"*To the solid ground*
Of Nature trusts the mind which builds for aye."—WORDSWORTH

London
MACMILLAN AND CO., LIMITED
NEW YORK: THE MACMILLAN COMPANY

Richard Clay and Sons, Limited,
BREAD STREET HILL, E.C., AND
BUNGAY, SUFFOLK.

INDEX.

ABBEY (George), the Balance of Nature and Modern Conditions of Cultivation, a Practical Manual of Animal Foes and Friends for the Country Gentleman, the Farmer, the Forester, the Gardener, and the Sportsman, 5
Abegg (Prof. R.), a Question of Percentages, 220
Ablett (C. A.), Tests for determining the Economy of Steam Engines Used in Driving Reversing Rolling-mill Engines, 437
Abraham (George D.), British Mountain Climbs, 485
Abruzzi (S.A.R. il Principe Luigi Amedeo di Savoia, Duca degli), Il Ruwenzori, parte scientifica, risultati delle osservazioni e studi compiuti sul materiale raccolto dalla spedizione di, 31
Absorption of Light in Space, the, J. A. Parkhurst, 314
Acarus Crossii, the, Charles E. Benham, 127
Acoustics: Musical Sands, Cecil Carus-Wilson, 69, 159; Rev. Dr. A. Irving, 99; Musical Sands in Chile, M. H. Gray, 126; Barisal Guns in Australia, Dr. J. Burton Cleland, 127; Further Experiments with the Gramophone, Prof. John G. McKendrick, F.R.S., 488; the Analysis of Sounds Used in Speech, Edwin Edser, 533
Adamellogruppe, die, ein alpines Zentralmassiv, und seine Bedeutung für die Gebirgsbildung und unsere Kenntniss von dem Mechanismus der Intrusionen, Wilhelm Salomon, 101
Adamson (E.), Tests on Cast Iron, 438
Adaptation in Fossil Plants, Dr. D. H. Scott, F.R.S., at Linnean Society, 115
Addenbrooke (G. L.), Public Supply of Electric Power, 228
Adhicary (Birendra Bhusan), Aurvedic Metallic Preparations, Part i., 270
Adie (R. H.), Junior Chemistry, 95
Aërodynamics: Experimental Method for Aërodynamical Researches, A. Rateau, 29
Aëronautics: the Aëronautical Society, Eric Stuart Bruce, 6; Prof. G. H. Bryan, F.R.S., 6; Ascent of Balloon *Albatross*, Lieut. Mina and Signor Piacenza, 225
Æther of Space, the, Charles W. Raffety, 127
Africa: Il Ruwenzori: parte scientifica: risultati delle osservazioni e studi compiuti sul materiale raccolto dalla spedizione di S.A.R. il Principe Luigi Amedeo di Savoia, Duca degli Abruzzi, Sir H. H. Johnston, G.C.M.G., K.C.B., 31; Résultats scientifiques des Voyages en Afrique d'Édouard Foà, Sir H. H. Johnston, G.C.M.G., K.C.B., 31; Wissenschaftliche Ergebnisse der deutschen Tiefsee-Expedition auf dem Dampfer *Valdivia* 1898–1899, das Kapland, insonderheit das Reich der Kapflora, das Waldgebiet und die Karroo, pflanzengeographisch dargestelt, Rudolf Marloth, 129; Bathyorographical Map of Africa, 187; Catalogue of the Freshwater Fishes of Africa in the British Museum (Natural History), G. A. Boulenger, 216; African Entomological Research Committee, 278; the Geology of South Africa, Dr. F. H. Hatch and Dr. G. S. Corstorphine, 455; Percy Sladen Memorial Expedition in South-west Africa, 1908–9, Prof. H. H. W. Pearson, 466, 499
Agriculture: Swine in America, F. D. Coburn, 35; Ideal British Wheat, A. E. Humphries, 78; Bacterial Disease of Lucerne, 79; Endoparasites of Australian Stock, Dr. Georgina Sweet, 79; Journal of Agriculture of South Australia, 79; Diminished Yield of Cotton due to Insufficient Drainage, W. Lawrence Balls, 80; Improving the Indian Cottons, P. F. Fyson, 108; the Experimental Breeding of Indian Cottons, H. M. Leake, 434; Fall in the Average Yield of Egyptian Cotton, 137; Cotton in America, Stewart J. McCall, 227; the Fixation of Nitrogen by Soil Bacteria, A. D. Hall, F.R.S., 98; Turkish Tobacco in Cape Colony, 108; Removal of Charlock from Corn Crops, G. F. Strawson, 108; Use of Soya Beans as Cattle Food, 137; Processes for the Fixation of Atmospheric Nitrogen, 143; the State and the Farmer, Prof. L. H. Bailey, 157; Boric Acid in Milk from Cows Fed on Indian Cotton Cake, Mr. Collins, 168; Wheat in South Australia, 168; Milk Testing, C. W. Walker-Tisdale, 187; the Journal of the Cooper Research Laboratory, 187; Agriculture in Russia, M. Hitier, 197; Sterilisation by the Ultra-violet Rays, Application to the Butter Industry, MM. Dornic and Daire, 210; Onions in Northern Indiana, 226; Estimation of Fat in Unsweetened Evaporated Milk, Messrs. Hunziker and Spitzer, 226; Milking Machine, 227; Recent Publications on Agriculture from India and Ceylon, 231; Thermal Effects of Moistening Soils, A. Muntz and H. Gaudechon, 239; Importance of Phosphates in Fertility, Messrs. Whitson and Stoddart, 265; Bovine Tuberculosis in Wisconsin, Messrs. Russell and Hoffmann, 266; the "King" System of Ventilating Barns and Cow-sheds, 266; Agriculture in the Transvaal, 268; the Administration of Agricultural Education, 428; Climatic Features of Wyoming and their Relation to "Dry-farming," W. S. Palmer, 435; Pests of Para Rubber Trees, H. C. Pratt, 462; W. J. Gallagher, 462; Attempt to Check Ravages on Tea-plants in Ceylon of the "Shot-hole Borer" Beetle by introducing a Predaceous Beetle (*Clerus formicarius*), E. E. Green, 462; Fertilisers and Manures, A. D. Hall, F.R.S., 483; Death of Prof. J. Scott, 493; *see also* British Association
Air Pollution by Smoke, the Nature and Extent of, Prof. J. B. Cohen and A. G. Ruston at Health Congress, 468
Aitken (Dr. John, F.R.S.), the Ringing of House-bells without Apparent Cause, 246
Aitken (Prof. R. G.), Double-star Measures, 138
Alcock (Dr. F. M.), Changes in the Habits of the Women of the Upper Middle Classes during the Last Fifty Years, 476
Alcock (Dr. N. H.), Report of the Committee on Anæsthetics, 507
Allen (E. Heron), Arenaceous Foraminifera, 79
Allen (Prof. Frank), Effect on the Persistence of Vision of Fatiguing the Eye with Red, Orange, and Yellow, 473; New Method of Measuring the Luminosity of the Spectrum, 473
Alliot (Henri), Washing of Cider Apples with an Oxidising Calcium Salt leading to Pure Fermentation, 420
Alsberg (Moritz), Recently Discovered Fossil Human Remains and their Bearing upon the History of the Human Race, 131
Alt (E.), Double Daily Oscillation of the Barometer, 81
Altitude Tables, computed for Intervals of Four Minutes between the Parallels of Latitude 24° and 60°, and Parallels of Declination 24° and 60°, designed for the Determination of the Position Lines at all Hour Angles without Logarithmic Computation, Frederic Ball, 4
Alty (Mr.), Electromagnetic Method of Studying the

