may be had from the hon. secretary, Mr. G. Stevens, 6, Albion Terrace, Wisbech.

THE GARDEN

No. 1632.—Vol. LXIII.]

[FEBRUARY 28, 1903.]

AMATEUR GARDENERS AND COTTAGE GARDEN SHOWS.

WE have on many occasions drawn attention to the beneficent influence of cottage garden shows upon village and suburban life. The Dean of Rochester, so well known as a great rosarian and helper in all movements that tend to the bettering of the men and women of rural England, sends a letter written by him to the *Chatham and Rochester News*, which we reproduce.

"We have so many societies in this neighbourhood for the extension of cottage gardens and the encouragement of amateur gardeners; so much has been done by our Kent County Council to confer the advantages of horticulture upon the working classes by the appointment of experts, to supervise, to give lectures and practical instructions, to establish exhibitions, to reward success; and the happy results of these beneficent endeavours have been so often seen in a closer attachment to home life, in escapes from temptations and evil habits to healthful and useful employment, in the variety and increase of wholesome food, in that admiration of the beautiful, which purifies the mind and exalts it to look through Nature up to Nature's God; all these considerations assure me that a large number of your readers will read with interest of a new and generous attempt to evoke enthusiasm, ambition, and experience among these cottage and amateur gardeners.

"In addition to the local shows, at which individuals compete with each other, Lady Algernon Gordon Lennox proposes an exhibition, on the Bank Holiday in August next, at Broughton Castle, Banbury, for societies or groups of villages, each society or group to select from its members a collection of hardy flowers, fruit, and vegetables, grown by cottage gardeners and amateurs only, of which full particulars are given.

"The Lennox Challenge Cup, value 50 guineas, will be awarded to the winner of the first prize, to be held for one year, and retained after three successive years of victory. The Royal Horticultural Society will present four of their Banksian medals, and £30 will be given in money.

"The exhibition is restricted to gardeners dwelling in Northamptonshire, Oxfordshire, and Warwickshire, but we may hope that this example will be followed in other counties by those who enjoy, and would impart to others, the happiness of a garden."

We hope, too, that the example of Lady Algernon Gordon Lennox "will be followed

in other counties by those who enjoy, and would impart to others, the happiness of a garden."

As we wrote last year in *THE GARDEN* in referring to cottage flower shows: "There is the hobby to work for all the year round; there is the incentive of emulation which human nature needs to rouse it out of its normal inertia; there is the pleasant intercourse over kindred interests to fill many an ill-spent Sunday afternoon with innocent occupation; there is wholesome food and rich reward of flower beauty at the command of instructed head and diligent hands in every rood of garden ground around each cottage door. All who have beautiful homes of their own may help on the good cause of bringing cheer into other lives by wise and kindly help to the neighbour with fewer opportunities."

"PHILISTINISM" AND THE HORTICULTURAL HALL.

"Philistinism" at least knows what it wants, while aestheticism is apt to waste its energies on what is not practical."—*Gardeners' Chronicle*, February 14, page 104.

OUR friendly contemporary, remarking, as we suppose, on our recent criticism of the new Hall, uses the above words.

Nothing is more true. The word aestheticism (if there be such a word) is either used by the artist in expressing his contempt for the many absurd affectations of the ignorant who pretend to a knowledge of fine art which they do not possess, and for the odious, useless, and taste-depraving mass of so-called "art" and "decoration" which has flooded the world during the past half century, or it is used by the pure "Philistine" to convey an idea of something which he cannot even describe or define, but that, being beyond his comprehension, he regards with suspicion and aversion. It is a term of reproach which he hurls at fine art in general, confounding, in his blissful ignorance, all expression of fine art or so-called fine art, whether good or bad.

If it be true that "Philistinism"—the term, in the case of the quotation from our contemporary, being unmistakably applied to those who approve of the Hall design—"knows what it wants," it is evident to anyone with a grain of sympathy with fine art that it deliberately "wants" an ugly building. The only possible alternative is that it does not "know" the nature of the thing that it "wants," and therefore is not ashamed.

We shall write nothing further about the designs. They have been passed by the

meeting recently held, and therefore all the Fellows have to do is to get the building built as quickly as possible. For this purpose funds are needful.

We have given our warmest support to the Hall scheme, and this support will never be relaxed, but the building will not add to the architectural beauty of London. This is our belief. We were anxious that the Hall should be simple and beautiful. Our efforts have failed we honestly confess, although there is satisfaction in knowing that even "Philistinism" is uncomfortable about the future.

THE NATIONAL ROSE SHOW.

THE National Rose Society have greatly added to the beauty and interest of their later exhibitions by awarding prizes to collections of "garden or decorative Roses," of which they have included a "selection of the fittest" in their admirable official catalogue. The committee are most anxious to increase the attractions of the show and to improve the arrangement of the flowers, and it might be helpful if some of those critics who are most severe in their denunciations of the present methods would kindly make a few practical and possible suggestions as to the future. We all desire more diversity, more graceful adaptations, more room and less heat in the tents, with the surroundings of a spacious garden, umbrageous trees, comfortable seats, and charming grottoes; but we are at present in the unhappy condition of Little Bo-peep, and "don't know where to find them." As to the cruel suggestion of a two days' exhibition, which, with its faded petals and *pot pourri*, intensified by a few "renovations," would represent the decline and fall of Queen Rosa's empire, the visitor would

"Feel like one who treads alone
Some banquet hall deserted,
Whose guests are fled, whose Roses dead."

Sad as Marius weeping over the ruins of Carthage, or as some enthusiastic "bedder-out" in his garden after a hailstorm. Better to bear the ills we have (trying to overcome them) than fly to others which we know not of. Sufficient unto the day is the evil thereof.

S. REYNOLDS HOLE,
President of the National Rose Society.
The Deanery, Rochester, Feb. 21, 1903.

KEW NOTES.

INTERESTING PLANTS IN FLOWER.

Temperate House.

ACACIA JUNIPERINA, A. myrtifolia, A. ovida, A. verniciflua, A. verticillata, and others, Camellia reticulata, Leucopogon lanceolatus, Rhododendron grande, R. hybridum, Strelitzia Reginae, and S. R. var. citrina.

Palm House.

Clivia macrophylla.

Orchid Houses.

Catasetum maculatum, Cattleya guttata var. Prinzii, Cirrhopetalum picturatum, Cynorchis compacta, Cypripedium siamense, Dendrobium chryso-discus, D. lituiflorum, D. Pierardi, D. sarmen-tosum, D. wardianum and others, Epidendrum stanfordianum, E. xanthinum, Lælia harpophylla, Masdevallia Ehippium, M. melanopus, M. schre-deriana, Maxillaria picta, Ornithidium coccineum, Phaius Marthæ, P. tuberculosus, P. Wallichii, Platyclinis glumacea, Selenipedium Sedeni var. candidulum, Tetramicra bicolor, Vanda suaviss, and V. tricolor.

† *Range.*

Anoiganthus breviflorus, Begonia phyllomanica and others, Kalanchoe Kirkii, Phædranassa chlo-racea, and Veltheimia viridifolia.

Succulent House.

Aloe nitens and *Protea cynaroides.*

Greenhouse.

Amorphophallus Rivieri, forced bulbs and shrubs, and other things.

Rock Garden and Herbaceous Ground.

Draba Aizoon, *Crocus* (various species), *Iris thunbergiana*, *Narcissus cyclamineus*, *N. minor* var. *minimus*, *Saxifraga apiculata*, *Scillasin* var., and *Tulipa violacea.*

Alpine House.

Bulbocodium vernum, *Corydalis kolpakowskyana*, *C. ledebouriana*, *Draba Gilliesii*, *Erythronium citrinum*, *Gagea arvensis*, *Hyacinthus azureus* var. *robustus*, *Ionopsidium acaule*, *Orchis longi-bracteata*, *Primula denticulata*, *P. megaseæfolia*, *Saxifraga burseriana*, and *S. oppositifolia* var. *alba.*

Arboretum.

Ericas in variety, *Nuttallia cerasiformis*, *Prunus Amygdalus* var. *dulcis*, *P. A.* var. *persicoideis*, *P. armeniaca*, *P. cerasifera*, *P. Mume*, *P. tomentosa*, and *Stachyurus præcox.*

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

March 2.—Société Française d'Horticulture Meeting.

March 3.—Meeting of National Amateur Gardeners' Association.

March 9.—Annual General Meeting of the United Horticultural Benefit and Provident Society, Caledonian Hotel, Strand, at 8 p.m.

March 10.—Royal Horticultural Society Meeting, 12 noon; Horticultural Club, 6 p.m.

March 24.—Royal Horticultural Society Meeting (Tulip and Hyacinth Show).

March 25.—Liverpool Horticultural Association Spring Show.

Royal Horticultural Society.
Alteration in rules for judging.

Everyone possessing a copy of the rules is requested to make the following alterations: Page 14, line 4, should in future read thus: Muscat of Alexandria or other Muscat Grapes, 11; and the word "other" should be inserted before "black Grapes."—W. WILKS, Secretary.

Well-grown Freesias.—I am sending you a photograph of a batch of Freesias, which, if you care to use in THE GARDEN, please do so. These beautiful flowers well repay good culture, and are always asked for by those who have extensive flower decorations or cut flowers in any one room, the scent being very strong. I flower my own bulbs as a rule year after year, but to do this give them good culture before and after flowering, gradually withholding water as the foliage turns yellow, and then put them on a shelf where the sun plays well on them all day. Thus there need be no fear of their failing to start freely when potted on again.—J. R. WILSON, *The Gardens, Sulby Hall, Rugby.*

Pear Beurre Rance in March.—This is our latest Pear, but unfortunately the

fruits this season are scarce, and like many others did not keep as well as usual. In some gardens this old variety is not always a favourite, but I have no fault to find with it, as in a light soil or gravel it does remarkably well. I well remember this tree many years ago in the western part of the kingdom in a light warm soil grown in standard form. It was one of the most profitable Pears grown, and, as far as my memory serves me, it rarely failed to crop. The fruits grown on standard trees are not so large, but they keep well. On the other hand, I have observed of late years that this variety in the northern counties did best on a west wall. Grown thus the trees made splendid growth. It is a very old variety and is grown under various names, but it is a very distinct fruit and readily known by its dark skin and russet spots, with its greenish white flesh, and rich vinous flavour. I think it is worth room in all gardens where late Pears are wanted, and in certain soils it rarely fails. Grown on a wall the fruits are large and good.

A valuable late dessert Apple (Armored).—There are plenty of dessert Apples, but none too many really first-rate kinds; but the new Armored promises to be when better known a standard fruit for use in the spring months. This new variety was raised by that well-known fruit grower, Mr. C. Ross, of Welford Park, and I place it in the front rank of dessert fruits for its splendid quality, its lateness, and free growth, as far as my experience goes. The fruits are small, but quite large enough for the dessert, yellow, russetty, and of splendid flavour; they keep well into May. To prove what a really good dessert variety the Armored is I may mention that it received an award of merit in March, 1890, and a first-class certificate on May 24, two years later. This is a very prominent position for any new fruit. It will be seen that an Apple to get an award at the end of May must be of good quality at such a late period of the year, and to get the highest possible award shows its superior quality. If it prove a heavy cropper it will be as great a favourite in private gardens.

A new Plum (Rivers' Late Orange).—This new fruit is well worth attention, as it is one of the best flavoured of the late Plums I have tasted, its season being the end of October. The Late Orange is a free stone and of medium size, with a bright golden skin covered with heavy bloom. The fruits are remarkably rich and juicy, and when its late season is considered it may be classed as a great gain to those who require fruit in variety as late as possible. The Late Orange was raised by Messrs. Rivers, and I can safely say the above variety will prove one of the best Plums we have had of recent years, and a good companion to the older Coe's Golden Drop. With these excellent varieties the Plum season will be greatly extended. It is not too late to add this new variety to the older kinds, and where Plums thrive I am sure Late Orange will prove profitable. This variety received a first-class certificate a short time ago from the fruit committee of the Royal Horticultural Society.—G. WYTHES.

The flora of Krakatoa.—"The Island of Krakatoa," says *Knowledge*, "lost all its vegetation in the terrible volcanic eruption of August, 1883, which covered the island to a depth varying from one to sixty metres with a bed of red-hot ashes and pumice-stone. Its appearance afterwards was that of a mountain isolated in the sea, rising with almost perpendicular sides to a height of 2,500 feet. The island, which is twenty-one miles from Java and twenty from Sumatra, was visited by Dr. Treub in 1886. He found it uninhabited, and not easily accessible. On the narrow beach he found fruits or seeds of seven species of Phanerogams, and young plants of nine species, all the latter, excepting one grass, being the usual littoral plants of tropical islands. In the interior the vegetation was quite different—Ferns, both in the number of species and individuals, predominating. Dr. Treub concluded that Ferns in such a flora precede and prepare the soil for a phanogamic vegetation. Their minute spores would be brought long distances by the wind, but

it was remarkable that these would germinate and develop into plants on the intensely arid soil of Krakatoa. A close examination of the ashes and pumice-stone, however, revealed the presence almost everywhere of Algae coating the soil with a thin gelatinous layer, in which the Fern spores would find a suitable place for germination. Besides lower Cryptogams, Dr. Treub found, in 1886, fifteen Phanerogams and eleven Ferns; but in 1897 the flora consisted of sixty-two species (fifty Phanerogams and twelve vascular Cryptogams) belonging to twenty-four orders. The Ferns still predominated in the interior, and several species of tall grasses formed a striking feature of the vegetation. Seeds or fruits of thirty species were found on the beach, and here and there seedling plants, showing that the seeds were capable of germination. Of the fifty Phanerogams, it is estimated that seventeen were introduced by the agency of the wind, thirty-two by water, and four by birds."

Canarina campanulata.—Now and again I am interested in seeing a note in THE GARDEN on the above beautiful winter-flowering plant. Some of your correspondents seem to have a difficulty in getting it to flower freely. A note on the treatment given the plant here may be of interest to others. After flowering and when the foliage begins to take on a yellow tint, which is generally about the end of March, we gradually withhold water until the foliage is quite ripe, when watering ceases altogether, and the plant is placed on a shelf in the greenhouse to rest during the summer. Generally about the end of August young shoots appear and a good soaking of water is given at this stage. When the young shoots are about an inch long most of the old soil is shaken from the plant, which is usually repotted in a pot two or three sizes smaller than that in which it has been grown. When the young growths are 6 inches high pinch out the tops, and when the growths resulting from this pinching have developed 6 inches pinch again. In about a fortnight the plant is ready for a shift into its flowering pot, which in our case is 10 inches. As soon as the roots are running in the new soil we give the plant a final pinch. From the above treatment we have a plant 3½ feet high and 3 feet through flowering beautifully. Early in January I counted the flowers and there were 105. This is a plant that should be more often seen in gardens, as it is so easily grown and never fails to attract attention.—P. WILSON, *The Gardens, Orchardton, Castle Douglas, N.B.*

The Alicante Grape.—A leading fruit authority states "this is the worst Grape on the market," for though good to eat, the tendency of the berries to shrivel tells against it. The market returns show it is fetching from 1s. to 2s. per lb. Gros Colman from Belgium are better, but fetch only 1s. per lb. Late black Grapes do not appear to be a paying speculation. The same report states that a few well-kept Muscats are yet to be seen, and are fetching fair prices: but larger bunches of better quality pay better. When we remember what late well-kept Muscat Grapes fetched in the market thirty years ago and compare them with what is paid to-day, it is possible to see what a revolution has taken place in commercial Grape culture.—R. D.

Helleborus olympicus and H. abchasicus.—These two Hellebores, planted in one bed, make up one of the prettiest spots in my garden in February. They are under a north wall in good soil, and show up strongly every year. *H. olympicus* is white externally, and *H. abchasicus* of various tints of reddish purple. Both differ from *H. niger* in having taller flower-spikes, which are branched and bear small floral leaves, enhancing the effect very much. Although the flowers are drooping this is no drawback, as the exteriors are as highly coloured as the interiors. Still, the beautiful ring of stamens in the purple one may be better enjoyed by cutting a good stem and splitting it well up before placing it in water. So treated they last fairly well. I have read somewhere that they last better if placed under a bell-glass, but I have never tried this plan.—T. J. WEAVER.

J. C. Tallack, is quite distinct from that species, its proper designation being *I. lanrifolia* nova. This title naturally leads to some confusion, and it seems a pity that it should not be generally known in this country by its Continental name of *I. camelliaefolia*, to which the shape of its spineless leaves sanction its right. When out of berry the casual observer rarely recognises it as a Holly. A few weeks ago I noticed a splendid specimen in the gardens of Chaddlewood, South Devon, the residence of Mr. G. Soltan Symons. This tree was very symmetrical in shape and fully 20 feet in height, and was bearing an abundant crop of berries.

Hibbertia dentata.—This Australian climber, mentioned by "H. P." on page 51, may be grown on a warm wall in the open in the south-west. Last spring I saw it bearing its yellow flowers on a house front in the neighbourhood of Penzance, and have since then seen the same plant on two occasions, namely, in July, 1902, and during the past January. The plant in question is only a small one, being scarcely 5 feet in height, but appears in perfect health. "H. P." says that the leaves are "deep green in the adult stage, but when young are tinged with bronzy red." Doubtless the colouring of the foliage much depends on whether the plants are grown in the open or under glass, for the one to which I allude shows no sign of green in either the young or old leaves, all being of a deep maroon-brown, which renders it particularly effective.

Agapanthus umbellatus albus.—About two years ago there appeared several letters on the culture of the above plant, in the course of which some writers stontly affirmed it to be evergreen, while others just as positively declared it to be deciduous. Doubtless there are two distinct plants—one a white variety of the evergreen *Agapanthus umbellatus* and the other a separate species—though none is recognised in horticultural dictionaries that is deciduous. The latter is the only one known to me personally. Recently I visited a neighbouring steeply sloping lawn where several large clumps of *Agapanthus* are growing. The great clumps of the blue type, over 4 feet in diameter, were carrying all their leaves intact, but not a trace of the white could be seen except some withered foliage level with the ground. On brushing this aside the tips of the young leaves could be seen about an inch in length. This is quite a month earlier than they usually start, but during the past winter there has been no frost registered in the screen and only 2° on the grass.—S. W. FITZHERBERT, *Kingswear, South Devon.*

THE INDOOR GARDEN.

FUCHSIAS FOR GREENHOUSE AND BORDER.

ABOUT seventy species of Fuchsias are known to botanists, but of these few are at all common in gardens. Most of those usually grown as pot plants are either seedling sports from the species, hybrids, or, still more often, seedlings from these hybrids. *Fuchsia macrostemma*, one of those species which go by the name of Bush Fuchsia in the south-west of England, is the ancestor, often very many generations removed, of many of our favourite Fuchsias. As this *Fuchsia* was only introduced into this country about the end of the eighteenth century it will be seen how comparatively modern most of our garden Fuchsias are. To-day the *Fuchsia* cannot be said to be in favour with florists, very few giving much space to it in their catalogues, while a striking evidence of the little demand for it is the fact that the *Fuchsia* is scarcely ever seen at the fortnightly exhibitions of the Royal Horticultural Society at the Westminster Drill Hall. At the time of writing I think it would be no exaggeration to say that less than a dozen plants of the garden hybrids have been seen there during the last twelve months. And yet it is so extremely useful

for such a large variety of purposes, and is always a graceful addition, though we sometimes see it growing in gardens in such a way that it has not a chance of showing its beauty. Add to this the fact that, with ordinary care and attention, it is an easy plant to grow, and it becomes more difficult to understand why it is not grown more. Few plants respond more readily and obviously to good treatment.

If it is desired to start a collection of Fuchsias rooted cuttings should be bought from a florist in March or early in April and put in 2½-inch pots in a hot-bed or in a greenhouse, plenty of silver sand being placed round them. In a fortnight, or at most three weeks, they should be ready to be shifted into pots a size larger. One of the secrets of raising strong plants quickly is frequent re-potting, never during the growing time allow the pots to become root-bound, and always put them into pots just large enough to admit of fresh earth being worked all round the ball of roots. A good soil to use for potting them consists of two parts of rotted turf, one part leaf-mould, and one part thoroughly rotted manure, with the addition of coarse sand. The rotted manure should be omitted while the plants are small, while if a heap of road sweepings, not scrapings, which has had some time to mellow, is handy, the rotted manure and the sand may be dispensed with for all stages of growth, the road sweepings being substituted in the same proportion as the rotted manure. Fuchsias like an open soil, and the more fibre in the turf the better, while ample drainage is most essential. I have broken up crocks or pieces of red brick into small pieces not bigger than garden Peas and mixed them with the soil and the plants thrived splendidly. If the plants are wanted for greenhouse or conservatory decoration solely they may be grown on in the greenhouse indefinitely, but if intended for outdoors they should be hardened off in June, in damp weather preferably, and placed where a sudden burst of sunshine will not affect them, when after a week they will be able to stand anything.

The best time to strike cuttings is in March in a greenhouse, and in April in a frame, from which all frost is excluded. The best and strongest cuttings are those obtained from old plants which have been kept in some dark place during the winter, and are brought out the latter part of February or early in March into daylight, or even into warmth. When the new shoots have pushed 2 inches they should be broken off at the junction with the old wood and put round the sides of small pots in a sandy soil. If given too much water they will damp off or lose their leaves, and if not given enough water the leaves will also fall, when, of course, the cuttings cannot form new roots. A good way to prevent both these evils is to put a cork in the bottom of a pot and set it in another pot a size larger, say, a 3-inch pot inside a 4½-inch pot, put the sandy soil in the space between the sides of the two pots, and the cuttings round the sides of the outer pot as usual, and then, after giving the cuttings a sprinkling at the time of inserting them, fill the inside pot with water. Nothing more will be necessary till the cuttings are well rooted, except to see that the inside pot is kept full of water. The porous sides of the pot will let through enough moisture to maintain the cuttings in health without keeping them wet enough to cause damping off. They should be potted off as soon as they are well rooted, as they will lose time if kept too long where they are, and besides feeling the move more when separated.

Fuchsias may also be raised from seed, and may even be treated as annuals, for if sown in February and brought on in heat they will be well in bloom by August. This is a very interesting method of raising Fuchsias, as often scarcely two will come alike if the seeds have been sown from hybrids, while if strong-growing plants are wanted for making large specimens, stronger plants may sometimes be got in this way than by cuttings, though one may have the trouble of rearing some plants, perhaps a good many, which turn out to be worth but little. The habit of growth will be as various as the colour and shape of the flowers, and

those which display a very loose straggling habit may be dispensed with as worthless, without waiting for them to flower.

As stated above, Fuchsias can be used in very different ways, more perhaps than almost any plant, *e.g.*, greenhouse climbers, bedding plants, herbaceous plants for the mixed border, shrubs for large pots or tubs, and ordinary pot plants for house or conservatory decoration. But the same *Fuchsia* will not answer all these purposes, and therefore selection has to be made of certain sorts for certain uses, and these have to be trained from the time they are small rooted cuttings with a definite end in view. We will deal in detail with some of the uses to which Fuchsias can be put, with the method of training necessary, and the sorts most suitable for the different uses.

ALGER PETTS.

(To be continued.)

TREES AND SHRUBS.

TRANSPLANTING LARGE TREES AND SHRUBS AT KEW.

WHEN laying out new gardens it is often advisable to introduce large trees or shrubs for special positions, and when alterations are being made in old gardens it is sometimes found necessary to remove similar plants, consequently a gardener should possess a sufficient knowledge of the subject to enable him to manipulate such plants successfully. At Kew a great many such plants are transplanted annually, two methods of procedure being adopted. In one case lifting machines, varying in size according to the size of the plants, are used, and on these machines weights ranging from half a ton to 7 tons can be moved; in the other case planks and rollers—and a trolley if the plant is to be taken any great distance—are used. In all cases where it is possible machines are used, but it sometimes happens that the plants are in such awkward positions as to make it impossible to use one, or the head of the plant may be too bushy to allow of the machine being placed in position without injuring the head, and it is in such cases that the advantages of the plank and roller method are seen.

When preparing a plant for moving on rollers the top should firstly be tied together as tightly as possible if in the way of work, after which the size of the ball should be determined upon and also the direction in which the plant is to be taken out. After these preliminaries have been settled, trenches 1½ feet in width should be taken out across the full width of the ball and to a depth of 6 inches below the lowest roots. When this is done make a tunnel through the centre of the ball below the roots wide enough to allow of two planks 11 inches wide and 4 inches thick being driven through the middle. These planks should be 18 inches longer than the ball is wide, to allow of 9 inches being free on each side. After these planks have been placed in position and made firm the other two sides of the ball should be dug out to leave a square mass of soil. When this has been done a strong canvas should be bound tightly round the whole, battens being used to keep the binding ropes from cutting into the soil. After this strong Oak boards 9 inches wide and 1½ inches thick should be placed on each end of the central planks and be worked under the ball until the outsides are level with the sides of the ball, two similar boards being afterwards worked under the remaining sides, the ends of which should rest on the ends of the first two.

The next operation is to make an incline to the bottom of the hole at the side where the plant is to be taken out, after which the ball should be tilted back with a jack—by lifting on one end of the central planks—high enough to place two planks three-quarters of the way under the ball, on which a roller 5 inches in diameter should be placed a little beyond the centre of the ball. When the jack is let down the plant should balance, a roller being placed in front for it to rest upon. A strong pulley block should then be fixed to the ball, through which a rope is run, one end of which is secured to some tree or other stationary object; by pulling on the rope the plant may then be drawn out of the hole.

To place on a trolley simply means more planks and rollers. When placing the plant in position again a large hole with an incline at the front and a central channel 6 inches deep and wide enough for the central planks to drop into should be made, pieces of planks being placed for the rollers to travel on.

loam. In addition to being evergreen, they have also other merits which place them among flowering shrubs. Although the flowers are not large, in one or two species they are borne in sufficient profusion to make a good show, and being white they are in good contrast to the deep green leaves. An additional qualification of the flowers is their fragrance. The cultivation of Phylliræas is simple, for after they have once become established they give little further trouble, as they grow naturally into shapely bushes. When pruning is desirable this should be done in spring just before growth begins, and the branches cut out in such a way that the cut portion is not noticeable. If after the plants have become established it is thought desirable to move any of them, take care to move a good-sized ball of soil with them, as they are rather impatient of root injury and take a long while to recover if moved without soil after they have attained the age of five or six years. Propagation may be done by cuttings of half-ripe wood in June and July, by layering in early spring, or by grafting on stocks of the common oval-leaved Privet. In many places the latter method is adopted, as

P. angustifolia.—In or about 1597 this was introduced from Southern Europe, where it is distributed over a considerable area. Planted where it has plenty of room to develop, it will grow to a height of 10 feet or 12 feet, with a width of 12 feet or 15 feet. It, however, varies considerably in habit, being sometimes met with 7 feet or 8 feet high and 15 feet or 18 feet through, a perfect symmetrical bush. The opposite leaves are lanceolate or linear lanceolate, $1\frac{1}{2}$ inches to 2 inches long, with entire margins, glabrous, and deep green. The flowers are small and white, and are produced from the leaf axils in April and May. The best known variety of this is *P. a. var. rosmarinifolia*; it has narrower leaves than the type.

P. decora.—In gardens this is often met with under the name of *P. vilmoriniana*, one of its several synonyms. It was the last of the set to be introduced, the date of introduction being given as 1885; its native country is Lazistan. It is very distinct and useful, making excellent beds or isolated specimens. The largest plant at Kew is $5\frac{1}{2}$ feet high and 13 feet through and of uniform outline. The leaves are ovate, acuminate, 4 inches to 5 inches long, and 1 inch to $1\frac{1}{2}$ inches wide, with entire, slightly revolute margins. In texture they are thick, and in colour dark green above and paler beneath. The flowers are white and fragrant and borne in small axillary clusters in May. It has been recommended as a good plant for forcing, but it is doubtful whether it will ever be very popular for that work, as it does not flower freely when young, and old plants do not care for much root disturbance. If, however, plants were grown in large tubs it could be dealt with successfully. Another synonym under which it is sometimes seen is *P. laurifolia*. An unnamed form with narrower leaves than the type is sometimes met with.

P. latifolia.—This is distinguished by its upright bushy habit and short, broadly ovate leaves—little more than 1 inch in length—which have serrated margins. It grows naturally to a height of upwards of 20 feet, but shapely bushes half that height with a similar diameter are very useful. As is the case with the others, the flowers are white. Several varieties are known, of which *P. l. var. ilicifolia* with smaller and *P. l. var. rotundifolia* with rounder leaves than the type, are most often seen.

P. media.—In appearance this is about halfway between *P. angustifolia* and *P. latifolia*. It is a very variable species, some varieties closely resembling one or other of the two mentioned species, the type being quite distinct from either. Its chief point of difference from *P. angustifolia* is that the leaves are serrated, though in some varieties, particularly *P. m. var. oleaeifolia*, the serration is very faint. It has been in cultivation upwards of 300 years, and seems to have been planted fairly extensively at some time, as large plants are met with 15 feet or more high. The varieties *P. m. buxifolia* and *P. m. oleaeifolia* are distinct; the former has Box-like leaves, and in the latter they are small and Olive-like.

W. DALLMORE.

WINTER-FLOWERING TREES AND SHRUBS.

The number of trees and shrubs that flower during the four dullest months of the year—say, from the middle of November to the early part of March—is perhaps larger than many would imagine. The following list contains over fifty species which may fairly be described as coming under that heading. It is based on the conditions that obtain near London, and could no doubt be lengthened considerably by those living further south and west,

TRANSPLANTING A YEW TREE IN THE ROYAL GARDENS, KEW.

When in position planks, rollers, &c. can easily be removed by means of the jack. If the plant is not quite upright it can be undermined and settled into position. The subject of the illustration is a spreading Yew 16 feet in diameter. The ball was 6 feet 6 inches square and 2 feet 3 inches deep.

The largest plant moved at Kew this winter in this manner was a Rhododendron 12 feet high and 18 feet wide, the ball being 9 feet by 7 feet 9 inches by $2\frac{1}{2}$ feet. This plant had two sets of central rolling planks 18 inches apart instead of one set. In all operations of this description it is essential that all planks, rollers, and ropes should be perfectly sound and strong to minimise the risk of accidents.

PHILLYRÆAS.

ALL the cultivated Phylliræas are evergreens, perfectly hardy, and thrive in various soils, ranging from that of a light sandy nature to heavy

the plants grow at quite double the rate of those raised from cuttings. Grafting is not, however, to be commended, as grafted plants, especially of *P. decora*, are not so long lived as plants on their own roots.

The uses to which Phylliræas can be put are many, for they can be made to play an important part in the formation of shrubberies, make excellent beds and fine specimen plants for the lawn, or they may be used for informal hedges in places where a wide unclipped screen is required. Being perfectly hardy they can be used in most parts of the British Isles, and might with advantage be planted in many instances as substitutes for the common Laurel. The species in cultivation are four in number, and are found in Europe in the region bordering the Mediterranean and in Asia Minor. Three of the species are of very old introduction, the fourth having been barely twenty years in general cultivation. One or two of the species have several distinct varieties, the best of which are enumerated with their respective parents below.

CAMPANULA TOMMASINIANA ON ROCK GARDEN.

just as it would have to be reduced to suit more northerly localities. The date of flowering, too, is to some extent dependent on the same conditions, and still more so on the mildness or severity of the winter. A long and severe frost, for instance, setting in before Christmas would defer the flowering of several shrubs from December and January to February or later. The conditions also under which individual plants grow influence the time of flowering. *Chimonanthus fragrans* growing on a wall is usually in flower at or before Christmas, but as a bush in the open it blooms a month or six weeks later.

Many of the plants mentioned would, if they flowered in April, May, or June, be eclipsed by the great host of more showy things that then burst into bloom, but now their modest beauties have a singular charm, added to in many instances by a sweet fragrance. It would be an interesting thing to bring together in some sheltered spot all, or as many as possible, of these winter-flowering trees and shrubs, adding to them others that flower by the beginning of April. By devoting some such place to them, the shelter from north and east that many need could then be more easily furnished—shelter which is not only welcome to the plants themselves, but to those who may love to watch and tend them. For such a purpose one imagines as an ideal spot a piece of fertile ground sloping well to south-south-west and surrounded on the north and east by a belt of trees, in the foreground of which are growing Hollies, Box, or other close evergreens. Many things, such as the Witch Hazels (*Hamamelis*), *Prunus davidiana*, some of the *Daphnes*, &c., being deciduous, require some such background to set off their beauty to greatest advantage.

In the following list there are doubtless omissions. Of course, by including others that flower a month or even a fortnight later, the list could be greatly lengthened, but such things are more strictly spring than winter-flowering.

November.

- Lonicera fragrantissima* (up to March).
- „ *Standishii* (up to March).
- Hamamelis virginica* (often earlier).
- Fatsia japonica*.
- Arbutus hybrida*.
- „ *Unedo* and its varieties.
- Jasminum nudiflorum* (up to February).

- Daphne Mezereum* var. *grandiflora*.
- Eleagnus glabra*.
- „ *macrophylla*.
- „ *pungens*.

December.

- Crataegus monogyna* var. *præcox* (Glastonbury Thorn).
- Erica mediterranea hybrida*.

January.

- Clematis calycina* (up to March).
- Erica carnea* (up to March).
- „ var. *alba* (up to March).
- Viburnum Tinus* (*Laurustinus*).
- Chimonanthus fragrans* and vars.
- Garrya elliptica*.

February.

- Erica mediterranea* (up to April and May).
- Daphne Laureola*.
- „ *Mezereum*.
- „ var. *flore albo*.
- „ *oleoides*.
- Berberis nepalensis*.
- Prunus davidiana* (often earlier).
- Pyrus* (*Cydonia*) *japonica*.
- Hamamelis arborea*.
- „ *japonica*.
- „ var. *zuccariniana*.
- Cornus Mas* and varieties.
- „ *officinalis*.
- Rhododendron altaclerense*.
- „ *dauricum*.
- „ var. *atrovirens*.
- „ *nobleanum*.
- „ *parvifolium*.
- „ *præcox*.

Early March.

- Forsythia suspensa*.
- „ *intermedia*.
- Rhododendron fulgens*.
- „ *Thomsoni*.
- Nuttallia cerasiformis*.
- Daphne blagayana*.
- Dirca palustris*.
- Populus tremula*.
- „ *tremuloides* var. *pendula* (*Parasol de St. Julien*).
- Stachyurus præcox*.
- Parrotia persica*.

- Corylopsis spicata*.
- Pieris* (*Andromeda*) *floribunda*.
- „ *japonica*.

- „ *smithiana*.
- Akebia quinata*.
- Arbutus Andrachne*.
- Cassandra calyculata*.
- Prunus Amygdalus* var. *persicoides* (generally two weeks in advance of the common Almond).
- Ulex europæus* (common Gorse).

Besides the above there are, of course, numerous trees with inconspicuous flowers which bloom early in the year, such as many of the Ashes, Elms, Alders, Willows, Filberts, and Poplars.

NOTES ON HARDY PLANTS.

CAMPANULA TOMMASINIANA

SHOWN in the accompanying illustration is a very fine specimen of *C. tommasiniana* (Koch), a plant I have cultivated for more than twenty years without attaining any such success. This species was long considered only a variety of *C. waldsteiniana*. It was described by De Candolle in his monograph of the genus *Campanula*, published in 1830 under the name of *C. waldsteiniana* var. *Fregneri*. He says that he dare not make it a distinct species, as the

habit, the leaves, and the generative organs are those of the type, though the flower differs from it in having a long narrow cylindrical corolla, very little cleft at the mouth. He omits, however, to notice that it is more robust than the type, generally having stems and leaves of nearly twice the dimensions. However, it is treated as a variety in Nyman's "Conspectus" and in "Index Kewensis," although described and figured in the *Botanical Magazine*, t. 6590, where Sir Joseph Hooker seems to consider it a true species. But in the first edition of the "Kew Hand List" (1895) it was still made a variety, and does not seem to have held specific rank in Kew Gardens until the publication of the latest edition of the "Hand List" in 1902, the verdict of which is final.

We can hardly wonder that this question has been so long doubtful. It is true that the extreme forms of *C. tommasiniana* and *C. waldsteiniana* seem at first sight quite distinct. But I have raised two or three generations of seedlings from *C. waldsteiniana* and found some which, both in the shape of the flower and in stature, approach *C. tommasiniana* very closely. There is certainly less variety between the two species than is to be found within the one species *C. persicifolia*, in which the flowers assume every shape, from a nearly flat disc to a cylindrical bell greater in length than in breadth; and, as to stature, I have raised some seedlings undistinguishable from the plant called *C. nitida*, 6 inches high, and others 4 feet high. Analogous variations in series may be picked out amongst forms of our native *C. rotundifolia*, some having flowers long and cylindrical, others short and widely expanded, and differing widely in stature and shape of leaf. *C. tommasiniana* is said to be a native of Istria and *C. waldsteiniana* of Croatia. Both are easily cultivated on well-drained rockeries if sufficient care is taken not to allow them to be smothered by encroaching neighbours.

Edge Hall, Malpas. C. WOLLEY-DOD.

SNOWDROPS AT KEW.

ONE finds all sorts of flowers at Kew, from the commonest to the most rare, and one therefore finds Snowdrops, and just now most of them are at their best; some few are already over. Both out of doors and in the small alpine house in the herbaceous ground there are Snowdrops in flower; those in the house are less weather-beaten than the ones outside, and are all the better for their protection. The flowers and the leaves are brighter and cleaner. In the alpine house the best of the Snowdrops is *Galanthus Elwesii*, with long broad leaves and large flowers well borne

GALANTHUS ELWESII VAR. WHITTALLII.
(From a drawing by H. G. Moon.)

above the foliage on stout stalks. *P. caucasicus* has larger leaves than *G. nivalis* and small flowers produced on slender stalks. *G. nivalis* is the only other one under cover.

Out of doors *Galanthus Alleni*, with very broad dark green leaves and flowers on long slender stems, is the most striking. *G. Fosteri*, whose leaves much resemble those of a *Scilla*, the pure white flowers contrasting prettily with them, is also to be seen in the rock garden and elsewhere. *G. nivalis* var *Imperati* is an improved variety of the common Snowdrop, or at any rate bears larger, bolder flowers; whether this constitutes an improvement or not is, perhaps, a matter of opinion.

Galanthus Ikarie has broad, short, dark green leaves and bold flowers, and is altogether a handsome Snowdrop. *G. plicatus*, with somewhat irregular foliage and moderately large flowers, is also more than ordinarily good. But the Snowdrops are not the only hardy flowers now worth seeing at Kew. There are also the Crocuses, Irises, Scillas, the early Narcissi, Lenten Roses, Heaths, &c., while the little alpine house already mentioned is a storehouse of beautiful flowers.—T.

PROTECTING CHOICE FLOWERS.

SEVERAL readers having asked about protecting choice hardy flowers from possible weather troubles in the immediate future, we thought it would be helpful to reproduce the illustrations of the coops used by the late Mr. G. F. Wilson at Wisley. Mr. Wilson wrote in *THE GARDEN*, February 10, 1900, as follows: "Perhaps the most useful flower in the hardy plant garden at this season is the Christmas Rose. We have a place at Wisley which suits both the Winter and Lent Hellebores. . . . As the flowers when out have often hard frosts and heavy rain to contend with, glazed lights are frequently recommended to protect them. My object in this note is to recommend coops as being much lighter and as covering larger plants. We began by using common wicker hen-coops covered with green scrim, but after a time the wood got out of shape and decayed, so iron wire was substituted for the skeleton. If these coops are put by in the summer, if not in use, in a dry place they will last for many years. After the Hellebores are over they are useful for *Anemone fulgens*." These coops may also be used for the protection of many other flowers, Irises and so forth.

FLOWERING PLANTS BENEATH TREES.

It is now very generally recognised that many flowering plants succeed admirably under deciduous trees. Winter and spring-flowering subjects, such as Snowdrops, Winter Aconites, Crocuses, Daffodils, and other spring bulbs receive almost the full benefit of the sunshine, the leafless branches intercepting but a modicum of the rays, while in the summer their roots are sheltered from the scorching heat by the overshadowing foliage. A correspondent lately writing on this subject stated that it was useless to endeavour to grow flowering plants beneath Beech trees or conifers. This has been so often repeated that it is generally accepted as a fact, but I have seen Crocuses as well as *Cyclamen neapolitanum* flowering well under Beeches, while in a certain open wood that I know Bluebells bloom close to the Beech trunks, and in Cornwall the ground beneath fine specimens of *Pinus insignis* is thickly carpeted with the *Cyclamen* referred to.

IRIS TINGITANA.

IN reply to Mr. E. H. Jenkins (page 75), who expresses a desire to know the behaviour of the group of the above Iris, figured on page 41, during the present year, I may say that I have received a letter from Mr. C. Dawson, of Rosemorran, Penzance, in whose garden I saw and photographed the Irises in question during the last week of March, 1902, informing me that about a dozen are showing flower-spikes. Last autumn I was kindly given a few bulbs by this gentleman, which I planted in a position facing S.S.W., flanked by a high wall a few feet distant on the south-east and protected by other walls on the north and east. I placed a layer of manure at the depth of 1 foot and planted the bulbs in a porous compost of peat, leaf-mould, light loam, and granite sand. On my return home a fortnight ago I found that four were throwing up flower-spikes, the tallest of which now measures 22 inches. This is, I imagine, very early, but up to the present we have experienced no frost in the screen and only about 2° on the ground this winter in this particular spot, which is absolutely sheltered from the north and east, and is only about 50 feet above the salt water at the mouth of the Dart. Whether

FRAMEWORK OF THE "COOP."

Iris tingitana will continue to flower annually with me it remains for future years to prove, the ripening of my present bulbs having been effected at Rosemorran. In that garden Narcissi, of which Mr. Dawson grows an excellent collection of the best varieties, succeed to perfection, the soil being evidently an ideal one for them, and this [is doubtless a factor in the well-being of the Irises.

SLUGS AND WOODLICE AND HARDY FLOWERS.

I NOTICE that Mr. Arnott, writing of *Adonis amurensis* (page 25), states that a zinc ring notched at the top is an unfailing preventive of slugs. So I thought until a few days back, and have for years surrounded my especial favourites with collars of perforated zinc some 4 inches in height firmly sunk into the ground. On arriving home lately after a six weeks absence, however, I found evidence that a collection of *Zephyranthes*, *Cypellus*, and *Tecophilaeas*, surrounded by the protecting zinc, had been attacked. Visiting the spot at night with a lantern I captured six slugs within the fence. They were small ones, but large enough to do a good deal of damage if undisturbed. As a

THE "COOP" WITH ITS COVER.

rule I think the zinc collar is an effectual safeguard, but it evidently is not to be relied on for six weeks of abnormally wet and mild weather. As to woodlice I echo the words of "An Anxious Amateur" (page 78): "If some reader can tell of a better method than prowling about half the night he will be a benefactor to hundreds." A few months ago I wrote an appeal for advice, which you very kindly inserted, but it remained unanswered. I have tried boiled Potato and arsenic, honey and arsenic, phosphorus paste on bread and butter, and also powdered borax, all of which have been recommended to me, but the woodlice ignore them and prefer the flowers, and this is in the open garden and not under glass. The blooms of Saxifrages, Arenarias, Agathæa, Malva lateritia, and other flowers are eaten before they expand. Over 20,000 of these pests were killed in a small area last year, and I find now (the first week of February) they are just as numerous and lively, and have been reinforced by legions of young about a twelfth of an inch long.

South Devon.

S. W. FITZHERBERT.

WALL GARDENING.

WALL GARDEN - MAKING.

IV.—THE TREATMENT OF EXISTING DRY WALLS.

OF new dry walls and their construction I gave full details in the last chapter (see THE GARDEN of the 10th ult., page 22), and I will now deal with old walls which were not built for wall gardening, but which it might be thought desirable to adapt to that purpose. In many gardens there may be several walls of that description, either dry walls or walls of masonry, which were originally built to mark a boundary or a division in the grounds, and which would admirably lend themselves to artistic adornment. Sometimes, too, such walls are of great age, having the surface of the stones or bricks darkened by years of exposure, and are, perhaps, even partly covered with moss and lichen. Such a wall might by careful treatment be easily converted into a thing of much beauty. I will take the dry walls first. We will imagine that we have to deal with an old dry wall, and that from

the soil between the joints of the stones weeds of all kinds have sprung. It should be fairly easy to eradicate such weeds by raking out the joints with an iron bar or a large chisel. Where weeds of an exceptionally robust nature have taken possession, it might even be advisable to use the iron bar as a lever for removing a few of the stones altogether, and either replacing them after the weeds are rooted up, or, if the absence of such stones does not seriously affect the stability of the wall, by filling these comparatively large holes with good soil and making them suitable for good plants of a bolder type. Rock Cistus, Heaths, and Alpine Rhododendrons are suitable plants for such a purpose, or, if the wall is in the shade, large Ferns might be used with advantage.

An important matter to be observed during this operation of planting is that the surface of the wall where we made the large holes must again be made good with small stones all around the plants. This will keep the roots moist and will prevent the soil from crumbling away and falling out after frost. Stones which are more or less wedge-shaped are best for this purpose, and after the planting they should be firmly driven in with a strong wooden mallet. This, if heavy enough, is preferable to an iron hammer, which would be liable to break the stones.

Care should, of course, be taken not to make these holes for large plants at regular intervals, or—still worse—in lines, but in such a way that the plants when in position would form an irregular and natural group. They should be sometimes close together, sometimes further apart, or scattered singly. For an example in Nature let us note a wall, say, in a shady country lane which, without the aid of man, Nature has bedecked with a luxuriant growth of Hart's-tongue and other Ferns, as well as all sorts of flowers. Let us take note of the way in which Nature has grouped these things, and then try and follow her admirable lessons.

The accompanying illustration shows a wall photographed in Cornwall during the middle of December; it encloses a farmyard and has never been planted. Nevertheless, as the picture shows,

SHOWING HOW THE PLANTS SHOULD BE DISTRIBUTED ON FACE OF WALL.

it is covered with Brambles, Ferns, Primroses, Foxgloves, and a whole wealth of other things. Even now without any of the plants being in bloom it is most picturesque. The broad leaves of the Foxgloves are distinctly shown in the illustration, and will convey a good idea of what is meant by a careless arrangement of plants. It will be observed that they are in clusters of five or six plants in one place, and form single specimens in another.

This is precisely the pattern on which we should work in arranging our plants on a wall. What was said about the larger plants also applies to small ones, except that these naturally should be placed closer together in irregular colonies merging into each other, but never in lines. When building a wall we do not pretend to imitate Nature, but we construct a piece of artificial work which no one could possibly mistake for anything else than the work of man. But when we adorn this wall with plants and flowers of various descriptions this decoration should in all cases be natural, not in the selection of plants, for that would mean decoration by means of wild native plants only; but in the disposition of various groups we should follow Nature's lessons, arranging some in large irregular colonies, others in smaller groups, and others again singly, while some portions of the wall might be left bare altogether.

To get good effects we must have bold masses of certain kinds, though it would be a mistake to let the chief aim in planting be to cram as many varieties of plants as possible into the space at disposal. A hundred plants of five or six kinds, disposed in irregular natural groups, will be a thousand times more effective than a hundred different things scattered over the same space.

It cannot be denied that when we are planting an existing wall the actual operation of planting is more difficult than it would be if the planting were done as the wall is being built, because in the former case one cannot be quite sure that the soil is suitable, neither can the roots of the plants be spread out so easily. In many cases, therefore, we should have to be content with smaller plants; but, on the other hand, the arranging of plants on a wall already completed is much easier and requires less skill than arranging plants placed into the wall during its construction, as described in a previous article. The reason for this is that in the latter case it is more difficult to picture in one's mind what the completed group of plants would be like, and plants once walled in during the progress of wall building cannot be altered or rearranged without trouble.

Then, again, if the layers of wall stones are anything like of even thickness there will be a strong temptation to put the plants too much in lines. I always find it a good plan in such a case first of all to take a review of the plants at disposal, and which are to be "built," so to speak, into the wall as the builder's

AN OLD DRY WALL IN CORNWALL (UNPLANTED).

work proceeds; then, secondly, on a piece of paper to make a rough sketch how these plants should be arranged, whether a group should be large or small, and where this or that colour should predominate so as to harmonise with the colour of the adjoining group; and, finally, where late or early-flowering things should be, so as best to ensure succession of bloom. Such a sketch need not be elaborate, nor need it be drawn to scale. Let a dozen crosses represent, say, a group of a dozen Aubrietias; twenty dots, say, a group of twenty Arabis, and so on. A few coloured crayons may help to facilitate distribution of colour, &c. Armed with such a sketch, however roughly done, we can feel sure of effects beforehand. The illustration will give an idea of the kind of sketch suggested.

Arranging plants on a wall already built is much easier, though the planting is more difficult. In this case a sketch is not required. The best practical method I always find consists in having sticks and twigs of various sorts and sizes, which might be stuck into the wall to indicate where the plants should be put. For instance, a cluster of Laurel twigs might be placed where we consider a batch of Alyssum would be most desirable, ordinary wooden labels might stand for a group of Campanulas, Bamboo flower-sticks for Helianthemum, &c. In this way we might arrange on the wall itself where the principal and most effective groups should go and how the plants should be placed before anything is actually put in. When the arrangement of sticks and twigs is complete stand back and look at it. We shall probably find that one group is too regular, another too small, and so on, and it will be a trifling matter to readjust the sticks to our entire satisfaction, but it would not be so easy to rearrange the plants after they have once been properly planted. Neither would it be easy to judge of the effect by simply writing the names on labels or slips of paper and putting these into the wall.

Suggestions as to what to plant and lists of plants for various purposes will be given in a later chapter. When a dry wall has been carefully planted and the plants have become established it may still be thought desirable to increase the number of decorative plants by sowing seeds of annuals and perennials into some of the chinks and fissures or even some of the larger joints. Since this sowing of seeds is practically the same for both dry walls and walls of masonry, I will deal with it in the next chapter when discussing the adornment of masonry walls.

Elmside, Exeter.

(To be continued.)

THE FLOWER GARDEN.

A BORDER OF ANNUAL AND BIENNIAL FLOWERS.

IN the accompanying illustration is shown the beauty of annual and biennial flowers when well massed. Note the group of Bell-flowers in the foreground, and the sprinkling of Poppies. Next week we shall devote much of our space to annual flowers, and to those things that give interest to the garden in spring.

A "BLACK LIST" OF HARDY PLANTS.

FOR some time past I have thought of preparing, for the careful study of amateurs about to embark on the fascinating cultivation of hardy plants, what I may be allowed to call a "black

list" of flowers and shrubs from among those which are most in request in the rock garden and herbaceous border at the present time, selecting them on account of (1) their too rampant and aggressive underground growth, and (2) their seeding too inordinately, and hoping thereby to sound a note of warning against their indiscriminate use in any select part of a garden.

With the assistance of several enthusiastic gardening neighbours and friends I have therefore ventured to draw up three lists, each arranged as far as possible in order of danger, list A (the "black list" *par excellence*) including the worst offenders, list B containing all those we can think of that require a great deal of supervision when once admitted into the aristocratic parts of the garden, and list C, those whose tendencies to spread or seed themselves too freely make them somewhat

BORDER OF ANNUAL FLOWERS AND GRASS PATH.

undesirable neighbours for their more delicate and less ambitious brethren.

It is well to remark that we have no desire whatever to exclude from the garden or shrubbery any one of the plants enumerated in these lists, our idea being simply to call attention to what may happen if they are indiscriminately planted before a knowledge of their habits has been acquired. Many of the worst characters in list A, for instance, are most beautiful and effective, and are even harmless if kept in bounds in suitable quarters.

As a rule it is a melancholy fact that the catalogues of the leading nurserymen contain absolutely no warning to purchasers, even in the case of such plants as Petasites, Polygonum, Calystegia, &c., so that a beginner has nothing to guide him. Nor do the modern gardening books, in our opinion, help him sufficiently in this matter. In neither do we find sufficient advice given as to the enormities of some of the most desirable and beautiful, though dangerous, things.

It is, of course, well known that the position and nature of the soil exercise a great influence

on the growth of a particular species, which may be harmless in one place, and undesirable, or even obnoxious, in another, and for this reason we are quite prepared to find a considerable divergence of opinion among plant lovers with regard to many of our "black sheep," some of which may even be "white-washed" by a majority. But our lists are prepared solely from actual experience in this neighbourhood, and we hope at any rate to draw forth opinions from fellow-gardeners in other parts of the country, and so start an interesting discussion on the subject, which is certainly a most important one.

LIST A.

"Black List" of dangerous plants.

Egopodium Podagraria fol. var. Gout Weed, Bishop's Weed, or variegated Angelica (a most dangerous plant), Tussilago Farfara

fol. var., Petasites fragrans (winter Heliotrope), Calystegia (all species), Arundo Phragmites, aur. var. Golden Lake Reed, Polygonum (all the large kinds), Coronilla varia, Linaria pallida (a terrible spreader), Campanula glomerata and C. rapunculoides, Lycium barbarum (Tea Tree), Ajuga (all except genevensis), Lathyrus tuberosus, L. grandiflorus, Symphytum caucasicum, Lysimachia vulgaris, Symphoricarpos racemosus, Physalis (both kinds), Acanthus (all species), Hypericum calycinum, Bocconia cordata (in suitable soil), Linaria vulgaris (common Toad-flax of the fields), Mimulus moschatus (common Musk), and Berberis Aquifolium (in borders).

LIST B.

Requiring a great deal of supervision.

Bamboos (nearly all, unless in Bamboo garden), Helianthus rigidus and var. Miss Mellish, Viola odorata (seedlings a terrible nuisance), Eschscholtzias (seedlings a terrible nuisance), Malva moschata alba (seedlings a terrible nuisance), Oxalis (miniature yellow-flowered creeping kind), O. corniculata rubra (very irrepressible), Sedum acre, Centranthus

ruber, *Asperula odorata*, *Heracleum* (perennial), *Nepeta Glechoma*, *Cerastium tomentosum* (in rockeries), *Alstroemerias* (want the whole place for themselves), *Elymus glaucus*, *Epilobium angustifolium* and white variety, *Hiacium aurantiacum*, *Roses*—Austrian, Copper, Persian and Scotch Briars (in herbaceous borders), *Convolvulus lineatus* (seems inclined to spread too freely), *Sorghum halepense* perenne, *Echinops Ritro* (deep-rooting and difficult to move).

LIST C.

Spreading or seeding very freely and requiring care.

Heracleum (biennials), *Saxifraga peltata* (in damp soils), *Cyperus longus* (in small bogs or ponds), *Menyanthes trifoliata* (in small bogs or ponds), *Vincas* (all sorts), *Corydalis lutea*, *Anemones narcissiflora*, *rivularis*, and *sylvestris*, *Meconopsis cambricum*, *Ornithogalum nutans* (except in grass), *Alliums* (nearly all), *Muscari racemosum*, *Vaccinium Vitis-Idæa* (in peaty soil), *Aquilegia vulgaris* (spoils choicer kinds), *Lathyrus latifolius* (seedlings root very deep), *Agrostemma coronaria*, *Anthemis tinctoria*, *Claytonias*, *Pulmonaria*, *Linaria dalmatica*, *Inula Helenium*, *Eomecon chionantha* (in light soil), *Tulipa sylvestris*, *Indian Balsam* (*Impatiens glandulifera* or *Roylei*).

Yalding, Kent.

S. G. R.

NOTES FROM A SMALL GARDEN IN NORTH WALES.

It is the middle of February and the weather lately has been more like April, without the showers. The children found wild Primroses in sheltered places at the end of January, in spite of a severe frost and several days' skating a fortnight earlier. The Snowdrops have been especially fine and long stalked this year; there are quantities semi-wild in a wood near, and they were in perfection on January 31. Christmas Roses have been particularly good, but the frost shortened their period of bloom. We give them a good deal of soot when growing, and they appreciate it. Blue Primroses of several shades are in full bloom; they are the earliest of all, and continue in beauty for months, at last becoming so full of flowers that the leaves are almost hidden. We have moved ours into a rough part of the garden under thin shrubs, where they look better than in full sun.

Hepatica angulosa is better than usual this year, and the flowers are very large. When they were expanding we had very strong winds, and I put a large broken bell-glass over the plant, which shelters while allowing it plenty of air. The *Hepaticas* bloom very well here, but the leaves are always spoilt by the spring winds. They are more beautiful in sheltered gardens, where the foliage remains perfect and surrounds the flowers, making them look like big bouquets.

In the peat bed a little bush of *Rhododendron præcox*, planted in the autumn, is a mass of mauve-pink blossoms. It is very valuable, flowering so early in the year. A bed of it edged with the white form of *Erica carnea* would be a lovely sight. On the sunny rockery bank there are already large patches of the sweet-smelling white *Arabis* in bloom, and here and there little bits of sweet *Alyssum* and *Aubrietia*, and one or two flowers of *Lithospermum prostratum*. The earliest Pasque *Anemones* are full of large buds, covered with silvery down; they are much earlier than usual, and will expand in a day or two. Two *Iris reticulata* are out, and in a week there will be dozens. *Iris alata* was well baked on the greenhouse shelf last summer, according to the advice of a kind correspondent of THE GARDEN. I planted it in autumn in full sun on the rockery bank, and it is coming up splendidly and showing some flower-buds. A *Berberis japonica* in the poorest soil, matted with roots at the edge of the shrubbery, where it has probably been for at least fifteen years, is flowering splendidly, every crown full of deliciously scented yellow-green spikes. I

never noticed their scent till this year. In future I shall like the plant as much as I have hitherto admired it.

I am sending two photographs taken last spring showing how satisfactory the Daffodils are here, although the soil is exactly the opposite to what they would naturally choose to grow in, being very poor, dry, and stony. The sorts that do best are Sir Watkin and Horsfieldii, which make a beautiful show and do not deteriorate. We give them liquid manure and occasionally a dressing of basic slag in the growing season. The same piece of grass is gay with sheets of yellow and purple *Crocuses* earlier in the year; the white ones do not succeed so well. A very large dark purple one with conspicuous orange pollen is the most satisfactory.

E. T. Ll. E.

THE BOG GARDEN.

RECENTLY the following instructive paper was read by Mr. Ernest Ladhams before the Shirley Gardeners' Association:—It may sound rather strange to many to talk of gardening in a bog. Nor, when we remember as an example a dank filthy-looking liquid mass, composed of decayed vegetable matter, and the washings of the adjoining land, the accumulation of centuries, fed by many small oozes or land soaks as well as the rainfall, and grown over in places like a tangled thicket with Alder, Birch, and Willow, and the usual matted undergrowth, such as Brambles and Blackthorn—when we look on such a blot, many of us no doubt would much rather such a spot did not exist—at all events on land under our care. And to desire such a place to "garden" in would be far from our thoughts.

MAKING THE BOG GARDEN.

We will suppose we have such an eyesore in the otherwise attractive park or pleasure grounds. We must do something with it, as it spoils the whole landscape. It may be a quarter of an acre or half an acre in extent, a hollow or depression, and creating a blot on what would otherwise be a gentle slope from the house. The accumulation of water, which at some time must exceed the capacity of the hollow, soaks the lowest boundary and escapes towards what may possibly be a stream of water running through the grounds. This would be then a charming spot could this bog be made presentable. The first thing we do is to find out how it came to be such an undesirable place. We find in this case it is a series of land soaks or small springs. These are formed by the upper soil on the hill allowing the surface water (rains, snows, &c.), to percolate through until it reaches a strata of heavier material, such as marl or clay, which is impervious. The consequence is that instead of sinking deeper into the soil the water thus accumulates on the higher ground, trickles along the surface of the clay, and eventually finds its way out at this particular spot, not as a spring of clear bubbling water in this case, but as a mere continual soak. It takes the water entering the ground on the higher level some months to emerge at this lower spot, and consequently a dry period has little effect on the bog, saving the evaporation, which is very much retarded by surrounding trees and undergrowth. Nine out of every ten (and perhaps more than this) are caused in this way—the water thus accumulates, being stopped from flowing in the form of a streamlet by the uneven ground forming a basin, the lower end of which allows of an overflow occasionally as the rains happen to overflow it, when it finds its way eventually by another surface soak into the stream.

We have now seen that our bog is composed of vegetable matter, combined with washings from the higher ground, mingled with a constant supply of water percolating through a higher strata and resting on a bed of close material, such as clay. We now set to work to clear all the superfluous bushes and undergrowth, saving a few only of the best-shaped trees—Birches only, if these are found there—in spots where they stand isolated, and many develop into well-grown trees. Then we open a broadish shallow outlet at the lowest point

to drain the surface water. Should there be a sharp drop only, for a few yards from the lower edge, a deeper entry may be made temporarily to more effectually drain the whole bog during the alterations, to be partially filled up after it is finished. We are now able to work at a minimum of discomfort, and probably have a surface of such consistency as will support planks for the wheelbarrows. Next we formulate a scheme to reclaim certain plots, to enable the garden, when finished, to be visited. In order to do this artistically, and at the same time to preserve the natural appearance, we have to be very careful, and to be guided in a very great measure by the surrounding landscape. In the majority of cases it is best to take out a winding devious main drain, which will later be a streamlet, from the highest part, eventually emerging at the lowest point, where previously we had made a cutting.

As little fall as possible should be maintained throughout this "main artery," although, for the sake of variety and facilities for planting, this may be both deeper and wider in parts. Into this we conduct other shallow irregular drains, varied both in depth and width as circumstances will allow and individual taste dictate. An important point to bear in mind is to have all these arteries as nearly as possible level, having only as much fall as is absolutely necessary to keep a slight movement in them all. The most important one may be slightly deeper than the remainder. The soil taken from them must be used to raise the spaces which are intended for planting and walking on, but not absolutely levelled—a mound here, a depression there, a wide stretch of soil here, narrowing into a point there, and again widening out into sufficient space in which to place a bold-foliaged plant, or scooped out to find a home for a colony of such plants as *Trillium grandiflorum*, &c.

STEPPING STONES

are introduced where necessary or in positions of effect. These give a good change and finish, as well as being useful for visiting any part of the garden. Soil should be thrown out here and there in spurs or tongues, to break up what might be a too regular or evenly-shaped basin: the recesses so formed are admirable to accommodate choice bog plants such as *Sarracenas*, *Cypripediums*, &c., whilst more bold-foliaged plants should occupy the raised portions thus prepared.

(To be continued.)

GARDENS OF JAMAICA.

(Continued from page 77.)

THE most wearisome part of our journey is still before us. We shall be able to ride another five miles, and then the remaining five miles must be accomplished on foot. By the light of day, and in warm dry weather, this is easy in comparison to what we must expect at night time, or when the weather is bad. Adventurous tourists who would fain see the sun rise sometimes undertake this, too generally to be disappointed, and to see from the summit little besides the snowy wreaths of the overhanging clouds. In some parts they grope their way in darkness along the precipitous paths shut in by the woods. Were it not for the extreme shrewdness of the guides it would be impossible to proceed. It is difficult to realise the irksomeness of the last five miles if there has been rain and the journey is attempted at night time. Some parts are almost perpendicular, and nearly all so steep as to try every muscle of the body. Without the assistance of the roots and branches which cover the mountain, forming so many steps and supports, the ascent could scarcely be accomplished. But the scene has peculiar beauties. Here the

TREE FERN

is seen in great perfection. The trees are beautifully festooned with mosses. Here is found the *Yacca* wood, which is peculiar to the island, and which from its rarity and beauty is much prized. If the traveller is fortunate the view from the summit will more than repay all his toil and exertion. It is seldom that a perfect view is obtained; when this is so, it may be regarded as

unequaled by any other prospect in the world. From this elevation of 8,000 feet it is possible in that climate to see the whole island, which is more than 150 miles long. The rivers trace their way like silver threads amidst the grasses and woods of the many-peaked mountains. The fields of Sugar-canes and other cultivated grounds are seen in the flat country. The beautiful harbours and ports of the island, with the ships lying at anchor or on their voyage, may be observed. All lies at the feet like a great map, inexpressibly grand and imposing.

We cannot fail to be attracted as we descend by the plants and flowers which line our path and cluster about the streams and rivers. Here is food for the botanist, enough to occupy a life of research. Some of the trees and shrubs which are in blossom emit a fragrant aromatic smell. The principal of these is

THE PIMENTO.

With the production of this tree our friends in England are very familiar. The fruit of it is called Allspice. Large quantities are sent to Russia, and other northern countries. Its warm and aromatic character when understood causes it to be much valued. The smell of the leaves is very fragrant, and the tufts of yellowish blossom mingle prettily with the dark green foliage. A full grown tree would arrive at the height of 20 feet or more. The seeds are sown by the birds, and when the plants are sufficiently grown then the underwood is cut down to make room for the fuller growth and cultivation of these trees.

THE MANGO

may be observed in almost every direction as we wend our way along the mountain roads. On the hills and in the valleys, in the jungles and by the roadside, we can at once detect it by its dark foliage and symmetrical form. There is no part of the island in which these trees are not found, and few places in which they do not grow in great abundance.

The Mango is not a native of the island. It was brought from Tahiti many years ago. The plants produced from the seeds which were introduced into the island were numbered for the purpose of noting which produced the best fruit. That numbered eleven was found to be better than the others. It is still regarded as the best kind of Mango; but it is not found in most parts of the island, or it may have degenerated from its former excellence.

There are many kinds of Mangoes. The most common are the most beautiful in appearance. The fruit, which is generally much larger than a Peach, rivals or excels it in its attractive bloom and bright hues. The trees are almost invariably of a beautifully rounded form and of a great size, and some idea may be conceived of their appearance when the dark foliage is interspersed by the luscious fruit. Another kind of Mango has a strong flavour of turpentine, which is, however, agreeable rather than otherwise. The skin of the fruit is sometimes quite green, even when it is ripe, while others have a yellow tinge. Horses and cattle are very fond of the leaves, so that they crop off all that comes within their reach; this gives a very even appearance to the under part of the trees. They are considered common property, and anyone may gather the fruit wherever it is found. We have again regained the low country, and find ourselves riding beside fields of

SUGAR CANES.

They look like immense reeds, jointed in the same way, and surmounted by a beautiful tuft of lilac-coloured blossom, like a bunch of feathers. They are planted in rows about 6 feet apart. When the Sugar Canes are cut they spring up again, and this is called *ratooning*. They will continue to do this for many years, but it is considered best to uproot them after four or five years. The labourers are engaged in cutting the canes in a field and conveying them in waggons to the works, to which we may follow them. They are taken

in the first place to the mill, and, the tops being cut off, the juice is expressed from them by means of rollers, which are worked by horse or water-power. The juice flows through gutters into the boiling house. Here there are immense coppers in which it is boiled. At certain stages it is taken from one copper to another till it arrives at a required degree of consistency or thickness. Then a little quicklime is introduced for the purpose of granulating it, and this being done the Sugar is removed into large wooden reservoirs to cool. After being drained it is packed in casks for exportation.

From the boiling-house we now pass into the still-house. Here they are engaged in distilling rum. It is from the skimmings of the Sugar and all the drainage, be it dirty or clean, that rum is made. The process is the same as that by which all spirits are manufactured. There are puncheons prepared for the purpose, into which the rum is drawn off for shipment. The quality of the Sugar and rum, like that of Coffee, depends much on the part of the country in which it is cultivated. As we ride along there is one tree that strikes us as being more beautiful than any we have yet seen. This is

THE ACKEE.

It is now covered with fruits, and the appearance

A CURIOUS WILD "FIND" IN A MASS OF BRACKEN (PTERIS AQUILINA). THIS FORM IS NAMED CONGESTA.

is most striking. In front it much resembles the Mango, though the leaves are not so dark. The outer skin of the fruit is of the richest crimson, which contrasts most pleasingly with the thick foliage. This outer skin is divided into three compartments. When the fruit ripens these divide and spread out. There is then seen three corresponding pieces of white vegetable, like the most delicate Marrow, at the end of each of which there is a jet-black stone the size of a small marble. The combination of green, scarlet, white and black colour is most beautiful.

Our journey is now directed towards the north side of the island. We are again in the midst of beautiful scenery. The Rio Cobra rushes on its way amidst gorges and overhanging rocks and hills rarely equalled in grandeur. We ascend Mount Diabla where the yawning chasms by which the road is bounded serve to show us how great would be our danger should our horses be restive or our carriage prove unsound. As we approach the parishes of St. Ann's and Trelawny we find ourselves in one of the chief parts for the cultivation of the

COCOANUT.

This tree seems to flourish most in the immediate neighbourhood of the sea. A sandy soil is most favourable to its growth. Some of the trees rise

to an enormous height—at least 80 feet or 90 feet, and we might be tempted to say 100 feet if we did not think that the straight trunk, without a branch or leaf until they strike out at the top, may render their apparent height deceptive to the eye.

Strong must be the limbs and steady the eye of these who scale these lofty pinnacles in order to gather the fruit. In many parts the Cocoanuts are planted in regular groves. They are also seen in detached groups in the neighbourhood of towns and dwellings. The large nut which they produce is well known in every part of the world, and a good tree will in the course of the year produce 300 of these, or even more. They are cheap enough on the spot, being sold at a price corresponding to a penny or even a half-penny each. A large Cocoanut plantation is a very valuable property, for great numbers are taken in as freight for ships which leave Jamaica for England and other parts of the world.

The fruit is most delicious when it is eaten in its young state. Here the inner part has the appearance and character of a white transparent jelly; it is scooped from the yet tender shell with a spoon and then eaten. The natives have many ingenious and agreeable ways of preparing the older fruit. Sometimes after being grated the juice is expressed from it, and it forms a very acceptable substitute for cream. The wood is not of much use except for cabinet work, but the fibre of which it is composed gives it the appearance of being covered with small dark spots where it is cut transversely and polished. The Cocoanut is one of the Palm tribe, of which all with the exception of the Date Palm are to be found in Jamaica. There is one which is commonly known as "The Palm," but which is rarely seen, and is used for no purpose.

(To be continued.)

THE FERN GARDEN.
AN EXTRAORDINARY
BRACKEN.

(PTERIS AQUILINA CONGESTA.)

SINCE everyone is familiar with the ordinary aspect of the almost ubiquitous Bracken, which covers vast areas of our waste land with dense vegetation, and in the shady woodland attains a size in which even the deer can hide themselves securely, the accompanying illustration will appeal to

most perceptions as representing a very remarkable variety. This was found wild in the Lake District many years ago, but is very rare in cultivation. This is the more to be regretted as a clump of it such as the writer has in his garden is very handsome. It has the further advantage that the dense, congested habit of the fronds appears to be participated in by the travelling roots, since for several years the plant has hardly spread at all, while other varieties near by have to be ruthlessly pinched back and checked to prevent their making a general invasion. Another advantage is that the fronds are exceedingly hard and tough; the congestion seems to be due to density and compression of cell growth, the result being that the roughest winds have no effect upon it, while the laxer-growing ones speedily lose their virgin charm. The plant figured was raised by the writer from spores, and, although it does not come very freely, like the other forms of Bracken, it develops very rapidly into specimen plants. Spores sown when ripe, *i.e.*, in the autumn, germinate in a week or two, but, except under artificial

warmth, rarely develop fronds until the spring, when a tiny one about three-quarters of an inch high appears; the next is 2 inches, the next 6 inches, and so on in increasing ratio until by the end of the summer a pretty characteristic plant is formed. When the third or fourth frond appears a little fleshy foot is formed which plunges into the soil and probably sends up a strong frond on the extreme edge of the pan, where its rambling propensity is checked. At this stage it is ready to shift, and a peaty admixture of soil should be made to form a station in the open where it is intended to establish it. The best plan is to drop the contents of the pot or pan unbroken into a hole made to receive it, packing it firmly in and watering well. In the late autumn the fronds will die down, but the following spring a new and strong crop will arise, and in that season full development as regards size may be expected.

Curiously enough, despite the absolute hardiness essential for a native Fern in these islands, if the young plants be kept under glass constantly until the winter and then allowed to get frozen they are almost sure to perish, hence the advisability of planting out as described and thus hardening them by exposure before the frost arrives. The same remarks apply, of course, to other varieties of this species, which, despite its commonness in the normal form, is very handsome. The best forms are: *Pteris aquilina cristata*, tasselled prettily at all tips; *P. a. grandiceps*, all crest, which is barren, but curiously enough comes true from spores of *cristata* to a considerable percentage; *P. a. revolvens*, with spiral tips and rolled-in pinnae; and, finally, a thorough oddity in the shape of *P. a. glomerata*, in which the frond tips and side divisions twist themselves up into hard ball-like knots, giving the fronds a rude resemblance to a bunch of Grapes. Nature, therefore, we can see, has exercised her fancy pretty freely in connexion even with our much-despised Bracken, which some people regard simply and solely as an abomination to be abolished, a view with which no Fern lover can concur.

CHAS. T. DRUERY, F.L.S., V.M.H.

GARDENING OF THE WEEK.

INDOOR GARDEN.

PRESSURE of work in this department will now be experienced, as a general repotting in many gardens is in progress. Where the various kinds of soil, pots, and all other potting materials have been prepared, as previously advised, there will be very little delay in making a start. *Ixoras* that were cut back some weeks ago may now be turned out and have the old balls of soil much reduced and replaced in pots one or two sizes smaller. *Ixoras* require good drainage, and prefer a compost of fibrous peat, sand, and charcoal, with a little bone-meal, to any admixture of loam. Use a blunt-ended rammer to work down the soil and to enable the workman to leave the soil uniformly firm. Young plants propagated last summer or autumn must be potted on into larger pots. Avoid filling the pots, as by so doing the plants seldom get sufficient water at one time. *Franciscea* and *Mussaenda* prefer all peat, but *Stephanotis*, *Rhynchospermum*, *Rondeletia*, *Clerodendron fallax* and *C. fragrans*, and most stove-flowering plants prefer a compost of equal parts peat and loam. After potting, the plants named will be benefited by being plunged in a bottom heat of 70° or 75° to encourage root action; maintain also an increased amount of moisture in the atmosphere. Use great care in ventilating the house; at this season air

should be admitted only by the ventilators placed near the ground in the side walls, it then becomes warm and moist before coming in contact with the plants. Another batch of

GLOXINIA TUBERS

may now be started where a succession of these flowers is required; those previously started should now be given more light, but shaded from bright sun. Frequently look over the young growths; thrips or mite soon disfigure the foliage.

AMARYLLIS.

Those early varieties now passing out of bloom must be encouraged to make a little growth, bearing in mind that the foundation for next season's crop of flowers is now being laid.

ANNUALS FOR POT CULTURE.

Make another sowing of *Acroclium*, *Rodanthe*, *Gypsophila elegans*, *Torenia Bailloni*, and *T. Fournieri*; these should be sown all over the pot, and from twelve to eighteen plants allowed to remain in a 5-inch or 6-inch pot. *Statice Suworowi* is an interesting annual for growing singly in pots, the choicer varieties of *Petunia*, *Nicotiana affinis*, *Kalanchoe flammea*, *Hunneimannia fumarifolia*, *Hibiscus Manihot*, *Ipomœa rubro-cœrulea*, *Gomphrena* (purple and orange), *Diascia barbera*, *Cockscombs*, *Clianthus Dampieri* and *C. puniceus*, *Celsia arcturus*, *Campanula pyramidalis* (*Syon House compact variety*), *Browallia speciosa major*, and *Angelonia grandiflora alba*. These all make very useful plants for the summer months. All germinate best in a warm, close house and require shading during the earlier stages of growth. As the late *Chrysanthemums* pass out of flower select the most useful varieties for propagating; even at this late period they are still very effective. See that all necessary shadings are now made ready to be fixed when required. Increase the temperature of the stove-house to 65° to 68° by night, and allow the day temperature to rise to 75° when there is sun, keeping the houses well damped.

Wendover.

J. JAKUES.

THE FRUIT GARDEN.

PINE-APPLES.

To meet the demand for early fruit, see that the bottom heat in which the first batch of *Queen Pines* are plunged does not fall below 80°, and let the top heat range from 70° at night to 80° through the early part of the day, and 85° to 90° afterwards, closing with sun-heat. Keep the evaporating pans filled with stimulating liquid, pay particular attention to root-watering with the same in a diluted form, and reduce the necessity of overhead syringing by damping all available spaces, including the surface of the bed, when the house is closed for the day. If the heat of the bed in which are the winter fruiting plants shows signs of declining, take advantage of a mild day for renovating it with fresh fermenting leaves or tan, and re-plunge the plants, keeping the *Smooth Cayenne* and *Rothschild* varieties which started late in October and November together in the lightest and best part of the house, where they can receive heat and moisture with stimulating food, as recommended for the early *Queens*. If well rooted and not over-potted, these plants will give excellent *Pine-apples* at a time when good *English fruit* is in great demand and not too plentiful.

Strong plants intended to make growth before they fruit should be examined, and if found very dry at the root a little tepid water may be given to prevent them from receiving too decided a check, which might cause them to throw up prematurely. If the bottom heat has declined to below 70°, it will be necessary to admit warm air into the pipes until the thermometer indicates a move upwards; but great caution must be observed, as the application of water to the fermenting material, combined with increasing solar heat, often produces the desired effect without having recourse to the hot-water pipes.

ORCHARD HOUSE.

Owing to the mildness of the season the buds on *Peach* and *Nectarine* trees still standing out-

doors are very forward, and altogether unfit to be exposed to moderately severe weather. In many places the orchard house is used for other purposes in winter, and early housing of the trees is often attended with inconvenience; but steps should be taken to get them under glass. They may be placed closely together for a time, provided the house is fully ventilated at all times, unless frost is very severe. In years gone by it was the practice to pot and top-dress trees quite up to the time of housing, but this remarkable season fully confirms the sound advice to get all work of this kind performed before if possible, or immediately after the fall of the leaf. When all the trees are under glass, keep them well supplied with water; also look to trees established in inside borders, mulch well, and give them repeated waterings until the soil is as moist as it will be found in a well-drained *Peach border* out of doors.

CHERRIES.

Be guided by the state of the weather in the management of early-started trees now about to blossom. When fire-heat is needed for the maintenance of the night temperature, 40° to 45°, with a little air, should not be exceeded; and in the event of a continuance of severe weather, a few degrees lower will be preferable. As *Cherry trees* cannot be fumigated or syringed when in flower, see that the trees are quite free from insects when the blossoms begin to open. Pay daily attention to fertilisation. Ventilate freely, without causing a draught, and avoid damping in dull weather.

WILLIAM CRUMP.

Madresfield Court Gardens.

KITCHEN GARDEN.

GLOBE ARTICHOKE.

If the weather remains open the protecting material may be removed and a dressing of manure forked in. In soils that are stiff and cold, or in cold districts, it is good practice to pot up some offsets in the autumn, and winter them in cold pits or in the orchard house. Where this has been done, the plants may be put out to harden in readiness for transplanting about the second week in March. Much earlier heads will be produced from these than from the old-established stools, thus prolonging the season. As is well known, seaweed is an excellent manure for *Globe Artichokes*, as it also is for *Asparagus*; and where this is obtainable a dressing may be applied instead of manure at this time. Apply early a good mulch of half-decayed farmyard manure for feeding the roots and for conserving moisture which this *Artichoke* delights in.

LETTUCE.

Plants wintered in frames or on a warm border may be transplanted in well-enriched soil on a similar site. *Cabbage Stanstead Park* we find excellent for turning in quickly. It is followed by the old hardy *Bath Cos*. The newer types of *Lettuce* are better adapted for present sowing for succession batches. In bleak, wind-swept gardens some kind of shelter should be given early *Lettuce*, such as evergreen branches.

CUCUMBERS.

The plants put out for early fruiting will be growing freely now that the days are lengthening. Seeds should be sown for successional houses as required. The aim should be to build up strong, short-jointed plants by the time the structure will be ready to receive them. It is better to shift into larger pots, and keep near the roof-glass, than to restrict their roots. The same remarks apply to *Tomatoes*, with the one exception of potting on. *Tomato plants* are the better for being kept in somewhat small pots, both in the young stage and when fruiting.

THE HERB BORDER.

As far as my experience goes, sufficient attention is not paid to this part of the vegetable garden. A border facing west is a good one for the cultivation of all kinds of herbs, and a few plants of each should be found room for if possible, and duly labelled with the botanical name as well as the common one. It would occupy too much space in this column to enumerate all of them, and the

HOW GRAPES ARE PACKED FOR MARKET.

The most convenient basket for market is one that will hold about ten bunches weighing from 12lb. to 15lb. The baskets are strongly but roughly made of white wicker, and should be deep enough to accommodate a good-sized bunch resting its full length on the side of the basket.

The basket is prepared as follows for the reception of the Grapes:— Wood shavings are placed in the bottom to the depth of about half an inch, and on this a layer of cap paper, lining the sides also with the same paper. The bunches are then placed in the basket in an upright position resting on the sides, and the shoot (which should always be cut with the bunch) is tied securely to the rim of the basket, allowing the base of the bunch to rest firmly in the bottom. Thus bunch by bunch (placed close together) should be fixed until the sides of the basket have been filled. Cover the top of the basket with paper securely tied on, and the Grapes will travel any distance without the least injury to bloom or berry. Another successful way favoured by many is, after filling the bottom with wood shavings and papering the basket as above stated, to place the basket on end at an angle of 45°, and then gradually build the bunches

from the bottom upwards, firmly placed one against another until the basket is filled.

This is an excellent way, and more weight can be got into the basket than by the other method, the only danger being that possibly some of the bloom may be rubbed off all round the bunch, whereas, with the other, the front of the bunch is not in contact with anything. The efficacy of packing in baskets instead of in boxes lies in the fact that railway officials dare not throw and bang baskets about as they do boxes, but are compelled to carry them by the handle, thereby securing immunity from porters' negligence and a safe delivery of the Grapes at the same time. A label should be attached to each basket stating the nature and weight of the contents and indicating the time when delivered to the railway company for transit, so that in case of delay the company can be held responsible.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

methods usually adopted for the culture of each. Suffice it to say that the perennial kinds should be divided and replanted at this time, working in some manure as the ground is dug. The annual herbs may now be sown. A sufficient stock of some, notably Tarragon and Mint, may be readily worked up by annually dibbling rooted pieces into well-enriched soil during the latter part of March. By keeping them partially shaded and frequently sprinkled, strong plants are quickly built up.

Stoneleigh Abbey Gardens H. T. MARTIN.

FLOWER GARDEN.

PLANTING.

By the end of the month all deciduous trees and shrubs should be planted, and all alterations and improvements in the flower garden completed. This is a good time to form rockeries, repair or replant box edgings, and turn or regravell walks. Should any of this work be neglected now, it will cause endless confusion later on when work gets into full swing.

PLANTING ROSES.

November and December are the most favourable months for planting Roses, but where the soil is wet and retentive, and the holes opened in the winter so that the mould becomes pulverised by frost, planting should be proceeded with at once. After planting give a surface dressing of at least 2 inches in depth of good rotted manure. This will help to keep the roots moist and eventually enrich the soil.

"RUSTIC" GATES AND FENCES.

These might receive a little more consideration than is generally accorded them. When gates and fences in suitable parts of the garden are constructed of strangely formed limbs of trees, they may, with a little taste and forethought, be made very interesting by training suitable climbing plants over them. Roses of the Crimson Rambler type, Honeysuckle, Clematis, and various other plants lend themselves to this object.

HERBACEOUS BORDERS.

The best time to plant is in September, but planting may be safely done now, with but little risk. Large tufts of Arabis, for instance, might be lifted any day with care from September to February, and would flower in the ensuing month of April.

ACHILLEA EGYPTICA

is one of the most handsome of all our herbaceous plants. Its heads of rich, clear, yellow flowers

makes it an object to be admired wherever it is well grown. This plant should not be allowed to remain more than three years without division or the flowers become small, and the foliage loses much of its beauty.

CIMICIFUGA JAPONICA.

This is another plant that I have found to do well if carefully divided at this time of the year. In good soil it makes a large mass of roots, and if well manured will throw up large spikes of its handsome flowers year after year, but where the object is to increase it, now is a good time to do so. Take the plant up carefully and with a sharp spade divide into as many pieces as is desired; replant with fresh soil, place the soil firmly round the plant, and give a good top-dressing of rotten manure. When the plants have made a start to grow give a good watering. This plant loves moisture and a good soaking of liquid manure will do it no harm just before the flowering season.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

THE FRUIT GARDEN.

HOW TO PACK GRAPES.

NOT the least important of the operations in connexion with the management of the Grape Vine is packing bunches for safe transit by rail or road, either for long or short distances. In consequence of the enormous increase in Grape culture during the last twenty years, both for market and private use, increased attention has been given to this important subject, not only by growers generally, but also by the Royal Horticultural Society in the encouragement they have given to good packing by the liberal prizes offered at their great annual exhibition of fruit held at the Crystal Palace during the last few years. In consequence of this increased attention and encouragement given to the subject, it is now generally admitted that the best way in which Grapes can be packed for travelling is by the use of cross-handled baskets of various sizes, according to the weight desired to be sent.

FRUITS THAT WILL MATURE IN ADVERSE SEASONS.

This was the subject of a lecture recently delivered by Mr. C. Hott, one of the technical instructors to the Cornwall County Council, and in the course of it he mentioned a number of interesting facts. He stated what is too well known as a fact, that some sorts of fruit trees which bear well in ordinary seasons fail entirely in adverse ones. In 1902 Cox's Orange Pippin, in the form of fine trees, almost failed; Peasgood's Nonsuch had given a good crop. It was added, by way of parenthesis, that those who observed the seasons would have noticed that once in every ten years there would be invariably an adverse season for everything; there would be a time unduly wet or unduly dry. When a season of abnormal growth happened there would be large fruit and little colour. Then it was advisable to remove the leaves which shaded the fruit and better colour would follow. It was pointed out that the foliage on the trees of this variety was of the strongest, and this was an important point, for it was the strongest foliaged varieties that did best in adverse seasons. On the other hand, Cox's Orange Pippin is a small-leaved variety, and upon the trees of this sort there was practically no fruit. The leaves of the tree were the breathing organs, and it

was obvious that the stronger and healthier the foliage in an adverse season the greater was the probability of the trees' bearing. Bramley's Seedling, Lane's Prince Albert, and Colonel Vaughan were all of vigorous growth, and there were fair crops on them in 1902; the moral of this was that in selecting fruit trees which would suit all seasons the texture of the foliage should be considered to some extent. It was true that in certain districts of Cornwall Cox's Orange Pippin and Gascoigne's Scarlet had produced fair crops, but in 1902 they failed, though in ordinary seasons they exist as croppers. The lecturer did not suggest the ignoring of Cox's Orange Pippin, because it bore well generally, and it always was a valuable crop; but Lane's Prince Albert not only does well in ordinary seasons, but bore a splendid crop in 1902. If any one were to set about growing Apples for profit they might plant only Lane's Prince Albert, 9 feet apart, the trees on the Paradise stock. This is a surface-rooting stock, and it would go on bearing for twenty-five years planted in a soil of good substance. Gold Medal was mentioned as an excellent companion, and Golden Spire for its earliness. The latter is a variety generally found to bear in bad seasons. Gold Medal had proved the best cropper in 1902. Mr. Ilott said he would not cultivate Keswick Codlin nor the American King of Tompkins County; it was a free grower in Cornwall, but gave little or no produce. Christmas Pearmain, one of Mr. George Bunyard's introductions, was highly spoken of; it is a good grower, and it is thought will take the place of King of Pippins. He would not recommend planting Blenheim Orange if immediate returns were wanted, but it could be safely planted for posterity. Worcester Pearmain had always cropped well, and should be planted for an early crop. The following were mentioned as the best Apples: Warner's King, Peasgood's Nonsuch, Lord Derby, Bismarck, Hambling's Seedling, a large green, late-keeping kitchen Apple; Gold Medal, Golden Spire, Stone's, Cox's Orange Pippin, Allington Pippin, Christmas Pearmain, Early Juneating, Baumann's Red Winter Reinette, and Gascoigne's Scarlet. The lecturer's experience is no doubt largely determined by what the varieties he names will do in the West, but there appears to be matter for consideration in what is said, and probably many of the conclusions arrived at by Mr. Ilott would apply to most of the southern counties. It is highly desirable to obtain a group of Apples which may be expected to bear under any conditions of weather common to the summer season. Some of Mr. Ilott's conclusions may be open to debate; still, he has opened up a subject of the highest importance to fruit cultivators.

R. D.

APPLE GOOSEBERRY PIPPIN.

THIS very ancient variety may not be so handsome as some of our more modern varieties, but it certainly possesses sufficient good points to warrant its more general culture. One comes across an old tree every now and again, and the verdict of all who grow it is the same—a valuable late keeping Apple. Given fair treatment it is one of the most regular croppers we have; indeed, it is as a rule so burdened that thinning is essential if medium to large fruits are required. As a culinary Apple it is only rivalled by such monarchs as Wellington, Bramley's Seedling, and Newton Wonder, and the tree is free from defects found in all of these. Its keeping properties are unexcelled.

H. W.

THREE EASILY - GROWN INCURVED CHRYSANTHEMUMS.

If the most successful grower of incurved Chrysanthemums were asked to name the varieties representing what may be regarded as ideal incurved flowers, there is good reason for believing the list would include Mrs. George Rundle (white) and its two sports, named respectively Mr. George Glenny (primrose-yellow) and Mrs. Dixon (rich yellow). These three varieties it will be seen

belong to one family, and they are now the smallest of the incurved varieties generally grown. These flowers are not seen at the shows in the stands as they used to be some twelve to fifteen years ago, but in centres where the claims of the incurved Chrysanthemums are still well recognised they are regarded as almost indispensable in their own particular department. I have often wished that those responsible for drawing up the schedules of prizes for the many shows now held throughout the country could see the really beautiful display made at the Sheffield show in a class exclusively confined to these three varieties. They have to be exhibited in pairs, making six blooms in all, and the competition is very keen for the eight prizes which are offered each season. There is little to choose between many of the exhibits in point of merit, and some of the blooms are superbly finished and very refined. This is quite an attractive feature in this fine show, and may with advantage be copied by other societies. The plants are very easily grown, and are valuable for the production of exhibition blooms for competitions of the kind just referred to or for the conservatory. Why the members of this family of incurved Chrysanthemums are not grown for grouping is a matter for surprise. The cuttings should be inserted in good time and the resulting plants grown on to terminal buds.

D. B. CRANE.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

ROYAL HORTICULTURAL SOCIETY AND ITS GARDEN.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—As a lover of horticulture I was pleased to read your leader on the new Hall, and whilst giving the society every encouragement to bring the new scheme to a successful issue, you point out at the same time the value of the Garden. You certainly put the matter most plainly when you state a garden is the foundation of the society's existence, and there are many Fellows who would take no interest in the society if it were merely for shows. Those who never think of anything else but the meetings I fear forget that before any new plant, fruit, or vegetable can become a standard variety it must have a thorough trial, and who can give it this better than the Royal Horticultural Society, which has no trade interest? Growers have their own trial grounds, but, naturally, they are more interested in their own things than in those of others, and here is seen the value of the Royal Horticultural Society's gardens. Again, take the committee formed of men with good knowledge of the subject. Some are the best experts in the various branches of horticulture; others, who may have less knowledge in some respects, have great interest in cultural work, and combined the two form a strong body that makes their opinion valuable. This is more seen at Chiswick than elsewhere, as at the society's gardens a better result is secured than at a crowded committee table at the Hall. I am aware Chiswick is not an ideal place for trials, but I trust in the future the council will not use the funds derived from the surrender of the lease for the Hall. I do hope we are not to become a mere flower show society. Now is the time before it is too late for the real gardening Fellows to point out to the council that they are willing to support them to bring the Hall to a finish, but they do so upon the conditions that a garden is, and must be, one of the society's chief aims. The council will be wise to keep a firm hold of the gardening Fellows who would like to see the new Garden a school of practical and scientific horticulture.

AN OLD FELLOW.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The fear lest in the haste to secure a handsome sum of £5,000 the Royal Horticultural

Society may presently find itself without any gardens materially dwarfs the important matter of the erection of a new Hall. I cannot have much sympathy with some of the council's critics at the recent annual meeting all the same, because it was their action at an earlier general meeting in starting up without much consideration as to what they were doing, and offering on the spur of the moment huge sums of money towards the erection of a Hall, which killed the effort then being made to secure a new Chiswick. But our position as Fellows of the Royal Horticultural Society now is that we have yet no Hall, although the site is there and the plans are ready. Is there anything like money enough to pay for the proposed erection? And upon that fact comes the even more disturbing one that very soon we may have no garden. It is poor consolation to learn that any agreement made with the Duke of Devonshire will stipulate for a year's notice to quit Chiswick. But we have already practically expended three years in looking for a new garden, and if driven into the short space of one year only in which to find one we may be forced to accept any site, however unsuitable, that may offer. We shall never get offered another Limpsfield site, one of the finest and cheapest in the whole kingdom, and where, had it been secured, we could have ere now laid the foundation of the best horticultural garden and training school in the world. That prospect was wrecked, and the society is in this foolish war over sites and designs being in danger of a similar misfortune. We must back up the council in their efforts to get the money and erect the new Hall on the best possible lines, but equally we must prevent the loss of Chiswick absolutely until the new garden has been found to replace it.

A. DEAN.

THE KITCHEN GARDEN. CLIMBING OR RUNNER BEANS.

ALTHOUGH the Scarlet Runner was introduced into this country from South America as far back as the beginning of the seventeenth century, it is only during recent years that the splendid varieties of Runners have been raised and placed upon the market. When one compares many of these with the old varieties, it is surprising to me that anyone should think of cultivating any but the newer and improved forms, which, as far as I know, have everything to recommend them, being quite as robust, indeed, more so, very prolific, much less trouble to pick and prepare, realise better prices, and the quality far superior to the older ones.

No vegetable cultivated is more appreciated or responds better to liberal treatment by way of making thorough preparation for the roots, and indeed the growths also, than the above. A deeply worked and well manured soil is of the utmost importance, and this applies to all land. That these will exist and give fair crops even on poor shallow ground I admit, but let anyone make comparisons, of course allowing for the extra work and expense in preparing and managing one short row, with one grown in a haphazard way and I venture to say (to the inexperienced) that the results will be astounding.

In kitchen gardens, many of which are of small dimensions, one has or ought to consider the best means of producing the greatest supplies from the smallest space, and by making a careful study as to this it is surprising what can be achieved in this way. Generally speaking it is not the farmer who has the largest acreage of land under his charge who produces the best crops, but the one that strives to make one blade of grass grow instead of two. The most profitable way to grow these is to prepare trenches about the end of March or beginning of April, precisely in the same way as is done for Celery. Fill up the trench to within about 6 inches of the top with thoroughly good half decayed farmyard manure, on which is placed

about 5 inches of the best of the soil taken from the trench, leaving it in this state till the time of planting. Allow plenty of room between the rows, 9 feet to 10 feet at least. The seed should be raised in boxes, and be sown about the middle of May and placed in quite a cool house to germinate. These should be carefully hardened and planted in the prepared trenches about the end of May or the first week in June. Plant in double lines, allowing 10 inches between each and 8 inches from plant to plant, and put them in right up to the seed leaf. Place some finely sifted cinder ashes around each plant which will successfully prevent the slugs from ravaging them; these often inflict considerable damage in some seasons. The rows should be staked at the time of planting. Good staking I contend is essential, and when well done these present a very pleasing appearance throughout the summer months. Extra strong and stout sticks should be prepared if possible, which should be not less than from 10 feet to 14 feet above the ground level. These should be thrust in perpendicularly as near the Beans as possible. At every 10 yards plant two strong poles on each side of the row in a line with the sticks, and thoroughly drive in. Strong tarred cord should be stretched from pole to pole about 10 inches from the top. The twiggy tops should be taken off neatly with the garden shears and put in between the sticks to give the young growths a start. The tops of the Runners should be taken off after reaching the desired height, when these will occasion very little further trouble till the frost puts an end to them, and are practically safe against the severe gales we generally experience during autumn. The ground should be thoroughly mulched with long litter between the rows, and apply slight dressings of some good artificial vegetable manure when in full bearing during showery weather, and during spells of drought give copious supplies of well diluted farm-yard manure. By syringing the growths during early evening in hot weather this will assist the pods to set and swell away freely.

Among the best varieties which have come under my notice are Sutton's Best of All and Prizewinner, Neal's No Plus Ultra, a fine type when true. Carter's Jubilee is the finest white flowered kind, and good for any purpose. The new French climbers are much liked by some, especially where French Beans are preferred to Scarlet Runners. These are unquestionably very prolific, but require to be picked when quite young. Veitch's Climbing French is an excellent Bean. E. BECKETT.

THE YELLOW TOMATOES.

I WAS pleased to read Mr. Beckett's note on page 104 of THE GARDEN advocating the extended use and cultivation of the Yellow Tomatoes. The one named Veitch's Golden Jubilee is certainly a beautiful fruit, and not so much grown as it deserves, but, as Mr. Beckett will know, it is not so great a favourite in the market as a red fruit. Why, I know not, except that the colour is against it, as the quality is superior to many red varieties. On the other hand, fortunately, many have not to study the market, and could give the Golden Jubilee a good place. I feel sure it would be much appreciated in many establishments. I do not know whether Mr. Beckett has noticed that some of the yellow fruits with a very tender skin do not keep so long as some of the old red fruits. I think this is the case, and it may affect the fruits when packed, but of course this only applies to the market, as the delicious flavour of the fruit referred to should not be overlooked for home supplies. There are now several beautiful yellow kinds, such as Golden Queen, Golden Perfection, Sunbeam, the small but delicious Golden Nugget, and the Cluster Tomato. All these are of fine quality and crop well. The new Chiswick Peach is also a splendid fruit, and just the size for salad purposes. G. WYTHES.

THE JASMINE.

HISTORY tells us that it was a Duke of Tuscany who was the first possessor in Europe of this very pretty shrub, and he was so fearful lest others should

enjoy what he alone desired to possess that strict injunctions were given to his gardener not to give a slip, not so much even as a single flower, to any person. To this command the gardener would have been faithful had not love wounded him by the sparkling eyes of a fair but portionless peasant, whose want of a little dowry and his poverty alone kept them from the hymeneal. On the birthday of his mistress he presented her with a nosegay, and to render the bouquet more acceptable ornamented it with a bunch of Jasmine. The young lady, wishing to preserve the bloom of this new flower, put it into some fresh earth, and the spray remained green all the year. In the following spring it grew and was covered with flowers. It flourished and multiplied so much under the fair maiden's cultivation that she was able to amass a little fortune from the sale of the precious gift which love had made her; when, with a sprig of Jasmine in her breast, she bestowed her hand and wealth on the happy gardener of her heart, and the Tuscan girls to this day preserve the remembrance of this adventure by invariably wearing a nosegay of Jasmine on their wedding-day; and they also have a proverb which says a

THE LATE MR. R. MACKELLAR.

young girl worthy of wearing this nosegay is rich enough to make the fortune of a good husband. We are afraid she would not make much of a fortune in these days out of sprays of Jasmine. But the story is a very pretty one and well worthy of preservation. W. N. B.

Nuttallia cerasiformis.—This is by no means a showy shrub, but flowering as it does during the month of February it is very welcome, added to which the flower racemes are graceful. Its usual habit is to form a roundish bush, seldom more than 6 feet high, and as a rule quite as much or even more in diameter. The flowers, which are borne in great profusion, are in short pendulous racemes, much after the manner of the flowering Currant (*Ribes sanguineum*). They are of a greenish white tint, but the profusion in which they are borne compensates for any lack of colouring, as an isolated specimen is, when at its best, extremely graceful. The *Nuttallia* itself is a native of California, and serves to perpetuate the memory of a noted American botanist—Thomas Nuttall. It is a neat ally of the Plum and Cherry family, and, indeed, is sometimes known as *Prunus californica*.—T.

OBITUARY.

ROBERT MACKELLAR.

THE news of the sudden death of Mr. Mackellar on the 27th ult. will be received with widespread regret. It has certainly been so to me, as one of his oldest and most intimate friends. As a clever, practical, and well-informed gardener, Robert Mackellar unquestionably stood in the first rank, and as an exhibitor of plants and fruit in the neighbourhood of Manchester he was most successful. He received his training in the first instance under his father, who still survives to mourn his son's loss, and afterwards at Floors Castle, the Royal Gardens Kew, Chatsworth, and Drayton Manor. He was for a short time head gardener at the Agricultural College, Cirencester, subsequently at Elvaston Castle, and for the last twenty-nine or thirty years head gardener at Abney Hall, Cheadle, near Manchester. He was one of the most unselfish and generous of men; nothing gave him greater pleasure than to be of service to others. The gardening charities had a warm place in his heart, and he took a keen interest in the local Literary and Technical Institute. His funeral was largely attended by residents in the village, by whom Robert Mackellar was greatly esteemed. OWEN THOMAS.

MRS. F. L. AMES.

MRS. F. L. AMES, eminent patron of horticulture, died on Wednesday morning, the 21st ult. She was a woman of noble character, charitable, and widely beloved. Her notable estate at North Easton, Mass., and her extensive Orchid collection, of which W. N. Craig has charge, have world-wide renown.—*The American Florist*.

CHARLES PENNY.

WE much regret to learn that Mr. Penny died recently, at the age of seventy-six. Mr. Penny became a well known personality in the horticultural world when head gardener to the Prince of Wales at Sandringham, and his name will always be associated with the Royal Gardeners' Orphan Fund, as he was one of its founders.

SOCIETIES.

BECKENHAM HORTICULTURAL SOCIETY.

MR. J. YOUNG, grower to Messrs. John Peed and Son, recently gave a lecture before the members of this society in the Church House on the "Cultivation of the Gloxinia," illustrating the same by coloured photographs. There was a good attendance of members. Dealing briefly with the history of the Gloxinia, introduced from South America and named after G. P. Gloxin, Mr. Young dealt with the items of watering, potting, insect pests, shading, and drying off the plants. A brisk discussion took place, in which many members assisted. A hearty vote of thanks to Mr. Young and Messrs. J. Peed and Son brought the meeting to a close.

ROYAL BOTANIC SOCIETY.

A REUNION of past and present members of the Society's Gardening School, which took the form of an evening entertainment and concert, was recently held at Regent's Park. Tea was provided in the class-room, after which a programme of music followed. During the interval between the first and second half of the entertainment, Mr. E. F. Hawes was presented with a large and handsome silver casket. Mr. E. J. Winstone, in making the presentation on behalf of the present students, said that this was a mark of esteem and in appreciation of the worthy manner in which the school work had been conducted during the past year. Mr. Hawes, in returning thanks, said it was a great pleasure to be the recipient of such a handsome present. This is the fifth occasion on which Mr. Hawes' work has been publicly acknowledged by the various classes of students under his charge at the Royal Society's Gardening School. Mr. H. D. Strathfield was also presented with a silver-mounted letter case.

BROMLEY AND DISTRICT CHRYSANTHEMUM SOCIETY.

THE members of the above society held their annual dinner on Wednesday evening, the 11th inst., at Bromley, when about eighty persons were present. The president (Mr.

Coles Child, J.P., D.L.) occupied the chair, and supporting him were Messrs. T. C. Dewey, A. C. Norman, J.P., E. M. Garner, H. J. Jones, W. Weeks (hon. treasurer), D. B. Crane, F. Tapper, J. Lyne, the hon. secretary (Mr. W. Collings), and others well known in the Chrysanthemum world. The dinner on this occasion was to celebrate the twenty-first anniversary of the society's existence, an event rightly regarded as a red-letter day in its history. After the usual loyal toasts had been given with enthusiasm, the chairman proceeded with the toast of the evening, "The Chrysanthemum Society." In doing so he briefly sketched the history of the society from its inception in 1882 until the present time—its coming of age. They began, he said, in a fairly flourishing condition, and offered £40 in prizes the first year. Subsequently the society proved itself capable of expanding, and under the presidency of Mr. Tedworth and the late Captain Torrens up to 1890 progressed favourably and was regarded as a success. In the succeeding year the chairman said he became president of the society, since which period he had occupied that position. It was mentioned that the income varied between £90 to £120 during the period just alluded to. With the advent of Mr. William Weeks as honorary secretary some twelve or thirteen years ago the society increased in popularity. Its income increased from £80 to £180 per annum, and the amounts taken at the door and sale of tickets from £18 to £50. The exhibits had advanced in numbers and quality. Six times they had competed at the National Chrysanthemum Society for the National Trophy, winning it on two occasions, placed second three times, and on one occasion third. The toast of the society was coupled with the names of Mr. W. Collings (hon. secretary) and Mr. W. Weeks (hon. treasurer). The toast was received with the greatest enthusiasm, and the responses listened to with much interest. Mr. A. C. Norman, J.P., gave the toast of "The Executive," to which Mr. F. Tapper responded. Mr. T. C. Dewey proposed "The Visitors," coupling the name of Mr. D. B. Crane with the toast. Mr. J. Lyne, in well-chosen words, spoke of the high esteem in which the president was held by the members. A most enjoyable evening was spent.

HASLEMERE GARDENERS' ASSOCIATION.

THERE is no place within a radius of fifty miles from the metropolis that has such a reputation for scenic beauty as Haslemere and the surrounding district. Hindhead is the home of many a man of outstanding ability, and it was here that the late Grant Allen found the repose from ungenial work in studying Nature. To the beauty of Nature has been added the skill of man, and hundreds of residences, presided over by men of sound knowledge encompass the town. Curiously enough, Haslemere, though boasting an excellent summer show and a fine autumn exhibition, has not had that most desirable of institutions—a gardeners' mutual improvement association—but this want will soon be filled. Something like forty gardeners have foregathered on Fridays during the past six weeks to hear Mr. Horace J. Wright lecture upon "Hardy Fruit Culture," under the auspices of the Surrey County Council, and Mr. Newman, the energetic chairman, thought the occasion a fitting one to start an association. The matter was placed before those in attendance at Mr. Wright's last lecture on the 13th inst., all of whom were in favour of the suggestion. A public meeting is to be called shortly, when the matter will be placed upon a business basis, and a committee and officers will be appointed. Practically all the leading gardeners of the district were present, and as they are supporting the movement, success is well-nigh assured.

SHROPSHIRE HORTICULTURAL SOCIETY.

ANNUAL MEETING.

THE annual meeting in connexion with the Shropshire Horticultural Society was held at the Music Hall, Shrewsbury, recently. The Mayor of Shrewsbury (Mr. H. R. H. Southam) presided, and among those present were Mr. E. C. Peele (chairman of committee), Major-General the Hon. W. H. Herbert, the Rev. W. Leeke, Colonel Robinson, Messrs. Admitt and Naunton (joint hon. secretaries), Mr. James Vine (treasurer), &c.

The honorary secretaries presented the annual report as follows: The committee have much pleasure in congratulating the members of the society on the successful results of last summer's show, when it will be remembered the very wet season experienced throughout the country naturally affected the quality of many of the exhibits and prevented exhibitors staging some of their best productions through want of sun to ripen and bring them up to the standard of perfection. The show was, however, favoured with splendid weather on the two days in August last, and the result was a record attendance of visitors, as evidenced by the fact that the total receipts from all sources amounted to the large sum of £5,001 15s. 5d., being £254 19s. 4d. in excess of the previous year, which up to that date was the society's largest income, viz., £4,746 16s. 1d. It has long been the ambition of the committee that the society's total return should reach £5,000, and therefore it is with a degree of pride that the success attending the twenty-eighth show has placed them in a position to announce such has at last been realised.

Mr. Vine presented the statement of accounts, which showed that the profit on the summer show was £873 18s., while the total profit for the year amounted to upwards of £1,000, compared with £827 10s. 3d. the previous year. During the past year the society voted from their funds several large sums, including £200 for the laying out of the Abbey Public Gardens. They also expended £154 8s. 7d. in "improvement of the river banks in the vicinity of the Quarry, making the total which the society have expended for this one purpose £1,500. Since 1875 the society have voted to various deserving objects no less than £6,953.

The Mayor, in moving the adoption of the report and balance-sheet, congratulated the members of the society on its continued prosperity. He remarked that it was very

creditable to the railway authorities that, notwithstanding the enormous traffic, there had been but one accident during the twenty-eight years the show had been held.

Mr. G. M. Salt seconded the motion, and it was carried. On the proposition of Mr. E. C. Peele, seconded by Mr. Salt, Lord Forester was elected president of the society for the ensuing year; and on the motion of Major-General Herbert, seconded by Mr. H. Owen, a vote of thanks was passed to Mr. H. J. Allcroft for his services as president during the past year and for his liberal gift of prizes.

The retiring members of the committee were re-elected, with the addition of Mr. R. Blakeway Phillips, who was elected to fill the vacancy caused by the death of Mr. W. Lyon Browne.

Mr. W. Thorne (superintendent of the Joint Railway Companies) said it would probably interest those present to learn that, apart from ordinary trains, on the occasion of the last show there were between fifty and sixty specials. So far-reaching was the popularity of the Shrewsbury floral fête that the honorary secretaries were always anxious to increase the number of excursions and tap new ground; and last year between 3,000 and 4,000 people were brought from a new district.

A vote of thanks to the Mayor for presiding terminated the proceedings.

BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

THE fortnightly meeting of this association was held at St. John's Rooms, Redland, on Thursday, the 12th inst., Mr. E. Binfield, Old Sneyd Park, occupying the chair. The subject for the evening was "Melons and Cucumbers," introduced by Mr. Collier, of the Cardiff Gardeners' Association. The lecturer detailed the best methods for cultivation, including time for sowing the seed, training, stopping, tying, and general treatment. He also described the insect pests and diseases to which they are liable, and the best means for eradication and prevention. Soils and composts also received his attention, and were fully explained. A good discussion followed Mr. Collier's lecture, and he was voted the thanks of the meeting for his able paper. Prizes for two Orchids were awarded equal firsts to Mr. W. Howell Davis, J.P. (gardener, Mr. Curtis), and Mr. J. M. Harris (gardener, Mr. Venn). Certificates of merit went to Mr. Garnish for some cut Tulips; Mr. W. Howell Davis, J.P. (gardener, Mr. Curtis); for *Odontoglossum crispum*; and to Mr. H. Killely for a pot of double *Daffodils* grown entirely in moss. The society's certificates of special merit were recommended to Mr. Hall (gardener, Mr. Ware), for two good pots of *Freesias*, and to Mr. Ayres for a fine collection of *Cypripediums*.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening, the 16th inst., the executive committee of the above society held a meeting at the Albert Hotel, Victoria Street, S.W., Mr. Thomas Bevan occupying the chair. After the usual preliminaries had been disposed of, it was announced that the vacant position of president of the society had been offered to and accepted by Mr. C. E. Shea. It was also announced that Messrs. Mackenzie and Moncur would offer a special prize at the next November show of the value of £10, the allocation of this prize being left in the hands of the schedule committee. A very satisfactory interim financial statement to date was submitted, and the usual motion made that the secretary's annual salary be fixed and paid at the same rate as last. Some discussion on ways and means then ensued, and it was requested that an estimate of receipts and expenditure be submitted at an early opportunity. In reference to the arrangements with the Crystal Palace, enquiry was made, and the reply received that it was hoped the agreement between the Palace Company and the National Chrysanthemum Society would be signed and handed over in a few days. The floral meetings during next season will be held in Essex Hall, excepting those that fall on the dates of the society's shows, and these will therefore take place at the Crystal Palace. There was a suggestion that a registration fee of 1s. per variety be made on all novelties submitted for adjudication by the floral committee, but this was allowed to drop. The annual excursion for 1903 was discussed and one or two places suggested. The event will take place as usual in July, but further details will be furnished later.

On the election of members for the floral committee, who retire in rotation, eight names were submitted for six vacancies. The successful candidates were Messrs. J. Brookes, Norman Davis, A. W. Sealbrook, T. L. Turk, C. Blich, and J. B. Riding. The election was by ballot, the scrutineers being Messrs. Berridge and Foster. Other elections followed, there being several vacancies to fill up in the schedule, finance, arbitration, and classification committees.

A member drew attention to the dressing of Japanese incurved blooms, but it was felt that little or nothing could be done in the matter.

New members were elected, and the meeting was brought to a close after a somewhat busy evening.

EALING HORTICULTURAL SOCIETY.

EALING is one of those localities in which matters horticultural have fallen to a lower stage than they once occupied in the estimation of the residents. This is to be accounted for to a large extent from the fact that the urban character of the place has materially changed of late, not a few small estates on which lived inhabitants who took a warm interest in local institutions, and in the horticultural society in particular, where plants were grown for exhibition, having been broken up for building purposes. These have given place to streets of small houses, and what was once country is now town. The new inhabitants, who are largely in London during the day, take little or no interest in the affairs of the neighbourhood, and old institutions decline. In this way the Ealing Horticultural Society has ceased to be as successful as it formerly was, partly on this account

and partly on account of the wet season of 1902. At the annual general meeting held recently the report of the committee stated that there was a serious deficit of funds owing to the wet character of the weather on the occasion of holding the annual flower show in Gunnersbury Park in July last. Some years had elapsed since the society had pitched its tents in these charming grounds, and some expense had been incurred in making the fact known in the large neighbourhoods south of Ealing. As the day proved wet, few could attend, and the loss was heavy, swallowing up all the means of the society. The autumn Chrysanthemum show which had been held for several years past had to be abandoned to the regret of many. The society therefore enters upon the year 1903 not only without funds but actually in debt. The annual show in the present year has been fixed for Wednesday, July 8, and will be held in the Walpole Public Park in the centre of the town, and it is hoped that a Chrysanthemum show may take place as usual. The officers and committee were elected, including the president (Mr. Leopold de Rothschild) and the secretary (Mr. George Cannon). The committee were instructed to take the necessary steps to bring the claims of the society more prominently before the people of Ealing.

HORTICULTURAL SOCIETIES' SCHEDULES.

THE fifty-second annual show of the Woodbridge Horticultural Society will be held in the Grange grounds, on Thursday, July 9. Roses, Carnations, pot plants, cut flowers, fruit, and vegetables are all well provided for in the classes. Mr. John Andrews, Gordon House, Cumberland Street, is the hon. secretary.

IPSWICH AND EAST OF ENGLAND HORTICULTURAL SOCIETY.

The summer show will be held on Wednesday, July 1. Messrs. H. J. Cutbush, J. Hudson, W. Allan, and S. T. Wright will be the judges. The Chrysanthemum show will take place on Tuesday and Wednesday, November 10 and 11. Secretary, Mr. H. E. Archer, 13, Museum Street, Norwich.

RICHMOND HORTICULTURAL SOCIETY.

In the annual report we read during the year 1902 energetic steps "have been taken towards freeing the society from debt. A substantial increase in the number of annual subscribers is the greatest present need, and the committee hope that the coming year will bring many new applications for membership. The accounts of the first and second annual dinners have been made up, showing a substantial profit to the society, which has enabled the committee to repay £150 of the loan from the bankers."

The next flower show will be held in the Old Deer Park, Richmond, on Wednesday, July 1. The Gunnersbury Park silver challenge cup for Roses, presented by Leopold de Rothschild, Esq., is to be held by the winner of the first prize in class 13 for one year, 1903-1904. Honorary secretary, C. R. King, 61, George Street, Richmond.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

The spring show will be held on Wednesday and Thursday, May 20 and 21, and the autumn show, Wednesday and Thursday, September 9 and 10. At the spring show prizes are again offered to under gardeners for a plan for laying out three acres of land. For both exhibitions the schedule is an excellent one. A special prize is offered in September by Mr. and Mrs. J. Martin White, Balrudery, Dundee, for the best essay on the preservation and lasting qualities of flowers, foliage, and plants in a cut state in water. Secretary, P. Murray Thompson, York Place, Edinburgh.

MIDLAND CARNATION AND PICOTEE SOCIETY.

The report for 1902 says:—The twelfth annual exhibition was held at the Edgbaston Botanical Gardens on Thursday and Friday, August 7 and 8, and, taking into consideration the exceptionally unfavourable season, was quite up to the society's standard. The committee regretted the absence of exhibitors from the South, but the Midlands were strongly represented. They were pleased to see Mr. Robert Sydenham again competing after his regrettable absence last year owing to ill-health.

Owing to the inclement weather on the first day of the show the attendance of the public was not so large as in 1901, a fact which has, unfortunately, largely affected the balance sheet. The new classes for undressed blooms, added by the committee last year, were a distinct success, the entries being numerous and the flowers staged being of the highest quality. It will be noted in this year's schedule that a very stringent rule has been made with regard to all the undressed classes—viz., "That the flowers must be shown with a perfect calyx, and not with the points of the calyx turned down," as some exhibitors have been in the habit of doing in the past.

Mr. Sydenham has, unfortunately, been obliged to give up the management after a splendid effort dating from the inception of the society; but Mr. W. H. Parton, jun., has undertaken the vacant post, and hopes, with the kind assistance of all the members, to maintain the prestige of the society in the future.

CARDIFF GARDENERS' ASSOCIATION.

THE usual fortnightly meeting took place at the Grand Hotel on Tuesday, the 10th inst., Mr. C. E. Collier in the chair. Mr. E. A. Parsons, gardener, Strathearn, Cardiff, gave an interesting lecture, entitled "Chrysanthemums," dealing with their history, cultivation, and exhibiting. Great emphasis was laid on the importance of noting the proper time for propagating various varieties, which, the lecturer added, was quite as essential as timing the buds. Owing to the growing popularity of the flower in this district there was a large attendance of members and friends, who contributed to an enthusiastic debate. At the close Mr. Parsons was heartily thanked for his lecture. For a nice spike of *Cattleya Harrisoni* Mr. Parsons was awarded a second-class certificate.

THE GARDEN

No. 1633.—VOL. LXIII.]

[MARCH 7, 1903.]

HARDY GARDENING UNDER GLASS.

GOOD WORK AT KEW.

AT Kew the alpine house is doing admirable service to the gardening public by bringing into notice new hardy plants as they are being introduced, by showing what can be done with them, and the illustrations on the next page of some of the first spring flowers to be found in bloom there at this early season come as a timely reminder. In April and May this house is crowded with visitors, but interesting as it is at that time of year, the chief use of such a structure is not then so clearly demonstrated. It is from the middle of January and for two months onwards, when spring flowers are few and far between, and wintry weather prevents our enjoying even these few out of doors, that we learn the real value of the alpine house.

Very many owners of greenhouses which for various reasons are insufficiently heated for ordinary tender plants, or not heated at all, would do well to turn their attention to this particular phase of winter gardening. It is often a subject of regret that so many of these structures are practically useless, when they might be made an unfailing source of pleasure and occupation. Looking over garden records of more than twenty years ago concerning an unheated greenhouse, such things as *Crocus Imperati*, *Sisyrinchium grandiflorum*, Christmas Roses, *Seillas*, *Orobis vernus*, *Anemone blanda*, *A. stellata*, *Milla uniflora*, Wallflowers, *Coronilla glauca*, *Myosotis dissitiflora*, and others are noted as being in good flower between January 10 and February 1. Hardy gardening under glass in those days had scarcely been tried, and was looked upon as a brave but hopeless attempt to make the best of adverse circumstances. Now Kew leads the way to show that so far from the unheated house being a make-shift, it presents exactly the right conditions under which certain plants can be most successfully flowered.

To get hardy plants into early flower is mainly a question of forethought and preparation. The present moment is not too soon to enter a resolution in any scheme of work for the year, to seek out and make ready as many suitable hardy plants as we can, so that we may have the enjoyment of them during the first inclement weeks of 1904. As to suitability, the behaviour of early-flowering hardy plants in the open borders will be a fair

guide. How many of these, like some of the Primrose tribe, wake up too soon in our uncertain climate and begin to make premature efforts to bloom? Any such may be noted, for they plainly ask for shelter.

A visit to Kew, or to one of the famous botanic gardens of Edinburgh or Dublin, of Birmingham, or at Cambridge and elsewhere, note-book in hand, will always be instructive and suggestive of new and desirable plants; but failing opportunities of making acquaintance with living examples, we can turn to garden literature. There is no lack of means of obtaining information where there is energy enough to seek for it. Given suitable plants, the one great secret of success is to get them well established, either in pans or pots in cold frames, or, in some instances, by a preliminary course of planting out in reserve quarters in the open ground, where they can be well cared for during the summer. In the case of bulbs, early potting—or repotting according to circumstances—is of utmost importance, or again it may be the sowing of seed or the putting in of fresh cuttings at the right moment. It is just upon this point of attention to apparently trifling matters that success or failure often turns. Time slips by unheeded, there is no immediate incentive to work, and the prospect of months of waiting is intolerably tedious. Nevertheless the reward, when it does come, is worth waiting for.

Nor need we wait for this kind of gardening until we have an alpine house—at any rate, to make a beginning. In most country houses there are positions that can be utilised. A glass porch, a covered verandah, a bay window in an unheated ante-room may each or all serve passably well for plants in flower. The only place to avoid is the ordinary warm greenhouse. Here such hardy things will quickly sicken, and, if they do not die outright, will become so drawn up and weakened that they will be of little future use, whereas the aim and end of such winter gardening must be to get strong established plants which will last for several years, growing better with each succeeding season. All timely notes—cultural and otherwise—on the subject of the alpine house at Kew, and the work going on there, will undoubtedly be welcomed by many readers of THE GARDEN.

We have illustrated the interior of the house again, because we have never seen so many interesting and beautiful flowers open at one time before, and the illustration of the exterior shows quite a modest little structure.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

March 9.—Annual General Meeting of the United Horticultural Benefit and Provident Society, Caledonian Hotel, Strand, at 8 p.m.

March 10.—Royal Horticultural Society Meeting, 12 noon; Horticultural Club, 6 p.m.

March 24.—Royal Horticultural Society Meeting (Tulip and Hyacinth Show).

March 25.—Liverpool Horticultural Association Spring Show.

Royal Horticultural Society.—The next fruit and flower show of the above society will be held on Tuesday next in the Drill Hall, Buckingham Gate, London, S.W., 1—4 p.m. A lecture on "Natural Selection *v.* Adoption" will be given by the Rev. Professor G. Henslow, M.A., V.M.H., at three o'clock. At a general meeting held on Tuesday, the 24th ult., 103 new Fellows were elected, amongst them being Baron Anthony de Worms, Sir John Dickson-Poynder, Bart., M.P., Lady Allen, Lady Cunliffe, Lady Constance Ryder, Lady Edwards, Lady Smyth, the Hon. Mrs. Charles Trotter, and the Hon. Mrs. Parry-Evans, making a total of 323 elected this year. At the society's fortnightly exhibition on the 24th inst. special prizes will be offered by the Royal Bulb-growing Society of Haarlem for Hyacinths and Tulips as follows: 120 Hyacinths in pots (one bulb in each pot), in not less than forty varieties and not more than three pots of any one variety (open), first prize, £7; second, £5; third, £3; 100 pots of Tulips (three bulbs of one variety in each pot), to include fifty varieties at least and not more than two pots of any one variety (open), first prize, £4; second, £3; third, £2. At least six days' notice must be given of intention to compete.

Primula kewensis.—This hybrid mule *Primula*, even though it thus produces no seed, can be rapidly increased by division, as the very fine stock of plants of it now in Messrs. Veitch and Sons' nursery at Feltham shows. The stock is sown largely in 5-inch and 6-inch pots, and is of very robust growth. Flower-spikes have been plentiful for some time, showing that the plants retain all that blooming precocity which characterises the seed parent, *Primula floribunda*, whilst the growth is so much stronger and the flowers larger, features due to the pollen parentage of *P. verticillata*. That this *Primula* will soon be in great request as a half-hardy greenhouse winter bloomer there can be no doubt. It may be described truly as being the only known real Primrose hybrid. Its mule character may be regarded as conclusive proof that it is a genuine cross product.—D.

Fresh impetus is given to good greenhouse plants by the appearance of a new hybrid or quite new species, and the placing in commerce of the above plant is almost a case in point. Singularly enough, like not a few other good plants the above is a natural hybrid I believe, the obvious outcome of the crossing of *P. floribunda* and *P. verticillata*. Not only is the new-comer a fine plant from every point of view, but it is a great advance upon the parents. This is so not only in the flowering and its great freedom, but in the effect produced. *P. verticillata* has pale yellow blossoms and quite whitish mealy stems and leaves—so much meal or

INTERIOR OF THE ALPINE HOUSE, ROYAL GARDENS, KEW. (Photographed on February 24 last.)

farina, indeed, that it detracts rather from the pale-coloured blossoms. In *P. kewensis*, fortunately, the colour of the leaves is that of *P. floribunda*, and these, coupled with the richer, deeper yellow coloured blossoms provide a plant of great beauty and effectiveness. The rich yellow flowers are exceedingly beautiful, and there is just that compact habit and freedom of blossoming that go to make an ideal pot plant for the conservatory or the greenhouse. In growth the new-comer is taller than *P. floribunda* and a little less tall to the first whorl of flowers than is usual in *P. verticillata*; in short, were the stems of the parents measured out, I believe one would find the new hybrid to be just nicely balanced between the two. *P. verticillata* or its influence has given a plant of taller stature as compared with the generally too low-growing *P. floribunda*, while the influence of the last-named species is clearly seen in the greener leafage and colour of the flowers. Thus analysed it will be seen to be almost intermediate between the parents. Curiously enough, while both species seed freely, the hybrid will not. There is consolation in the fact, however, that both parents may be largely increased by division, an attribute imparted in the freest manner to the new plant. There is yet one point of interest and merit to be mentioned—*P. verticillata* is a wonderful plant for fragrance, possessing the pure scent of the meadow Cowslip, and just this identical and welcome fragrance has been inherited by *P. kewensis*. In the former the fragrance of a single strong plant in flower may be detected a dozen feet away, and that *P. kewensis* is similarly endowed I quickly noted the other day even in the much-maligned Drill Hall, where colour and fragrance and all other meritorious points are said quickly to vanish away.—E. JENKINS, *Hampton Hill*.

Extension of Brockwell Park.—Residents in the neighbourhood of Brixton, Camberwell, and Norwood who have appreciated the advantages of Brockwell Park will also be delighted with its extension. The

new part was formally opened on Saturday last by Mr. John Piggott, chairman to the Parks Committee of the London County Council. The park can be reached by thousands of dwellers from long distances, as the services of trains, trams, &c., in the district are good. That portion opened contains fine cricket and football fields; the whole forty-three acres are not yet available, as the leases of several acres have not run out.

A notable concert.—The seventh annual concert, organised by the George Monro committee, took place at the King's Hall, Holborn Restaurant, on Thursday, the 26th ult. The audience was

crowded and representative, and composed of members of the trade and many eminent growers, with some foreign and colonial guests engaged in the fruit growing industry. The programme left nothing to be desired. The chairman, Mr. George Monro, received an enthusiastic vote of thanks, and in reply paid a warm tribute of praise to the entertainment committee and the zeal and energy of Mr. H. Baker, the honorary secretary.

Damage in Phoenix Park, Dublin.—During the recent storm it is estimated that no fewer than 1,000 trees were uprooted. Surrounding districts have suffered severely.

Acacias in Flower at Kew. The following Acacias are now in flower in the Temperate house, Kew, many of them represented by fine specimens:—*A. acinacea*, *A. armata*, *A. var. undulata*, *dealbata*, *decurrens* var. *mollis*, *dietrichiana*, *Drummondii*, *glaucescens*, *hastulata*, *juniperina*, *latifolia*, *leprosa*, *linearis*, *limifolia*, *longifolia* var. *magnifica*, *Meissneri*, *myrtifolia*, *obliqua*, *peninervis*, *pentadenia*, *pubescens*, *pycnantha*, *riceana*, *urophylla*, *verniciiflora*, *verticillata*, v. var. *ovida*.—C. R.

Wandsworth Park, which has been acquired and laid out by the County Council, the Wandsworth District Board contributing part of the cost, was opened recently. It is more than 19 acres in extent, and lies between Putney Bridge Road and the Thames, having a frontage of 1,456 feet to the river. In a description of the park, Mr. Gomme, Clerk of the County Council, says: "The locality is shown by the names of Point Pleasant and Frying Pan Creek to be connected on the one hand with Thomas Cromwell and the general history of England, and on the other hand with the Huguenot refugees and the consequent growth of English industry, while the history of the park as part and parcel of the common fields of Wandsworth points to an interesting economic stage in the world's progress." This is a notable addition to London's open spaces, and one that citizens cannot fail to enjoy.

THE ALPINE HOUSE AT KEW.

(Inside measurements: Length, 40 feet; width, 9 feet; height at apex, 8 feet 6 inches; at sides, 5 feet 6 inches.)

Colours in Rose-beds.—I note in THE GARDEN of February 14 a suggestion of colour with regard to a Rose-bed. May I suggest another which I think blends the colours red and white closer. Plant four or five plants of Ulrich Brunner (having good long trailers) in the centre, draw the branches out and train on bent twigs of Willow about 4 inches to 6 inches above the surface; between each plant put in bushes of Viscountess Folkestone. The colours I have found are better blended and catch the eye sooner than when the red is higher, and therefore becoming too prominent detracts from the whole.—C. W. CROSBY.

Encouraging juvenile gardening. Very commendable facilities are being offered for the encouragement of horticulture among the juvenile section of the community by the Buckinghamshire County Council, which is under the presidency of Lord Cottesloe. The idea is to establish a "County Council garden," the technical education authority undertaking to employ a skilled instructor, and also to supply the necessary seeds, manure, &c., and each lad instructed will not only have the superintendence and cultivation of his own plot, but the absolute advantage of the crops which by his industry he produces. Beyond a minimum fee for a course of lectures, these amateur gardeners will not be put to any other expense.

Destroying the Devonshire hedgerows.—Efforts are being made in Devonshire to put a stop to the wholesale destruction of the hedgerows—which are the pride of the county—by Fern and flower gatherers. There are men who make a business of plucking up Primroses by the roots and sending them to Covent Garden and the Midlands. So systematic are the spoilers that they leave some of the hedgerows as barren as if there had been a plague of locust. In fining William Johnstone, Fern and flower gatherer, London, £2 and £1 costs for digging up Primrose roots belonging to Sir Edmund de la Pole, the Colyton magistrates said any others brought before them for this offence would be sent to prison without the option of a fine.

Colletia cruciata.—This fiercely-spined shrub, alluded to on page 36, is comparatively rare in gardens. If employed as a fence it would prove an even more formidable barrier than the American Aloe, which in certain countries is used for this purpose. I note that your correspondent says that the flowers "do not add much to the effect of this singular shrub." This is doubtless usually the case, but I know of one instance where the blossoms were borne in such countless thousands that the great bush, 9 feet high and almost as much in diameter, presented a striking sight in December, even at some little distance. I believe the specific term *bictonensis*, sometimes applied to this shrub, arose from its having been raised from seed of *Colletia horrida*, which carried spike-shaped spines at Bicton about fifty years ago. For a considerable period it was thought that a mistake had been made, and that the seeds sown were not those of *C. horrida*, but of another species. Later experience, however, as detailed by the writer of the earlier note, proved the two plants to be identical, both forms being found on the same branch.—S. W. F.

Burchellia capensis.—Some well-flowered examples of *Burchellia capensis* recently noted in flower at Messrs. Veitch's nursery at Chelsea showed this pretty South African shrub in the new light of a winter-blooming subject, for late spring and summer is usually recognised as its period of flowering. It is in every way a very desirable plant for the warm greenhouse or intermediate structure, forming as it does a freely branched shrub, clothed with ovate, oppositely arranged leaves, about 4 inches long, and of a deep green tint. The flowers, which are borne in

clusters on the points of the preceding year's shoots, are tubular in shape, a little over 1 inch long, and of deep orange-scarlet colour, a tint which shows up very effectively against the dark green background. This *Burchellia* is a native of South Africa, where from the hardness of its wood it is known as the Buffalo-horn. The order to which it belongs (*Rubiaceæ*) contains many beautiful flowering plants, such as the different members of the genus *Bouvardia*, *Gardenia*, *Ixora*, *Manettia*, *Rondeletia*, and others. The cultural requirements of this *Burchellia* are not at all exacting, provided a warm greenhouse temperature is maintained. Cuttings of the half-ripened shoots strike without difficulty if put in well-drained pots of sandy soil and kept in a close propagating case in a structure rather warmer than that in which they have grown. A good soil for established plants is two-thirds loam to one-third peat, and a liberal sprinkling of sand.—T.

The Pink Coralita.—Under the name of Pink Coralita, *Antigonon leptopus* is a well known climbing plant in West Indian gardens, where, according to the *Agricultural News*, it is much

and will do much good. A great development of irrigation systems has been going on for years, and by means of great reservoirs, more economical distribution, and the development of all resources, such as tunnelling springs or boggy spots and pumping from gravel beds, the supply of water from mountain streams has been so much increased as to not only make present communities safe, but to allow the reclamation of large additional areas of arid lands. A large area of true desert land west of the Colorado River, in what is known as the Colorado Desert, is now being irrigated by means of a great canal from the Colorado River. This region is practically both rainless and frostless, and the soil, which is an ancient lake bed, is exceedingly rich. In all probability the earliest fruits and vegetables in the United States will be grown there. Extensive irrigation systems in Central California are being extended. While in regions where we have always considered irrigation unnecessary, experience is proving that a thorough wetting in midsummer much improves the fruit in size. In such locations the water is pumped from wells or the beds of streams. Fuel was a great

WISTARIA-COVERED LODGE IN WINDSOR GREAT PARK.

appreciated for its sprays of rose-pink flowers. Attention is drawn to the existence of a white variety of this charming plant which was recently seen at Antigua. It has also been introduced from India into Montserrat. Seeds of this variety have been distributed to several of the botanic stations of the West Indies, the plant being a distinctly interesting one and worthy of more extended cultivation.

The famous Wistaria at Windsor. The accompanying illustration represents one of the finest specimens of *Wistaria sinensis* in the British Isles. The wealth of flower is clearly portrayed, and we are not surprised that many come from far and near to see it when it is in full beauty. It covers the front and part of the roof of the lodge.

A note from California.—California is just now experiencing the coldest wave for many years. Snow fell in the mountains throughout California during the week ending February 7, while in many valley towns the inhabitants had their first sleigh rides. The last reports would indicate that cloudy weather had saved the Lemons and Oranges, although some injury is probable. The storm that brought the snow in northern California gave the south a thorough drenching,

item of expense until within the last few years, when large deposits of petroleum were developed, and that fuel is now supplanting both coal and wood for all purposes. It seems probable that oil will, in its turn, soon be supplanted by electricity. The Sierra Nevada range slopes very abruptly to the west, giving 7,000 feet fall in a little over 60 miles. The snowfall is heavy, and the numerous resultant streams are rapidly being put in harness, and the power is being distributed as far as 200 miles away. The greatest horticultural problem in California is labour, and a very serious one it was in 1902, for great quantities of fruit were wasted for lack of it. However, 1902 was a year of great prosperity to us, in which the producers of grain, live stock, Raisins, and wine shared to a marked degree. The crop of deciduous fruits, too, was great, and profits were in many cases disappointing, as great quantities could not be harvested or disposed of. The rural industries of the Pacific slope have profited much by the great extension of American activity in Alaska, the Sandwich Islands, and the Orient, and even more by the growing scarcity of beef. The future of California is bound up in the labour problem and transportation. We have so specialised in Raisins, wines, fruits of all sorts,

Hops, and Nuts that a very large supply of labour is needed from June to October. Only Oranges supply a considerable amount of winter work. The mildness of our summers, with the absence of rain, makes out of door living pleasant, and a large number of white people lead a nomadic life, moving from point to point as the harvest proceeds, and settling in some town for the rainy season. By far the greater part of the labour is done by white people. This life is in many ways excellent in the dry season, but our country towns are nearly destitute of factories, and winter employment is precarious. The present labour supply is not sufficient even in ordinary harvest, and no one here wants another influx of Japanese or Chinese, and the solution of the problem is not in sight. Bulb and seed growing have passed the experimental stage, but they, too, are dependent on a cheap and trustworthy labour supply. Whenever that is solved, Europe will have a dangerous competitor to cope with in these industries.—CARL PURDY, Ukiah, California.

Leucojum aestivum.—On February 8 last year I sent a note on the Summer Snowflake, mentioning my experience with a strain that for years proved flowerless. As I related, Mr. S. Arnott, with whom I had some correspondence on the subject, kindly sent me some bulbs of this *Leucojum*, which flowered well. On my departure from Torquay I sent some of each lot of bulbs to a neighbouring garden, and was much surprised on visiting it during the first week of 1902 to find my hitherto flowerless Snowflakes in bloom, while those I procured from Mr. Arnott showed but a few inches of leafage. In the past summer I imported into my present garden on the banks of the Dart a dozen or so bulbs of both strains and planted them side by side. On going into the garden on February 2, after my return from Cornwall, I found that my original Snowflakes, that formerly refused to flower, but blossomed in January last year at Torquay, were in full bloom; in fact, rather past their best, while the foliage of Mr. Arnott's bulbs was only about 3 inches in length. It is curious that after a period of flowerlessness that extended over some years, these bulbs should have developed such a precocious habit, for January is certainly an abnormal time for the flowering of the Summer Snowflake.

Clematis calycina.—This *Clematis*, perhaps more generally known under the synonym of *C. balearica*, referred to on page 35, though not particularly showy, is almost indispensable on account of its early blooming. In January and February its greenish white flowers, spotted in the interior with purple, are borne in great profusion, having as companions few open-air flowers besides the Winter Jasmine, *Chimonanthus fragrans*, the Wych Hazel, *Prunus davidiana*, *Iris stylosa*, Christmas Roses, and the earliest bulbs. I see that in the note I have alluded to it is stated that its branches are 10 feet to 12 feet long. In the south-west its growth is far stronger, and I know of one specimen that has climbed fully 25 feet into the branches of a variegated Tulip Tree; in fact, from its vigour in this and other instances I should consider it almost as good a tree climber as *C. montana*. Another very similar *Clematis* is *C. cirrhosa*, this being later in flowering and bearing greenish white unspotted flowers rather smaller in size than those of the subject of this note. Both are grown on a trellis in a Falmouth garden, where I have had the opportunity of comparing a late flower of *C. calycina* with an early one of *C. cirrhosa*. In the illustration of *C. cirrhosa* given in Nicholson's "Dictionary of Gardening" the foliage appears to me to be that of *C. calycina*, as the leaves of *C. cirrhosa* are, so far as my observation goes, composed of three oval segments slightly indented.—S. W. F.

Natural habitat of *Lilium speciosum*.—A few weeks ago I sent you an article on *Lilium auratum*, in which I gave the grounds for my belief that without doubt *Lilium auratum* is a native of Japan. As Mr. Augustine Henry, in the article which caused me to write the above-mentioned account, also speaks of *L. speciosum* (*THE GARDEN*, vol. lxii., page 284, October 25, 1902) I send an account of some

discoveries I have made during the last few months. I must acknowledge that up to now I had believed that *L. speciosum* must have been introduced from China or Corea, for I had never found it wild here in Japan, and as China is such a vast and comparatively unexplored country I took it for granted that this plant was one of the many which had reached Japan in such a way, especially as Mr. Elwes states that it was found wild by Dr. Hance in Kiu-Kiang, China. However, the very bad Lily harvest of 1902 has led to unexpected discoveries. The past spring and summer were so extraordinarily cold and wet that all the Lilies exported from Japan have suffered greatly, and none more so than *L. speciosum*. The production of cultivated bulbs was not half of the normal crop, and the natural result, the great rise in price, led some enterprising Japanese dealers to search for districts where the Lily grew in abundance. Following them, I have in this way discovered through a good Japanese botanist that *L. speciosum rubrum* grows wild and most abundantly in the group of islands Koshikijima, situated south of Nagasaki and west of the province of Satsuma. In these islands the same variety is found on the volcano, Kirishima, near the village Noshitakemura in the province of Hyuga Kinshin, also in the province of Tosa on the island of Shikoku, especially in the following places: (1) near the mountain pass, Kabanotoye in Yokohatamura; and (2) in Sakawa, near Takaoko. But in all these places the red variety alone is found, a fact that the dealers also substantiate. *L. speciosum album* seems, therefore, to be a garden variety not known in Japan, at least in the wild state. Mr. H. J. Elwes, in his monograph of the genus *Lilium*, states that the Japanese call *L. speciosum* Koraijuri. This is not right, for the Japanese name of *L. speciosum* is Kanoko Yuri, the red form Akai=red Kanoko, and the white form Shiroi=white. The Japanese name for Corea is Chosen, and has certainly nothing in common with the name above mentioned.—ALFRED UNGER, Yokohama, Japan.

SWEET PEAS.

THESE charming flowers have now become universal favourites, and this is hardly to be wondered at when one considers the ready way with which they adapt themselves to all forms of decoration, and their great variety of colour and delicate perfume. Moreover, there is no reason why they may not be brought to perfection by the humblest cottager as well as by the professional gardener. The great secret consists in selection of varieties, deep tillage of the soil, keeping the seed-pods

SWEET PEA EMILY HENDERSON. PART OF A HEDGE.

picked off, and supplying the roots with copious quantities of moisture during spells of dry weather. There is probably no other class which repays the cultivator so amply for any trouble he bestows upon them, and here I may mention, as with all other plants, success is not obtained without a reasonable amount of care and attention. To grow Sweet Peas really well a border should, if possible, be devoted entirely to their culture, and each variety grown in a clump by itself. The old-fashioned way of growing them in a mixed hedge has little to recommend it, but by isolating the various colours one is able easily to determine the best and most distinct sorts to grow, and the seed of each variety, if it is desired to save it, can be kept separate for further cultivation. The past year was a bad one for ripening the seed-pods in many parts of the country, owing to the lack of sunshine and prevailing dampness, notwithstanding the fact that the rainfall did not reach the average quantity at many stations. Consequently the home-grown seed this year will not have such good germinating powers as it has when we experience a favourable season, and when sowing it will be advisable to allow for this.

CULTIVATION OF THE SOIL.

Sweet Peas enjoy a well-tilled soil, and in dry weather the roots penetrate deeply in search of moisture, yet this is often disregarded by many who expect the best results. Therefore a thorough trenching should be given in winter and some good manure freely incorporated. Leave the ground in a rough and lumpy condition till planting-out time arrives, as the action of the weather will prove

most beneficial to the subsoil brought to the surface, and after the keen winds and frost have penetrated the clods will break up and rake down easily afterwards.

SOWING THE SEED.

The practice of sowing the seed in the open ground in the autumn has, I think, little if anything to recommend it, for unless well protected, which would mean a considerable amount of labour, birds and mice are sure to find it out and work havoc. Frost and rain will also prove detrimental, and nothing will be gained in the end. The method I practise, and have always found successful, is to make a sowing about the middle of March in a light porous compost consisting of two parts fibrous loam, one part leaf-mould, and some road or silver sand to keep it open. Clean, well-drained 3-inch pots should be used, and the seed sown as thick again as required, about half an inch below the rim. A sufficient number for planting is then assured. Cover the seed lightly, carefully label, damp over with a fine rose water-pot, and place in a gentle heat. An early Vinery or Peach house is a very suitable place. When the young seedlings are well above the soil remove to a cold frame for a few days, and then place them under a south wall in the open to harden off thoroughly, where they may be protected in case of frost.

PLANTING OUT.

When the plants are of sufficient size to place in their final quarters the surface of the ground should be got ready by breaking up the lumps with a fork and rake down finely. Choose a day when the ground is not pasty. A very good distance at which to place the batches apart will be 5 feet. Before removing the plants from the pots thin out to the required number. I always find from five to seven plants to a batch ample, as nothing is gained by overcrowding, and more vigorous growth and finer flowers will result than if a large number is grown at one station. Turn the plants out carefully so that the roots are not damaged in any way, and do not attempt to remove the crocks. Plant firmly, and if it is needed add a little fresh soil to start the roots into growth. When the planting is completed, damp over with a rose water-pot, place some finely-sifted cinder ashes round each group, and stake on the same day if possible. Good bushy sticks should be used, about five to a group being sufficient, and after being pressed firmly into the ground should measure not less than 6 feet. To keep them in position tie round not too tightly with tarred string, and clip off the tops of the sticks all to the same level. These twiggy pieces of stick will be just the thing for placing round the plants and assisting them to climb the large stakes. If sparrows are very numerous, tie some cotton round the sticks. Place a good label to each, and leave the border in a tidy condition by lightly forking it over.

In dry weather a thorough mulching of long stable litter should be placed over the border. This will prevent the soil from cracking, and will keep the roots cool and moist. Give copious supplies of water, and if extra good blooms are wanted a little soot in liquid form will prove beneficial. Keep the growths tied up to the sticks if any require it, and on no account allow any seed-pods to form or a short flowering season will be the result. If any blooms are wanted for exhibition pick off all those expanded about a week before the event, and if the sun should prove very hot the blooms must be protected in some way, light tiffany being as good as anything for this.

STAGING.

When arranging the flowers either for exhibition or for home decoration these, in my opinion, always look best when staged loosely and in as natural a

way as possible. Use a small quantity of the young growth or foliage, which is far more pleasing than any other. When two or more varieties are used in the same vase a careful blending of the colours should be studied, and when arranging a collection for exhibition endeavour to show the colours as distinct as possible, and arrange them so that they harmonise effectively and pleasingly.

VARIETIES.

In giving a selection of the best varieties only the most distinct are named, as there are a great number which differ but little except in name. I give them in their respective colours.

White.—Undoubtedly the best white is the new Dorothy Eckford. It has a thoroughly good constitution, flowers of great substance, immense size, and the majority of spikes carry four flowers. The next best white is Sadie Burpee.

Crimson.—George Gordon and Salopian.

Lavender.—Lady Grisel Hamilton and Lady Nina Balfour.

Pink.—Countess of Lathom and Hon. F. Bouverie.

Orange.—Miss Willmott, Triumph and Gorgeous.

Magenta.—Captivation.

Maroon and dark colours.—Duke of Westminster, Othello, and Dorothy Tennant.

Primrose.—The Hon. Mrs. E. Keayon and Queen Victoria.

Rose.—Prince Edward of York, Prince of Wales, and Lord Rosebery.

Striped.—America and Princess of Wales.

Cream, tinged pink.—Gracie Greenwood and Venus.

Bright pink.—Countess Spencer. This variety is not yet in commerce owing to the bad season last year for seed saving. It is a very large flower, distinct in colour, and the spike is well formed. This should be made a note of to obtain when offered, in all probability next year.

Blues.—Countess Cadogan, Navy Blue, and Emily Eckford.

Lilac.—Colonist and Lady Skelmersdale.

A GROWER.

EARLY SWEET PEAS.

The Sweet Pea, which has been so much improved during late years, is grown for its beauty and usefulness. As in the case of other things, it is thought more of when a good supply of early bloom is obtainable. Methods innumerable have been employed to secure

an early supply, and out of these many have failed. Autumn sowing in favoured localities and sheltered spots may be the means of securing blooms early in May. In North Wales, for example, I have seen them do exceedingly well when sown in November on a warm south border; but in the cold Midland counties the sowing of Sweet Peas before Christmas would be attended with disastrous results should the weather be very cold. In order to minimise the risk of failure there is a decidedly better principle, thoroughly modern, and one which, if carefully carried out, will guarantee a supply of cut bloom early in the season, and of good quality.

The following is a *résumé* of the methods employed: At the end of February or early in March secure some small boxes, say, about 18 inches long by 6 inches deep and wide, possibly with rather thin bottoms. Place some rough leaves in them as drainage, and then fill up with good loamy soil; water, and allow them to drain. When this has been accomplished sow the seeds about 1½ inches apart, covering with about 1 inch of soil. The sowing completed, place the boxes in a frame where the average temperature does not exceed 56°. Here they will soon germinate, and great care must be exercised to prevent the young seedlings becoming drawn.

To prevent this place them as soon as possible in open frames, where they can be protected at night and in cold weather. As soon as the seedlings are 4 inches or 5 inches high they are ready for planting out. Dig trenches to correspond with the size of the boxes, placing some well-decayed manure at the bottom, and after knocking out the bottoms of the boxes place the plants in the trenches and fill up with soil. Place a few light twigs to support the young plants, increasing them as the seedlings grow. As the sun gains in strength liberal waterings should be given, occasionally supplemented with weak liquid manure, the result of which will be an abundance of fine flowers.

J. DENMAN.

The Laurels, Cains Cross, Stroud, Gloucestershire.

EVERLASTING PEAS.

ALL the Everlasting Peas are useful, but the pure white variety is especially so for supplying cut flowers during the hottest summer months. Everlasting Peas may be easily increased in spring by taking off the young growths as soon as they

JARFUL OF WHITE EVERLASTING PEA.

have pushed about 6 inches through the soil. Take a sharp knife and run down so as to sever them about 2 inches below the ground level. Insert these cuttings round the edges of pots or pans and treat like any other soft-wooded cuttings at that time of the year. A very large percentage of them will soon root, and may be potted singly and hardened off before planting out.

DIVIDING AND TRANSPLANTING HARDY PLANTS.

No small part of the charm of this increasingly popular class of plants consists in their healthy and robust growth under good conditions, these conditions including as absolute essentials a sufficiency of plant food and moisture and an ample root run, the latter being the main factor in obtaining the former. No one but the most ignorant of jobbing gardeners uses a spade among herbaceous perennials, whether in beds or borders, the consequence being that the ground necessarily becomes very hard, especially in dry weather, and also very deficient in plant food. Moreover, as the only plant food that can be given has to be applied to the surface, the roots are attracted there, and are apt to suffer in dry weather, no matter how much the ground is mulched. It is a most common thing in dry weather to see Phloxes, Michaelmas Daisies, Lychnis, perennial Sunflowers, and many other things with their leaves hanging round their stems as if they had been scalded. Such plants present a pitiable spectacle, and can never produce fine flowers. If a plant in this condition was taken up it would be found that the ground underneath and all around was quite dry, while the soil directly under the plant was as hard as a millstone, the wonder being, not that the plants were doing badly, but that they managed to live at all. The plants themselves would be found to consist, not of a few stout well-developed stems, but of a multitude of weakly stems crowded together, each one only just strong enough to produce a few blossoms. This is the result of leaving the plants to take care of themselves. People sometimes say they like to have things in the garden that "come up year after year" and need no attention. Some plants will fulfil these conditions for a good many years, but it is doubtful if there are any which succeed by this method indefinitely. The object of this article is to mention a few things, and the ways of doing these few things, which are really necessary if even the hardest plants are to do their best, and unless they do their best they are, to any true lover of flowers, unsatisfactory.

The heading of this article—Transplanting and Dividing—is not mere tautology, for the two operations are not the same.

TRANSPLANTING

does not necessarily imply dividing any more than dividing necessarily implies complete transplanting, for many people have a lazy way, when a clump is getting rather big, to shear off pieces of the outside with a spade, leaving the central woody part of the clump unmoved, a practice which is much to be condemned, not because good young plants are not obtained in this way, but because the old part of the clump remaining after such an operation is almost worthless, and should not be allowed to cumber the ground. Funkias, Kniphofias, Geums, Heucheras, Phloxes, Sunflowers, Crane's-bills, and others are often treated in this way. When a plant has been growing on the same spot for, say, half a dozen years, it has almost exhausted its special plant food in that particular patch of soil, and, if it cannot be moved into a different position altogether, the earth should be dug up deeply, some of it taken away, and its place filled up with some good new soil and rotten manure. Then, not only will the plant have a fresh supply of food, but it will have such an increased and renewed root run, both below and all around it, that it will be able to withstand the driest summer unharmed with a little help in the way of mulching.

When replanting it is better, instead of relying upon one large clump to make a display, to put

three small ones in a triangle 1 foot or more apart, according to the nature of the particular plant treated, when, though the effect may be thin the first season, there will be a fine display the following seasons. The best time to do this for most plants which make hard woody clumps is in late October, when the young plants will get so well rooted before the winter that no watering is necessary when growth takes place in the spring, however dry it may set in. But there are many things which also do well if moved and divided in damp weather any time in May, if not put into a dry or hot situation. The summer of 1902 will be remembered as a very damp one, and thus perhaps it is scarcely fair to quote results in that year as a fair index of what may be done in this direction, but I will give my experience. At the end of May of that year I severed from a clump of *Helianthus multiflorus maximus*—a tall, single perennial Sunflower—two or three small-rooted pieces, each with two or three shoots 6 inches or 8 inches high, put them into good ground and watered them, keeping a flower-pot over them by day for a few days until they began to get hold of the soil. Each of these little pieces made a clump 6 feet to 8 feet high during the summer, and though they were later than the others coming into bloom by a full month, yet they remained in bloom till October, and made the handsomest clumps of that particular Sunflower in the garden, being quite 2 feet higher than the clumps from which they had been taken, and the flowers much finer. The same method may be successfully adopted with Phloxes, perennial Asters, border Chrysanthemums, *Achillea Ptarmica*, and others. With early summer or spring-flowering things the operation must be done at the time most suitable to the particular sort dealt with, some moving well during flowering time, some just before, and some not till a good time after. Discretion is necessary, as it would be simply ruin to *Pæonies*, *Delphiniums*, and *Irises*, not to mention others, to move them in the spring, as old-established plants usually take a year to recover from a careful autumn moving. Many spring things, however, never move better than just before coming into bloom, some even when in full bloom. Daisies, for instance, may be pulled all to pieces when just coming into bloom and the after display be but little affected, while each piece will make a fine large plant the following season. Daisies need moving every other year. With Primroses it is pretty much the same, though many prefer to divide them up as soon as they have finished blooming and cutting the plants through with a sharp knife, inserting each rooted piece in a prepared bed in a shady place and keeping moist for a few days.