Theory of and Solving Algebraical Equations of any Degree, 119
Alway (Prof.), Soil Problems, 536
Amaftounsky (A.), Changes of Form in Sun-spots, 110
Ameghino (Dr. Florentino), Supposed New Genus, Diprothomo, 353; the Antiquity of Man in South America, 534
America: Swine in America, F. D. Coburn, 35; Mineral Resources of the United States, Prof. Henry Louis, 174; Twenty-sixth Annual Report of the Bureau of American Ethnology, 230; Ethnology in America, 268; American Invertebrates, 299; Peat in North America, 490; the Antiquity of Man in South America, Dr. Florentino Ameghino, 534; Señor Outes, Dr. Ducloux, and Dr. H. Bücking, 534
Amphlett (J.), the Botany of Worcestershire, 422
Analytical Engine, a New, designed by Percy E. Ludgate, Prof. C. V. Boys, F.R.S., 14
Anatomy: Death and Obituary Notice of Prof. D. J. Cunningham, F.R.S., 15; *Nervus terminalis* in the Frog, Mr. Herrick, 107; Pair of Nerves in the Carp, R. E. Sheldon, 107; Development of the Auditory Ossicles in the Horse, Ray F. Coyle, 149; Death of Prof. A. Fraser, 166; an Introduction to the Study of the Comparative Anatomy of Animals, Prof. Gilbert C. Bourne, 513
Anderson (Col.), Deep Water and Railway Communications, 448
Anderson (Dr. Tempest), Volcano Metavanu, 447
Andrew (J. H.), Liquidus Curves of the Ternary System, Aluminium-Copper-Tin, 26
Andrews (Dr. C. W., F.R.S.), Remains of Rhinoceros and Mammoth from the Thames Alluvium, 21; the Systematic Position of Mœritherium, 305
Anemographic Observations in India, 521
Angler's Season, an, W. Earl Hodgson, 37
Angot (Alfred), Magnetic Disturbance and Aurora Borealis of September 25, 1909, 480; Earthquake of October 8, 1909, 510
Animals: the Place of Animals in Human Thought, Countess Evelyn Martinengo Cesaresco, 276; an Introduction to the Study of the Comparative Anatomy of Animals, Prof. Gilbert C. Bourne, 513
Annandale (Dr. N.), Baskets used in Repelling Demons, 38; New Species of Japanese Fresh-water Sponges, 225; Globular Organisms in the Tide-wash on the Orissa Coast of India, 296; Indian Cirripedia Pedunculata, 373; the Occurrence in India of the Pappataci Fly (*Phlebotomus papatasii*), 518
Anrep (Mr.), Investigation of the Peat Bogs and Peat Industry of Canada during the Season 1908–9, 490
Anschütz (Dr.), V. v. Richter's Chemie der Kohlenstoffverbindungen oder organische Chemie, 215
Antarctica: the South Polar Expedition, E. H. Shackleton, 16; Former Extension of the Antarctic Continent, Prof. H. Kolbe, 167; Government Grant in Aid of Shackleton's Expedition in Antarctic Regions, 263; Lieut. Shackleton's Antarctic Expedition, 295; Polar Expeditions and Observations, 338; Projected British Antarctic Expedition, 401
Anthropology: Cult of the Python at Uganda, Rev. J. Roscoe, 18; Baskets used in Repelling Demons, Dr. N. Annandale, 38; Mediæval Sinhalese Art, Ananda K. Coomaraswamy, 39; Head-hunting among the Hill Tribes of Assam, T. C. Hodson, 80; Recently Discovered Fossil Human Remains and their Bearing upon the History of the Human Race, Moritz Alsberg, Dr. A. C. Haddon, F.R.S., 131; Origin and Rites of the Gypsies, 142; the Home of the Gypsies, Prof. R. Pischel, 142; Gypsy Rites, E. O. Winstedt, 143; the Flight of Nigerian Arrows, Dr. C. G. Knott, 149; Hair- and Eye-colour of School Children in Surrey, Miss B. Freire-Marreco, 167; Different Types of Human Ears, R. B. Bean, 227; Filipino Ears, a Classification of Ear Types, R. B. Bean, 435; Somatological Study of the Benguet Indians, R. B. Dean, 266; Eoliths Found with Remains of *Elephas meridionalis* at Dewlish, in Dorset, W. G. Smith, 266; Beliefs and Customs of the Australian Aborigines, Prof. J. G. Frazer, 275; the Bandar Cult among the Kandyan Sinhalese, Dr. C. G. Seligmann, 403; Prehistoric Cemeteries at Koshtamna, in Nubia, Dr. G. A. Reisner, 463; Drs. G. Elliot Smith and D. E. Derry, 463; an Anthropological Survey of the Sudan, Dr. A. C. Haddon, F.R.S., 491; Death and Obituary Notice of Prof. C. Lombroso, 494; Semitic Magic, its Origins and Development, R. Campbell Thompson, 514; Rock Paintings of the Lower Ebro, l'Abbe Breuil and Juan Cabré, 522; the Antiquity of Man in South America, Dr. Florentino Ameghino, 534; Señor Outes, Dr. Ducloux, and Dr. H. Bucking, 534; *see also* British Association
Antimony, its History, Chemistry, Mineralogy, Geology, Metallurgy, Uses, Preparations, Analysis, Production and Valuation, Chung Yu Wang, 68
Antoniadi (M.), Observations of Mars, 355, 436, 465; Mars, 498
Apiculture: Black Wax of Burma, D. Hooper, 108
Apsit (Jean), Seeds Killed by Anæsthetics, 90
Arber (E. A. Newell), Fossil Plants, 304
Archæology: Ancient Modelled Heads of Various Races, Prof. Flinders Petrie, F.R.S., 21; Chalk Figurine Discovered in a Stratum containing Instruments and Weapons Characteristic of the Stone Age, 43; Polished Stonework in the Haut-Oubanghi, A. Lacroix, 59; Ionia and the East, D. G. Hogarth, 94; Roman Antiquities in Wiltshire, E. H. Goddard, 108; Notes on a Stone Circle in County Cork, Captain Boyle T. Somerville, 120; Sun and Star Observations at the Stone Circles of Keswick and Long Meg, Dr. John Morrow, 128; a Guide to Avebury and Neighbourhood, R. H. Cox, 154; Forest Boundary Stones in Essex, 195; Discovery at Jaederen of a House of the Middle Iron Age, 198; Archæological and Ethnographical Explorations, 232; Remarkable Discovery in the Neighbourhood of Peshawar, Dr. D. B. Spooner, 232; Origin and Date of the So-called Dene-holes, Rev. J. W. Hayes, 313; Excavation of the So-called Roman Amphitheatre at Charterhouse-on-Mendip, H. St. George Gray, 313; Bronze-age Interments in Switzerland, F. A. Forel, 371; Discoveries along the Colorado River, 372; Excavations at the Roman Camps of Chester and Caerleon, 374; Supposed Ancient Canoe Discovered near Lochmaben, Thomas Henderson, 435; Notable Discoveries at Susa, 435; Remains of a Lake-dwelling in Sweden, Dr. Otto Froodis, 460; Discoveries on the Site of the City of Sparta, 463; Prehistoric Cemeteries at Koshtamna, in Nubia, Dr. G. A. Reisner, 463; Drs. G. Elliot Smith and D. E. Derry, 463
Archibald (Prof. E. H.), the Atomic Weight of Platinum, 29; New Determination of the Atomic Weight of Iridium, 474; Electrical Conductivity of Solutions of Iodine and Platinum Tetraiodide in Ethyl Alcohol, 474
Archibald (R. D.), Electrical Laboratory Course for Junior Students, 66
Arctica: the Attainment of the North Pole, 306; Polar Expeditions and Observations, 338; Captain Bernier's Arrival at Point Amour, Labrador, 432; Forthcoming Attempt to Reach North Pole, Evelyn Baldwin, 460; Proposed Zeppelin Polar Expedition, Prof. Hergesell, 493
Arithmetic: the Invicta Number Scheme, J. W. Ladner, 515
Armstrong (Dr. E. F.), Chemical Properties of Flour, 476; Proteins, the Relation between Composition and Food Value, 476; Difference in Composition of Different Proteins, 508; Strength of Wheat, 536
Armstrong (Geo. A.), Drought in South-west Ireland, 487
Armstrong (Prof. H. E., LL.D., F.R.S.), Opening Address in Section B at the Meeting of the British Association at Winnipeg, 279; on the Three-fold Emission Spectra of Solid Organic Compounds, 470
Arnsperger (Dr. Hans), die Röntgenuntersuchung der Brustorgane und ihre Ergebnisse für Physiologie und Pathologie, 222
Arth (Prof. G.), Death and Obituary Notice of, 134
Ashby (Dr.), Prehistoric Antiquities of Malta, 478
Ashford (C. E.), the Elementary Theory of Direct Current Dynamo Electric Machinery, 66
Asia: Asiatic Society of Bengal, Calcutta, 30, 150, 270; Bathy-orographical Map of Asia, 187; Explorations in Central Asia, Dr. Stein, 368
Assmann (Dr. R.), Island of Norderney, 143
Association of Economic Biologists, 114

Asteroidea, an Account of the Deep-sea, Collected by the R.I.M.S.S. *Investigator*, Prof. René Koehler, 67

Astronomy: Our Astronomical Column, 19, 46, 82, 110, 138, 170, 199, 229, 267, 298, 314, 355, 376, 404, 436, 465, 498, 528; the Transvaal Observatory, Johannesburg, 20; the Transvaal Observatory, 356; the Comets of 1907 and 1908, Prof. Kobold, 20; Astronomical Occurrences in July, 19; in August, 138; in September, 298; in October, 404; Comet 1909*a* (Borrelly-Daniel), 20; the New Daniel Comet, M. Javelle, 29; Observations at the Observatory of Marseilles of the Comet 1909*a* (Borrelly), Henry Bourget, 29; Observations of the Comet 1909*a* (Borrelly-Daniel) made at the Observatory of Besançon, P. Chofardet, 29; Comet 1909*a* (Borrelly-Daniel), M. Chofardet, 46; Comet 1909*a*, 83; Ephemeris for, Dr. M. Ebell, 267; the Shape of the Planet Mercury, R. Jonckheere, 20; Observations of Sun-spots, 1908, E. Guerrieri, 20; Radial Motion in Sun-spot Vapours, Mr. Evershed, 82; Changes of Form in Sun-spots, A. Amaftounsky, 110; a Large Group of Sun-spots, 138; Magnetic Fields of Sun-spots, Dr. Hale, 137; Water Vapour in Sun-spots, W. M. Mitchell, 229; a Large Group of Sun-spots, 356; Another Large Sun-spot, 405; Observations of Saturn and its Rings, M. Schaer, 20; Observations of Saturn's Rings, Prof. Barnard, 199; Observations of Saturn, Prof. Lowell, 405; Mr. Slipher, 405; Tables for the Reduction of "Standard Coordinates" to Right Ascension and Declination, A. Hnatek, 20; Nature of the Hydrogen Flocculi on the Sun, Prof. G. E. Hale, 26; Origin of Certain Lines in the Spectrum of ϵ Orionis, Sir Norman Lockyer, K.C.B., F.R.S., F. E. Baxandall and C. P. Butler, 26; la Planète Mars et ses Conditions d'Habitabilité, Camille Flammarion, Dr. William J. S. Lockyer, 33; Observations of Mars, R. Jonckheere, 229, 376; M. Jarry-Desloges, 229, 355, 376, 436; M. Antoniadi, 355, 436; M. Quénisset, 355; Prof. Lowell, 405; J. H. Elgie, 405; the South Polar Spot on Mars, Dr. Lohse, 298; Changes on Mars, M. Jarry-Desloges, 314; R. Jonckheere, 465; M. Antoniadi, 465; the Approaching Opposition of Mars, William E. Rolston, 336; Presence of Free Oxygen in the Atmosphere of Mars, P. Lowell, 390; Water Vapour in the Martian Atmosphere, Prof. Campbell, 376; Mars, M. Jarry-Desloges, 498; M. Jonckheere, 498; MM. Quénisset and Antoniadi, 498; Observations on the Surface of the Planet Mars from June 4 to October, 1909, R. Jarry-Desloges, 510; Quantitative Measures of the Oxygen Bands in the Spectrum of Mars, Prof. Very, 529; der Bau des Weltalls, Prof. Dr. J. Scheiner, 36; die Planeten, Dr. Bruno Peter, 36; Possibility of an Extra-Neptunian Planet, 41; the Assumed Planet, O, beyond Neptune, Prof. W. H. Pickering, 268; a New Form of Comparison Prism, Prof. Louis Bell, 46; Halley's Comet, Dr. Holetschek, 46; L. Matkiewitsch, 46; Halley's Comet Rediscovered, Prof. Max Wolf, 355; Messrs. Cowell and Crommelin, 355; Halley's Comet, Prof. Burnham, 376; Prof. Millosevich, 528; Father Searle, 528; Prof. Newall, 529; Visibility of Halley's Comet, W. F. Denning, 395; Observations of Halley's Comet, 1909*c*, Prof. Wolf, 404; Elements and Ephemeris for Halley's Comet (1909*c*), 436; Ephemeris for Halley's Comet, 1909*c*, Mr. Crommelin, 465; the Polarisation of the Solar Corona, M. Salet, 46; the Solar Constant and the Apparent Temperature of the Sun, Dr. Féry, 47; Variations of Brightness of Encke's Comet and the Sun-spot Period, J. Bosler, 59; the Identity of Comets 1908*a* and 1908*b* (Encke), Dr. Ebell, 83; Death of Prof. Simon Newcomb, 78; Obituary Notice of, Sir Robert S. Ball, F.R.S., 103; Binary Star Orbits, Father Stein, 83; R. H. Baker, 83; Micrometric Measures of Double Stars, Phillip Fox, 83; Double-star Measures, Prof. R. G. Aitken, 138; Parallax of the Double Star Σ 2398, Dr. Karl Bohlin, 356; Double-star Measures, Prof. Burnham, 376; Double-star Observations, Prof. Doberck, 436; Stationary Meteor Radiants, Prof. W. H. Pickering, 110; Comparison of the Spectra of the Centre and Edge of the Sun's Disc, MM. Buisson and Fabry, 110; Mutual Occultation of Jupiter's Second and Fourth Satellites, M. Pidoux, 110; Observations of Jupiter's Fifth Satellite, Prof. Barnard, 138; Observations of Jupiter, Prof. Barnard, 170; Jupiter's South Tropical Dark Area, Scriven Bolton, 487; Zenographical Fragments, ii., the Motions and Changes of the Markings on Jupiter in 1888, A. Stanley Williams, 125; the Yerkes Observatory, Prof. E. B. Frost, 111; Prominence Observations, Prof. Riccò, 111; Azimuth, G. L. Hosmer, 126; Sun and Star Observations at the Stone Circles of Keswick and Long Meg, Dr. John Morrow, 128; on the Cause of the Remarkable Circularity of the Orbits of the Planets and Satellites and on the Origin of the Planetary System, T. J. J. See, 132; Physical Interpretation of Lunar Features, M. Puiseux, 138; Origin of the Contrasts of Colour in the Moon, P. Puiseux, 150; Why has the Moon no Atmosphere? Prof. Alexander Johnson, 486; Probable Influence of the Motion of the Moon on Atmospheric Radio-activity, some Meteorological Consequences, Paul Besson, 510; Artificial Imitation of Lunar Landscape, Paul Fuchs, 356; Motion of Neptune's Satellite, David Gibb, 149; Maximum of Mira in 1908, M. Luizet, 138; Naozo Ichinohe, 267; the Maximum of Mira in October, 1908, Dr. Nijland, 376; the Orbit of χ Sagittarii, a Cepheid Variable, J. H. Moore, 170; the Leeds Astronomical Society, 170; the Solar Eclipse of June 17, 1909, Father Rigge, 171; Movements in the Sun's Upper Atmosphere, M. Deslandres, 170; Search-ephemerides for Comet 1896 VII. (Perrine), F. W. Ristenpart, 170; R. Castro and A. Repenning, 170; Re-discovery of Perrine's Comet, Herr Kopff, 229; Herr Ristenpart, 229; Comet 1909*b* (Perrine's 1896 VII.), Herr Ristenpart, 267; Prof. Kobold, 267; Comet 1909*b* (Perrine, 1896 VII.), 298; Observations of Perrine's Comet, 315; Dr. Max Wolf, 376; Dr. Ebell, 376; the Perseids of 1909, W. F. Denning, 189; the Recent Perseid Shower, J. H. Elgie, 267; J. C. Jefferson, 267; E. Hawks, 267; a Brilliant Meteor, M. Borrelly, 200; August Meteoric Shower, W. F. Denning, 224, 246; Meteor Observations, 315; Remarkable Meteors, 465; the Meteor in Sunshine, October 6, W. F. Denning, 487; September Meteors, Torvald Köhl, 498; the Relative Atmospheric Efficiency of Telescopes, R. T. A. Innes, 199; the Motion of the Pole, H. Kimura, 199; Reports of Observatories, Mr. Hough, 200; M. Baillaud, 200; Solar Research, A. A. Buss, 200; the Figure and Mass of the Planet Uranus deduced from the Motions of the Two Interior Satellites, Œsten Bergstrand, 210; Annuaire astronomique de l'Observatoire royal de Belgique, 1909, 219; Death and Obituary Notice of William F. Stanley, 225; the Number of the Stars, Gavin Burns, 229; the Faint Companions of Procyon and Sirius, Prof. Barnard, 229; Prof. Lowell's New 40-inch Reflector, 229; the Palisa and Wolf Celestial Charts, Dr. Palisa, 230; the Spectroscopic Binary β Orionis, J. Plaskett, 267; the Planar Arrangement of the Planetary System, Dr. T. J. J. See, 275; the Orbits of Certain Spectroscopic Binaries, R. H. Baker, 298; F. C. Jordan, 298; New Spectroscopic Binaries, 315; the Bolide of April 20, as Observed in France, M. Quénisset, 298; les Observations méridiennes, Théorie et Pratique, F. Boquet, 301; the Absorption of Light in Space, J. A. Parkhurst, 314; Planets and their Satellites, Prof. Lowell, 315; Temperature and Pressure Conditions in the Solar Atmosphere, Mr. Buss, 356; Mr. Evershed, 356; Movements of the Upper Solar Atmosphere above and round the Faculæ, H. Deslandres, 390; the Nature of Solar Faculæ, M. Deslandres, 465; Entwickelung und Untergang des Kopernikanischen Weltsystems bei den Alten, O. T. Schulz, 365; Death and Obituary Notice of Bryan Cookson, 372; the Spectroheliograph of the Catania Observatory, Prof. Riccò, 376; Hα Images on Spectroheliograms, M. Deslandres, 376; Mr. Buss, 376; the Future of Astronomy, Prof. E. C. Pickering, 405; Multiple Monochromatic Images of the Sun given by the Large Lines of the Spectrum, H. Deslandres and L. d'Azambuja, 420; the Recent Magnetic Storm and Aurora, Basil T. Rowswell, 436; the Aurora of September 25, Torvald Köhl, 498; a Newly Discovered Nebula Cluster in Cetus, Prof. Wolf, 436; Observations of Variable Stars, W. Münch, 436; Terrestrial Refraction in Egypt, Mr. Xydis, 436; Messrs. Craig and Keeling, 436; Magnetic Storms and Solar Eruptions, Sir Oliver Lodge, F.R.S., 425, 456; Dr. C. Chree, F.R.S., 456; Death of J. A. Fraissinet, 432; Fireball in