From the above instances it will be seen that some knowledge is necessary for the amateur who takes in hand the transplanting of old-established things in a garden, or he may not only lessen very considerably the floral display, but may even lose some of the things altogether. As a general principle it may be laid down, though there is no rule which will apply to all plants, that the best time for taking up and dividing is late October, and the next best the spring, the winter being an unsatisfactory season, as the plants do not re-establish themselves in the cold wet ground, and their roots may fall a prey to worms and other underground creatures, and their shoots to slugs in the meantime.

PLANTS THAT ARE BEST LEFT ALONE.

Though we are dealing with the removal and division of plants it should be stated that there are some things which it is best to leave alone for a good many years at a time. Japanese Anemones, Sea Lavenders, and Sea Hollies are cases in point. They are deep rooters, and it is not easy to take them up without considerable damage to their roots. Hence they should be well planted in the first instance with a good depth of soil underneath them, and then left to themselves till they show signs of weakness. The Hepaticas, a very different class of plants, seldom seen in modern gardens, though they will stand removal, do not take at all kindly to being divided, and when they are doing

well it is a good plan to leave them alone. As with Lilies of the Valley, they should only be disturbed when the flower supply is diminishing through overcrowding of the crowns. Hellebores, which include both the Christmas and Lenten Roses, are best left alone as much as possible. If increase of stock is wanted, or the plants are becoming too dense, they may be taken up about midsummer, and carefully divided with a sharp knife, but there will probably be no bloom for two years. *Pæonies*, referred to above, are also difficult to move, and at whatever time it is done, if they have become large congested clumps, it means the loss of bloom the following season. If done in September, taking them up very deeply and separating the tubers very carefully while the leaves are still not quite dead, they may get so far re-established by the winter that some will bloom the next season. As their next season's shoots are well developed by July they need to be moved correspondingly early. White Lilies (*Lilium candidum*) are somewhat unique in their manner of growth, nearly all the foliage dying off before, or soon after, the flowers open, while bunches of leaves, which are really the basal leaves of the next year's stems, appear above the ground towards the end of August. If these Lilies are taken up in the spring they are certain to fail that year, and even if taken up in October the heads of bloom will at best be but small. The best time to transplant—and they will pay for a change of soil every three or four years—is soon after they have bloomed, when they will show but little ill-effects from it the following season.

Dicentra spectabilis is another rather peculiar plant in this respect. It is almost impossible to take it up without breaking some of its large roots, as they go very deep down and are very brittle. The first year after it is moved it does little, but gets better year by year if in a suitable soil, growing as much as 4 feet or 5 feet high if the soil is damp and rich. About the fourth year it begins to decline, and gets smaller each succeeding year. It should be taken up directly the decline begins, the best time being about August or September, as its next year's buds are well developed by that time.

Auriculas, too, need special mention. In light, sandy soils not too dry and hot they will go on for years without disturbance, whilst in others they need moving at least every other year. As a general rule, when getting crowded or lanky they should be taken up and divided in the spring before flowering or early in the autumn. If earthed up a month or two before they emit rootlets from the bare stems, which help growth after the plants are cut up. Columbinas and Everlasting Peas are two things which should never be moved, and as a contrast to these may be mentioned the giant *Marguerite* (*Chrysanthemum uliginosum*) and some of the spreading Sunflowers, which it is well to take up and reduce to proper limits every autumn. The

METHODS OF DIVIDING PLANTS

are as diverse as their habits of growth. Daisies may be pulled all to pieces, each little piece making a plant. Primroses, Polyanthuses, and Pansies need to be cut up into rooted pieces with a sharp knife, the cutting up of the two first being one of the sweetest smelling operations in gardening. Some things that grow with a tap-root cannot generally be divided at all, but advantage may be taken of side shoots arising from the crown or below it which will develop roots. Many things which grow in solid clumps, like Phloxes, many species of Sunflower, some of the taller Veronicas, Michaelmas Daisies, Crane's-bills, and others need the help of a cold chisel to divide them, as the rough-and-ready method of the spade breaks off shoots and knocks the earth from the roots. A cold chisel is a wedge-shaped piece of iron 8 inches or 9 inches long and an inch or more broad, with a sharp edge at one end and a flat surface at the other for striking with a hammer. Most woody clumps can be separated in this way. As a rule it is best to take off all the younger growths, that is, the outside part, as these are usually furnished with the best fibrous roots. The woody

and congested middle portion should be rejected unless stock is very limited. It is often a help if a month or two before it is intended to divide a plant earth is put round the stems or crowns, for by this means pieces may be obtained with roots which would otherwise possess none.

ALGER PETTS.

SWEET VIOLETS.

FEW flowers are more universally loved than Violets; they bloom at the dullest time of the year under glass, or, in the south, may be picked out of doors from October up to the time when the spring flowers come to cheer us with their fresh beauty. The little old-fashioned Russian Violet nothing can surpass as far as sweet scent

enjoy. In April rake it over evenly and plant firmly, letting the ground be moist, though not wet. Choose strong, healthy single crowns, and put them about a foot apart for all large varieties. During summer it is not generally thought that there is much to do except to keep the plants free from weeds and all the runners cut off, but they must have a good mulching now and then, and if the weather is dry give a thorough watering and syringe hard to keep down red spider, for on their growth now depends the future blooms for winter. If frames are to be used for planting they must be prepared in September. See that the drainage is good, and then fill the remainder with good loam, not too rich in case it becomes sour, the plants having stored their food for the winter while they were making such fine growth in the summer. It may interest some and also

help in the growing if the idea is once grasped that Violets, like many other plants, absorb and assimilate a great quantity of food, far more than they need at the time. Let the frames then be made up, the soil being as near the glass as possible, 6 inches or 9 inches, according to the varieties, and then lift the plants with a good ball of earth and plant so that the leaves of one plant do not quite touch those of another. Give plenty of air and keep them hardy, guarding against frost and rain.

If air is given they will not get mildew, which otherwise sometimes happens. Syringe in the autumn to keep the leaves clean and free from red spider, though this is less likely to attack the plants if they have been well cultivated. Pick off all dead leaves. For outdoor culture the single varieties are best, and the beds should be remade every two years on fresh ground.

For varieties I cannot do better than recommend the best of those I have seen growing in a Devonshire nursery. Last year I was there, and in one house (the entire length) was a bed some 5 feet or 6 feet wide, upon a stand about 3 feet or so from the ground, of

La France, a perfect sheet of purple, with just the groundwork of green. Then there are other single ones, viz., Kaiser Wilhelm II., much like La France, only a little lighter and with a very long stalk; Admiral Avellan, a rich rose; Sulphurea, a dainty apricot, pretty, but rather curious; but the daintiest, almost a fairy-like little thing, is the Princesse de Sumont, white, with a sort of Picotee edge of clear blue and sweet scented. These are the chief single ones, with one or two newer, such as Mnie. le Pages (a pink variety) and Perle Rose (rich rose colour). In the double ones Parma Perfection is a good one for early bloom, giving large flowers. Lady Hume Campbell with us is deep lavender and is always admired. A very lovely double white, one of the best, is Comte de Brazza, which does very well for pots or in frames. Mrs. J. J. Astor is a very sweet and beautiful rosy heliotrope, quite distinct in colour. There is no need to mention the old

favourites Marie Louise and Neapolitan; they were the first, and one will always have an affection for them.

M. MITCHELL.

School of Horticulture, Torquay.

A CHAT ABOUT ANNUAL FLOWERS.

WHEN the hardy perennial came forward, and gardening began to be a preoccupation with many people who had previously been unable to find their places in horticulture, nearly all annuals shared to some extent in the *début* which overtook the Alternantheras, the Iresines, the cropped Beets and plucked Lobelias, and the Cabbage-headed Echeverias of the unlightened early and middle Victorians. Penny packets were the base uses to which most of them were consigned. Children's gardens were good enough for them, and juvenile culture, or its parallel in simplicity—which is a roundabout way of saying cruel neglect—was generally all that they received. A very few, Nemophila, Virginian Stock, scarlet Linum, and Mignonette being perhaps the most usual, with the unconquerable Nasturtium, most self-assertive of all plants, enjoyed a sort of contemptuous toleration only a shade less galling than oblivion, and were scratched into the front of shrubby borders, in patches whose duration, what with thick sowing, starvation, and drought, was sufficiently fugacious to justify the curt epitaph "Untidy things!" with which they were generally dismissed.

But within the last few years, the fever of reaction being past, we have been finding out what virtue, after all, lies in a race no more to be despised than any other, and even in certain cases to be preferred.

What flower-picture, for example, could be found more exquisite in its way—and that way not an insignificant one—than such a group of crimson, rose-red, shell-pink, and snow-white Lavateras as one may see in the rich loam of a West country garden? Were this plant—*Lavatera trimestris* (the Tree Mallow), a thing to be bought in any seed shop for two or three pennies the packet—a novelty or an expensive rarity, its beauty would be not a whit the more, but those who will not trouble about it now would be the loudest in its praise.

It is true that, like all annuals, and, indeed, all plants of any kind, Mallows are poor things if they are neglected. But none would blame Hollyhocks for failing in dry soil and without support, and the Mallows, to do their best, need exactly the same conditions as suit the stately Althea. They are massive in growth, and when the rich leaves clothe the plants, as they should, well down to the ground, while the flowering, with blossoms of the size and shape of the large white hedge Convolvulus, is profuse and continued over a very long period, it will be readily seen that they need liberal treatment, and will repay it nobly. *Lavatera arborea variegata*, with large leaves marked and splashed with white, is well worth growing as a foliage plant, and is suited to background work and sub-tropical bedding. Strains of these plants vary, and the best I have ever seen were in a cottage garden, where the soil was that fat loam of much cultivation, over yellow clay, that in these tiny plots sometimes produces an almost tropical luxuriance of bloom on common plants.

It would be impossible to imagine anything easier to grow than dwarf Marigolds—unless it were the despised Nasturtium, refuge of the idle that know not the spade—and where a poor strain exists and is allowed to have its own way we may frankly own it detestable, raw in colour, pushing in habit and manners,

VIOLET LA FRANCE. (The flowers are over an inch in width.)

goes; not one of the fine monster blooms that tower about this tiny friend.

The variety La France, one of the largest single varieties, is a handsome room plant and deliciously scented. The flowers are as much as 1½ inches across sometimes. This is one of the best for frame culture; it blooms freely and holds its head well above the foliage. The best position for growing Violets in is what we must next consider if we wish to have the full pleasure out of these favourites. Out of doors partial shade is the best, not under trees; a border facing north is better than a south aspect, because if fully exposed to the sun they are apt to be troubled with red spider, which is one of their worst enemies. In winter prepare the ground by trenching deeply and digging in good manure, leaving it in the rough until about March, when a further dressing may be given by forking in short manure from a hot-bed, so that the plants may have a rich soil to

and evil as to odour. But the tall orange and lemon African Marigolds are without this latter drawback, and are beautiful in colour, with a certain prim stateliness of growth that makes them valuable: also, they require good soil and good care, and do credit to the grower who can show them at their finest. The dwarfs might be replaced by certain annual Chrysanthemums that are among some of the most charming of hardy flowers lately introduced—Golden Queen and Morning Star. The latter has been for a season or two past a good deal grown in pots for sale by florists, and even in these stiff receptacles and the unbecoming surroundings of a shop the pretty sulphur-yellow Daisy-shaped flowers, which have plenty of substance and stand out well over the neat Fern-like foliage, were very attractive. Morning Star is quite dwarf, but Golden Queen, which is much deeper in colour, is taller, and cannot conceivably be accused, as the daintier flower might be, of being "squatty."

For sweet smell it would be hard to find a flower, unless it were that compendium of spicy delights the insignificant *Dianthus superbus*, that could beat the old Sweet Sultan. There is something not quite pleasing about the colour of the ordinary white form, though the yellow is very good indeed in this respect, while the pink is frankly magentish, and therefore the giant white *Centaura Margarita*, which is perfectly pure white, and has all the delicious quality of the older forms in scent, is most welcome. Here we have a flower that with ordinary care and a little lime will grow anywhere, and it is easily doyen of all summer annuals for cutting—though that is a purpose which should never come first with a true flower lover—since it lasts miraculously in water, keeping its fragrance to the end. The Blue Butterfly *Delphinium* (Carter's) and pretty Annual Rose have both been praised in THE GARDEN pages, and therefore need no more recommending. The latter, however, if it is like other so-called annual Roses, will become on invitation a perennial, and make a dainty little bush akin to the "pet" type—*Mignonette* and *Paquerette*. Some of the newer Candytufts, in crimson and carmine tones, are good, and with the delicate blue *Nigella* (Love-in-a-mist) that will never grow too old-fashioned for the eye that rejoices in its exquisite pure turquoise blue, rarest of all flower colours, and the jewel variety of a good strain of *Phlox Drummondii* are worthy of places in all gardens. It is the fashion nowadays to dislike anything approaching to mixture in colours, and as these latter flowers, as also the *Verbenas*, that always seem associated with them and perhaps also with *Petunias*, are uninteresting to most people when massed in one shade, and are also scarcely classed as annuals, though their duration is only of a season, they need not be discussed.

The *Nasturtium* family nearly always manage to disappoint the grower in one way or another. Either they go all to leaf or they straggle, anything but produce the masses of bloom in compact heads over the leafage that catalogues offer us. But if they can be kept dwarf and even, and here strain is everything, a bed of straw, primrose, and orange shades, leading up to vermillion, is exquisite. The dark-leaved *Tropeolum lobbianum* may be grown as a creeper over low shrubs to very good effect, but needs raising in heat, or winter will take it unawares before its time to go.

With the Sunflowers this brief review of a vast army, many of whose best must perforce be left unnoticed, must end. The new dwarf miniature bush Sunflowers, many branched,

and growing from 3 feet to 4 feet high, are most valuable, and ask for no special culture. *Helianthus cucumerifolius Stella*, in primrose colour with a dark brown disc, is very charming; so, too, is the taller *Primrose Perfection*, while the tiny *Perkeo* is a very distinct novelty, said to be only 12 inches or 18 inches high, and those who like double forms—which in the Composites are apt to be lumpy—should try another novelty in *Cactus* or *Sun's Eye*, a flower of good form and colour. M. L. W.

THE ROSE GARDEN.

ROSE PLANTING IN MARCH.

ANY other time than November the planting of Roses to some is little short of utter folly. I do not go so far as to recommend March as a more suitable time than November, for all authorities on Rose culture agree that there can be no better month wherein to plant; but I do believe that cold, heavy, badly-drained soils are not in a fit state to receive the plants before the spring unless the ground is well prepared beforehand by trenching or ridging. Rather than plant when the ground is wet and sticky, the plants would be better heeled in under some north wall or hedge until March, when wind and frost will have played their parts in sweetening and aerating the soil. Its condition should be somewhat similar to that which all good gardeners wish for when potting, namely, neither too dry nor too wet. It may be urged that one can give the plants even in November some fresh soil at planting time, and doubtless this is so, but on a large scale this would be somewhat impracticable, so that my advice is avoid planting Roses late in the year if the land is unfit, but rather wait and seize the first favourable opportunity in February or March.

Where many fail in spring planting is in the omission to trench or ridge the ground beforehand. Bastard trenching is best for most soils. By incorporating the manure with the forked-up subsoil, the roots of the plants are encouraged to strike down deeply, which enables them to withstand a season of drought much better than they would do if only the top spit were moved as in ordinary digging. I have seen the greatest success attending spring planting of Roses. Why should not they succeed equally as well as seedling or cutting Briars and Manetti stocks, which are rarely planted before February or March, and invariably make fine plants by the autumn? I would always recommend that Rose plants be rather severely pruned first, save those of a climbing nature. Obviously the roots have less work to perform in supplying these fewer eyes with nourishment than they do when the growths remain for a considerable time unpruned.

It is often asked how late may one plant Roses. I may say, providing the plants are dormant, they may be planted as late as the first and second week in April.

I do not say wait until this time before plants are secured. Preferably I would purchase in autumn, and heel my Roses in until an opportunity occurred to plant, but I should take the precaution to move them now and then in order to keep them as dormant as possible. March is an excellent month wherein to plant own-root Roses, especially those that are pot-grown and have been hardened off in cold pits. The plants are naturally much smaller than budded ones, but providing they are hard and well ripened they make rapid progress as soon as the influence of the sun is felt upon the soil. Anyone with a very light gritty soil would do well to try some own-root Roses; their fine roots seem peculiarly adapted to soil of this description. In all cases where Roses are planted now the roots should be moistened previously to putting them in the soil. Dipping in thin mud is very good for plants from the open, and pot-grown Roses should be previously immersed in a bucket

of water for a few minutes. All plants must be artificially watered once or twice after planting, unless heavy rains arrive. I prefer to defer watering until April, unless the plants show signs of needing it before this time, but when water is given let it be applied copiously, and the soil hoed a day afterwards. I think we are wrong in not planting in the month of September—especially in respect to Roses. Last year in the first week of the month just named we transplanted some old half-standard Tea Roses. These plants had not been moved since they were budded some four or five years before. When transferred to another part of the garden in September they were in full growth and covered with bloom, but I think all have survived and apparently are little the worse, if any, for being transplanted at such an unusual season.

We were careful to cut back the growths pretty severely, and all flowers and tender foliage were removed, and of course we did not allow the plants to remain exposed to the air and sun, but replanted immediately they were lifted. One has always some compensation for late planting, and that is one obtains flowers just when the established plants are waning. This is no small advantage where large demands are made for cut blooms. We have had splendid blooms in August from bushes planted as late as the second week in April; in fact, these late-planted Roses will often escape the spring frosts, which play sad havoc among established plants. PHILMEL.

THE FRUIT GARDEN.

MARCH APPLES.

VERY many kinds require more care than others at this season; indeed, it would be much better if some of the earlier Apples had separate storage from the later ones, the last-named being gathered later and with more care. There is ample room for new varieties of both dessert and cooking kinds if they are late and of good quality. I find those that keep best have a firm skin, as if at all soft they soon bruise and travel badly. If we take the imported Apples as a test as regards quality, it will be observed that the best of them are very firm and have a thick or hard skin. The well-known *Blenheim Orange* gets very soft early in the new year. What a gain this would be to growers if it could be had as good in March as in October. Of late years we have had some excellent new varieties added to the list, but not many late kinds. Two certainly stand out prominently, viz., *Newton Wonder* and *Royal Late Cooking*, and these will when better known be largely grown. In the dessert section the new *Charles Ross* promises well, but it is not later than *Cox's Orange*; at least such was my impression when exhibited a season ago.

DESSERT APPLES.

A few varieties that are new or little known do excellently in well-drained soils, and these are worth noting. Most of them are either of continental or American origin, and it would in this case be advisable to grow them at first on a small scale. If they succeed they are certainly a valuable addition to the fruits in season.

Buckingham.—This is an American variety, and I have seen good results in some soils. It is a fine fruit, handsome, of beautiful shape, and excellent quality. It is not to be recommended for heavy clay soil or late districts, but it is worth culture for its size and appearance; the fruits keep sound till April.

Wagner.—This is a Canadian Apple of considerable merit, and is in season from March to May; it has a peculiar Quince-like flavour which many like. The fruits, in addition, are remarkably showy, being of a bright scarlet colour, and it is an excellent bearer. This is one of the best I have grown of the American varieties. With careful storage it may be kept till June.

Reinette du Canada.—This is a better-known dessert variety than those named above, and,

though not so prolific in all gardens as one may wish, it is one of our best March dessert Apples, as the quality is first-rate. It does well in warm or well-drained soils. To obtain fine fruits it does best when grown on what may be termed a dwarf standard, not hard pruned, as it is a vigorous grower, gathered late, and given cool storage.

Prince Edward.—This is a new Apple introduced by the well-known fruit growers Messrs. Rivers of Sawbridgeworth, and is in season from December to March. It is a remarkably pretty dessert fruit, bright red on the side next to the sun, and with russet markings. The flavour is brisk, and the flesh good and juicy. It is well worth growing as a cordon or bush fruit.

St. Martin's.—This is another new introduction of Messrs. Rivers, and a larger fruit, conical in shape, dull red in colour, covered with a greyish bloom. The flavour is very rich, and if it crops well it will be a valuable addition to the fruits now in season.

White Nonpareil.—A fruit of medium size, but one of the most delicious of the dessert varieties at this season. It is larger than the old Nonpareil, handsome, richly flavoured, and a good bearer, the trees making a close growth and doing well in a sheltered spot.

Lord Burghley.—This is not nearly as well known as its merits deserve. It is a medium pretty dessert fruit, at its best in March, and when grown on dwarf trees is a profitable garden variety. A yellow fruit, with bright crimson cheek, tender flesh, very juicy, and of excellent flavour.

Allen's Everlasting.—An old but good variety, of medium size, and keeps well; the flavour is good. A most valuable late sort, and can be grown in any form, as it usually does well.

Court Pendu Plat.—A very useful late dessert variety and a good bearer, as it blooms late, thus often escaping spring frosts. It does well as a standard, being a compact grower, and is equally valuable as a bush or pyramid in small gardens.

Claygate Pearmain.—A valuable dessert Apple, in season from Christmas to April, not large, but a good cropper, and in flavour something like a Ribston. It is very suitable for gardens of limited size, as the tree is a compact grower, though drooping. It does well as a small standard or as an espalier or bush on the Paradise stock.

Sturmer Pippin.—A valuable dessert Apple. It will keep sound till June. The fruit is of medium size, brisk flavour, and good when season is considered, being sweet, firm, and juicy. It does well as a standard, and should be grown in all gardens for late supplies. There are others, such as D'Arcy Spice, Brownlee's Russet, and Fearn's Pippin, worth including for late use.

COOKING APPLES.

These are quite as important, as the demand is even greater, and I find few crops give so good a return as the best cooking Apples. Fortunately we have of late years paid more attention to hardy fruits, so that some of the best kinds are more valuable if given good storage and the crop is carefully gathered.

Royal Late Cooking.—A most valuable cooking Apple that will keep for nine months, so that it is at its best at this season. A large, handsome fruit, of splendid cooking qualities, with a light yellow skin and pleasant flavour. A vigorous grower, doing well as a standard and as a bush on the Paradise stock.

Wellington (Dumelow's Seedling).—Doubtless where this variety succeeds it is one of the most profitable late Apples grown. It is scarcely necessary to describe it, the fruits being so well known. It makes an excellent standard, but is remarkably fertile on the Paradise. Grown thus the fruits colour well and are very handsome. I would recommend that it should have a well-drained soil.

Newton Wonder.—An Apple of recent introduction, and one that has become a standard variety in a short time. It is a large, handsome fruit, midway between the Wellington and Blenheim. It is very handsome, keeps well into the spring, is a free grower and good bearer, and

its cooking qualities are excellent. If not too severely pruned it soon attains a bearing stage. I have kept this variety well into May when not gathered till late and given cool storage.

Lane's Prince Albert.—Certainly one of the most valuable late cooking Apples. It is the best Apple we have, and never fails. As it blossoms late, it often escapes spring frosts. Its quality is excellent indeed. I place Prince Albert in the highest list among the late Apples for its keeping, cooking, and cropping. The tree does well in any form, grown as a bush or pyramid. On the Paradise stock it produces handsome fruit, and useful for the dessert at this late season. When grown as a standard it bears very freely, and grown thus, owing to its pendulous growths, it is out of the reach of cattle.

Bramley's Seedling.—A good cooking fruit, in season from December to April, and when well grown making a vigorous growth. Grown in bush form on the Paradise stock it does not like severe pruning, and it fruits more freely as the trees attain size. The flavour is briskly acid. The fruits are solid and keep well without much care. It makes a fertile standard.

Alfriston.—An old but good Apple, and a variety that does well near large towns. It is of close growth and prolific. We have both bush and standard trees of this variety, and the first-named give large fruits; the standard trees crop very freely. It is an excellent variety for light soils, and the quality of the fruit, which is in season from December to April, is first-rate.

Norfolk Beautifin.—Though not such a good grower in some soils as most of those noted above, it is valuable for its good keeping properties. It is a large fruit, of dull red colour, hard, and of brisk flavour; a free grower in good soil, but not suitable in wet or poor land. The tree grows freely in a young state and crops well; in season from March to June.

Sandringham.—This is a very good Apple, in season from Christmas until April, and at this later date is a good dessert variety. It is a free grower. Here in bush form on the Paradise stock it is one of our best croppers and the quality is excellent. This is one of the varieties that has found favour of late years, and it is a decided acquisition.

Hambling's Seedling.—This also is an Apple of recent introduction that will become a standard variety. The fruit is very large and handsome, dull green, firm flesh, of brisk flavour, and a splendid cooking variety. It is a robust grower, crops freely, and is in season from December to April. It gives very fine fruit on the Paradise stock.

Northern Greening.—A valuable old variety and one of the best when grown in standard form for use from December to May. It is a medium-

sized fruit and a great cropper. A strong grower, and the fruit is of excellent quality when cooked; it is reliable as regards crop and quality.

Royal Russet.—Valuable for its lateness, but not always a great cropper. The fruit cooks well and is a great favourite where it succeeds.

Syon.

G. WYTHES.

CONVOLVULUSES.

For forming a pillar of lustrous green, frequently touched with bud and blossom of large size and snowy purity, some of the more common species of Convolvulus or Bindweed are without rival. It is true that some of the perennial sorts are troublesome weeds, but they are beautiful weeds if rightly placed. Among such plants some of the Convolvuluses occupy a front place as pillar plants, and for rambling over porch, trellis, or balcony. More beautiful still are they when in woodland or copse, or shrubby border, they overtop their host and produce an effect which in these unkempt surroundings is delightful in the extreme. In saying this I recall a fine Holly hedge, the boundary fence of a wayside garden, that for a long time each year is bespattered with pure white blossoms of perhaps $3\frac{1}{2}$ inches across. Such occasional instances of how Nature clothes her bowers should not be lost sight of; indeed, it is just here that the

LARGE WHITE CONVULVULUS ON PILLAR.

plant may be tolerated and provide its wealth of blossom. In all probability the bits of roots were planted with the Hollies, and while the latter have developed to large size the climber has not asserted itself in any alarming degree. One of the best for this purpose is the greater Bindweed (*C. sepium*), with large arrow-shaped leaves and square flower-stalks, producing white or slightly tinted rose flowers of large size. It is a British hedgerow plant. It is possible this kind is surpassed by *C. sylvaticus*, which has very large white flowers, but whether this is in cultivation is doubtful. In any of the foregoing positions or in those places where the root area is restricted this is a fine plant. Of coloured kinds, *C. althæoides*, with rosy purple blossoms, is very pretty, and to this may be added *C. tenuissimus*, with blossoms of a full deep pink shade. All these are perennial and of climbing habit. Then there is that useful plant known as *Convolvulus major* (*Ipomœa purpurea*), one of the most popular of hardy annuals, that with its variety *I. p. incarnata* should be grown by all who require quick-growing free-flowering climbers. E. J.

THE FLOWER GARDEN.

ANNUALS NOT MUCH GROWN.

IT has always been surprising to me to find that annuals are not more widely used in the flower garden, and in speaking of annuals I do not refer to Sweet Peas, Stocks, Asters, &c., which everyone who has a garden grows to some extent, but such things as *Linaria reticulata aurea*, *Bartonia aurea*, and *Brachycome iberidifolia* for example; they are easily obtained, inexpensive, and easily grown, and yet are very seldom seen. One reason for their neglect may be traced indirectly to their cheapness; a liberal supply of seed of most of them can be had for 3d. or less. The would-be grower obtains a packet, and directions thereon tell him to sow the seed in March or April, which he does, often in one or two patches about 1 foot in diameter. The seed comes up thickly—almost every seed has grown—with the result that about one hundred plants occupy the space which is sufficient only for one. One hundred flowers are obtained on one hundred plants, instead of one hundred flowers on one plant; the natural effect of the plant is lost entirely because it has no chance to develop, and the

whole bunch soon dries up and is dead. This is no imaginary statement. I have seen it in numbers of gardens, and I am not surprised that persons interested get tired of annuals under such conditions.

To grow them successfully good liberal treatment is necessary; they ought not to be sown on shrubby borders, because the ground if bare above is full of roots below, and in dry weather, when annuals want the most support, they get next to nothing, because the shrubs have first choice. For such positions herbaceous plants or ordinary bedding plants will give better results if a judicious selection is made. In large gardens it may sometimes be possible to devote a separate portion to annuals; in others a few kinds may be grown in a small bed or border by themselves, and those who have herbaceous borders may add to their beauty and interest by interspersing good-sized groups of some of the best annuals where other plants have failed or in spaces left for the purpose. Some partially decayed manure from old hot-beds or farmyard manure, for instance, should be dug in about two months before sowing. When the seed is sown it is necessary to have an idea of the ultimate size of the plant under good cultivation, and to remember that most of the seeds sown will grow. Overcrowding means starvation and failure, thinning is tedious and apt to be neglected, and transplanting cannot be successfully carried out in the majority of cases, therefore thin sowing is absolutely essential to success.

The following will be found both ornamental and distinct, and may be sown in the open ground early in April for the Midland Counties. For warmer parts of the kingdom the middle of March is more suitable. *Anagallis* (various colours), *Bartonia aurea*, *Brachycome iberidifolia*, *Coreopsis atrosanguinea*, *C. Drummondii*, *C. nigra speciosa*, *Centaurea Cyanus minor*, *Clarkia elegans rosea fl.-pl.*, *C. marginata*

fl.-pl., *Cosmos bipinnatus*, *Delphinium grandiflorum*, *Dianthus Heddeggii*, *Didiscus cœruleus*, *Godetia* (various colours), *Gypsophila rosea*, *Hunnemannia fumariæfolia*, *Lathyrus sativus*, *Lavatera trimestris*, *Linum grandiflorum*, *Linaria reticulata aurea*, *Lupinus hybridus atrococcineus*, *L. mutabilis Cruickshankii*, *Malope grandiflora*, *Phacelia campanularia*, *Sanvitalia procumbens*, *Shirley Poppy*, *Salpiglossis* (various colours), *Scabious* (various colours), *Stachys coccinea*, and *Viscaria oculata*.

This list might easily be made longer if more are required. Some of those mentioned will occasionally survive the winter and flower again the next season. They are not, therefore, true annuals, although for cultivation they are best treated in this manner.

A few choice and distinct things succeed best if sown in March in a gentle heat and transplanted to the open borders after being gradually hardened. Some of the best of these are *Ageratum* (dwarf blue), *Alonsoa Warscewiczii*, *Celosia* (various colours), *Diascia Barberæ*, *Gaura Lindheimeri*, *Gaillardia aristata*, *Helichrysum* (in variety), *Heliotrope*, *Nemesia strumosa*, and *Sweet Sultan* (various colours). Another class I would mention consists of those kinds which may be sown in September, and will flower early the following spring. *Shirley Poppies* are always the finest if treated in this way, and the same may be said of most of the following: **Bartonia aurea*, *Centaurea Cyanus minor*, *Clarkia pulchella marginata fl.-pl.*, *C. elegans rosea fl.-pl.*, *Collinsia bicolor*, *Erysimum perofskianum*, **Eschscholtzia californica*, *Leptosiphon hybridus*, *Limnanthes Douglasii*, **Malope grandiflora*, *Nemophila insignis*, *Saponaria calabrica*, and *Xeranthemum annuum*. Those marked * will not always survive the winter north of London. The foregoing lists may all be lengthened if desirable. I have endeavoured to give only the choicest in each section.—

Belvoir Castle
Gardens, Grant-
ham.

THE WHITE PINK.

HOWEVER many new forms of garden Pink may arise, it is not likely that there will ever be one that will put the old white Pink out of favour. First of its kind to come in the early summer, of sweetest fragrance, and with that simple charm that makes some of our garden flowers individually lovable, it will ever be one of the most welcome. It is also one of the best of plants for an edging, not only in summer bloom but in the depth of winter, when its neat bluish foliage appears to be at its best.

THE OLD WHITE PINK.

THE ROCK GARDEN.

ROCK GARDEN-MAKING.

VII.—LESSONS FROM NATURE IN ROCK BUILDING WITH STONES OF THE STRATIFIED KINDS.

IN the previous chapters on rock garden-making the illustrations dealt with the igneous rocks, and depicted not only natural rocks of that class, from which valuable hints from Nature's own work might be obtained, but also various rock gardens artificially constructed. I will now deal with rocks of a totally different kind, viz., the sedimentary or stratified rocks, and their treatment in the rock garden.

Sedimentary or stratified rocks were formed under water. In some cases they consist of the minute shells or skeletons of small organisms; in others they were formed by disintegrated previous rocks, sorted by the water into successive layers. Some of these layers might be fine as dust, while others are of a coarser nature, but as time went on became consolidated. But though ages have elapsed since their formation these distinct layers or strata are more or less plainly discernible in all sedimentary rocks, though not to the same extent. In sandstone, slates, chalk, &c., these lines are very distinct. In limestone, oolite, flint, and others they are more irregular and indistinct.

Now, among some rock builders a notion seems to prevail that just because originally all such rocks were formed in horizontal layers, the only proper way of imitating them in our gardens would be to place stone upon stone in horizontal, or at least parallel lines. I have even seen so-called rock works built up with small stones and cement or mortar, after which the whole structure was uniformly plastered over with coloured cement, into which (with a trowel) horizontal lines were scratched to represent "strata."

This method of rock building, in my opinion, is a thing to be avoided. It is monotonous in effect, unpractical to the highest degree, for none of the choicer kinds of alpine plants can grow in rocks so constructed, and finally it is extremely ugly. It may be said to be in imitation of Nature. Perhaps so. If we look at the natural rocks where perhaps a railway cutting was made through sedimentary rocks, we may, in certain districts, see miles of such parallel lines of strata, either horizontal or elevated to the same angle throughout. This is natural, it is true, but when we imitate Nature in our gardens why should we choose the ugliest works for our models? Let us rather select the choicest bits of scenery. The stratified rocks which we admire most in Nature are not those which show monotonous and even lines all at the same angle of inclination, but the wild and rugged scenes, where massive rocks—no matter how evenly or regularly their successive layers might have been disposed originally—have become disturbed by subterranean forces which shattered their once regular strata in the wildest profusion.

We admire the rocks which during violent convulsions or upheavals were cleft asunder, or which, when the water under which they were formed receded, toppled over each other in the greatest disorder. We admire rocks which by the

mysterious forces of Nature have been broken up, and which have been distributed into groups of varying shapes and sizes, sometimes massive or pierced by caves and ravines, sometimes scattered or vanishing altogether below the surface of the sward and reappearing further away amongst a mass of vegetation, either flowers or greenery.

Such are the stratified rocks with which Nature has provided her most charming pictures. Such should be our models. Our illustration, from Nature's own handiwork, is prepared from a photograph, which, by the courtesy of Mr. Ford, I was allowed to take in that gentleman's garden at Lynmouth (North Devon).

The magnificent rocks and charming picturesque scenery of Lynton and Lynmouth have a

groups of boulders of all shapes and sizes and of every conceivable angle of elevation.

But, in spite of this apparent chaos, it will be observed, even in the illustration, that each section shows distinctly its stratified character. Not only the massive rocks in the background, but also each group, and even each boulder, shows parallel layers. But though these strata in each individual group may be parallel, they are anything but parallel collectively. In one group they may be running from north to south, in another from east to west. In one they may be horizontal, in another at an angle of 45° and so on. Even the picture here illustrated shows that wherever a sudden change occurs in the direction of the strata, there it is distinctly seen that such rocks or boulders or groups of rocks have no connexion with each other, but were severed from the adjoining block.

It may be only a narrow fissure which intervenes, or it may be a broad gap, a cave, or a patch of greensward studded with plants, but, whatever the cause of the divergence in the strata may be, the separation will be plainly visible.

This, then, is the lesson Nature teaches, and this should be our keynote for arranging in a picturesque manner such rock gardens as are to be constructed with stones of the stratified kind. When we arrange our artificial rocks let us have no continuous masses, but let us break them up into groups of varying sizes, some large and bold, others small and scattered and gradually vanishing towards the outskirts. Let us introduce between the groups of stones places of varying sizes on which suitable plants can grow. Let the scene appear as if an earthquake had been at work among the regular strata of the rocks, cleaving and shattering them in all directions. By all means let us have stratification more or less distinct, according to the kind of sedimentary stone used, but though this stratification should be more or less parallel in each individual group, let us have no two adjoining groups at the same angle. Above all wherever an alteration in the angle of the strata is to occur let us give a reason for it by plainly showing a separation from the adjacent block.

It must not be thought that I am presumptuous enough to desire to lay down the law. This is Nature's own law, and a careful study of the natural rocks depicted in the illustration will prove my argument. If I had been able to photograph the rocks in question during the summer season the picture would also have shown the numerous flowers which adorn the scene, but having been taken at midwinter the rocks are comparatively bare. For this reason, however, their structure is more plainly seen.

In a later chapter I hope to illustrate in a practical manner the actual construction of rock gardens arranged on the principle referred to above.

Elmside, Exeter.

F. W. MEYER.

(To be continued.)

NATURAL STRATIFIED ROCKS IN THE GARDEN OF MR. FORD, LYNMOUTH.

world-wide reputation. But their wild grandeur generally is beyond anything which might be successfully introduced into a garden. The illustration, however, shows an exceptional case, viz., an absolutely natural rock garden within a private garden, whose owner is an enthusiastic admirer of mountain plants, and alpine plants in particular.

The picture shows plainly what a wild and rugged appearance Nature can impart even to rocks which were originally regularly stratified. The rocks consist of the rugged Devonian slaty grit known as "bastard shale." The rocks shown in the illustration were not rearranged by man, but were left untouched in all their wild glory as their owner found them, and a glance at the picture will show how terrific must have been the natural forces which had split the rocks into boulders and

Crop production in the United Kingdom.—The agricultural returns for 1902 give the following yields: Beans, 7,703,966 bushels; Peas, 5,105,608 bushels; Potatoes, 5,919,919 tons; and Turnips, 29,116,224 tons. There is a decrease in Potatoes, but a decided increase in the other crops mentioned.

DELPHINIUMS.

THERE is a characteristic boldness about the Larkspurs, as the Delphiniums are not infrequently called, quite apart from their predominant colour feature, that appeals at once to all lovers of hardy flowering plants, and in such a way that some at least of the many varieties find favour with a very large majority of those who direct their attention to effective border gardening. No group of hardy herbaceous plants flowering in the first half of the year attracts more attention than the Delphiniums when these are well grown. To be well grown, however, and quite representative, the plants must be fairly well established, because small crowns can but produce proportionately small spikes of bloom. This is always the case when plants supplied late in the season as these must of necessity be in pots. When orders for plants are received in good as well as seasonable time, and planted with due care, they quickly develop into flowering examples that display their worth in a very definite way.

TIME OF PLANTING OR TRANSPLANTING.

In those districts with a light soil and with a sand or gravel subsoil, thorough drainage is secured naturally, so a considerable license may be allowed, although even in such cases as these I am well assured upon one point—that no time in the year suits the plants so well for removal and replanting as the early spring. Where the soil is heavy I would interfere with the plants at no other period. Why? Because the roots of these plants are at rest in the winter season, and removal at such time of necessity throws the plant upon its own resources until new life appears with the longer and warmer days. Left alone in the ground the crowns maintain their fullest development. When taken in hand early in the year, when the freshly appearing shoots are some 3 inches or 4 inches long, we have every assurance that presently fresh young roots will also appear, and indeed so quickly do they appear that the growth comes away without more ado. Spring planting is, of course, of infinitely more importance when the breaking-up of the stools become necessary in greater or less degree. At such times, if the welfare and future progress is considered at all, spring planting is absolutely without equal. My remarks apply to plants grown in the open ground, which is infinitely the best means of securing strong vigorous growth and, naturally, finely developed crowns also. Such as these planted at the right moment and with a clear growing season ahead make up really grand specimens as the result of a single year's growth.

Very different is the case of the plants which have long been confined to pots. The latter can only be regarded as a prison for these stout, vigorous-growing perennials. Freshly established pot plants—that is, stock divided in March to be planted out in May or thereabouts—are open to very little objection, but plants that have remained a year or more are not only in a very weakly condition as compared with ground plants, but they are also the least likely to give satisfaction when liberated from the pots. The season wherein to plant them is ample, and it but remains for those who would do justice to so fine a group to take advantage of it. A word or two as to

SOIL AND ITS PREPARATION.

The Delphinium is a deep-rooting plant and a gross feeder, therefore a deeply trenched, heavily manured soil is best. The manure may with advantage be buried 12 inches or 15 inches deep at least. Sandy loam suits the Delphinium excellently, heavy clay soils being less well suited, and in such the plants are more subject to root canker. Heavy soils may be improved by the addition of burnt earth, ashes from the rubbish fire, and a good addition of leaf-soil or grit. Any of these or a combination of all will render material help to the plants. Such a mixture will render much assistance to the roots and give the plants a good start. If the plants are liberally dealt with in the original planting, it is possible for them to remain three years in the position, provided also there is room for development. At the end of such a term

a single good crown of a vigorous variety will produce as many as eighteen to twenty-four splendid spikes of bloom. Such a plant will require a space 3 feet square where effective grouping is the aim. The beds may be so arranged, however, that some plants may be removed for stock as soon as they break through the soil.

SEEDLING STOCK.

Break up some of the plants each spring and so maintain a vigorous stock. Where plenty of good plants exist already it will not be necessary to multiply them unduly. Where a specially good sort is wanted in quantity then every crown, with root attached, should be separated, and such plants may with advantage be potted for a month, particularly if only feebly rooted. On no account should these divisions be placed into artificial heat. It is almost fatal to the plants, as it elongates the stem, while below no equivalent in roots is forthcoming. The most that is required then is a close cold frame for a short period. Frequently with good varieties there are many growths that by reason of the trunk-like character of the stool cannot be detached with roots, and it may be helpful to some to know that if these shoots are pulled off with a good heel many will root in a cold frame in sandy soil. In this way I have raised much valuable stock. It is, however, only by early spring propagation that this can be done. Without the heel these cuttings are valueless; indeed, the shoots should be torn off and inserted under a handlight. The knife should never touch them. In planting these in the ground later, and, indeed, in all planting, the crown tuft should be buried about 2 inches deep. This is ample, as the Larkspur is not surface rooting in the least degree. E. JENKINS.

TREES AND SHRUBS.

THE APPROACH OF SPRING.

THE CATKIN-BEARERS.

OF the earliest-flowering hardy trees and shrubs the majority are those whose flowers are borne in catkins. Their appearance is one of the first evidences of the approach of spring. It is to the catkin-bearing group that the Poplars, Willows, Birches, and Alders belong. These catkins are pendulous, cylindrical, often slender inflorescences, carrying flowers of one sex only, which spring from the axils of scaly bracts. Being mainly dependent on the wind for their fertilisation they have none of the varied or bright colours that are characteristic of flowers fertilised by insect agency. Often, indeed, sepals and petals are entirely absent. Still many of these catkin-bearers possess a quiet charm and beauty of their own, which, taken with the early, often inclement, season when they appear, make the best of them indispensable in gardens where early spring effects are desired. As a rule it is the male or pollen-bearing catkins that are most ornamental. They are longer and more graceful than the seed-bearing ones.

POPLARS.

First among Poplars to bear its flowers and almost before winter is past is the Aspen (*Populus tremula*). This and its weeping variety bear their catkins in February. But closely following it, and perhaps still more ornamental, is the American Aspen (*Populus tremuloides*). This species flowers early in March near London in mild seasons, but later farther north and when kept back by severe weather. The pendulous variety of *P. tremuloides*—known commonly as Parasol de St. Julien—is, at the flowering time, probably the most beautiful and striking of all catkin-bearing trees. Both it and the type produce long slender catkins

so light as to be swayed by the gentlest movement of the air. The weeping variety, whose branches naturally keep low, is especially well adapted for growing, more or less isolated, on a lawn. In all these Poplars the male catkins are 3 inches to 4 inches long, chiefly of a grey-brown colour; the scale-like bracts, however, are suffused with a reddish tinge. The weeping varieties of these two Aspens are frequently grafted on the White Poplar, which is not a suitable stock. The species to which the varieties severally belong should be used for the purpose. It would be even better if they could be got on their own roots by means of layers or cuttings, and trained up to the required height before allowing the weeping habit to develop.

There are other Poplars that bear their catkins freely, such as *P. alba*, *nigra*, and *balsamifera*, but being of loftier habit they do not show to the same advantage as those of the Aspen group.

HAZELS.

Between the middle and the end of February the flowers on the catkins of the various species of *Corylus* begin to expand. Early as that date is the catkins have, nevertheless, been in evidence since the previous autumn; they were, in fact, formed before the nuts fell. Being comparatively low and shrubby the different varieties of the Hazel (*Corylus Avellana*) show their catkins to best advantage, and there are few among the catkin-bearers more charming. It is not often that any but the coloured-leaved varieties find a place in the garden proper, but either in the orchard or in the woodland the soft yellow of the Hazel catkins is one of the most pleasing notes of earliest spring. The Tree Hazel (*Corylus Colurna*), a fine and interesting tree, growing 30 feet or more high, also bears its catkins in February.

WILLOWS.

Of the almost innumerable species and varieties of *Salix*, it is only a few that need be mentioned here for their beauty when in flower. So far as I have been able to judge, the most ornamental of the Willows in catkin time is *Salix smithiana*, known also as *S. mollissima*. This tree flowers about mid-March, producing its shortish, thick male catkins in very great abundance; the numerous exposed anthers give a soft but glowing yellow tone to the tree, and entitle it to rank as one of the most ornamental of early-flowering trees. The pendulous variety of *Salix Caprea* is known as the Kilmarnock Willow. Although of weeping habit it is somewhat stiff in character; but towards the end of March and later it is exceedingly pretty loaded with its grey catkins. The flowers of the typical *S. Caprea* (the Goat Willow) are commonly known in many country places as Palm, and are used for decorating churches on Palm Sunday. The slender, coloured twigs of the Purple Willow (*Salix purpurea*) bear red or purplish-tinted catkins in early April. *Salix stipularis* may also be mentioned for its beauty when in flower.

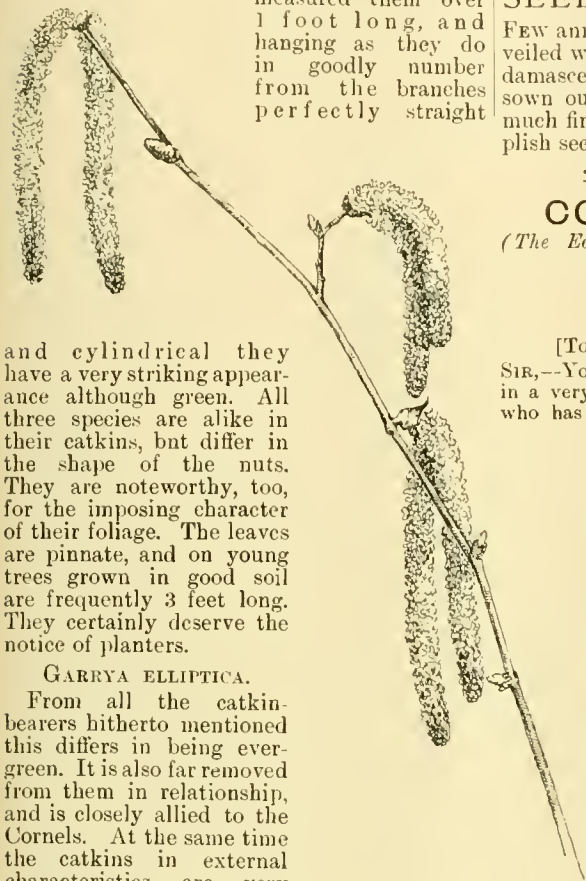

ALDERS.

With the exception of a few species, such as *Alnus nitida* and *A. maritima*, which flower in September and October, all the Alders develop their blossoms in February and March. The common Alder (*A. glutinosa*) and its varieties are perhaps as ornamental as any at that time. Like the Willows, they look best and grow best in association with water. In such a position an Alder at that time, leafless, but laden with its slender greenish yellow catkins, is a beautiful object, and characteristic, too, of our English landscape. Other species possessing a similar quiet beauty are *Alnus*

incana, A. viridis, A. oregona, and especially A. cordifolia with its green and yellow catkins.

JAPANESE WALNUTS.

Juglans sieboldiana and its close allies J. mandshurica and J. cordiformis do not flower till May, but bear at that time very remarkable male catkins. I have measured them over 1 foot long, and hanging as they do in goodly number from the branches perfectly straight

HAZEL CATKINS (REDUCED).

and cylindrical they have a very striking appearance although green. All three species are alike in their catkins, but differ in the shape of the nuts. They are noteworthy, too, for the imposing character of their foliage. The leaves are pinnate, and on young trees grown in good soil are frequently 3 feet long. They certainly deserve the notice of planters.

GARRYA ELLIPTICA.

From all the catkin-bearers hitherto mentioned this differs in being evergreen. It is also far removed from them in relationship, and is closely allied to the Cornels. At the same time the catkins in external characteristics are very similar. Not only the catkins but the plants themselves are unisexual, and, as is usual with the catkin-bearers, it is the male that is most ornamental. These catkins are from 4 inches to 8 inches long, and I have heard of (but not seen) them as much as 1 foot in length. The time at which the flowers expand depends, as with all the early catkin-bearers, on the mildness of the season. This year on a wall the catkins have been in beauty ever since the first week of January. They are very attractive in their grace and quiet beauty.

Chiefly of soft grey and green colours, the bracts are, however, suffused with a warmer reddish tint. In the neighbourhood of London Garrya elliptica is quite hardy in ordinarily sheltered positions, but does not flower so freely as against a south wall. As it is of Californian origin this is not surprising. This shrub resents disturbance at the root, and in transplanting great care is necessary.

There are other species of Garrya in cultivation, but they are more suitable to the south-western counties than to the average climate of Britain.

To the catkin-bearing family belong several other well-known trees, such as the Birches, Hornbeams, and Sweet Chestnut; but flowering later in the year their beauty is apt to pass without notice in the great flush of bloom that comes in with April. The beautifully fragrant Sweet Gale must not be passed without

mention. Its reddish brown catkins are formed before autumn, and expand on the still leafless twigs in spring. W. J. BEAN.

AN ARTIST'S NOTE-BOOK.

SEED OF LOVE-IN-A-MIST

Few annuals are prettier than the blue flowers veiled with foliage of Love-in-a-mist (Nigella damascena). It is very easily raised from seed sown outdoors in March. There is a variety much finer than the ordinary type. The purplish seed-pods are quite handsome.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

ROSE ECÆ.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Your correspondent "Tuscan" (page 118), in a very interesting note, asks: "Will anyone who has tried the Afghanistan Rose Ecæ give their opinion of its wants and merits?" I have grown this for more than twenty years, and the more I see of it the more interesting I find it to be. It is not one of the most showy of the single Roses; the flower reminds one of a miniature Christmas Rose, it is so very like it in appearance. Last season it was in flower with me until quite late in the autumn. It is growing in rich soil and in a rather shady situation, but these are not the conditions I should recommend for its best cultivation. This Rose is perfectly hardy, and delights in dry, loamy soil. If grown against a low wall, or where it can be sheltered from cutting winds, the flowers will last much longer than when grown in the open, but I like to see it best as a bush. Here its thorny nut-brown wood helps to show off its pretty flowers and make it an interesting feature, either in the front of the shrubbery or in the herbaceous border. T. B. FIELD.

Ashwellthorpe Hall Gardens.

PROPAGATING EUPHORBIA JACQUINLEFLORA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Some gardeners are very clever in propagating the above beautiful winter-flowering plant, and some are quite the reverse. It may be increased to almost any extent by firmly adhering to a few simple rules. Most people are extremely partial to planting in a peaty soil, which is a mistake. A strong soil or a good brick earth to one half, and a similar material well burnt into ballast for almost the other half, is far better. This indeed will, with certain modifications, such as the addition of sand and charcoal, make a capital mixture to grow the plant in. When potting is done, let the soil be so dry that firmness may be assured. Now as to the propagation. When flowering is past plant the old plants, if only a few, in a half reclining position on the stage in an intermediate house, not in a stove, nor yet under the stage, where so many of these and

Poinsettias often go. Shorten the stems to below the flowering axils. Plant firm in moderately dry, well-drained soil, and keep dry for a few days (about fourteen), subject to the condition of the soil at the time. Then give one good watering. At no time should the plants be kept continuously wet. Such a condition and much warmth result in soft cuttings. With roots moderately dry, the tops in full light and in a medium temperature, cuttings can be produced that will root to 99 per cent. almost with the stems (tops) in a reclining position. Each axil will presently produce a good cutting, which must be cut clean out with a perfect heel attached, and inserted without more ado save the removal of the tiny leaves on the lower part of stem. Dip the base of the cuttings in dust-dry sand as soon as these are separated from the parent plant, and in this way seal up the exuding milky juices. Cuttings 3 inches or 4 inches long are excellent, and these sturdily-grown cuttings rarely droop at all. The best propagating medium I ever found for these may be made by plunging a 5-inch pot inside one of 7 inches, using a 6½-inch bell-glass for cover. Treat the cutting pot thus: One-third clean crocks, one-third sandy soil and fine ballast made firm, one-third pure sand. In this way the cuttings rest in pure sand when inserted. Get them in as quickly as possible, keeping all sunlight away in the meantime. Water thoroughly, and fifteen minutes later place on the bell-glass. Give no more water for a week, then another watering. Take off the glasses each morning and wipe out. On a bottom heat of 85° or 90° such cuttings root in three weeks. In this way I have rooted many hundreds in a season, and with less than 5 per cent. of losses. Hampton Hill. E. J.

LILIUM SPECIOSUM ROSEUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The query by Mr. Max Leichtlin in THE GARDEN (page 127) concerning this Lily is full of interest to me, as I have never been able to

SEED OF LOVE-IN-A-MIST (NIGELLA DAMASCENA). (About half natural size.)

fathom any real distinction between the varieties roseum and rubrum, though the two are kept separate in all the lists of Lilies. In a paper read at the Lily conference at Chiswick by Mr. E. H. Krelage of Haarlem, the writer speaks of rubrum having brown stems and roseum green. This is all very well as far as it goes, but unfortunately for this theory the brown stems do not always bear the deepest-coloured blossoms, and a rubrum lighter in colour than roseum is, to say the least, a misnomer. I cannot go back to the year 1842, but the form alluded to by Mr. Max Leichtlin as having flowered in that year must have been a very beautiful one, and well merited the varietal name of roseum. The nearest approach to a flower of a uniform rose tint that has ever come under my observation occurred a dozen years ago among an importation from Japan. At that time we used to receive more dissimilar forms from the Japanese than we do now, probably from collected rather than cultivated bulbs. The individual just alluded to had green stems. While on the subject of this Lily, I am induced to supplement Mr. Max Leichtlin's query by another: "What is the typical *Lilium speciosum* of Thunberg, which equals *L. lancifolium* of many old-fashioned gardens?" H. P.

IRIS ROBINSONIANA NOT FLOWERING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Some fifteen years ago I purchased from the late Dr. Wallace of Colchester a plant of *Iris robinsoniana*. I have always taken very great care of it, and it is now 6 feet high and 6 feet through. It is growing in what is known as a No. 1 pot. I always keep it in a cool greenhouse, and sometimes give it a little liquid manure, but never over-feed it. When I purchased this plant I was told it was a fine species, with large pure white flowers, and that it required a warm sheltered position. I believe it is a native of Lord Howe's Island. With all my care and attention up till the present time I have not been successful in flowering it. I should be glad if any of your numerous readers who have had experience with the cultivation of this interesting plant, and have been fortunate enough to flower it, would give me the benefit of their experience.

Norwich.

T. B. FIELD.

BOOKS.

Guide to Hope Gardens. *—Mr. Fawcett, Director of Public Gardens and Plantations, Hope Gardens, Jamaica, has issued this guide under the authority of the Governor. The general description of the gardens is by Mr. Walter Jekyll, a resident of the Port Royal Mountains, whose knowledge of plants, sympathy with beautiful nature, and ready pen combine to produce a practical guide which in itself is pleasant reading and will be a help to visitors. After a fairly complete survey of the gardens, Mr. Jekyll adds:—"It is hoped that this article may supply here and there a missing name. Everything cannot be labelled, though much is done in that way. Yet that is not its chief object, for names matter little. It is on the writer's part a small thank-offering for the ready helpfulness and courtesy which has been so freely extended to him by those who have charge of the gardens. And the pleasure of writing it will be doubled if it serves to help anyone to see and appreciate that beauty of Nature which makes up so large a part of our happiness. At Hope the weather is almost invariably fine, and there is always something beautiful to see. At one time there will be the *Poinsettias* and *Erythrina*. As the splendour of these wanes the *Bougainvillea* and *Spathodea* come in, then the *Poinciana*. And even should there happen to be none of these greater glories, there are always the yellow stretch of *Crotons*, the delicate masses of *Plumbago*, the mist of the *Olives*, the great lawn, and the encircling hills." The guide also gives

in a few words the history of the Hope Gardens as an experimental and teaching station, with a notice of the principal economic plants grown for observation and distribution, these being Sugar-cane, Cocoa, Coffee, Tobacco, Banana, Nutmeg, Citrus, Grape Vine, Pine-apple, Yam, Sweet Potatoes, &c.; also a list of such plants as may be bought from the gardens at almost nominal prices.

SASSAFRAS (LAURUS).

THE demand for trees and shrubs would seem to be steadily on the increase with each succeeding year, not so much as to the quantity of common things planted as to a careful selection of things hitherto comparatively rare—the reason for calling attention to the tree named above as a most interesting specimen for a small lawn. The flower is quite insignificant, but the foliage is handsome right away from spring until late in autumn, when it assumes a bright golden shade with a tinge of red in the majority of the leaves, which, except in the case of severe frost, are long maintained. A decidedly pronounced Bay-like scent is emitted alike from foliage, green, and dry wood. The specimen here is probably the largest in England, being close on 40 feet high and 8 feet in circumference at its base. In common with many other things, it has during the last few years changed its name, and is now generally known as *Sassafras officinale*.

Claremont.

E. BURELL.

GARDENING OF THE WEEK.

INDOOR GARDEN.

(GREENHOUSE CLIMBERS.)

WHERE planted out in corridors or conservatories the drainage of the borders in which they are growing should be carefully examined, perfectly free drainage being essential to good cultivation.

Borders in positions such as we are now considering often suffer from excess of moisture, therefore remove sufficient soil to allow the outlet and make the drainage good where necessary. Whatever is necessary must be thoroughly done. Where the soil is sour remove it, and renew the border with fresh soil suitable for the plants that are to occupy it, generally speaking equal parts of peat and loam will satisfy the requirements of these plants. There are, however, some exceptions. Probably *Fuchsia corymbiflora* and *F. dependens* are as effective for this purpose as anything, and require only loam. *Lasiandra macrantha* for late summer blooming is a gorgeous plant and requires peat. *Diplacus Sunbeam* for covering back walls where plenty of light is assured will reward the cultivator with six months of continuous bloom. *Swainsonia galegifolia*, suitable for the same purpose, is of rapid growth, free blooming, and of a striking colour. *Tacsonias* are useful greenhouse climbers. *T. militaris*, recently introduced by Messrs. Sander and Sons, is a free bloomer, and requires an intermediate temperature.

BAMEOS.

When planted under glass these are very decorative and require good drainage, moderately deep borders, and abundance of water; red spider is their bane, and a free use of the syringe is necessary to keep it in check. *Arundinaria falcata* is the most useful for general purposes, but for planting under lofty domes *Phyllostachys Mitis* is much stronger and produces a grand effect; to have these plants in their most attractive form the foliage must be kept clean and healthy.

PALMS.

Attend to the repotting of these very useful plants. Guard against the use of too large pots. For *Kentias*, *Latantias*, *Seafortthias*, and the

stronger growing *Cocos*, a compost of good fibrous loam with coarse sand and charcoal and a liberal allowance of bone-meal or Clay's fertilizer will do well when established. For young plants a little peat or leaf-soil is necessary. Pot them firmly, and leave sufficient space on the top of each pot to hold a good supply of water. Place the plants in a temperature of 65° to 70° by day, and use the syringe freely in bright weather, keeping the plants shaded from bright sun to retain the fresh green colour of the fronds.

HANGING BASKETS

should now be prepared for summer work. Very effective baskets may be arranged with *Asparagus plumosus*, *A. p. nanus*, *A. Sprengeri*, and for choice small baskets *A. S. variegatus*. *Dracena godsefiana* is much more effective as a basket plant than in any other position. *D. sanderiana* is also very effective used in this way. *Goniophlebium subauriculatum* with its long pendulous fronds is very graceful. Several of the *Davallias* also lend themselves to this kind of work. Flowering plants adapted for baskets are not very numerous. *Achimenes* and all the stronger growing varieties are very suitable, and in such a position display their choice flowers to great advantage.

CAMPANULA ISOPHYLLA MAYII

is charming in a basket. Young plants propagated by division last season should now be in readiness for this purpose; the size of the baskets must be determined by the plants used in their arrangement. As a general rule avoid using them too large. Place green wood moss in rather thick layers inside the wire frame of the basket, then fill in with suitable soil, and place them in a growing temperature till established.

CANNAS.

Where it is desirable to increase the stock of any particular variety they should now be taken in hand. Cut up the rhizomes into short lengths of about two joints, which place in 3-inch pots filled with a light fibrous soil, plunged in a bottom heat of 70° to 75° they should quickly make roots, and as soon as growth is made pot them on. Ordinary varieties can be raised from seeds; before sowing the seeds place them in a bottle of water, which plunge in a bottom heat of 100° to 120° for twenty-four hours. Seeds of *Grevillea robusta* and *Solanum marginatum* if treated in the same way will germinate much more quickly.

Wendover.

J. JAUQUES.

THE FRUIT GARDEN.

VINES.

REMOVE all surplus bunches from the early Vines before they come into flower, leaving the most compact and best placed for the crop, and fertilising with *Hamburgh* pollen when they are dry and the temperature of the house has reached the maximum. All the *Muscata*-flavoured varieties, with the exception of *Madresfield Court*, require a little more heat than *Black Hamburgh* to set them properly, and on this account they should be grown at the warmest end of the house. Thinning Grapes is a very important operation, and requires great care both in the manipulation and selection of the berries. If insufficiently thinned the berries become wedged and distorted, and seldom keep well even in summer, while, on the other hand, too much thinning results in a large berried, straggling bunch, which never travels well, and spreads all over the dish or exhibition boards. A thorough acquaintance with the capabilities of the Vine is first essential, the rest is a matter of mechanical skill; but in all cases the early and complete thinning of free setting sorts as soon as they are out of flower should never be neglected. With increasing length of days and a continuance of mild weather good progress may be made by closing early, but 60° to 65° for *Hamburghs* and 65° to 70° for *Muscats* through the night will be quite sufficient to secure stout, leathery foliage and good health.

SUCCESSION HOUSES

containing such as *Black Morocco*, *Alicante*, *Mrs. Pince*, *Gros Colman*, and some of the best white

* "Guide to Hope Gardens." Aston W. Gardner and Co., Kingston, Jamaica.

varieties, exclusive of Muscats, should be helped forward with fire-heat and fermenting material to ensure an early break and a long growing season. If Hamburgs are not grown with them for fertilising purposes see that pollen is collected from the early house when in flower. The much-neglected Black Morocco, one of our best January Grapes, when left to itself is invariably a failure, but careful fertilisation with Hamburg pollen for several days in succession secures to us a set equal to the most prolific Hamburg. Provision should also be made for fertilising the Muscats when in flower, not with their own, but with foreign pollen, which may be kept for several weeks in a dry, warm place after it is collected. The roots must be kept active by a warm, well-drained inside border, and where these conditions do not exist the vigorous applica-

outside, and quality being of more importance than quantity, the borders should be elevated on good drainage, with a run of 6 feet to 9 feet inside and out.

KITCHEN GARDEN.

POTATOES.

IN many gardens with raised warm borders facing south or south-west the earliest varieties will have been planted before this for tubers to follow those grown under glass, but if not a plot should be planted without delay. In the midland and northern counties it is unsafe to plant before this date owing to late spring frosts. Sharpe's Victor, Ashleaf, and Duke of York are good first early varieties. The last-named is very prolific and of good flavour, and may be classed as one of the best earlies. Some of the second early varieties may also be planted, such as Windsor Castle, Snow-drop, Beauty of Hebron, and Syon House Prolific. Of late varieties we depend solely upon Up-to-date and Sutton's Triumph. These may be planted as the ground becomes ready for them. Methods of planting are various. We usually plant the tubers as the ground is dug and manured, by which method the ground is left quite level. If frosts occur when the sprouts appear some earth may easily be drawn up for protection. Potatoes growing in pits and frames should be top-dressed with fairly rich soil, taking the precaution to have it warmed before placing about the tender stems. Apply tepid water frequently.

CARROTS.

The main crop may be sown if the ground is sufficiently dry. Drills should be drawn 12 inches apart for the long, strong-growing varieties, while 10 inches will suffice for the Horn Carrots that will be first drawn for use. Where exhibition specimens are required boring with an iron bar should be practised, filling the holes

with some finely sifted rich soil and sowing a pinch of seed in each.

ASPARAGUS BEDS

will now require forking lightly over in order to bury the manure that was applied as a winter dressing. Cut out the alleys by setting a line on either side, and throw the soil therefrom on the beds, but avoid laying the roots bare in so doing; rake over if dry enough, and dress with salt. Sow Asparagus seed for producing plants for forming new beds. Drills should be drawn 2 inches deep and 18 inches apart and the seed sown thinly. These should make strong plants for transplanting to permanent beds two years hence.

CELERY AND CELERIAC.

For the main batch of plants seed should now be sown in pans or boxes and placed in heat as soon as the seedlings appear. Place near the roof glass

of a warm pit or house, afterwards removing to a cold frame to harden preparatory to pricking out into rough frames. Veitch's Superb White is excellent. Veitch's Early Rose is one of the best coloured varieties I have grown for main crop; it is reliable in every way.

CELERIAC (Turnip-rooted Celery)

is easy to grow and deserving of extended cultivation. The Turnip-shaped sorts are excellent when properly cooked, and, as they may be laid by in sand in the root shed for the winter, they form a welcome change in that dull season when vegetables are scarce. When large enough plant on a well-manured plot of ground in rows 18 inches apart and 14 inches from plant to plant.

Stoneleigh Abbey Gardens.

H. T. MARTIN.

FLOWER GARDEN.

CARNATIONS.

WHERE these are grown in beds or in the mixed borders no time should be lost in the preparation of both plants and soil. The soil in most gardens may be made suitable for Carnations, but heavy additions of rich manure are not advisable, as they tend to encourage disease. Where road scrapings can be procured nothing suits them better, add to this some wood ashes from a garden fire, and a little mortar rubbish well incorporated with the soil when the bed is dug. The end of April is the best time to plant. Where the plants are wintered in cold frames air should now be freely given night and day, and whenever the weather is favourable the lights should be drawn completely off. In planting press the soil firmly about their roots and give a good watering. To raise seedling plants sow the seed now or early in April, in pans of good sandy soil, and cover the seed about half an inch deep. Keep only moderately moist; do not force the seeds to germinate. A cold frame is the proper place for the seed pans. Patience and attention will result in success.

THE PANSY.

I am not certain that any other plant can be named that will produce such an amount of bloom at any season as the Pansy will, in April and May particularly. That it is a favourite flower is not surprising; it is easily cultivated, is exceedingly pretty, and continues in bloom for the greater part of the year. For borders, clumps, or pot plants it is useful and elegant, and the cut blooms last well in water. As young plants produce the finest flowers, it is best to sow seeds at intervals during the spring and summer. This applies more particularly to the spotted or fancy varieties; but where such varieties as Imperial Blue, Cardinal, Golden Gem, Purple King, and Yellow Prince are grown to give a mass of bloom, the best way to have these in perfection for large beds in spring is to propagate in September and plant out in March. Where the soil and climate are moist they bloom well nearly all the summer. They are very fond of well rotted hot-bed manure. Cliveden Blue is a good winter and spring variety, and yields a very heavy crop of flowers in March, April, and May, but in hot weather it does not bloom so well.

SAXIFRAGA.

The Megasea section of Saxifraga includes several very showy plants that flower about this time, but are liable to be cut down by frost. They are nearly all natives of the Himalayas, but are hardy in most places. A position should be given them where they can receive the protection of a handlight or bell-glass when in flower. They are handsome plants, with bold, thick, quite leathery leaves, which are of a rose-crimson and bronzy green colour in winter. They are very desirable plants when grown in pots in a cool greenhouse, and last a long time in flower. The best are cordifolia, purpurea, Stracheyii, Milesii, and crassifolia. Saxifraga oppositifolia and varieties are very pretty early-flowering plants, and their flowers will need protection where sparrows abound. Wire netting placed just above the plants will prevent these depreddators from pulling them to pieces.

WALLFLOWERS.

Where it is desirable to have this favourite in flower, either in beds or borders through the

SASSAFRAS (LAURUS) OFFICINALE AT CLAREMONT.

(Probably the largest specimen in England. It is nearly 40 feet high and 5 feet in circumference at the base.)

tion of steel forks, new drainage, and fresh compost will be found the best remedy.

LATE HOUSES.

The worst managed Vines in many gardens are the late ones. They are expected to accommodate themselves in a house full of bedding plants through the early spring, to break into growth, and set with a minimum of fire-heat, to ripen their fruit and wood by September, and support a full crop until Christmas, the usual time for bottling Grapes. Another drawback is the inconvenient season for renovating the borders, but this should not stand in the way, as first-rate old Grapes which will keep until the advent of new ones cannot be expected where the roots are not in the best condition. Inside borders may be renovated at any time after the Grapes are ripe; the month of February is perhaps the best for lifting and relaying the roots

summer months, a sowing should now be made of the Parisian Early. As soon as the seedlings are large enough to handle prick them off into pans or boxes. Keep for a time in cold frames, gradually harden off, and plant out about the end of May. T. B. FIELD.

Ashwellthorpe Gardens, Norfolk.

CHRYSANTHEMUMS.

EARLY OR SUMMER-FLOWERING VARIETIES.

THIS section is, I am glad to notice, becoming more generally cultivated each year, and when one considers their hardiness and the little trouble which they incur to bring them to perfection this is not to be wondered at. Not only are they admirably adapted for all kinds of bedding, either for the flower garden, grouping about in the shrubbery, or herbaceous borders, but to enjoy them fully a space should be devoted to a good collection, carefully arranging them as to heights and the pleasing blending of colours. They are equally useful for supplying large quantities of cut flowers, and adapt themselves readily to almost any purpose. By choosing colours which harmonise well and selecting suitable foliage these will make delightful dinner table ornaments quite as suitable for filling either large or small vases and specimen glasses. The propagation of these should be done any time during March. Mix up a nice light gritty compost, and dibble them in thickly either in pots or shallow boxes. These will root away quite readily if kept close in cold frames for a few days, after which pot off singly into small pots and return to the cold frames, when they will be found to make nice sturdy plants by the middle of April, and if properly hardened may be planted in the open quite safely by that time. A portion of the dwarf free-flowering kinds may also be potted and grown on to bloom in small pots for conservatory decoration, and are equally valuable for the embellishment of rooms, as they last for a considerable time in such places uninjured. The position in which these are to be planted outside should now be well dressed with good farmyard manure and the ground either deeply dug or trenched, when by the time of planting this will be found to be in a suitable condition for receiving them.

SPECIMEN PLANTS.

Though these are not generally so largely or so well grown as in times past, no doubt partly owing to the amount of room they require when the time comes round for housing and the little encouragement offered by way of prizes at our autumn exhibitions in comparison to that for cut blooms, yet when seen at their best they make fine features and demonstrate the skill of the cultivator as a plantsman; but, on the other hand, such poor attempts as we often meet with are unsightly and certainly not worth the space they occupy.

An ideal specimen plant to whichever section it belongs should not be stiffly trained, though a certain amount is necessary; it should be clothed with good foliage from top to bottom, and each bloom should be of good quality. One good bloom is worth a dozen poor half-developed ones, and to attain this every inducement should be afforded to make the foundation of the plant as early in the year as possible. To ensure this the plants when young must be kept in a growing temperature, but not unduly forced until this is practically achieved. Keep the young shoots freely pinched after making sure that a clear stem above the soil is assured. Pot on firmly as the plants become pot-bound, syringe frequently, and train out the young growths carefully as they need it. Some varieties when grown on in this way are persistent in showing flower-buds, but by keeping these picked out as fast as they are made, the plants will in time out-grow this trouble and in the end be none the worse. Even at this early date the foliage must be clean and healthy, and it will need a watchful eye to prevent their damage by the many pests which beset them, such as mildew, rust, thrip, green and black aphid, and always bear in mind that prevention is better than cure. E. BECKETT.

Aldenham House Gardens, Elstree, Herts.

ORCHIDS.

REPOTTING.

THIS may now begin in earnest. On either side we find a vast number of plants that need attention, and owing to the greater amount of sunshine during the past month—February—many will commence growing and rooting earlier than in seasons when February is a dull and almost sunless month. Plants must therefore be carefully watched, though it is never necessary to repot a plant at any specified time. This, however, should be done as much as possible when the plants are in the proper stage of growth or when new roots issue from the base of the last made bulb.

LÆLIA ANCEPS AND ITS VARIETIES.

These are now bristling with new roots from the base of the bulbs, and if the plants have far overgrown their receptacles they should be repotted, though with this *Lælia* it is not so important a matter as with some Orchids to keep them within bounds, for we find they thrive remarkably well when they have far overgrown them, providing watering, syringing, &c., is properly carried out. Nevertheless it is always advisable to keep them within a certain limit, and repot sufficiently often so as to keep the plants compact and as neat as possible in appearance. Repot the plants as soon as the new roots are visible at the base of the bulb, for if they are allowed to grow a few inches it is difficult to perform the operation without injuring the roots. Remove all old material and cut off dead and decaying roots. If the specimens are compact transfer to other receptacles of ample size sufficient to allow them to grow on two years or more without being disturbed. Place the plants in their receptacles to bring the base level with the top. Allow two-thirds drainage, and the compost, which should consist of equal proportions of peat and sphagnum moss, should be pressed moderately firm and brought level with the base of the plant. A few large crocks should be worked in the surface layer, which will keep the compost open and allow a free egress of water, for they need a good supply at the root and frequent overhead syringing during the growing season. *Lælia anceps* and its varieties are some of the easiest Orchids to propagate, for they seldom fail to produce young growths wherever the rhizome is severed, either at the first, second, or bulbs further back. The simplest way is to take a specimen that has overgrown its receptacle. Sever the rhizome so as to leave the back part of the plant as even and compact as possible, and let it remain undisturbed, then place the leads together in a compact specimen, or to increase the number pot up singly. Plants repotted must be sparingly watered until the new roots have taken to the fresh compost. Spray the plants lightly overhead on bright days, and syringe in among the pots. Sprinkle the surface of the potting material to prevent the sphagnum moss from drying, and that is all that will be needed until the plants are freely growing.

ONCIDIUM MANTINII.

This supposed natural hybrid between *O. marshallianum* and *O. Forbesii* is certainly one of the most beautiful *Oncidiums*, and one which ought to be in every collection and in quantity if Orchids are exhibited in groups. This *Oncidium* is beautifully adapted to the purpose. The flowers are large, and produced in numbers upon erect spikes 2 feet to 3 feet high. The sepals and petals are yellow, the centre covered with rich chestnut-brown, lip clear yellow, with a few purplish-brown spots. It is a good grower, and does not deteriorate under cultivation as some of the *Oncidiums*. It should be grown in the cool intermediate house, and now that it is beginning to grow any necessary repotting should be done in the usual way. Repot in equal proportions of peat and sphagnum moss, with Fern roots used in place of crocks, or leaf-mould may be used alone, or a portion mixed with peat and moss. If any Orchids are benefited by leaf-mould it is the *Oncidiums*.

ANGULOAS.

These, as soon as new growth is visible, should be repotted at once if more rooting space is needed,

as the flower-spikes push up with the young growths, and the latter emit roots when about 2 inches long. If attention be not given at once the flower-spikes are apt to get checked, and if left over until after blooming the growth and root action are too far advanced for repotting the plants without causing injury to some extent. Repot in peat and moss in the usual way. Although water must be somewhat sparingly applied until the new roots have penetrated the fresh material, the plant must not become very dry or the flowers may be injured.

F. W. THURGOOD.

Roslyn Gardens, Stamford Hill, London, N.

THE KITCHEN GARDEN.

ASPARAGUS FORCING.

TO have a supply of Asparagus from the middle of November to the end of February the best system to adopt, in my opinion, is to grow the plants specially for forcing, and to take the roots up and force them in heated pits, Mushroom houses, or other structures available where light and heat are at command.

To produce a supply from the end of February until the beginning or middle of April, when they come in naturally out of doors, the best plan to adopt (where the materials and appliances are available) is no doubt to force gently the permanent beds. There are many ways of doing this, the commonest and easiest way being to make a rough wooden frame with boards wide enough to cover the beds, laying pieces of wood across to support a layer of mats. Fill the alleys each side the beds to the depth of 18 inches or 2 feet with fermenting material composed of littery straw and leaves well pressed together. Cover also the mats with the same material to the depth of 6 inches. The heat generated by this quantity of manure will not be great, but it will be sufficient to stimulate the plants into growth (very little is needed to do this so early in the year), and to produce shoots fit to cut in the course of a fortnight or three weeks after it has been applied. More litter will have to be added from time to time, mixed with the original to keep up the necessary heat.

A better way of forcing the permanent beds where it can be managed is to make use of those useful small portable span-roofed pits, with portable boilers and pipes also. These are now to be purchased at a reasonable price, and are excellent for this purpose, as they undoubtedly are also for the growth of many early vegetable and salad crops. Both the houses and boilers are easily fixed and readily moved from one bed to another, and the heating is under perfect control. Should it be desired to blanch the "grass," this is effected by covering the glass, and if green "grass" is preferred the covering must be discarded.

As regards the system of taking up the roots for forcing under glass, the method of cultivation should be somewhat modified to meet the exigencies of this method of forcing. There are differences of opinion among growers as to the best roots to use for forcing. As regards age many prefer roots from six to eight years old. My experience does not confirm this belief. On the contrary, I think that three or four year old roots, when well grown, are the best, and will give the greatest return of useful Asparagus. In the case of old roots the crown buds (if they may be so called) in the centre invariably decay, leaving only the marginal ones to produce "grass," and these are never

so good as are the crown ones. Moreover, in the forcing pit two three-year-old roots can be accommodated where only one of the older ones could find room, a point of some importance where forcing accommodation is limited. When the system of growing roots to be lifted at the age of three or four years for forcing under glass is adopted, it may be naturally thought that the cultivator will hesitate to go to the same expense and labour in preparing the land for this fugitive crop as for those of a permanent character. In practice I have found that the returns obtained justify the most liberal treatment in the way of cultivation, to say nothing of the splendid condition the soil is in afterwards for the growth of such vegetables as Potatoes, Cauliflowers, Onions, Brussels Sprouts, &c. Indeed, it is not too much to say that the system of trenching and manuring the land to produce these three-year-old roots is one of the best possible ways of bringing poor land into a condition of the highest fertility.

The best structures for forcing the Asparagus in I have found to be lean-to pits or frames, having beds 3 feet deep, and heated with a flow and return 4-inch pipe. The pit is filled with fermenting material such as littery straw and leaves to within a foot of the glass and well pressed down. On this material 4 inches of ordinary garden soil should be placed upon which to rest the roots. These should be packed as closely as possible without overlapping. When packed in this way with strong young roots one light will furnish a surprisingly large supply of "grass." Cover them over with 3 inches of soil. If strong, sturdy heads are desired a high temperature must be avoided; a minimum of 48° and a maximum of 60° Fahr. during winter should be the rule. Water must occasionally be applied and always at about the same temperature as the atmosphere of the pit—say about 60°. There is not much to be said as regards the merit of one variety of Asparagus over another, size and quality being more the result of superior cultivation. The Giant, Conover's Colossal, and the Argenteuil are excellent.

O. THOMAS.

A NEW CUCUMBER.

CUCUMBER SATISFACTION, a houseful of which is shown in the accompanying illustration, was raised by Mr. Mortimer of Farnham, who exhibited it at the Temple show in 1902 under the name of British King. It is now in possession of Messrs. Sutton and Sons, who have renamed it Satisfaction. A descriptive note about it was given in *THE GARDEN* of the 14th ult., page 115.

SELECT VEGETABLES FOR PRESENT SOWING.

The next few weeks will be busy ones in the kitchen garden, and the sowing of the various kinds of seed will occupy a large share of attention. It is impossible to lay down any hard and fast rule as to the precise date at which many of the smaller seeds can be sown in the open, much depending upon the weather, the nature of the soil, and the locality. But it is well to bear in mind that there is nothing to be gained by being in too great a hurry at this season, and it is the best practise to wait for a favourable opportunity,

HOUSE OF CUCUMBER SATISFACTION. (Raised by Mr. Mortimer of Farnham.)

but this should not be missed when it comes. The soil should always be in a good workable condition, and if it has been properly prepared, as it should have been beforehand, by either trenching or deep digging and applying suitable dressings to the surface, a few fine days at this time of the year will render even the most stubborn ground a genial seed-bed. It will be well to bear in mind that last season was a very unfavourable one for ripening the seed crops of many things; indeed, one of the worst for some time past, especially for such as Onions, Carrots, Beetroot, and the like, consequently extra pains should be taken to ensure them having a good start, or many failures are certain to occur. The germination, as I have proved in many cases already, is very weak, and unless these receive special care a large percentage will never properly develop and come to perfection. Though I am by no means an advocate for thick sowing, for not only is it a waste of seed to do so, but it necessitates much extra work in thinning, and overcrowding even in a very young state is detrimental to the crop.

Fortunately, many vegetables can be raised in frames placed on very mild hot-beds, suitable boxes, or seed pans, and if properly hardened can be planted out not only with safety, but with advantage, when more favourable weather can be looked for, and in cold districts and on heavy land will prove to be a great gain.

PARSNIPS enjoy a long season of growth, and should be one of the first things to claim attention in the open. The land should have been thoroughly trenched, but not manured, some time previous to sowing, especially on heavy soil. I always prefer to make the bed for these on that which has been occupied with Celery. Fork over and rake down finely. Draw drills about 1½ inches deep, allowing a distance of 18 inches between the rows. When extra fine specimens are required deep holes should be bored and finely sifted soil used for filling them up before sowing the seed. Tender and True, the Student, and a good type of Hollow Crown are all excellent.

CARROTS.—Further sowings of Early Nantes and Intermediate should be made on mild hot-beds or cold pits. Allow a good depth of finely prepared soil. These will prove to be invaluable, not only when required for exhibition for early shows, but also for home use, long before those sown in the open.

PEAS should be sown largely in boxes for planting out. For many years I have raised all our first

and second earlies in this way, and if properly hardened and carefully planted I am convinced this is far preferable to sowing in the open, and in the end occasions less labour, as one has them under much better control during their early stages of growth and the yield is better. There is now such a fine selection of wrinkled suitable for early work, and which are vastly superior to the old white seeded forms in every way, that these are really hardly worth cultivating. Gradus, Early Morn, and Early Giant are among the best, and for a dwarf kind Daisy is unsurpassed. I have grown this variety since it was first offered, and have always considered it one of the finest Peas introduced. For second supplies Alderman, Duke of Albany, and Edwin Beckett are all good.

BROAD BEANS should be raised in boxes under glass in cool houses or pits. Leviathan cannot be beaten for general purposes. These come into bearing much quicker when transplanted than if sown in the autumn.

TURNIPS.—Sow in cold frames on last season's hot-beds. Carter's Forcing, a grand early Turnip, should be grown by all. It is a long-rooted variety of the finest quality, and remains a long time fit for use.

DWARF OR FRENCH BEANS.—Make good sowings of Ne Plus Ultra and Canadian Wonder either in 8-inch pots or in rows in heated pits and grown on in a brisk heat.

BEETROOT.—Make a small sowing of Globe Beet in cold frames, which will be much appreciated for salads.

CAULIFLOWERS.—Sow thinly in boxes in a gentle heat Autumn Giant and Magnum Bonum, and prick out immediately when ready.

BRUSSELS SPROUTS.—Sow in boxes or on very mild hot-beds about the end of the month Cambridge Champion and Sutton's Dwarf Gem, and prick out when in the seed leaf.

CAPSICUMS AND CHILLIES.—Sow in 6-inch pots in heat.

CELERY.—Sow about the middle of the month White Gem and Early Rose. The main sowing ought to be made about the first week in March. Standard Bearer and Giant White are both excellent and reliable varieties.

CELERIC should also be sown at the latter dates mentioned.

CUCUMBERS may now be sown for growing in heated pits and hot-beds. Telegraph and the

three varieties Ideal, Victory, and Achievement are all good and reliable.

VEGETABLE MARROWS.—Sow a few seeds in heat of Moore's Cream and the new variety (Sutton's Perfection) for growing on hot-beds under frames.

PARSLEY should be started in boxes and planted out, the best way to grow good Parsley. Veitch's Extra Curled is an excellent strain.

LEEKS.—Sow in boxes in gentle heat The Lyon, Model, and Champion. Prick out when large enough. These will make good specimens by late autumn.

LETTUCE.—Sow Mammoth Cos and All the Year Round Cabbage variety in gentle heat, and prick out in boxes as soon as they can be handled.

ONIONS.—Make the main sowing of these in the open whenever the ground is in a good condition. The end of February or beginning of March is the best time, but miss no chance if the soil is suitable. Sow 1 foot apart, dress well with soot, and rake down to a fine tilth. Veitch's Main Crop, and James Long Keeping are good reliable sorts. Sow in rows 1 foot apart.

POTATOES.—Plant fairly deep on a warm border, where protection can be given, Sharpe's Victor, May Queen, Harbinger, and Improved Ashleaf. Cover the sets with old Mushroom bed manure.

RADISHES.—Wood's Early Frame should be sown thinly broadcast on mild hot-beds.

SPINACH may be sown on a warm border in drills 1 foot apart of a good round leaved variety.

TOMATOES should be sown for the principal supplies under glass. Perfection and Polegate are among the best red kinds, and Golden Jubilee is a grand yellow. I have mentioned all those varieties which I have proved to be excellent, but there are many more belonging to the various classes which are undoubtedly of much merit, and many of which are equal to those named.

E. BECKETT.

Aldenham House Gardens, Elstree, Herts.

MISCELLANEOUS.

SOME REMARKABLE VINES.

IN Britain there are many splendid examples of the vigorous old age to which the Vine can attain, even under artificial cultivation. I will mention the most remarkable ones so far as my acquaintance with them goes, but there are doubtless others of which I do not know, and much interesting information on the subject of the longevity of the Vine might be imparted if correspondents would send particulars of other unusually fine Vines of which they happen to know. The Vine that has a world-wide reputation, although it is not the largest in this country, is the one in the gardens of Hampton Court Palace. In fact, it is almost one of the sights of London and suburbs, and is of as much interest in its way as is Hampton Court Palace itself.

This Vine was planted during the reign of King George III., in the year 1768, and is therefore now 135 years old. During this long period it is supposed never to have failed to crop, despite the fact that one does not know where the bulk of its roots are to be found, and that it has not been possible adequately to assist them with manurial applications. The girth of the stem is $3\frac{1}{2}$ feet, and the Vine's branches cover a root area of 2,200 square feet. At the height of $3\frac{1}{2}$ feet from the ground the stem is divided into three huge limbs, the largest of which is 90 feet long, the others are 80 feet and 82 feet respectively. Strange though it may seem, the roots also are divided into three at the base of the stem, in the same manner as the branches. In its early days the Vine is said to have matured 2,000 bunches of Grapes annually, each bunch averaging 1lb. in weight. Now it is allowed to carry only about 1,200 bunches, these in the aggregate weigh some 600lb. As is to be expected from the great age of the Vine and the difficulties of root cultivation, the bunches are small, and so also are the berries, but the old Vine makes amends for this by the

delicious flavour of its Grapes. The variety is a very good Black Hamburg. The Hampton Court Vine is open to the inspection of visitors every day in the year, and as many as 9,000 persons have passed through the viney in one day.

Another Royal Vine is the one in the gardens at Cumberland Lodge, and in some respects it is even more remarkable than the one at Hampton Court. It is not quite so old, though its age is known to be at least 120 years. Evidence of this is found in the statement of the attendant lately having charge of the Vine, whose father and grandfather were in the neighbourhood before him. It is more remarkable than the Hampton Court Vine so far as its size and crop are concerned; the branches cover a roof surface of 3,450 square feet, and annually bear over 2,000 bunches, nearly twice as many as are produced by the old Vine at Hampton Court. The Cumberland Lodge Vine is in the gardens adjoining the residence of H.R.H. Prince Christian in Windsor Great Park, about midway between Windsor and Virginia Water. In the gardens at Silwood Park, near Ascot, is another Vine of remarkable age and proportions.

Scotland boasts of one, if not more, Vines of great age. It is said to rival the Cumberland Lodge Vine in size and bearing, and is in the garden of Taymouth Castle, Perthshire, the residence of the Marquis of Breadalbane. Another celebrated Vine deserving of mention is that at Manresa House, Roehampton. This, however, is comparatively modern, having been planted within the memory of Mr. Davis, who lately died, and who had charge of the Vine for many years. It has filled several houses, and, had there been more room for its development, it is reasonable to suppose that it would now be larger still. It produces excellent crops of good quality Grapes every year; the variety is Black Hamburg.

Such instances of Vines that have borne and still bear excellent crops of Grapes throughout several generations naturally lead one to wonder whether much better results would not always be obtained by allowing Vines to grow much more freely than is usually the case. For example, instead of filling a viney with half a dozen Vines, why not let one Vine develop instead? It would be an easy matter to make use of pot Vines or to plant temporary ones so that valuable space should not be wasted; as the branches of the permanent Vine made progress, so in proportion could the others be removed or cut away. There is no doubt that Vines live much longer when allowed to grow freely than if restricted to one stem and subjected

annually to a severe pruning. This seems such an unnatural method of culture that it is difficult to understand why or how it has attained such popularity and is so generally practised. Perhaps some of your Grape-growing correspondents can say if they believe that Vines restricted to one stem, and therefore necessarily hard pruned, give better results than one Vine allowed to fill the viney, if any have tried this latter method. A. P. H.

NURSERY GARDENS.

BEGONIAS AT TWERTON, BATH.

DURING the past year the firm of Messrs. Blackmore and Langdon, Twerton Hill Nursery, Bath, have made a name as cultivators and exhibitors of Begonias. Commencing early in the season, they continued all through, exhibiting at the leading flower shows about the country, and always staging flowers representing the highest levels of quality yet reached by raisers of this interesting class of plants.

The Twerton Hill nurseries occupy a breezy height at Twerton, a rapidly growing village on the western boundary of Bath. The grounds comprise about six acres. There is a slight slope to the north, but a considerable one to the south. On the rising ground are show and propagating houses, the two leading specialities of the firm being Begonias and Carnations; but Roses, hardy plants, greenhouse soft-wooded plants, and other subjects are grown for sale. The soil is a fertile loam resting on clay. Begonias and Carnations alike do well in it. The same remark may be made of both the leading specialities that this young firm (for the business is of recent origin) cultivate. Some of the seedling border Carnations they exhibited during 1902 were of a highly promising character. Special mention may be made of Millie, a beautiful white ground fancy, the petals pencilled with rose and purple, which gained the highest honours at the annual exhibition of the National Carnation Society in London in July last.

Finding myself at Bath I went on to Twerton to see the Begonias. It had rained heavily all the preceding day and during the morning, and yet I could not help being struck with the brightness

SINGLE BEGONIAS IN THE NURSERY OF MESSRS. BLACKMORE AND LANGDON, TWERTON HILL, BATH.

and effectiveness of the Begonias in the open air under such depressing conditions. On the high ground near Mr. J. B. Blackmore's residence were some long borders planted with certain varieties which had been selected specially for bedding purposes, varieties of a compact free growth, very free of bloom, and remarkably persistent. Considering the weather the brilliance of these beds surprised me. The head of bloom was dense and unharmed or disfigured by the rain. The varieties were in panels, a goodly number of each, and an admirable opportunity was then afforded for making suitable selections; the colours varied from white to the darkest crimson. Some of the most effective, characterised alike by brilliance, effectiveness, and freedom, were Gladstone, rich crimson, very fine in colour, dwarf, narrow leaved, an excellent bedder; Marquis of Stafford, of a deeper shade of crimson, very fine, the flowers not so large as those of Gladstone; Argus, bright scarlet, very dwarf, and highly floriferous, a glorious bedder; Hollyhock, soft rosy pink, a beautiful double variety, of perfect form, of the build of a medium-sized Hollyhock, and of a delightful tint; Calliope, another very fine pink variety, but of a deeper tint of pink, the flowers fully double; R. B. Parsons (Cannell), of a pleasing pink shade, suffused with rose in the centre, dwarf, a most effective bedder; Mrs. French, creamy white, small, very double, like a perfect miniature Hollyhock, dwarf, very free; Hilda, bright carmine-rose, remarkably free, the flowers large, excellent shape, and standing up well to view; and Miss M. Griffith, white, with a tint of blush, bleaching to white in the open, fine form, dwarf, and very free. The foregoing list does not exhaust all the varieties bedded out, but all were most effective, and they had dwarf, compact habits, with a reserve of bloom that appeared to be as fine and plentiful in late summer as it was two months previously. These plants were put out the second week in June, in a compost of good loam and rotten manure. The ordinary bedding plants looked washed out in contrast with these Begonias. The Begonia is perhaps the best wet weather bedding plant in cultivation.

Passing down to the southern slope a remarkable sight met the eye; really a sea of brilliant colours afforded by named and selected seedling varieties planted out for stock and seed. Flanking these was a huge mass of seedlings, in which could be seen many individuals marked for naming or for the best selections. The former division were planted out in shades of colour, crimson, scarlet, rose, pink, apricot, blush, white, yellow, &c. The presence of yellow and apricot shades was very remarkable. The accompanying illustration gives some idea of one of these slopes of Begonias, but to appreciate their effectiveness they require to be seen. The splashing rain had not dimmed their beauty; the multitudes of blooms were heaped up in happiest profusion; the high quality seen on every hand was most noticeable.

In the large show houses were many fine examples in pots, all characterised by splendid quality; they represented the cream of the collection, and nearly all double flowered. For exhibition purposes they seemed to be unbeatable. I made a note of the following as remarkably fine: Marchioness of Bath, pure white; Mrs. Arthur Hall, very rich orange-scarlet; Vulcan, bright crimson; J. Chamberlain, rich crimson, with very fine quality of petal; Winnie Cook, delicate salmon, flushed with rich sunset hues; Mrs. Heathcote, clear yellow; Pollie, soft rose flowers of very fine shape; Sir Thomas Lipton, very rich deep shaded orange, extra fine; Catullus, rich dark red, large shell-like petals; Mrs. Joseph Chamberlain, delicate blush, extra fine; The General, brilliant scarlet; Mabel Keevil, white, large shell-like petals; and Brightness, a remarkably novel double variety, shaded orange, with white spots, very striking and distinct.

Several of the named varieties in the open ground arrested attention, such as Mme. Gaubier, bright salmon-rose, double, very fine, and Mrs. S. Pope, pale ground, with a distinct Picotee edge of rose, very large, and fine shape.

In the hardy border *Hemerocallis aurantiaca*

major was very fine, and in the open ground was a large batch of Tomato Blackmore's Success, a medium-sized round, red variety, of perfect shape, which was selected seven years ago, and which appeared to be doing remarkably well in a season not favourable to outdoor Tomato culture. Really a very interesting nursery to visit at Carnation time (for a large collection is grown) and when the Begonias are at their best. R. DEAN.

SALE OF POISONS.

The report, published by the committee appointed to consider the sale of poisons, with reference to the Pharmacy Act contains information of much importance to horticulturists, and particularly the following:—

"Under the law as it stands, certain poisons and poisonous compounds (other than liquid carbolic acid for sheepwash or other agricultural or horticultural purpose) cannot be legally retailed except by a registered chemist and druggist, and the Pharmaceutical Society is charged, under the 15th Section of the Act, with the duty of proceeding against unauthorised vendors.

"The administration of this section has been characterised by considerable uncertainty and irregularity, arising, your committee believes, out of the inadequate means at the disposal of the society, which has no staff of inspectors nor other regular machinery for detecting the sale of poisons by unregistered persons.

"It follows from this that the effect of the 749 prosecutions undertaken during the six years 1896-1901 by the Pharmaceutical Society, and of the numerous cases in which penalties were exacted without prosecution, has been very unequally felt; for while the law has been enforced in some districts, it has been wholly inoperative in others.

"Your committee are of opinion that the obligation laid upon the Pharmaceutical Society by the 15th Section of the Act is unduly onerous, seeing that even the limited extent to which they have taken action under it has involved them in a net loss of £700 a year beyond the sums received as penalties, which are due to be dealt with as the Treasury may direct, but which the society has been allowed to retain.

"Inconvenience has been experienced by farmers and gardeners owing to the restriction of the sale of poisonous material to registered chemists and druggists in such districts where there is no such qualified tradesman within easy reach. Your committee are convinced that the inconvenience would have amounted to a very serious interference with legitimate industry had the provisions of the 15th Section been universally put in effect. For example, in the Highlands and islands of Scotland, where sheep farming is the principal business of agriculture, farmers are sometimes upwards of fifty miles distant from the nearest registered chemist and druggist, and the sale of sheep-dips is regularly carried on by ironmongers and other traders, in contravention of the statute.

"A nurseryman and florist in Kent gave evidence as to the extreme inconvenience caused to cultivators when, owing to the successful prosecution of a firm of seedsmen, the sale of weed-killers and insecticides was discontinued by nurserymen. He alleged that in horticulture there are numerous small cultivators and amateurs who would use these materials if they could get them, to the advantage of their greenhouses and gardens; but that chemists and druggists do not know what to recommend, whereas the nurserymen have

knowledge of the proper remedies, and ought to be in a position to supply them.

"Your committee consider that it would be going beyond their reference to suggest changes in the administration of the 15th Section of the Pharmacy Act; they are of opinion, however, that preparations for use in connexion with agriculture, horticulture, or sanitation, might be placed in a third part of the Schedule, to be sold only by licensed persons, and subject to regulations to be made by the Privy Council.

"Your committee further recommend that the traffic in arsenic should be regulated either by an amendment of the Arsenic Act, 1851, or by more stringent enforcement of the provisions of the 17th Section of the Pharmacy Act, 1868."

NOTES FROM SCOTLAND.

THE TRANSACTIONS OF THE SCOTTISH HORTICULTURAL ASSOCIATION are to hand, from which it appears that the year 1902 was the most successful the society has had to record. Abstracts of good papers are provided for the great body of members who are precluded on account of distance from being present at the meetings of the association. We wish the papers were not curtailed, more especially that on "Pear Culture in Pots," by Mr. Moir, Rosehaugh Gardens, Ross-shire. In that extreme northern locality this able gardener produces high class Pears by means of pot culture. This paper is given, if not *in extenso*, at least fairly complete. The following varieties are recommended very highly, viz., Mme. Treyve, Conference, Emile d'Heyst, Princess, Beurré Baltet Père, Glou Morceau, Olivier des Serres, Nouvelle Fulvie, and Pitmaston Duchess, the largest fruits of which are the best flavoured. Some of the above sorts on walls in very favoured positions in Scotland do not succeed, hence the value of a paper like that referred to. It may be added that the lecturer seems to like trees not double grafted. The compost he recommends is worth noting: Gritty loam of red sandstone, ten barrowloads; sharp river sand, lime rubble, charred soil, and wood ashes, two barrowloads each; two bushels charcoal nuts, half a hundredweight of bone-meal, and half a hundredweight of basic slag. Mr. J. Brown, Houston House, Renfrew, one of the best cultivators of vegetables, contributes an excellent paper on "Vegetables for Exhibition"; Dr. Wilson, F.R.S.E., St. Andrew, one on "Experiments on Hybridising," and of the others may be mentioned a discursive paper on the chief northern horticultural societies, tracing their growth, &c.

THE CHRYSANTHEMUM SHOW of the association is fixed for November 19, 20, and 21, thus effecting a change in not having the closing day on a Saturday. A novel item in the prize schedule is a series of prizes, in all amounting to £36 10s., called the Queen Alexandra Prize, and confined to growers within the municipal boundaries of Edinburgh and Leith. In the

ROYAL CALEDONIAN SCHEDULE there is nothing novel, but Mr. and Mrs. Martin White again offer prizes for the best essays on cut flowers, viz., £5, £3, and £2. These sums may at the option of the society be increased, and the donors are prepared to devote £50 towards producing a reliable guide on the subject of flower uses. Last year these essays proved a distinct failure, the essayists as a whole failing to grasp the subject in its chief phases. Mr. P. Murray Thomson, S.S.C., 5, York Place, will be pleased to provide all applicants for information with full details.

THE WEATHER.—SPRING FLOWERS.—If it were not for the high winds and the heavy rainfall flower lovers would have had nothing to complain of as regards the earliness of spring flowers. Besides the usual flowers that we expect in February, I have noted *Iris Krelagei* and *I. reticulata* already in flower. A remarkable feature of the winter is the number of Roses that still carry last year's foliage, and new growth has commenced in the case of the more excitable. Perhaps

more wonderful still is the fact that Rose buds are expanding in one or two instances. The most glorious flowers at present are undoubtedly the Hellebores. They are perfect in colouring and stand upon strong bold foot-stalks that fortunately have never been damaged by frost. During the only severe frost of the winter, though the buds were pushing they were protected by a thick coating of leaves as well as by their own foliage. The prospects of a good Daffodil year are encouraging, the growth being strong, though perhaps pushing forward too hastily. Some of the earlier have, indeed, buds well advanced. Home-grown forced bulbs are, however, not so strong as usual, but notwithstanding the untoward season of 1902 let us hope the Daffodils will have overcome any bad effects previous to flowering.

THE MARKET GARDEN.

WATERCRESS: ITS HISTORY AND CULTIVATION.

A "MAN in Berkshire" and "T. W." ask for a paper upon Watercress growing for market. As the subject will be probably generally interesting, we have decided to reproduce extracts from an excellent paper contributed a few years ago by Mr. Glenny to the Journal of the Royal Agricultural Society of England.

Watercress adds no decided flavour to a mixed salad, but is rather detrimental. In France it is sometimes served up as a dish instead of Spinach, it makes admirable soup, it is used as a decoration to roast fowl, and often instead of Parsley for garnishing. In this country it occupies a unique position, and stands nearly alone in public favour. It is on the table of rich and poor alike, and is appreciated as a relish as well as for its medicinal virtues. No condiment is needed with it but salt, and it loses its individuality when partaken of with any other herb. Watercress grows freely in wet, and especially in shallow, places. It is generally assumed to owe its pungent taste and medicinal value to the presence of an essential oil, containing, like that of Mustard, a considerable quantity of sulphur. But the chief constituent of the essential oil of Watercress, though rich in nitrogen, contains no sulphur. There is, however, much sulphur in one form or another in this plant.

The multitude appreciate highly Watercress, and eat it freely as a simple relish with bread and butter. It may be truly described as the most popular and most wholesome of salad plants. Growing wild in brooks and streams in the neighbourhood of London, it was carried in a basket on the back of the itinerant vendor, and we read of "the barefooted nymph, who at sunrise had dipped her feet into the bubbling runnel, and used to carry this luxury to the breakfast table of our citizens." The

AREA OF CULTIVATION

is spread over Europe, Asia, and America, in the temperate zone of those continents. Watercress has been reported as grown in Hindostan, under sheds. Wherever John Chinaman has settled as a gardener, in Australia or California, there is an abundance of vegetables and salads. On the continent of Europe, Watercress was cultivated to a trivial extent in France at the commencement

of the fourteenth century, in the departments of Oise, Nord, and Pas-de-Calais; but in Paris and the neighbourhood there is no record of its cultivation until the last century. It had been grown previously with marked success in the environs of Erfurt and Dresden, on a large scale, and by intelligent methods.

In England, the regular cultivation commenced rather earlier than in France, for whilst the Frenchman was thinking of his enterprise, an Englishman was already in the field. It was in 1808 that William Bradbery first started Watercress as a crop. Springhead, about a mile and a half from Northfleet, in Kent, close to the out-of-the-way village of Swanscombe, was the birthplace of this adventure, and Cress has been grown there, without intermission, until the present moment. Thus England, Germany, and France have cultivated this plant as a crop for well-nigh a century; and since its introduction as a vegetable it has received a very general and popular support. The primary step in establishing Cress beds is to choose a suitable locality. This must be in the neighbourhood of a populous town, or within a reasonable distance of railway accommodation. Cress needs as much caution in transport to market as Strawberries; consequently the choice of situation is a serious matter, and the disposal of the crop must play an important part in the deliberations. If the journey is prolonged, if delay occurs, the Watercress will suffer on the way, and on its arrival at market will be faded or yellow. Stale

goods are of no value, and unless the Cress has a brilliant dark colour when unpacked it might as well be left at home. Railway companies offer special facilities from certain stations during the Cress season, which afford opportunities for quick delivery. When the formation of Cress beds is under consideration it will be prudent to learn, before commencing operations, what is the train service and what is the rate per ton to an eligible market. The

CHOICE OF SOIL

is an important feature in the success of any crop, and Watercress is no exception to the general rule. Land with a sandy subsoil should be avoided, as much water will disappear by downward filtration, and difficulty will arise with the gangways and the sides of the Cress beds, which will slip in. Wharfing along the sides with short posts and rough boards is used to some extent, but when constructed by the tenant is a serious outlay of capital. Clay land is sticky and awkward to work, and peat requires much judgment in its manipulation, whilst both are apt to give grave inconvenience in wet seasons. Chalk in some places makes a capital foundation for the bed, covered with loam for the rootlets to strike into. Gravelly loam, with a clay basis, retains the water, makes a firm bottom, and furnishes nutriment for the plant. But all will be of no avail without an ample supply of suitable water. The source of the water may arise in natural springs. The prosperity of the Cress bed depends mainly on the continuity, force, and regularity of the current. An abundant and perpetual stream is an absolute necessity, as the health of the plant depends on this condition. Without it the Cress cannot be well nourished, the leaves will be stunted, and there will not be a bountiful growth throughout the season. The water affords protection from the heat of the summer and the cold of the winter, both of which extremes must be guarded against; the

former burns the foliage and makes it sticky (hard); the latter freezes the stems and irretrievably damages the crop. A strong stream, maintaining a fair volume of water during heat and cold, is invaluable. The temperature of the water follows the temperature of the earth whence it originates, and should not fall below 51° Fahrenheit. It does not answer to carry the Cress beds too far from the source, as the water naturally cools down as it travels away from the orifice. This factor limits the length of the Cress beds, for when the temperature of the air is lower than that of the water the latter soon loses heat. Exposed to the cold atmosphere it falls below the required temperature, and the Cress suffers in consequence. Were it not for this hindrance, Cress beds would only be limited by the strength of the stream. The depth of the beds must depend on the level of the stream; some are not above a foot deep, whilst others have been constructed at great expense, and are perhaps 3 feet or 4 feet below the level of the surrounding ground. There must needs be a slight inclination downwards from the spring, so that the water may flow gently through the Cress. The fall of the bed should be extremely gradual, for if the declivity be sharp the celerity of the current increases and washes away the soil, disturbing the plants. A gentle movement of the runlet from end to end of the Cress bed is what is required. The beds are made of no particular size, but mostly follow the configuration of the land; they may be 6 feet or 30 feet in breadth, but in the latter case longitudinal gangways will be required at suitable widths to carry off the crop when picked. These gangways are generally only banks of earth, but in some cases they are cemented on the surface, which makes the labour of gathering easier in a rainy season. Little bridges of rinde planks are constructed across the beds, whilst dams are erected in suitable places to hold back the water at ordinary times, and to give opportunity to flatten down and submerge the plants in severe weather. Different practices prevail in this respect, as the severity of the cold is most felt in exposed situations. In certain months of the year, when the demand for Cress is slack, the beds are cleaned out, and brook water may be utilised for irrigation, but facilities must be at hand to divert all subsidiary supplies at the approach of cold weather. Careful precautions should also be taken to keep out storm water, and special channels must be provided where Cress beds from their level and situation are liable to flood. It may be advisable to construct a tunnel or culvert of a considerable length when there is backwater that may inundate the Cress bed. The best authorities recommend annual cleansing and replanting.

(To be continued.)

TRADE NOTE.

THE FOUR OAKS UNDEXTABLE SYRINGES.

THESE syringes have already received the approval of many eminent practical gardeners. They are guaranteed against

indentation of the working barrel for three years. The illustration herewith given of a section will show how impossible almost it is for the barrel to become indented, on account of its corrugated protective covering.

It is a well-known fact that even the best syringe is irretrievably ruined by the slightest indentation of the barrel, and this is effectually prevented by the Four Oaks

Undeatable Syringe. Gardeners will give this syringe a hearty welcome; in fact, many have already done so, judging from the numerous testimonials received by the Four Oaks

Nursery and Garden Sundries Company, Sutton Coldfield, near Birmingham, and published in the Four Oaks Manual.

Full particulars of all other garden sundries are also given in the Manual.

THE GARDEN

No. 1634.—VOL. LXIII.]

[MARCH 14, 1903

THE CAPE FOR PROFITABLE FRUIT GROWING AND FRUIT EXPORT.

THE following is a continuation of the articles that have appeared already in THE GARDEN upon "Fruit Culture at the Cape." Many young men are embarking for the Cape—some, unfortunately, in search of health, others to acquire knowledge as farmers and fruit growers with a view to remaining permanent settlers on the land. At the meeting of the Horticultural Club on Tuesday last, Mr. H. E. V. Pickstone gave an interesting address upon this subject, and it may be remembered that his name was mentioned in THE GARDEN of October 11, 1902, page 248, as the "skilled Californian orchardist" engaged by the Government department to give lectures at the Cape upon the methods of cultivation.

There are some countries which do not seem to have made a successful draw out of the lucky-bag. They have a share of blessings, and apparently excellent conditions for success in the neck-and-neck race after wealth and prosperity, but somehow the advantages fail to work, and are more or less negated by disadvantages which often are very difficult to define, and whose retarding power can no more be eliminated than can the inevitable constant of friction in a machine. It is thus with the Cape. There is no lovelier climate on earth. All the fruits and crops of the warmer temperate zone grow there to perfection. Health seems almost a matter of course. The laws sit easy on the shoulders of the subject. Yet with all these favourable conditions it has never appeared to the European agriculturist a desirable country of refuge when things went badly with his special industry at home. There are a good many reasons for this. Exploited originally by its former masters, the Dutch East India Company, not on its own merits, and not with a view to its individual prosperity, but solely as a tool required in the management of tropical Dutch colonies further east, the country was for a couple of centuries practically closed to the outer world. It exported little or nothing, and therefore had to stand aside while the roaring stream of traffic rushed on to other lands. Besides, even long after its transfer to England, its acquired habit of self-containedness and easy *laissez-aller* was very little interfered with, and the Colonial Office, while not preventing enterprise, did next to nothing to call it forth locally or introduce it from abroad. It was a land for the more adventurous class of tourist, the sportsman, and the missionary.

The notion which the average Englishman a generation ago had of the Cape was truly curious when considered in the light which gold and diamonds have cast upon it of late years. The inhabitants were supposed to be all Boers, dressed in fustian if they were fairly well off, in leather crackers and *batjes* if less well to do, shod with

veltschoons, and armed with a large waggon whip in one hand and a sjambok in the other. They all lived in the Karoo, which was everywhere outside Cape Town. The people who were not Boers were Hottentots, and this servile race spoke kitchen Dutch, wore nothing but a skin kaross, and rubbed themselves all over with sheep-tail fat and buchu. Nobody but the Hottentots did any work, nobody ever bothered to grow anything for sale, pay any taxes, make anything, do anything, be anything, save give orders to the *scheepsels*, sleep through the hot noon, smoke pipes, and drink Coffee. Every man had a *plaats* which grew as much grain as he wanted, as many Grapes as he cared to make into wine of a sort, as many fruit trees as he had sowed pips, and the rest of the place was in a state of nature, unenclosed bare veldt, not even fenced off from his neighbours', and given over to as many native sheep and goats as would keep him in milk and mutton, with perhaps a couple of dozen oxen. Did he desire to go on a journey, say to the Orange River, 600 miles away, he loaded up a sack of meal and some Coffee, a gridiron, a cooking-pot, and a kettle, spanned in his oxen, and started with a *trek-jou* and a crack of the huge whip. He crept along, road or no road, some twenty miles at most, day after day, stopping whenever and wherever he pleased, quite at home everywhere, and victualled by his marksman skill—for was not the veldt alive with springbucks, koodoos, and elands, to say nothing of elephants and zee-koes? There was no such thing as trespass, for the *woonhuizen* were about one to a dozen square miles, and when the country was so vast and the population so small, what was the good of keeping people off your great wilderness of desert veldt? So in three or four months he reached his destination, and when he chose went home again, just the same easy-going way, a bit at a time. But one never worked hard, never had any definite object in life, never tried to take a new line in anything, but simply lived, enjoying the bright sun and genial climate, and letting things manage themselves.

Something of this sort used to be the prevalent and ludicrous conception of the Cape fifty years ago in the average Englishman's mind when recalling what he had read in books of travel and sport. A land of pleasing drowsiness it was, a country where it was always afternoon. Even now, after the changes of the last half century, Johnny Newcomes are sometimes to be found landing with such Munchausen traditions, and very much surprised to find that the upper and nether millstones of necessity are set pretty close together here and grind exceeding small. And this long-prevailing impression of the easy-going life lived at the Cape, and the belief in the utter recklessness and lack of enterprise among its inhabitants, did the country incalculable injury. It never seemed to loom in the far distance as a land of promise or to beckon to the crowds of emigrants passing westward to the new world. Even the great Irish exodus lent few new-comers hither. What opening could there be in a land already parcelled out, and where it was supposed every man had his huge slice and got out of it all he wanted by the labour of native serfs? And under this idea the outgoing English and Irish labourers trooped away to the States, to Canada, to Australia, and to New Zealand, where a free grant of land awaited them, and

where they knew that each would get his slice on the sole condition of tilling it for his own profit. There certainly was a spasmodic effort in 1820 to fill up a part of the country by immigration from certain English manufacturing counties, just at the period when the inevitable struggle between the old-established hand labour and the new-fangled machine production was commencing, with its inevitable concomitants of falling wages and personal distress. True, also, that with the rank and file of weavers and pin-makers (a crowd exceptionally ill-suited for pioneering as agriculturists in a new land) there came out a contingent of better men, with traditions of the English country life in place of that of the factory, and also with some little capital. And, but for the unhappy series of wars on the frontier, brought about by a one-sided false philanthropy here, and the densest ignorance at home, the Cape East might then, that is, fifty years ago, have started to the front as a progressive colony. But things have moved very slowly, and it has been left to the long-hidden mineral treasures beneath the soil to do for South Africa what neither governments nor local enterprise nor happy climatic conditions have been able to achieve. First the discovery of diamonds on the northern frontier, then the totally unexpected gold production in the Transvaal, revived the memory of the great exodus to the sister colony in 1850-51. There is one thing to be borne in mind concerning these unexpected blessings. They have been earned by our exceptional luck, certainly not by our exceptional desert. We neither toiled nor spun for them. They have dropped into our lap, instead of being won by our industry and enterprise.

EUSTACE PILLANS.

Assistant Agricultural Department of Cape Colony.
(To be continued.)

EDITOR'S TABLE.

CLEMATIS INDIVISA LOBATA.

I am sending for your table flowers of *Clematis indivisa lobata*. All who have a greenhouse and love white flowers should grow this plant for training to the roof or rafters. Nothing can be more useful. Through the summer the plants are best grown outdoors, and should be taken into the greenhouse again in October.—T. B. FIELD, *Ashwellthorpe Hall Gardens, Norwich*.

ABNORMAL CALLA ÆTHIOPICA AND C. ELLIOTTIANA.

Mr. Thomas Winkworth sends from the gardens of Haughton Hall, Tarporley (the residence of Mr. Ralph Brocklebank), curious forms of these beautiful Callas. Those of *Calla æthiopica* were double-spathed, and one approaching to the green colouring of the natural leaf. We have seen similar departures from the normal before, but not of such a pronounced character.

FLOWERS FROM EXETER.

Messrs. R. Veitch and Son, the Royal Nursery, Exeter, send many interesting flowers. They comprise flowers of *Rhododendron nobleanum* and the beautiful variety album (white with reddish spots), *Erica lusitanica* (Codonodes), varieties of *Anemone St. Brigid*, the charming little *Fritillaria armena*, and *Laurustinus lucidum*, all from the open ground.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

March 24. — Royal Horticultural Society's Meeting (Tulip and Hyacinth Show).

March 25. — Liverpool Horticultural Association Spring Show.

April 1. — Royal Botanic Society's Spring Show.

April 4. — Meeting of the Société Française d'Horticulture de Londres.

Forced Asparagus at Syon.—The recent exhibit from the Duke of Northumberland's gardens at Syon House, staged at a recent meeting of the Royal Horticultural Society, illustrates what can be done by annual forcing of permanent beds, and to this method of forcing we would call attention, as grown thus results are obtained at a small cost both in labour and expense. The method of forcing adopted has been given in these pages and is very simple. The same beds are forced every year with excellent results, but only leaves are used, at least for the most part to create a slow heat. Manures are merely used as a top covering. Beds forced in this way last many years; indeed, given good culture they improve yearly. This is a great gain over the ordinary methods of forcing, where the plants are lifted and placed in heat, and are useless afterwards. Another important point is that the grass so forced is very succulent and most of it is edible. The grower does not require glass, but merely protection from cold winds when the growth is active. We note that Mr. Wythes has made this mode of growing early Asparagus a special one for many years, and in some gardens it would be a ready means of getting rid of surplus leaves in the late autumn. The old forcing material is valuable for many purposes, especially so on heavy soils for potting and plunging tender plants in the open.

Water-colour drawings at the Dowdeswell Galleries.—An exhibition of extreme interest to garden enthusiasts is now open at the Dowdeswell Galleries, New Bond Street, "Old World Gardens in England and Italy" being the descriptive title of the show of water-colour studies here exhibited, and to which Mr. E. Arthur Rowe adheres closely, being a collection of, for the most part delightfully quaint old formal gardens, many of them of well known beauty. The colour throughout the series is pure and brilliant. There is a regrettable lack of breadth of treatment, but here, again, in the wealth of detail a direct appeal is made to the flower lover, who recognises with pleasure old-fashioned favourites such as Delphiniums and Peonies. Passing from generalities to a few singled out as being specially noteworthy, we come to "A Grey Day, Castle Ashby" (No. 9), a restrained, sober, little drawing of great delicacy, which is altogether happily carried out. In direct contrast is "The Pergola Walk, Great Tangley Manor" (No. 31), here we have brilliant sunshine lighting up a vista of colour. The artist has evidently felt the enchantment of the grounds at Holme Lacy. Many of his most successful studies have been among the Yew walks there, noticeably No. 17, 18, 35, and 38. Another picture of distinct interest is "Dean Hole's Garden, the Long Border" (No. 54), the bright flower border being very happily rendered; Mr. Rowe has another study treating the same subject, but covering a rather wider range; of the two the smaller seems the more successful. The Italian gardens have not been touched on at all, but "Roses on the Guidecca, Venice" (No. 87), should not be overlooked.

Corylopsis pauciflora at Kew.—In the Himalayan house at Kew a plant of this pretty Japanese shrub is flowering well, the protection afforded by a perfectly cold house being just what it requires about London. Grown outdoors it certainly keeps alive, but does not flower so freely or grow so well as under glass, while the flowers seldom escape being frozen when outside. In the *Garden and Forest* for 1892 a very fine specimen is figured, the dimensions being 6 feet in height and 36 feet in circumference. This particular plant was brought from Japan by Dr. George

Hale in 1874, and was planted by him in his garden in Rhode Island. So far no plant has been recorded in this country with anything like those dimensions. The habit of the shrub is all that can be desired, the branches being borne rather loosely, and are semi-pendulous. The leaves are light green and dainty, and take on a pretty orange or yellow colour previous to falling in autumn. The flowers are borne profusely in short pendulous catkins; they are primrose-yellow in colour with reddish brown anthers. Although, except in favoured localities, it cannot be recommended for the open ground, it is valuable for walls or cold houses.—W. D.

Dwarf French Bean Early Wonder.—The dish of early French Beans staged by Mr. Crook at the recent meeting of the Royal Horticultural Society was meritorious, as the dwarf Bean forced in midwinter is poor and unprofitable, and the plants produce so sparingly that very few can stage a dish of this vegetable at this time of year. Another point often overlooked is that when this vegetable is forced the time taken in maturing the pods should be considered. Mr. Crook gave about seven weeks, if I remember rightly, as the time taken in growing the sample referred to. Now seven weeks at this season is very quick, which proves that the variety can be trusted, and that is a great point in growing this vegetable at the worst season of the year. We grow many dwarf Beans, and endeavour to get them as early as possible, but our worst season is from December to February. There is no great art in growing dwarf Beans, say, from March to June, but there is when the pods are produced from December to March. I know several growers, even in the most favoured localities, who have given up Bean culture at the early season named as being most unprofitable. The pods staged were very tender, a deep green, of medium size, good shape, and superior as far as size goes to some of the older kinds forced at this season.

Sutton's garden Swede in spring. In many gardens great difficulties are experienced in maintaining a good supply of Turnips at this season, as the roots grow out and the flavour is impaired. For some years both in the north and in the south we have relied upon the garden Swede for a spring supply. There are two kinds, the white and the yellow, both being of splendid table quality. Of the two I prefer the yellow, but that is a mere matter of taste, and I am aware some persons would object to the colour. Both kinds I regard as superior to poor Turnips, the Swede being so much sweeter, firmer, and keeping sound until the new Turnips are ready; I mean the first sowing in the open ground. Many would think the Swede a common vegetable. My advice is to try it at this season, and I do not hesitate to say that we have very few, if any, more wholesome vegetables. Though very similar in appearance as regards growth to the field roots, the garden Swede differs in quality. The latter is a dwarf root, having a smaller top. The roots are well shaped, very clean, of good colour, and if sown specially for spring supplies are most useful; they are also very hardy.—G. WYTHES.

Grahame Memorial Fund.—It has been very widely felt amongst rosarians and others that the remarkable services to Rose culture of the late Mr. C. J. Grahame ought to be commemorated by some adequate memorial. Mr. Grahame's services to horticulture in general, and to the National Rose Society in particular, were of no ordinary kind. He was an enthusiastic lover and grower of flowers; he was one of the best and most appreciative of judges, especially of Roses; he was always ready to help any flower show with his accustomed liberality; and his gifts include a beautiful challenge cup for the smaller growers at the National Rose Society. But his special service was the establishment, after much contest, in which at first he was almost single-handed, of the present system of classes at the National Rose Society's exhibitions, according to the number of varieties grown, which in 1892 for the first time gave the smaller growers an adequate chance in the competition. The great value of this reform is now undoubted,

and has been generously acknowledged by those who at first opposed it. If it were for this reason only, there ought to be some memorial of him; but Mr. Grahame's friends were so numerous and so warmly attached to him, that we cannot doubt that an opportunity of the present kind will be very widely welcomed. Subscriptions are earnestly requested as speedily as possible, much time having been already lost. They should be sent to Captain Ramsay, Yvery House, Fareham, Hants. Cheques should be crossed "Capital and Counties Bank." John Ramsay, Yvery House, Fareham, treasurer; G. E. Jeans, Shorwell Vicarage, Isle of Wight, secretary.

The Poison Ivy. — A dangerous plant.—Lord Annesley, in his interesting lecture recorded in the last volume of the Royal Horticultural Society's Journal upon the trees and shrubs at Castlewellan, writes thus of *Rhus Toxicodendron* or Poison Ivy: "A very beautiful climbing plant, somewhat like *Ampelopsis Veitchii*, but smaller and more delicate in the foliage, which turns a reddish yellow in the autumn. Professor Sargent says 'it is one of the common plants in all the central parts of Hondu and Yezo, where it grows to its largest size and climbs into the tops of the tallest trees.' It is so exceedingly dangerous and poisonous that I doubt whether it ought to be allowed in any garden, at least where ladies and children can have access to it. After touching the leaves in a short time the victim becomes aware of irritation in the eyelids, which rapidly increases till it is almost intolerable. They become so swollen that they are almost closed. The rest of the face becomes gradually involved, the eruption and swelling always moving from the forehead downwards. Blisters form upon the surface and weep copiously like those of eczema, the glands of the neck become enlarged, and there is much difficulty in eating or even speaking. Last autumn we had the usual harvest service in the church, and the ladies and children helped to decorate it. Unfortunately, they chose the Poison Ivy to adorn the pulpit, from the beauty of its colouring; one after another they all became ill, some more and some less. The German governess was confined to her bed for more than a week and suffered terribly. One lady consulted a specialist for skin disease, and she was told she had blood poisoning, and went to Harrogate for three weeks. The specialist wrote to me to say that blood poisoning often was caused by bad drains, and strongly advised that they should be tested. I did not quite know what to think about it, when one day three undergrounders were laid up with it, though very slightly. That settled the matter: it was *Rhus Toxicodendron*, and not blood poisoning at all! I heard a story of a lady living in the country who suffered from eczema and blood poisoning every autumn; so bad was it that her husband thought the house unhealthy and decided to leave it and take another, which he did. However, his wife was so fond of a fine plant of *Rhus Toxicodendron* which they had in the garden that she moved it to the new house, and it was not till some time after that she discovered that it was the cause of her illness. It is well to note that this *Rhus* has been sent out by some nurserymen as a variety of *Ampelopsis japonica* under the name of *A. Hoggi*; therefore anyone having a plant under that name should be very careful not to touch it. It is curious that some people are not affected by it, but it is so terribly painful that I do not advise anyone to experiment much with it. I have had the only plant that people could easily get access to in my garden burnt. Mrs. Tweedie in her travels in Mexico mentions that she was confined to her bed for fifteen days from Poison Ivy. She says: 'The parasite in hot climates grows rank, generally in damp shady barrancas, where it spreads prolifically. It is most poisonous when in bloom. Then the pollen flies, and you may be poisoned without touching the plant. The Indians live in constant dread of approaching the creeper. The poison raises large lumps, red and swollen like bites, pus forms, and a kind of blood poisoning attended by pain and danger sets in.'

Prunus tomentosa.—This is a charming shrub belonging to the Apricot section of the

genus *Prunus*, and it is by no means so well known as it ought to be in our gardens. It is among the earliest of the species to flower, and does not appear to be so easily damaged by frost as some early-flowering shrubs. At Kew it has been in cultivation since 1888, a plant having been sent to the Royal Gardens in that year from the Paris Botanical Garden, other plants being sent at a later date from the Arnold Arboretum. Seeds of it appear to have been sent to the Arnold Arboretum as long ago as 1882, Dr. E. Bretschneider having collected them on the mountains about Peking. Like many other shrubs from the East it inhabits both China and Japan, and it is described as being a beautiful shrub both in flower and fruit. So far fruits have not been matured at Kew, but on several occasions it has been recorded as fruiting freely in America, the fruits of some forms being pleasant to eat. Although when mature it attains a height of from 6 feet to 8 feet it flowers freely in quite a small state. The flowers are borne in profusion, are white in colour and half an inch across, the flowering period being February and March. In America the fruit is said to ripen during June and July. In form the fruit is Cherry-like, in colour red. As it makes a shapely bush and flowers freely in a small state, it should form an excellent subject for forcing for the greenhouse in January.—W. DALLIMORE.

Etherisation of plants.—Some interesting statements upon this subject were made by M. Lemoine in his lecture recently given before the Royal Horticultural Society. He said by experiments it had been proved that some plants were more quickly forced into flower by the use of ether. Previous to being placed in the forcing house the plants in sealed boxes were subjected to ether for two periods of forty-eight hours. This had the effect of bringing them into flower quite a fortnight earlier than plants not so treated.

The Carnation fly.—I do not think the larger grower of the Carnation will quite agree with your correspondent, M. Mitchell, when (see issue of THE GARDEN, January 10, page 32) the above pest is spoken of as not one of the very common pests that assail this favourite flower. It is so abundant in this district as to have ruined some thousands of plants last season alone. This, too, in a by no means large area and to my personal knowledge. Indeed, I think I may say I have lost a long way over a thousand plants that were layered in the open through this pest, and I am not alone. Two neighbours, each widely apart from the other and in opposite directions, have also fared badly. The same two lost a large number the year previous, and took care to burn all affected plants. The fly is present and active, too, for a much longer season than is usually supposed. Under these circumstances, I am ever a ready reader of anything concerning the pest, in the hope some day of securing a remedy, or, better still, a preventive measure. This fly is called the Carnation fly, but it is curious to note the difference of pot plants standing in the open as compared to layers layered in the soil. This leads me to ask whether, as the pot plants are set upon a bed of black ashes, these ashes in any way act as a deterrent to the fly, whether the colour is objectionable. Black gauze or muslin is to some extent supposed to act as a deterrent to swarms of bees in certain instances. If so, we had best put the plants into mourning as soon as they are layered. Be this as it may, it is an undeniable fact that while pot plants are not affected to barely 1 per cent., layers in the soil may be even to 50 per cent., and far worse if the grower permits the ground to become weedy at the time. Indeed, a weedy plot may be responsible for a very large increase of the maggot, which seems that the fly may be even more attracted by the weeds than by the Carnation plants. This is no fancy, but a fact, therefore keep the soil about the plants absolutely clean and free from weeds. The above may be proved by taking note of the layers in a bed on the lawn as against others in a large quarter with soil only around. Formerly, I had an idea that the fat-leaved kinds, such as Old Clove, Gloire de Nancy, &c., offered a greater attraction to the pest, but I have since found the narrow leaved sorts

equally badly attacked. Syringing the plants with Quassia and Tobacco water may possibly render them less liable to attack. Then on the other side one may ask, Why do Tree Carnations in pots escape the fly? They assuredly do so! Is it that the soil of the open garden is more the haunt of the pest and the dark colour usual of the standing ground in a sense opposed to their nature? If so, we have at least a clue to their likes and dislikes.—E. JENKINS, Hampton Hill.

Cacao in Trinidad.—On the authority of the *Agricultural News* we learn that the Cacao crop of Trinidad is expected to be a very large one this season, and that the *Port of Spain Gazette* estimated that during the month of December last close upon 20,000 bags (of 130lb. each) would have been brought down by the railway.

Melons.—Referring to a recent article upon Melons, I have never stated that Melons were not well grown; but I may have said, as I say now, that so uncertain are Melons that when grown as well as it is possible to produce them they cannot always be relied upon to display those high qualities of flavour which they sometimes show. That is the great weakness of Melons, and no new variety has overcome that defect. Still further, I assert fearlessly that in the matter of flavour we have not in the past twenty years advanced one atom. We have some varieties no doubt which produce better crops, or even handsomer fruit, or even maybe a little easier to cultivate; but even so much is questionable. Many of the fruits which come before the fruit committee of the Royal Horticultural Society are superb examples of culture, and grown, too, under varying conditions, yet so largely have they, perhaps, a nice soft flesh devoid of flavour, or are the product of crosses between scarlet and green varieties, the product fruits showing the inner flesh soft, pulpy, and scarlet, the outer flesh green, hard, uneatable. Really, Melons have been crossed and intercrossed so much that they rather retrograde than advance. If anyone could give us a variety that, well grown and not over-fruited, should in every fruit give high class flesh and flavour without variation to mediocrity, then the gain would be immense. Setting up high class Apples, Pears, Peaches, Plums, Grapes, Strawberries, Pine-apples, and Cherries are standards of excellence always reliable. We have nothing in Melons like them. The quality of Melons is as varied and mutable as is the weather. In cutting a fruit you never know what you may find.

Costly Potatoes.—The offering in commerce of some varieties of Potatoes that are new at the high figure of 10s. per lb., may be to many persons a form of investment that is hardly safe or desirable, yet there have been cases in which high figures have been repaid practically 100 per cent. That was so a good many years since, when Messrs. Hooper and Co. imported from America and sold here at very high prices two heavy cropping varieties of Potatoes. A competition for the greatest produce from 1lb. of seed tubers of each variety resulted in the production of some 13 bushels in one case and about 8 bushels in the other. Thus the original outlay was repaid fully one hundredfold. That so great a product may result from similar methods of propagation of English varieties as was seen then is not probable, because home-raised tubers have fewer eyes. But no doubt were a pound each of a couple of these 10s. per lb. varieties put into warmth, caused to push shoots, these being employed as cuttings and rooted, then in time planted out into good soil, each variety could be made to produce several bushels in return.

Two months' rainfall.—It is interesting to learn from the County Hall at Kingston-on-Thames that the registered rainfall up to the end of February exceeded by 2 inches that of the months of January and February of last year. That is indeed satisfactory, and yet we have not had any appreciable heavy downfall of rain in the time. Slow rains or drizzles, with much cloud and absence of sunshine, yet giving great mildness, have been the marked characteristics of the year so far. We find if the wind comes from the north or east that it is dry and exceedingly cold,

very trying to both animal and vegetable life, yet it has the merit of keeping vegetable life in check. But the reverse conditions most generally have prevailed, the wind being west, south, or intermediate, and often very boisterous. This has brought much cloud, great dullness, and drizzle, also soft atmospheric conditions that have been so far acceptable, yet encourage too much vegetable growth. This naturally creates great uneasiness so far as the fruit crop is concerned, and militates against hopeful prospects.

Fruit preserves.—If the examples of preserved fruit shown on the 24th ult. at the Drill Hall from New York are to be regarded as presenting the best of what the United States can show in the matter of fruit preserving in bottles, it is evident that here at home we can excel our Transatlantic friends a long way in that industry. Possibly, in relation to climate, they have advantages we do not possess, but the country over there is of such enormous extent that it almost includes the regions of the tropical and the Arctic circles. Our more humid climate has its variations, and for fruit culture far too many to be pleasant, but all the same, given that high-class culture which marks the good class British grower, we can produce fruit second to none anywhere. That is so much to our credit, because on the whole Nature favours us so little. Still, we cannot grow Peaches, Nectarines, and Apricots on ordinary standard trees as is done in America, and these fruits in a commercial sense cannot enter into our fruit preserving industry, except in a very limited way. But we do grow and preserve, whether in the form of jam or jelly, or in bottles, Apples, Pears, Plums, Cherries, Gooseberries, Currants, Raspberries, and Strawberries in the finest possible condition. Our fruits in their natural form are superb, and when preserved as our bottlers or preservers now do them cannot be excelled. The New York fruit preserves shown at the Drill Hall were all so highly charged with glucose saccharine as to be far too sweet—indeed were, when tasted, quite unpleasantly so. In them all natural flavours were killed. Whole Pears, apparently first soaked in alcohol or in vinegar, then put into syrup, were devoid of natural flavour entirely, though, perhaps, pandering to created palates. Some of the members of the committee spoke strongly against the granting of any award to the exhibit for the reasons named and undoubted inferiority to home products. I could not agree with a suggestion that it was not the duty of the committee to encourage the introduction of preserved fruit from America or elsewhere outside the United Kingdom. That was taking a very parochial view of the subject, which happily found few supporters. Horticulture, it is to be hoped, is far too cosmopolitan to be here influenced by such insular ideas. We must welcome all good products, come whence they may, and try, if in our power, to excel them if possible. Certainly we have done that in relation to fruit culture, and most materially so in respect of fruit preservation as a commercial industry. Apart from the exceeding excellence of our home preserving, whether in the form of jams, or jellies, or whole, our bottling methods are so much superior. The hydrostatic capsule, as now so largely employed here, is a long way ahead of anything seen on the New York bottles. All the same, the enterprise of the lady exhibitor of those merits praise.—A. DEAN.

A West Indian Nettle.—The *Agricultural News* of Barbados draws attention to a formidable stinging plant under the name of West Indian Nettle which is met with in some of those islands. The plant in question is not a Nettle as we understand that term, but a member of the order Loasee—*Mentzelia aspera*. The genus consists of hardy annual, biennial, or perennial herbaceous plants, for the most part coming from Mexico, California, and the Southern United States. Our colonial contemporary says wherever it is found it is carefully shunned by all classes of the community. It is a large green annual weed about 3 feet to 5 feet high. It is rather common in Nevis by the roadside beyond the Bath. It is also found in Grenada, and, according to Grisebach, it occurs in dry savannahs near

Kingston in Jamaica. It may readily be recognised by its rather large, rough, green leaves, somewhat resembling those of the Castor Oil plant. The flowers are small, white or yellow, star-shaped, and produced at the ends of the branches. Every part is covered with stinging hairs, and if incautiously handled the plant may cause considerable pain, and not infrequently fever. Some well-known garden plants belonging to the genus *Loasa* will be familiar as close allies to *Mentzelia*, and as possessing the same stinging properties. — JOHN R. JACKSON, *Claremont, Lympstone, South Devon.*

Arctic Garden at Kew.—An extract from the *Times* was sent by the editor of the *Cold Storage and Ice Trades Review*, in which it was suggested that an Arctic house should be formed at Kew, "wherein dwarf Willows and other curious vegetation of the Polar regions might be seen associated with some pretty effects of snow and ice, which might be produced in summer." It was observed by the committee that Arctic plants grow better in temperate climates than in the Arctic regions, as *Papaver nudicaule*, which is found in Spitzbergen, and that many of them are now growing in Kew Gardens, so that the addition of a cold house would be superfluous. — *From Report of last Scientific Committee, Royal Horticultural Society.*

Flower gardening in the grass at Kew.—Flowers are appearing in abundance now in the grass at Kew. Our illustration shows a sea of Daffodils in the lower part of the gardens. We have frequently described the grass gardening at Kew, and the illustration will remind those who wish to create such pictures in their own gardens of the wealth of available kinds, and of the best ways to use them.

ROUND ABOUT A GARDEN.

AN ILL-OMENED LETTER.

MOST of the worst things in a garden seem to begin with W. There are Worms and Wire-worms, White Butterflies and Winter Moths, and many kinds of Whats-its-names that reduce the leaves of foliage plants to a sort of fine lacework—Weevils, Wandering Cats, and Wild Animals; the Willow Wren when the Peas are ripening, and the Weather at all seasons; but about the Worst of the W.'s for

the garden is the Wind. The "big W" might almost take the place in horticultural expletive of the "big D" familiar to annoyed persons who are otherwise employed.

THE WINDS OF FEBRUARY.

We certainly want some soothing phrase to help us to express all that we have felt respecting the wind during the last month. The essential thing about a garden, to my mind, is that you should know, when you get up in the morning, on which side of the house to look for it. Owners of sheltered inland gardens may never be in doubt under this head, but when you have tried to anchor a garden on a seaward slope and hear the earth from your front flower-beds pattering against the dining-room window, you have little confidence of finding things "as they were" next day. When, moreover, you have two conspicuous flower-beds shaped like Maltese crosses and filled with growing bulbs, what are you to say when a large bough of a Poplar tree comes bang into the middle of one of them?

THE COMMON PRIMROSE.

These are aggravating thoughts, however, so let us get away from them—and the wind—into the shubbery, where the Primroses and Violets are a delight. Perhaps the soil has something to do with it; but my experience is that no flower repays you literally a hundred-fold for any little care bestowed upon it, except the Primrose. There are Primroses of many colours, and Polyanthus Primulas of many more; but if you eschew all these, and, having a wild shrubbery that is almost a coppice, stuff it with the common wild Primrose you will find that you have done the best day's gardening of your life, because it will be a growing joy for years to come.

A FIGHTING PLANT.

For the Primrose, given suitable soil, is a gladiator among plants. You would not suspect this from its appearance. Its beauty is that of tenderness and modesty, but you would soon discover the truth if you had to struggle against it for growing space. That neat rosette of crinkly, deep green leaves looks

simple and humble; but it must have killed scores of rival plants in order to occupy so much space. What was a seedling Primrose last year is a rich-flowering clump to-day. Next year it will be a large patch of Primroses, and the year after a Primrose-bed. The Primrose achieves this end by strict attention to business.

PATIENCE AND PERSEVERANCE.

The seedling Primrose seems a feeble thing. It has, perhaps, half a dozen small flat leaves, none of which rise 2 inches above the ground, and it is smothered out of sight by the woodland weeds around it. But the Primrose can stand a great deal of smothering in summer and autumn when it has done its work; and when the rain and snow and wind of winter have reduced the rampant weeds to their original constituents as leaf-mould, the Primrose comes uppermost again with twice as many leaves as before. Every leaf is larger, too; but it still spreads itself out humbly as a tufted rosette upon the soil. Yet it occupies 16 square inches of ground, instead of the eight which it held when you saw it last. The Primrose is not idle when it is out of sight in summer.

A STURDY COLONIST.

And the ground which the Primrose occupies it holds. It is no use for weeds to scatter their seeds over it. The leaves of the Primrose smother the seedlings, and unless shrubs or trees, with their deep roots, drain the soil under the Primrose it remains in undisputed ownership of so much soil as its close-packed leaves can cover. And at this season it flowers profusely. Later, the flower-stalks will bend outwards on every side with their heavy heads of ripened seed. These will lie flat upon the ground, and over them the Primrose will spread out a wide circle of flat leaves which will cover them entirely. Over these again the woodland weeds may flourish luxuriantly as they did before, but it will not matter.

THE WAR OF PLANTS.

When the weeds have died in winter, what shall we see? Why, that from the seed-pods, sheltered by the spreading rosette of leaves, a score of strong seedlings have sprung; and, since these cannot spread inwards—where the parent plant still occupies the ground—they all spread outwards. Each occupies and holds its own little patch of ground; and, though buried out of sight in summer and autumn, each reappears, after winter's storms, as the settled owner of its own square inches of soil. It is no use whatever for other herbaceous plants—except a few like the creeping *Ranunculus* or the *Periwinkle*, which can creep along the ground like snakes, and so get under the Primrose's defence—to jostle the Primrose. Its trick of sending its leaves straight up in the first instance and then letting them fall outwards, layer upon layer, ensures them the upper hand of rivals; and, in the struggle of small plants for daylight, whoever goes under dies. Thus year by year the Primrose spreads in a wider circle, smothering out even the grass, and since there is no flowering plant which more graciously arranges itself in starry constellations of early bloom in spring, you will never regret converting your shrubbery path into a milky way of Primroses.

DAFFODILS IN THE GRASS AT KEW. (From a photograph taken last spring.)

THE INDOOR GARDEN.

PRUNUS SUBHIRTELLA.

COMPOSED largely of species and varieties which flower in spring is the *Cerasus* section of the genus *Prunus*. The species under notice is probably the rarest in the section in British gardens, for it has not been sufficiently long in cultivation to become well known. It was first sent to Kew about eight years ago by Professor Sargent, director of the Arnold Arboretum, and it flowered and was figured in the *Botanical Magazine*, t. 7508, in April, 1896. Its native country is Japan, and it is said to be found in quantity on the mountains of Nippon. Although a native of Japan it is popular in that country, being known under the name of Higansakura, and grown for the sake of its flowers. In habit it forms a small tree with a bushy head. The leaves are 2 inches to 3 inches long, ovate and acuminate, with serrated margins. The flowers, which appear about the end of March or beginning of April, in advance of the leaves, are borne in small fascicles of from three to five blooms each. Individually the flowers are three-quarters of an inch across, and white with a tinge of pink. In addition to being a useful outdoor tree, the accompanying illustration gives a good idea of its value for forcing, the specimen shown in the photograph having been in flower in the greenhouse at Kew for over a fortnight. It is not difficult to grow. The subject of the illustration is one of a number rooted four years ago from cuttings and grown in nursery quarters until January of the present year, when it was lifted for forcing. It is 3½ feet high and 2 feet through. W. DALLIMORE.

out by the end of May, care being taken to harden them off very gradually. Ample space should be allowed them as they grow very rapidly, forming plants 1 foot to 1½ feet across in a season in the open ground. Some prefer to put out old plants into beds, but they are not generally so successful, unless they have been cut right down so as to form a stool from which strong upright shoots will grow, or trained with a foot at least of clear stem, otherwise they are apt to grow too compactly and form a dense mass of foliage which hides the bloom, instead of bold upward-growing sprays. As different Fuchsias grow such varying heights, some slowly and some quickly, the most successful bed is that of one sort only, and any of the stronger growing single Fuchsias will do for the purpose, the single being the better as a rule, as they are of such free growth, though of course there are exceptions. If mixed varieties are put in a bed some judgment is necessary in arranging them or the bed may have a very lop-sided appearance. A bed of good Fuchsias, unless a stock already exists, is a somewhat expensive one. One or two varieties, which, though by no means among the best as specimen plants, make very good bedding plants, are *Beauty of Trowbridge*, white sepals with pink corolla; *Mme. Corneillioen*, similar to the preceding; *Wave of Life*, golden foliage, scarlet sepals and violet corolla; *Sunray*, variegated foliage; and *Fuchsia macrostemma globosa*, dark handsome foliage and a free bloomer, but not a showy one, as the sepals are not at all reflexed.

THE RARE PRUNUS SUBHIRTELLA IN FLOWER IN THE GREENHOUSE AT KEW IN LATE FEBRUARY.

FUCHSIAS FOR GREENHOUSE AND BORDER.

(Continued from page 140.)
GREENHOUSE CLIMBERS.

ANYONE who knows Kew at all well will remember the climbing Fuchsias in the houses there, running riot across the roof and forming a canopy of hanging blossoms. For this style of growth the young plants should be confined to a single stem by pinching in all the side shoots, secondary as well as primary, not removing them at first, but leaving a pair of leaves to each, as they will help to thicken the stem and add to the vigour of the plant. When the plant gets 5 feet or 6 feet high, and the stem is getting thick and woody, these lower side shoots may be removed one or two at a time, beginning at the bottom, and the plant either put into a large pot or into the soil, so that the plant can be trained up against a rafter. If kept growing in a gentle heat and never allowed to get stunted for want of room, or to use its strength in producing bloom, the plant should reach this height some time during the second season. Amongst the sorts suitable for this purpose may be mentioned the old-fashioned *Rose of Castile*, the equally old-fashioned *Venus de Medici*, *Royal Standard*, *General Roberts* (the corolla and sepals of which form a fine contrast), and *Charming*. These will all become climbers fairly rapidly, and there are many others that will answer the purpose, though some will take a longer time. *Fuchsia corallina* and *F. gracilis* are two beautiful species for this purpose, but as they are very hardy room in a greenhouse is not often spared for them.

BEDDING PLANTS.

These may be all of one sort, like the bed of *Fuchsia macrostemma globosa* at Kew last summer, or they may be of mixed varieties. If the cuttings are taken in February or early March in heat, or rooted cuttings are bought in March or early April, they will make nice little bushy plants for bedding

ALGER PETTS.

(To be continued.)

NOTES ON HARDY PLANTS

IRIS SINDJARENSIS.

SINCE February 16 this early bulbous *Iris* from Mesopotamia has been in flower in my unheated greenhouse. It is not often mentioned amongst the newer race of winter-flowering Irises, and is of somewhat different type from most of them, but has many good points which make it worthy of notice. It grows to a height of 9 inches to 12 inches, and has long stem-clasping leaves, which are deeply channelled and tapering in growth. The flowers are produced in a spike thrown well above the arched and drooping foliage, and are of a soft slate blue, shading off at the ends of the broad, crested falls to cream colour. In character they suggest a small form of *I. xiphoides*, and grow alternately on the stem to which they are so closely adpressed that they lose a little in effectiveness, which seems to be the only drawback to this desirable species. The topmost flower opens first, lasting about a week, and the rest follow in succession, but more quickly, so that several are open at

once, and last well. This staying power, which is beyond most, and is possessed by *I. sindjarensis* in common with several of the more recent introductions from Asia Minor, like *I. Heldreichii*, is much in its favour, and it seems admirably adapted for winter-flowering in an alpine or unheated greenhouse. Like *I. reticulata* it is very sweet-scented. Though I have several strong bulbs, only one has flowered, and that by no means the strongest plant, but the foliage is ornamental in itself. I received them in the autumn from M. Tubergen, jun., of Haarlem, but am not sure whether they were collected or cultivated bulbs, and it will be interesting to see how they will fare with such summer treatment as can be given them. K. L. D.

HARDY FLOWER NOTES.

ENCRUSTED SAXIFRAGES.—It is in the winter, when there is so little to charm in the outdoor garden, that the beauty of these little alpine gems can be fully appreciated. Varieties of *Aizoon*, such as *altissima* and *intermedia*, in the form of good-sized clumps, are charming, and the big rosettes of *pyramidalis*, arranging themselves among stones at an angle which guarantees the crown against excess of moisture, are finer in colour than I have ever seen them. Such little gems as *crustata*, *cochlearis major*, and *rosularis* have this year with me made an exceptionally fine growth. Although these little alpine dislike stagnant moisture round the crowns or roots, they in common with the rest of the family dearly love an abundant supply of moisture in summer and early autumn. The frequent rains in the autumn of the past season did this class of hardy flowers an immense amount of good, the crowns

GALANTHUS IMPERATI ATKINSII.

(The natural size is: Height, 12½ inches; sepals, 1¼ inches in length.)

being larger and the encrustations much brighter than usual.

HARDY CYCLAMEN.—*C. Coum* and its near relative *Atkinsoni* are now throwing up their earliest blooms. All through the winter they have delighted with their handsome more or less variegated foliage, which, although it droops and looks withered in a time of hard frosts and very cold winds, revives and recovers its primitive freshness and beauty as soon as mild weather again sets in. If you have a score or so of these Cyclamens, do not fritter them away by dotting them about, but plant them in colonies, where they may cover the ground with their handsome foliage, and where they may get any special attention such as an annual top-dressing of some very light material, and where the soil around them is never touched by fork or hoe.

CROCUS IMPERATI.—One may go through a score of gardens, large and small, without seeing one of the winter-blooming species of *Crocus*. To most hardy flower lovers they seem, indeed, to be unknown. There are about a score of them in cultivation, and by their use the outdoor garden may be made enjoyable from mid-January till April, just the time of year when there is so little floral beauty in the open air. The above-mentioned species is one of the best, and as it can now be bought at about 4s. per 100, there is no reason why it should not be largely used, not only in the garden, but also in the woodland; and seeing that it is almost as vigorous as the common spring-flowering ones, there should be no difficulty

in naturalising it in the grass. It is surprising how bravely the apparently fragile flowers withstand inclement weather. I have known them pass safely through 20° of frost and then expand their delicately-tinted blooms as freely as if nothing in the way of bad weather had been experienced.

IRIS STYLOSA.—It is a pity that this is not a bit hardier so that it could be extensively used as an occupant of the herbaceous border. In the warmest portions of the British Isles, where not more than 15° of frost are ever experienced, this *Iris* may certainly be so used, as even if a few flowers are cut off others follow ready to expand on change of weather. A clump of this *Iris* established some five or six years will bear a large number of flowers, which are of great use for cutting, and which come at a time when anything in the way of flowers is so welcome. In the colder portions of the British Isles I should advise that this *Iris* be either grown in pots or planted out in a cool house. It is a capital subject for unheated structures. I have several clumps of the white variety planted out against the back wall of a vinery where no heat is used in winter, and for the last two months they have given a succession of good blooms. In the warmer counties this *Iris* will do very well in the open ground if sheltered from east and north wind. The foot of a south wall is the best place, as there the growths get fully ripened.

J. CORNHILL.

A RARE SNOWDROP.

"It is impossible," to quote the words of Henry Phillips in his delightful "*Flora Historica*," "to observe the Snowdrop without acknowledging with what infinite wisdom Nature has formed her lowest works. The delicacy with which the corolla is attached to the flower-stalk enables it to move with the winds in every direction, without fear of snapping or suffering the air to defraud the stigma of its necessary part of the farina, whilst its modest and pendent position is calculated to throw off all superfluous moisture in order that the parts of fructification may be so secured as to replenish the earth with its seed. The pure white that is given to the petals of this flower contributes, in a no less happy degree, to the perfecting of the pollen, as it causes them to act as reflectors to throw all the light and warmth on the anthers, which at the chilling season of the year, when the Snowdrop flowers, are particularly necessary."

Of course everyone grows the common Snowdrop (*Galanthus nivalis*), but there are few who have interested themselves in the rarer *Galanthi*, and the writer can only claim to be a novice in the matter. Amongst those who have made a special study of these charming flowers several names

will at once occur to readers of *THE GARDEN*, notably those of the late Mr. James Atkins, Mr. James Allen, Mr. S. Arnott, and Mr. Whittall, who has enriched our gardens with several beautiful varieties.