Sunshine, W. F. Denning, 456; the Ursa-Major System of Stars, Ejnar Hertzsprung, 465; Search-ephemeris for Winnecke's Comet, C. Hillebrand, 465; Method Permitting the Measurement of the Effective Temperatures of the Stars, Charles Nordmann, 480; Publikationen des Astrophysikalischen Observatoriums zu Potsdam, Doppelsterne, Prof. O. Lohse, 492; Solar Observations: a Novel Spectroscope, W. M. Mitchell, 498; Hydrogen Layers in the Solar Atmosphere, MM. Deslandres and d'Azambuja, 498; New Binary Progression of the Planetary Distances and on the Mutability of the Solar System, Dr. H. Wilde, 509; Stars having Peculiar Spectra, New Variable Stars, 529; the Natal Government Observatory, Mr. Nevill, 529; *see also* British Association
Astrophysics: the Tidal and other Problems, Profs. T. C. Chamberlin and F. R. Moulton, F. Stratton, 102; Death and Obituary Notice of Eugen von Gothard, Herr von Konkoly, 166
Athanasiu (J.), Suprarenal Capsules and their Exchanges between the Blood and Tissues, 239
Atlantic, North, First Magnetic Results obtained on the *Carnegie* in the, Dr. L. A. Bauer and W. J. Peters, 529
Atmosphere, Diurnal Variation of Temperature in the Free, E. Gold, 6
Atmosphere, Researches on the Action Centres of the, 467
Atmosphere, Temperature of the Upper, F. J. W. Whipple, 6
Atmospheric Absorption, Molecular Scattering and, Prof. Arthur Schuster, F.R.S., 97
Atmospheric Nitrogen, Processes for the Fixation of, 143
Attention, Prof. W. B. Pillsbury, 483

Larmor, 473; Prof. MacDonald, 474; the Relative Motion of the Earth and Æther and the FitzGerald-Lorentz Effect, C. W. Chamberlain, 474; New Cemented Triple for Spectroscopic Use, Lieut.-Colonel J. W. Gifford, 474; Magnetostriction, Dr. H. G. Dorsey, 474

Section B (*Chemistry*)—Opening Address (Abridged) by Prof. H. E. Armstrong, Ph.D., LL.D., F.R.S., President of the Section, 279; New Determination of the Atomic Weight of Iridium, Prof. E. H. Archibald, 474; Electrical Conductivity of Solutions of Iodine and Platinum Tetraiodide in Ethyl Alcohol, Prof. E. H. Archibald and W. A. Patrick, 474; Anti-putrescent Effects of Copper Salts, in Particular towards the Bacteria of Milk, Dr. Alfred Springer, 474; Dynamic Isomerism, Dr. T. M. Lowry, 475; Sir J. Larmor, 475; Useful Improvements in the Technique of Optical Investigations, Dr. Lowry, 475; History of the Wheats, Dr. Stapf, 475; Factors Determining the Yield of Wheat, Dr. E. J. Russell and A. D. Hall, 475; Influence of Environment on the Composition of Wheat, F. T. Shutt, 475; Quality in Wheaten Flour, A. E. Humphries, 475; Chemical Properties of Flour, Dr. E. F. Armstrong, 476; Influence of the Minerals of Flour on its Quality, W. B. Hardy, 476; Comparative Milling and Baking Qualities of a Number of Canadian Wheats, Prof. R. Harcourt, 476; Proteins: the Relation between Composition and Food Value, Dr. E. Frankland Armstrong, 476; Prof. Starling, F.R.S., 476; Problems of the Stock Feeder, Dr. E. J. Russell, 476, Pig Feeding, F. T. Shutt, 476; Changes in the Habits of the Women of the Upper Middle Classes during the Last Fifty Years, Dr. F. N. Alcock, 476; Feeding of Stock, Prof. J. Wilson, 476

Section C (*Geology*)—Opening Address by Arthur Smith Woodward, LL.D., V.P.Z.S., Sec. G.S., Keeper of Geology in the British Museum, President of the Section, 290; the Bearing of Pre-Cambrian Geology on Uniformitarianism, Prof. A. P. Coleman, 446; the Pre-Cambrian Rocks of Canada, Prof. W. G. Millar, 446; the Faunal Succession of the Lower Carboniferous (Avonian) of the British Isles, Dr. A. Vaughan, 446; New Faunal Horizons in the British Coalfield, H. Bolton, 446; the Glacial Lake Agassiz, Dr. Warren Upham, 446; Extent of the Ice Sheets in the Great Plains, Prof. A. P. Coleman, 446; Mining in Canada, Prof. Miller, 447; Metal Mining in Canada, Prof. Coleman, 447; Placer Mining, J. B. Tyrrell, 447; Rare Metals of Canada, Prof. T. L. Waller, 447; the Volcano Metavanu, Dr. Tempest Anderson, 447

Section D (*Zoology*)—Opening Address by A. E. Shipley, M.A.Cantab., Hon. D.Sc., Princeton, F.R.S., President of the Section; I., Charles Darwin, 315; II., Organising Zoology, 317; III., International Ocean Research, 321; Origin of the Vertebrates, Dr. E. Goodrich, 504; Subcutaneous Fat-bodies in Bufo, C. L. Boulenger, 504; Osteology of the Lophobranchii, Prof. H. Jungersen, 504; on the Germinal Disc in Naturally Incubated Eggs of *Passer domesticus*, Prof. C. J. Patten, 505; the British Pleistocene Canidæ, Prof. S. H. Reynolds, 505; Geographical Distribution of Rotifera, C. F. Rousselet, 505

Section E (*Geography*)—Opening Address by Colonel Sir Duncan Johnston, K.C.M.G., C.B., R.E., F.R.G.S., F.G.S., President of the Section, 323; Floods in the Great Interior Valley of North America, Luella A. Owen, 506; the Hudson Bay Route, Dr. Robert Bell, 506; Agricultural Development of Canada, 1904–9; Prof. Mavor, 506; Major Craigie, 506; Formation of Arroyos in Adobe-filled Valleys in the South-western United States, Prof. Dodge, 506; the Water Route from Lake Superior to the Westward, Lawrence J. Burpee, 506; Physical History of Nantasket Beach, Prof. Douglas W. Johnson, 506; the Geographer David Thompson, J. B. Tyrrell, 507; Progress of the General Magnetic Survey of the Earth in Recent Years, Dr. L. A. Bauer, 507

Section G (*Engineering*)—Opening Address by Sir W. H. White, K.C.B., Sc.D., LL.D., F.R.S., President of the Section, 342; Peculiar Geographical Position of Winnipeg, 447; the Grain Industry, John Miller, 447; George Harcourt, 447; Deep Water and Railway Communications, Colonel Anderson, 448; Mr. St. Laurent, 448; Major George Stephens, 448; Works on the Canadian Pacific Railway, T. E. Schwitzer, 448; Organisation for the Collection and Transport of Grain in the Wheat Area, H. W. Lanigan, 448; the Panama Canal, Colonel Goethals, 448

Section H (*Anthropology*)—Opening Address (Abridged) by Prof. John L. Myres, M.A., F.R.S., President of the Section, the Influence of Anthropology on the Course of Political Science, 370; Ethnographic Survey of Canada, Sidney Hartland, 477; Dr. Franz Boas, 477; Problem of the White Immigrants, Dr. Shrubsall, 477; Ethnology of the Okanagan of British Columbia, Mr.