Galanthus Imperati Atkinsii came to my garden through the kindness of Mr. Arnott, and I believe I am right in saying that it came originally from the late Mr. James Atkins of Painswick. It was the first Snowdrop to come into bloom in this garden, and its noble appearance and beautiful flowers attracted considerable attention. One thing seems rather difficult of explanation, and that is the reason why one bulb should produce two flowers—one of perfect form and the other mis-shapen. I send a photograph in which this defect—to a certain extent caused by an additional perianth segment—will be clearly seen. The height of this beautiful Snowdrop was 12½ inches—10½ inches without including the spathe—and its lovely snow-white sepals, which are of singular beauty, were 1¼ inches in length. These are further set off by the petals, which are irregularly marked with light green on the interior, as well as slightly on the exterior, and also by the orange-tinted stamens. The leaves are sturdy, and attract immediate notice on account of their large size, and, as they spear their way through the ground, at first sight one would almost take them for those of a Daffodil.

Kidderminster.

A. R. GOODWIN.

PLANTS FOR CUT FLOWERS.

ESTABLISHED clumps of hardy perennials that are specially in request for cut flowers should have been overhauled in the autumn, but if this was not done they ought to be taken in hand at once. It is strange how the opinion "that any sort of soil and treatment will do for hardy flowers, and that once planted they may be left alone for many years," still holds good with many. It is doubtless true, in a certain sense, for the hardy flowers of the border are long-suffering, but it is also true that they respond quite as much as fruit and vegetables to good treatment. There is no comparison as to the quality of flowers obtained from a clump that is well cared for and that which is left to shift for itself. I have said that any replanting should be taken in hand at once, and this is especially true of the earlier flowering things, such as *Doronicum excelsum*, *Aquilegia Stuarti*, *A. glandulosa*, and *Pyrethrums*, also the tall *Campanulas*, *Linum narbonneuse*, *Pentstemon barbatus*, with other things that require some time to get a firm grip of the ground. Lift and replant, carefully selecting the strongest pieces, work in a bit of fresh soil and well-decomposed cow manure if the border is poor, and mulch rather heavily (the last is imperative after spring planting on light soils). I may note that in the arrangement of borders planters will have to be guided in a great measure by the taste of employers. Big heavy masses and few species may be required in one place, and in another the order may be small clumps and plenty of variety. Where the latter is the case it is always advisable to sow a few packets of really good things annually so that plenty of stock is available when established things on borders are deteriorating. Pay special attention to plants that are inclined to ramble, as *Hemerocallis*, some of the *Asters*, *Pyrethrum nigrinosum*, and the like, and keep them well within bounds.

E. BURRELL.

GERMINATION OF SEEDS UNDER SNOW.

IN my book on the cultivation and acclimatation of mountain plants, I have already treated of this subject, and especially of seeds of alpine plants which are of slow and difficult germination, for instance those of the *Gentian* and *Primula*. Yet I should like to make known some new and curious facts, which appear to me to be likely to interest your readers. Last autumn (about the middle of November) a snowstorm, accompanied with severely cold weather, took place in the neighbourhood of Paris. I profited by it, as I do

every year, to sow not only seeds of alpine plants, but also of perennial and annual plants which I cultivate. Now in my mountain excursion last year (I chose the Engadine) I gathered some specimens, in the Col de l'Albula, of *Primula integrifolia*, that charming alpine Primrose with large flowers of lilac-pink, and of *Doronicum glaciale*, bearing Marguerite-like flowers of golden-yellow, similar to the flowers of *Arnica montana*, but yellow not orange, which I found side by side, close to a field of snow. These plants, pulled up while in full blossom at the beginning of July, 1902, were kept for a month in my bag, and accompanied me in my excursions until the commencement of September.

During their peregrinations seeds had begun to form and ripened in October, after the plants had been planted in my rockery. I had scarcely any hope that these seeds—taken as they were from plants uprooted while still in leaf, and which had undergone a month's sojourn in my trunk, and which had been transplanted from their mountain heights to Paris—would germinate. To my great astonishment, however, these seeds, placed in earthenware pans containing soil and exposed to the direct action of the snow, sprang up within a month, and the young plants have already been repotted and are in perfect health. I am convinced that these seeds sown only in the spring would never have germinated without the help of the snow; and, as I said before, it is not a question of bringing the snow to facilitate and hasten the germination of the seeds of alpine plants alone. All horticulturists, in order to obtain a more rapid and more abundant germination, as well as more vigorous seedlings, should sow all kinds of seeds under the snow. I will give two examples.

All the world knows and appreciates the hybrid plant called *Mimulus cupreus*, which is in much request for garden borders. Gardeners generally sow this plant in autumn, preserve the seedlings in pans and pots during the winter, and do not plant out till after May 15. Instead of this they ought to sow it in winter under the snow, and then they would be able by March 15, two months after sowing, to have the plants in the open ground ready to blossom. I tried the experiment at Boulogne in 1902. Let us now take the example of a perennial plant, viz., that of *Primula verticillata*, that pretty yellow-flowered Primrose which came originally from Abyssinia, and whose seeds germinate very freely under snow, though the plant itself must be kept through the winter, either under a glass frame or in a slightly heated greenhouse. Horticulturists think it is not possible to get flowers on the young plants before the second year. They sow in the spring, prick out into pans in the summer, and again into pots for the autumn, and get no flowers until the following year. I ask why do they thus lose a year? My experience in this respect also refers to the year 1902. In January I sowed under the snow some seeds of this Primrose, and since October I have had a quantity of these plants in blossom.

But why multiply examples? The fact is indisputable; and I ask, why do horticulturists still refuse to adopt this method of sowing? I will not speak again here of the different methods employed, for I have already given the details, that is to say, as to sowing in pans with the soil covering the seed, in pans exposed to the snow, sowing in pans already covered with snow, and finally sowing upon soil placed in the bottom of pans and directly exposed to the snow. I always practise the third method, for I consider that it gives more rapid results. When the snow has melted the pans must be taken into a greenhouse or placed under glass frames slightly heated, and the seeds be slightly covered with soil suitable to the particular plants. They should be watered just sufficiently to maintain humidity, and in a few days germination will result.

This action of the snow upon the germination, though hardly at present explicable, is undeniable. Moreover, agriculturists have noticed that in the fields cereals shoot much more vigorously if their seeds germinate when snow covers the soil. Have they not already tried in France, as in other countries, to double the cereal crops by means of metallic plates placed in the soil and connected with poles for conducting the electricity to them? This year, if the weather permits, I am going to try the result of submitting seeds of alpine plants, before sowing them, to the action of the snow, without any soil above or below them; then after a few days I will sow the seeds thus "electrified" in pans in the ordinary way. I have spoken of the seeds as "electrified," for it really seems as if by the action of the snow a more or less intense electric phenomenon was produced, accompanied by a development of vitality in the seeds.

G. MAGNE, in *Le Jardin*.

THE FLOWER GARDEN.

CALCEOLARIA INTEGRIFOLIA.

SELDOM seen in gardens is this *Calceolaria*, and I have never met with it in quantity except in one spot in South Devon, namely, Kingswear, at the mouth of the Dart. It is also to be found in gardens a few miles distant from this place, and I have noticed it in a Cornish garden, whose proprietor also owns a seat on the banks of the Dart, in close proximity to Kingswear. The inference in these cases is that the plants in question are descended from the original Kingswear stock. I have endeavoured to ascertain the source from which these plants, with whose race I have been familiar for over twenty years, were first obtained, but without success. Apparently, from the uncertain date of its introduction to the present time, it has been grown merely as a showy subject of easy culture, rather hardier than the majority of shrubby *Veronicas* so much in evidence along the south-western coast line. As seen at Kingswear it is not a

herbaceous plant, but a flowering shrub that is a sheet of bright yellow in July, and carries a fair amount of flowers well into October. It is very common, and is to be found in cottage and farmhouse gardens as well as in the grounds surrounding the larger residences, and is invaluable for its masses of glowing colour. As far as I know it is never killed by frost, which is rarely severe in this spot, as it is entirely sheltered from the north and east, and whose steep slope immediately overlooks the salt water; but old bushes have a way of becoming bare in their lower branches, when they are usually destroyed and their places filled by young plants. For this reason it is hard to say to what size this *Calceolaria* will attain, but during the past summer I measured a single bush standing in an isolated position, which proved to be 5 feet 6 inches in height and 7 feet in diameter. The plants in the border shown in the accompanying illustration average over 4 feet in height, and, as will be seen, are well clothed with foliage to the ground. As these occupy a sheltered site they will in all probability retain their lower leaves for a longer time than specimens standing in a more exposed position.

This *Calceolaria* has the merit of being indifferent to soil. In deep and rich compost it makes exceptionally strong shoots and flowers profusely, while in shallow, stony ground, though making but little growth, it blooms with equal freedom. In one instance a line of plants is growing in very shallow, shaly soil immediately at the top of a dry wall, over which *Mesembryanthemums* hang, backed at a distance of 18 inches by a *Laurustinus* hedge. This site, facing due south and entirely unshaded, is dust-dry during the summer owing to the combined action of the burning sun and the roots of the *Laurustinus*; but the plants, though stunted, never fail to blossom abundantly. I had for many years been under the impression that the correct name of the plant was *C. integrifolia*, but in order to assure myself during last summer I sent flowers and foliage to the Royal Gardens, Kew, whence I

CALCEOLARIA INTEGRIFOLIA (4 FEET HIGH).

received the information that my presumption was correct. I was at the same time told that the plant was not included in the Kew collection, and was glad to be able, later on, to forward cuttings. Mr. F. W. Burbidge, to whom I sent flowers and cuttings, very kindly forwarded in exchange cuttings of *C. Burbidgei*, which will be tried in the open at Kingswear, though I am very doubtful of its surviving the winter in the open, even in this exceptionally mild spot. S. W. FITZHERBERT.

Kingswear, South Devon.

A FEW NOTES ON ANNUALS.

PERHAPS a few notes as to the annuals we have grown during the last few years may be timely. As our space is not large we try to have a few different ones each year. I shall not say much about the ones that are universally grown, such as Sweet Peas, Stocks, Asters, &c., but wish to draw attention to some that are less known.

Sutton's rosy Stock-flowered Larkspur is one of the best, and it always attracts so much attention that it cannot yet be very well known. It is perfectly easy to grow, but should be got on early, and it will continue blooming till cut off by the early frost. Last year a friend gave me some seeds of *Cosmos bipinnatus*, which had been sent home from Ladysmith. As our summers are so short here and the *Cosmos* come into bloom late we raised them very early in heat, and potted them on till it was safe to put them out. They were very good, especially a beautiful large white one, but they make rank growth. Still, we had quantities of flowers till a few weeks before Christmas.

We intend to try and prevent their growing so strongly by planting them in poor soil and perhaps in their pots. A dwarf early white sort is advertised this year which ought to be an acquisition.

One year *Argemone grandiflora* succeeded particularly well. Its large white flowers are very like those of *Romneya Coulteri*, only smaller, and the reddish stems, spiny buds, and handsome leaves are very striking. The foliage of *A. mexicana* is handsomely variegated, but the yellow flower is small and disappointing. *Commelina celestis* is well worth growing as an annual for the lovely blue of its three-petalled flowers.

Lathyrus azureus, the small blue Pea, is also a lovely colour, but its blossoms are not produced very freely.

Another blue annual, *Sedum ceruleum*, sown in small pots and turned out when established, is very pretty among rockwork.

Salvia coccinea we find does well in very poor soil, where we are glad to get anything to grow.

Antirrhinum semi-nanum, Queen of the North, is an excellent white one; Yellow Gem and Ruby King are also very good.

Two annuals that I saw in friends' gardens last summer were very beautiful, *Diascia barbera*,

with curious two-spurred flowers of a very uncommon crushed strawberry colour, and *Collomia coccinea*.

At Kew, in October, I saw two annuals which I should like to grow, but I do not see them in the seed lists, viz., *Hysterionica pinifolia*, a pretty starry yellow Daisy, and *Anagallis linifolia*, a large blue Pimpernel.

Lavatera trimestris splendens, both rose-coloured and white, is among the most satisfactory of annuals for the border and for cutting. One year there were some lovely Sweet Sultans, mauve and yellow, called *Centaurea Margaritæ*, in a garden near. I have often tried them, but they will not grow properly. I should be glad if any one would tell me how to treat them.

For their sweetness we grow *Mignonette*, *Matthiola bicornis*, the night-scented Stock, and *Nicotiana affinis*, which is almost perennial in our light soil.

Datura meteloides is a very striking plant with white flowers, veined with purple as large as saucers, and curious Fig-like fruits. I believe it would climb if it had the chance.

There is a Stock called Mauve Beauty, which I read of in "The English Flower Garden," and

Exeter will give an idea of the free flowering habit of the plant. It has already been briefly mentioned in THE GARDEN of the 14th ult., page 120, where it is described among the new plants exhibited before the Royal Horticultural Society as resembling both *S. longifolia* and *S. calyciflora*, bearing purple flowers on hirsute peduncles 4 inches to 5 inches long. I may here state that the plant is perfectly hardy, and that those grown entirely out of doors bloomed here in January without showing the least injury from a rather severe frost. The flowers, too, are much brighter during their early stage of flowering. The stout wiry peduncles as well as the bract-like leaves which clothe them are of a clear bright rosy-pink, while the flowers at the end are almost blood-red and bear yellow stamens. The flowers last a considerable time, but with age the bright pink of the flower-stem and leaves changes to mauve, the bright green at the apex of these leaves becomes more diffused and the flowers assume a purplish red tint. The imbricated silvery rosettes of encrusted leaves are a great ornament all the year round. At Exeter the plants had no protection whatever, and were fully exposed to the sun, planted in gritty soil with an admixture of limestone chippings.

ERANTHIS HYEMALIS (the Winter Aconite) with its bright yellow flowers is one of the earliest of flowering bulbs, and does not mind a shady place, though it will flourish equally well fully exposed; to look effective it should be planted in masses.

ADONIS AMURENSIS, whose home is Manchuria and Japan, is a robust and handsome perennial growing about 9 inches high, bearing bright yellow flowers, which are now fully expanded.

OF IRISES quite a number are already in bloom. *I. reticulata* is one of the first; it is a native of the Caucasus, and its bright violet-purple falls form

a pleasing contrast to the yellow stripe which runs through the centre of the keel. *I. r. histrioides* is also now blooming; it is of more recent introduction, with white flowers diffused with lilac. *I. alata* is bright purple with a yellow throat, a native of Spain and Northern Africa; it is now flowering in several gardens. *I. Danfordiæ* is also in bloom; it has handsome yellow flowers spotted with brown.

Among early spring-flowering bulbs now in flower there are, of course, Snowdrops, Crocuses, Scillas, and *Chionodoxas*, which always brighten the rock garden when most other flowers are still dormant. Here and there in warm positions Arabis and several Saxifrages are beginning to open, but their proper flowering time is not until March.

Elmside, Exeter.

F. W. MEYER.

SAXIFRAGA GRIESEBACHII IN FLOWER AT EXETER (FEBRUARY).

was delighted with last year. This year I shall try some fresh annuals, and will tell you the results if any are satisfactory.

North Wales.

E. J. LI. E.

THE ROCK GARDEN.

SAXIFRAGA GRIESEBACHII.

IT is still too early (February 24) for a large display of flowers in the rock garden.

Winter has not yet vanished, although we have had a spell of mild weather. The earliest harbingers of spring are always welcome, and when a new plant of real sterling value swells the list of the earliest bloomers it is doubly welcome. Such a plant is the new Macedonian Saxifrage (*Saxifraga Griesebachii*), which began blooming during the last week of January in the nurseries of Messrs. R. Veitch and Son at Exeter, where it is still in flower. This plant recently obtained the first-class certificate of the Royal Horticultural Society as a new plant. The accompanying illustration from a photograph taken at

BEAUTIFUL WALL PLANTS.

THE subjoined list comprises a few good wall plants that are growing here, and although few in number includes some of the best for general purposes. I have made no attempt to arrange them alphabetically, evergreen, deciduous, or other-

wise, they are simply taken as they are growing on different walls.

Chimonanthus fragrans var. *grandiflorus* has been in commerce a long time, but is not common. It is a great improvement on the type, being more vigorous in growth, with flowers nearly double the size, of greater substance, and more pronounced in colour. Our plant covers some 300 square feet of wall. Like the type it will adapt itself to almost any soil, and may also be increased by layers, which should remain two years before lifting.

Choisya ternata.—Another plant not at all particular in the matter of soil, and should be included in every collection for its flower, foliage, and scent. One point in its culture is of interest, i.e., that considerably increased vigour of growth is obtained on good soil; but this is more tender than that of plants where the soil is poor with sand or gravel beneath. Good bushy plants can be obtained easily and quickly from layers.

Rhamnus Alaternus variegatus.—From a purely foliage standpoint this is undoubtedly one of our brightest wall plants, the silver bands being deep and clear, and on light sandy soils well retained throughout the length of the long slender shoots. It shows to the best advantage if planted between things possessing dark green foliage such as *Magnolia grandiflora*, *Choisya*, or *Escallonia macrantha*. It can be increased by layers or cuttings as may be deemed advisable.

Cydonias.—Between the common scarlet and its less known white form are a considerable number of shades obtained from seed, and all make beautiful wall plants possessing the merit, if on a warm aspect, of flowering very early when there is little in the way of colour in the garden. The flesh-coloured variety fruits and seeds more freely with me than the others, and it is from this that most of the seedlings have been obtained. A rather heavy loam is the best compost for this family, short sturdy growth and large flowers being obtained in this way. The latter remarks apply to

Eriobotrya (the Loquat), which is worth a place on a warm aspect if there are long stretches of wall.

Ceanothuses are useful semi-evergreens, supplying a shade of colour not often found among wall plants. *Azureus* is the best known, and of this there are several fine varieties, larger in flower, and equally vigorous in habit.

Spiraea prunifolia fl.-pl. covers a large pier, and is very beautiful in late spring and autumn. It requires a fair amount of room, so that the long slender branches can hang over and show themselves to advantage. Where this is not practicable I should hardly advise its inclusion among wall plants.

Deutzia crenata fl.-pl. fills a large recess with some of the back branches fastened to the wall. There are few more beautiful shrubs. A few *Kerrias*, and the old *Weigela*, with *Magnolia grandiflora*, *Cercis canadensis*, and *Wistaria sinensis*, both very old, still remain as examples of some of the things used for walls by a bygone generation of planters.

Claremont, Esher. E. BURELL.

Where a suitable position can be found and sufficient space is at command a most interesting feature of the garden may be formed by growing a

collection of choice and rare creepers. An ideal place is a terrace wall. Nearly all the creepers mentioned below are practically small growing, and do not require large spaces to develop their full beauty as with the large majority of so-called climbing plants. There are many of our most beautiful shrubs which

may be thus treated that are not sufficiently hardy to withstand the severity of our winters in many parts of the country, and where a southern or western aspect can be chosen these will thrive and be of great beauty during spring, summer, and autumn, and the

GARRYA ELLIPTICA (NATURAL SIZE).

(From a drawing by H. G. Moon.)

lightest protection during winter will ensure their safety.

Actinidia Kolomikta.—A plant rarely seen in cultivation, yet most desirable for this purpose. It has conspicuous pure white, cup-shaped flowers half an inch or more in diameter.

Vitis (Ampelopsis) sempervirens.—A beautiful hardy evergreen, small in growth compared with the imposing varieties generally seen.

Berberidopsis corallina.—A very handsome evergreen climber, with coral-red flowers in drooping racemes, and requiring the protection of a wall facing south.

A. E. THATCHER.
Aldenham House Gardens, Elstree, Herts.
(To be continued.)

AN ARTIST'S NOTE-BOOK.

GARRYA ELLIPTICA.

As a hardy evergreen that is especially ornamental during the winter season, this Californian shrub might with advantage be grown much more frequently than it is at present. Specimens at this time of year that are large enough to flower have a singularly graceful appearance by reason of the long pendent catkins they bear. The leaves, which have a close resemblance to those of some varieties of the Holm Oak, are opposite, 2 inches long and elliptical, shining green on the upper surface and hoary beneath. It is from the axils that the catkins are

borne, these being of a greyish green colour, and from 4 inches to 8 inches long, with the flowers almost enclosed by cup-like bracts. Although comparatively rare in gardens, this shrub has long been introduced, Douglas, the Horticultural Society's collector, having sent it home in 1828. It was named in compliment to Mr. Garry, at that time secretary to the Hudson's Bay Company. The plant bearing the catkins as here described is the male; the female is very rare and not so ornamental. As a rule this *Garrya* is planted against walls, but it is quite hardy in the open or in shrubberies, where groups of it might very well replace the banks of Laurel so often seen.—T.

[It was described by Mr. Bean in his article upon catkin-bearing trees last week.—ED.]

NOTES FROM SWANSWICK.

ON visiting Messrs. Cooling's nursery the other day I was struck by something very gay in gold and green at a little distance. On approach it proved to be a group of *Elaeagnus variegatus*, and for winter colour this shrub is indeed a gem. It should make a lovely effect planted behind *Rhododendron præcox*, which is not at all such a bad pink as some people tell us, but is apt to have a pinched and only half-happy look, due possibly to its want of foliage when in bloom. This is the first season I remember *R. præcox* being able to flower here to perfection. Last time it was cruelly and effectually frosted exactly at the critical moment, and the year before a blizzard took its beauty. This year it has been exceedingly pretty, and being the only pink thing in the garden aided its popularity.

That woeful volume that records garden expenditure is just now full of entries after this manner: "Loam, one sack; peat, one cwt.; sand, one cwt." All these things are daily needed for rockery planting, and the only shadow of a shade of natural peat is a mile away in a supposititious bog-hole. Leaf-mould

of Nettles, "Crazy," and Comfrey, all of which flourished gallantly among the crockery and under the partial shade of a Yew, a huge Tree Ivy, and a backing of *Philadelphus*. The mound is about 30 feet long, 6 feet high in the middle, and the cultivatable portion about 10 feet wide, this embracing the long slope to the north. The southern and larger aspect is occupied by the trees and shrubs aforesaid, with the inevitable Periwinkle below. All the same, the golden-variegated *Vinca* is not at all a bad plant, and would be immensely admired if it wouldn't grow without coaxing and cost 10s. a root. After "cleaning" the heap, it was quickly landscaped into a very desirable rockery, and I have devoted it to the smaller *Campanulas*. Up to the present, *C. garganica* and *C. g. alba*, *C. muralis*, *C. abietina*, *C. barbata*, *C. carpatica* and *C. c. alba*, *C. Erinus*, *C. Hostii* and *C. H. pallida*, *C. portenschlagiana*, *C. pulla*, *C. pusilla* and *C. p. alba*, *C. Raineri*, *C. turbinata*, and *C. waldsteiniana* comprise the collection; but it is hardly needful to say that *C. tommasiniana* is to be added—in hope! The soil, of course, has been specially made at the site of planting for each. Besides these, a part of the rockery takes a few alpine

Phloxes, which in this garden seem to dislike the full sun, and promise to do better in a shadier place. The low end, close up to the *Philadelphus* bushes, we have planted with the nine varieties of *Epimeediums* from Mr. Perry.

The sunny rockery here is by no means so satisfactory or promising. A bank about 50 feet long and 3 feet high was grassed over, with a bed on the top, backed by thick shrubs. This bed, in the fullest south aspect, and completely sheltered from every breeze of roughness, we found occupied by some *Michaelmas*

Daisies, which were shockingly deteriorated, as might be expected under the circumstances, the soil being very fibrous, and containing a good deal of leaf-mould. We planted tender shrubs—*Cistus laurifolius*, *Ceanothus Ibis* (the pretty pink form from Newry), *C. dentatus* (the little evergreen form, with its very bright *Lithospermum* blue flowers), *Clethra alnifolia*, *Deutzia gracilis*, *Polygonum baldschuanicum* on poles as a centrepiece, *Choisya ternata*, and a variegated form of *Daphne Cneorum*, which came from an auction, and is, I believe, a bit of a "find." Among these are tiger and longiflorum *Lilies*, and the upper end tails off into a planting of *Iris germanica*. These things all do well so far, but the grass bank—very weedy—was an eyesore, and, having been stripped, is in process of formation into a rockery. It is of a yellow clay-loam, with many small stones in it, and will, I imagine, bake famously if we ever get a hot summer again. Consequently, much barrow work is required, and in spite of unnumbered loads thereby conveyed I hesitate to venture on any but confirmed *Parsees* in the way of plants. Some of the *Linarias*, *Sedums*, *Veronica saxatilis*, *Lewisia rediviva*, *Lychnis Lagascea* (in rock chinks), *Malvastrum Gilliesii*, *Cyananthus lobatus*, also chinked, and of

course provided with peat, sand, and leaf-mould to taste, and *Geranium argenteum* as the forerunner of more of its elegant relations, are all that are in position so far, and any suggestions as to other suitabilities would be gratefully received. We are having a lovely planting season, and the only fear is that it is altogether too good to last. Meanwhile, showers of much more than vernal softness, with airs somewhat boisterous, but little felt in this very sheltered garden, from west and south, have ushered out a February to be held in ever affectionate remembrance as gracious and clement. M. L. W.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A CABBAGE CURIOSITY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I send you a photograph of a remarkable Cabbage grown on the farm here. It has not been eaten by insects, and the reason of its strange growth is at present a mystery. It appears in the photograph exactly as it was when cut. I enclose it thinking that it may be of interest to readers of your valuable paper. B. BLACKBOURN.
Royal Agricultural College, Cirencester.

CHRYSANTHEMUM MR. G. RUNDLE, &c.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I read with much pleasure Mr. D. B. Crane's note regarding the merits of the above in a recent issue, as only a few days previous I had been speaking to a friend about these varieties for decoration. Mr. Crane is perfectly right as to their being easily grown, and one has little to fear in the matter of buds coming blind. The late Mr. R. W. Nicholson, who was for many years gardener to Alexander Mackenzie Smith, Esq., Bolton Hey, Roby, Liverpool, was the finest grower of these that I ever remember. How he used to pride himself on his front row in the conservatory, which were composed alone of these varieties, whilst behind he had standard-trained plants, grafted specimens with the three varieties on the one plant, a feature that met with very hearty approval from visitors. It was not with the yearling plants that he excelled, but with those of two years' growth, carrying over fifty perfect blooms each, and it was on these that he constantly relied. After blooming they were cut down, placed in a frame and kept somewhat dry until a good break was secured, then potted in a good compost and returned to the frame. I am taking these up again this season for their incomparable beauty alone, and in the matter of staging may I make a suggestion, viz., that instead of showing two blooms of each make them trebles, then, as in the Rose exhibits, the effect will be greatly enhanced. A. B.

THE ROSE GARDEN.

PRUNING ROSES FOR EXHIBITION.

WITH the advent of March I thought perhaps some notes on the method I have adopted during the past three years when pruning my Roses might be of interest to some of your readers. For the purpose of making these notes explicit I have placed the varieties I succeed best with in three classes—Hybrid Perpetuals, Hybrid Teas, and Teas. Dealing first with the

A CABBAGE MONSTROSITY.

exists on the premises, but although there is the *débris* of twenty years under some Beeches, the practicable layer is only about half an inch thick, and entails a disproportionate amount of scraping and stooping to disinter it from under superincumbent undecayed leaves. The haulage up a long hill is so expensive that it pays better to fetch small quantities of soils than to buy them in bulk. Sharp sand is about worth its weight in copper in these parts.

Can there be a more fascinating garden operation than choice rockery making? It is neither hard nor dirty work, and one finishes up as one goes, which is always satisfactory. What I mean is not the actual piling of Pelion, but the planting and the arranging of the smaller stones. A legacy—a blessing disguised under several tons of broken bottles and like *débris*—of a vast mound of burnt rubbish mixed with very decent soil was left to us by the former inhabitant of this garden, and with rare discrimination they chose for it exactly the sheltered and shaded spot where a half-shade rockery should succeed. Like the very interesting mine refuse heaps lately illustrated, this mound seems to possess a considerable amount of fertility, and had done the best it could for itself by putting on a thick cloak

HYBRID PERPETUALS,

Mrs. John Laing, Prince Arthur, Victor Hugo, François Michelin, Alfred Colomb, Duke of Wellington, Marie Beaumann, A. K. Williams, Ulster, and Earl of Dufferin, these I prune down hard to two eyes, the upper one pointing outwards, and leave only three shoots. Disbud *gradually*, and allow three of the new growths to carry flowers. To Fisher Holmes, Mrs. Cocker, Mme. Gabriel Luizet, Marchioness of Londonderry, Mrs. Sharman Crawford, Charles Lefebvre, Etienne Levet, Hienrich Schultheis, S. M. Rodocanachi, Captain Hayward, Margaret Dickson, and Helen Keller I allow three eyes and disbud to four new growths. Her Majesty and Ulrich Brunner I allow five eyes and disbud to the new growths. I always thin out the weak and old wood the previous autumn and never allow a plant to carry more than three ripe growths. With the

HYBRID TEAS

there seems to be a diversity of opinion as to how these should be pruned. I find it best to cut down hard to two eyes, *gradually disbud*, and only allow at the most three new growths to carry flowers, with the exception of Caroline Testout and La France. Apparently this latter Rose only requires just thinning. One of the finest specimens I know of is growing in a cottage garden here. Every year it just gets the tops cut off and a pail of road sweepings put around its roots. During the summer it carries some magnificent blooms, quite up to exhibition standard. The varieties I grow are Killarney, Kaiserin Augusta Victoria, La France, Caroline Testout, Mrs. W. J. Grant, Bessie Brown (best on half standard), Marquise Litta, White Lady, Papa Lambert (best on Manetti), and Mme. Eugenie Boulet. Coming to the

TEAS,

I usually find on removing the protection that there is not a great deal of sound wood left to cut at. This season will, I think, be an exception. If possible I like to leave a good shoot—provided it is quite ripe—a little long and cut the others down to the best plump eye. Disbud *gradually*, and only allow the plant to carry two or three flowers. I always remove the protection and prune about April 7. The varieties I grow are White Maman Cochet, Maman Cochet, Mrs. Mawley, Marie van Houtte, The Bride, Medea, Catherine Mermet, Bridesmaid, Mme. de Watteville, Elise Vardon, S. A. Prince, Ernest Metz, Hon. E. Gifford, and Muriel Graham.

I am afraid owing to the forward state of the present season the Roses will bleed a good deal when cut, but I do not think it will matter, as the plants never seem to suffer through it. In conclusion, I may say all my Roses are given a dressing of cow manure in November, lightly turned in in the spring. I give them a dressing of Tonks' manure in February. From the middle of April onwards I give each plant once a fortnight, if the weather is wet, two gallons of liquid cow manure. About May 27 I give each plant two gallons of liquid chemical manure composed of nitrate of potash and phosphate of potash equal parts, half an ounce

to one gallon of water, repeating the watering ten days or so later. The liquid must on no account touch the foliage. Hoe the ground after each watering.

Enfield.

C. PAGE.

THE BEECH FERN IN AN IRISH GARDEN.

THE Fern shown in the photograph covers a space about 6 feet by 6 feet, and rambles among some rocky steps as well. It grows very luxuriantly.

ROGER HALL.

Narrow Water, Warrenpoint, County Down.

INSECT PESTS.

LEAF CURL IN PEACHES.

CONSIDERING how often questions are asked as to the cause of the malady commonly known as leaf curl, which so frequently attacks the foliage of Peaches and Nectarines, it is obvious that the real nature of the disease is not generally recognised, and it may be useful therefore before there is any chance of trees being affected by it to relate what is known at present about it, and what means should be used to prevent trees from being attacked. This disease is unquestionably caused by a fungus known as *Exoascus deformans*, and in spite of what some gardeners assert (that it is cold winds that are responsible for the complaint) it is certain that if this fungus did not exist there would be no leaf curl. It is easy to understand, as I will show presently, why this theory takes such hold on persons. The leaves are liable to be infected in two ways, either from the mycelium or spawn, which at times infests the young shoots, and from them spreads into the leaves, or more frequently from spores which have passed the winter on the buds. When these spores germinate a germ tube issues from them which pushes itself over the surface of the young leaf until it reaches one of the stoma or pores into which it enters. As soon as it is inside the leaf it

begins to branch and force its way among the cells of the leaf. If the condition of the leaf favours the growth of the fungus it grows very rapidly, ramifying in all directions among the cells of the leaves, causing an increase in their number and size, particularly of those of the upper surface, as the cells of the midrib are not affected to the same extent as those of the softer parts. The former does not lengthen at the same rate as the other parts, consequently they are obliged to assume the well-known puckered and crumpled up condition which is so characteristic of this disease, and from which it derives the name of the curl. In due time the fungus forms a number of cells full of spores, which force their way between the outer cells of the upper surface of the leaf, giving it the peculiar velvety grey appearance which is so well known. When these cells are quite ripe they burst and the spores are liberated into the air, to be carried about by the slightest breeze or wind. Some of these spores are sure to fall or be wafted on to the buds at the base of the leaves and to other parts of the trees, where they remain until the next spring.

The welfare of this fungus, like that of all living organisms, is greatly dependent on its environments. When the weather in the spring is cold and wet, and particularly if a cold wind follows a spell of warm weather, the leaves become saturated with moisture, and are soft and flabby, their powers of transpiration are considerably lessened, and the general vitality of the tree is lowered. Under these conditions, which are very favourable to the growth of the fungus, the disease makes rapid strides, and the tree is soon in a pitiable condition; but if the weather be favourable to the growth of the young leaves, and consequently unfavourable to the fungus, the latter, though present in the leaves, is unable to do them much injury.

It is easy therefore to understand that trees grown under glass are seldom attacked by this pest, for the conditions then are not those suitable to the fungus. It is evident that when the leaves are infected from the shoots there is nothing to be done but to cut back the shoots beyond the infested part. This may usually be known by the swollen appearance of that portion, but it is tolerably certain that this is not often the case, because if certain precautions are taken

THE BEECH FERN AT NARROW WATER, COUNTY DOWN.

to prevent the spores from germinating in the leaves the disease can be kept under control.

The large Peach orchards in America often suffer very much from leaf curl, but there it is found that the disease can be kept away by spraying the trees just before the buds begin to open with Bordeaux mixture. The spores are then just beginning to germinate, a condition in which the fungicide has the most effect on them. It is far better to perform the operation at this time than later, when the leaves are opening, as they are then more liable to be injured by the fungicide, and it is quite possible that the leaves may have been already infested. The spraying would then be useless. I am not aware that this method of dealing with this pest has been tried in England, but it has met with such success in America, where it seems to be very generally used, that anyone whose trees are liable to be attacked should certainly give it a trial. Bordeaux mixture leaves a deposit of lime on the trees; but though somewhat of an eyesore, it has this great advantage, that it is easy to see if the mixture has been properly applied to every portion of the tree. In the American orchards the trees are all standards, so that it is much easier to spray the trees properly than it is with us, where the trees are mostly fastened against walls. Still, if the spraying be carefully done there is no reason why every part of the tree should not be reached. Spraying has not the slightest effect on the fungus when shoots are infested by it, so that if it be found that the ends of the shoots for some inches are swollen or distorted, such parts should be cut off and burnt before the spray is applied. G. S. SAUNDERS.

ORCHIDS.

ODONTOGLOSSUM BRADSHAWÆ.

VERY handsome and striking is this flower, the result of crossing *O. harryanum* and *O. andersonianum*. It was exhibited by J. Bradshaw, Esq., The Grange, Southgate, N. (gardener, Mr. G. G. Whitelegge), at a recent Drill Hall meeting of the Royal Horticultural Society, and was awarded a first-class certificate by the Orchid committee. The sepals and petals are long and symmetrical, the ground colour pale yellow; upon the lower portion of the sepals are blotches of red. The base of the petals is white, and the flat, rather large white lip is prettily marked with dull red in its upper half.

CYPRIPEDIUM FAIRRIEANUM HYBRIDS.

WITH reference to the fact that hybrids of this plant refuse to cross with each other, Mr. James Douglas sent the following communication on the subject to a recent meeting of the scientific committee of the Royal Horticultural Society: "Some remarks were made at a recent meeting of the committee on crossing *Cypripediums*, and a misunderstanding arose thereupon. It was stated as a fact, and so far as I am aware the statement is correct, that hybrids of *C. fairrieanum* will not cross with each other. *C. fairrieanum* is a very scarce plant in Britain; except a small plant in the collection of the president of the Royal Horticultural Society I am not aware of any other. Consequently, hybridists are anxious to obtain seedlings with as much of the character of this scarce variety as possible. They have made many attempts by recrossing the *F. C. fairrieanum* hybrids in existence, but have always failed, although other hybrid *Cypripediums* will cross with *C. fairrieanum*. For instance, *C. oenanthum superbum* crossed with *C. fairrieanum* produced a very scarce and beautiful variety, Baron Schröder; *C. vexillarium* was obtained by crossing *C. barbatum* with *C. fairrieanum*, and this hybrid on being crossed with *C. bellatulum* produced *C. bellatulo-*

vexillarium, but *C. vexillarium* was the pollen parent. The object of bringing this matter before the scientific committee at all would be to ascertain why, if other hybrid *Cypripediums* will cross with each other, it is that *C. vexillarium* will not cross with *C. Niobe*, or why *C. Juno* will not cross with *C. arthurianum*, or any other of the numerous ways in which the *C. fairrieanum* hybrids may be crossed with each other? The pollen is potent enough if used on other species of *Cypripediums*."

NURSERY GARDENS.

MESSRS. CARTER & CO.'S PRIMULAS.

IT is our custom annually to pay a visit to the Forest Hill Nursery of Messrs. James Carter and Co., the seed merchants of High Holborn, for there the seeds of Primulas, Cyclamen, Cinerarias, and other indoor flowers for which they are so famous are grown. Just now the chief attraction at the Forest Hill Nursery is made by the Primulas. Several houses are full of them in various and shades of colour innumerable. Each variety is represented by a large number of plants, and these are kept distinct, so that one sees masses of flowers all of the same colour. Looking down the span-roofed houses the effect is striking, with large groups of one variety the colours are much better appreciated. To see just two or three plants of two varieties somewhat similar in colour one might think them to be insufficiently distinct to warrant Messrs. Carter (or anyone else) calling them by different names, but see a mass of them, say several hundreds of plants in flower, and the difference in colour is at once recognised, and one wonders how they could have been confused before, or that one could have been sceptical as to their distinctness. The reason is probably that the eye of the average person is not sufficiently trained to distinguish the true colour values of flowers, a few plants are not enough to enable one to judge of the true colour, a large number of them is necessary, and the two varieties must be side by side. Then is it quite simple to decide whether and how much they differ.

Thanks to the forethought of Messrs. Carter's representative at Forest Hill we were able first to see small selections of each of the varieties grown, and in order to appreciate fully their colour values we made the round of the houses afterwards. We always look forward with interest to a visit to Messrs. Carter's Primulas, for it is good to see how well these plants are grown at Forest Hill, surrounded as they are by bricks and mortar, and it also serves to convince us that the Chinese Primula is not only a plant for the country, but for town gardens too, and even for those most unfavourably situated, or it could never grow and blossom as it does at Forest Hill. Of course we know that skill and careful cultivation, taught by long experience, have much to do with Messrs. Carter's successful flowering of these plants; but allowing even for this, we are convinced that the town, as well as the

country, gardener need not be afraid to attempt the culture of this most valuable of early greenhouse flowers.

So much for The Primula, now for Primulas, and first the semi-double ones. Prince of Wales, a Palm-leaved variety, has rosy salmon flowers; while those of the one named Princess of Wales are almost white; Lilac Queen, with rich rose lilac blooms; Double Scarlet, which is self descriptive; Aurora, with pink and white flowers borne on strong stems; Vivid, carmine; Snowflake white, very slightly tinged with pink; Carmine Empress, which is more than carmine, it is rich carmine. All have semi-double flowers and Palm-shaped leaves. Among the single Primulas Holborn Queen forces itself into notice, its well-formed blossoms being white with a yellow centre; while Ruby is a flower of beautiful colouring, of which rosy carmine is perhaps the nearest pen description; Elaine, the edges of the pure white, green-centred flowers being prettily frilled; Rose, which defines itself; Venus, the blooms flaked and spotted with crimson upon a white ground; Salmon, well named as regards the colour of the flowers, which are borne well above the foliage; Rose Queen, which blooms more freely than the variety Princess May, which it resembles; and Vermilion, a splendid colour, the term crimson-red (which, perhaps, is the best word description one can give to it) does nothing like justice to the blooms; these are possibly the best of the doubles. With the exception of Salmon, Princess May, Rose Queen, and Vermilion they are all Fern-leaved varieties.

We have said possibly the above are the best, but we would add the following also, they may be even more highly thought of by Messrs. Carter than those mentioned: Carmine, Elaine Improved, Holborn Scarlet, Holborn Magenta (not nearly so unlovely as its colour would lead one to suppose), Holborn Pink (a beautiful flower), Edward VII. (bearing large white blooms with beautifully fringed edges), Crimson King (a splendid dark crimson), and Holborn Blue—as blue Primulas go one of the best in colour. Of Star Primulas (forms of *P. stellata*) we noticed lilac, white, and pink-flowered varieties, and doubtless before long we shall be able to chronicle the advent of a true blue.

FLOWER OF ODONTOGLOSSUM BRADSHAWÆ.

(First-class certificate, Royal Horticultural Society, February 24.)

THE FRUIT GARDEN.

PEAR PASSE CRASSANE.

KNOWING well how few varieties there are of really good late Pears, and also how very much a good flavoured one is appreciated, leads me to wonder why Pear Passe Crassane is not more generally cultivated. I have had the pleasure of exhibiting fruits of this variety before the fruit committee, and they have received a first-class certificate of the Royal Horticultural Society. This year I again showed it, and many were astonished by its size and, what is more important, its splendid flavour. The fruits exhibited recently were grown on a west wall and given very liberal treatment. The accompanying illustration shows one of them. I think it is generally admitted that last season was the worst experienced for many years for the proper development of fruit, and especially of late Pears, but with me Passe Crassane was as good as ever. My object in writing this note is to encourage those who have hitherto not been successful with it to give it liberal treatment, using well both manure and water in the late autumn. Plant it in very rich soil, such as that from an old Cucumber bed.

G. WOODWARD.

Barham Court Gardens, Maidstone.

HOW TO PACK GRAPES.

THIS is always an interesting subject, and the article on page 149 gives a good account of how to do it. From my own experience, and also from what I see very often in the markets, 12lb. is quite heavy enough for the majority of the buyers, unless at a very cheap rate. It is also interesting to note your good illustration, which at once practically demonstrates the advantage of the local and suburban growers over those who have to send a longer railway journey.

Were I to advise, and I am now speaking from my own experience, it would be a large "handle" to hold more than 8lb. or 9lb., a 6lb. size being more in request, especially when Grapes are more than 1s. per lb. Then I never advise standing the bunches upright. My favourite handles, not the deep Channel Islands ordinary basket, are more shallow, and the bunches actually rest full length, the shoulder only being upright. I am also pleased to note that this style of handle, specially made at a low rate in Wiltshire on the borders of Hampshire, is much in use still, quantities coming to market from Fordingbridge and Wimborne. These who remember the Inventions Exhibition of 1885 may recollect my premier packing exhibit. This was a very shallow cross-handled basket to hold 12lb. Not only with the Grapes in this particular handle, but in all, I venture to assert every bunch is practically perfect, except for the side resting on the basket. I have also tested this way of packing for a 500 miles railway journey.

What we as growers have to do is not to fill the handles, as per the Channel Islands, but, on the contrary, to so pack every bunch that each presents a perfect face, and yet they are firmly packed so that unless actually turned over would travel well. Did space permit there are several little details that I could touch on, even though the actual packing to the experienced is so simple.

THE ALICANTE GRAPE.

THE note of "R. D.," page 138, does not go far enough *re* the cause of the Alicante shrivelling.

FRUIT OF PEAR PASSE CRASSANE (ALMOST NATURAL SIZE).
(Shown by Mr. Woodward at a recent meeting of the Royal Horticultural Society.)

Only recently a leading grower informed me that he had cut out a large quantity of berries, but admitted he was not likely to repeat the error, which was caused through want of fire all through the growing season.

Quite possible, had the season been a normal one, Grapes would have kept as well as usual, even though the fuel had been pinched or stinted, but a bad season following no Grape suffered more than Alicante. The true cause of this is that not only were the skins of berries unripe, but berries also were fuller than usual of watery not saccharine matter, which as it wasted away caused the skins to collapse. Because of the hardy nature of the Alicante liberties were taken with it all through the season, both with regard to fire-heat and also reduced ventilation.

Many never gave fire-heat until the berries began to colour. Fire-heat was then applied, and it was useful in so far that it assisted the ripening, but it never could promote the necessary quality in the berries for keeping. I have this week (the last days of February) seen bunches of Alicante both under canvas and also a few in the open. In each case they are being marketed quickly before they get more shrivelled.

I know it is the season, combined with want of fire, which is the reason why bunches of Black Alicante do not keep. This variety, when well grown, is a good keeper. I have not only had it good in April, but also sent the fruit 400 miles during the first week of April, and being second only to Lady Downe's; this, too, where the latter Grape is grown to perfection—in Edinburgh and its neighbourhood.

Lastly, a word as to flavour. With some growers it is very deficient, but when well done it is good, the chief drawback being the tough skins. Also good flavour is possible when the Vines are well cropped.

STEPHEN CASTLE.

RECENT PLANT PORTRAITS.

THE *Botanical Magazine* for March has portraits of *Aloe rubroriolacea*.—Native of Southern Arabia, and an exceedingly handsome Aloe, which bloomed in Sir Thomas Hanbury's garden near Mentone. It is admirably represented on a fine double plate. *Sophora vicifolia*.—Native of China. It is also known under the name of *S. mecroftiana*. This is an extremely pretty small shrub with bunches

of white flowers, which have conspicuous purple calyxes, forming a charming contrast.

Hamamelis mollis.—Native of China. This is a very handsome form of Wych Hazel, with brightly conspicuous golden-yellow flowers, much larger and of a brighter shade of colour than those of *H. zaccariniana*.

Phalenopsis Kunstleri.—Native of the Malayan Peninsula. This is a rather small and thin-flowered variety, but very bright in colour; the centre of the flower is crimson, and the tips of the petals golden.

Chrysanthemum grande.—Native of Algeria. This plant is also known under the synonyms of *C. grandiflorum*, *Plagiis grandiflorus*, *Balsamita grandiflora*, *Matricaria grandis*, *Tanacetum grandiflorum*, and *Cetula grandis*. This is a large, coarse-growing plant, with conspicuous yellow flowers with no ray florets and but little beauty.

The first part of the *Revue Horticole* for March figures

Brachychiton acerifolium.—A native of Australia. Its native name is the Flame Tree, from its conspicuous bunches of most curiously formed red flowers. It is hardy in the south of France, but an exceedingly shy bloomer. Those planted twenty years ago at Monte Carlo have only bloomed on one or two occasions.

The *Revue de l'Horticulture Belge* for March figures

Hymenocallis or *Ismene calathina*, a well-known stove bulb, with large and pure white flowers.

Dianella Tasmanica variegata.—A very handsome gold variegated foliage plant, resembling in appearance one of the variegated forms of *Phormium tenax*.

The seventh and eighth parts of volume xvii. of *Lindley*, appearing as a double number, give portraits of the following Orchids:—

Odontoglossum crispum var. *Griselidis*.—An exceedingly distinctly marked and beautiful variety.

Cypripedium lawrenceanum var. *Ardens*.—A very handsome variety, somewhat inappropriately named.

Cypripedium Miss Louisa Fowler.—A most distinct and delicately beautiful variety.

Cattleya Triana var. *triumphans*.—A most bright and beautiful variety.

Cypripedium lecanium var. *olivaceum*.—A very distinct and beautiful variety.

Cattleya Loddigesii var. *Harrisoniae* sub. var.

porisiana.—An exceedingly bright and beautiful variety.

Tanda tricolor var. tenebrosa.—This is quite an acquisition, and an immense improvement on the well-known type. Its flowers are in every respect larger, handsomer, and of brighter colouring, which will doubtless cause it to be much sought after by all Orchid lovers.

W. E. GUMBLETON.

GARDENING OF THE WEEK.

FLOWER GARDEN.

ORNAMENTAL HEDGES.

PLANTS of an ornamental character suitable for growing close to or round a garden, for the purpose of forming divisions between different parts of the enclosure, should possess some special qualifications. They should be evergreen, and not subject to lose their lower foliage or fall out of form in parts, but should be fairly quick-growing and submit to be shorn or clipped at frequent intervals without suffering a check to growth. They should, in fact, grow all the quicker for constant pruning if it be desirable to have them in any way; but, where there is space to admit of the plants developing their natural form, no clipping, pruning, or training will compensate for loss of gracefulness of outline as obtained in a shrub or tree naturally grown. A strange custom existed in many gardens years ago—and, I am afraid, still exists in a few up to the present time—of adopting a system known as “topiary work”; that is, the plants are grown in all conceivable shapes in imitation of various fantastic things instead of that graceful, careless habit usually resulting from natural growth. We should do much better in matters of this kind by closely following the example set by Nature than by introducing into our gardens such devices as these.

THE FOXGLOVE.

Where the soil is good and a little shelter can be given, I know of no hardy flower that will give a better return for any little trouble that may be taken with it than our old-fashioned Foxglove. When grown as a garden flower the Foxglove should never be planted in a dry, breezy, starving situation. It is a moisture-loving plant. The fernery or any snug wild nook suits it well. These conditions will promote a good growth, and at the same time set off the peculiar beauties of the plant. In common with Lilies, Foxgloves associate well with Rhododendrons. They also do well in mixed borders, appearing to be well placed no matter where they are. In any case a good clump is better than a few single plants, and it matters not how the sorts are mixed; in fact, the more mixing the better. Seed should be sown in April or May. The plants should have a little nursing in a frame and be planted out the following spring.

GENERAL WORK.

Hyacinths and Tulips planted in October and November will now be pushing through the soil. They will be rather tender, owing to the warm weather in February. Spread over the beds a mulch of stable litter or cocoanut fibre refuse to protect them from frost. Crocuses will need protection from sparrows; so will the double Primrose. I find in many gardens these birds are now playing sad havoc with both leaf and bud. The best way to stop the little depreducers is by stretching black cotton fairly tight over the blossoms.

HERBACEOUS PEONIES.

The proper time to lift and plant large roots is from August to October, but pot plants from nurseries should be planted out now and have abundance of water the first season.

T. B. FIELD.

Ashwellthorpe Hall Gardens, Norwich.

KITCHEN GARDEN.

CHINESE ARTICHOKE (*Stachys tuberifera*).—This is a delicate vegetable, and requires more care in

planting and tending than the Jerusalem Artichoke. The tubers of this Artichoke are quite distinct, and if they are not grown to a good size it is a tedious process to prepare them for the table. Plant in deeply dug ground that has recently been well manured, placing the sets 12 inches or 15 inches apart in the row; the rows may be 2 feet apart. A good sprinkling of charred garden refuse thrown upon the tubers before filling the drill with soil is beneficial.

VEGETABLE MARROWS.

Plants already raised for growing in pits and frames for early supplies should be encouraged to grow freely without a check. When planted in their fruiting quarters apply top-dressings of warm rich soil. Attend to training the leading growths. Admit air freely when the weather is mild; cold draughts will encourage mildew. Should this appear dust the foliage with flowers of sulphur without delay. Those who have not convenience for growing this vegetable so early may sow some seed at this date. Sow sound seeds of such good varieties as Pen-y-Byd, Moore's Cream, or Long White singly in 3-inch pots. Press the seed edgewise 1 inch under the surface of the soil, then give the pot a smart tap on the potting bench, but do not make the soil firm. Plunge the pots in the propagating house, and when the seedlings appear place on a warm shelf near the light. As the first rough leaves develop place in a somewhat cooler structure to harden and plant out where they are to be grown. A frame placed on a hot-bed that has, perhaps, produced a crop of forced Asparagus will answer well for these early Marrows, as the remaining warmth will be just sufficient to encourage the formation of healthy roots without unduly forcing the plants. Add soil as required and peg down the growths, removing any that are unfruitful.

CAULIFLOWER.

Some of the strongest plants raised from seed sown last autumn, if the weather is favourable, may be planted out on rich ground that has not recently carried a crop of Brassicas. Lift the plants with plenty of soil and insert them with a trowel. Some protection must be given, such as inverted flower-pots with the drainage hole stopped up, placing them over the plants at night, to be removed during fine days. Evergreen branches placed about them will also answer, and these could remain until danger of sharp frosts is past. Some seed may be sown on a warm border for providing plants as a succession to those raised under glass in February.

OTHER SEEDS TO SOW

comprise Broccoli (Snow's Winter White and Self-protecting), Savoy of the Early Elm variety, Leeks for main crop, and successional Peas, Beans, Spinach, Radish, Lettuce, and other salads. The Brassica tribe, other than those enumerated above, should not be sown until the end of the month; if sown earlier the plants become drawn in the seed-beds and receive a severe check when transplanted to their permanent quarters. It is better to have smaller and sturdier plants that will grow strongly at once.

Stoneleigh Abbey Gardens. H. T. MARTIN.

INDOOR GARDEN.

GLORIOSA SUPERBA.

SUCH tubers of this plant as were advised to be started some weeks ago should now be making growth. Where this is the case keep them in the warmest part of the house near the glass. Sometimes these tubers refuse to start early, and where this difficulty has been experienced fresh tubers must now be plunged in a sharp bottom heat of 70° to 75°, and if watered with tepid water should start freely.

CROTONS.

The Croton is quite indispensable where choice decorative plants are in demand. Young plants rooted from cuttings put in last autumn will now be ready for a shift into 5-inch and 6-inch pots. Such plants as were propagated from strong leading shoots will require the larger size. Before

repotting see that the plants are free from the small brown scale which frequently infests them. A good wash for this purpose may be made by dissolving 4oz. of soft soap in one gallon of water and adding one ordinary wine glassful of paraffin. Keep it frequently moved while being used, and thoroughly wash the stems and foliage. Avoid damage in the foliage while cleaning or the plants will never look well. A compost of two-thirds good fibrous loam and one-third peat with an addition of rough hard charcoal and an 8½-inch potful of Clay's fertilizer to a barrowload of soil and sufficient coarse sand to render it porous will be suitable. If the young plants are well rooted on being turned out of their pots disentangle the roots a little before repotting and pot them quite firmly. Place the plants in a hot moist house and syringe them lightly two or three times a day, and see that they do not become very wet at the root.

BOUVDIARIS.

Old plants that were shortened back immediately after blooming will have made shoots large enough for cuttings. Insert these in sandy soil and plunge in a sharp bottom heat; they will then root freely. Some varieties propagate freely from root cuttings. When this method is adopted the plants should first be started into active growth, and portions of the stronger roots may be taken, retaining a few fibrous rootlets if possible with each root cutting; these, inserted in sandy peat in a good bottom heat, make plants quickly.

COLEUS.

Where specimen plants for summer decoration are required cuttings should at once be taken; these easily root in a hot house, and if grown on will make plants of a pyramidal form 4 feet to 5 feet high by July or August. A few of these trained as standards are often useful. Such plants as *Centropogon lucyanus*, *Reinwardtia*, *Sericographis*, *Libonia*, and *Eranthemum* now passing out of flower should be cut back, well cleaned, and placed in a warm house with a view to providing abundance of cuttings in a few weeks' time. Look over cold frames and remove Lilliums and other plants from the material in which they were plunged before the young growth becomes blanched or weakly plants will result. Remove any damped or decayed foliage from *Cinerarias* or *Calceolarias*, and where the flower-stems of the former are advanced see that the necessary support is given them in the way of small neat stakes. Keep the plants clean by frequent fumigation.

Wendover.

J. JACQUES.

THE FRUIT GARDEN.

HARDY FRUIT.

ALTHOUGH hardy fruit trees are forward, yet, owing to the absence of sun, they are not so much advanced as at one time we expected to find them. The abundant blossom buds justify the expectation of an excellent crop of fruit, provided we can protect from the troublesome spring frosts which generally follow mild winters. In all cases where movable screens can be adopted no time should be lost in getting them fixed, as much may often be done by shading from bright sunshine and so-retarding the blossoms of Apricots and Peaches, but, as we have before stated, coddling must be regarded as one of the greatest evils. On the other hand, it will be well to avoid being lulled into carelessness by the favourable appearance of the early night. The first important item in wall covering is protection of the blossoms from wet, either by use of glass or boards. The weather having been favourable for outdoor work, it is hardly possible that any part of the winter routine can be in arrears, but where this is the case no time must be lost in setting matters straight, as a busy time is at hand, and doing things at the right time is quite as important as doing them well.

CUCUMBERS.

Since our last notes were written we have experienced a change to rather colder and squally weather, which will necessitate extra firing. Few plants are so easily and injuriously affected by

sudden changes. The cultivator must be ever on the watch for the appearance of red spider and thrips, which invariably spring into existence when old plants are placed under the influence of overheated hot-water pipes. If taken in time the most effectual remedy is sponging with warm soapy water; but prevention being better than cure, frequent syringing with a weak solution of Gishurst Compound on mild evenings or dull days will keep these troublesome enemies in check. If mildew, the outcome of insufficient bottom heat, hard cropping, and a low stagnant atmosphere puts in an appearance, syringe well with clear sulphur water, renovate the beds, and stimulate the plants with copious supplies of clear tepid liquid or guano water. As young growths break away under generous treatment, gradually remove old leaves, crop lightly, fertilise the most promising flowers, and cut the fruits before they are full grown.

VENTILATION AND CLEANLINESS.

These two important items in successful culture must not be overlooked; but draughts being harmful the air should be conducted through ventilators placed in front of the pipes and on a level with the surface of the fermenting material from which moisture and ammonia will be carried to the foliage and fruit. Cleanliness may be secured by the removal of all decaying matter and the frequent washing of the floors, shelves, and glass. Give every attention to spring-sown plants intended for pits or houses, and pinch or train to suit the position they are to occupy. If not already sown, a few seeds of some good prickly varieties may now be sown for fruiting in ordinary pits and frames. Although we have tried a great number of good novelties, we have not yet met with anything to surpass a variety sent out by a Worcester firm under the name of Smith's Frame. Many people think the prickly sorts superior to the smooth Syon House section. As consumers we do not feel competent to venture an opinion: as growers we prefer the first for frames in summer and the last for house work all the year round.

Madresfield Court.

WILLIAM CRUMP.

KEW NOTES.

INTERESTING PLANTS IN FLOWER.

Temperate House.

ACACIA (various species), Arundinaria Simoni, Begonia dichotoma, Camellia reticulata, Chorizema ilicifolium, Clianthus puniceus, Coriaria nepalensis, Echium callithyrsum, Geijera parviflora, Grevillea linearis, G. punicea, G. thelemanniana, Loropectalum chinense, Polygala myrtifolia var. grandiflora, Psychotria capensis, Pultenaea flava, Rhododendron arboreum, R. ciliatum, R. grande, R. hybridum, Rondeletia cordata, Rubus incisus, and Vaccinium Myrsinites.

Palm House.

Acokanthera venenata, Brownea Crawfordii, and B. grandiceps.

Orchid Houses.

Bletia striata, Cymbidium eburneum, Cynorchis lowiana, C. villosa, Dendrobium aggregatum, D. crassinode, D. chrysoideus, D. Juno, D. kingianum, D. nobile var. virginale, Epidendrum o'brienianum, Epiphronitis Veitchii, Eria confusa, Hexadesmia fasciculata, Liparis nervosa, Masdevallia triangularis, Odontoglossum Cervantesii, O. cirrhosum, O. Hallii, O. triumphans, Oncidium altissimum, O. lucasium, Ornithidium densum, Phaius Cooksoni, P. Norman var., and P. Wallichii.

Range.

Amphicome Emodi, Anoiganthus breviflorus, Brunfelsia calycina, Clerodendron Thomsoniae, Erica persoluta var. alba, Hypoxis stellata var. elegans, Kalanchoe Kirkii, Lacheralia Nelsoni, L. triflora, Plumbago rosea, Scilla peruviana, Sinningia concinna, and Tetranema mexicana.

Greenhouse.

Among other things the following are conspicuous: Acacia (various species), Coleus thyr-

soideus, Cytisus fragrans, Darwinia hookeriana, Ericostemon (several species), Eupatorium (several species), Hippeastrum (garden varieties), Primula kewensis, Tree Paeonies, and forced shrubs and bulbs.

Aroid House.

Chamaedorea lindeniana.

Alpine House.

Anemone intermedia, Corydalis bulbosa, Cyclamen libanoticum, Draba Gilliesii, D. grandiflora, D. hispanica, Dodacatheon ellipticum, Erythronium Hartwegi, Fritillaria pudica, Gagea arvensis, G. lutea, Hyacinthus azureus var. robustus, Ionopodium acanle, Iris pumila var. cerulea, I warleyensis, Muscari (several species), Narcissus cyclamineus, N. triandrus var. concolor, Primula denticulata, P. d. var. alba, P. frondosa, P. Palinuri, Romulea Columnae, R. Requienii, Soldanella montana, and Trillium nivale.

Rock Garden.

Anemone angulosa, A. blanda, Cardamine polyphylla, Daphne blagayana, Draba aizoides, D. stellata, Hocquetia epipactis, Lathyrus cyaneus, Leucocjum Hernandezii, Omphalodes verna, Primula marginata, Saxifraga apiculata, S. Kotschyi, S. oppositifolia, S. rocheliaana var. coriophylla, S. Salomoni, [S. sancta, and Scopolia carniolica var. concolor.

Bulb Borders.

Brodiaea uniflora, Chionodoxa cretica, C. Luciliae and varieties, Fritillaria aurea, F. astrabadensis, F. Lowerzowii, Hyacinthus orientalis, Muscari hotryoides and varieties, M. commutatum, M. racemosum, Scilla bifolia and varieties, S. meseniaca, S. sibirica and varieties, Tulipa kaufmanniana and T. violacea.

Arboretum.

Acer opulifolium var. obtusatum, A. rubrum, Berberis Darwinii, Clematis alpina, Cydonia japonica, C. Maulei, Erica lusitanica, E. mediterranea and varieties, Forsythia intermedia, F. suspensa, Parrotia jacquemontiana, Prunus triloba and others, Rhododendron campanulatum, R. fulgens, Spiraea Thunbergii, and Stachyurus praecox.

RIVIERA NOTES.

THE new hybrid Tacsonia militaris is flowering well, and is a fine large flower, blood-red in colour, and quite distinct from Van Volxemii, but yet showing little of the T. ignea blood save in the suppression of the tube. As the long, pendent flower-stalk is there, one misses the usual tube! If only the leaves did not turn yellow in the sun it would be a real acquisition, as it is—one hesitates to say it—superior to its parents, though it is of undoubted beauty on account of its rich colour. The other day at Cannes I was much pleased to see

Rose Anemone in flower already; if it proves a constant winter bloomer it will be indeed a treasure with its shining foliage and vigorous growth. Tea Rose Dr. Rouges is another admirable addition to winter-blooming Roses for verandahs; so far this winter it has contrived always to keep in flower, and the spring crop is now far advanced towards flowering.

Primula verticillata is very gay just now; it will be interesting to see if the new P. kewensis is superior to it in the open. Pot work and open borders demand different habits, and the pretty little P. floribunda is useless here unless quite under cover; its flowers and flower-stems are so soft.

A magnificent Oncocyclus Iris in a friend's garden is a great puzzle to me; now in flower it is handsomer than I. Gatesii or I. Lortetii, and I think so great a beauty must be well known somewhere. Its earliness shows its distinctness, as neither I. susiana, I. Gatesii, or I. Lortetii are nearly out in other gardens. I.

tingitana is well out, and when the falls become white—just before they fade—the contrast of colour with the yellow eye and the blue standards is very charming, but until the falls lose the grey shade they have at the first its beauty is a little overrated in my judgment. The wealth of flower now is so very great that perhaps one becomes over critical.

What a charming shrub Coronilla Valentina is for the wild garden; earlier and hardier than Coronilla glauca it has naturalised itself in some places and makes a lemon-yellow background to the wild Anemones and grey Rosemary. In a fine season like this, perhaps the end of February is the best moment for the gardener here. In such places as La Mortola, where huge masses of flowering Aloes such as A. supralveis and A. dyckiana are crowned with their branching heads of Tritoma-like bloom, the effect against the blue sky or sea is well worth the journey out, and it is pleasant to hear the note of wondering admiration struck by those newly arrived, whose eyes are as yet unaccustomed to such brilliance!

A small plant of Exochorda Alberti macrantha has surprised me by flowering. If it is always as early and as free as it seems to be it will be quite an addition, but to ordinary eyes it is marvellously like the older and well-known forms.

E. H. WOODALL.

MISCELLANEOUS.

THE IMPROVEMENT OF TOWNS AND CITIES.

OLDER European cities have been built too compactly, with most of the streets so narrow that there was no room for ornamental trees for beauty and shade. Many cities were surrounded by fortification walls and trenches. In the warlike times of the past the growing population was huddled closer and closer together, and the only beauty spots within the city limits were mostly the residence grounds of a few noblemen or princes. Many citizens cultivated vegetable and fruit gardens of small size near the outside of the fortifications, and here they could enjoy, behind closely-clipped hedges, the advantages of an invigorating country life. Here the children received their highly-valued lessons of floriculture and horticulture, and the family raised on very limited ground their fruits and vegetables. On Sundays and holidays the family, with its neighbours and friends, would stroll among the near-by farms and enjoy the meadow scenery and woodlands, or would go to the city forest, generally situated on the nearest hills. In times of peace this was an enjoyable and civilised condition.

But the times have changed and cities have grown to enormous size. The walls and ditches of the former fortifications have been converted into circles of beauty in many cities where the citizens can promenade on spacious, clean walks, bordered by well-kept lawns, with beautiful trees, shrubs, and flowers, and with spaces for monuments.

In our United States certain conditions have led to the much more rapid growth of small cities and towns into large cities, with the great disadvantage, except in rare cases, of having secured no land holdings of any extent for the rural enjoyment of those of its citizens who have to depend on such for their families, and who should thus be provided for. Park lands are bought apparently cheap, but they often consume enormous sums for development as a pleasure park, whereas a forest park might be equally desirable. Enough acreage for a number of pleasure parks is often bought in one plot, affording great advantages to the section of a city contiguous to it, but to the disadvantage of other parts, although the neglected section

may lie just as near to as desirable a piece of property for park purposes. Boulevards and walks, connecting links between the different pleasure parks, of moderate size, are not provided for until the land to be obtained for it has a value out of all proportion. When the pleasure parks are included in one large area, instead of a number of smaller ones on different sides of the city, connected by a boulevard, they generally assemble a jumble of many different incongruous features, and no unity of purpose prevails.

What has a music stand to do in a landscape park? Only to disturb the quietness of Nature. A sufficiently large enough space set apart on the boulevard would be all that is needed for this purpose. What has a museum to do in a landscape park for all the people? It belongs with the library more to the centre of a city, built on a beautiful square, easily accessible for research and study. What have monuments to do in a park, when the right place is on a boulevard or on the corners or in the centre of a city square? Aviaries, aquaria, and deer parks should be in a zoological garden. Conservatories, greenhouses, nurseries, geometric, or formal gardens, should be in a botanic garden. The botanic garden should show the floras of different continents in geographical distribution. The park for landscape effect only should show the possibility of this art in its highest perfection by the simplicity of its material, the great variety of expressive pictures, and the infinity of natural form of the local or country's flora. City squares as well as children's playgrounds should be bought in time before property rises to exorbitant prices. All school yards should be large, with plenty of playground.

A forest park would be the greatest blessing to the population of a city. I choose this term in preference to that of forest or reservation, because it should have much artistic natural park-like scenery instead of scientific forest plantings alone. A forest park well managed would be no expense to a city after a certain number of years; it might even be profitable in some cases. It could contain wild berry patches, such as Gooseberries, Blackberries, Dewberries, Huckleberries, &c., and wild Strawberries; also wild tree fruits like Cherries and Plums, and all for children to pasture on at their own will. The many wild flowers could be picked, but no plants unnecessarily destroyed. Birds and harmless small animals should here find a home without fear of molestation. Drives and walks should be very few and only the most necessary, but plenty of paths must be provided. All pleasure vehicles should be left on the outside, but should be cared for in appropriate buildings, free of charge. Laws and rules should be very few, but such as are necessary should be strictly enforced. The city should have its own street car lines to such a park, and many a town or city might afford a forest park when it would be, for the time being, out of the question to create and develop one of the other parks of a park system.

W. VORTRIEDE, in *Park and Cemetery*.

SOCIETIES.

REDHILL, REIGATE, AND DISTRICT GARDENERS' ASSOCIATION.

THE fortnightly meeting of this society was held at the Mutton Hotel on the 17th ult., Mr. Bound in the chair. Mr. Mould was awarded the society's certificate for Parsnips. Ten new members were elected. The chairman introduced the lecturer, Mr. Duncan, of South Park, Reigate, to give his lecture on "Insect Pests of the Garden." Mr. Duncan gave a most interesting lecture on the life history and structure of these pests, and also the best means of eradicating them from our gardens. He gave the members some very useful recipes for the destruction of insect pests and the best time to apply them. The lecture was well illustrated with lantern slides. A hearty vote of thanks was accorded the lecturer, who had given his services free of charge to the society.

CARDIFF GARDENERS' ASSOCIATION.

THE usual fortnightly meeting took place at the Grand Hotel on Tuesday, the 24th ult., Mr. C. E. Collier in the chair. Mr. Waller, Cucumber grower, Eastbrook Nurseries, Dinas Powis, Glamorganshire, delivered an exceedingly exhaustive lecture entitled "The Culture of Cucumbers." He dealt first with the best methods of sowing seeds

watering, and transplanting; then the best soils, manures, training the plants, &c. Mr. Farmer opened the debate, which occasioned a good discussion, more particularly as to the best ways and means of fighting against the ravages of the dreaded mildew and insect pests, without injury to the foliage. The best thanks of the meeting were accorded Mr. Waller for his excellent lecture. A first-class certificate was unanimously awarded to Mr. Waller for a collection of well-grown fruits of Cardiff Castle Cucumbers.

CHISLEHURST GARDENERS' ASSOCIATION.

MR. H. CANNELL, the well-known florist, &c., of Swanley, gave a very instructive lecture on Tuesday, the 24th ult., before the Chislehurst Gardeners' Society, on "How to Grow Onions." In the course of his remarks Mr. Cannell said when the properties and value of the Onion were known, so sure would growers be able to produce fine ones, from the very fact of their knowing how necessary they were to keep us in health and strength. He was convinced that a capable grower could get a good living from Onion growing alone on light rich soil. The first thing necessary to know was their several diseases—blight, maggots, &c., and how to prevent these pests alighting and injuring the crops. A good, deep, rich soil should be selected, facing the sun as much as possible, in as warm and sheltered a spot as could be obtained. The ground should be covered with a quarter of an inch of soot, with a good strong coating of guano, followed with 4 inches or 5 inches in depth of good fresh horse or farmyard manure. This should be incorporated regularly amongst the soil as it is turned over and trenched 3 feet deep. Care should be taken that the top spit comes on the top again, and the second spit immediately below it. When watering in the dry weather in summer the moisture should go down at least a foot. When the plants are about 1 foot high they should be sulphured at the top and bottom to prevent moths settling and laying their eggs. This also would prevent mildew. This dusting should be applied every fortnight, and is easily applied by the "Ideal" bellows. The lecture was listened to with attention, and the meeting concluded with the usual votes of thanks.

WYLAM AND DISTRICT HORTICULTURAL SOCIETY.

THERE has lately been formed at Wylam a society whose object is to arrange discussions on horticultural and educational subjects, and to promote the welfare of horticulturists in the district. Meetings are held twice every month in the hall of the Wylam Reading Institute. The president is Mr. N. C. Cookson, F.R.H.S., Oakwood, Wylam, whose interest in horticulture (more especially in the growing of Orchids) is well known. The chairman is Mr. Chapman, F.R.H.S., head gardener to Mr. Cookson at Oakwood. The secretary, Mr. Waugh, is a well-known technical education enthusiast. The society opened the session a few weeks ago with a lecture by Messrs. Clive and Kenneth Cookson on "Bird Life," with lantern slides. The lecture was largely attended and very much appreciated. Since then Mr. E. M. Bidgood, M.A., of Gateshead, has given a lecture on "Botany," also with lantern illustrations, and he has promised to give another lecture later in the session. At the next meeting Mr. Chapman will lecture on "Cypripediums," with illustrations.

BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

THIS association met at St. John's Rooms, Redland, on Thursday, the 26th ult., to hear Mr. W. Staddon of Weston-super-Mare read a paper on "Annals." Mr. Staddon's visit was the means of bringing together a good attendance, as he was an active member of the society prior to his removal to Weston. Mr. Staddon remarked on the usefulness and beauty of our annual flowers, and by careful cultivation a good display could be obtained throughout the summer months. The most essential point was to obtain the best seed from a good seed merchant, and not buying the cheap trash so prevalent on the market, the results from which only caused the greatest disappointment. The finest strains could only be obtained by paying a fair price. Sweet Peas, the lecturer remarked, were undoubtedly the favourite, their perfume and variety of colours making them indispensable. Among others Asters, Stocks, Salpiglossis, and Nasturtiums were useful. Deep digging and manuring were points not to be overlooked. Sowing thinly was also an important factor to be considered; many annuals were spoiled by overcrowding. The time of sowing must depend on the state of the weather, the end of March being generally considered the most suitable. Mr. Staddon's lecture was much appreciated, and he was unanimously accorded the best thanks of the meeting. Mr. E. Soole, F.R.H.S., occupied the chair, and remarked how pleased they were to have Mr. Staddon among them, and it was hoped he would again pay a visit to his old association, in which he had made so many friends. Prizes for three pots of Freesias went to Mr. W. A. F. Powell (gardener, Mr. Raikes) and Mrs. Hall (gardener, Mr. Ware), being first and second respectively. Certificates of merit were awarded to Mr. Jennings for two Cypripediums, Mr. Gilbert Howes (gardener, Mr. White) for Platyclines glunacea, Mr. Wakefield for a seedling Begonia of Gloire de Lorraine, and to Mr. Hunt for *Veltheimia vividiflora*.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening, the 2nd inst., the executive committee of the above society met at the Albert Hotel, Victoria Street, Westminster, S.W., Mr. Thomas Bevan presiding. A letter was read from Mr. C. E. Shea acknowledging his election as president, and expressing the hope that he would be able to discharge the duties to the satisfaction of the committee. He also intimated his desire to offer a special prize of £5 5s., which was heartily accepted and allocated as first prize in the class for twenty-four Japanese cut blooms. Referring to the annual outing in July, a letter was read from Mr. George Stanton, of Park Place Gardens, Henley-on-Thames, offering suggestions on the contemplated visit.

The secretary was then called upon for an estimate of the receipts and expenditure prior to the consideration of the new schedule. This was regarded as very satisfactory, and the consideration of the schedule, based upon the information thus supplied, various alterations owing to altered circumstances were made, particulars of which had been gleaned from the schedule when published. We may, however, mention that the special prize recently announced to be offered by Messrs. Mackenzie and Moncur of £10 value in plate will form the first prize in the class for six vases of incurred Chrysanthemums at the November show. A slight alteration in the definition of an amateur (Section B) was made by no longer allowing him to sell either sports or seedlings. On the election of judges by ballot Messrs. Ingamells and Foster were appointed scrutineers, who announced the results as follows: October show—Messrs. Gleeson and R. Parker. November show—*Plants and groups*—Messrs. J. F. McLeod and H. Turner; *Incurved*—Messrs. C. J. Salter and Fullard; *Japanese*—Messrs. Inglefield and W. Robinson; *Decorations*—Messrs. J. Jennings and O. Thomas; *Fruit and vegetables*—Messrs. J. Smith and W. Allan. December show—Messrs. C. Orchard and King, suitable reserves being named in each case. New members were elected, and the meeting, which was a very busy one, broke up at a somewhat later hour than usual.

MANCHESTER AND NORTH OF ENGLAND ORCHID SOCIETY.

THE usual meeting was held in the Conl Exchange, Market Street, Manchester, on Thursday, the 5th inst., and some very good exhibits were staged.

O. O. Wrigley, Esq., Bridge Hall, Bury, gained a silver medal for fine forms of *Dendrobium wardianum*, *D. xanthocentrum*, *D. Rolfei*, *Cypripedium villosum*, *C. Eurayades* Low's variety, *C. Swinburnei magnificum*, &c.

W. Duckworth, Esq., Flinton, showed very fine *Dendrobium nobile murhianum*, *D. schneiderianum*, *D. splendissimum*, and others. Silver medal.

W. Thompson, Esq., Stone, was given a bronze medal for choice *Odontoglossums*, *Cypripediums*, and *Dendrobium kingianum*, splendidly flowered.

S. Gratrix, Esq., Whalley Range, showed a specially fine form of *Dendrobium Cybele*.

T. Statter, Esq., Stand Hall, exhibited *Dendrobium nobile* album with about twenty flowers, *Cypripedium macrochilum* giganteum, &c.

Mr. Cypher, Cheltenham, gained a silver medal for *Laelio-Cattleya* Mrs. Gratrix and some very fine forms of *Dendrobiums*, &c.

Messrs. F. Sander and Co., St. Albans, had a bronze medal for *Cypripedium elmirianum superbum*, *Laelio-Cattleya Lucia magnifica*, *Trichopilia suavis*, *Miltonia blenana*, &c.

Messrs. S. Allen and Sons, Sale, gained a bronze medal for *Dendrobium wardianum*, *Lycaste Skinneri*, *Cypripedium villosum*, &c.

Messrs. Cowan and Co., Gateacre, showed *Dendrobium wardianum*, &c.

Messrs. Hugh Low and Co., Bush Hill Park, showed very fine forms of *Dendrobium nobile* *virginale* Low's variety, &c.

Messrs. Keeling and Sons, Bradford, exhibited *Bulbophyllum picturatum*, &c.

AWARDS.

To W. Duckworth, Esq.: First-class certificate for *Dendrobium d'Alvry Salomon*: awards of merit for *D. Cybele* Oakwood variety and *D. nobile burfordense*.

Samuel Gratrix, Esq.: Awards of merit for *Odontoglossum hybrid Amelia*, *Cypripedium beechense*, and *C. cardosianum*.

Lady Brunner, Liverpool: Award of merit for *Cattleya Trianae* Lady Brunner.

Mr. Cypher: Award of merit for *Dendrobium splendissima albeni*.

W. Thompson, Esq.: Award of merit and cultural certificate for *Dendrobium kingianum*, a remarkable display of lovely purple flowers; and awards of merit to *Cypripedium* Miss Fowler and *Odontoglossum harrayo-Crispi* alba.

Messrs. Keeling and Son: Award of merit to *Bulbophyllum picturatum*.

CROYDON CHRYSANTHEMUM SOCIETY.

THE fifteenth annual meeting of the Croydon Chrysanthemum Society was held at the Royal County House Hotel, West Croydon, on Thursday, the 26th ult., the Mayor (Alderman Sir Frederick Edridge) in the chair. There was a large attendance.

Mr. W. B. Beckett (secretary) presented the report and accounts. The report recorded the thanks of the committee to the subscribers, and stated that the subscriptions for the year were £3 less than in 1901, and the "gate" proceeds were £2 less. The prizes awarded at the show amounted to £116, out of a schedule total of £125. At the last annual meeting the president suggested that 1902 being Coronation year a special effort should be made to create a commemorative prize. The suggestion was freely endorsed, and subscriptions amounting to upwards of £7 were received, a solid silver cup, with £3 in cash, being offered as first prize for ten blooms in vases. This was won by Mr. Pantia Ralli (gardener, Mr. G. J. Hunt). The challenge cup presented by Mr. Frank Lloyd in 1900 was, for the second time in succession, won by Mr. Pantia Ralli. The entries for flowers for competition were 87; not for competition, four; fruit for competition, 123; not for competition, two; total, 216. The exhibits included six groups, 760 cut blooms, 12 collections of vegetables, and 48 pot plants. The entries of fruit and Grapes were above the average in number and excellence. The allotment holders were again very successful. The judges were unanimous as to the high standard of all the exhibits. It had been decided that trade exhibits should not be allowed unless a payment were made towards the expenses. Donors of special prizes and others who helped were thanked, and the committee asked for increased support. The net balance was £7 10s.

THE GARDEN

No. 1635.—VOL. LXIII.]

[MARCH 21, 1903.]

PLANT NAMES.

AS many gardeners and others are becoming interested in plant nomenclature, the following letter from Mr. W. Pettigrew is timely, as showing that the nomenclature adopted by Kew is creating some confusion in the minds of those who cannot be accounted botanists.

We wish nurserymen throughout the country would adopt the Kew standard. It is followed in *THE GARDEN* and in all the books issued in connexion with this journal and its contemporary, *Country Life*, but with few exceptions nurserymen's catalogues do not recognise in any way the great change towards simplification and uniformity as revealed in the "Index Kewensis." This work is not, of course, for the office table or the gardener's library, but the hand lists cost little, and are intended for constant use. They are sold at Kew without profit to that establishment, and we are surprised that the demand for them is not greater.

We have drawn attention to this subject before, but the letters we have received from time to time show that gardeners (professional and others) are in a dilemma, which will continue until all nurserymen adopt the Kew standard. It is quite a simple matter to give the synonyms from the Kew hand lists until the present classification has become familiar. As Mr. Wolley Dod mentioned in *THE GARDEN* of February 8, 1902: "Uniformity in naming will never be attained amongst gardeners unless we agree to follow one authority, and that authority should be the hand lists of the Royal Gardens, Kew. . . . Of course 'Index Kewensis' is a work not within reach of everyone, but the hand lists of the different botanical classes cultivated at Kew may be bought on the spot at trifling cost, and are most carefully compiled and revised, and are intended to supersede all other authorities, even the 'Index Kewensis.'" A list was given, with prices, in *THE GARDEN* of February 21, page 134. The letter we have referred to is as follows:—

"Few things are more puzzling or give rise to more annoyance to the average gardener than does the nomenclature of the plants with which he daily comes in contact. For many years past the botanical authorities as well as the leading horticulturists of this country have done their best to reduce plant names to something like a standard, and in this direction Kew has recently done excellent service to the

whole gardening community by the publication of the various hand lists of plants cultivated in the Royal Gardens. Notwithstanding all that has been done, the fact remains, however, that plant nomenclature is still in a very chaotic condition, and it is not at all an uncommon thing to find plants with several generic and specific synonyms.

"Of course botanists were the original cause of this muddled condition of things, but the continuance of it is now in a very great measure due to the gardening press and nurserymen, and before ever anything like a standard nomenclature becomes a realised fact, these are the two forces which must bring it about. At the present time one can hardly read a gardening paper without finding some plant or other called by two or more different names in different parts of the issue, a fact which gives rise to much confusion and indignation among garden workers, and naturally leads to the disuse of botanical names.

"Again, many gardeners depend almost solely upon nurserymen's catalogues as a guide in naming their plants, and although there are many exceedingly trustworthy ones for this purpose the majority are most unreliable where the correct botanical name is required. What is still more annoying than this, however, is that many catalogues contain the names of plants which are not recognised botanically at all, and in this way collectors are liable to be misled into buying a simple variety of a plant instead of a distinct species, examples of which I shall speak about later on.

"The first requirement needed to put an end to the present state of confusion in plant names is to decide what is to be the recognised standard to follow, and I think it will readily be granted that that standard should be the one set up by Kew—admittedly the one authority on systematic botany throughout the whole world. Hence the 'Index Kewensis' naturally becomes the standard, and should be regarded as such by the gardening press and the trade, and if this were once done, order would soon take the place of what is now confusion and tangle.

"Needless to say it is obvious in such a vast subject as this that it would be quite impossible to have a perfect standard, and I am quite aware that even the one now set up as such does not always maintain its own standard. This, of course, I take it is not because there was a lack of system in adopting plant names—rather the reverse—but is simply as a result of the fact that during the many years this vast work was in progress fresh light was thrown upon the nomenclature of plants recorded in its earlier parts, which necessitated their alteration. This slight contradiction, however, is of so little importance in comparison to the great good it has accomplished that it is hardly worth noting.

"As illustrating the chaotic condition of plant nomenclature I have culled the following

names of a few hardy herbaceous plants from the catalogues of several leading nursery firms.

"Most catalogues contain the names of several species of *Armeria*, and among them one named *cephalotes*. Now, according to Kew, there are four distinct species of *Armeria* known by this name, yet it is not the recognised name of any one of them. *A. lauchiana* is the name of another plant offered in most catalogues, but does not appear in the 'Kew Hand List,' whereas another known in the trade as *A. setacea* is correctly (by the Kew standard) called *A. juncea*.

"The genus *Aubrietia* is a good example of a case where varieties are often offered for sale as distinct species. The greater number of garden *Aubrietias* are merely varieties of *A. deltoidea*, but are invariably given specific value and catalogued as *A. Campbellii*, *A. græca*, *A. Leichtlinii*, &c. This naturally raises the whole question of what constitutes a species and what a mere variety, a subject which can only be dealt with by botanists, and when any standard nomenclature is accepted these fine distinctions must also be accepted with it. *Bocconia cordata* appears in many lists as *B. japonica*, and under this name was once purchased by myself and added to my collection, already containing it under its correct name.

"*Saxifragas* again are very badly named, for recently, when trying to get the correct names for a collection, I found that such plants as are known in gardens as *S. apiculata*, *S. Bucklandii*, *S. capillaris*, *S. Churchilli*, &c., are not even recorded, while others, such as *S. cochlearis*, *S. lautoscana*, *S. nepalensis*, and *S. sturmiana* are given as being only varieties of other species. On the other hand, the name *S. palmata* stands for three distinct species, but is not accepted as the official name of any.

"*Sedums* are quite as confusing. The Kew list does not record *S. Brownii* nor *S. Michauxii*, both of which find a place in the majority of catalogues. *Sedum glaucum* has at one time and another been the appellation given to four different plants but is not regarded as the correct name of one. The genus *Sempervivum* is quite as bad as any of the foregoing. *Oenothera missouriensis* is constantly offered by the trade as *O. macrocarpa*; *O. biennis* var. *grandiflora* as *O. lamarciana*. Very many more examples similar to the foregoing could easily be given if time and space would permit.

"Catalogues perpetuate many generic names which have become obsolete, and should no longer be used on account of the confusion they cause. Among other such names so used are *Pyrethrum*, *Hepatica*, *Leptenella*, *Orobus*, *Ligularia*, &c. The only method of doing away with all this confusion among plant names is, as I have already stated, to accept the Kew standard as the one and only authority."

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

March 24. — Royal Horticultural Society's Meeting (Tulip and Hyacinth Show).

March 25. — Liverpool Horticultural Association Spring Show.

April 1. — Royal Botanic Society's Spring Show.

April 4. — Meeting of the Société Française d'Horticulture de Londres.

The Horticultural Hall.—Amy Lady Tate has given £500 and J. Wernher, Esq., £100 towards the building fund.

Rose Show Fixtures in 1903. — Wednesday, June 24, York (three days); Thursday, June 25, Holland House (Royal Horticultural Society, two days); Saturday, June 27, Windsor; Wednesday, July 1, Temple Gardens (National Rose Society), and Richmond (Surrey); Thursday, July 2, Canterbury, Colchester, Norwich, and Reading; Saturday, July 4, Sutton and Walton-on-Thames; Tuesday, July 7, Gloucester and Wolverhampton (three days); Wednesday, July 8, Croydon and Southampton (two days); Thursday, July 9, Bath and Woodbridge; Wednesday, July 15, Glasgow (National Rose Society), Formby, Ipswich, and Thornton Heath; Tuesday, July 21, Tibshelf; Wednesday, July 22, Cardiff (two days); Thursday, July 23, Salterhebble; Monday, August 3, Sheffield. The above are the only dates of Rose shows, or of other horticultural exhibitions where Roses form a leading feature, that have yet reached me. I shall be glad to receive notice of any other Rose show fixtures for publication in a future list.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Royal Horticultural Society.—The next fruit and flower show of the above society will be held on Tuesday next in the Drill Hall, Buckingham Gate, Westminster, 1—5 p.m. Special prizes will be offered for Hyacinths and Tulips by the Royal Bulb-growing Society of Haarlem as follows: 120 Hyacinths in pots (one bulb in each pot) in not less than forty varieties and not more than three pots of any one variety; open; first prize, £7; second prize, £5; third prize, £3. 100 pots of Tulips (three bulbs of one variety in each pot), to include fifty varieties at least and not more than two pots of any one variety; open; first prize, £4; second prize, £3; third prize, £2. A lecture on "Photo-micrography as an Aid to the Study of Plant Life" (illustrated by lantern slides) will be given by F. Martin Duncan, Esq., F.R.H.S., at three o'clock. At a general meeting held on Tuesday, the 10th inst., eighty-two new Fellows were elected, amongst them being the Countess of Stamford, Lady Caroline Gordon-Lennox, Lady Harriet Cavendish, and the Hon. Mrs. Alfred Egerton, making a total of 405 elected since the beginning of the present year.

The president and council have requested the following gentlemen to be so kind as to act as representatives of the society at the Ghent quinquennial show, viz.: The Right Hon. the Lord Redesdale, Frederick G. Lloyd, Esq., High Sheriff of Buckinghamshire; Mr. James Hudson, V.M.H., all members of the council of the society. Mr. Charles E. Pearson is attached to the deputation as their secretary.

Examination in horticulture.—The society's annual examination in the principles and practice of horticulture will be held on Wednesday, April 22. Full particulars may be obtained by sending a stamped and directed envelope to the society's offices, 117, Victoria Street, London, S.W. Intending candidates are requested to send in their entries by the 31st inst., if possible. The questions set at all the previous examinations are now published; price 1s. complete.

Pinguicula caudata superba.—The Pinguicula or Butterworts are almost unknown to the majority of gardeners with the exception of those who practise bog gardening. The best known species is, of course, our native Butterwort (*P. vulgaris*), a dwarf herb with purplish flowers and radical, succulent leaves, the juice of which is commonly supposed to be poisonous to insect life. At the last Drill Hall meeting considerable interest was manifested in a plant which Mr. J. T. Bennett-

Poë exhibited under the name of *Pinguicula caudata superba*, and which gained an award of merit. This proved to be an exceedingly fine form of *P. caudata*, which was raised from seed in Mr. Poë's garden. The colouring reminded the writer very much of some of the newer varieties of herbaceous Phloxes described as being of a rich carmine, which invariably means magenta in some form or other. However, although one would describe the flower of the plant under notice as being vivid magenta, there is no suspicion of the crude colouring so often associated with that term, and there can be no hesitation in recommending it as a beautiful plant for the cool greenhouse. The typical *Pinguicula caudata* is a native of the mountainous regions of Central America, and Nicholson gives it as introduced from Mexico in 1881. The blossoms are solitary, five-parted, and borne on the end of hairy scapes 5 inches to 10 inches in height. In Mr. Poë's plant the leaves bore considerable resemblance to those of an *Auricula*, and were closely pressed to the surface of the pot.—A. G.

Montbretia Germania.—In more ways than one this is quite the finest of the Montbretias, and was well worthy of the award of merit bestowed upon it by the Royal Horticultural Society. I obtained a few corms soon after distribution, and these have now increased to substantial clumps, which proved most fertile last year. Most of the spikes were 3 feet or more in height, and the flowers were 2½ inches across. They are of a brilliant orange-red colouring, with a deep red throat, and remain on the plants a long time in good condition. The habit of growth, while being compact, is very vigorous. A fine plant to group in the border, and one that is especially useful for decorating a greenhouse during summer if some of its corms are potted up.—A. R. GOODWIN.

The Spring Cabbage crop in 1903. For the past few seasons the Spring Cabbage failed to turn in as early as expected, and this loss is much felt during the early part of April, as at that time the other Brassicas are getting past their best. Other choice vegetables are very scarce. For many years I have kept a record of the season, and find that only in a very few years have we cut Cabbage in March and in some quite late in April, and not at all in quantity until May. This year we have been able to cut a few stray heads the third week in March, and the crop will be quite plentiful by the middle of April. This is not entirely owing to the culture or season, as during the past few years there has been a splendid advance in variety. A quarter of a century ago we had very few, if any, varieties equal to Ellam's Dwarf Early or Sutton's April, and others well worth special notice. These compact, distinct Cabbages are a great advance in size on the large-leaved older and coarser kinds when grown for a first or early spring supply in a private garden. Much depends upon the soil and situation as regards earliness. I have noted how free certain kinds grow if sown and planted so that the plants obtain a firm root-hold before the cold weather arrests growth. I place much importance upon this point, and feel sure that as regards earliness the sooner the plants are taken from the seed-bed and are in their permanent quarters the better. As regards sowing dates or culture, I have never had any very early supplies from seed sown after July 25, but there must be no crowding in the seed-bed. Of course I should not advise anyone to sow all their spring crop at the earlier sowing. The aim is to get a succession, and this is readily secured by, say, a three weeks' interval between the first and second sowings. Another point is the position of the seed-beds. These require full exposure and moisture, as want of the latter will cause later growth, so that the second sowing may be superior to the first if the weather is hot and dry at the date noted.—G. WYTHES.

Poisons for trade purposes.—At a meeting of the council of the Royal Horticultural Society held on Tuesday last, a deputation consisting of myself, as secretary of the Traders in Poisonous Compounds for Trade Purposes Protection Society, Mr. G. H. Richards, and Mr. T. Peed, of Messrs. T. Peed and Sons, waited upon the council. After bringing to the knowledge of the

council the report of the Departmental Poisons Committee appointed by the Privy Council to consider Schedule A of the Pharmacy Act, 1868, and explaining that such poisonous substances as insecticides, weed killers, sheep dips, &c., could not be lawfully sold by nurserymen, seedsmen, and others, although required for agricultural and horticultural purposes, the council passed a resolution asking the Government to bring in a Bill adopting the recommendations of the Poisons Committee, and a petition in favour of the recommendations for allowing duly licensed persons to sell poisonous compounds, where they are required for agricultural or horticultural purposes, was signed by the chairman of the council, Sir Trevor Lawrence, Bart., on behalf of the council.—T. G. DOBBS.

The Horticultural Directory.—This useful year-book has now reached its forty-fourth year of publication; it is indispensable to horticulturists throughout the kingdom. Full and revised lists of gardeners and their addresses are given, as well as of nurserymen and botanical and horticultural societies. In addition to these valuable lists the book contains many useful garden recipes, and certificates and awards of merit granted by the Royal Horticultural and other societies from October, 1901, to September, 1902. Published from the *Journal of Horticulture* office.

Daffodils in pots.—At the Royal Horticultural Society's meeting on the 10th inst., a remarkably fine group of forced Daffodils was contributed by Messrs. W. Cutbush and Sons, Highgate, for which they were awarded a Silver Floral Medal by the Narcissus and Tulip Committee. The plants bore evidence of careful forcing, and the flowers were fine and well developed. Amongst the numerous varieties staged, I particularly noted the following:—*Maximus*, Mr. J. Berkeley (very fine), *Golden Spur*, *Emperor*, and *Empress*. The incomparabilis group was also well represented by *Sir Watkin*, *Beauty*, *Frank Miles*, and *Queen Bess*. Mention should also be made of that exquisite variety, *Poeticus Almira*, of which several beautiful examples were exhibited.—ARTHUR GOODWIN.

Antigonum leptopus.—This, which is referred to in THE GARDEN (page 155) under the name of the Pink Coralita, though such a charming object in many of the West Indian gardens, is not easily grown in this country, for even where it grows freely its flowering can by no means be depended upon. It is a member of the Polygonum family, and, as in the case of *Polygonum baldschanicum*, its attractiveness is owing not so much to the individual flowers as to the profusion in which they are borne, hence a few scattered flowers convey no idea of the effect produced in the tropics by its large cloud-like masses of bloom, which are admired by all, and especially by those who see it for the first time. The conditions most favourable to its culture in this country are planted out in a well-drained border in an intermediate temperature and in a structure fully exposed to the sun, as if shaded not only is the growth developed at the expense of flowers, but these last are paler in colour and much less effective than if exposed to the sun. Of the white form referred to in the above-named article I recently saw seeds offered in the catalogue of one of our leading nurserymen.—H. P.

Giant Sequoias.—I notice in a contemporary that a splendid section has been taken from one of the giant trees of California, to be shown at a forestry exhibition, and in an account of the tree itself we read that it was over 300 feet high and 90 feet at the base (the latter, of course, being the circumference measurement). Can any reader of THE GARDEN say if in America the bulk and height of these trees increase proportionately, or is the bulk considerably developed after the maximum height is attained? I ask, because we have in the grounds here a *Sequoia sempervirens* that is close on 100 feet high, but the bulk circumference is barely 12 feet. The trunk under such conditions seems very slender compared with the height. It is a fine specimen, well clothed with branches from base to summit.—E. BURRELL, *Claremont, Esher.*

Pyrus (Cydonia) japonica cardinalis.—This is an intensely brilliant form of a good flowering shrub, and apparently the best yet raised. I saw it last June flowering in Kew Gardens, and the blossom was produced on a growth somewhat shaded, hence its late appearance. Compared with the brilliant single Rose Royal Scarlet the colours seemed almost identical. I do not think we overvalue these beautiful early-flowering shrubs. They are usually found upon walls, whereas they are far more elegant treated as bushes if planted sufficiently thinly to display their individuality.

Rose Captain Hayward.—This beautiful Hybrid Perpetual is valued by all who force Roses in spring. The somewhat thin flowers enable it to expand freely even when there is an absence of sunshine, and English growers are not favoured with too much of this during the early year. The brilliant scarlet-crimson colour of its deep petalled flowers, the bold massive foliage, and good stiff growths make it an ideal forcing Hybrid Perpetual for our climate. Then, too, it is deliciously fragrant, no small attribute in the opinion of some. I well remember Mr. Bennett first showing this Rose. He evidently had a high opinion of it, for he had the Rose jealously guarded the whole time the show was open. It is a capital seeder, so therefore it should give some good seedlings, for we can well multiply such Roses.—P.

Cleansing fruit trees.—I have not anywhere seen fruit trees so remarkably clean as are the Apples, Pears, and Plums growing either in dwarf or standard form in the gardens at Woodhatch, Reigate. When I saw them on the 27th ult. every tree, almost to the tips of the shoots, was coated in a dull white solution of lime, root clay, and including some paraffin. This mixture is laid on the trees in November, an ordinary long-handled tar brush being used for the purpose. Generally frost causes the coating to peel earlier, but this winter it was longer in evidence than usual. Still, when presently the sap causes the wood to swell, the whole of this coating will peel off readily. Not a score of dressings of any other description or of even sprayings with the caustic soda solution could produce cleaner wood than these trees here exhibit in the summer, and insects give very little trouble. When to this cleansing is added manure mulchings and waterings in dry weather, also summer as well as winter pruning, it is no matter for surprise that the fruit is of the finest quality.

Vase flowers v. specimen plants.—Ever since its formation, twenty-seven years ago, the Kingston Chrysanthemum Society has included one or more classes for specimen plants of Chrysanthemums. But interest in these had of late become so small, few persons caring for them evidently, although quite large and good, and in consequence the Kingston committee have now withdrawn the class altogether, ignoring trained or other Chrysanthemum plants entirely except in groups, and in place thereof have included one of twelve Japanese blooms, any varieties, on long stems, set up in pairs of vases, any decorative or draping foliage being added to give pleasing effect. The judges will be left absolutely free as to what points they may hold as important. It is believed that if a class of this kind shall include a dozen fine vases of flowers the result will be a great attraction, and far outweigh a few specimen plants. Quality of bloom will show culture, and effect will evidence decorative art.

Cucumber growing at Farnham. The capital illustration of the interior of one of Mr. S. Mortimer's Cucumber houses at Rowledge, Farnham, Surrey, given on page 169, is to many readers valuable as showing not only the rude health of the plants and the abundance of the fruits, but also it evidences the very limited root area allotted to the plants. How different now is the practice in relation to root area for both Melons and Cucumbers, as compared with the old practice in which great masses of soil were placed for the roots to ramble in! No wonder if then shoots and leaves greatly prevailed over fruits. In Mr. Mortimer's Melon and Cucumber houses the beds are really wood troughs, 20 inches

wide, having open trellis bottoms. To each side of this trellis stout 7-inch boards are fixed. The troughs are placed along on each side of the span houses, just over the side pipes, so that the warmth from them permeates the soil. Rough pieces of turf are first put in, then the soil, which is slightly ridged in the centre. Plants are put out from 15 inches to 18 inches apart. When fruits are set the roots get stimulants from the surface. All fruits are grown for seed production, hence the strain on the plants is very great.—A. D.

The Sweet Potato.—Concerning Mr. G. Wythes' interesting note on the Sweet Potato in your issue of February 14, he is right in saying that it takes some time to grow accustomed to the flavour (in most cases at least), but when the taste is once acquired it is preferred to most other vegetables. Here the New York market prefers a dry and mealy Sweet Potato, such as the growers about Vineland, New Jersey, produce in the highest possible quality; but our southern friends prefer one that is moist and sugary, with a tendency to exude syrup while cooking. As for methods of serving, they are legion. Baked, as suggested by Mr. Wythes, they are excellent; better still when cooked in the drippings under roasting meat, like Yorkshire pudding. Roast 'possum, with Sweet Potatoes cooked in the gravy, forms the acme of culinary delight to the Southern negro. Plainly boiled, the Sweet Potato is satisfying and nutritious; the skin should be left on until cooked, then removed before sending to the table. Boiled and cut into slices, then fried brown, the Sweet Potato forms a nice breakfast dish, and is also admirable as an accompaniment for roast poultry, especially duck. A rich baked pudding is made from Sweet Potatoes, and the same vegetable, in the Southern States, takes the place of Pumpkin in making pies. They are also made into biscuits (I mean buns, according to the speech of the home country), and are slowly baked with butter and sugar until glazed with a rich caramel sauce. I am sure that English people who once acquire a taste for Sweet Potatoes would welcome this addition to their tables, though, unlike green Corn, which every foreigner loves upon first introduction, a taste for them must be cultivated.—EMILY TAPLIN ROYLE, *Maywood, N.J.*

National Fruit Growers' Federation.—We have received a copy of the rules of this recently-formed association, of which Colonel C. W. Long, M.P., is president, and its objects are set forth as follow: The objects of the federation are to create a permanent central organisation representative of the fruit growers and market gardeners of the United Kingdom, for the promotion of their common interests as a whole, while reserving perfect local liberty of action to the constituent members. (a) To prevent by every possible means the granting by railway companies of preferential rates and facilities for the carriage of foreign fruit and market garden produce. (b) To secure quicker means of transit and fair rates from railway companies, and consider complaints which are likely to be ignored by companies when made by individual members of the federation. (c) To prevent jams made of foreign fruit being sold by misdescription, misrepresentation, or implication, as being made of home-grown fruit, and to urge the distinct labelling of British fruit jams; and also to prevent the sale of fresh fruit, either wholesale or retail, by misdescription or misrepresentation. (d) To affiliate with any other kindred society or societies. (e) To promote, support, or oppose legislative or other measures affecting the aforesaid trade. (f) The doing of all such things as may be conducive to the prosperity of fruit growers and market gardeners, or incidental to the attainment of the above objects. (g) The collection and dissemination of statistical and other information relating to the fruit-growing industry. The association's offices are at 28, Eaton Rise, Ealing, W.

Birds and fruit.—The news in various papers as to the great damage done to crops by starlings recalls an experience of last year, when a crop of Cornish Gilliflower Apples was utterly ruined by these birds. I suppose no one will

question the fact that the above-named variety, with Cox's Orange and Ribston, are the three best flavoured Apples. Of this trio I should put the Gilliflower a shade the best (from a purely flavour standpoint), just as Doyenné du Comice is a shade the best Pear, and the starlings evidently think the same, for it is the first Apple they attack in this particular season. Together with jays they attack, amongst others earlier in the season, Quarenden, Gravenstein, and Duchess of Oldenberg, but later the Gilliflower is the first victim. Why is this? There is absolutely nothing in the appearance of the Apple to attract them. Are they attracted by the aroma, or is the knowledge that here is something worth eating transmitted by bird lore? I said above that the crop of 1902 was lost—a sharp attack of illness about August kept me both from getting about and concentrating my thoughts on the hundred and one things that want attention in the garden at that time, or we generally save the crop (the trees being large bushes) with the aid of long poles and close meshed fish netting, the close mesh being necessary to keep the tits out as well as the starlings. I have several times saved occasional fruit only slightly tapped right up to the ripening stage by the aid of plaster of Paris, but it was too far gone for this last year, the majority of the Apples being half eaten.—E. BURRELL.

Williams Memorial Trustees.—At a meeting of the Williams Memorial Trustees held recently, Dr. Masters in the chair, it was decided to offer two medals for competition at the British fruit and vegetable show at Chiswick to be held in September next. It was also resolved to subscribe the sum of £10 to the funds of the new Horticultural Hall.

Tulipa violacea.—This handsome species is, I believe, the earliest of all the Tulips to flower. The specific name is perhaps peculiar, for one would naturally look for some reason for it in the colouring of the flowers, but there is more of rosy carmine than ought else, and externally the buds are almost wholly of this colour. Quite apart from the name, however, the species is a very beautiful one, and especially where the corns have been collected wild, which improves very much under cultivation. A little patch with several flowers has represented this North Persian kind these past few days in the Kew collection, where in the open border it is quite the only thing of its kind, and its flowers are yet in evidence. It is quite a choice bit of colour for late February and early March.

Muscari azureum.—Strictly speaking I suppose this should be *Hyacinthus azureus*. It is a beautiful plant, hardy, sturdy, vigorous, and free, the pure porcelain-blue spikes of flowers being singularly charming in the open garden. A cluster of a dozen or two spikes is pretty in the early days of the year, and the plant when grown in sandy soil increases freely. The variety *robustum* is larger, but precisely the same colour. These are worthy subjects for border, rockwork, or pots in a cold house.

Pulmonaria rubra.—We have so few truly winter-flowering alpine or dwarf perennials that it is well to record any that may be regarded as even ordinarily good—that is to say, a flowering plant rightly regarded as of second-rate importance when coming into bloom in May could well be given a first place if it flowered naturally in the open in January. This, then, is the position of the above species, a plant by no means generally known or cultivated, at least under the above name. I believe a short time ago Mr. Upton, of the Guildford Hardy Plant Nursery, exhibited a plant quite early in the present year in flower under the name of *P. rosea*. I am not quite clear, however, that this latter and the above are identical. The species now referred to is a native of Transylvania, the plain, that is, not mottled or figured leaves as in some kinds, forming a low tuft of about 6 inches high, the reddish-coloured bells appearing in considerable profusion for weeks together. Indeed, there is now a plant in the Kew collection that without protection and without a break has flowered away from January to the present time. It is one of

those plants that everyone may succeed with. So good a winter flower deserves to be better known.—E. JENKINS.

Deutzia Lemoinei.—When this beautiful hybrid *Deutzia* was first distributed by its raiser, M. Lemoine of Nancy, in the autumn of 1895, one of the claims put forward on its behalf in the catalogue of that firm was that it stood in the front rank as a shrub for forcing, a claim which time has fully justified. It is now largely grown for this purpose, and for flowering under glass it is certainly second to none, the only one to contest its place being the old and popular *Deutzia gracilis*. As an outdoor shrub, at least in many parts of this country, *Deutzia Lemoinei* is not seen at its best, but, as above stated, for flowering under glass it is unsurpassed. It is not winter but late spring frosts that seem to do the damage. This *Deutzia* is largely grown in Holland in the establishments where shrubs for forcing are made a speciality. Its early history is generally well known; therefore it will suffice to briefly say that it is the result of fertilising *D. parviflora* with the pollen of *D. gracilis*. The plants so obtained first flowered in 1894, and *D. Lemoinei* was, as above stated, sent out in 1895. Since then two forms—*D. Lemoinei* *Boule de Neige* and *D. Lemoinei compacta*—have been put into commerce.

How Brambles climb.—In *Knowledge* for March Mr. R. Lloyd Praeger, writing on "British Wild Flowers," remarks that Brambles are great climbers. "Their stems are furnished with very strong hooked prickles—remarkable structures, arising, like hairs, from the skin, not from the wood, as do, for instance, the thorns of the Hawthorn. By aid of these prickles, the Brambles support themselves amid tangled thickets, and may be often seen bursting into blossom 10 feet or 15 feet up in the air. It is interesting to note that the long arching stems in autumn, when their growth is nearly over, frequently again seek the ground, and their tips root themselves firmly in the soil. Next year the shoot produces flower and fruit and dies. But from the rooted tip proceeds a fresh plant, which in turn loops away and produces new offspring far from the parent. The plant may in this manner travel forward at the rate of 20 feet or more per year, and may cross obstacles such as a 10-foot wall in a single season."

Thysanacanthus rutilans.—Had any new plant afforded a display equal to that yielded by this old-fashioned subject at the Drill Hall meeting of the Royal Horticultural Society, on February 24, I would have been the praises bestowed on it, and deservedly so, yet somehow or other its great merits are only too often overlooked. Even when represented in gardens it is frequently disfigured by red spider upon the foliage. This is the result of growing the plants in too warm and dry a temperature, for once these insect pests effect a lodgment on the leaves they cause them to turn yellow and drop. This *Thysanacanthus* was first introduced from Colombia in 1851. Cuttings of the young growing shoots strike root very readily in the spring, and owing to the excessive length of its drooping flower racemes the plants must be fairly tall to show them at their best. According to the "Dictionary of Gardening" there are about twenty species of *Thysanacanthus*, but the above appears to be the only one in cultivation. It belongs to the natural order Acanthaceae, thus having for its immediate relatives the *Eranthemums*, *Justicias*, *Jacobineas*, *Aphelandras*, and many other beautiful flowering plants.

Primula kewensis.—Numerous as are the many beautiful garden plants obtained by a regular system of hybridising and cross-breeding, some equally desirable are the result of Nature's unassisted efforts, at least as far as can be determined. Such an one is *Primula kewensis*, which made its appearance quite accidentally at Kew, but as some plants of *Primula floribunda* and *P. verticillata* had been in flower in close proximity to one another, there is no doubt that this *Primula* is a hybrid between the two, and what renders it of greater importance is the fact that as a garden plant it is better than either of its parents. It is now three years since this *Primula* received a first-class certificate from the Royal Horticultural

Society, since which period the stock has passed into the hands of Messrs. Veitch, who have been exhibiting it this year in such grand condition that its admirers have greatly increased. It will take longer to become generally distributed than many new *Primulas* have done, for I believe the only course available for its increase is by division, as good seeds (at least, as far as I know) have yet to be obtained. It is, however, such a meritorious plant that its propagation will doubtless be pushed on as rapidly as possible.—H. P.

Loropetalum chinense.—Some well-flowered plants of this uncommon and pretty Chinese shrub were very noticeable among the things shown by Messrs. Veitch at the Drill Hall on February 24. It is a near ally of the *Witch Hazels* (*Hamamelis*), and, like them, the most conspicuous portion of the flower consists of four strap-shaped petals, which are, however, in the case of the *Loropetalum* much longer than those of the *Hamamelis*, and pure white. They are abundantly produced, being disposed six or eight together at the tips of the branches and in the axils of the uppermost leaves. It is excellent for flowering under glass, one great point in its favour, apart from the beauty of the flowers, being the uncommon appearance presented by a well-flowered specimen, for at a little distance it seems to be veiled with clusters of white ribbon. This *Loropetalum* is, as its specific name implies, a native of China, but it also occurs on the Khasia Hills. It was introduced in 1880, and was awarded a first-class certificate by the Royal Horticultural Society on March 13, 1894, during which year no less than thirty-two different trees and shrubs were given either certificates or awards of merit, a number which has not been approached since. It is much less effective as a shrub in the open ground than it is under glass.—T.

Pear Passe Crassane.—The fruits staged by Mr. G. Woodward, of Barham Court, Maidstone, on the 24th ult. before the fruit committee of the Royal Horticultural Society were much admired, and were well worthy of the cultural commendation awarded. We have so very few really good Pears for use at this season that any sort that is of good quality will find favour. This variety received a first-class certificate some time ago when shown by Mr. Woodward, and it shows how well this excellent gardener can grow hardy fruits, as I consider the above variety anything but a good grower—that is, on our very light soil. *Passe Crassane* will not stand severe pruning. I have found it useless as a cordon, and it requires plenty of food. In the Thames Valley the flavour does not compare with Mr. Woodward's fruits. Ours are much firmer, and at times gritty. This shows how necessary it is to grow fruits under different conditions before condemning any variety, old or new. Doubtless such fruits as those staged will prove that, given good culture and suitable soil, some of our oldest varieties are worth more attention than they receive. To keep the fruits so long they must be left on the trees as late as possible. If gathered too soon they shrivel badly.—G. WYTHES.

THE ROCK GARDEN.

ROCK GARDEN-MAKING.

VIII.—PRACTICAL HINTS ON THE CONSTRUCTION OF STRATIFIED ROCKS.

IN the last chapter I dealt with stratified rocks and their disposition, giving an illustration of natural rocks, which, though stratified, were so broken up as to almost resemble the rugged character of igneous rocks were it not for the fact that each block or each group shows the parallel layers distinctly, although at an angle quite different from that of any adjacent group. I have tried to upset the theory that stratified rocks artificially constructed should show parallel "strata" at the same angle throughout the work, and I suggested that stratified

rocks to be picturesque should have the appearance as if an earthquake had been at work among the regular strata. As a model I must refer to the picture of Nature's own work in the last chapter on page 163 of *THE GARDEN*.

My last essay was more or less theoretical, describing the work of Nature and pointing out the lessons to be gleaned therefrom. I will now turn to the practical side of the question, and will consider how these lessons may be applied to the construction of rock gardens. As practice is better than theory, I cannot do better than give an example from my own practice in the shape of the accompanying illustration. I do not for one moment wish to point to this as a model (for models we must look to Nature), but I give it because it explains in a practical way what would otherwise require several pages of explanation.

The present illustration represents a small rock garden at Liskeard, and is the property of L. C. Foster, Esq. Facing the front door of the house a deep slope presented itself, and as the ground adjoining this had been kept in the irregular style the site was a very suitable one for a rock garden; in fact, no other treatment would have fitted in quite so well. For grass the slope would have been too steep, and a wall would have been too formal under the circumstances. The geological formation of the neighbourhood, like that of the natural rocks illustrated in the last chapter, belongs to the "Devonian" order, and stone in sufficient quantity was easily obtained close by in the shape of fairly regular blocks of "schist" and "shale."

The site, of course, required preparation. Near the centre a cave was contemplated, which required deep excavation. A bog garden, too, was to be included, and last but not least special places for choice alpine had to be prepared. The decomposed soft shale or shelly which formed the subsoil was not entirely carted away, but a portion of it was mixed with leaf-mould, loam, and stone chippings, and thus mixed it was used for the planting of many alpine. Peat was added for such plants as required it. In beginning to arrange the stones I make it a practice to begin at the lowest level furthest away from the point from which the principal view is to be obtained. When building rocks on that principle it is far easier to judge the effect of this recess or that projection, &c. When space is limited it sometimes seems difficult to get sufficient boldness into work of this kind, but this is facilitated by letting recesses and projections adjoin and emphasise each other by way of contrast. It is surprising how bold even a small projection will appear if contrasted against a dark recess of which some portions are partly hidden from view. The fact of some parts of a rock garden being hidden from view will make it appear larger than it really is, because the observer will invariably give an imaginary extent to the hidden parts. For this reason the little cave seen in the picture was so constructed that its depth cannot be ascertained from a distance. The exterior blocks forming the mouth or roof of the cave were fixed in such a position as to appear as if they had naturally tumbled together, and it will be observed that the "strata" on each side are in direct juxtaposition.

When imitating natural strata calculated for distant effect, it will, as a rule, be found most practical to place flat stones together in successive layers, taking care to spread a thin coat of soil on each flat stone before the next one is bedded. But unless the stones are

tilted with a downward slant, the narrow crevices thus left between the stones will be suitable only for plants that would be content with but little moisture.

For choice alpine plants that require almost vertical deep and narrow fissures it would be best not to bed the stones on their flat sides at all, but insert them into the ground on their edges in such a way as to be not only perfectly firm, but also to furnish precisely the conditions best suited to the choicest alpine. Sometimes this can be done in a way suggestive of almost horizontal or but slightly inclined strata, although (for the sake of the plants) the stones may be really vertical. As a case in point I would refer again to the illustration. The stones in the foreground on the right have the angular edges more or less parallel with the "strata" of the higher portions in the background, and might appear as having the same angle of stratification, but as a matter of fact they are fixed vertically, and the picture shows how well the plants are thriving in consequence.

I will now briefly deal with a few other points in the illustration. Near the centre, it will be observed, is a rough kind of pathway partly formed with flat stones. This is a bog-bed, and the stones are stepping-stones facilitating access. Only a portion of this bog-bed is visible from the point from which I took the photograph; the other part recedes behind the more prominent rocks, which latter form shady nooks for hardy *Cypripediums*, *Polygala chamaebuxus*, and other good things. Various *Gentians* are flourishing, including, until recently, *Gentiana bavarica*. The latter did well for a year or two, but has now succumbed. Special corners were reserved for such gems as *Campanula Zoysii*, *Edraianthus serpyllifolius*, and various choice *Androsaces* and *Dianthus*. Of other small rock plants used I may mention *Campanula turbiuata*, *Saxifraga longifolia*, *S. Rhei*, *S. lantoscana superba*, *Sedum spathulifolium*, *Edelweiss*, &c. The dry ledges just outside the little cave were chiefly

devoted to *Sempervivum* and similar plants, while *Ramondias* and other shade-loving plants clothe the fissures to which more moisture can have access.

The expanded star-shaped flower almost in the centre of the picture is *Carlina acaulis*. Immediately above is a rocky ledge devoted to a group of alpine *Rhododendrons*, viz., *R. ferrugineum* and *R. hirsutum* in various forms. To the right of this will be seen a mass of *Helianthemum*, and below the latter a fine group of the bold *Megasea*. The top ledge on the right shows a batch of *Genista præcox*, and on the left a mass of *Zauschnerina californica*, &c. Between the cave and the ledge of *Rhododendrons* above referred to are some rocky steps leading from the bog-bed to a path on a higher level, but in the illustration this is not visible. The steps were clothed with *Thymus lanuginosus*, *Acæna microphylla*, *Veronica repens*, *Arenaria balearica*, &c.

The construction of the rock garden took scarcely two weeks, and the photograph was taken about twelve months after completion. In subsequent chapters I hope to give illustrations of various other styles of rock gardens.

Elmside, Exeter.

F. W. MEYER.

(To be continued.)

WALL GARDENING.

WALL GARDEN - MAKING.

V.—THE CONSTRUCTION OF WALLS OF MASONRY FOR WALL GARDENING.

HAVING dealt with the most practical way of adorning "dry walls," both during building and after their completion, I will now consider walls of masonry, or, in other words, walls of stone or brick which have their joints filled with mortar or cement. These may be either retaining, terrace, or boundary walls. A

retaining wall of masonry would most probably be not perpendicular, but slightly reclining against a bank or terrace. A boundary wall, on the other hand, will in most cases be quite upright. All such walls are, as a rule, intended as architectural rather than horticultural features, and their surfaces are, therefore, smoother and more even than those of dry walls. Especially are such masonry walls necessary when walls are required to be of such a height that a dry wall would have been unsafe. Sometimes, too, the immediate proximity of architectural or geometrical features, such as a house, steps, balustrading, a terrace, &c., would make it imperative that such a wall should present a more highly finished surface than would be possible in the case of dry walling. This would, for the sake of harmony, apply particularly to a terrace wall adjacent to and built of the same material as the dwelling-house. Or, in another case, this terrace wall might be of such a height as to require being built on arches with the additional support of projecting buttresses.

In all such cases dry walling would be out of place, but it does not follow that we cannot use masonry walls for wall gardening. On the contrary, though the difficulties in adorning such walls are greater, we may, nevertheless, attain excellent results by planting them. Since it may not infrequently happen that wall gardening is being contemplated at a time when the house or adjacent terrace walls are being built, it would in such a case be possible to build a wall of masonry specially constructed to facilitate wall gardening without encroaching on the susceptibilities of the architect or the builder. I will, therefore, consider two kinds of masonry walls—viz., (a) those built with a view to wall gardening; (b) walls of masonry not built for wall gardens, but which might be adapted to that purpose.

MASONRY WALLS BUILT FOR WALL GARDENING.

There are naturally two kinds of masonry walls, viz., retaining walls, *i.e.*, which show one face only, and walls standing free and showing both sides. I will deal with the former first. Retaining walls are usually intended to keep up high banks of soil or terraces, and have therefore to be of great strength. Their original purpose is use rather than ornament, but that is no reason why they should not be adapted for the latter as well, without interfering with their stability.

The plants which are to adorn such walls must have something besides bricks and mortar to grow in, and if we can manage to cater for their requirements at the time when the wall is in course of construction this will be an enormous advantage, especially if we can make up our minds beforehand as to what kinds of plants we would use, and consider what soil would be best for them. As a guide I would strongly recommend a rough sort of sketch similar to the one illustrated in the last chapter. Whether such walls are to be of brick or of stone, or whether cement or mortar is to be used in the construction, generally depends on the strength required, and is therefore more a matter for the architect or for the builder to decide. But if a choice can be made, stones would be preferable to bricks, as most plants are greatly benefited by stones, and derive also a small

THE ROCK GARDEN AT TREVILLIS CORNWALL, CONSTRUCTED WITH STONES OF THE STRATIFIED KIND.

ELEVATION OF A REGULAR WALL OF MASONRY, WITH HOLES FOR PLANTS AT IRREGULAR INTERVALS (THE ROUND HOLES SHOW THE POSITION OF DRAIN-PIPES). (2.)

amount of nourishment from this material, which in the burnt bricks would be absent, and if stability can be ensured by the use of mortar instead of cement this would be an additional advantage to the plants. Even when circumstances demand that bricks and cement must be used exclusively we need not despair of growing plants on the wall if we make provisions for them according to the following method.

Let us assume, then, that the builder has put in a good foundation below the level of the ground, and is now ready to proceed with that part of the retaining wall which will show above ground, and is to be, say, 8 feet or 9 feet high. In the first place it will be our duty to see that ordinary drain-pipes 2 inches or 3 inches in diameter are inserted into the foot of the wall, say, 3 feet or 6 feet apart, and that when these drain-pipes have been walled in (sloping outwards), the space behind the pipes is filled in with loose stones, brickbats, or clinkers as drainage. On sloping ground the soil behind retaining walls of this kind often becomes waterlogged, and with new work there is a danger of the whole wall collapsing in consequence of the increased weight of soil and water pressing against it.

I have tried to make my meaning clearer by the accompanying rough sketches, which, however, must be taken as diagrams only and not as absolutely correct to scale. Sketch No. 1 shows a transverse section of such a retaining wall. *A* represents the original firm soil which has not been moved; *B* represents the body of new soil filled in as the wall is being built; *C* represents the loose stones or brickbats referred to, which are to act as drainage and convey surplus water through the drain-pipe *D*. The spaces *E, F, G, H, I,* and *J* show open channels filled with soil and communicating with the soil inside.

Sketch No. 2 shows the elevation of such a wall with the mouths of the drain-pipes (indicated by black circles) at the bottom, and with the openings for plants and soil at irregular intervals. For wall gardening the most important operation in the building of the wall is, of course, that of providing suitable soil, and this should not be left to the mason or builder, but should have the gardener's careful attention simultaneously with the builder's work. As the masonry progresses so the stones or bricks must be "backed up." Usually this is done by filling in brick rubble, dry clay, gravel, or rubbish of any kind, and ramming it firmly. But in this case the material must be good soil mixed with a few broken stones. Every now and then—preferably at irregular intervals, as shown in sketch No. 2—openings 3 inches to 6 inches wide are left in the wall, and these likewise should be filled with good soil communicating with the greater body behind the wall. It is in planning beforehand

what to plant that we may greatly facilitate the gardener's work in placing this or that kind of soil according to the requirements of the plants—say, for instance, peat or leaf-mould where there would have *Ramondias, Gaultheria procumbens, Polygala chamæbuxus, Ferns, &c.*; stony soil, preferably mixed with limestone chippings or old mortar for such decided lime-lovers as *Scolopendrium, Dianthus, &c.* It may seem a little troublesome to take all this precaution, but every lover of plants knows that planting at haphazard into unsuitable soil cannot be conducive to success. Besides this we must bear in mind that the application of this or that kind of soil can never be attended to with quite the same facility as at the time when the wall is being built.

But, whatever soil is used, one thing is most essential, and that is well ramming it down—not only behind the wall, but also in the openings left for the plants. The soil must be so firmly rammed that there would be no danger of its settling down afterwards and leaving hollow spaces, which would be a source of danger to the plants and a great delight to slugs and snails. The actual distance between the openings on the face of the wall must, of course, greatly depend on the plants to be used and the room these would require to show to their best advantage, but it is also necessary to have regard to the stability of the wall, as naturally it must be weaker in proportion to the number of openings.

The planting of a retaining wall constructed of masonry on the lines mentioned is comparatively easy, but requires some careful finishing touches. What to plant I will mention in another chapter, and I will here content myself with only a few general hints as to the

ACTUAL PLANTING

operation itself. Assuming, then, that the wall was built in accordance with all the suggestions given above, that the openings are about 4 inches to 6 inches across, and that they were filled with soil as directed, we next proceed to the work of planting. Well-established plants in pots with a good ball of roots are infinitely better and more likely to succeed than plants only recently divided. I have often seen walls constructed with openings in the way I have mentioned, which were planted by the simple expedient of pushing the plant sideways into the hole in the wall, filling a little more soil around the roots, and the operation was considered finished in a satisfactory manner. Now such planting might do in the case of some coarse-growing plant with a long tap-root, which it would be almost impossible to kill, but choicer plants would surely die if planted in that manner. This is what would happen: The first shower of rain or the first application of the watering-pot would wash away a considerable portion of the newly-placed soil, however firmly it might have been rammed. Possibly the next rain

would be heavy, beating direct into the opening and washing away still more soil till the roots would be almost bare and the plant sicken and die.

A much better plan is to have at hand a number of broken bits of the same material as that of which the wall was built, either white bricks, red bricks, or stones, as the case may be, and to use these for entirely closing the outside of the opening into which the plant was put, without, however, preventing moisture from having access to it. This is done as follows: Flat fragments of stone (or small pieces of brick as the case may be) are placed at the bottom of the opening. A thin layer of soil is then so placed as to slope inwards, *i.e.*, towards the interior of the wall, and on this the plant is placed with its crown slightly protruding from the face of the wall. When the plant is thus in proper position its roots are surrounded by suitable soil, which is well rammed and gradually filled in till the front of the opening is reached. Now comes the most important part of the operation, namely, that of filling up the whole opening all around the plant in such a way that it is tightly wedged in and no soil can be washed out, although rain or other water could get to the plant and even soak through to its roots.

The actual operation of filling up the opening is best described as the building of a miniature dry wall all around the plant, using a layer of soil, say, half an inch thick over every course of small stones or small pieces of brick perhaps 2 inches or so in thickness, and rather flat in shape so as to rest firmly on each other. Wedge-shape pieces, too, are very useful, as they can be driven in firmly, and are then not likely to shift afterwards. When the whole of the openings have thus been filled out flush with the face of the wall they will, seen from a little distance, appear as part of the wall itself, and in a year or so, when the plant would have attained a larger size, it would completely cover this miniature dry walling, which latter would then be invisible even on the closest inspection. This method of planting does not only ensure the well-being of the plants, but since the surface of the wall was made good it will be impossible to tell that holes and openings were left on purpose, and the presence of the plants on the face of the wall will appear like an accident rather than design, and this is as it should be.

In illustration No. 3 a rough sketch is given showing a section of a free upright wall of masonry, constructed with a view to wall gardening. It has openings in precisely the same manner as retaining walls, and is built on the principle of "cavity" walls, in which the space in the centre has been filled out with suitable soil. Should such a wall be at the same time a boundary wall, say, facing a road

SECTION OF UPRIGHT WALL WITH SOIL IN THE CENTRE AND OPENING FOR PLANTS AT THE SIDES. (3.)

SECTION OF MASONRY WALL, WITH OPENINGS (E TO J) FOR SOIL AND PLANTS. (1.)

or someone else's property, it would, of course, have only one face prepared with openings for planting. For the sake of greater security iron clamps or flat stones might now and then be used in the construction for tying together the outer and inner surfaces. In the next chapter I hope to deal with masonry walls which were not originally intended for wall gardening, but might be so adapted.

(To be continued.)

TREES AND SHRUBS.

SPIRÆA DISCOLOR

(S. ARLEFOLIA).

OF the scores of Spiræas that have received names one of the most distinct is *S. discolor* (or *S. arlefolia*). Some German botanists have classified and named the numerous hybrids and forms of Spiræa to such an extent that it is often difficult to distinguish one from the other, but *S. discolor* stands by itself. Besides being distinct it is also one of the most beautiful and useful. The accompanying illustration gives an admirable impression of the grace and free-flowering qualities of a healthy plant. It is valuable because it is one of the comparatively few tall-growing shrubs that are to be seen at their best in July. It is one of the largest of the Spiræas, reaching, when fully grown, from 8 feet to 10 feet in height. The main branches are erect, but their tops as well as their side shoots are gracefully pendent. The flowers, of a creamy white, are crowded on large pyramidal racemes, which frequently measure 8 inches across at the base. This Spiræa makes an imposing mass when planted in large groups, but more charming effects are produced by planting it in positions where it has a semi-wild character. Such a position is evidently enjoyed by the specimen in the illustration. One of most pleasing impressions I had at Dropmore a few summers ago was made by the informal planting of numerous specimens of this Spiræa in the delightful woods of that place. Although planted in semi-shaded places, they were flowering with great freedom, and were a charming variation from the usual shrubby undergrowth one sees in even well-tended woodlands. W. J. BEAN.

THE BARBERRIES.

(Continued from page 125.)

B. HETEROPODA.

In the United States this species is spoken of very highly as a distinct and desirable shrub, but little has been done with it in Britain. It is a native of Turkestan, and was introduced to cultivation through the agency of the St. Peter-burg Botanic Garden about twenty-five years ago. In habit it is vigorous, of medium height, and in the way of *B. vulgaris*; but the branches are usually unarmed, although the older parts are sometimes furnished with undivided or three to five parted spines. The spoon-shaped leaves are broad and rounded at the end, tapering down to a long slender stalk. The flowers are borne on long branching

racemes and are orange-yellow and fragrant, each one half an inch in diameter. The berries being covered with blue-white "bloom," add much to the ornamental quality of the shrub.

B. LYCIUM.

If not quite so striking a shrub as *B. aristata*, this species, which is also a native of the Himalaya, is very handsome. It is like that species in habit, but in winter can be distinguished by its red-brown wood. It has narrow obovate leaves, glaucous beneath, and without teeth. The flowers are borne on drooping, often branched racemes, 2 inches or more long. It is particularly beautiful in fruit, the berries being very abundant and covered with a purple bloom. It is found on the Himalaya up to 9,000 feet from Kumaon westward to Kashmir.

B. SIBIRICA.

A low bush, rarely more than 1½ feet to 2 feet high, and a native of the Altai Moun-

ains. The flowers, of a paler yellow than those of *B. vulgaris*, are borne in a corymbose raceme 2 inches to 3 inches long. The fruit is very ornamental, each berry being half an inch long and bright scarlet. The foliage changes to a bright orange-scarlet in favourable seasons before it falls.

B. SINENSIS.

Of all the deciduous Barberries this is one of the most elegant in habit. It grows 6 feet or more high, sending out long, slender, pendulous branches, which in mid-May and later are wreathed with very beautiful racemes of pale yellow flowers. These racemes are slender, pendulous, 2 inches to 3 inches long, and numerous flowered. The flowers themselves are some of the smallest in the genus. The leaves vary in size from 1 inch to 2 inches in length, and are narrow obovate and usually without teeth. The species is a native of China and Japan, and although introduced as

SPIRÆA DISCOLOR (S. ARLEFOLIA) IN MR. LENEY'S GARDEN, SALTWOOD, HYTHE. ONE OF THE FINEST SPECIMENS IN ENGLAND.

tains, where it grows in crevices of rocks and similar places. Like *B. cretica* and *B. ætensis*, it is a suitable plant for the rock garden. Like those species, too, it is of scrubby habit, producing dense rosettes of small leaves, but it differs in producing its flowers singly on their stalks. The flowers are large and drooping, and followed by dark red fruits. The species was introduced by Sir Joseph Banks in 1790.

B. SIEBOLDI.

Whilst being generally regarded as the Japanese form of *B. vulgaris*, this species is, from a garden point of view especially, quite distinct. It was introduced from Japan by Messrs. Veitch (through the late Mr. Charles Maries), and flowered at the Coombe Wood Nursery fifteen or more years ago. A shrub of similar character to *B. vulgaris*, it is, however, probably not so large. The leaves are large (as Barberries go) and glossy, they are rounded at the end, and have ciliated (scarcely toothed)

long ago as 1800, during Lord Macartney's mission to China, is still an uncommon shrub in gardens.

B. THUNBERGII.

In recent years this Japanese Barberry has become very popular. It is a very distinct shrub of dwarf habit, charming when in leaf and flower, but beautiful in autumn when loaded with its bright red berries, and still more so later on when its leaves turn a brilliant crimson. Although noticed in Japan by Thunberg in 1784, it was long before it got into cultivation. Like many Japanese shrubs it has a very dense, twiggy mode of growth, and does not seem likely to grow more than about 4 feet high. The leaves are half an inch to 1 inch long, and are arranged in crowded tufts on the red-brown branches. From most Barberries it differs in the spines being "simple" (unforked). It blossoms towards the end of April, and the flowers are pale yellow suffused with red, the outer segments being quite red.

The flowers are small, but very abundant. The low, dense habit and slow growth of this Barberry give it a very distinct character, and make it useful in positions where a low, close growth is desired which will not require much attention to keep in order. It has even been used for game cover.

Var. Dawsoni has been sent out from the Arnold Arboretum in recent years. It is still dwarfier, more twiggy, and closer in habit than the type.

B. VIRESCENS.

Although this plant was first noticed by Sir Joseph Hooker when travelling in Sikkim in 1849 and has been cultivated in Britain since 1855, it was not until about fifteen years ago that it was given a specific name, having been till that date confused with *B. aristata*. Sir Joseph then named and figured it in the *Botanical Magazine*, t. 7116. From *B. aristata* it is very easily distinguished by its flowers being produced in very shortly corymbose clusters, not in elongated racemes. It is a very

not a native, it has become naturalised, and in some parts of the Eastern States is more frequently met with than *B. canadensis*—the native Barberry. It occurs wild in many parts of England, chiefly in hedgerows and thickets, but it is doubtful if it be truly native of Scotland. Under cultivation it will grow 10 feet to 15 feet high (under certain conditions even more), and is really a very beautiful shrub, both at the flowering and fruiting seasons. Its hardy constitution and accommodating nature make it especially useful for filling up rough corners of the garden, where, when once established, it can be trusted to take care of itself. But even in ordinary tall shrubberies a mass of the Common Barberry is always worth its place. In sunny positions where, of course, it flowers best, a single big specimen makes a wonderfully beautiful picture in mid-May, with its myriads of drooping racemes of bright yellow flowers. In the typical form the berries are red, but in cultivation there are varieties with white and black berries.

of the popularity of this is undoubtedly due to the increased interest taken in Nymphaeas and their culture. Many varieties of these Water Lilies have of late years been introduced to our gardens from France and America—varieties that are remarkable for their extreme beauty, hardiness, and vigorous growth.

The delights of water gardening appear forcibly to appeal to Mr. Leopold de Rothschild, for in the lake in the picturesque grounds of Gunnersbury House one may see what is perhaps the most representative collection of Nymphaeas in English gardens, and the margins of the water are clothed with many handsome moisture-loving plants. Mr. Hudson has altogether transformed the aspect of the lake at Gunnersbury by his successful cultivation of the Water Lilies, of whose vigour and arrangement the accompanying illustration gives some idea. The clumps of the numerous varieties are arranged informally over the surface of the lake, more particularly towards either side, and the distinctive characteristics that each variety possesses, in the mode and vigour of growth, disposal of flowers, &c., add to the charming irregularity and natural beauty of the effect.

The cultural requirements of the hardy Nymphaeas are simple and easily supplied. Messrs. James Veitch and Sons, whose experience with these plants is unusually extensive, say that any pool of water or pond of moderate dimensions, and from 1½ feet to 2 feet deep, will suit them admirably.

The best months for planting Nymphaeas are end of April, May, June, July, and August. They should first be planted in baskets, previously filled with good loam, taking care to make them firm. The baskets are then lowered into the water in places where the Lilies are desired to grow. The baskets will not decay for several years, and by that time the Nymphaeas will have become well established.

Some of the stronger growing sorts, the marliacea hybrids for instance, if not planted fairly deep, say 3 feet, will in a year or two push their leaves out of the water, making quite a massive clump, and thereby losing somewhat in beauty. Nymphaeas will even succeed when planted 6 feet deep or more. Of course with the less vigorous growing ones shallow planting is quite satisfactory, for the long slender petioles spread out and the leaves float gracefully. A list of some of the best Nymphaeas is appended.

White.—*Alba candidissima*, with large pure white flowers, an early and continuous bloomer; *alba plenissima*, pure white, more double than the former; *caroliniana nivea*, sweet scented; *marliacea albidia*, fragrant, pearly white flowers; *odorata*, the North American Water Lily, which produces its cup-shaped flowers very freely; *pygmaea*, the smallest of Nymphaeas, fragrant.

Yellow.—*Chrysantha*, yellowish red, with bright orange stamens; *fulva*, light yellow, tinted with red; *flava*, citron-yellow; *marliacea chromatella*, a beautiful straw colour with yellow stamens; *odorata sulphurea* and the variety *grandiflora*, sulphur-yellow, fragrant; *pygmaea helvola*, flowers slightly larger than *pygmaea*, sulphur-yellow; *Seignouretti*, light yellow, tinted with carmine.

Dark.—*Atropurpurea*, dark crimson, large flowers; *gloriosa*, rich purple, one of the most

A GROUP OF PINK WATER LILIES.

elegant spreading bush with slender branches and luxuriant foliage of a bright but rather pale green. The leaves vary from two-thirds of an inch to 1¼ inches in length, are obovate, borne in rosettes, the larger ones only toothed. The flowers are only about one-third of an inch in diameter and are of a sulphur-yellow. The berry is narrow, long-stalked, and black, that of *B. aristata* being rounder and comparatively shorter. This shrub occurs at an elevation of 9,000 feet in Sikkim and is perfectly hardy. Its reddish brown bark gives it a pleasing character in winter. Two varieties are included in the "Hand List of Trees and Shrubs at Kew," namely, *macrocarpa*, with more strongly nerved leaves and large black fruits containing a much larger seed; and *fructu rubro*, with reddish fruits.

B. VULGARIS.

This, the Common Barberry, is the most widely spread of all the species, being found wild in Europe, North Africa, and Temperate Asia. Even in North America, where it is

The purple-leaved Barberry (var. *foliis purpureis*) is one of the best shrubs of its class, and useful for colour groups. A certain proportion of its seeds come true.

Besides these varieties there are almost innumerable other forms in existence. This, one would, indeed, expect, from the length of time and the extent to which it has been cultivated, and the varied conditions under which it is found in a wild state. These forms differ in such unimportant matters as length of raceme, shape of leaf, &c., and a particularised account of them is not necessary.

Kew.

W. J. BEAN.

SELECTING AND PLANTING WATER LILIES.

As the time for planting Water Lilies is approaching we may well draw attention to this beautiful family. Few phases of gardening have made more rapid progress during recent years than has water gardening, and much

beautiful; Laydekeri fulgens, rich crimson and orange; marliacea ignea, one of the most richly-coloured, crimson; odorata exquisita, deep rose-carmine; William Falconer, the deepest coloured hardy Nymphaea yet raised.

Pink.—Caroliniana, clear rose-pink; Laydekeri rosea, delicate rose-pink; marliacea carnea, blush; marliacea rosea, bright pink; odorata rubra, rose-pink; odorata suavissima, a beautiful pink; tuberosa rosea, delicate pink.

Other good Nymphaeas.—Ellisiana, brilliant carmine-purple; Frœbelli, bright carmine-red; odorata luciana, a deep and rich rose-pink; robinsoniana, red toned with yellow.

AN ARTIST'S NOTE-BOOK.

SAXIFRAGA (MEGASEA) CORDIFOLIA GRANDIFLORA.

MANY are the uses of the broad-leaved Saxifrages; indeed, they have a kind of special usefulness of their own that is shared only by the very few other garden plants that are leafy and well furnished throughout the year. In the flower border they are valuable as informal stretches of edging that run back here and there among other plants; their solid build makes them admirably suited for associating with step or wall or any kind of masonry. They will make a large and bold effect planted in the joints of a north or east dry wall and at its foot, and scarcely anything better can be found for filling shady outer spaces between shrubs. The variety represented in the accompanying sketch is unusually handsome in leaf and flower.

ROUND ABOUT A GARDEN.

THE GROWTH OF BULBS.

ONE of the charms of the garden in spring is the voluntary absence of weeds. They have not recovered their spirits from the "doing-up" which the gardener gave to the flower-beds in autumn. You may have felt some resentment against him in winter, when you gazed through the window upon so much bare, brown mould; but by the middle of February he was abundantly justified. Everywhere the clean earth bristled with fat green points and spikes that were pushing up from the bulbs below to support the skirmishing Crocuses, which already flaunted the yellow-white-and-blue flag of spring on the heels of retreating winter. Besides the bulbs there is an especial joy in the way in which the Peonies bulge out of the ground with fat red points almost as stout as Rhubarb, but best of all are the Crown Imperials. First you see the ground swelling and cracking as if a lot of little moles were at work below. Next day you see ruddy points poking out, and every morning after that it is worth while wandering to that part of the garden to see how much the Crown

Imperials have grown since yesterday. If a man gave thought and care to it a very accurate thermometer for spring use might be made of a scale for measuring the growth of Crown Imperials.

LOOKING TO THE LAWN.

The absence of weeds, which is such a striking feature of the spring flower-bed, does not extend to the lawn. "Lawns should now be looked to," says the gardening book, and the first discovery which you make, on looking to the lawn, is the amazing progress which the pestiferous Plantain has made. If you have ever come into occupancy of a garden which "the previous tenant" had permitted to become undermined with a mat of Bindweed roots, you understand the tenacity with which

rosette upon that spot of earth where Providence has placed it. This is usually, and, unfortunately, in the most conspicuous part of the lawn.

SUPPRESSING THE PLANTAIN.

If you attend to your lawn with more zeal than discretion you can fill all your finger-nails with earth in trying to get hold of the stalk which the Plantain has not got, or you can assail it with a spud. With this you quickly learn to bring the Plantain up with a workmanlike jerk, which tosses it 2 feet in the air, and it is said, no doubt with truth, that if another person with a salt-cellar follows the spud welder and applies a pinch of salt to the white neck of each decapitated root, visible at the bottom of the hole left by the spud, that Plantain will not grow again. If you do not do something of the kind it is a sure fact that a whole colony of flat rosettes will, later on, adorn the spot whence you excavated one. By that time perhaps you will almost welcome them as a decent covering for the naked patch you made, and I have even known persons to persuade themselves that those dark green patches on the lawn are very restful to the eye.

DAISIES IN DIFFERENT ASPECTS.

As a nuisance on a lawn, the Daisy only differs from the Plantain in two respects. In return for the comparative compliance with which it yields to your efforts to uproot it, it multiplies many times faster, and it does not hide its presence under a pretence of green humility. On a really well-kept lawn a single white Daisy looks almost as aggressively untidy as a scrap of newspaper; and if you cut the grass in the morning you can, where the weed is well-established, make a Daisy-chain in the afternoon. Nor can you say that the Daisies on a croquet lawn look restful, because they do not; on the contrary, they will put you off your favourite stroke. Yet when you leave your lawn behind you and wander down some lane with budding hedges on either hand and Daisy-starred banks where the small, wild bees are tumbling over each other with the eagerness of spring, you feel in your heart all the nice things which the poets say in their books about this wee, crimson-tipped wild flower.

WHAT IS A "WEED"?

For "weed" is only a term of locality. Dirt, for example, has been well defined as "matter in the wrong place" (wherefore it does not include the mud on a farmer's boots, which shows that he has fairly tramped round his fields) as a "weed" is only a plant which is, from the human point of view, in the wrong place. Man, with his wholesale horticulture and agriculture, creates a revolution in nature. Hundreds of plants accept defeat and disappear; only a dozen or so rise to the occasion and, on behalf of the independence of the vegetable kingdom, dispute with him for the possession of every inch of soil. These we angrily call "weeds," although, as a matter of justice, we ought to honour them for the activity and intelligence which they display in a losing cause.

IRREPRESSIBLE FLOWERS.

Besides, what is one man's "weed" is another's garden flower. Who has not seen cottage gardens which were pretty enough to make a photograph for THE GARDEN, filled only with such things as Marigolds, Arabis, Foxglove, Periwinkle, Evening Primrose, and Canterbury Bell? Yet once let loose the Marigold in your wild garden and you have sown the seed of endless worry. The Canterbury Bell, undermining the whole shrubbery

SAXIFRAGA (MEGASEA) CORDIFOLIA GRANDIFLORA (REDUCED).
(From a drawing by H. G. Moon.)

some weeds, like Irishmen, cling to the soil. Although equally hard to eradicate, in many respects the Plantain on the lawn is the antithesis of the Bindweed among the Rose bushes. While the latter tangles itself, like whipcord, over everything around, the other apes humility by plastering itself in a flat

border, will spring up in commandoes round every delicate plant which you wish to cherish. The Foxglove will sow itself wherever there is not room for it, and flourish exceedingly.

The Evening Primrose will calmly come up in colonies upon your gravel path; while the Arabis from the rock work will invade and overrun the whole place with woolly carpets of dull, matted leaves, which harbour nations of slugs and bloated battalions of

of high endeavour. At the same time you disarrange the roots of the Phloxes a good deal. E. K. R.

THE PROPAGATION OF LILIES.

THE quick and profitable propagation of Lilies on a commercial basis is not a matter that enters into the present everyday life of the gardener or amateur who seeks to grow these splendid plants—his efforts are mainly directed to improved cultivation

—a matter in which the recent Lily conference has proved of great help. There is, however, much in Lily propagation that would interest and benefit every gardener; any chance seedling of merit that passed into his hands would be saved to cultivation if he were able to perpetuate the form carefully and with all the elements of success at his command, whilst the renewal of stock, now an annual necessity, would be reduced considerably if he were able to improve upon Nature's methods of bulb increase.

Moreover, there are signs that the country's stock of the rarer Lilies is appreciably decreasing; the ever-increasing popularity of Lilies has resulted in greater demand for the rarer kinds, and units, passing from the parent stock to less skilful hands, have not always succeeded. Again, there are marked signs that stocks of some of the rarer Japanese species have been overtaxed, for it must be noted the Japanese do not propagate the Lilies they send here, but collect them and grow them for a season, or possibly two, before shipment, hence they add nothing to the economy of the world's stocks, but *vice versa*.

On the other hand, we, as horticulturists, are not doing our best as Lily propagators. Several varieties are already lost to cultivation—it is safe to say they were not understood; many varieties that fail now are equally misunderstood, and the misunderstanding in each case has its origin in disregard of the bulb's functions and frailty; these can only be understood by nursing the seedling or hurbil to the adult stage, when the indescribable characteristics of each would be apparent, and these would form the nucleus on which all requisite cultural details would be based. The great powers most Lilies have of rooting from the base of the stem would be usefully employed and encouraged; close-scaled bulbs, woefully liable to decay in retentive soils, would be planted among the fibrous roots of other plants, and the flower-stems fed by an annual surface mulch. With regard to

SOIL AND EXPOSURE

best adapted for propagating Lilies, there is no place better than a well-tilled kitchen garden, not too rich in humus, and as free from grubs, wire-worm, and other depredatory insect life as good cultivation and the remedy to be hereinafter mentioned can render. The shade of well-thinned fruit trees is a great boon, inasmuch that a seedling or tiny scale-produced hurbil would find it a hard struggle in a warm sunny position to store sufficient nutriment to carry it through the nine months of comparative rest in the two or three months' active growth it makes as a young plant. The natural method of propagating Lilies is by means of

SEEDS,

but with the exception of *Lilium cordifolium*, *L. giganteum*, *L. tenuifolium*, and *L. polyphyllum*, and in the raising of hybridised seedlings and seeds of rare species, whose roots are not available, the method is not generally employed, being slow and uncertain. In common with those of all flowering monocotyledons, the seeds should be sown as soon as ripe or obtainable. Small lots of seeds should be sown in pans and introduced to greenhouse temperature if available; a whole season is thus gained, and seeds of low germinating power, such as invariably occur in hybridised capsules, are thus given a better chance of making headway. Seedlings, I find, revel in a turfy loam, broken up small and freed of perennial weeds, a little very coarse sand being added to the actual

SCALE OF *L. MARTAGON*
ALBUM AND YEAR
OLD BULBILS.

compost. The layer of soil directly over the seeds should be very sandy, so that seedling leaves can emerge freely. If sown in autumn seeds germinate more regularly than when sown in spring; the *umbellatum* group germinates first, *elegans* secondly, *candidum*, *longiflorum*, *auratum*, *speciosum*, *tigrinum*, and *Martagon* groups germinating in succession till the following midsummer. Seedlings of many Lilies, be

it noted, may grow to the size of a Hazel Nut without making any leaf growth whatever, hence pans of seeds should not be thrown away within three years of the date of sowing, or even later, without careful examination.

In general practice and where seeds are sown in quantity it is best to prepare a roomy frame with a west aspect, filling with friable meadow loam and coarse sand, rendering the whole distasteful to depredatory insect life by watering thoroughly with an infusion of quassia chips at a strength to be obtained by steeping 1lb. of chips in four gallons of boiling water, adding another eight gallons of cold water when the infusion has "stood" for a day. Apply this liberally to the soil, and when drier sow the seeds as one would sow Peas, in broad drills, covering with 1 inch of sandy soil, adding another inch of soil in the second season before growth recommences in January. *Lilium tenuifolium* makes flowering bulbs in the second and third year; *L. polyphyllum*, which is very slow and irregular in germinating, takes four to five years; *L. giganteum* five years onwards. The two former plants are really best flowered in the seedling frame.

For general purposes it is not necessary to differentiate between different species of Lilies in the matter of raising from seeds, the young seedlings have low vegetative powers, and from the cultivator's point of view seeds of every known Lily may be treated as if produced by one plant. When the seedlings are two or three years old from date of germination leaves and roots are very active, and it is then that their respective requirements, duly set forth in the concluding chapter, must be fully met. Seeds, whether dormant or germinating, must not be subjected to extremes of heat and drought in summer, and must be protected from cold and wet in winter. An equable temperature proportionate to the season of the year, and a greater degree of moisture in summer than in winter, will be found all that is necessary for them in the seedling stage.

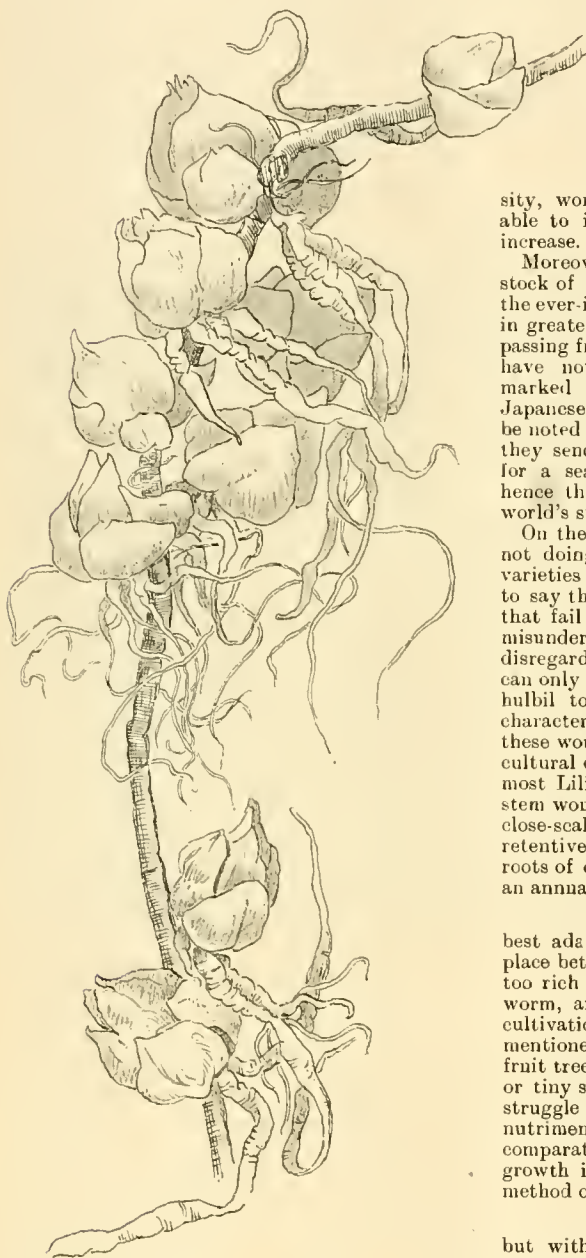

PROPAGATION BY SCALE BULBILS

is at once the quickest, best, and most certain of all methods of increase.