Hill-Tout, 477; the Blackfoot Medical Priesthood, Dr. John Maclean, 477; Present Native Population and Traces of Early Civilisation in the Province of New Brunswick, William McIntosh, 477; Copper Implements from a Site in Western Ontario, Prof. E. Guthrie Perry, 478; Race Types in the Ancient Sculptures and Paintings of Mexico and Central America, Miss A. Breton, 478; Arms and Accoutrements of the Ancient Warriors at Chichen Itza, Miss Breton, 478; Tribes Inhabiting the Koskokurm Valley, Dr. G. B. Gordon, 478; Recent Hittite Research, Dr. G. Hogarth, 478; Prehistoric Antiquities of Malta, Dr. Ashby and Mr. Peet, 478; Archæological and Ethnological Researches in Sardinia, Dr. Duncan Mackenzie, 478; Researches in Crete, C. H. Hawes, 478; Neolithic Sites in Thessaly, 478; Excavations at the Nubian Cemetery at Anibeh, Dr. Randall-MacIver, 478

Section I (*Physiology*)—Opening Address by Prof. E. H. Starling, M.D., F.R.S., President of the Section, the Physiological Basis of Success, 384; Report of the Committee on Anæsthetics, Dr. Waller, 507; Dr. N. H. Alcock, 507; Prof. A. R. Cushny, 507; Prof. W. T. Porter, 507; Use of Atropine in Conjunction with Anæsthetics, Dr. Webster, 507; Inorganic Composition of the Blood in Puerperal Eclampsia, Prof. A. B. Macallum, 507; Tracts in the Spinal Cord, Dr. Page May and Prof. Sutherland Simpson, 507; the Delimitation of the Motor Area in the Cerebral Cortex Demonstrated by the Method of Retrograde Chromatolysis, Dr. Page May, 508; the Pyramidal Tract in the Sheep and Guinea-Pig, Dr. Sutherland Simpson, 508; Study of the Thyroids and Parathyroids, Mrs. Thompson, 508; Effect of excluding the Blood Passing Through the Adrenals from the Circulation, Dr. Young, 508; Effect of Local Heat on Vegetable and Animal Tissues, Dr. Waller, 508; Difference in Composition of Different Proteins, Dr. E. Frankland Armstrong, 508

Section K (*Botany*)—Opening Address by Lieut.-Colonel David Prain, C.I.E., LL.D., F.R.S., President of the Section, 406; Organisation and Reconstruction of the Nuclei in the Root-tips of *Podophyllum peltatum*, Prof. J. B. Overton, 537; Nucleus of the Yeast Plant, Harold Wager and Miss A. Peniston, 537; Nuclear Phenomena of Ascomycetes in Relation to Heredity, Miss H. C. I. Fraser, 537; Production and Dispersion of Spores in the Hymenomycetes, Prof. A. H. R. Buller, 537; Number of Bacteria in the Air of Winnipeg, Prof. Buller and C. W. Lowe, 537; Prothallium and Embryo Sporophyte of Danæa, Prof. D. H. Campbell, 537; Ancestry of the Osmundaceæ, Prof. D. T. Gwynne Vaughan and Dr. Kidston, 537; Structure of a New Zygopteris, W. T. Gordon, 537; Fundamental Causes of Succession among Plant-associations, Prof. H. C. Cowles, 537; the Rocky Mountain Flora in Relation to Climate, Prof. F. Ramaley, 537; Observations and Experiments on the Ecology of *Spiraea ulmaria*, Prof. R. H. Yapp, 537; History of the Wheats, Dr. O. Stapf, 538; Delayed Germination of Seeds, Prof. Pammel, 538; the Industry of Rubber Cultivation, J. Parkin, 538; Chemistry of Chlorophyll, Prof. R. Willstätter, 538; Evolution of the Inflorescence, J. Parkin, 538; Life-history of *Trichodiscus elegans*, Miss E. J. Welsford, 538; Effects of Tropical Conditions on the Development of Certain English Œnotheras, Dr. R. R. Gates, 538; Perception of Light in Plants, Harold Wager, 538

Sub-section of K (*Agriculture*)—Opening Address by Major P. G. Craigie, C.B., F.R.S., Chairman of the Sub-section, 411; Experimental Farm System in Canada, Dr. W. Saunders, 535; Possibility of extending the Food Production of Canada, Prof. Brigham, 535; Prof. Mavor, 535; Factors Determining the Yield of Wheat, A. D. Hall and E. J. Russell, 535; the Influence of Environment on the Composition of the Grain, F. T. Shutt, 535; Strength of Wheat, A. E. Humphries, 536; Dr. E. F. Armstrong, 536; Baking Qualities of Certain Flours, Prof. Harcourt, 536; Experiments in Breeding Wheat, Dr. C. Saunders, 536; Forestry Problems, Prof. Somerville, 536; R. H. Campbell, 536; History of the Aberdeen-Angus Breed of Cattle, Prof. Wilson, 536; Soil Problems, F. T. Shutt, 536; Prof. Alway, 526; Soil Moisture, Prof. King, 536; Conservation of Soil Fertility, A. D. Hall and E. J. Russell, 536

Section L (*Educational Science*)—Opening Address by the Rev. H. B. Gray, D.D., Warden of Bradfield College, Berkshire, President of the Section, the Educational Factors of Imperialism, 442

British Birds in their Haunts, Rev. C. A. Johns, 100
British Birds and their Eggs, with a New Method of Identification, J. Maclair Boraston, 99
British Explosives Industry, the Rise and Progress of the, 190
British Medical Association, Physiology at the, 200
British Mountain Climbs, George D. Abraham, 485
British Museum: Guide to the Whales, Porpoises, and Dolphins (Order Cetacea) Exhibited in the Department of Zoology, British Museum (Natural History), Cromwell Road, London, S.W., 4; British Museum Report, 78; Catalogue of the Fresh-water Fishes of Africa in the British Museum (Natural History), G. A. Boulenger, 216; Catalogue of the Lepidoptera Phalænæ in the British Museum, Vol. viii., Catalogue of the Noctuidæ, Sir George F. Hampson, Bart., 455
British Rainfall, 1908, Dr. Hugh Robert Mill, 514
Britton (Prof. N. L.), the Genus Cereus, 462
Bronson (Dr. H. L.), on Clark and Weston Standard Cells, 471
Bronze-age Interments in Switzerland, F. A. Forel, 371
Broom (Dr. R.), the Organ of Jacobson in Orycteropus, 28; Milk Dentition of the Aard-vark, 166
Browne (Miss E. N.), Production of New Hydranths by the Insertion of Small Grafts from another Individual of the same Species, 496
Browning (Dr. Carl H.), Studies on Immunity, 214
Bruce (Eric Stuart), the Aëronautical Society, 6
Bruce (Dr. William S.), Scottish Expedition to Spitsbergen, 87
Brunton (Sir Lauder), on the Poison of Venomous Snakes and the Methods of Preventing Death from their Bite, 186
Bryan (Prof. G. H., F.R.S.), the Aëronautical Society, 6; the Stability of Aëroplanes, 366; Aviation, 397
Bryant (Father A. T.), Materia Medica among the Zulus, 298
Bücking (Dr. H.), the Antiquity of Man in South America, 534
Building Materials, Introduction to the Chemistry and Physics of, Alan E. Munby, 62
Buisson (M.), Comparison of the Spectra of the Centre and Edge of the Sun's Disc, 110
Buller (Prof. A. H. R.), Production and Dispersion of Spores in the Hymenomycetes, 537; Number of Bacteria in the Air of Winnipeg, 537
Bumstead (Prof.), Ascertained Properties of Light of very Short Wave-lengths ("Schumann Rays"), 469
Burkill (I. H.), Coptis, 30; *Cymbopogon Martini*, Stapf, 30
Burnham (Prof.), Double-star Measures, 376; Halley's Comet, 376
Burns (Gavin), the Number of the Stars, 229
Burpee (Lawrence J.), the Water Route from Lake Superior to the Westward, 506
Burrard (Col. S. G., F.R.S.), a Sketch of the Geography and Geology of the Himalaya Mountains and Tibet, 424
Burton (E. F.), Influence of Electrolytes on Colloidal Ferric Oxide Solutions, 470
Buss (A. A.), Solar Research, 200; Temperature and Pressure Conditions in the Solar Atmosphere, 356; Hα Images on Spectroheliograms, 376
Butler (C. P.), Origin of Certain Lines in the Spectrum of ε Orionis, 26
Butler (Dr. E. J.), Fungal Disease, *Coryneum mori*, in the Mulberry Nurseries near Srinagar, 226
Büty (M. de), Application of the Magnetic Properties of Metals to Automatic Coin Machines, 150

Cabré (Juan), Rock Paintings of the Lower Ebro, 522
Cadastral Survey of Egypt, 1892–1907, the, Capt. H. G. Lyons, 194

Cady (W. G.), Phenomena Exhibited by Electric Arcs between Metal Electrodes, 297
Caillou (Pousse), the Region Known as Changchenmo, 354
Cajori (Prof. F.), Invention of the Slide Rule, 470
Calcutta: Asiatic Society of Bengal, 30, 150, 270
Caldecott (W. A.), Development of Heavy Gravitation Stamps, 539
Calendar, Styles of the, W. T. Lynn, 277
Callendar (Prof. H. L., F.R.S.), Osmotic Phenomena and their Modern Physical Interpretation, Discourse at Royal Institution, 235
Calmette (Dr. A.), Determination of the Bovine or Human Origin of Tuberculosis, 135; Venoms, Venomous Animals, and Anti-venomous Serum-therapeutics, 154
Cambage (R. H.), Native Flora of New South Wales, 240; New Species of Eucalyptus from the Monaro District, N.S.W., 240
Cambridge, the Darwin Celebrations at, 7
Cambridge, the Meeting of the International Geodetic Association in London and, 426

Chassy (A.), Conductivity of a Gas at Atmospheric Pressure under the Influence of a High Alternating Voltage, 90
Chatley (Prof. Herbert), the Force of the Wind, 366; the Stability of Aëroplanes, 366
Chatterjee (G. C.), Ova of a Distoma found in the Skeletal Muscles of *Saccobranchus fossilis*, 270
Chemistry: the Atomic Weight of Platinum, Prof. E. H. Archibald, 29; Use of Platinum Felt as a Filtering Medium, W. O. Snelling, 404; Dimethylcamphor and Dimethylcampholic Acid, A. Haller and Ed. Bauer, 29; Action of some Organo-magnesium Compounds on Methyl-2-pentanone-4, F. Bodroux and F. Taboury, 29; Pseudo-morphine, Gabriel Bertrand and V. J. Meyer, 29; Evolution in Applied Chemistry, Prof. Otto N. Witt at Seventh International Congress of Applied Chemistry, 51; Fermentation of Glucose, Mannose, and Fructose by Yeast-juice, A. Harden and W. J. Young, 57; Mutarotation of Glucose, Y. Osaka, 528; Pharmacological Action of Protocatechyltropeine, Prof. C. R. Marshall, 59; Gases of Volcanic Fumaroles, Armand Gautier, 59; Ordinary Carbon, H. Le Chatelier and M. Wologdine, 59; Action of Metallic Oxides on Methyl Alcohol, Paul Sabatier and A. Mailhe, 59; Hydrolysis of Salts in Amphoteric Electrolytes, Miss H. H. Beveridge, 59; Formation of Oxygen Compounds of Nitrogen and their Metallic Combinations (Iron and Lead) in the Production of Ozone for the Sterilisation of Water, Ed. Bonjean, 60; Processes for the Fixation of Atmospheric Nitrogen, 143; New Alkaloid Extracted from the Bark of *Pseudocinchona Africana*, Ernest Fourneau, 60; Formation of Lactones from Acid Alcohols, E. E. Blaise and A. Koehler, 60; Introduction to the Chemistry and Physics of Building Materials, Alan E. Munby, 62; Modern Organic Chemistry, Dr. C. A. Keane, 64; Practical Organic Chemistry, Dr. J. J. Sudborough and T. C. James, 64; the Elements of Organic Chemistry, E. J. Lewis, 64; Abhandlung über die Glycole oder Zwei atomige Alkohole, Adolf Wurtz, 64; Practical Physiological Chemistry, Prof. Philip B. Hawk, 67; Value of Benzidine for the Detection of Minute Traces of Blood, Prof. E. J. McWeeney, 89; Trialkylacetophenones and the Trialkylacetic Acids derived from Them, A. Haller and Edouard Bauer, 90; Tautomeric Changes Elucidated by Means of the Magnetic Rotatory Power, P. Th. Muller and M. Thouvenot, 90; Evolution of Hydrogen from Silicochloroform under Silent Discharge, A. Besson and L. Fournier, 90; Oxidation of Aldehydes of Silver, Marcel Delépine and Pierre Bonnet, 90; Hydrolysis of Proteid Materials by Means of Hydrofluoric Acid, L. Hugounenq and A. Morel, 90; Naturgeschichte einer Kerze von Michael Faraday, 95; Junior Chemistry, R. H. Adie, 95; Chemistry, Prof. W. A. Tilden, F.R.S., 95; Histoire du Développement de la Chimie depuis Lavoisier jusqu'a nos Jours, Prof. A. Ladenburg, 96; Nature of the Change undergone by Crystals of Heptahydrated Sodium Sulphate in Contact with Crystals of the Decahydrate, D. Gernez, 120; New Method of Separating Uranium X, B. Szilard, 120; Rate of Helium Production from the Complete Series of Uranium Products, Hon. R. J. Strutt, F.R.S., 158; Chemical Action of the Penetrating Rays of Radium on Water, Miroslaw Kernbaum, 120; Hydrolytic Decomposition of Bismuth Bromide, René Dubrisay, 120; the Hydrolytic Dissociation of Bismuth Iodide, René Dubrisay, 330; Extraction of Lutecium from the Gadolinite Earths, G. Urbain, MM. Bourion and Maillard, 120; Rapid Method for Testing Plants for Hydrocyanic Acid, Marcel Mirande, 120; Essays, Biographical and Chemical, Sir William Ramsay, K.C.B., F.R.S., C. Simmonds, 122; Death and Obituary Notice of Prof. G. Arth, 134; Synthesis of Papaverine, Amé Pictet and A. Gams, 150; the Catalysis of the Fatty Acids, J. B. Senderens, 150; New Base extracted from Rye containing Ergot, Ergothioneine, C. Tanret, 150; Grundriss der allgemeinen Chemie, Wilhelm Ostwald, 183; Grundriss der Pharmakochemie, Dr. O. A. Oesterle, Prof. Henry G. Greenish, 184; Southall's Organic Materia Medica, J. Barclay, Prof. Henry G.

Greenish, 184; the Rise and Progress of the British Explosives Industry, 190; Death of Prof. S. W. Johnson, 194; Properties of the Monatomic Gases, Dr. H. Happel, 198; Recent Advances in Our Knowledge of Silicon and of its Relations to Organised Structures, Prof. J. Emerson Reynolds, F.R.S., at Royal Institution, 206; New Method of Analysis by Curves of Miscibility, its Application to Oils used for Food, E. Louise, 209; the Allotropic States of Phosphorus, Pierre Jolibois, 209; Action of the Ultra-violet Rays upon the Acetic Fermentation of Wine, Victor Henri and Joseph Schnitzler, 210; the Latent Heat of Fusion and the Specific Heat of Propionic Acid, G. Massol and M. A. Faucon, 210; Paralysing Influence exercised by Certain Acids on Alcoholic Fermentation, Mlle. M. Rozenband, 210; Chemical Technology and Analysis of Oils, Fats, and Waxes, Dr. J. Lewkowitsch, C. Simmonds, 211; V. v. Richter's Chemie der Kohlenstoffverbindungen oder organische Chemie, Dr. R. Anschütz and Dr. G. Schroeter, 215; Analyse und Konstitutionsermittelung organischer Verbindungen, Dr. Hans Meyer, 215; the Cyanamide Industry of France, M. Pluvinage, 222; Estimation of Fat in Unsweetened Evaporated Milk, Messrs. Hunziker and Spitzer, 226; Osmotic Phenomena and their Modern Physical Interpretation, Prof. H. L. Callendar, F.R.S., at Royal Institution, 235; Ethyl Acetal of Tetrolic Aldehyde, P. L. Viguer, 239; Method for the Rapid Estimation of Metallic Aluminium, E. Kohn-Abrest, 239; Decomposition of Carbon Dioxide by the Ultra-violet Rays, H. Herchefinkel, 239; Hexone Bases of Egg-white, Dr. J. M. Petrie and Dr. H. G. Chapman, 240; Influence of the Reaction of the Medium on the Development and Proteolytic Activity of Davaine's Bacteridium, Mlle. Eleonore Lazarus, 269; Synthesis of Unsaturated Fatty Ketones, F. Boudroux and F. Taboury, 269; Genesis of the Chemical Elements, James Moir, 270; Aurvedic Metallic Preparations, **Part i.**, Panchanan Neogi and Birendra Bhusan Adhicary, 270; Death of Prof. Emil Christian Hansen, 294; Obituary Notice of, Arthur R. Ling, 310; Death of L. Bouveault, 311; Action of Iodo-eosin as a Test for Free Alkalis in Dried Plant Tissues, Dr. A. C. Hof, 312; Apparatus for Determining the Calorific Power of Gaseous Combustibles, P. Lemoult, 330; Chemistry in the Service of the State, Sir Edward Thorpe, 340; Curious Case of Corrosion Occurring in a Stand-by Boiler, G. N. Huntly, 354; Calorimetric and Cryoscopic Constants of Mercuric Bromide, M. Guinchant, 360; a Manual of Volumetric Analysis, Dr. H. W. Schimpf, 364; Liquefaction of Clay by Alkalis and Use of Fluid Clay Casting in the Ceramic Industry, Dr. E. Weber, 375; the Magnetic *Rôle* of Oxygen in Organic Compounds, P. Pascal, 390; Estimation of Phosphorus in Combustible Substances by the Calorimetric Bomb, P. Lemoult, 390; the Manufacture of Rubber Goods, Adolf Heil and Dr. W. Esch, 391; Oxidation of Phenol, H. D. Gibbs, 404; Washing of Cider Apples with an Oxidising Calcium Salt leading to Pure Fermentation, Henri Alliot and Gilbert Gimel, 420; Corrosion of Iron, Dr. J. Newton Friend, 437; Action of Air and Steam on Pure Iron, Dr. J. Newton Friend, 437; Process of Manufacturing Artificial Magnetic Oxide of Iron, F. J. R. Carulla, 437; Death and Obituary Notice of Richard Bannister, 460; Thermal Properties of Silver Nitrate, M. Guinchant, 480; Examination of Essence of Turpentine, Paul Nicolardot and Louis Clément, 480; Revision of the Density of Gaseous Hydrochloric Acid: the Atomic Weight of Chlorine, Otto Scheuer, 510; Derivatives of Hexahydro-oxybenzoic Acid, P. J. Tarbouriech, 510; Total Sugar of the Plasma and Globules of the Blood, R. Lepine and M. Boulud, 510; Gay-Lussac's Law, its Centenary, Dr. A. N. Meldrum, 519; Death of Dr. Hermann Endemann, 524; a Series of Isomeric Phenylphthalimides, Mr. Kuhara and Mr. Komatsu, 528; *see also* British Association

THURSDAY, JULY 1, 1909.

THE IMPERIAL GAZETTEER ATLAS OF INDIA.

The Imperial Gazetteer of India. Vol. xxvi. Atlas. New edition. Pp. vii+45; 64 plates. (Oxford: Clarendon Press, 1909.)

THIS atlas, which forms the twenty-sixth volume of the series, is practically an epitome of all the information contained in the "Gazetteer," and, as such, it presents to the reader in a concrete form of illustration most of the physiographical conditions of the Indian Empire. The authorities for the information contained in it are of the very highest, and the publisher is Mr. J. G. Bartholomew, which is in itself a guarantee that the maps are of the very best. Geology, meteorology, ethnology, language distribution, and archæology are all included; there are four special maps illustrating the position of the British frontier at different periods, and a series of admirable city maps which might have been extended with advantage.

In the first general map which presents itself the singular position of Ceylon as forming no part of the Indian Empire is curiously anomalous; and inasmuch as Ceylon cannot be wholly left out of account (as in the railway maps, for instance), it would, we think, have added to the appearance, if not to the usefulness of the atlas, to have included it generally. With this doubtful exception the general maps are complete, clear, and most instructive. The special maps are also good, although, of course, it would be easy to suggest other and possibly better methods of presenting the physical features of India than those which have been adopted. The one special map which deals with the subject of vegetation is perhaps the most open to criticism. Here the classification of area by colour, exhibiting the nature of vegetable growth, or the want of it, seems inadequate. There is one green tint in particular, which denotes "grass or sparsely cultivated," which is rather too comprehensive. We find it, for instance, covering wide tracts to the north and south of the Indravati affluent of the Godavari river in the Central Provinces. Undoubtedly this is a grass country, and it is also sparsely cultivated. The grass in the cold-weather seasons is thick and rank along the low-lying flats, bunched with tangled masses of dew-soaked undergrowth, and almost impassable in the hot weather by reason of the stuffy atmosphere which envelops it; but it is always associated with a low scrub (chiefly of various species of dwarf palm) and sheltered by a more or less scattered tree jungle which occasionally rises to the dignity of forest and is never altogether wanting although it thins out on the higher land. This is, in fact, the nature of the "jungle" which covers half the surface of India, distinct from the official forest areas, which contain timber of commercial value or fringe the foot-hills of the Himalayas.