It is simple in practice, requiring less care and attention than is the case with seedlings, whilst the returns are really great. Practically all the known Lilies may be increased by this means, the exceptions being those mentioned previously, whilst some that will be mentioned,

ONE YEAR OLD SCALE BULBIL OF *L. X*

YEAR OLD.

armoured snails and woodlice. Vegetables, too, which are coy in the kitchen garden, throw out their leaves with abandon and riot in flower and seed, once they find themselves on the "ornamental" side of the hedge. Perhaps they try to live up to the level of the exalted company in which they find themselves, so that when in late summer you pull up a 4-foot flowering Radish plant from among the Phloxes, you may be destroying the crown

though capable of being increased by scale bulbils, have other means of increase which have so far proved best. All scales of Lily bulbs have the power to produce offsets at all seasons under certain suitable conditions, but for practical purposes there is a season and a particular type of scale better than the rest. The season is autumn, and the type of scale is found in all Lily bulbs, and is distinguished by a distinct contraction about the middle, a narrow-waisted scale. These are remarkably prolific in offsets as compared with normal scales. Even when young they have tiny cellular excrescences which, under favourable conditions, without fracture or other external aid, develop into scale bulbils. Again, bulbils produced from the middle of the scale are invariably larger than those produced from a fractured base or tip, and bulbils produced from a whole scale scratched transversely with a steel pen or knife point are greater in number and size than those produced from a scale broken in three pieces. These are small matters, but important when dealing with very rare bulbs and large quantities. The scales must be ripe, those surrounding the previous year's flowering stem are best. Any bruised, decaying portions should be cut clean away and the withered scales of some imported bulbs avoided altogether. Having prepared the scales, they may be stratified in boxes of sand or light soil to develop, the depth of covering material should not be less than 3 inches. Place the boxes outside to catch any rain that falls, and protect from sharp frosts during winter. Many advise a frost-proof building in which to store the scales, but generally one can get on well without it. Full exposure to sunshine, wind, and rain keeps down fungoid growths, the one trouble Lily propagators have to reckon with. By the following April most of the scales will have developed bulbils and are ready to plant in nursery quarters. Choose a site screened from strong sunshine, dress the soil with Quassia infusion, and raise the beds 6 inches above the general level of the garden in order to drain surplus moisture freely. Sow the bulbils as one would sow Peas, in broad drills, not more than 2 inches deep; the less hardy species may be grown in a frame, but most of them will take no harm outside. If the soil is naturally heavy it should be ridged up at the time the scales were prepared, in order that frosts, winds, &c., may pulverise it and render it as free from insect life as is possible to do by this means. Their first year's growth will be slight, a leaf apiece may be all that will be seen; nevertheless, growth is proceeding apace, and an occasional watering during dry weather will keep them going. In autumn give a dressing of light soil an inch thick to stifle mossy growth, young weeds, &c., and in the case of the auratum and longiflorum groups a protective layer of Bracken or similar cover to ward off frosty winds.

In January-February following they will make their appearance in quantity, each tiny plant having two leaves at first, developing others as the season advances. Their growth will now be rapid, and they will want attention as to watering, and a wind-screen in March if cold winds prevail. If the plants keep healthy and the soil is open and free they may with advantage remain three seasons, at the end of which time they may be regarded as plants requiring specific treatment, particulars of which will be given.

PROPAGATING ESTABLISHED BULBS.

Another method of increase by scale bulbils, and one useful to employ with bulbils of the Martagon group, is to free the bulbils of soil whilst still rooted, and scratch the scales transversely with a sharp knife. The practice has some advantages in that the flowering of the bulb is not materially impaired; it could be recommended for very rare and valuable bulbils slow of natural increase. A certain percentage of bulbils is assured without preparing nursery beds for them, and the risk of injury to the parent is reduced to a low minimum. The bulbils will need to be relieved of their offsets in the second year, and if necessary they may be again prepared for bulbil production without disturbing the roots.

G. B. MALLETT.

(To be continued.)

THE FRUIT GARDEN.

A NEW AUTUMN-FRUITING STRAWBERRY.

WE are indebted to *Le Jardin* for the accompanying illustration of the new Strawberry Odette and the following description of it: This Strawberry, sent out by M. Lapiere fils, bids fair to become very popular. It fruits uninterruptedly from early summer until the frosts in late autumn; not only in form but in their bright colour do the fruits differ from existing varieties. A seedling from St. Antoine de Padoue, Odette, so far as we have been able to ascertain, is a far better Strawberry. The fruit is shown natural size in the accompanying illustration, old fruits are often cockscomb-shaped and very large. The shining red colour of this Strawberry will make it a favourite in the market; the pale pink flesh is firm, sweet, perfumed, and of very good quality. As one may gather from this short description, Strawberry Odette is likely to prove popular not only with amateur but with professional growers.

GRAFTING.

I HAVE in my garden two old Apple trees which I wish to graft this spring. A few hints in THE GARDEN upon grafting would be very gratefully received.

Nottingham. AMATEUR.

The art of grafting is not merely an interesting pastime, but when done successfully and due care is used in selecting both suitable stocks and scions, a garden or orchard hitherto only containing inferior varieties may be made to yield full crops of superior and valuable fruits. The above letter from one of our readers reaches us at a seasonable time. It is only when the sap commences to rise that a speedy and successful union between stock and scion, or graft, can be secured. So really there is not a day to be lost in making the necessary preparations. The grafts themselves certainly may not be placed in position until the end of the present month, when the searching and drying winds have somewhat abated, but the trees which are to receive them must be taken in hand at once. It is most important that these, though perhaps only of third-rate merit as regards productiveness or quality, should be quite sound, clean, and healthy. Any that show signs of canker, or are badly infested with American blight or natural decay, should be condemned. Aged trees, providing they are healthy, may practically be rejuvenated by being cut back and grafted with approved varieties. Those with well placed and spreading branches may also be treated, each to receive several varieties, but this is not generally advised unless it is that space in the garden is limited.

CUTTING BACK THE TREES.

By this we mean shortening back all the branches in such a way that when the grafts are placed in position and commence to grow they are not far removed from the main stem or trunk. Where several dozen branches originate closely together a few of the most crowded ones in the centre might be cut right out, reserving those evenly placed to receive the grafts, and thus in a few years form a well-balanced head. In reducing the length of these branches—where there are only a few cut back more severely than when there are many—it should vary from 2 feet to 4 feet. Pruning in the first instance should be done with a sharp pruning saw, and in

such a way that the falling branch does not rend the bark beneath the cut. The latter, too, should be made so as to slant away from the centre of the tree. This will allow rain and snow to pass off freely, otherwise moisture might collect in the cavity made to receive the graft. The surface of the wound should be neatly smoothed over with a sharp knife or broad chisel, as it then heals more quickly. It is better that the sap in the trees to be grafted should be more active than that of the grafts, therefore partially bury the latter behind a north wall or in some cool moist and sheltered spot. This will keep both the bark and buds plump until required. Exposure to sun and wind would have the result of causing the bark to shrink, which is fatal.

SELECTING THE GRAFTS.

Shoots of last season's growth should be selected and graded according to size in the autumn, and then buried half their length, as previously advised. With Apples the grafts should be about the thickness of one's little finger. They should be clean, short-jointed, and well-ripened shoots, with well-developed wood buds. Where the desired number of shoots were not selected and stored away some

STRAWBERRY ODETTE (NATURAL SIZE).

weeks ago, not a day should be lost in doing this, each variety to be tied in small bundles and carefully labelled. The soft or unripened tips might be cut back; indeed, the grafts may be now made the desired length, leaving, of course, the cutting away of the bark, &c., at the base of each until immediately before they are placed on the trees. Having so far got the trees and grafts in hand, attention should be paid to other things required, so that everything will be in readiness when the time for grafting arrives.

TOOLS, WAX, STRING, AND CLAY.

A most important matter is to use suitable tools. A strong and very sharp pruniog-knife will be found sufficient probably where only small branches have to be grafted, but when these are several inches in diameter a rather broad chisel with a keen edge and a light mallet would be better to form the clefts or notches. A ball of soft twine, a bottle of grafting wax (which can be obtained from any seedsman), and a quantity of well-worked clay are necessary. The latter is, of course, to be used as a thick coating over the end of the branch and surrounding also the lower part of the graft as protection from drying winds and rain, as well as for keeping the united parts air-

tight and continually moist. When only well-moistened clay is used for this purpose it quickly becomes hard by the action of sun and wind and then cracks. This prevents the covering being air-tight, and thus the object for which it is used is not achieved. It is better to make this covering as follows: Use two parts of clay, one part of cow manure, and finely chopped hay or moss; the latter when well mixed holds the whole together and prevents cracking. Having got all in readiness, the mode of grafting should be decided upon. There are three at least, viz., cleft grafting, crown grafting, and notch grafting. It would probably confuse amateurs to explain each method, and for the present purpose the latter mode will meet our requirements, and perhaps be found the most simple. Even this, however, is not easily understood, but would be quickly grasped after seeing the work once done, or perhaps the accompanying sketch may assist in carrying out successfully the remarks we have to make.

MAKING THE GRAFTS.

Towards the end of March grafting may be commenced. Everything needed should be close at hand, so that the work can be done quickly and with the least exposure of the cut or wounded parts of the stock or scion. The grafts should be, say, about 9 inches long, so that at least three well-developed wood buds remain above where it is connected to the stock or branch. The lower part of the graft should receive two clean and straight cuts from 3 inches to 4 inches in length, bringing the two cuts to an edge on one side, and leaving about one-third of the other side with the bark intact. Clean cuts are very necessary, as bruised bark or wood does not readily unite. Having formed the graft, place it in the position it has to occupy, but with the cut and bark side next to the branch. This will give the operator an idea of the length and width it will need, and can be marked on the bark of the branch with a pencil or small-pointed knife. Then the cleft or notch should be cut out of the latter in such a way that the graft fits in exactly, and for the under bark on either side of the graft to meet that of the stock. It is most important to enable the sap from the tree to meet that in the graft and support it until a union takes place. If this is done neatly and not the smallest cavity is left success is almost certain, but it must be accomplished with the same true exactness as a superior joiner dovetails his handiwork. The graft must be kept firmly in position by binding it round with soft twine, and then over this and all round where the knife has been employed cover with grafting wax. This is to prevent any air reaching the parts operated on. As a further precaution a coating of clay should follow when the wax has hardened, and thus seal up the whole. Little more attention will be needed until the grafts commence to grow, and when they have taken a firm hold they should be carefully uncovered and the string which binds them loosened or removed and retied less firmly, so as to allow room for the expansion of the swelling bark. In all probability before the buds on the grafts commence to grow freely young

GRAFTING: STOCK AND SCION.

shoots will form on the main branches beneath. Most of these should be removed, but a few retained close under the graft; these, too, should be stopped after they have made a few leaves. Their presence would tend to draw up the sap more freely and so feed the graft, but after the latter commences to grow freely all other growth from the stem and branches should be removed.

Goodwood.

RICHARD PARKER.

CHRYSANTHEMUMS.

PROMISING NOVELTIES OF 1902.

(Continued from page 127.)

UNDER this heading the following varieties may be added to those in the previous notes. Although many of them have not received recognition at the hands of the respective floral committees of the National Chrysanthemum Society and Royal Horticultural Society, there are points of merit in the flowers which are sure to place the different kinds in the leading stands another season.

JAPANESE VARIETIES.

Lady Conyers.—A very large Japanese bloom, having broad petals incurving at the ends, of good substance; colour inside the petals good rosy pink, reverse silvery white. This is a full flower which some growers think resembles that of Mrs. George Mileham, but in this instance the flowers are larger and of more substance.

Mrs. F. W. Vallis.—A bloom of this novelty of promise was placed before the National Chrysanthemum Society's floral committee on October 20 last, and so well did that body think of it that they accorded a vote of thanks. Being only one bloom the committee could not make an award. It is a very large and handsome flower, with long and fairly broad drooping petals; colour yellow, striped and suffused reddish crimson. As an exhibition Japanese this variety gives promise of being a decided acquisition.

Edith Smith.—This refined Japanese bloom was first noticed under the name of Miss Smith. The blooms are large and spreading and of even form, having very long drooping petals of good breadth, indented at the ends. The colour may be described as creamy white, deepening to a yellowish tint at the base of the petals. Some of the blooms measured 12 inches in diameter, with a depth of about 7 inches, surely large enough for any purpose.

Florence Penford.—This variety is generally valued for the pleasing and interesting colour of its blooms, which may be described as pale buff, with yellowish centre. It is a large and compact Japanese incurved of compact build, with broad petals twisting and curling and tightly incurving. F.C.C., N.C.S., October 27, 1902.

Countess of Harroby.—An English-raised seedling and a bloom of a most refined and charming character. The petals are fully 8 inches long and rather broad, also slightly curled and incurving. The colour is one of its most pleasing traits, which is a lovely soft pink, lined and suffused a deeper shade of the same colour. This is a Japanese flower, of which type there are too few in commerce.

Mrs. Harry Emmerton.—Some growers may question whether this variety can be regarded as a 1902 novelty. In any case little was seen of this handsome flower till last season. It is a most consistent variety, developing large and full blooms of good quality, and is another testimony to the excellence of the productions of our Antipodean cousins. The blooms are of Japanese reflexed type, being beautifully even in form and having long and drooping petals of medium width; colour bright amber, deepening in colour towards the centre.

Captain Percy Scott.—Several who saw this variety last autumn expressed the opinion that it was a bloom worth noting. The bloom is of large and massive build, with petals of medium width,

incurving and curling at the ends, and developing a flower of good substance suitable for exhibition purposes; colour clear yellow.

Ezmouth Rival.—This is a Japanese bloom which the National Chrysanthemum Society's floral committee commended for its colour. An apt description of this latter is very deep rich crimson, not at all dull in colour, with a bronze reverse. The petals are not over long, and they are fairly broad and pointed. Although the blooms cannot be classed with the monsters which exhibitors always seem to expect in these times, they should materially improve an exhibit owing to their colour alone.

Countess of Arran.—This is one of the most chaste of Mr. Henry Perkins' seedlings, and is a type of Japanese Chrysanthemum to which every encouragement should be given. It is a large flower of grace and refinement, having petals of great length, quite 8 inches long, and fairly broad withal. The colour is a lovely shade of cerise-pink on a pale creamy buff ground—quite novel. When finished some of the blooms were almost 9 inches in diameter and proportionately deep.

Mme. Waldeck Rousseau.—A Continental introduction which, though not absolutely novel, gained considerable notoriety last season. It is a bloom of large proportions, and for exhibition uses has in consequence value where "weight" is desired; colour carmine-red.

Sir Wm. Acland.—This is another English-raised seedling of great promise, developing large flowers of even form, with very long, drooping, and twisting petals. When cupped up for exhibition the blooms impress one with their superb quality; colour reddish bronze.

S. T. Wright.—A distinct acquisition of last season. The blooms, although not of the largest, are quite large enough for all purposes, and have broad florets of good substance neatly reflexing. The central florets, however, incurve, revealing the golden-bronze reverse; colour brilliant crimson. A.M., R.H.S., November 4 last.

Mrs. A. R. Knight.—There are points of merit in this flower, but these are not so pronounced as are some of the other sorts. The petals are of good length and fairly broad, the lower ones being slightly twisted; colour bright golden-yellow, shaded at tips of petals chestnut-red. A deep bloom when finished. F.C.C., N.C.S., November 10 last.

Hon. Mrs. A. Acland.—A very lovely full flower, having long and broad petals which incurve slightly at the tips. As the bloom finishes it develops into a large exhibition flower of good substance. The colour is a rich shade of yellow, midway between the yellows of Edith Tabor and R. Hooper Pearson. The reverse of the petals is a lighter shade of the same colour. A.M., R.H.S., October 21, 1902.

D. B. CRANE.

PLEACHED ALLEYS.

IN the period when formality ruled in the garden and topiary work was considered the highest form of embellishment for the pleasure, when, as Victor Hugo writes, "trees were forced to submit to the grotesque caprices of the shears and line, and natural order was everywhere contradicted, inverted, upset, destroyed," the pleached alley was in vogue, and few were the better class dwellings of the time that did not number one or more of these shaded walks among their chief attractions. Now, along with other fashions of that age whose disappearance is a subject for congratulation, the pleached alley is well nigh extinct, though here and there an example, such as that portrayed in the accompanying illustration, is to be met with. The advent of the foreign-titled stranger from sunnier climes, the pergola, had doubtless, owing to its superior attractiveness in holding aloft a canopy of blossom in place of a roof of uniform green and permitting the culture of Lilies and other beautiful flowering plants between its supports, no little part in the banishment of the pleached alley, but if we believe all we read the interloper's reign is not destined to be a lengthened one, for in a late number of THE GARDEN a correspondent prophesies that the garden books of

THE PLEACHED LIME ALLEY AT HOAR CROSS.

the future will speak of the pergola as "a horticultural artifice which had considerable vogue at the beginning of the twentieth century, but which, owing to the truer conception of art in the twenty-first century, has fallen into disuse!"—a prophecy whose fulfilment is not, from all appearances, likely to seriously disquiet the minds of the present generation. Fashioned generally from native Hornbeam, Beech, or Lime, the pleached alleys furnished pleasant resorts through many months of the year. On fine spring days the birds might be watched breaking on the shoots above against the blue sky. Little by little the sprays gathered green as the foliage expanded, and later, on clear evenings, one of the most beautiful sights in Nature was to be seen when the rays of the setting sun shone through the emerald transparency of the young Beech leaves, still margined with fringes of silkiest down. Throughout the springtide the alley ways were haunted by bird life appearing and disappearing amid the greenery. Finches, white throats, willow wrens, warblers, and the tiny gold-crest, whose nest, already half-finished, hung beneath an outstretched branch of a neighbouring Yew. In July, when the alley was composed of Limes, the air was redolent with the perfume of their blossoms, and the now silent bird voices were replaced by the murmurous hum of myriad honey bees. In the sultry heat of summer noons the pleached alley afforded grateful

shade, and in autumnal days the fading leaves shone transformed in russet, ruddy bronze, and gold. In the winter the alley was left severely alone, and the winds whistled unheeded through the bare branches. The foregoing has reference solely to pleached alleys fashioned of deciduous subjects. Sometimes they are formed of evergreens, such as Yew, Box, Holly, or Cotoneaster microphylla. The advantage seems to rest, however, entirely with the deciduous trees, whose varying conditions from month to month contrast agreeably with the monotonous sameness of the evergreen, the shade of which is also often too dense. Within one of the latter that I know of there is a "dim religious light," even on the brightest of summer days. Other good trees for use in the construction of alleys are the weeping forms of the Ash and Elm. That this habit of growth is not indispensable is shown by the majority of pleached alleys of old time being formed of trees of upright growth, but those with naturally pendent branches more readily assume the required shape. Flowering trees may be used, but it must be remembered that if the branches are so thickly trained as to form a shaded walk in the summer they will probably be too crowded to ripen well and therefore to blossom as profusely as if they enjoyed more air and light. *Prunus Mahaleb pendula* is a very pretty weeping flowering tree, and this, as well as *Laburnum* and

Wistaria, may well be used if the branches are thinly trained overhead. In Japan the *Wistaria* is widely employed for covering overhead trellises and archways, the variety used being generally *W. multijuga*, whose flower racemes are 3 feet and more in length. This form is but rarely seen in England, and I only know of two gardens where it is doing well. Where *Wistaria* is grown as a covering for a shaded walk, the roof should be of sufficient height to permit of the space of a clear 2 feet intervening between the boughs and the heads of those traversing the path beneath. *Wistaria* is generally of slow growth in its earlier stages and annual climbers, or what is practically annuals in this climate, such as *Cobaea scandens*, *Mimosa lobata*, *Tropaeolum carariense*, and *Lophospermum scandens* may be utilised with good effect until the *Wistaria* shall have made good growth. A pleached alley requires considerable attention if it is to be kept in good order in the matter of cutting out old wood and bending down and laying in the young shoots. Pretty covered ways are often seen composed of Pear or other fruit trees, but these have little in common with the alley, since the branches, to flower and fruit well, can not be so closely trained as to throw a dense shade. In writing of the pergola in "Trees and Shrubs for English Gardens," Mr. Cook says: "It often occurs that in laying out ground the owner wishes to have a pergola, as it were, in the air, and when

there is nothing to justify its presence. It should not be put haphazard over any part of the garden walk, but should lead from somewhere to somewhere of importance in the garden design." This excellent advice applies every whit as strongly to pleached alleys.
S. W. FITZHERBERT.

GARDENING OF THE WEEK.

THE FLOWER GARDEN.

MOSSY LAWNS.

OLD grass lawns, more especially in humid climates and pent-up situations, are very liable to become overgrown with various species of Mosses, rendering them less firm to tread upon, and, by choking the grasses, destroying that cheerful green appearance which makes our lawns the admiration of all strangers, unless it be in shady walks and places where it would be impossible to get grass to grow. There, indeed, nothing can be better than Mossy covering; but on the lawn, whether in the flower garden or around the house, Moss should be extirpated altogether, or so kept under that the healthy growth of the lawn grasses may not be interrupted. The early spring is the best time to give a top-dressing of finely-sifted leaf-soil and rotten manure or any of the fertilisers that are congenial to the growth of grass and destructive to the Moss—lime, guano, soot, or finely-sifted coal ashes are all of this class of fertilisers—and where their application may be objected to on account of their colour they may be employed in a liquid state, and if applied during rainy weather neither their colour nor odour would be objected to.

VINCAS.

For forming permanent edgings to large beds the Golden and Silver Vincas are most effective. They can be trimmed to any desired height and form when they get well established, and will also bear pegging down. These and the common Periwinkles are excellent plants for planting in shaded situations, or for planting round the sides of baskets, or for hanging over raised beds, covering unsightly walls, and one often sees them used with good effect when covering the stumps of old trees. They increase themselves into stools, which can be lifted and separated when it is desired to increase them; or cuttings put in when the growths become moderately firm root freely.

CALCEOLARIAS.

These generally thrive best after they are planted out without ever having been put into small pots at all. In the absence of cold pits and frames, the plan I would recommend is to throw out trenches like those generally used for Celery beds, put 6 inches of rotten leaves in the bottom, and then 6 inches of light rich soil. Here the young plants, lifted with as little injury to their roots as possible, should be pricked out about the end of the month, 6 inches apart each way. When all are planted water well, and lay some sticks or trellis work across the trench, and cover with mats or canvas when cold weather renders it necessary. For the first fortnight after being transplanted they should be shaded through the day when the sun shines. Thus managed they make fine strong plants with very little trouble. As they grow they should be looked over at intervals and topped, so as to keep them dwarf and well furnished. About three weeks before they are planted out the spade should be run along the lines each way, cutting to the depth of 6 inches. This cuts off the roots of each plant from its fellow, checks them for the time, but causes them to make fresh roots nearer home, and the result is that they lift well and scarcely receive any check when planted out.

ANTIRRHINUM (THE SNAPDRAGON).

To grow this plant from seed is most easy. Now is the best time to sow it, and the best way to treat it is to sow in shallow pans in a cool frame, and plant out the seedlings in a bed of light soil. As soon as they are large enough to handle grow

them on till the end of May, when they will be fit for planting out. The dwarf kinds are the best for beds and massing. Golden Queen, with its large golden-yellow flowers, is a gem for beds or pots.

T. B. FIELD.

Ashwellthorpe Gardens, Norwich.

FRUIT GARDEN.

PEACHES.

IN the earliest house still attend to the thinning, disbudding, and tying-in of the young shoots intended to form next year's fruit-bearing wood. As we have before observed, the disbudding of indoor Peach trees is an important work which requires daily attention, combined with a knowledge of the condition of the roots. If the latter have been recently disturbed, or the trees have been weakened by heavy cropping, a little delay will give them time to pick up before many of the shoots are removed; but as trees of this kind generally set freely the timely removal of a great number of the least promising fruit may precede disbudding, when good mulching, followed by a moderate supply of warm liquid manure, will soon start them into growth. Vigorous young trees, after being divested of fore-right shoots, may have many of the side shoots pinched either to form spurs or to supply foliage where there is likely to be a scarcity; but it must always be borne in mind that the best shoot which starts from the base of this year's fruiting wood must have plenty of room for growth and exposure to the influence of warmth and light. Where

YOUNG TREES

are trained upon the extension principle and last year's shoots are from 2 feet to 4 feet in length, the latter may be allowed to carry a Peach at every foot run, and, provided they were well thinned out at the autumn pruning, two or more shoots may be laid in full length. If borders are well made and properly drained there is little danger of over-watering inside borders. Let the temperature range about 55° by night and 10° higher by day from fire-heat.

VINES.

Practical Grape growers who have to keep the varieties Mrs. Pince, Black Alicante, and Lady Downe's Seedling fresh, black, and plump until new Black Hamburgs are ready, will hardly need reminding that the houses should now be closed. When buds begin to swell a somewhat higher temperature than that recommended for early houses may be given; indeed, to have Lady Downe's thin skinned, full flavoured, and capable of keeping fresh and plump until May the Vines should receive Muscat treatment until the Grapes begin to colour, when Hamburg treatment will ensure colour. Black Morocco and Gros Colman, when properly managed and allowed a long growing season, are valuable for use from January to March, but they should be ripe in September. Bunches of Gros Colman should hang for some time on the Vines after the leaves fall. An excellent late Grape, Mrs. Pearson, is well worthy of a place in every autumn and winter vinery. As a grower it is quite as free as its inferior relative, the Golden Queen. It shows an abundance of handsome bunches, which set well, and my experience justifies me saying it will keep for a long time and improve in quality after it is ripe.

Madresfield Court.

WILLIAM CRUMP.

KITCHEN GARDEN.

FORCING.

MAINTAIN a succession of Seakale, Asparagus, Rhubarb, and Chicory by introducing fresh plants as often as the needs of the establishment demand. Very gentle forcing suffices at this date, for by growing as naturally as possible the flavour will be retained. Especially does this apply to Asparagus, which may now be cut from frames quite green and of full flavour if abundance of air has been admitted whenever the weather allowed. Asparagus in frames requires copious applications of warm water pretty frequently to ensure quick

growth, which is so essential for the production of tender heads.

FRENCH BEANS.

Where large quantities of these are required during spring, and accommodation is limited for fruiting under glass, it is a good practice to sow a large batch now in pots, or in narrow boxes specially made, for planting in the open at the end of April. If pots are utilised, 4½-inch will be best. Sow five Beans in each, leaving sufficient space for top-dressing, place in a temperate house to germinate, and as soon as up remove to cold frames and keep near the glass. Do not admit air for the first three days, and even then it must be done cautiously, as nothing is so harmful to this delicate vegetable as draughts. On quiet days give air freely and apply tepid water at the same time. When the weather is quite favourable and the ground to a fit condition transplant them in rows on a warm border and protect with evergreen branches or treble thickness of fish netting. Osborn's Forcing and Ne Plus Ultra are good varieties for this purpose.

SEED SOWING.

Tomatoes for open air culture may be sown at this date in pans of finely sifted soil; the chief aim should be to raise the plants in medium warmth and keep them sturdy, yet steadily growing throughout. As it is unsafe to plant Tomatoes out until the end of May or early in June, it is obvious that strong plants must be available at that time, as our summers are generally short.

Well-grown plants, if well tended, will give good crops of fruit in the open in sunny seasons. Ham Green is the best variety with us.

LEEKs

for the main and late crops should now be sown on a warm border for transplanting into trenches or in holes bored with the Potato dibbler. The Musselburgh I have found the best to follow the earlier and more tender varieties.

BETROOT

for summer use is in demand in most gardens for saladings, and some of the early round variety may be sown to precede the main crop.

TOMATOES UNDER GLASS.

Sow for the late summer crop in pits and cool houses, and grow on as advised above. Remove all side shoots from plants that are flowering or fruiting, and tie and encourage the leading shoot to grow freely. Afford adequate protection to all vegetables raised under glass and planted out.

Stonleigh Abbey Gardens.

H. T. MARTIN.

INDOOR GARDEN.

LAPAGERIA ROSEA AND L. ALBA.

WHETHER growing on trellises, on the roof of the greenhouse, or allowed to ramble at will over rock-work, which is its natural position, the borders in which they are growing should be periodically examined. Where found necessary perfect drainage must be restored, and a top-dressing of peat and sand with an admixture of broken sandstone or rough corks must be given. The border should be kept sufficiently open to allow the water to pass freely through it. The young shoots frequently suffer from attacks of aphids, and should the plants be growing where fumigation is inconvenient syringe them twice weekly with diluted Quassia extract, directing the mixture chiefly to the affected parts.

EPACRIS

and the soft-wooded section of Ericas now passing out of flower should be cut hard back, leaving only from half an inch to three-quarters of an inch of last year's wood at the base of the stronger and medium-sized shoots, cutting the weaker ones quite close in. After pruning the plants may be syringed lightly on every bright morning, and as soon as the buds begin to swell a little the plants may be repotted. Anything like shaking out the whole of the soil must be avoided, and any sickly or unhealthy plants had better be consigned to the rubbish heap. On repotting use pots of only one

size larger. The plants thrive best in peat with a good admixture of coarse white sand and charcoal broken somewhat fine, but with all the dusty particles sifted out of it. Very firm potting is necessary; therefore use a thin, flat stick to work the soil tightly round the roots. Keep the plants cool, and avoid fire-heat as much as possible provided the temperature does not fall below 32°. In the event of bright sun a light shade of tiffany must be given. The repotting of the general collection of *Ericas* had better be deferred for some time yet.

CARNATION CUTTINGS

of the winter-blooming section put in some weeks ago will now be sufficiently well rooted to be potted off; for this purpose use very small pots and place one cutting in each. Use a compost of two-thirds light friable loam with one-third decayed leaf-soil and a little sand; after potting place the young plants in a close case (which can be ventilated as required) for about a week, keeping the temperature from 50° to 55° until root-action commences. As soon as the young plants are rooting freely place them on a shelf, shading them from bright sun, and gradually harden them off.

SALVIAS

Cuttings of *S. Brauntii*, *S. Pitcherii*, *S. rutilans*, and *S. gesneriflora* for autumn blooming should now be put in, as these plants are exceedingly useful for grouping and give variety of colour and form at a season of the year when the *Chrysanthemum* dominates the entire garden.

Wendover. J. JAQUES.

ORCHIDS.

DENDROBIUM × THWAITESÆ.

MR. R. G. THWAITES, Christchurch Road, Streatham (gardener, Mr J. M. Black), exhibited this new hybrid *Dendrobium* before the Orchid committee of the Royal Horticultural Society on the 10th inst., when it received an award of merit. The parents of this beautiful hybrid are *D. splendidissimum grandiflorum* and *D. Wiganie*. Sepals and petals are pale buff tinged with purple towards the apices, the base of the lip is also pale buff, while the centre is dark crimson. It is the purple tint in sepals and petals that gives to this flower its charm.

SOCIETIES.

READING AND DISTRICT GARDENERS' ASSOCIATION.

A VERY pleasant evening was spent by the members of the above association at their last fortnightly meeting, when Mr. W. Townsend, of Sandhurst Lodge Gardens, Wellington College Station, gave a paper entitled "A Berkshire Garden in Summer," illustrated with limelight views. Of course, the garden dealt with was that under Mr. Townsend's charge, and which is noted for its beautiful outdoor flowers. The visitors were, so to speak, shown the principal features, which were the *Roses*, *Lilies*, *Fuchsias*, *Hydrangeas*, &c., which bloom profusely here. The slides were run through a second time so as to enable the members to ask questions, and, needless to say, the opportunity was taken great advantage of. Mr. J. Gibson, of the Gardens, Danesfield, Marlow, made a splendid exhibit of the Sutton Variegated Kale, staging about three dozen heads. A hearty vote of thanks was accorded the lecturer and exhibitor.

CROYDON HORTICULTURAL SOCIETY.

A MEETING of this society took place recently, when a good attendance welcomed a member, Mr. W. Briscoe, who is one of the staff at the Royal Gardens, Kew, and who kindly came down to read his prize essay on "Propagation." Perhaps some will remember the occasion of this society's annual dinner in January last, when a presentation for the first prize essay on "Propagation of Plant Life" was made to Mr. Briscoe, and at the time mention was made that the recipient would read the paper before the members of the society at a future date.

For the last two years Mr. Briscoe has been at Kew, where the many facilities offered there have greatly benefited him, both in technical and practical horticulture, and his reception was extremely hearty from his many friends and members of this society.

In his paper he dealt with every part of this important subject, giving full description of the propagating house, where the multiplication of plant life may be carried on, and classifying the subject into eight headings—viz., seeds, Fern spores, division of plants, suckers, leaf, root and flower-stem cuttings, layering, grafting, and budding.

Splendid specimens of plants in bloom were exhibited by members of the society—viz., Mr. E. Kromer, who brought well-grown *Lelia jongheana*; Mr. M. E. Mills, who showed *Cyclamen Papilio* and *Dendrobium Pierardii* in fine form; and Mr. A. Edwards bringing good flowered plants of the double *Cineraria*.

The next paper will be read on Tuesday next, when Mr. A. C. Roffey will discourse on the treatment of Cucumber culture.

LIVERPOOL HORTICULTURAL ASSOCIATION.

AS a conclusion to the winter evening meetings, Mr. J. Hathaway delivered on Saturday a paper on "Profitable Fruit Culture." The subject was ably treated as far as possible in the limited time at command. Some interesting details were given as to the imports of hardy fruits. The site advised was that of a slope falling to the south or south-east, which was preferable to flat land. A marly loam was suggested as the best soil; it should be well treated to the depth of 2 feet to 2½ feet, and well drained. The best season for planting was given as from the middle of October to the middle of December. Stocks, planting, form of tree, pruning, and general culture were treated in detail, and the best fruits to grow for market.

DENDROBIUM × THWAITESÆ (NATURAL SIZE).
(Exhibited by R. G. Thwaites, Esq., before the Royal Horticultural Society on the 10th inst., and then given an award of merit.)

At the conclusion of the paper, Mr. T. Foster (the chairman) opened the discussion, in which Messrs. J. Skitt, R. G. Waterman, Joseph and John Stoney, G. Symons, F. Twist, W. Mercer, and S. Haines took part. Vinegar was strongly advocated by one of the speakers as an antidote to American blight, to be used with a soft brush during the spring. Mr. G. Symons of Formby exhibited some excellent *Gloria Mundi* Apples. A cordial vote of thanks was tendered to Mr. Hathaway for his excellent paper and to Mr. Foster for presiding.

BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

A WELL-ATTENDED meeting of this association was held at St. John's Rooms, Redland, on Thursday the 12th inst., Mr. E. Binfield presiding. This was the evening set apart for the official visit of the Bristol Amateur Horticultural Society, and they received a hearty welcome. Two amateurs, prominent members, came forward with well written papers, Mr. Batson choosing for his subject *Cyclamen* culture, while Mr. Johnstone did justice to *Roses* from an amateur's standpoint. Both lecturers imparted their experiences in a lucid manner, showing that they were no mean horticulturists. Mr. Batson himself is a most successful cultivator of the *Cyclamen*, while Mr. Johnstone makes a special study of *Roses*. Mr. Batson dealing with his subject emphasised the necessity of obtaining the very best possible strain of seed, as success depended especially on this point. He carefully described the composts most suitable, as also the time of sowing and after treatment. Good drainage and careful potting are items not to be overlooked. Attention to every detail meant bringing the cultivation of the *Cyclamen* to a successful issue.

Mr. Johnstone detailed his mode of cultivating *Roses* from the time of budding till the blooming season in a clear and masterly way, and the amateur association is to be congratulated on having such good men among its members. His lecture was listened to with a great amount of interest, and was much appreciated by all present. At the close of

each lecture many questions were put to the lecturers, who answered each in a clear and concise way. A hearty vote of thanks to each lecturer brought to a close a very pleasant and instructive evening. It is hoped the good feeling which exists between these two flourishing societies will continue, both working for the good of horticulture. The prizes for the evening were for two *Cyclamen*, the competition being very keen. The prize winners were Mr. W. A. F. Powell (gardener, Mr. Raikes), who came off first, while Dr. Eager, Northwoods (gardener, Mr. Cane), was an excellent second. Certificates of merit went to Mr. Gilbert Howes (gardener, Mr. White) for *Cymbidium gibberum*, and to Mr. J. Chetwood Aiken (gardener, Mr. Clarke) for *Cymbidium lowianum*. The final meeting of the winter session will take place on the 20th inst., when Mr. W. Ellis Groves, the energetic secretary, will give a lecture on the value of mutual improvement associations, which will undoubtedly be worthy of a full attendance, Mr. Groves being a capable lecturer on this subject.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.

FROM the report, &c., of this excellent institution the officers and executive have every reason to be pleased with the progress that is being made. The association came into existence in 1890, so that it has now entered upon the thirteenth year of its operations. The membership is well maintained, finances are better, the monthly exhibitions during the past year showed great improvement in every respect, and the monthly lectures were a distinct source of pleasure and profit to all who attended them. The two social functions of the year—the conversation in July and the annual dinner in December—were most enjoyable, and proved a capital means of bringing members into closer union. For the current year several excellent Saturday afternoon outings to gardens and nurseries of more than ordinary interest have been arranged. A capital series of lectures has been arranged. The first was given by Mr. J. Cheal on the 3rd inst., entitled "Rambles in the States and Canada," and the others are as follows: April 7, "The Loves of the Flowers," by Mr. A. Boulton, F.R.H.S.; May 5, "Hardy Primulas," by Mr. S. Hillman; June 2, "Gloxinias and Streptocarpuses," by Mr. A. J. Foster, F.R.H.S.; August 11, "The Influence of Air on the Roots of Plants," by Mr. G. M. Gross; September 1, "Hardy Flowers," by Mr. D. B. Crane, F.R.H.S.; October 8, "Tomatoes," by Mr. W. Iggulden, F.R.H.S.; November 3, "Ferns," by Mr. H. A. Smith; December 1, "Vegetables," by Mr. G. Hobday, F.R.H.S.; and January 5, 1904, "Diseases of Plants," by Mr. T. W. Sanders, F.L.S. The prospects of the current year are very bright indeed, and the enthusiasm of the members in the pursuit of their hobby is also very keen. The subscription is only 5s. per annum. Mr. F. Finch, 117, Embleton Road, Vicar's Hill, Lewisham, S.E., is the hon. general secretary.

THE HORTICULTURAL CLUB.

AT the monthly dinner of this club, held on Tuesday the 10th inst., under the presidency of Mr. Harry Veitch, when some fifty members and friends attended, an extremely interesting discussion on fruit cultivation at the Cape was initiated by a verbal address by Mr. Pickstone, who is now on a visit from the Cape, who for a long period controlled the various fruit plantations established by the late Mr. Cecil Rhodes. Mr. Pickstone, on his first arrival at Cape Colony, found that for more than a century fruit culture had been carried on entirely by the Dutch, and despite the fact of long-continued British occupation, absolutely nothing had been done by the English in that direction, Mr. Pickstone being the first and solitary pioneer. Mr. Cecil Rhodes, however, speedily grasped the fact that no branch of land cultivation gives employment to so many men as that of fruit culture, and with his usual farsightedness in connexion with the future development of the country, he took steps to extend the very limited orchard area by engaging Mr. Pickstone, first of all to acquire a number of farms at an expense of some £150,000, and eventually to stock them with suitable trees. As was to be expected, this task was by no means an easy one in either of its sections, since in the first place the Dutch landowners, as is their wont, were not easy to deal with as regards the purchase, and eventually, when the question of acquiring the trees arose, it was found that no stock was available of the sort hitherto cultivated there, and that these, moreover, were of any most heterogeneous description, only two or three of any one such being obtainable. The climatical conditions also were such that the only area suitable for deciduous fruit trees was a comparatively small one on the flanks of Table Mountain and within 150 miles of it, where the winter rains provided the useful moisture. Elsewhere in the Cape these were lacking, and as irrigation was, and is still, practically non-existent, experience had to be dearly bought when fruit culture was attempted in other quarters. Mr. Pickstone gave a vivid description of the results of furious windstorms which wrecked and destroyed the young plantations. The soil is of a loose granitic gravelly nature, and after one of these storms he found that the wind had torn up this soil and hurled it with such violence, sand-blast fashion, that the young trees were eroded away to the very pith and completely destroyed, over some eighty acres in extent. To counteract this, oat crops were grown on the loose soil, but a storm which succeeded the reaping of these crops actually blew the very stubble out of the ground and annihilated the trees once again, when the task at that point was abandoned. In other parts of the Cape deciduous fruit growin; is handicapped by the climate preventing a thorough rest, with the result that when trees are pruned,

as is done here, soft sappy growth is produced, which is a prey to all the pests, fungoid and insect, known to fruit culture, a partial cure for which was found in leaving the trees unpruned altogether. Mr. Pickstone's speech was so replete with interesting facts that space precludes more than a mere allusion to salient ones, so that we must refer our readers to the forthcoming full report in the Royal Horticultural Journal. In the subsequent discussion, however, in which Messrs. A. C. Pearson, Bunyard, Paul, Drury, H. Veitch, Dr. Horace Browne, Rev. G. Engleheart, and others took part, other important points were elicited, and among them the lack of fine flavour in the imported Cape fruits was alluded to, and though Mr. Pickstone could not deny this altogether, he pointed out that some of the Japanese Plums produced there surpassed those obtained in any other part of the world, even Japan itself, and certainly some specimens produced at the last club dinner could hold their own with the most delicious. As regards the other fruits, Mr. Pickstone pointed out with justice that at the Cape fruit growing on high quality lines was a young industry, but he was sure that to time selection would lead to improvement, and even now the finest sorts of Pears were produced. Mr. Cecil Rhodes had also introduced fruit drying on the Californian system with promising results. Although many of our English Apples will not do well owing to climatical disadvantages, Mr. Pickstone had established one Apple which would grow side by side with the Orange, a probable pioneer which he regarded as a precious acquisition in the way of adaptation.

Some remarks were made as to the possibility of glutting the market by over-production, and Mr. Pickstone fully agreed that this possibility existed, though he believed that by proper control over quality and packing there would always be room for the best at remunerative prices. A hearty vote of thanks concluded a very pleasant and instructive meeting.

EAST ANGLIAN HORTICULTURAL CLUB.

There was not quite such a good muster of members as usual at the March meeting of this club. The subject for the evening—an essay competition, restricted to single-handed gardeners—was full of interest, and brought forth a good debate. The judges had made their awards prior to the meeting, with the following results: First, Mr. C. Matthews, Holly Lodge, Thorpe; second, Mr. G. W. Meade, Hethersett; third, Mr. E. C. Ramus, Hethersett, Norwich. The papers were carefully compiled, and contained many pithy practical points. Mr. J. C. Abel also read a paper entitled "How to Keep a Garden Gay from April to October." In the course of his paper Mr. Abel dwelt upon raising spring-flowering plants from seed in wide borders, allowing room to plant the summer occupants before these were past their best to keep up the succession. There was a pretty display upon the exhibition tables. Mr. C. Burtenshaw and Mr. F. Williams staged ideal Cinerarias. The former named exhibitor staged also a nice plant of *Pteris Alexandræ*. Mr. C. Fox, Old Catton, showed fine *Rhubarb* and good Apples for so late a date. Mr. C. H. Hines was a notable exhibitor in the vegetable classes. There were also upon the table for inspection two charming sprays of *Tussilago alba* (the white Winter Heliotrope) from Mr. T. B. Field, Ashwellthorpe, which attracted much attention. Mr. C. Burtenshaw also brought up charming sprays in full bloom of *Forsythia suspensa*.

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.

The nineteenth annual general meeting of the above society was held on the 11th inst., the High Sheriff of Middlesex (Mr. C. F. Cory-Wright, J.P., D.L.) presiding, and there was a large attendance of members. The annual report and financial statement were submitted, from which it appeared that the last exhibition of the society, which was held at the Alexandra Palace, was a great horticultural success, and was patronised by a larger number of visitors than on any previous occasion. The receipts for the year show a great increase upon former years, especially the donations towards the special prize fund. The committee have arranged for their exhibition for this year to take place at the Alexandra Palace on November 4, 5, and 6.

The chairman, in moving the adoption of the report, said that he was very glad they went to the Alexandra Palace last year, for until that time they had never had a place where they could do justice to their exhibits; on the last occasion the public were not sufficiently aware of the fact that the society were moving to the Alexandra Palace. Mr. J. McKechar seconded the adoption of the report, which was carried unanimously. Votes of thanks were accorded to the retiring president (Lord Mansfield), the officers, committee, and auditors. The election of officers for 1903 then took place. Mr. T. Bevan proposed that Mr. C. F. Cory-Wright, J.P., D.L., should be president for the ensuing year. Mr. J. McKechar seconded the motion, which was carried by acclamation. The treasurer (Mr. J. McKechar), secretary (Mr. W. E. Boyce), and auditors (Messrs. Attkins and Smyth) were re-elected. In returning thanks, Mr. Boyce said that the society's show at the Alexandra Palace would be the great show of the year there. The following were elected to serve on the committee: Messrs. Turk, Webber, North, Witty, Bevan, Saunders, Pannell, Blanch, Bone, Taylor, Treney, Marriott, Bittern, Rand, Sedgwick, Bignell, Ransom, and Antrobus. The meeting closed with a hearty vote of thanks to the chairman for presiding.

CARDIFF GARDENERS' ASSOCIATION.

The usual fortnightly meeting took place at the Grand Hotel on the 10th inst., Mr. C. E. Collier presiding. Mr. F. S. Daniels (chairman and representative of the Newport Gardeners' Mutual Improvement Association) delivered a most practical and instructive paper on "The Cultivation of the Strawberry," giving general details regarding the aspect, soils, and manures, as most likely to aid successful culture. The four best recommended for a small collection

were as follows:—Vicomtesse Héricarte de Thury, Green's President, La Grosse Sucrée, and Royal Sovereign. The best thanks of the meeting were voted Mr. Daniels for his splendid paper.

ANSWERS TO CORRESPONDENTS.

Names of plants.—A. T. Bowles.—*Acacia leprosa*.—J. T. D.—The flower is *Eupatorium ianthinum*.

Soil for Rhododendrons (QUEENS).—In many districts Rhododendrons grow quite as well in loam as in peat, but it is essential that it be not clayey, absolutely free from lime, and not parched up in the summer. These conditions fulfilled, chopped up sods, but not the manure, would suit the Rhododendrons well. What is known as a good friable loam will grow Rhododendrons well without any admixture.

Canna seeds.—In response to a recent question I may say that I find it is a good practice when sowing *Canna* seed to cut through the hard outer shell, being careful not to go near the eye, with a sharp-edged file. With this treatment every seed will germinate in a good bottom heat in a water pan of ten days.—J. R. WILSON.

Water plants in glasses (S. D.).—We presume your question refers to the ordinary *Ilyacinth* glasses. If so, there are very few water plants that may be grown in them. Perhaps the best would be *Cyperus alternifolius*, with Rush-like stems, terminated by bright green leaves, arranged after the manner of the ribs of an umbrella. There is also a variety with variegated leaves.

Flower bedding (C. H. C.).—We can but regret that you should in your bedding arrangements have any penchant for designs in flower-beds. Whatever may have been the popularity that once attached to bedding of this description, it certainly has none now. Still further, all the most pleasing effects now obtained in summer bedding are those of the least formal kind, and where effort is made rather to be natural than to follow mathematical lines or figures. Some of the prettiest effects have been secured by creating carpets in the beds of neutral tints, and then putting out plants thinly of one line of colour, amidst which are interspersed pleasing tall grasses or flag-like plants, or some having pleasing foliage or flowers. Many entirely mixed beds of plants that are of similar habit of growth are very effective. In making bedding arrangements every effort should be to keep as far as possible from stiff or formal designs.

Manufacture of spawn (A GROWER).—In reply to your correspondent, I regret if I have not made quite clear in my article on the manufacture of spawn the character and quality of the spawn to use for impregnating the bricks. What I did say was (see THE GARDEN of the 7th ult., page 97): "That on the quality of the spawn to be used will depend almost entirely the success of the operation. In any case, doubtful spawn must not be used in impregnating the new bricks." The spawn spoken of here for the purpose of impregnation is the ordinary brick spawn. The best quality bricks of the previous year's make should be reserved for this purpose. This is the only spawn I have ever used, and invariably with best results. "Best quality" spawn, as purchased from our nurserymen, will answer the purpose equally as well. The spawn should be crushed rather small (the size of French Beans), and the holes punctured in the brick partly filled, leaving sufficient space effectually to seal over the spawn with the same material as formed the brick.—D. THOMAS.

Grafting Rhododendrons (PONTREU).—This requires a considerable amount of skill, and it must be done under glass. If your seedlings are good plants you may lift them now, put into as small pots as you conveniently can, and place in a cold frame, keeping fairly close till they are established, after which the lights may be left off altogether. The month of August is a good time for carrying out the operation of grafting. Various methods have been employed, but that generally followed is what is known as veneer grafting. In this the stock only needs shortening back to a convenient length, as the graft is inserted at the side in the following manner: In the first place the scion must be formed of a shoot of the current year, from 4 inches to 6 inches long, and the bottom portion to a length of 1½ inches finished off with a clear sloping cut. The side of the stock then has a piece cut out into which the sloping cut of the scion will exactly fit, and is tied securely in its place. After the operation the plants must be kept quite close and shaded till union is complete, which will be in about six weeks, after which they must be gradually hardened off. Then a portion of the stock may be cut off, and early in the following spring before growth recommences they may be cut back to the graft.

Pegging down newly-planted Roses (CARNATION).—If you pegged down the strong shoots this season the result would be unsatisfactory, for there is insufficient root action in recently transplanted bushes to support the extra demand made upon them, consequently the new growths would be weakly and stunted. Better to cut back rather hard this month, then next season at pruning time reserve some of the longest and ripest shoots for pegging down. To see that pegging down Roses answers well, one has only to pay a visit to Kew Gardens and inspect the fine beds of Grace Darling, Gloire de Dijon, Mme. Abel Chatenay, &c., which are pegged down. They are a glorious mass of blossom. Many Roses well established and that have a natural spreading habit, such as *Gloire de Margottin*, *Bardou Job*, &c., would be infinitely more beautiful if their growths were allowed greater freedom. By partly bending the shoots bloom buds form almost their entire length. In like manner some of the rambler Roses, planted as single specimens and permitted to spread and bend outward, are one mass of bloom. We have had *Crimson Rambler*, *Electra*, *Polyantha grandiflora*, *Una*,

and others with such growths each carrying some dozen or more trusses of blossom, and making a floral picture of surpassing beauty.

The best zonal Pelargoniums (J. W. B.).—One of the finest exhibits of winter-flowering zonal Pelargoniums that has come under our notice recently was staged by Mr. H. Cannell of Swanley at the December exhibition of the National Chrysanthemum Society. The following were all in splendid condition, and you can make a good selection therefrom. *Single*: *Barbara Hope*, salmon-pink, large white eye; *Captain Holford*, crimson, suffused orange; *Countess of Hopetoun*, white margin, bright salmon centre; *Crabbe*, soft cherry-red; *Dorothy Burroughs*, bluish-pink; *Duchess of Marlborough*, soft salmon, mottled white; *Duke of Norfolk*, magenta-crimson, large white eye; *General Walseley*, clear rosy red; *Ian Maclaren*, deep salmon, shaded orange in centre; *King of Crimsons*, bright glowing crimson; *Lady E. Malet*, pure white; *Lady Roscoe*, bluish; *Lady Sarah Wilson*, a fine bright flower of the *Souvenir de Mirande* class; *Lilacina Improved*, lilac-pink; *Lord Curzon*, bright magenta-carmine; *Lord Roberts*, magenta-purple, base of upper segments orange; *Mark Twain*, white, freckled and flaked carmine; *Mary Beaton*, pure white; *Mary Hamilton*, rich crimson-scarlet, white eye; *Mrs. George Cadbury*, salmon; *Mr. T. E. Green*, orange; *Mrs. Brown Potter*, clear bright pink; *Mrs. Williams*, bright rose-pink; *Princess of Wales*, rosy cerise; *Sir John Llewellyn*, intense crimson; *Sir Wilfred Laurier*, white centre, outside magenta; *Snow-storm*, white; *The Maine*, rich rosy lake; *The Mikado*, soft cerise; *The Sirdar*, bright scarlet; *W. E. Corden*, clear bright scarlet, white eye; and *Winston Churchill*, magenta-pink, white centre. *Double*: *Colossus*, deep crimson; *Dr. Deprés*, a large rich scarlet flower; *Double Jacoby*, crimson; *Golden Glory*, one of the best of the orange-coloured class; *Gustave Emich*, clear bright scarlet, unsurpassed for winter blooming; *Miss G. Ashworth*, pure white; *Mme. Charlotte*, salmon, mottled white; and *Raspail Improved*, deepscarlet.

Camellia buds dropping (BRANSTON).—It is difficult to say without seeing the plant what causes the buds of your *Camellia* to fall. The branch you send looks perfectly healthy. It is probable that the soil around the roots has become sour, and also that the drainage is bad—both these things cause buds to drop. Bud dropping is also caused by an excess of water being given and also by allowing plants to become very dry, the former especially. It is advisable to examine the roots now, and if the soil is sour remove as much as possible, retrain, and fill up again with a fresh mixture of sandy fibrous peat and loam, watering carefully afterwards.

APPOINTMENTS.

MR. MATRICE GRAY has been appointed to represent Messrs. J. Peed and Son, Roupell Park Nurseries, West Norwood, in the Isle of Wight and South and South-East Coast towns, in place of the late Mr. Harrington.

MR. A. R. OSMAN, who represented Messrs. Cripps and Sons, Tumbleidge Wells, for three years, is now similarly engaged, in addition to Mr. Slack, for Messrs. Sankey and Son, Bulwell Potteries, Notts.

TRADE NOTES.

SHANKS' LAWN MOWERS.

THE booklet about lawn mowers issued by Messrs. Shanks and Sons, Limited, Denis Iron Works, Arbroath, N.B., and Bush Lane House, Cannon Street, E.C., contains illustrations of a variety of these machines. Among the hand lawn mowers we notice one especially constructed for mowing long grass. This has three knives in the revolving cutters, iron side rollers, and adjustable delivery plates. They are particularly strong. There are numerous different styles of machines illustrated, from the popular one known as "The Britisher," adapted for use in the smallest gardens, to the Patent Horse Mowers, fitted with steel axle, springs, and other improvements, and the prices are such as to suit all pockets. Full particulars of rollers of all sizes are also given in the booklet.

MESSRS. BARE AND SONS' SPRING CATALOGUE.

THIS contains descriptions of numerous hardy herbaceous plants, alpines, and aquatic for present planting. Comprehensive collections of Michaelmas Daisies, hardy border Chrysanthemums, Delphiniums, Helianthus, Christmas and Lenten Roses, Irises, Peonies, and many other plants grown in the Ditton Hill Nurseries are detailed.

OBITUARY.—MR. JAMES J. FROMOW.

THIS gentleman, the eldest of three brothers, proprietors of the nurseries of Messrs. W. Fromow and Sons, Sutton Court Nursery, Chiswick, died on the 13th inst. at the age of 48. Mr. Fromow, who was in vigorous health, met with an accident in the public roadway which did injury to his knee; this took fatal effect inwardly and resulted in his death after a month's illness. He married two years ago, and leaves a widow and one child. In addition to the home nurseries at Turnham Green, there is a large one at Bagshot, of which Mr. James Fromow had the management, and the firm also have the business in Hounslow Town, formerly carried on by Messrs. Dobson and Sons. The present proprietors represent the third generation in the business, which has rapidly extended in late years. Mr. Fromow was buried in the Ealing Cemetery on the 18th inst.

THE GARDEN

No. 1636.—VOL. LXIII.]

[MARCH 28, 1903.]

IMPROVEMENT OF ROSE SHOWS.

IT is with no desire to criticise unkindly the present ways of exhibiting Roses at summer exhibitions that we again give prominence to the subject, for we know that secretaries and others deeply interested in the societies for which they labour are as anxious as the general public to institute reforms. We have received the following letters in reference to our remarks in *THE GARDEN* of February 21 and the note from the Dean of Rochester in the issue of February 28. We hope to receive other opinions, as this is a matter not only of exhibitions of Roses but of those of more miscellaneous flowers. We are anxious for definite advice, and not mere abuse of existing practices.

Our first contributor advocates strongly the gardens of the Royal Botanic Society for the show of the National Rose Society. He writes:—

"It is true that the Temple Gardens are central, but so is Regent's Park or Holland House, at least quite central enough for the public to patronise the show. I fear that unless the National Rose Society looks after the comfort of its patrons they in return will withhold their support. If it is a question of paying for the use of the Royal Botanic Gardens surely some arrangement could be come to between the prize winners for settling this account. As to the supplying of Palms, &c., to make the tents more attractive, there are several London firms that would do this for a mere trifle. It is a small matter, yet one of those matters that enhance the beauty of a show considerably.

"With regard to the society adding to the beauty of their later exhibitions by awarding prizes to collections of garden or decorative Roses, I maintain that the cramped space allowed has hindered rather than helped the proper display of this beautiful class. How can anyone make an adequate display on 36 square feet? Why, 200 feet I should consider small. One can see any day in June and July packed displays of Roses and other flowers if one visits Covent Garden. I am ready to give the National Rose Society the credit of endeavouring to popularise decorative Roses, but they have not been the only agent. The Roses themselves, in my opinion, have forced their way upon our notice mainly owing to the displays seen in large private and commercial establishments in the land. I could name several popular decorative Roses which are rarely seen at the National Rose Society's shows.

"As to a two days' show, I am glad to think

I am not alone in its advocacy. Those who wish well by the society from a financial point of view will, I think, support me. Suppose the first day happened to be a wet one, the flowers would remain fresh, and there would be a chance of retrieving loss on the second day, which in all probability would be fine.

"I should like to ask whether it was quite impossible for the National Rose and the Royal Horticultural Societies to combine their two shows, which take place this year within six or seven days of each other. I am quite aware a week at that time of year makes a vast difference to Roses, but I think the matter is worth considering another year, so that a really good show could be held at Holland House, supposing the generous owner should again lend his beautiful grounds for the purpose. Surely a little diplomacy could have managed this this year; and we should all do well to bear in mind that the Rose being the national flower, the 'best' place and the 'best' manner of displaying it should be accorded to it. In my opinion exhibitors of decorative Roses should be given a free hand to make the best display upon a given space, and this space should be considerably increased. As to the admissible list, all Roses known to be good decorative kinds, although capable of being produced exhibition size by severe thinning and disbudding (quite unnatural aids), should be included. If necessary, let this list be revised by all the members of the National Rose Society. If put to the vote, we should find many Roses included in this list of decorative varieties that are now debarred. "A WELL-WISHING CRITIC."

"In reply to Canon Hole's appeal may I suggest that more and simpler classes might with benefit be added to the schedule of the National Rose Society in regard to the decorative section: Classes for pot Roses shown growing, say, six to nine pots; vases of cut blooms, from six to eighteen, same kind or various; and baskets of cut blooms, either decorative or show. This, of course, for the amateur section.

"CHAS. WM. CROSBY."

"All I can suggest is to get away as much as may be from the usual weaknesses of shows and give more encouragement to Roses arranged for house decoration. It is well to remember that it is the free arrangements of Roses in vases, bowls, baskets, &c., that makes a pretty show and that points out how they may be used and best enjoyed. I think it would be a great advance in taste and usefulness if in certain classes, especially the Tea Rose, that it be shown so as to give an idea of its growth and habit. No limit of number of blooms, just what will show it best, cut rather long, such as five blooms and a few buds, and, of course, its own foliage.

"X. Y. Z."

"I greatly enjoyed reading your excellent leader and the note from the Dean of Rochester.

May I suggest that beautiful groups of Roses be shown, perhaps from pots, in the centre of the tent, or at least a portion of the tent, to show the glory of the varieties in their full flower beauty. The trade would do this with satisfaction to everyone I am sure. Another point is to institute more classes in which the flowers are to be shown, cut with long stems. Such an exhibit was seen at the last National Rose show, and proved of immense interest apart from its beauty. It would be well if there were more classes to show beauty of arrangement, that is, bowls and baskets of Roses. The present decorative classes are interesting, of course, but the flowers are too closely bunched. I hope other rosarians will contribute to this interesting discussion. I am secretary of a Rose show, but please use initials only, as I am too occupied for private correspondence. "E. R. T."

THE BEST SWEET PEAS.

IN *THE GARDEN* of the 7th inst., on page 157, one of your contributors gives a list of Sweet Peas, which, with your permission, I should very much like to criticise, feeling in my own mind that the list as there given is most misleading.

To begin with the whites. Dorothy Eckford may certainly be the best white that is at present in cultivation that maintains its present character, but your contributor should add that it is a new variety, and that the seed is very expensive in comparison to some of the good standard varieties. It is only this year that it has been put upon the market at a cost of 1s. for each ten seeds, whereas many of the other whites may be had at about 6d. per ounce of 400 to 500 seeds, a very serious consideration with many small gardeners.

In speaking of the next best white there always seems a very great diversity of opinion as to which is the better of the two, *i.e.*, Sadie Burpee or Blanche Burpee, but when one looks at the number of times Sadie Burpee and Blanche Burpee were exhibited at the great Bicentenary Exhibition, and at the general exhibitions of the country, we find Blanche Burpee was exhibited ninety-six times at the great Centenary Exhibition, and it was seven times in the first prize stand; it was also shown in the provinces fifty-six times, whereas Sadie Burpee only has a record of sixty-five and thirty-seven. That Blanche was a much greater favourite than Sadie is demonstrated by the fact that in 1902 it was shown 227 times at the leading exhibitions, whereas Sadie Burpee only appeared 170 times.

In the crimson shades, to class George Gordon and Salopian is most misleading. Salopian is certainly a rich dark crimson, but George Gordon is more of a bicolor than it is a self; it has a carmine-crimson standard, with more of a rosy purple or dark lavender wing, and is, in my opinion, a decided bicolor.

The lavender varieties may be very well as they are, as the two most distinct of that particular shade; but when we come to talk of pink varieties, and put Countess of Lathom and the Hon. F. Bouverie as the two represented in this class, I should say is decidedly wrong, both these being more of a pinkish buff, or a pink overlaid with buff, the latter colour being rather more prominent, particularly in the first-named variety. What I should think would be the two best represented as pink would be Prima Donna and Lovely, the Hon. F. Bouverie may come as a third, but it has a decided salmon-pink tinge over it rather than a pure pink.

In the orange section, to class Miss Willmott, Triumph, and Gorgeous all in one is another most misleading statement. Miss Willmott is a decided self, and much more of a salmon-red than orange; it is a grand flower in its way, and worthy of its name, but to put Triumph by the side of it as an orange variety is very erroneous, for it is really more of a bicolor, having a carmine shade in the standard, with a decided pink wing, which at times comes decidedly grained or streaked. Gorgeous, as far as standards are concerned, is the nearest approach to orange we yet have, and may really be called orange, but the wings are a decided pink or pale crimson, and quite a bicolor rather than a self.

In speaking of magenta, and putting Captivation in that class, and then putting Duke of Westminster and Dorothy Tennant amongst rose and dark colours, is again very misleading, because I think they all ought to have been put in one class rather than divided; and in the maroon or dark colours put Othello if you like, although Othello is a variety I do not care about much, preferring Black Knight or Stanley, which, however, are so near alike that one may be very well substituted for the other.

The pale primrose varieties are right, but when we come to rose and speak of Prince of Wales, Lord Rosebery, and Prince Edward of York together, the first two may be in their right class, but Prince Edward of York I look upon as a bicolor rather than a self; it has a sort of salmon-carmine standard and rosy wings, a very pretty combination of colour, and a great favourite of mine, but certainly could not be classed as a rose with Prince of Wales and Lord Rosebery.

Speaking of Countess Spencer, it may interest your contributor and your readers generally to know that I have a good stock of this variety now growing, and hope to be able to distribute it amongst your readers or horticulturists generally in 1904, although I am afraid the stock the first year will be somewhat limited.

The other classes, which I do not criticise, I consider fairly good, although when you speak of Colonist and Lady Skelmersdale, they are two varieties which are now very rarely seen on exhibition tables. Colonist is more after the style of Prince of Wales, but there is so much variation in colour that it cannot be called one thing or the other. I have often seen four or five distinct shades of colour in a row 4 feet or 5 feet long. Lady Skelmersdale is hardly ever seen now on the exhibition stand, and is one of the weakest flowers that is mentioned in the whole of the list.

Birmingham.

ROBERT SYDENHAM.

NOTES FROM SCOTLAND.

HORTICULTURAL EXHIBITIONS.

THE balance-sheet of the Dundee Horticultural Society shows a condition of affairs that must give the liveliest satisfaction to its members, the year's working terminating with a balance on the

credit side of over £500. No less than £700 was taken for admission to the show in August last, but against that the expenses were very high, amounting in all to £807, of which only £240 19s. was disbursed in prize money. The chief item in the prize list for the present year is a "Decorative Dessert Table," the first prize for which is a challenge cup and £7. Mr. and Mrs. Martin White, Balruddery, offer prizes for cut flowers under somewhat novel conditions as to judging. Instead of being judged on the morning of the first day of the show, the competing vases are to be left alone till the third day and then judged, this in order to test the lasting qualities of the material employed.

The schedule of the Dumfriesshire and Galloway Horticultural Society is also to hand. The most desirable prize offered by this recently-resuscitated association for a group of plants is a 15 guinea challenge cup and £5. Other prize lists include those of the royal horticultural societies of Aberdeen and of Perthshire; this, the oldest society in Scotland, dating from 1805, gives evidence of a very pleasant and vigorous spirit permeating their doings. A remarkable feature of Scottish horticultural societies in general is the great number of prizes offered in the various sections. Those of the Aberdeen society, for instance, amount to nearly 750, and Dundee has almost as many. It is not possible to offer prizes of any great value under these circumstances, and it says not a little for the keen spirit of rivalry existing that very strong competition is secured.

R. P. B.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

April 1.—Royal Botanic Society's Spring Show.

April 7.—Royal Horticultural Society, meeting of committees; Horticultural Club, paper by Mr. F. W. Burbidge, M.A., F.L.S., V.M.H., on "Horticultural Progress," 6 p.m.

April 8.—East Anglian Horticultural Club meeting.

April 15.—Shrewsbury Spring Show.

April 18.—Ghent Quinquennial Show (opening day).

National Auricula Society (Midland section).—The annual report and schedule of prizes of this branch of the National Society has just been issued; the Rev. F. D. Horner, V.M.H., is the president. From the report we learn that the third annual exhibition, which was held in the Botanical Gardens, Edgbaston, Birmingham, last year, was the most successful yet held by the society; the exhibits increased threefold, and the quality of the bloom was of the highest order. By means of the operations of the society a great impetus has been given to Auricula culture in the Midland district. The show is held a few days after that in London, the advantage being that growers from the south and north can meet in friendly rivalry, the date suiting both, and when such northern growers as the Rev. F. D. Horner, Kirby Lensdale, and Mr. Thomas Lord, Todmorden, can be found in competition with such a southern champion as Mr. James Douglas, of Great Bookham, and other southern growers, quality is certain to rank high. To this exhibition last year the Rev. F. D. Horner was able to bring some of his newest productions in Auriculas, and especially of selfs, and with them he carried off some of the highest honours. This year the annual exhibition is fixed for April 30, and will be held in the Temperance Institute, Corporation Street, Birmingham, in order to afford better opportunity for the dwellers in the city to see the flowers. The strong protest made at Birmingham last year against the laxity in insisting upon the observance of the old procedure in exhibiting Auriculas, namely, that a pin-eyed flower, that is, a long-styled flower, in which the pistil protrudes above the anthers, has borne fruit, and disqualification is to be visited upon any such in the future. Whether the same treatment is to be meted out to any pin-eyed

flowers which may be shown at the Drill Hall on April 21 remains to be seen. Another point which came up for discussion at the last exhibition in Birmingham, and also on the occasion of the annual meeting of the supporters of the southern section a short time ago, was—Should alpine Auriculas be restricted to one stem and truss only, as in the case of the show varieties? It is the present intention to admit a plurality of trusses at the show of the southern section, but at Birmingham a kind of compromise has been arrived at, as, while there is to be no restriction as to the number of trusses on a plant, for the rule sets forth "the trusses not for competition must be tied down;" but this does not make it quite clear whether one only or two or three competitive trusses may be left on the plants. The old-fashioned gold-laced Polyanthus are recognised in the schedule, and there is also a class for a group of any sorts of Primulas arranged in a basket or box; these last year afforded an extremely interesting feature.—R. D.

Winchester New Park and Recreation Ground.—The Winchester Town Council recently offered two premiums, the first of £75, the second of £25, for the best designs for a new park and recreation ground. These premiums have now been awarded, but the decision appears to have caused considerable dissatisfaction. Several letters have appeared in the *Hampshire Chronicle* criticising the accepted plans; one of them is from Mr. A. G. Jackman, Woking Nurseries, Surrey, and we append extracts: "Upon reading the account of the proceedings of the Winchester Town Council in your paper of March 7, and that the plans were to be on view, I decided to take the opportunity of going down to see them, and very glad I was that I did so, as I could have never believed that such an injustice could have been done to the twenty-five competitors, or that the members of the council who passed the resolutions awarding the premiums should have so little artistic taste or practical knowledge of the subject before them. To my mind it was a great error of judgment not to call in the assistance of an expert to advise them in a competition of such importance. If such had been the case I have not the slightest hesitation in saying that 'Venta's' design would not have been placed in the first dozen. . . . From the observations made by different members of the council, and the designs selected, it is evident to everyone that artistic display did not enter into the adjudication. What evidently was desired was a recreation ground pure and simple, plain in design, and, above all things, economical, and these were the main points which influenced them in their selection. I happen to have known Winchester intimately for several years, and also live within five miles of a very chalky locality, and have had a considerable experience with very many sorts of trees, shrubs, and plants, and if there are any shrubs which dislike and absolutely refuse to grow in soil impregnated with lime such as this ground is it Rhododendrons and Azaleas, to say nothing of other plants 'Venta' has mentioned. To a man with any practical knowledge of the cost of growing trees and shrubs 'Venta's' idea of a nursery of two acres in an exposed and damp situation for growing trees and shrubs for renewing deficiencies or carrying out any future planting is, to say the least, amusing; it would, I presume, consist of a Poplar grove, withy bed, and Rhododendron cemetery. . . . I do not see any sum set apart for drainage, road and walk making, always expensive items, but he has evidently allowed £260 for contingencies, as his figures do not agree, and I think he will want it, and probably another 0 tacked on to the end."

Mr. J. Ashton Sawyer, of Winchester, writes as follows: "'Venta's' design (placed first) is to my mind a long way from being the best. It does not comply with the instructions, inasmuch as it has net two cricket grounds of four acres each, as set forth in instruction No. 4, but only one of 6½ acres. No drains are shown on the plan or otherwise described, as there should be according to instruction No. 2.

Spring bedding at Edinburgh.—

Mr. McHattie has introduced a novel form of spring bedding into East Princes Street Gardens, Edinburgh. Looking across the valley from the General Assembly Buildings two series of brilliantly coloured designs, one on each of the steep slopes, force themselves upon one's notice. On a close inspection these are discovered to be arrangements of various Crocuses, white, yellow, and mauve predominating. The corms have been planted in the grass, but at a short distance this cannot be detected, and one supposes that these are beds cut out on the slopes. A large star at the east end of the garden is quite as brilliant as the others. Other arrangements to follow these are planted with Daffodils. The series of new beds on the Princes Street level will soon be gay with Tulips and other flowers.

Pinguicula caudata superba.—This fine and striking form of the Mexican-tailed *Pinguicula*, exhibited by Mr. J. T. Bennett-Pöe at the last meeting of the Royal Horticultural Society, recalled to my memory the sight of a number of plants of the type which I saw at the Queen's Road Nursery, Cheltenham, in November, 1901. They were then in full bloom, and occupied a place in a house with cool Orchids. The plants, several of which had bloomed freely, were in 3½-inch pots, and Mr. Cypher informed me they were in a compost formed of peat, sand, and sphagnum moss in about equal parts, and had been potted lightly. Autumn is the time of blooming, and the flowers appear to possess lasting qualities. When the plants go out of flower they are rested for a time, during which season they require but very little water; but when growth commences more is given, and it is at that time increase is made by division. The temperature in which the *Pinguicula* is grown is the same as for cool Orchids, about 45° to 50° at night during winter, and plenty of moisture in the atmosphere both summer and winter. In addition to propagating by means of division, increase can be obtained from leaves similar to the method adopted in the case of *Gloxinias*. They are found to strike root freely in such a compost as that named above. Seed can also be obtained from the plants, and it is probable Mr. Bennett-Pöe's fine form originated in this way.—R. DEAN.

Grease-banding fruit trees.—A few years ago when the grease-banding of fruit trees was recommended as a means of capturing the female insects of the winter moth when crawling up the stems for the purpose of egg laying, the custom became very common amongst the proprietors of orchards. But whether the novelty of the thing has worn off, or whether growers have found that the remedy is not so efficacious as it was supposed to be, the fact remains that the practice has dropped into disuse, and comparatively few people grease-band their trees now. At the same time, I am of the opinion that there is something in grease-banding, as on various occasions I have seen quite a number of the female moths made captive by the sticky material. Abuse has probably been responsible for grease-banding getting into ill-favour, because I have seen instances where the practice has led to positive ill-health of trees. This was in instances where grease containing poisonous matter was applied so carelessly that a portion of it ran off the papers and down the bark of the trees. The thing to do when applying grease-bands is to secure paper that is grease-proof and smear it over with grease that does not run, and, at the same time, does not dry quickly. The bands should be in position by the middle of November. In some instances I have seen dwarf trees grease-banded, but this is more or less a waste of time, for when the lower branches are close to the ground the insect finds means of getting on to them without going up the stem; indeed, if fruit trees generally are kept in a state of cleanliness by winter washing, and spraying if necessary in the spring, it is an open question whether grease-banding is not a superfluous operation.—G. H. H.

Chrysanthemum Gladys Gray.—This is a bright yellow sport from Mme. Ed. Lefort, and properly looked after should prove one of the most useful early-flowering Pompons of recent years. Those who have grown plants of

the parent variety know well that it is one of the very best Pompons extant. On October 27 last a few insignificant blooms of the sport were placed before the floral committee of the National Chrysanthemum Society, but nothing could be done with them. This note is written in the hope that interested growers will acquire stock for next season's display. The sport is in the hands of a north country grower.

Euonymus and caterpillars.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Carter, of 22, Pelham Crescent, enquired as to the best method of dealing with the caterpillar which attacks the *Euonymus*. Mr. Saunders replied as follows:—"The caterpillars on *Euonymus* are those of the 'maggie,' or 'Gooseberry and Currant moth' (*Abraxas grossulariata*), a very common insect, which may often be seen fluttering about during the daytime—it flies very badly; the general colour of the insect is creamy white ornamented with black spots, but they vary very much in colour, some nearly white specimens having been found, and others which were almost black. The insect measures 1½ inches to 1¾ inches across the open wings. The chrysalides are not made in the ground, but in dead leaves, which they spin together, or in some similar kind of shelter. Any leaves which do not fall with the others should always be examined, as it will be often found that the caterpillar has spun the edges together and attached it to the bush, and has undergone its transformations within it. Picking the caterpillars off by hand is no doubt one of the most effectual ways of dealing with this insect, but it is tedious; spraying the bushes with a solution of paraffin emulsion would probably kill a large number. In the winter, all the dead leaves beneath the bushes should be collected and burnt. The moths may be caught very easily in a butterfly net." Mr. Drury observed that he had tried dusting with Hellebore powder freely into the web colonies, and that it was effectual in destroying them.