Again, we find the same tint of green overlying many hundreds of square miles of the Baluch highlands where never a tree has been seen for a century, and where it would be vain to look for a blade of grass after the close of summer. It is true that in the spring months a green tint does actually steal gradually over the hill-sides, and it fills in the spaces between the wormwood scrub of the flats. Then, indeed, the flowers bloom freely, and for a period Baluchistan is gay. Then, too, the shepherd takes his sheep to the hills, and the landscape becomes dotted with white specks of scattered flocks. There is grass undoubtedly —for a time—and equally true it is that the land is "sparsely cultivated"; but about the season that the Indravati basin is rank with cane-brakes and undergrowth and swarming with game, the hills of Baluchistan take on their normal aspect of dead, dull stony desolation, and the "dasht" becomes grey and insipid. So far as vegetable growth is concerned the two countries are in utter contrast, although it is true of both that grass grows in them, and that cultivation is sparse. A very considerable extension of the "steppe-desert" tint is required in Baluchistan (where it is not introduced at all), nor is it quite reasonable to ignore the magnificent cultivation of the valleys of the Hari Rud, near Herat, and of the Helmand; or to paint the summit of the Sulaiman range with the colour of the "sandy desert or barren land," considering that the chilghosa forests of these mountains (which are all about these summits) are of great economic importance to the tribes people who make use of them. It will be observed that these criticisms point, not to the maps of India with which the "Gazetteer" is principally concerned, but to the maps of the Indian frontier and trans-frontier. Of the maps of India it is enough to say that they are all admirably clear and most instructive, each in its distinct and separate line of illustration; but inasmuch as the frontier is now very rightly included in all works dealing seriously with Indian problems, it is time that the public were supplied with map information of a class equal to that of the Indian peninsula generally. This is not quite the case in this atlas.

Take, for instance, the map of Baluchistan amongst the "district" series. Were no attempt made at reproducing the orography of that remarkable country the map might pass sufficiently well as a sketch; but the crude representation of the mountain features which at present disfigures the map is absolutely misleading. All the beauty (and it is very beautiful) of nature's arrangement of sweeping flexures and folds which border the trans-Indus highlands; the orderly curves of their looping up where the inset of the Kach Gandava desert occurs (just like the looped-up flexures in hanging drapery) pushing back and forming the massive mountain entourage of Quetta; then sweeping away in graceful flexures seamed with a thousand wrinkles to Karachi, or through Makran to Persia—all this is lost in the graceless disposition of a few fat slug-shaped forms over the yellow surface of the map. This is not the orography of Baluchistan, or Makran, and it is misleading. The traveller who trusted, by following this map, to turn the northern end of the Kirthar range and to walk into Khozdar on the flat plains would be grievously disappointed. The wall of the frontier hills is not even represented as continuous, and even if the scale of the map does not admit of giving full value to many important, but minor, features, there is at least no excuse for fundamental errors such as this. The map is certainly not overcrowded with names, and this fact renders it all the more desirable that those which exist should be correct. The "Central Makran" range is an invention which is hardly permissible. Not only is it not near the centre of Makran, but it is doubtful whether it is, all of it, even in Makran. As regards the frontier, we must, however, be thankful for small mercies. It is something to find a map of Baluchistan which is correct in its political boundaries, and it is a great deal to find a map of Afghanistan which is in almost every respect a far better illustration of the country it represents than that which we have just criticised.

The city maps at the end of the series are wholly admirable, and so are the railway maps which precede them. It would have added greatly to the interest of the series could we have had maps of some of the most ancient, and, historically, the most important, of the cities of the past; Chitor, Ujjain, Udaipur, and many another that we could mention, will always possess an undying interest for the student of India. On the whole, this atlas is an admirable addition to the "Gazetteer," and as it is probably the most useful volume for reference in the whole series, so may we hope that in due time it will become the most accurate.

T. H. H.

ESSAYS ON LEONARDO DA VINCI.

Etudes sur Léonard de Vinci, ceux qu'il a lus et ceux qui l'ont lu. By Pierre Duhem. Seconde Série. Pp. iv+474. (Paris: A. Hermann, 1909.) Price 15 francs.

THIS volume contains four essays, on Leonardo da Vinci's views on the infinitely great and the infinitely small, on his ideas on the plurality of worlds, on his dependence on the philosophy of Nicolaus de Cusa, and on his ideas on the origin of fossils.

When endeavouring to estimate the value of the notes and jottings of the great painter it is necessary to consider the books accessible to him and the problems under discussion among philosophers of his day. M. Duhem has made a detailed study of the works of mediæval thinkers, and he traces the development of the ideas by which Leonardo's mind was influenced, and the advances he made, by which, unfortunately, the world did not profit since they remained locked up in his note-books. The foundation on which every speculation rested was still the philosophy of Aristotle, viewed in many cases through the spectacles of the scholastics, and often influenced by the commentaries of Arabian philosophers. But Leonardo reasoned independently on every subject, and though he often adopted opinions held by his predecessors, he never followed slavishly in their footsteps. This is well illustrated by his attitude with regard to the question whether there might be more worlds than the one of which the earth was the central part, and which was bounded by the starry sphere. Aristotle had denied that there could be more than one universe, because a body can only be at rest in its natural place, so that the earth of a second world would fall down on our earth, and no body can therefore exist outside the starry sphere. The question was a difficult one to the scholastics, because to deny the possibility of the plurality of worlds seemed to involve denying the omnipotence of God; but a curious compromise was proposed by Albert of Saxony, that if there were another world it would have to be concentric with ours, because the centres of gravity of our earth and the other one would have to coincide if there were to be equilibrium, and this could only be the case if the other earth were in the form of a spherical shell—unless we assume a permanent miracle. Undeterred by this, Leonardo in a note considers what would happen if there were, not one, but two centres of gravity. He assumes two worlds of equal size and a heavy body outside the line joining their centres, but at equal distances from these; and he asks how will this body move and where will it come to rest? The answer is that it will move along the perpendicular to the line joining the centres, and be in equilibrium at the point midway between them. Here, as in many other places, he shows that he had a clear idea of the composition of forces, at a time when the fundamental principles of dynamics were unknown.

The writings of the German philosopher Nicolaus de Cusa seem to have made a profound impression on Leonardo, and M. Duhem shows how suggestive they were to him in his studies on the motion of bodies. Leonardo discussed the motion of an arrow shot vertically upwards from the earth, assuming the latter to rotate in twenty-four hours, not because he wanted to prove or disprove the rotation of the earth, but merely as a problem of dynamics. Here, as well as in his general investigation of the motion of a projectile, he found it hard to free himself from old ideas; he believed, for instance, that a cannon ball at first moves in a straight line while influenced by a "violent force," next in a curved path while that force and gravity are struggling for supremacy, until it finally drops to the earth in a straight line. Though he cannot be considered a precursor of Copernicus (he says repeatedly that the earth is at the centre of the universe), he reasons as freely as Cusa about the nature of the stars, and rejects the Aristotelean distinction between the terrestrial elements and celestial matter. He believed the moon to be composed of the four elements which it supports in space in itself and by itself, as the earth does with its component parts. This is much the same as the statement of Copernicus that gravity is a natural tendency of all particles to join themselves into a whole in the form of a sphere, a tendency which is innate in the sun, moon, and planets.

The fourth essay deals with speculations on the origin of fossils. Leonardo did not consider them to be "plays of nature," or to have been carried to the tops of mountains by a deluge, but recognised that they are the remains of animals which actually lived on the spot where the fossils are found.

PARA RUBBER.

Hevea brasiliensis, or Para Rubber. Its Botany, Cultivation, Chemistry, and Diseases. By Herbert Wright. Third edition. Pp. xviii+204. (Colombo: A. M. and J. Ferguson; London: MacLaren and Sons, 1908.) Price 10*s*. net.

A REVIEW of Mr. Herbert Wright's valuable work on Para rubber appeared in NATURE about two years ago. The present edition (third) has been considerably enlarged, and in Mr. Wright's words "has been compiled in consequence of the many advances which have been recently made in methods of cultivation and tapping, coagulating and curing." The text has been increased from 177 pages to 304 pages, and the really well reproduced and instructive illustrations from 86 to 272. Many of the chapters have been re-written and expanded, especially the one on uses of rubber. There is now a separate chapter on the botany of the Para tree, *Hevea brasiliensis*, and one on the effect of tapping on the trees.

Chapter iv. contains a great deal of useful and up-to-date information on planting operations and on catch crops. The advantages and disadvantages of close planting are fully considered. The most general distance now employed is from 15 feet to 20 feet. The main justification for close planting is the increased tapping area which is available in the first few years, but there is a note of warning in the following passage:—

"No one who has seen the uncultivated thirty-year-old trees at Henaratgoda can doubt that such specimens require at the very least a distance of thirty to forty feet if they are to be allowed to continue in their growth and maintain a healthy constitution."

Catch crops, says Mr. Wright, are all very exhausting, and their profitable cultivation is limited to about the first four years.

Considerable space is devoted to a description of the various methods of tapping and tapping implements, but, apparently, the systems employed are far from perfect, as the following passage implies:—

"The adoption of better systems of tapping which obviate the necessity of paring away the tissues wherein the milk accumulates, and drawing supplies of latex by merely cutting and not excising the laticiferous tissues is bound to result in an increased yield since the life of the tapping area is so much prolonged."

At present the average yield per tree per year for the Malay States would appear to be about 2 lb. Most of the trees, however, are still young. The cost of production is about 1*s*. 6*d*. per lb. Various methods of coagulating and treating latex are described: the use of centrifugal machines is more or less experimental; "the principle . . . . of causing a separation of the caoutchouc globules by mechanical means is one which cannot be too strongly impressed on the experimentalist."

There is very little doubt, from Mr. Wright's remarks and his inquiries amongst manufacturers, that plantation Para is inferior in quality to fine hard (wild) Para. A wise manufacturer would not dare to buy 50 tons of cultivated rubber and store for six months, for fear of grave deterioration in quality, but he would buy thousands of tons of up-river fine Para with a full knowledge that it would grow better in storage. Mr. Wright appears to have very little faith in the so-called "synthetic rubber."

Natural rubber consists chemically of very complicated compounds. The "resins" and "proteins" are in themselves highly complex bodies, the components of which are but little understood.

"How can it then be possible, since we do not fully understand the chemical composition of the various components of natural rubber, to have synthetic rubber already on the market?"

Mr. Wright's book is perhaps the most comprehensive and up-to-date work on Para rubber published in this country, and has proved of great utility to practical men in the various branches of the rubber industry.

L. C. B.

ALTITUDE TABLES FOR NAVIGATORS.

Altitude Tables, computed for Intervals of Four Minutes between the Parallels of Latitude 24° and 60°, and Parallels of Declination 24° and 60°, designed for the Determination of the Position Line at all Hour Angles without Logarithmic Computation. By Frederic Ball. Pp. xxxvii+313. (London: J. D. Potter, 1909.) Price 15*s*. net.

THERE are many circumstances connected with actual navigation which tend to make calculation on board ship difficult to the inexpert, and we naturally welcome any effort intended to shorten an onerous task and to introduce greater simplicity. The substitution of tables which give an approximate solution of a spherical triangle, involving only a very easy interpolation, is the form that assistance usually takes, and the main feature in the book before us is to make tables, already published, available for wider limits of latitude and declination. As tables extend, and contrive, perhaps, to serve more than one purpose, complications are likely to arise, and however great an ingenuity is displayed in adapting trigonometrical formulæ to tabular arrangement, if simplicity is sacrificed to ingenuity, the ultimate gain is questionable.

Accuracy is as necessary as brevity of calculation, and it is possible to be so enamoured with the apparent advantages of tables that the chances of misusing them are overlooked. We have a slight fear that the author has not sufficiently considered this point. It is a mistake to cumber the work with many rules, which put too great a strain on the memory. For instance, the rules for determining the "name" of the azimuth; using different methods within ten degrees of the meridian or of the prime vertical; interchanging latitude for declination under certain conditions; all these things are apt to be a little burdensome in a moment of stress or excitement. Further than this, there must come a time when tables do not shorten the work, for the number of interpolations becomes excessive. Tables of double entry are always inconvenient to the computer, and when, as in nautical problems, we get three arguments, latitude, declination, and hour angle, for other values than those in the tables, the process becomes very laborious. In an example given, it is necessary to take out four altitudes with arguments of even degrees of latitude, and of declination, and to make three interpolations between these altitudes. Not a word is said about the signs of the corrections, and it is quite possible to use an incorrect sign. In any case, the attention is kept on the strain more than if a direct calculation of altitude was made from the ordinary trigonometrical formula.