Camellias dropping buds.—Although I have seen many very large *Camellias* in the open air, I have never seen or heard of their dropping buds. The complaint seems not even to apply to *Camellias* planted out under glass where reasonably attended to; but it is so easy in the case of rather old plants to understand how the roots, cramped and confined in pots, or even in tubs, may at times, as it were, resent what is such unnatural cultivation, and cast well-formed flower-buds at critical moments. When planted out in congenial soil *Camellia* roots run wide, and seem to revel in freedom. They are, so planted, very fibrous, and as a rule in very diverse condition from what may be seen in pots. Then the moistenings the roots and foliage obtain are more plentiful, and there is no danger that on the one hand through neglect they may become starved by drought or suddenly forced into rapid top action by a flooding of water. That there are many gardens in this country in which *Camellias* will do well as hardy shrubs there can be no doubt. Like so many other quite hardy things introduced from Japan, it became the rule to regard them as tender, whereas they rank amongst the hardiest of evergreen shrubs. Some have found failures after planting out because they have put out old pot-bound ones that cannot possibly form good roots. To plant these out is to court failure. To have good specimens outdoors they should be planted whilst young, and have been well seasoned by a summer's exposure outdoors. The few specimens growing on a cold north border at Chiswick are often referred to as evidences of the *Camellia*'s hardiness. But there in uncongenial soil, and where the summer shoots do not well ripen, the plants are far from being favourable examples of outdoor growth. At Glen Eyre, Southampton, noble specimens there grow in the full blaze of hot sunshine, and do equally well as those in shaded aspects, and when in bloom are indeed superb examples of outdoor *Camellias*.—A. D.

"The Veitchian Nurseries."—Mr. James Herbert Veitch, F.L.S., has compiled a booklet descriptive of the various nurseries of Messrs. James Veitch and Sons, Limited, Chelsea,

and containing many illustrations at Langley, Coombe Wood, Feltham, and Chelsea, where the several nurseries are situated. Portraits are given of the founder of the firm (Mr. John Veitch, 1752-1839), James Veitch, 1792-1863, James Veitch, jun., 1815-1869, John Gould Veitch, 1839-1870, and Arthur Veitch, 1844-1880. The illustrations are from photographs, and are reproduced upon art paper. The most attractive are those showing views in the nursery at Coombe Wood, Kingston, for instance, "Looking South-West Towards the Wood," "Water Lily Pond in Bamboo Garden," "New Plant Ground" (in which is shown *Astilbe Davidii* flowering for the first time in Europe), and "Maples in the Nursery." Mr. Veitch has produced a dainty and interesting booklet that gives one a good idea of the extent of the Veitchian nurseries and the variety of their products.

Andromeda (Cassandra) calyculata.—Some pot plants of this shrub are in flower just now, and look sufficiently attractive—whilst the species is known to be one of the hardiest and neatest—to merit special notice. Owing to the peculiar position of the leaves their rusty under surface is very conspicuous. The numerous pure white bells suspended from the branchlets, relieved by the bronzy foliage, make up a handsome and distinct shrub worthy of a good position in the peat shrubbery. Like most *Andromeda* the plants begin to flower at an early age.—J. Wood, *Plant Club, Kirkstall, Leeds.*

Sefton Park, Liverpool.—The special attraction in the large Palm house is at present the *Amaryllis*. Hitherto they have been spoken highly of, but there can be no doubt that this exhibit is well ahead of that of previous years. The number of bulbs is about 1,500, and when it is considered that these have undergone severe selection it will be understood that the display as a whole must be in advance of previous ones. The colours vary from nearly pure white through pink, salmon, scarlet, to rich crimson. As the collection is simply for the public no names are given to the varieties, but simply the best are retained and the worst rejected. Mr. H. Herbert, the superintendent, is to be congratulated upon this successful venture, as all the bulbs have been grown from a very small beginning. Small pots, very little water, and deep plunging in some suitable material after flowering, with a little feeding, are the chief cultural points followed. The exhibition is open free to the public every day, and is worth a long journey to see.

Ornithogalum Hausknechtii.—When it becomes better known this pretty *Ornithogalum* will probably be a favourite plant with those who admire spring flowers. It appears to share with some others of the genus their accommodating ways of flowering in shade as well as in sun, while its flowers are large and of a good white. It produces a tuft of broad leaves, from the centre of which appear its clusters of white flowers, which are almost close to the ground. They opened here early in March this year, although in a shady position and almost under a *Rhododendron*. *O. Hausknechtii* comes from Asia Minor, whence it was first introduced in 1897. So far as the few years experience we have had of it warrants one in speaking, one may say that it is hardy in our climate. The drawback of many of the *Ornithogalums* is that they increase too rapidly. Possibly *O. Hausknechtii* may have this fault, but it has yet to be proved, and so pleasing a flower deserves a trial.

Iris willmottiana.—This lovely little *Iris* is at present in bloom here after having again been cultivated in the open without any protection during winter. It was fully in flower on my return home on March 18, and to prolong the flowering it is now covered with a small handlight. It is a charming little flower with its delicately coloured blooms of blue and white, and has been cultivated for the past two seasons in a rather peaty soil at the base of a rockery and in a position facing south-south-west. One of the most recent of one's treasures in the shape of *Irises*; it is also one of the prettiest.—S. ARNOTT, *Carse-thorn, by Dumfries, N.B.*

Royal Botanic Society.—The spring exhibition of this society will be held on Wednesday next in the Gardens, Regent's Park, and will remain open for one day only. Special prizes are offered for Daffodils, the first being a silver vase specially designed by H. G. Moon, and offered by Messrs. Barr and Sons.

Spring flowers in Scotland.—A bed of the Winter Aconite in the middle of February was a beautiful sight in the gardens of Dr. Tait, Inverure. Thousands of the yellow flowers peeping from their green frills made a striking ground covering, and especially when the sun shone upon them. We often see clumps and rows of Snowdrops, but away north in Banffshire Mr. Fraser, gardener to the Dowager Countess of Seafield, showed me recently a plot of grass land about two acres in extent quite white with them. It is rarely one has an opportunity of seeing Snowdrops so plentiful.

Choisya ternata in Scotland.—The value of *Choisya ternata* as a hardy shrub is only partially recognised. It seems to pass through the hardest winter quite uninjured. As an evergreen only it is as pretty a shrub as the broad-leaved green *Euonymus* at its best, whilst in the spring with its lovely white, sweet-scented flowers it is a perfect picture. In the gardens of Keir House, near Stirling, Mr. Lunt, of Grape growing fame, has a plant of *Choisya ternata* on a wall; it is clothed with lovely dark green foliage, and well set with flower-buds. Mr. Lunt speaks most highly of its behaviour at Keir.—SPECTATOR.

Windsor Rose Society.—By gracious permission of the King, the twelfth annual exhibition of this society will be held in the private grounds of Windsor Castle, known as "The Slopes," on Saturday, June 27. Mr. W. Colin Romaine has given up the honorary secretaryship, to which Mr. W. Titt has succeeded, while the post of honorary treasurer has been relinquished by Mr. J. F. Hoddinot in favour of the Rev. S. K. Tabourdin, The Cloisters, Windsor Castle.

Gardeners' Royal Benevolent Institution.—The committee of this institution are sending out collecting cards with the earnest hope that those who receive them will kindly do what they can to collect or personally contribute something, however small, in aid of the work which for sixty-four years has been the means, in large measure, of removing the anxiety, smoothing the pathway, and brightening the declining years of those aged gardeners, &c., and their widows, who through sheer misfortune and no fault of their own have found themselves stranded in their old age. There are now 204 persons—116 men and 88 widows—receiving £20 and £16 a year respectively for life, at an annual cost of £3,728, whilst last year £104 was distributed from the Victorian Era Fund amongst those candidates who had been subscribers and were unsuccessful at the previous election. This year as much or more will be given away from the same fund in like manner. Gratuities are also granted from the Good Samaritan Fund as temporary help in urgent cases of distress and need. The cards may be obtained from the secretary, Mr. G. J. Ingram, 117, Victoria Street, London.

Propagating early Chrysanthemums.—There appears to be an impression that early-flowering Chrysanthemums should be propagated fairly early; in fact, that cuttings should be inserted during the same period as the ordinary November flowering ones. Experience has taught one that the propagation of the early sorts may be continued for some time to come. The late Mr. Piercy, than whom there was no more enthusiastic cultivator of the early-flowering varieties, used to point with pride to plants which were the results of cuttings inserted in May and June, and when visiting him during September these same plants were to be seen blossoming profusely, and without any protection whatever. At this moment the old stools are simply bristling with numerous growths, and for this reason the present time is best to insert cuttings for next autumn's display.

Waterlow Park, spring prospects. This park is situated on one side of Highgate Hill,

and has a southern aspect. The hardy borders afford the keenest interest to many. The lower entrance is the more popular means of approach to, and exit from, the park. It is here that the present superintendent (Mr. Carson) and his assistants carry out a bold and comprehensive scheme of bedding for effect. On one side of the principal walk is a broad sloping border with a southern aspect, and here are massed in regular designs groups of Wallflowers, Primroses, Tulips, Narcissi, Daisies, Arabis, and other equally useful plants. There has been an attempt at naturalising the Crocuses here, and very pretty was the effect on the occasion of our visit. Groups of white, yellow, purple, and striped Crocuses made a dainty display. To residents in the immediate neighbourhood, and to others living within easy access by public conveyance, this lung of North London is an inestimable boon, and from the way in which the work of the garden is done visitors cannot fail to be impressed with gardening as one of the most interesting and delightful of all recreations.—D. B. CRANE.

Fruit from Queensland.—The Queensland Fruit Growers' Association, which was formed last year for the purpose of organising the export of fruit in the coming season, hopes to send forward shipments to London. Up to the present the association has been directing its energies to the sale of fruit in New Zealand and other states, but with the break-up of the drought it is proposed to ship to Europe. Grape growing has much increased in Queensland of late, the coast districts from Bundaberg to the New South Wales border being particularly suited for the industry. The following sorts are grown with success in the state:—Chasselas d'Or or Sweetwater, Prococe de Courtiller, Madelaine Augurine, Madelaine Royal, Luglienga, all early varieties; Chasselas Negrepoint, Blue Portuguese, Black Hamburg, early coloured varieties; and later varieties of Mrs. Prince Muscat, Muscat Hamburg, Muscat Beaume, Ronsette, Golden Champion, Bermestia Gros Guillaume, and Wortley Hall. All those mentioned are European varieties. American varieties grown are Concord, Delaware, Wilder, Geethe, Iona, Alvey, F. de Lesseps, and a so-called Wantage.

Garrya elliptica.—So much has been written of the wall shrub *Garrya elliptica* that I fancy the enclosed photograph will interest you, although it may not be of any use for reproduction. The *Garrya* is the climber nearest the porch of the house on the left side as you face it. You will see that it reaches the eaves and projects possibly 3 feet from the wall. I know it was constantly cut back to prevent its encroachments on the windows. The catkins were very long and beautiful. This photograph was taken at least twenty years ago, but I do not know how old the shrub was then. The house is on the eastern slope of the Gareloch, Dumbartonshire, a part of Scotland most favourable to the growth of tender shrubs. I cannot give you the measurements of the *Hydrangea* bushes growing at the sides of the porch, but I know a child of twelve could easily be hidden inside of them. The colour of the flowers of one was a beautiful blue, and they were never moved or protected. They grew in heaps of large stones which had probably once been rockeries. A *Fuchsia* grew right over the porch, having a thick, woody stem, and not far off a *Myrtle* some 12 feet high growing against a house used to flower almost every summer.—FRANCES GIBSON, *The White House, Lansdowne Road, Aldershot.* [The photograph, which, unfortunately, was not suitable for reproduction, showed a remarkably fine growth of the *Garrya*, which was figured in THE GARDEN of the 14th inst.—Ed.]

The promise of Pears.—At the time of writing the bloom on the Pear trees is not out, but the swelling buds reveal the fact that whatever the crop may be there will be an abundance of blossom. Trees, old and young, on walls, in gardens, and in orchards look most promising; but there are fears that if the bloom is out early, as it gives every promise of being, there will come a biting frost, the like of which has on so many occasions blighted the hopes of the Pear grower. Curiously enough, there is rarely any dearth of

Pear bloom, although it is frequently so thick that much is infertile, and then it is out at a time when it has to run the risk of sharp frosts, consequently the Pear crop is always an uncertain one.—H.

Zonal Pelargonium Pink F. V. Raspail.—The original scarlet coloured F. V. Raspail, from which the new plant takes its name, is so well known, and its value for showy displays as well as for cutting so highly appreciated, that the distribution of a pink variety should be welcomed. A recent visit to the Rycroft collection of these plants revealed the existence of this fine pink flower. The stock appears to be in excellent condition, so the ensuing season should see the novelty in large demand. Mr. H. J. Jones has a great opinion of its worth, and says it is just what is wanted by private as well as market growers.—D. B. C.

Lime-washing fruit trees.—Anyone travelling through the fruit-growing districts of Kent during spring may observe the stems and lower branches of standard fruit trees made spotlessly white by their annual lime-washing. When in the train one hears all sorts of questions asked as to why it is done, and amusing answers are sometimes given by persons who are evidently not acquainted with the ways of fruit growers. Indeed, I am not sure whether some of the growers themselves have a definite idea why they treat the lower parts of the trees to the annual plastering of lime-wash, but the process has been in practice so long that it has got to be part of the routine work. The object, no doubt, is a good one, namely, that of destroying moss and lichen on the stems and the destruction of insect pests, but I can imagine nothing more unsightly. In fact, this white-washing of trees makes them hideous and a blot on the surrounding landscape. Again, is it necessary? Perhaps it was before the introduction of the caustic alkali solution, which does away with any need of whitening, and is the best-known winter wash for fruit trees. But old customs die hard, and in spite of the expense there is attached to the whitening of tree-stems, scores of fruit growers still do this, though they might, by means of the solution referred to and a spraying apparatus, clean, not only the stems and lower branches of the trees, but every particle of growth, at considerably less cost. Only the other day I was in a large fruit-growing establishment where the trees are sprayed once every winter with the caustic alkali solution formed as follows: 1lb. of caustic soda and 1lb. of pearlash are dissolved in 10 gallons of water, along with half a pound of soft soap that has been previously dissolved in a little boiling water. The operator wears an old suit of clothes, and is provided with gloves. By means of a knapsack sprayer all the parts of the trees are damped with the mixture, which has the effect of killing every particle of obnoxious growth, and the bark assumes a shining, healthy appearance. It is too late to use the caustic solution now, as the buds are on the move, but the hint may be useful in view of next winter. I am quite convinced that the general use of this wash would be more efficacious, less costly, and far more sightly than the common custom of making the trees hideous to look at by coating them with white-wash.—G. H. H.

Poison Oak—Case of poisoning.—A case of poisoning from contact with *Rhus Toxicodendron* occurred here last autumn. Though warned to be careful in handling a plant that was being transplanted, the man in charge of the other workmen encircled the shoots with his bare arms, which resulted in several days terrible agony—two days and nights without sleep. The plant moved was of the variety known as "radiicans." I have pruned and trained a specimen of the other form commonly called *Ampelopsis japonica* annually for the last ten years at least, and have used the beautifully coloured foliage for decoration on several occasions without ever feeling any bad results. The poisonous nature of the plant has long been known, Dillenius in "*Hortus Ethnensis*" gives a detailed account of both forms of the plant, with good engravings, and remarks on its poisonous qualities.—R. B., *Tynningham.*

Perpetual or Beet Spinach in spring.—The ordinary Spinach fails in many gardens in the winter months, and there is some difficulty in keeping up a supply when the best possible culture is given. This does not apply to the above variety, as it will grow almost anywhere and needs little attention. It has a large root, not unlike the Beetroot, and is a very hardy green variety; indeed, it may be classed as a true Beet with a Spinach-like leaf. The plant is well known, and as regards quality it cannot be compared to the ordinary Spinach. It is, however, a good substitute, therefore it is well worth a note at this season, as it produces such a quantity of leafage, and is a valuable plant for producing a continuous supply of leaves when it is impossible to obtain the better variety. Sown late in the spring and severely thinned a full supply will result from October to May, but I advise its use from December to the end of April, as if cut then it continues to grow and the new leafage is of better quality than when grown at other seasons. It grows rapidly at this date, and if not cut over the seed-stalk will soon form. This should be prevented. I have retarded growth by taking up the roots and laying them in a north shaded border. In the northern parts of the country, in a cold soil or situation, this plant is most valuable.—A. C. N.

“Went Slugging.”—In an old garden diary, from the middle of March to the beginning of June, each day begins and ends with the same interesting item, “Went slugging,” but whereas the morning entry is generally followed by the words “Found none,” in the evening come figures, increasing from thirty or ninety on March evenings to hundreds in April, and gradually falling again to from twenty to two in May. The means used to catch the slugs were simple but effectual. Late in the afternoon large pieces of Orange-peel were placed, the white side underneath, near any plants especially favoured by slugs; then at ten o'clock in the evening, armed with a candle-lantern, a pot of salt and water and a flat stick, the slug-hunter visited, not the plants, but each piece of Orange-peel, and on turning it over found slugs clinging to the white surface, attracted by the scent and coolness. When they were brushed off with the stick into the water, the peel was replaced until after the morning visit; then it was taken away for two reasons—first, because it was unsightly, giving the garden a Bank Holiday appearance; secondly, because the sun would make the peel too dry to be of any further use. Woodlice were not troublesome in the garden, probably because a broom was used with energy in all the corners of greenhouse and potting-shed; but the following makes a good trap, either in glass houses or frames: Take two slates, slant one against the wall, then lean the second against the first. In order to leave room for woodlice to crawl in between, keep the two slates from quite touching by a small stone or piece of wood. Then water the ground, so that the rising moisture will keep the slates damp. The next morning, on taking away the outer slate, the inner one will be found covered with woodlice. These devices are recommended to energetic youth, but to busier seniors a more excellent way is to keep toads in the garden.—W. SPURLING.

Forced Beetroot—Sutton's Globe. It frequently happens that the last season's roots are used up, and the new ones sown in the open in April are not ready for use, therefore there is a want of really good roots for salad in May and early June to supply the deficiency. I would advise sowing seed under glass at this date (March), and by growing for a time in frames and then planting out on a warm border a much earlier supply may be secured. Beets force freely in their early stages provided free ventilation is given, ample space in the seed-pan or box, and the plants are grown near the glass. For forcing one of the best early Beets I have grown is the Sutton Globe, a Turnip-rooted variety of splendid quality; the flavour is very fine, and the colour far better in every way than the ordinary form of Turnip-rooted Beet, such as the Egyptiau, the latter when forced lacking colour. Sow the seeds thinly in a box in frames, and when large enough

prick out the seedlings singly into small pots or boxes, give frame room for a short time and they will make good planting material. It is surprising how well the Beet stands forcing. Grown thus, the plants planted out in richly manured soil will grow rapidly, and the quality will be vastly superior to the old stored roots that were housed in autumn.—G. WYTHES.

Earliness of Asparagus this season.—The Asparagus in open beds promises to be earlier than usual. This will be a great gain to those who have a scarcity of green vegetables. Of course we are not yet safe, and cannot expect the Asparagus to progress very freely with frosty nights, but this so far has not much influenced the growths, as they were not on the surface. The warm sun will now force the growth to the surface, and it will well repay growers who can cover the beds for a short time at night with strawy litter, removing it in the daytime. We have this year cut our first Asparagus from open beds nearly a month earlier than last season. The supply is small, but upon examination I find the growths close to the surface and well worth timely shelter. I should add that our soil is very light, and the beds mostly face the south. In the open they are not shaded in any way.—S. M.

Pelargonium disease. At a recent meeting of the scientific committee of the Royal Horticultural Society, Dr. Cooke reported as follows upon the leaves sent by Mr. Meredith, Tibberton, Newport, Salop: “Two leaves of Pelargonium submitted were spotted indistinctly, and in one instance with an appearance of rotting, as caused by the rot moulds. It is reported that the disease appears on this variety only ‘like blisters on the young stem and cracks on the older wood; the leaves are attacked by these spots, which soon cause them to wither.’ The leaves sent were closely crushed and compressed, so that all trace of any delicate mould, if present, would have been destroyed. Examination of the spots under the microscope exhibited no trace of mycelium or spores; stems not seen. From the specimens sent no evidence can be found of fungus parasite, otherwise the appearance would suggest the attacks of a Peronospora, of which one species is known in Germany and Belgium to attack wild species of Geranium. Possibly it might prove to be the early stage of one of the white moulds, such as Ramularia, but it has not the appearance of Ramularia Gerani. At any rate, the leaves sent afford no evidence from which to determine the disease.”

Crown Imperials.—It is possible that the moist, cool summer of last year did something towards maturing the bulbs of Fritillaria imperialis. A clump of the large-flowered single form is sending up very strong stems; indeed, indicating

the possibility of a good head of bloom. As soon as the leaves show themselves I loosen the soil round the stems, remove some of the surface, and apply a dressing of fresh soil and Clay's Fertilizer, watering it in soon after. Fine blooms and rich colour result.—R. D.

LARGE LEAVED VINES.

APART from the different members of the genus Vitis that are grown solely for the sake of their fruits, there are numerous others remarkable for their handsome leafage, combined in some cases at least with edible berries. Regarded solely from an ornamental standpoint their merits are by no means sufficiently recognised,

JAPAN VINE (VITIS COIGNETIÆ) OVER ARCH.

for all are beautiful, and may with advantage be grown in different ways; for instance the large leaved forms are, as shown in the accompanying illustration, seen to very great advantage in clothing an arch or pergola, or in rambling over neighbouring trees as at Knap Hill, while nearly all the species form delightful wall plants, and failing these positions they may be grown as at Kew, where the entire collection of Vitis is treated in the same way, i.e., each plant fastened to a secure stake, and spurred back annually, so that the whole series consists of gracefully disposed bushes, which are, from their uncommon appearance, very attractive throughout the summer, and doubly

so in the autumn when the foliage of many of them becomes very richly coloured. This latter feature is common to the various members of the Vine family, particularly in that portion which used to be included in the genus *Ampelopsis*.

Of the large leaved Vines the species which has attracted the greatest share of attention within the last ten or twelve years is that herewith figured.

Vitis Coignetia.—A native of Japan, said to have been first introduced in 1874, but it is only within the last decade or so that it has become at all common. The large thick leaves of this species are cordate, irregularly toothed, and as much as 8 inches to 10 inches across. They are rich green on the upper surface, and clothed with a brownish tomentum on the undersides. The autumn tints are particularly bright, various shades of orange, yellow, and crimson being represented, but in this respect there is a good deal of individual variation, as well as that caused by the vagaries of our climate and the different soils in which the roots may be situated. It is not so easily increased as most Vines, cuttings, eyes, and layers having all been tried with only partial success, but of late years seed has been obtained in quantity from Japan, which has made it far more common. In Professor Sargent's "Forest Flora of Japan" is an illustration of a lofty forest tree—*Acanthopanax ricinifolium*—the topmost branches of which are festooned by this noble Vine.

V. Thunbergii.—This is another Japanese Vine, thought highly of by Messrs. Veitch, who regard it as one of the finest of all Vines for ornamental planting in this country. It is described as having the general habit and aspect of *V. Coignetia*, but more vigorous, the leaves somewhat larger, and clothed with a soft down on the under surface. The foliage in autumn assumes the most brilliant shades of orange and crimson. It has been long known both under the specific name of *Sieboldii* as well as that of *Thunbergii*, but it has only come prominently forward within the last few years.

V. Romaneti.—A species from Western China, remarkable from the fact that the young branches and petioles of the leaves are clothed with stout bristles, this giving it on close inspection a very singular appearance. The leaves are large, varying from cordate to five-lobed, of a bright green above and silvery beneath. In autumn the foliage becomes heavily tinted with purplish red. It has yet to make its mark in this country, but though the leaves are large it does not appear likely to form such a vigorous specimen as the preceding species.

V. amurensis is the last of the Old World species to mention here; it has foliage a good deal like that of *V. Coignetia*, but is almost entirely wanting in the rich autumn tints that have made this last-named species so much talked about. It is a native of Northern China and Amurland, and is altogether a vigorous grower. North America is very prolific in species of Vines, some of which are valued for fruit as well as for their foliage. One of the most ornamental is the Northern Fox Grape.

V. Labrusca.—The leaves of this show a considerable amount of variation, some being entire, while others are deeply lobed. They are thick in texture and clothed on the undersides with russet down. In a wild state the musky flavour of its fruits has obtained for it the name of the Fox Grape, but under cultivation many superior forms of it have been obtained. It is well worth attention as an ornamental Vine.

V. aestivalis (the Summer Grape).—This was one of the first of the North American Vines to be introduced into this country, and though the leaves are not equal in size to those previously mentioned, it is for all that well worth growing for its ornamental qualities. A particularly vigorous specimen bears a considerable resemblance to *V. Labrusca*.

Mention of these few large leaved species by no means exhausts the members of the Vine family, which are, from their ornamental qualities alone, worthy of a place in gardens, as all the following have a decided claim to recognition: *V. inconstans* (syn. *Ampelopsis Veitchii* and *A. tricuspidata*), with its dark-tinted variety *purpurea*; *V. quinquefolia* (Virginian Creeper) and its self-clinging variety *Englemanni* or *muralis*, which attaches itself to a wall after the manner of *V. inconstans*; *V. vinifera apiifolia* (Cut-leaved Grape), *V. v. purpurea* (Claret Grape), *V. heterophylla*, which on a sunny wall produces its blue fruits in the autumn; *V. serianifolia*, with pretty divided leaves; and *V. californica*, *V. cordifolia*, *V. riparia*, and *V. vulpina*, all four of which are North American species. H. P.

WAITING.

THROUGH my garden fair I roam,
Ever of my loved one thinking,
While the Rose's glorious crown
Humbly in the dust is sinking;

And the Lilies bloom and blow,
Though my love's not here to cull them.
He their beauty cannot see—
I will never stoop to pull them!

So the summer wears away,
Blossoms one by one are dying.
Oh! that I might go to him,
On the fleecy cloudlets flying!

For the flowers my heart doth grieve,
All unplucked, unloved, they wither
Through the hours and days and weeks—
But my love comes never hither.

And the hours like useless leaves
From the Tree of Life are falling;
Without him my life becomes
But a dream fled past recalling.

Come! My heart is full of love,
Longing for thee through the hours.
Come! Ere love and youth are gone—
Faded—withered—like the flowers.

SYDNEY HESSELRIGGE.

—(From the German of Rückert.)

THE ROSE GARDEN.

TEA ROSE TRIFLES.

"Trifles make perfection, but perfection is no trifle."

IT is not my intention in these short notes to go fully into the cultivation of Tea Roses, but simply to mention a few of those trifles which, in my opinion, tend to success or failure; and I am confident that success depends more on a common-sense observance of trifling details than on the adoption of a system of culture differing materially from the practice that generally obtains.

Every phase in Rose cultivation has been so fully discussed that I feel that much I shall say will savour of repetition, and to many it will not prove particularly interesting or instructive because of their intimate acquaintance with the subject. I am fully aware, also, that to many rosarians my remarks will seem too obvious and elementary; my remarks, however, are not specially intended for the skilled rosarian, and I hope that those who are not far advanced in our art may gain some hints that may be useful in themselves and tend to promote a desire for further information. I also hope that what I shall say will induce those who have not already done so to commence the culture of the Tea-scented varieties, which, in my opinion, are the most charming of all our Roses.

Many rosarians say that they cannot grow Teas, as their soil or situation, or both, are not suitable;

but I believe in many instances they have come to this conclusion without having given them a fair trial. I have not found them more difficult to grow or less hardy than many varieties usually looked upon as easy of cultivation, and able to bear without injury our average winters.

I do not propose to give what are my ideals as to position and soil, as I prefer to speak of the details from actual experience rather than to theorise, and I shall endeavour to show some of the conditions under which I have grown the Roses I have exhibited. It is my firm belief that anyone with a true love for Roses may grow Teas successfully in nearly any position, though, of course, some positions are much more desirable than others.

My garden is on the side of a hill—130 feet above sea-level—and faces south-east. It is well protected on the north-east and north-west by a high fence and by fruit trees. I consider the position and aspect as good as can be found for the purpose, and am of the opinion that the side of a hill is a better position than on a flat plain, as the frosts are less severe, the air as it cools rolling down into the valley below.

The question of height above sea-level I do not consider of any importance; but high ground relatively to that near it I consider a great advantage. I am convinced that the pure dry air of East Anglia plays a more important part in the cultivation of Roses, and especially of Teas, than anything else.

While many rosarians would probably approve of the position of my garden, I am sure not one would select the soil as suitable to Roses of any kind. Resting on a subsoil of gravel, the greater part is very light and stony, and totally different from that in which the Roses in this district are mostly grown. I think that for Teas this light open soil has its advantages over those of a heavier texture, as there is no necessity to raise the beds above the ordinary level to ensure perfect drainage and warmth to the roots, and in it the plants do not make coarse growth late in the autumn which has no chance to ripen sufficiently to stand even an ordinary winter. The soil has been deeply cultivated, but I have not added to it any other soil of a heavier or more retentive character. It is very necessary, when preparing ground for Roses, that the trenching should be done as early in the autumn as possible, to give time for it to settle before planting in October or November. Many advise, where part of an old meadow is to be prepared for Roses, that the turf should be put in the bottom of the trench, and I think that this practice has much to recommend it; but great care must be taken that the sods are well broken up, and, if dry, they should be trodden somewhat solid before the trench is filled in. If this is not done, when the grass rots, the ground under the plants becomes hollow and does not provide a firm root-run. I prefer to plant as early in the autumn as possible; but if this is done before the plants have lost their leaves, and while the sun has still considerable power, much withering of the shoots will be the result. This can be prevented by cutting off all the leaves, and so checking evaporation. This takes rather a long time, but I have proved the plants to benefit so greatly from the defoliation as to fully repay the time devoted to it. I have examined plants a month or so after planting, and have found that they had started rooting at once. Many failures in the cultivation of Tea Roses, I am sure, are due to a want of care in planting. The roots are not spread out sufficiently, and unsuitable soil is frequently put into direct contact with them. Some leaf-mould containing plenty of grit should be put under and over the roots before the ordinary soil is filled in.

With reference to the stocks on which Tea Roses should be worked, I will at once state that I prefer the standard Briar budded 2 feet to 3 feet from the ground, but for some of the stronger varieties the Briar-cutting stock gives good results. I know the seedling Briar finds favour with many rosarians, but the tendency this stock has to throw up suckers is, I consider, a disadvantage. In no class of Roses is the influence of stock upon scion more marked than in Teas; and my experience is that the majority of varieties must be grown as

standards if grand specimen blooms be the end in view. I know of no variety which cannot be grown in that form, but I have found many which have failed to produce flowers of appreciable size when grown as dwarfs. Standards can easily be protected against frost by Bracken tied

When a broken stump, such as is here shown, has to be sawn off the proper place to amputate is from A to B, the wrong place from D to C.

to the centres of the heads. This will keep the union dry, and consequently this vital part will be less liable to be frozen. The plants here are too large to be thatched as recommended by some authorities. Should some plants be killed, as was the case during the frosts in February this year, I think the loss is more imaginary than real, only the weakest, or those with bad unions, being seriously damaged. With many it has been the practice to use the hoe only when there were weeds to be destroyed, and I believe some of the older men employed in gardens still look upon this as sufficient. I am certain it is as necessary for Tea Roses to have plenty of pure air to their roots as it is to their foliage, and this can only be secured by the frequent use of the Dutch hoe or some other suitable tool. Many authorities deprecate the use of the spade among Roses, but I consider it absolutely necessary for turning in manure and deeply moving the soil between the rows. Roses grown for exhibition blooms require so much attention that the ground is frequently trampled on, and often when it is very wet, with the result that it becomes almost impervious to air and moisture; therefore mere surface cultivation with a hoe or a pricking over with a fork is wholly insufficient to loosen the soil to a proper depth to give free access of air to the roots. I know that many will think that great risk is run of damage to the roots if the spade is used, and I readily admit that in the hands of a man who does not understand what he is doing some harm would no doubt be done, but not so much as many would anticipate. The spaces between my Teas are dug over early each winter, when they receive a good coating of manure. The soil is only stirred to the depth of not more than 2 inches near the plants, where the roots are close to the surface and where there has been no traffic to consolidate it; but in the middle of the space between the rows, where there are no roots near the surface and where the summer traffic has been, I like to see the spade pushed down into the soil to nearly its full length. This treatment ensures the soil being sweetened and so well pulverised by frost as to render surface cultivation in the year following much more easy and efficient.

For moving the surface of the soil where it has become too consolidated for the Dutch hoe to be readily used, I have a "crome" with two prongs 5 inches long and 3 inches apart. There is another and equally important reason for good surface cultivation—that is, the cutting off of capillary attraction, so that the moisture in the soil, though attracted up to the roots, may not be lost by evaporation from the surface.

To prevent this loss, the top 2 inches or 3 inches of soil must be kept broken down very finely, so that the air between the small lumps may act as a non-conductor. With regard to mulching, except as a protection to newly-planted Roses and against the splashing of dwarfs by heavy rains, I do not use any. I have never had any standard Teas mulched. I consider a thin coating of fresh

stable litter the best mulch; but sodden, half-rotten manure should not be used. A thick coating of wet manure prevents free access of air to the roots, and I believe that the vapour arising from it after rain assists the growth of mildew. I am not in favour of watering save in a few exceptional cases, and then, of course, sufficient must be applied to thoroughly moisten the soil. Last year, with a total rainfall of between 15 inches and 16 inches only, my Roses had no water given to them. As opinions differ so greatly on the question of how much or how little Teas should be pruned, I will close my remarks with a brief reference to it. If the frosts leave any choice I am distinctly in favour of letting some strong shoots—if well placed and thoroughly ripened—remain at nearly their full lengths. I consider this absolutely necessary in the case of the stronger-growing varieties. If at the time of pruning the young new growths are very advanced, I like to leave one or two of the stronger of them, as I believe that they prevent such a great check being given to root action as would be the case if all were removed. These can be taken off later or shortened back if it is found that they are not likely to carry perfect blooms.

There is one item of plant revision or pruning I must refer to, and that is late summer pruning. I think all plants should be looked over not later than the end of September, and all useless wood removed. This enables the sun and air to reach all parts of the heads, and good, hard, ripened wood is the result. Careful summer pruning rids the plants of a lot of useless growth, to their great benefit, and it greatly lessens the work in the spring when pruning proper has to be carried out.

Nothing has then to be done in the spring but to shorten the shoots, and it is astonishing how much more easily this can be effected when there has been a careful revision of the plants the previous year.

I have always found that strong natural healthy growth, brought about by good cultivation, is much more likely to carry fine blooms than that coarse sappy growth caused by too much manure. — OSMOND G. ORPEN, F.R.H.S., of Colchester, in the *Journal of the Royal Horticultural Society*.

NEW ROSE IDEAL

THE new pink Rose Ideal, which originated with Jacob Becker of Philadelphia, and which is to be sent out by him the coming spring, is being watched with great interest by Rose growers not only in his vicinity but throughout the country. It is a free and continuous bloomer, producing large, clear pink flowers about the colour of Bridesmaid, but a more rounded flower like La France. It is delightfully fragrant, and said to be a good keeper. At the autumn exhibition of the Pennsylvania Horticultural Society it received the first prize as the best pink Rose in its class and also a certificate of merit.—*Gardening* (America).]

TREES AND SHRUBS.

THE CARE OF OLD TREES.

IN most old gardens and parks there are trees to be found which, although possibly of the commonest types and long past their best, are still regarded with interest and even affection because of the memories and associations that belong to them. Often, too, there are fine trees of rarer species that have reached or passed their zenith which their owners naturally wish to preserve from the decrepit state as long as possible. Belonging to this latter class are numerous specimens, scattered over the country, of American and other foreign trees that were amongst the first of their kind to be introduced to Britain, such, for instance, as the Tulip Tree, the Robinia, and various Oaks, from America; the Sophora, from China; and various European trees. There is no doubt that many of these might have their days considerably lengthened and their symmetry preserved if they had a little timely attention that they now frequently lack.

The two most potent factors in the destruction of old trees are storms and fungoid parasites. Nothing is more grievous than to have a favourite tree from which every violent storm wrenches a limb or branch. A good deal may be done in the early training of a tree so to control its building up that it may

SOPHORA JAPONICA WITH BRANCHES CHAINED TOGETHER (KEW).

best withstand the violence of gales. And the most important matter in this connexion is the development of a strong erect trunk—a central axis of such height and strength and bulk as to be capable of supporting its head of branches easily. It is advisable, therefore, always to prevent the premature forking of the trunk in important trees. In other words, the leading shoot should always be watched, and, by the repression of any rival leaders that may appear, allowed to retain its predominance. This is by no means so troublesome a matter as might appear, for when once a strong leading shoot has been developed it usually keeps its place till the tree begins to assume the shape natural to it. In the best English nurseries only trees with good "leads" are sent out.

In the accompanying illustration of an old specimen of *Sophora japonica* one sees the danger of allowing a tree to fork near the base. It has already lost a large limb, and had it not been given artificial support it would in all probability have been torn in twain long ago. Still, in the case of trees a century or more old such a matter is past redemption. The question in such a case is: Should artificial support of twin trunks be necessary what is the best way to afford it? The illustration is of value as showing a right way and a wrong one. The lower support, which consists of two iron bands, one encircling each limb, held together by a stout chain, is unsatisfactory. Growth of the branch is prevented at the point where it is clasped by the iron belt, and not only is the flow of sap arrested, but ultimately the thickening of the branch above and below constitutes a source of weakness to the tree. Unless the iron band is periodically shifted (a matter apt to be overlooked) it gradually becomes embedded in the wood and causes an unsightly swelling, until at last it is almost impossible to remove it at all. And the end usually is that the portion of the limb above the support is blown down. Such, however, is the method almost universally adopted in this country.

A better method is shown in the upper part of the illustration. This is an altogether simpler and better way, and is intended to replace the chain-and-belt fastening below. As will be seen a hole is bored right through the centre of each of the two limbs (or it may be trunk and limb) to be held together, and a stout steel rod is used to connect them. At the outer side of each limb a square iron plate—curved sufficiently to fit the wood—is held in place by a screw nut.

A few things have to be remembered. The rod should be of tough iron or steel and should exactly fit the hole bored by the auger; the portions embedded in the wood should be smeared with coal tar before they are pushed through, so as to make the holes as nearly as possible air and water-tight; one end of the rod should be "threaded" sufficient to allow of the limbs being braced slightly by screwing up the nut and thus supporting some of their weight; finally, the bark should be neatly cut away so as to let in each of the iron plates closer to the living wood, for by this means the time required for closing over the plate by new wood is shortened. The advantages of this system are, first, its neatness, for in time the wood grows over the plate and nut, and the only evidence of support is the rod passing from one limb to the other; and, secondly, its non- (or very slight and temporary) interference with the growth of the tree.

A frequent source of premature decay in trees is to allow the stumps of branches that have been sawn or blown off to remain on the tree. Even at this day, when the evil of such

a practice has been exposed time after time, it is no uncommon thing to see such stumps left (from a few inches to 1 foot in length) where branches have been lopped. When a limb or branch has to be removed it should be sawn off at the point where it joins the trunk—that is, the saw should travel from point A to B, as in the accompanying sketch. When a stump is left (as would be done by sawing off at C D) decay sets in sooner or later, and, although the tree often succeeds in healing over the dead part, it more often fails to do so until the decay has reached the trunk itself. With the softer-wooded trees, like the Horse Chestnut, disease frequently reaches the heart of the tree quickly by this means, and even in harder-wooded ones, like the Oak and Sweet Chestnut, I have frequently seen a core of decayed wood reaching down into the trunk, whose origin could be clearly traced to the neglect of a short stump left from a branch torn off by wind or carelessly lopped.

W. J. BEAN.

THE FLOWER GARDEN. CARNATIONS IN THE OPEN.

WHEN writing of Carnations in the open I intend my remarks only to refer to varieties which are hardy and strong enough to stand the winter in the open border without any protection whatever, and there are so many Carnations that will do so that it is quite unnecessary to try, and probably fail, to grow in the open the more delicate show varieties which should be wintered under glass. Now these border Carnations, which are so useful and satisfactory when well grown, do not receive half the attention they deserve, and I am strongly of opinion that if at our large shows there were always two classes—one for the show varieties grown under glass and the other for purely border Carnations—this would result in the introduction into our gardens of a greater number of the hardier sorts. The border varieties should also be distinctly specified in nurserymen's lists. If this were done I am sure the Carnation would soon become much more popular as a border plant, and, in consequence of the increased demand that would result, Carnation growers would aim at producing a strain of plants more suitable for this purpose, which most people I think at present experience some difficulty in procuring. I am certain there is an immense amount of disappointment suffered by enthusiastic amateurs who visit shows and see the blooms as they still are, unfortunately, only too often exhibited, with their necks encased in paper collars and nothing but the petals showing, and of these only a percentage of the natural number arranged with geometrical precision instead of as Nature intended them to be arranged. These are mostly show and not border varieties, but layers are ordered and in due course received, and the purchaser plants them out with the utmost care in his or her garden and waits with keen anticipation for the time when they will produce blooms like those seen at the show.

Now what follows? I am afraid the results seldom come up to the expectations. If they have been planted in the autumn—and this is by far the best time of year to plant border Carnations—many of them, unless the district be a very favourable one, will probably have suffered severely during the winter, and this

for the simple reason that they are the offspring of plants which have been accustomed to protection from the heavy rains and gales, which they are now expected to weather in the open border and have not constitutions strong enough to do so. If planted in the spring after having been wintered in pots under glass they will stand a very much better chance of succeeding, but when I speak of Carnations in pots I am deviating from the subject of border Carnations, to which this article is intended solely to refer. I do not advise anyone to plant border Carnations in the spring if they can possibly plant them in the autumn, except, of course, to fill up any gaps in the beds which may be occasioned by the ravages of such pests as the Carnation maggot, wireworms, slugs, hares, rabbits, and other enemies which Carnations have to contend with, but to these pests I will refer in a subsequent article. For this purpose it is as well when planting in the autumn to have a few plants of each variety kept in reserve to meet such contingencies. These can be put in any spare corner of the garden and carefully labelled. It is very disappointing to find gaps in your beds in the spring, and to have no spare plants of even the same colour, much less the same variety, with which to fill them up. The careful labelling of such emergency plants is, of course, important for obvious reasons. However, to return to the subject of

SPRING PLANTING.

As I intend what I am writing for the guidance of those who are only now commencing to grow Carnations as well as those who have their beds already filled, I will just give a few hints on spring planting, which will, I hope, prove of service to those who must plant now or do without Carnations next summer, and to these my advice is: Procure, if possible, only hardy varieties which have proved themselves strong enough to stand out through the winter without protection, and state your requirements in this respect when ordering your plants. It is well also to give the grower from whom you order them an idea of what the soil is composed of, and I would strongly advise the beginner to deny himself the pleasure of marking a list himself and to trust to the grower to send the varieties most likely to succeed in his particular locality, only stating the colours required; by so doing I feel sure a great deal of disappointment will be avoided. In going through a list one's fancy is so apt to be taken by a name or by the fact that a certain variety is a new introduction which may not have been proved to be of good enough constitution to flourish in the open.

Order the plants, which you should do at once. When they arrive they will most probably be in pots, from which you may gather that they have been wintered under cover. If the weather is not favourable and the ground in a sodden condition keep them in a cold frame, giving as much air as possible.

The bed which is to receive the plants should have been prepared some time before in order to give it time to settle. Perhaps it may be useful if I describe in detail how the bed should be prepared and the position most suitable. The best site for Carnations is an open, airy place which gets plenty of sun, but at the same time it should not be too much exposed to strong winds. A good loamy soil suits the plants best, and I prefer one rather inclined to be heavy than light. Do not choose too hot a position, where the plants will get scorched up in summer, nor yet a damp, low-lying one, which, especially if the

soil be heavy, will be very trying to the plants in the winter, and would result in their becoming diseased, as in a damp position "the spot" (a disease which attacks the foliage) would be very troublesome.

Having chosen a suitable position, spread some fresh loam, the top spit from an old pasture which has been previously stacked and turned in the usual way (one word of warning about such fresh loam; beware of wireworms, which usually abound in pasture land; these should be searched for carefully when the soil is turned over and destroyed), or some road scrapings, leaf-mould, old Mushroom or hot-bed manure, or a mixture of two or more of these over the surface, and let it remain for a few days so that the birds may pick up any wireworms or other insects which have been brought with it. Then trench the ground, which should be done thus: First throw the top spit of the first trench from one side of the bed to the other, then break up the subsoil, but do not bring this to the surface. Turn the next spit, the manure being well mixed with it, over into the first trench. Repeat this process across the bed, filling up the last trench with the soil you have thrown from the first. Let the ground settle, and when the soil is in good condition bring the plants to the bed and carefully remove them from their pots, taking out the drainage crocks; if the roots are matted round the sides of the pots loosen them with a pointed stick, but be careful not to injure the small fibrous ones. Plant firmly about 1 foot apart, putting a handful or two of fine prepared soil round the roots to give them a fair start (beware of fresh manure, which is not good for Carnations at any time); press the soil firmly round them, and plant so that the soil is level with the lowest foliage, but never bury the roots deeply; it is better to have too much of the stem above ground than below. The best way of

SETTING OUT THE PLANTS

is to stretch a line lengthways slightly to one side of the centre of the bed, which should be about 3 feet 6 inches across when three rows only are intended to be planted in each bed; it is not wise to have more than four rows in a bed, since it would then be difficult to reach the plants in the centre when the layering season comes. If your space is not limited it is therefore better to have only three rows, and the first row should be set out down the middle of the bed, and the plants in the other two rows opposite the spaces, leaving 1 foot between the rows and 9 inches between the outside plants and the path. If, however, the plants are seedlings or layers from very strong growers it is as well to allow a little more room and plant them 15 inches apart, allowing the same distance between the rows. The more space you leave for the paths the easier will be the work of layering, for it is most difficult for anyone, especially if he possesses a pair of long legs, to get amongst the plants without injuring them if there is no room to kneel down.

If any of the plants have a lengthy growth put a small neat stake and tie it loosely to this to prevent its being blown about and loosened by the wind. When planting in the autumn it is as well to cut off any flower-stems

that the layers may throw out; these would be of little use the following season, and by cutting them off the plants become more bushy. Now the plants are safely in the ground they will subsequently receive the same attention as those which were planted in the autumn, so I will proceed to describe the treatment which my Carnations receive. I always plant as early in the autumn as I can after the layers are well rooted. I look them over carefully once or twice during winter in quest of the

CARNATION MAGGOT,

which can generally be detected by the leading shoot looking slightly withered; a gentle pull, if the maggot is there, will result in the shoot coming out, when the small whitish yellow grub will be found in the stem just below where the shoot has been detached, but frequently the shoots come off thus after a small slug has been feeding on the centre of the succulent stem. A little experience will soon teach you how to detect the presence of the maggot, which, when found, should of course be destroyed. At the same time cut off any unhealthy or diseased "grass," and burn this with the shoots which have been pulled off, then go carefully round the plants pressing the soil firmly about the roots: this is necessary after a frost, which raises the ground and loosens the roots considerably, especially those which have been planted late in the autumn and were not able to get hold of the ground before the winter set in. These are sometimes thrown quite out of the ground and must be replanted. Now wait for a favourable opportunity after a shower of rain and give the plants a good dusting over with soot and wood ashes, mixed about half and half; to this you may add some slaked lime (it is as well to give the beds a dressing with this mixture in the autumn if they are planted then). Do not mind if the plants look rather unsightly for a few days until the next shower of rain falls, as this will soon clean them and wash the mixture into the ground, the foliage is thus rendered unpalatable to pests such as

slugs and sparrows. Sparrows, where they abound, work great havoc among Carnations at this time of the year by nibbling the young shoots apparently out of sheer mischief.

When the ground is dry enough, and it will be all the better to do this as soon after applying the soot and wood ashes as you can, stir the surface of the soil around the plants with a small rake so as to let warmth and air into the ground, which will have become hard and smooth after the heavy winter rains; this will also mix up the soot and wood ashes with the soil. You should repeat this operation whenever the surface gets beaten down again, and another dressing with the soot and wood ashes will do good. I generally give my plants a second dressing, for this mixture, besides rendering the foliage distasteful to the pests above ground, helps to drive away the underground enemies, such as wireworms, from the roots, and acts as a manure, the soot especially having a very beneficial effect. There will be little more to do to the plants now until the flower-stems begin to grow, except keeping down weeds, so I will leave them for a short time and deal with another phase of Carnation culture, which is, I consider, by far the most fascinating branch of this most interesting pursuit, and that is the raising of Carnations from seed.

St. Asaph.

(To be continued.)

THE PAMPAS GRASS.

In the accompanying illustration, the photograph of which was kindly sent by Mr. Draper, gardener to the Marquis of Londonderry at Seaham Hall, this noble Grass is shown in handsome groups. Standing out boldly as represented, without encroaching neighbours, the beauty of Pampas Grass is well displayed.

ANNUALS FOR TOWN GARDENS.

MANY useful notes have lately appeared in *THE GARDEN* on the seasonable topic of annuals, and

GROUPS OF PAMPAS GRASS IN SEAHAM HALL GARDENS, THE RESIDENCE OF THE MARQUIS OF LONDONDERRY.

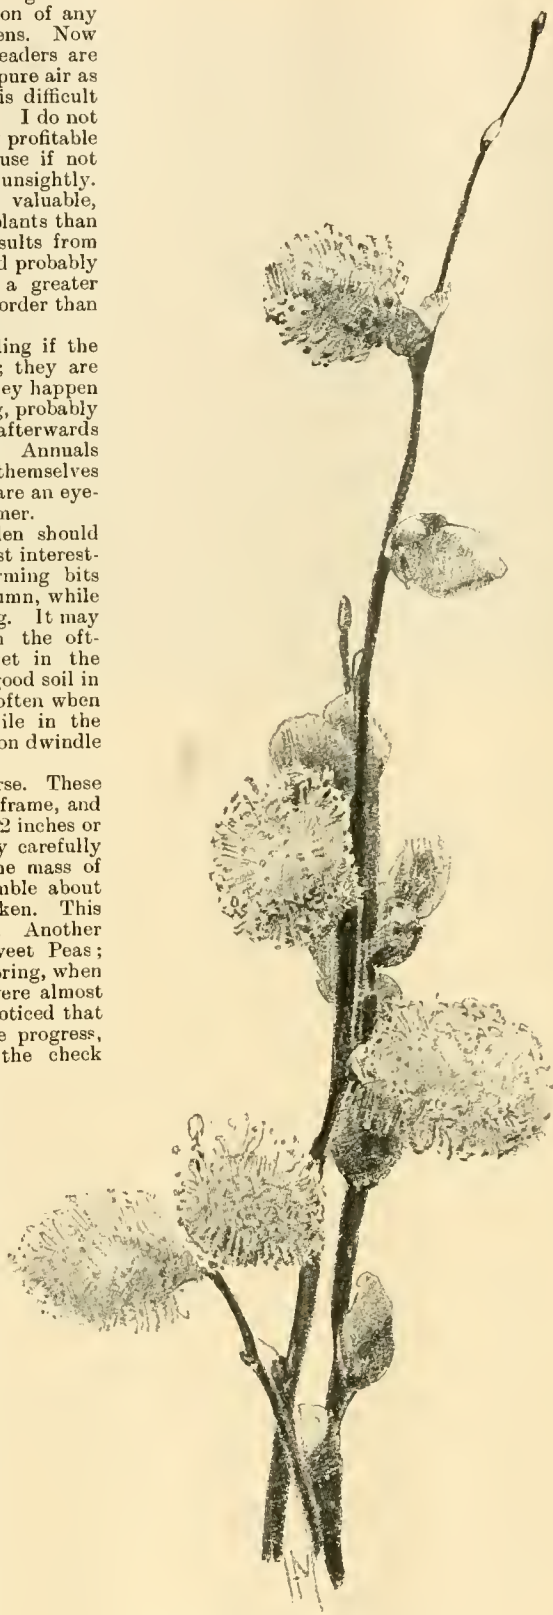

although selections both for large and small gardens have been given, I have seen no mention of any that are known to do well in town gardens. Now it is very probable that some of your readers are not able to grow their flowers in such a pure air as they could wish, probably with some it is difficult to make plants grow at all satisfactorily. I do not think that on the whole annuals are very profitable plants to grow in town gardens, because if not really well cultivated they are most unsightly. In town gardens space is usually very valuable, and one grows a far greater variety of plants than we really should to obtain the best results from each, but there is charm in variety, and probably the town gardener always will grow a greater number of species and varieties in his border than he ought to.

Annuals grow very weakly and spindling if the ground is not well prepared for them; they are so different from perennials, which, if they happen to do badly the first season after planting, probably give a far better account of themselves afterwards when their roots are well established. Annuals have not this opportunity of reinstating themselves in favour; if they do not succeed they are an eyesore and a nuisance throughout the summer.

Yet it is a pity that the town garden should be without a few annuals. They are most interesting plants to grow, and provide charming bits of colour throughout summer and autumn, while some of them are invaluable for cutting. It may be superfluous to say any more upon the oft-reiterated subject of thick sowing, yet in the town garden this is all important. In good soil in the country garden annuals will thrive often when they are sown much too thickly, while in the atmosphere of town and suburb they soon dwindle away.

Sweet Peas must be included, of course. These I find do best if sown in pots in a cold frame, and the seedlings planted out of doors when 2 inches or 3 inches high. They need to be very carefully turned out of their pots, otherwise the mass of soil falls to pieces, the tiny plants tumble about in all directions, and many roots are broken. This means delay, and delays are dangerous. Another word of caution with reference to Sweet Peas; sparrows are very fond of them. Last spring, when some 3 inches or 4 inches high, ours were almost ruined by these little rascals. It was noticed that they looked sickly and made but little progress, but at first this was attributed to the check when planted out. We soon found, however, the real cause of the mischief, and forthwith stretched pieces of thread tightly over and around them. This had the desired effect, for after that our Sweet Peas grew famously. There is an excellent protection for Sweet Peas and Carnations, of which sparrows are also fond, now to be had. I remember to have seen it among the advertisement pages of *THE GARDEN* last year. It gives far less trouble than the old-fashioned method of using thread.

Shirley Poppies we tried, but they did not succeed; annual Lupins were good, while *Linum grandiflorum* was splendid, its patches of pretty red flowers were much admired. *Nigella damascena* (Love-in-a-Mist) also did very well; it is one of the prettiest annual flowers. *Mignonette* failed to grow satisfactorily, as also did Iceland Poppies. Marigold and *Nasturtium* of course grew like weeds. Although the *Nasturtium* is often strictly kept out of many gardens, some of the dwarf compact varieties are excellent plants for border edgings, and their flowers are most brilliantly coloured. *Brachycome iberidifolia*, *Gypsophila paniculata*, Virginian Stock, Snapdragons, Scabious, *Lavatera trimestris*, Malope, Malva, Larkspur, Annual Candytuft, *Eschscholtzia*, Chinese Pink, and some few more were responsible for most of the attractiveness and colour, so far as annual flowers were

THE GOAT WILLOW OR "PALM."

(From a drawing by H. G. Moon.)

concerned. It is a mistake to grow too many things in a town garden, and certainly the annuals must not be allowed to run riot. Tropæolums in particular need to be kept within reasonable bounds.

A. P. H.

AN ARTIST'S NOTE-BOOK.

THE GOAT WILLOW.

IN the wilder parts of the garden, particularly in the neighbourhood of water, many of the stronger growing Willows can be very effectively used, each one having its special season of beauty. In winter, when destitute of leaves, the red and yellow-stemmed Willows are very attractive; in spring the Weeping Willow *Salix babylonica* is particularly charming, each pendent branch being studded with bright green leaves; in autumn the leaves of many turn a brilliant yellow; then, again, another attractive feature is given in early spring at the time of flowering, for when in full flower a male specimen of *Salix Caprea* is decidedly showy. In rural districts the name of Palm is given to this Willow, and in some places flowering branches are used extensively both for the decoration of houses and places of worship on Palm Sunday. Although *Salix Caprea* is the species to which the name of Palm is most often applied, there are several other species whose male inflorescences are quite as ornamental as those of the plant under notice, and of these *S. smithiana* is one of the most conspicuous. On this the fluffy yellow catkins are borne very freely, and when in flower the whole bush is a mass of yellow. In places where *S. Caprea* grows wild in quantity the effect of large masses of old plants smothered with yellow is very beautiful.

W. DALLIMORE.

ORCHIDS.

CATTLEYA ENID MAGNIFICA.

AFIRST-CLASS CERTIFICATE was awarded to this *Cattleya* when shown by Messrs. Charlesworth and Co., Heaton, Bradford, Yorks, before the Orchid committee of the Royal Horticultural Society on March 10. This is one of the finest hybrid *Cattleyas* yet raised, of rich colouring and beautiful form. The flower is large, the petals of extremely graceful contour, slightly drooping, the lip beautifully frilled. The colour of the sepals and petals is soft rose-white, the lip is a rich purple, tinged, and slightly veined with a lighter shade towards the edge, and the frill is rose, showing well against the mass of purple. The throat is yellow veined with purple. This *Cattleya* is fairly intermediate between the two parents *C. gigas* and *C. Mossiae*. The raceme shown bore four splendid blooms, one of which is shown in the accompanying illustration.

CALANTHES AND MENDEL'S LAW.

MR. CHAPMAN forwarded the following reply to Captain Hurst's observations reported at the last meeting of the Scientific Committee of the Royal Horticultural Society: "I am not at all surprised to find Captain Hurst claiming the fact of *C. Oakwood Ruby* and *C. Sibel* having been derived from the same seed-pod, and bearing directly on the action of Mendel's law. Had the rose or rose-carmine characteristics been maintained, Captain Hurst might have been sure of my support of the principles of which he is such an able advocate. Let us see what has really taken place. The first cross producing *C. Veitchii* from *C. vestita* and *C. (Limatodes) rosea*; the second cross was between *C. × Veitchii* and *C. vestita rubro-oculata* (giving a second cross with *C. vestita*) produced *C. Cooksonii*, with a yellow eye or disc, also *C. Alexanderi*. Here the first change takes place.

The deep ruby eye as seen in *C. vestita rubro-oculata* is removed to the front lobe of the lip and each of the petals, the sepals only being white, in some cases slightly tinted with the colour of the petals. It is remarkable to note that the rose or rose-carmine colours have disappeared. I cannot get at the exact parent that was used in the next generation, but from the information I can gather the darkest varieties were selected and crossed with each other, until the remarkable variation between *C. Sibyl* and *C. Oakwood Ruby* was produced. In the latter case the flower of *C. vestita rubro-oculata* had been turned inside out. I cannot trace any of the rose or rose-carmine of *C. Veitchii* or the shape of *Limatodes* in the flower as seen in *C. Veitchii*, but in the bulb the shape and general structure resemble *C. (Limatodes) rosea*. I cannot see what advantage can be procured by intercrossing *C. Oakwood Ruby* with *C. Oakwood Ruby*. I cannot expect to gain more from this than I procured nearly six years ago when crossing *C. Veitchii* with its own pollen, and the result was that it reproduced itself from seed. I might add to this another instance in which I procured a primary crossed hybrid from seed. Nearly ten years ago I crossed *C. leeanum* (a very fine form of it), and the result brought its parent, with no more variation than constitutional or cultural conditions are capable of bringing about. With such clear results as these I, at least, cannot see where the application of 'Mendel's laws' applies."

Cotoneaster thymifolia and *C. horizontalis* are two very desirable shrubs for wall culture. The former has bright red berries, and the foliage of the latter changes to a pleasing red in autumn, succeeded by scarlet fruit.

Styrax japonica.—One of the most lovely Japanese shrubs we have, needing protection in severe weather until it becomes thoroughly established. The charming white flowers are freely produced in May.

Hedera maderiensis variegata.—Of all the Ivies this is probably the most beautiful, the variegation being especially good at this season of the year. It is a fairly strong grower, thickly clothing a wall, and though considered by some to be tender, it has proved perfectly hardy here, having gone through the winter of 1894-95 when the glass fell to 2° below zero without the slightest protection. Most effective when growing on a red wall.

Vitis heterophylla variegata.—Another extremely beautiful variegated climber, by no means a rampant

Carpenteria californica.—A little-known shrub with white flowers of great beauty, requiring a warm sheltered position. After becoming established it flowers freely, but must be protected in cold districts.

Palurus aculeatus.—Said to be the true Christ Thorn; interesting on account of the great length of the thorns, but somewhat tender.

Clerodendron fatidum.—A desirable plant for a south wall with lilac-rose flowers and purplish green leaves. The stems die down in winter unless well protected. A most effective plant.

BEAUTIFUL WALL PLANTS

(Continued from page 181.)

ERCILLA SPICATA, SYN. *BRIDGESIA SPICATA*. A quick growing evergreen, soon covering considerable space, and clinging closely to the wall. The flowers are freely produced and purplish blue in colour.

Menispermum canadense.—Rarely seen in cultivation, but a handsome climber, preferring a shady wall.

Berchemia racemosa variegata.—One of the most delightful deciduous climbers we have, and should be included in all collections.

Periploca graeca.—A very rapidly growing deciduous climber, with curious flowers, green outside and purplish within. Succeeds well on a north wall.

Photinia serrulata.—A handsome evergreen wall shrub, with large deep green foliage, but does not appear to flower in a young state. Should be protected in severe weather.

Calycanthus floridus.—A desirable shrub, succeeding better with us on a wall than in the shrubbery. The flowers are purple and sweetly scented.

Myrtus communis (Common Myrtle).—If a warm position by a south wall can be found for this charming plant, with thorough protection given in winter and plenty of drainage, it will prove hardy around London, and flower freely.

Phlomis fruticosa (Jerusalem Sage).—One of the most showy plants for this purpose, the leaves being thickly clothed with a white tomentum, and the flowers are produced in whorls; colour, yellow. Should be protected in winter.

Phlomis cashmeriana.—The leaves of this variety are similar to the above. Colour of flowers pale lilac; needs protection.

Escallonia langleyensis.—A very distinct evergreen with red flowers. One of the most refined free-flowering wall shrubs, and deserving of a place in all choice collections.

Escallonia philippiana.—A white-flowered shrub of great beauty. The ground for this should be well drained, of a light porous nature, and a warm position on a south wall chosen. Like the above, it must be secured against severe weather.

Caryopteris Mastacanthus, with pale violet flowers, and the white variety *albus*, are two of the most charming shrubs, succeeding well against a wall.

CATTELEYA ENID MAGNIFICA (NATURAL SIZE).

(Exhibited by Messrs. Charlesworth and Co. before the Royal Horticultural Society, on the 10th inst., and then given a first-class certificate.)

grew, and well worthy of a place in any collection. Succeeds best on a south or west wall.

Rhus Toxicodendron (Poison Oak).—The magnificent colouring given us by this in autumn renders it worthy of cultivation in every garden. It should be planted in poor soil to be seen at its best, and care taken when handling its beautiful foliage.

Griselinia littoralis.—A very neat evergreen shrub with light green foliage; it is well worthy of cultivation, and is rarely seen.

Clerodendron trichotomum.—One of the handsomest shrubs we have, succeeding well in the shrubbery, but the young growths get injured by spring frosts, rendering the protection of a wall necessary in many parts. Flowers red and white.

Azara microphylla has dark green shining leaves and orange-coloured berries. Valuable for covering walls, and should have slight protection in winter.

Pyrus japonica and varieties.—Probably there are no shrubs more beautiful for covering low walls

than *Pyrus japonica* and its varieties, as they produce flowers almost throughout the year, and bear large fruits, which are edible when made into a preserve. The best varieties are *sinica*, Knap Hill Scarlet, *carnea*, *cardinalis*, and *Mallardii*, with white flowers. These should be allowed to grow up as naturally as possible to see them at their best.

Pyrus Maulei.—A handsome shrub with light red flowers and large quantities of golden fruit. There is a variety named *alba*, but the flowers are not a good white. A. E. THATCHER.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

THE GREAT WOODPECKER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It may not be generally known how useful this bird is in the pleasure ground. It is usually seen in trees, particularly old trees, such as Elm and Oak. It devours large numbers of injurious insects besides those which prey upon trees. It is naturally a shy bird, therefore where it is desired to encourage it the gun should not be used. I have watched it carefully about the grounds here, and it was a long time before I could discover which insect attracted it to certain parts. I, however, discovered at last what it was in search of, viz., the leather jacket and the cockchafer grubs. This bird will very quickly clear a lawn of these and other insects if not disturbed. I watched it from my window the other day for a long while searching every inch of ground, and when it came upon one of these insects pulled and tugged at the earth and roots of plants with all its strength, digging deep holes and pulling out large quantities of earth until it reached the grub. It would then carefully reject certain parts of the insect, which I examined. These appeared to be the head and some of the skin of the leather jacket. This undoubtedly is the most useful bird we have, and it should be encouraged as much as possible. It is grievous to see it so often in glass cases as a stuffed specimen.

T. A.

A "BLACK LIST" OF HARDY PLANTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—“S. G. R.’s” notes on the above subject (page 145) are of particular interest, since they refer to a topic which, although but rarely ventilated in the horticultural press, must for ever hold a foremost place in the minds of those who love their gardens. Some years ago a series of letters having the same object in view appeared in the pages of THE GARDEN under the title of “An Index Expurgatorius,” the perusal of which was instructive owing to the difference of opinion expressed by the various writers as to the desirability or the reverse of the numerous plants alluded to. It is but natural, having regard to the diversity existing in human likes and dislikes, that subjects exciting the admiration of some may to others appear objectionable, and that we therefore find one person excluding from his list of meritorious plants the very things that another is particularly anxious to grow to perfection. Soil and environment are preponderating factors in the successful culture of hardy plants, and subjects that are found flourishing with a minimum of attention in one garden may be seen languishing in another but a few miles distant, although treated with every solicitude that horticultural art can suggest. In like manner these same conditions affect the growth of some species to such an extent that certain plants, as remarked by “S. G. R.” “are harmless in one place and obnoxious in another.” Much, however, depends upon the amount of care lavished on the herbaceous border in determining what plants may be allowed a place within its precincts. If the

occupants are permitted to grow for weeks and months without any attempt being made to check the undue exuberance of those of naturally spreading habit, these will, naturally, eventually crowd out their less vigorous neighbours, but where constant supervision is given it is a comparatively easy matter to keep them within bounds. I am not alluding in this connexion to subjects such as *Polygonum cuspidatum*, *P. sachalinense*, and the *Calystegias*, which should be afforded isolated positions, but to some of those mentioned in “S. G. R.’s” list of “dangerous plants,” such as *Bocconia cordata*, *Physalis Franchetti*, *Lathyrus grandiflorus*, and *Acanthus*. The Bergamot or Bee Balm (*Monarda didyma*) is another plant of spreading growth, a small piece of which will attain a diameter of almost 3 feet in a season, which comes in the same category. *Acanthus latifolius*, the strongest grower of its race, has never given me any trouble, though remaining undisturbed in the same position for over eight years, having formed a fine symmetrical clump which annually throws up numerous tall flower-spikes 7 feet or more in height, while the others I have always been able to keep within due limits by an autumnal reduction of the clumps.

Had I left them severely alone during the time they have been in the borders they would doubtless by now have appropriated far more ground than desirable. It is wonderful how much may be effected in the way of the repression and even extermination of unwelcome plants by constant watchfulness. I remember a case where a narrow border between a wall and lawn was occupied by the Winter Heliotrope (*Tussilago fragrans*), one of the most difficult of plants to eradicate. The *Tussilago* was dug up and *Anemone japonica* planted in its place, but in a short time such roots of the former as still remained deep in the ground commenced to show growth above the earth. As soon as this was observed a daily visit was made to the border, and every tightly-folded leaf that pierced the soil was cut off about 2 inches beneath the surface. The *Tussilago* died hard, but at the end of two years it ceased to appear, and the border has since then been free from it. In many cases a fortnightly or monthly clearing away of the *Tussilago* foliage would doubtless have been deemed sufficient, but in the intervals the leaves would have strengthened the roots, whereas in the other instance they died from inability to express themselves above ground. The only one of the *Alstroemerias* alluded to by “S. G. R.” that gives the slightest trouble with me is *A. aurantiaca*, *A. chilensis* and *A. psittacina*, though increasing in size and beauty, never spread to excess, and *A. pelegina* and its white form would be far more valuable if they would assume that habit to a certain extent, for as it is they are too delicate for culture in the open air in the majority of gardens. *A. aurantiaca* would become a weed if allowed, but by following down the outlying shoots with a trowel in the autumn and digging up the roots I find the clumps may be kept from spreading unduly. A list is given of plants “requiring a great deal of supervision,” but, surely, this is only what should be given to every portion of the garden, and the lack of it in any section can only be productive of disastrous results. Self-sown seedlings of *Viola odorata* and other plants mentioned by “S. G. R.” have no terrors for me, for a finger and thumb will easily remove them while they are still small if they appear where they are not wanted, while in some spots they may be allowed to remain with advantage. The Welsh Poppy (*Meconopsis cambrica*) propagates itself freely in gardens where it is once established, though often proving difficult to raise from seed where this is not sown as soon as ripe. Flowering among trailing plants on stone edgings or by the verges of paths it has a pretty effect, and if the seedlings spring up in positions where their presence is unwelcome it is by no means a laborious task to clear them off. *Ionopsidium acaule* seeds itself freely over a portion of my garden, the seedlings growing where they list among the other occupants of the borders, but they are never interfered with unless to make room for new introductions, and I confess to a certain fondness for dwarf surface-

rooting things, that do no harm to the neighbours amongst which they grow, informally spangling the surface of the soil. S. W. FITZHERBERT.

HARDY PLANT GARDENING UNDER GLASS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The illustrations of the hardy plant house in the Royal Gardens, Kew, and your leader on the subject of hardy gardening in general are most opportune. There are hardy plant gardeners who set their face against any hardy plant if it has to be given protection. They are forgetful of those earlier flowering plants whose merits not only entitle them to such protection as is now advocated, but permit the owner enjoying his plants without fear of their being spoilt by the weather.

By “hardy plant gardening under glass” we understand that so far as the plants require it, and in respect to their hardiness particularly, the glass covering is not at all an essential. Those who grow alpine plants are inclined to place a sheet of glass over some specially admired plant or great rarity, and this glass house is but an enlargement of the idea. The idea is by no means new, for I did the same thing in 1876 or 1877 to admit of my employer (the late Mr. Latimer Clark, of Sydenham Hill) seeing the plants he loved so much during winter. Our alpine house was not only absolutely cold, but fitted with swinging front lights that were rarely, if ever, closed. A narrow stage fronting these lights contained the choicest plants, and plants that were very scarce then are much more plentiful to-day. The late Mr. Joad at Wimbledon then had an alpine house, a structure chiefly intended, I believe, to protect the choicest of alpine gems, and in particular the *Androsaces* and such like, from winter wet. This latter was, therefore, more of an experiment in a given direction, in the hope of saving the plants at all hazards if possible, and with a group of plants that largely could not be regarded as winter or early flowering.

The work that for the past few years has been carried on at Kew agrees generally with my first conception of the idea when I had such plants as *Iris reticulata*, *I. persica*, *Orobans*, *Saxifraga burseriana*, *S. juniperina*, *S. calyciflora*, *S. aretioides*, *S. squarrosa*, *S. cæsia*, and others; and even then I did not confine myself to plants that flowered only quite early, but to others that appealed to me by beauty of foliage alone. For example, *Saxifraga longifolia*, *Sempervivum triste*, then a scarce and expensive plant, the *Arachnoid Houseleeks*, the variegated *Astrantia*, the pretty *Anthemis aizoon*, *Agave Utahensis*, and others of an attractive nature, in company with the early and winter *Crocus*, of which alone a large collection was grown. The number of good and suitable plants for the same purpose to-day is infinitely greater; indeed, in one or two directions the increase is remarkable. So that now anyone who elects to take the matter in hand may be certain that the year will have scarcely started on its way ere some of the earliest buds are bursting into blossom.

Nor are the shelter afforded and the possible exemption from bad colds or worse troubles the only advantages derived from this method of alpine gardening. What is perhaps the best feature is the increased beauty of all the plants; their flowers are almost perfect, unspotted, and untarnished. It is not forcing these plants into flower that we aim at, but protection in the only way we can in England, where snow—Nature’s blanket—no longer shelters them. In a large degree this alpine shelter has been rendered necessary during recent years by the very considerable increase of quite good early-flowering things—Iris for example. These, in conjunction with the best of old plants, will be found ample to make a small airy house one of the most attractive features in a garden. In certain directions and with certain classes of plants little preparation is needed. All plants of a bulbous nature—*Fritillaries*, *Iris*, *Cyclamens*, *Snowdrops*, &c.—may be planted in August or as soon after as convenient. It is, however, the evergreen alpine plants that most require preparation,

THE NEW BRUSSELS SPROUTS CAMBRIDGE CHAMPION.

allowing them a season's growth in pots and pans before the period of flowering under cover. Take, for example, all the varieties of *Saxifraga oppositifolia*, *S. burseriana*, *S. Boydii*, and *S. B. alba*, the pretty hybrid *S. Salomoni* (a good grower and free bloomer), and *S. apiculata* (not only one of the most valuable and earliest, but one of the most profuse). To these may be added any *Primulas*, for instance, *P. marginata*, *P. rosea*, *P. denticulata*, *P. alba*, *P. megaseeifolia*, *Trilliums*, *Arabis*, *Draba*, *Orobis*, *Epimediums*, *Corydalis thalictrifolia*, *Anemone blanda*, also the true *Wood Anemones*, *Shortia*, and some of the most distinct of the *Houseleek* family; all the forms of *Sempervivum arachnoideum*, for none are more beautiful than these when the rosettes are pricked out singly and given a year's growth before being placed in the house. To these may be added a large number, and all that is required is liberal cultivation in pots and pans beforehand.

E. JENKINS.

THE KITCHEN GARDEN.

BRUSSELS SPROUTS CAMBRIDGE CHAMPION.

UNQUESTIONABLY the above variety is the best that has come under my notice, and I was glad to see in *THE GARDEN* for January 17 that Mr. Wythes also thinks highly of it. I am sending a photograph, which you may perhaps find room for, which represents a fair sample. I understand that Mr. Ridgewell has disposed of the stock, the bulk of it being purchased by Messrs. Charles Sharpe and Co. of Sleaford.

The seed of Brussels Sprouts is often sown too early, the last week in February or first week in March being quite soon enough to make the first sowing. This should be raised under glass in a very gentle heat, sowing the seed thinly in shallow boxes or pans. Care should be taken not to allow the plants to become drawn, and immediately the young plants are large enough prick out either into other boxes or skeleton frames in a warm sheltered position, 3 inches apart each way, and protect in cold weather till the young plants become well established. Though Brussels Sprouts are among the hardiest of our winter greens they require a good start, and should be properly

hardened. The ground on which these will be planted should have been well manured and thoroughly trenched during winter, and left in a rough lumpy condition, thus allowing the frost and cold winds which we are sure to experience during spring to thoroughly penetrate, Nature's best remedy for pulverising and sweetening the land; this, previous to planting, should be pointed over with the fork and made level. When the plants are about 6 inches in height they should be lifted with good balls of earth and firmly planted; indeed, on light soils this can hardly be done excessively.

These enjoy an open position and plenty of room, 3 feet between the rows and 2 feet 6 inches from plant to plant being none too much. In very exposed positions time will be well spent in placing a stake to support them, especially so when extra fine buttons are required.

During very hot and dry weather the plants will derive much benefit if the ground between them is well mulched with long stable litter and thorough soakings of farmyard liquid or sewage are applied. Grown in this way there is no reason why Sprouts should not be picked from early in October till late in spring. However, it is well to ensure a constant supply by making another sowing early in April; the seed should be scattered thinly broadcast, well protected against birds, and the plants put out in their permanent quarters as soon as fit.

In many localities and on land which has been over-cropped with the *Brassica* family, a mistake too frequently made, not always the fault of the gardener, but owing to insufficient room, clubbing is very troublesome, and when this is the case fill up the holes with finely-sifted cider ashes, the best remedy I am acquainted with, and a good one too.

E. BECKETT.

Aldenham House Gardens, Elstree, Herts.

SORREL IN SPRING.

THIS is a plant not largely grown, but one that should not be overlooked. It is useful as a salad, and by no means inferior as a vegetable. There are not many varieties, and the one best known is not the best—at least, such is my opinion—as the one so largely cultivated on the Continent has a larger leaf, and does not run to seed so quickly as the common variety; it is a smaller variety, with more acidity than the larger. Sorrel used as a vegetable is so distinct from others that it should find a place in all gardens where variety is valued,