We may ask, too, whether the use of logs. for solving the simplest question in rule of three is not a little overdone. We have a problem, in which is given the difference of altitude for 60′, and it is required to find the proportional amount for 41·6′. The correction is worked out by logs. involving three entries.

But these are little technical points, on which, no doubt, the author's information is a safe guide. He has actual experience to lead him aright, and we are prepared to surrender our opinion to his practical judgment. On a more important point we are entirely with Mr. Ball. We recognise that this is part of an effort to impress, especially, on the Mercantile Marine, the necessity and the advantage of employing modern methods of tried excellence, and the desirability of abandoning obsolete processes. In these days of rapid locomotion at sea, it is more than ever necessary to produce a correct result in the shortest possible time, and when the expenses of ship management are so enormous, it is a matter of prime importance to know the exact position of the vessel, and to ensure accurate landfall. No time must be lost in groping about to pick up a light, no hesitation must be allowed in determining the ship's course and speed. We trust the author will be successful in enforcing the lesson he has at heart.

OUR BOOK SHELF.

Guide to the Whales, Porpoises, and Dolphins (Order Cetacea), exhibited in the Department of Zoology, British Museum (Natural History), Cromwell Road, London, S.W. Pp. 47. (London: British Museum [N.H.], 1909.) Price 4*d*.

THE whale-room in the Natural History Museum is one of the most notable and interesting features of the national collection, and the publication of a new guide to its contents calls for a word of comment. Within fifty pages Mr. Lydekker has compressed not only a series of clues to the models, skins, and other preparations, but has furnished students of zoology generally with a most useful and well-illustrated summary of the chief characters of the Cetacea and of their presumable ancestors. In a prefatory note, Dr. Harmer gives reason for confining exhibits of this order to skeletons and models, but it is to be hoped that the public will always have an opportunity of seeing the skins of some of these impressive animals, in order to judge of their proportions. The only feature of this excellent guide that we could have wished more fully expounded, relates to the puzzling vernacular names of whales that are used by fishermen. The members of our own branch of the international sea investigation are often quite at a loss to know what these names correspond to in scientific nomenclature, and their experience is not unique. The matter has some importance since the cetacean fauna of the north-western seas is probably more familiar to fishermen than to naturalists, and the fisherman's records cannot be stated precisely until we are able to understand the vernacular terms in use.

La Naissance de l'Intelligence. By Dr. Georges Bohn. Pp. 350. (Paris: Ernest Flammarion, 1909.) Price 3.50 francs.

THIS book is the latest addition to the well-known series of volumes entitled the "Bibliothèque de Philosophie scientifique," and, in both matter and style, easily reaches the high standard of excellence set by its predecessors. The author restricts his attention to the psychology of the lower organisms, and has succeeded in giving an extremely interesting account of a part of modern comparative psychology hitherto rendered attractive only at the expense of truth. An implacable foe to the "anthropomorphism" of the last generation of comparative psychologists, Dr. Bohn devotes a large part of the earlier chapters of his book to a full statement and vigorous defence of Loeb's theory of tropisms, relieving it of several serious misconceptions on the part of the critics by distinguishing it from and relating it to the theories of "differential sensibility" and "associative memory," respectively, which were adumbrated by Loeb himself, and are equally necessary to the explanation of many forms of behaviour of lower organisms. From this general standpoint he finds himself in a position to criticise, on the one hand, the modern mechanistic school of the Germans (Beer, Bethe, Uexküll, &c.), who deny *sensations* to animals only to be forced, later on in the argument, to attribute *intellect* to them, and, on the other hand, Jennings and his American supporters, whose theory of "trial and error" is accused (somewhat unjustly, we think) of an anthropomorphic taint. Other interesting points in the book are discussions on the vital rhythms of marine animals, on the criteria of psychism (where the author rejects Yerkes's various criteria—discrimination, docility, initiative—in favour of that suggested by Loeb, viz. associative memory), on the laws of associative phenomena, and on instinct, a term which the author scornfully expels from comparative psychology as being "metaphysical" and useless. Such a method of getting rid of difficulties should not be encouraged. W. B.

The Dyeing and Cleaning of Textile Fabrics. A Handbook for the Amateur and the Professional. By F. A. Owen. Based partly on notes of H. C. Standage. Pp. vi+253. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1909.) Price 8*s.* 6*d.* net.

A HANDBOOK was published some time ago under some such title as "Every Man His Own Lawyer." To what particular class of people such a book is useful it is not easy to say, but it is fairly safe to assume that the work of the legal profession was not materially lessened by its publication. The book above mentioned might with equal aptness have been termed "Every Man His Own Dyer," but the probability is that the people who are successful in dyeing their own clothes will be even smaller in number than those who are satisfied with the result of their own legal efforts.

The first portion of the book is taken up with such general matters as solution, maceration, &c., and here the author drifts into pharmacy. "The ordinary dose of such infusions is 1 to 2 ozs., three or four times per day." He does not explain, however, the connection between the internal application of infusions and the renovation of garments. His remarks on maceration are equally illuminating. "Its object is usually to impregnate alcohol with the principles of a substance which would be but slowly extracted without the aid of heat, such as the *sun or other warm situation.*"

It is a matter for regret that the book should have been published in its present form. It contains many trustworthy and useful recipes for the removal of stains, the cleaning of gloves, &c., but these are associated with so much useless and even misleading matter that their value is greatly discounted.

WALTER M. GARDNER.

Codex of Resolutions adopted at International Meteorological Meetings, 1872–1907. Prepared at the request of the International Meteorological Committee by H. H. Hildebrandsson and G. Hellmann. Pp. 80. (London: H.M.'s Stationery Office, 1909.) Price 1*s.* 3*d.*

PROGRESS in the observational sciences depends to a great extent on cooperation among those engaged in collecting and making generally available the observational data, and in no subject is this more true than in meteorology, in which the number of individuals who have to be brought within the meshes of the general organisation is exceptionally great. Much has been accomplished in the direction of drawing up rules for general guidance, but the lack of a satisfactory index to the various reports in which these are embodied has hitherto made it difficult to find the information bearing on any given point. Recognising this difficulty, the International Meteorological Committee, at its meeting at Southport in 1903, requested the authors to prepare a summary of what had been already accomplished.

The manuscript of the "Codex," which takes the form of a reprint from the minutes of the meetings of all important resolutions, with short explanatory paragraphs interspersed, was submitted for approval at the International Conference of Directors of Observatories and Offices, held at Innsbruck in 1905. Subsequently Dr. Hellmann incorporated the decisions adopted at that meeting, and the German edition of the work was issued by the Royal Prussian Meteorological Institute in 1907. In the English edition, Dr. Shaw has incorporated the resolutions adopted by the International Committee at Paris in 1907, and we have thus a complete summary of the work accomplished by the seventeen international meetings which have been held since 1872, the date of the first conference, held at Leipzig. In view of the large area over which the English-speaking peoples hold sway, the publication of an English edition of the work is very welcome, and should prove of great service to all engaged in meteorological or magnetic work. A full index to the "reports on progress" in particular branches, and to the scientific papers which have appeared as appendices to the minutes of the meetings, is not the least valuable part of the book.

The Balance of Nature, and Modern Conditions of Cultivation: A Practical Manual of Animal Foes and Friends, for the Country Gentleman, the Farmer, the Forester, the Gardener, and the Sportsman. By George Abbey. Pp. xlvii+278. (London: Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., 1909.) Price 7*s.* 6*d.* net.

IN his preface the author, who appears to have had a very large experience in trapping vermin, states that the only natural-history works he has consulted are "Wood's Natural History" and "The Popular Encyclopædia." All we can say is the more's the pity, for had he undertaken a somewhat wider and more modern course of reading we might have been spared such out-of-date statements as that the hedgehog is a member of the same family as the one which includes the mole and the shrewmouse, or that there are two British species of dormice and also of water-shrews. Such errors are possibly excusable in a writer who is not a zoologist; but what can be said of a so-called sportsman or outdoor naturalist who states that only tame red deer are hunted in England, and that wild roebuck are unknown south of Scotland?

But if the text be bad the illustrations, which the author declares to be diagrammatic, are ten times worse, the climax being reached in the figure of the roebuck, which is represented with a long tail!

As regards the economic portions of the work, the author appears to know more of his subject, and we trust his observations will be found of use to the country gentlemen and farmers for whom the volume is specially intended. We must, however, express surprise at the merciless manner in which he advocates trapping and other methods of destruction; and we are still more concerned at the statement on p. 201 that fish-preservation societies scruple not to destroy the kingfisher, especially if they countenance the use of the cruel pole-trap depicted on the same page.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Diurnal Variation of Temperature in the Free Atmosphere.

THE following results, which I have recently obtained by a discussion of temperatures obtained in kite and captive balloon ascents, may be of interest in connection with Prof. Clayton's letter (NATURE, February 4) and Mr. Dines's remark that at a height of 1 km. the daily temperature variation becomes insignificant (NATURE, June 17). The daily variation of temperature at a height of 1 km. over Berlin, deduced from 2232 observations made during the five years 1903–7, is given in degrees C. by

$$T = T_s - (4 \cdot 40 \pm 0 \cdot 08) + (0 \cdot 87 \pm 0 \cdot 13) \sin(nt + \theta_1) + (0 \cdot 14 \pm 0 \cdot 10) \sin(2nt + \theta_2),$$

where T_s is the mean surface temperature, and the probable errors are deduced by the method of least squares. The most probable values for θ_1, θ_2, are 197° and 123° respectively, the time being measured from midnight.

The variation deduced from 962 observations, made during the four years 1903–6, in which the wind at a height of 1 km. was 8 metres per sec. and upwards, is given by

$$T = T_s - (3 \cdot 97 \pm 0 \cdot 15) + (0 \cdot 84 \pm 0 \cdot 23) \sin(nt + \theta_1') + (0 \cdot 35 \pm 0 \cdot 15) \sin(2nt + \theta_2').$$

The most probable values of θ_1, θ_2, are 173° and 102° respectively.

The close agreement in the values for the amplitude of the whole day wave for the two cases proves that there is no large error due to the influence of solar radiation on the instruments, and that the variation is a real variation of the temperature of the atmosphere.

The mean daily range is, then, 1·7° C. (or 3·1° F.), compared with a mean daily range of about 5° C. at Kew, where the temperature variation is given by

$$T = T_s + 2 \cdot 56 \sin(nt + 226°) + 0 \cdot 42 \sin(2nt + 45°).$$

The maximum temperature at a height of 1 km. appears to occur from two to three hours later than at the surface in the whole day wave, and two to three hours earlier in the semi-diurnal wave.

The variation at a height of 2 km., deduced from all (1132) observations, is given by

$$T = T_s - (9 \cdot 84 \pm 0 \cdot 23) + (0 \cdot 64 \pm 0 \cdot 31) \sin(nt + \theta_1) + (0 \cdot 25 \pm 0 \cdot 23) \sin(2nt + \theta_2),$$

the most probable values for θ_1, θ_2, being 270° and 72° respectively.

The magnitude of the probable errors precludes the results from being regarded as final. More observations are needed. But it appears certain that we do not get, on this side of the Atlantic, the remarkable diminution in amplitude and change of phase in the diurnal component which Prof. Clayton found in the first 1000 m. at Blue Hill. The amplitude of the semi-diurnal component does show an increase at 2 km. over its value at 1 km., but, having regard to the relatively large probable errors, one cannot attach any real significance to the result. At the same time, it is of interest to find that at 1 km. and 2 km. altitude in these latitudes the temperature variation is as great as it is over the ocean near the equator, where the value of the daily range is about 1·5° C.

Cambridge, June 20. E. GOLD.

Temperature of the Upper Atmosphere.

AN explanation of the existence of an isothermal layer may possibly be found in the fact that carbon dioxide condenses and freezes at low temperatures even when the pressure is low. The strata in which CO_2 circulates, falling as small drops and then evaporating, must be comparable in the irregularity of their temperature gradients with the strata near the earth in which water circulates. The temperature of the bottom of the mist of CO_2 must be approximately a function of the pressure, so it is to be expected that the height of the mist will vary from day to day and from place to place. In particular, it appears that the change of temperature gradient should occur in the tropics at a greater altitude and lower temperature than elsewhere. The observations to which Mr. Cave refers (NATURE, June 17) confirm this part of the theory.

F. J. W. WHIPPLE.

Merchant Taylors' School, E.C., June 28.

The Aëronautical Society.

IN reference to Prof. Bryan's remarks on the aims and objects of the Aëronautical Society of Great Britain in NATURE of May 27, I would point out that the general scientific character of the proceedings of a society is not annulled because one or more writers have fallen into error, any more than it would be reasonable to say that Prof. Bryan is not a profound mathematician because, in a Friday evening discourse at the Royal Institution, he fell into inaccuracy in scientific history, and said that the Aëronautical Society of Great Britain was at one time called the Balloon Society, and changed its name to its present title, the fact being that the Balloon Society was quite a separate affair, which had its meetings at the Westminster Aquarium and discussed every subject under the sun. In that remark Prof. Bryan showed he had not closely followed the work and career of the Aëronautical Society of Great Britain.

During my eight years of honorary secretaryship of the society, amongst the readers of papers and those who made communications will be found Dr. W. N. Shaw, F.R.S., Mr. W. H. Dines, F.R.S., Prof. C. V. Boys, F.R.S., the late Prof. G. F. Fitzgerald, F.R.S., Prof. Bryan himself, Sir Hiram Maxim, Mr. Lawrence Rotch, Dr. Hergesell, Mr. F. H. Wenham, Captain R. F. Scott, Lieut. E. H. Shackleton, Mr. Orville Wright, Mr. Charles Harding, Mr. W. F. Reid, &c. These names vouch for the general high standard of the proceedings of the society in recent years.

While making these criticisms on Prof. Bryan's remarks, I sincerely hope he will continue his own epoch-making aëronautical researches, for the sake of aëronautical science and for the honour of the Aëronautical Society, of which he is a member.

Airth, Sunningdale, June 14. ERIC STUART BRUCE.

I HAVE no desire to do injustice to the Aëronautical Society, neither do I expect its proceedings to be free from all errors. But in view of the fact that mathematical formulæ and physical considerations now frequently enter into papers bearing on aëronautics, I consider that the time has come when the society should realise the importance of dealing more efficiently with papers of a theoretical character than was necessary formerly. As I have communicated my views on this point to the society through Mr. Bruce, a detailed reply may be unnecessary.

I do not wish all aëronauts to be profound mathematicians. I consider that papers dealing with practical aëronautics have been the most valuable feature of the society's work. Many of the eminent writers to whom Mr. Bruce refers have dealt with the practical and experimental rather than the theoretical side of the subject. Further, a distinction must be drawn between inaccuracies made in discourses or discussions at meetings and those which are allowed to find their way uncorrected into print. But when papers are published in a scientific society's journal which deal with questions of a theoretical character or contain formulæ, it is not unreasonable to expect that the authors shall correctly state and properly apply such principles of mathematics, physics, and mechanics as are found in ordinary text-books, and I trust that, as the result of this correspondence, the exceptions will be less frequent in the future than they have been in the past.

May I, in answer to very numerous inquiries, state with regret that it has been impossible, as yet, to publish a detailed account of my Royal Institution lectures, and some time will elapse before the work in which I am interested is in a suitable form for publication?

G. H. BRYAN.

THE DARWIN CELEBRATIONS AT CAMBRIDGE.

A GENERAL account of the proceedings of the Darwin celebrations at Cambridge on June 22–24, and a list of distinguished delegates and other representatives of science who came from the four corners of the earth to proclaim the greatness of Charles Darwin and his work, was given in last week's NATURE. As the chief speeches were delivered on the day we went to press, and on Thursday last, we were prevented from including any report of them in the article, which, however, we are now able to supplement. Short speeches were made in the Senate House on June 23, when the delegates were received by the Chancellor, Lord Rayleigh, and the addresses were presented; and also at the banquet given in the evening of that day.

Eloquent as this testimony was of the universal recognition of Darwin's influence upon scientific work and thought, the scenes in the Senate House and in the new examination hall where the great banquet was held were even more impressive. In each place there was an assembly of naturalists gathered from far and near charged with the spirit which animated Darwin, and alert to respond to any note of appreciation of the man or his work. As more than one speaker remarked, what Newton did to reduce celestial movements to law and order by his discovery of the law of gravitation, Darwin did for the more complex world of animate things. All bodies in the material universe are bound together by the bond of gravitational attraction which decides their past, present, or future paths; and in a similar way the unifying influence in the organic world is the principle of evolution established upon the foundation of natural selection.

The character and dignity of the celebration made a permanent impression upon the minds of all who were fortunate enough to take part in it, and the occasion has been made memorable for the scientific world in general by the publication of a number of works relating to it. One of these, on "Darwin and Modern Science," was noticed in detail last week, and we now take the opportunity of referring to others.

PUBLICATIONS OF THE DARWIN CENTENARY.

Each delegate was furnished with a copy of two publications which will be of lasting value as souvenirs of this memorable occasion. Perhaps the most remarkable of the publications is the beautifully printed volume issued by the Cambridge University Press under the title of "The Foundations of the Origin of Species." This contains the brief abstract of the theory of natural selection written by Charles Darwin in June, 1842, sixteen years before the famous meeting of the Linnean Society at which the theory was first made known to the scientific world. The MS. of 1842, which was afterwards expanded by its author into the essay of 1844, consists of thirty-five pages written in pencil. It had been "hidden in a cupboard under the stairs, and only came to light in 1896 when the house at Down was vacated." It was, as the editor says, evidently written rapidly, and is in Darwin's most elliptical style, with much erasure and correction, the whole being "more like hasty memoranda of what was clear to himself than material for the convincing of others." Mr. Francis Darwin has laid the scientific public under an immense obligation by his admirable introduction and notes, and by the care he has taken that readers should be able to study the sketch exactly as it stood in its original form. Each of the delegates present at the celebration received a copy of this most valuable work, the importance of which in the history of evolutionary theory it would hardly be possible to overestimate.

In addition to this work, a second volume, admirably printed by the University Press, was put into the hands of the guests at the commemoration. This production, which is purchasable by the public at the price of two shillings and sixpence, is entitled "Order of the Proceedings at the Darwin Celebration held at Cambridge, June 22–June 24, 1909; with a Sketch of Darwin's Life." It opens with a brief preface, which records the names of the committee—to whom many congratulations are due for the successful issue of their labours—and also narrates the steps that were taken, beginning with a meeting of the council of the Senate in December, 1907, to organise a celebration worthy of the man who has revolutionised science, and whose influence has made itself felt as a power and an inspiration in every department of intellectual activity. Following the programme of the commemoration proceedings comes a very interesting sketch of Darwin's life, which gives in brief compass the principal events of his career, and the dates of the publication of his various works. This short biography, in the preparation of which the secretaries to the committee acknowledge the assistance they have received from Mr. Francis Darwin, is rendered especially valuable by well-chosen quotations from the "Life and Letters," and from the appreciative comments of Judd, Lyell, Huxley, Schwalbe, Goebel, and Thiselton-Dyer. Good photographic views are given of Darwin's birthplace at Shrewsbury, of the exterior of his rooms at Christ's College, of his house and favourite "Sandwalk" at Down. There are also reproductions of several of the well-known portraits of Darwin and of his wife, including a picture of Charles Darwin and his sister Catherine as children. An excellent likeness of Sir Joseph Hooker, taken in 1897, and an interesting print of H.M.S. *Beagle* in the Straits of Magellan, complete the series.

The Rede lecture on "Charles Darwin as Geologist," delivered by Sir Archibald Geikie, K.C.B., on June 24, has been published also by the University Press, with notes, at the price of two shillings net. Reference was first made in the lecture to the early geological interests of Darwin and the formative influence of Lyell upon his mind. The first volume of Lyell's "Principles of Geology" was published early in 1830. Darwin took the book with him on his voyage in the *Beagle* and studied it, with a result that changed his opinions and began the life-long indebtedness to Lyell which he so sincerely felt and never ceased to express. In four distinct departments Darwin enriched the science of geology with new material during the voyage of the *Beagle*. First, he added to our knowledge of the volcanic history of the globe. Secondly, he brought forward a body of striking evidence as to the upward and downward movements of the terrestrial crust, and drew from this evidence some of the most impressive deductions to be found in the whole range of geological literature. In the third place, he made important observations on the geology of South America; and, finally, he furnished new and interesting illustrations of the potent part taken by the denuding agents of nature in effecting the decay and disintegration of the land. Sir Archibald Geikie proceeded to review Darwin's work under each of these four heads, and to express his appreciation of it. Finally, he sketched the later geological work carried out by Darwin and the geological side of "The Origin of Species."

Another noteworthy outcome of the present commemoration is the special Darwin centenary number of the *Christ's College Magazine*.

The proceedings on June 23 were opened in the Senate House by the following address from the Chancellor of the University, Lord Rayleigh.

The Chancellor's Address.

In opening the proceedings to-day I must first, in the name of the University, bid welcome to the delegates and other guests who have honoured us by their presence. A glance at the list will show that we have assembled here distinguished men from all parts of the world who have willingly responded to our invitation; and, indeed, the occasion is no ordinary one. We have met to celebrate the centenary of the birth of Charles Darwin and the fiftieth anniversary of the publication of the "Origin of Species." I am old enough to remember something of the stir caused by the latter event. To many the results of Darwin's speculations were unwelcome, and it must be confessed remain so, at least in their application to the origin of man. Fifty years ago it would have been thought a strange prophesy if anyone had predicted to-day's celebration. We may perhaps take it as proven that Cambridge is not held so fast in the bonds of mediævalism as some would have us suppose. We are prepared to face whatever strict methods of investigation may teach to be the truth. I need not remind you that on many important questions raised by Darwin's labours opinions still differ, and I imagine that he would proudly recognise as disciples some of the distinguished biologists who meet here to do honour to his name. I do not attempt even the briefest survey of these labours. We shall presently hear appreciations from men of distinction well qualified to instruct us. What appeals to all is the character of the man, loved by everyone who knew him, and admired by everyone with a spark of the scientific spirit. It is a pleasure and a stimulus to think of him, working on in spite of ill-health in his study, in his garden, and in his hot-houses, and from his retirement moving the minds of thinking men in a manner almost without parallel. I esteem myself fortunate that a visit nearly forty-one years ago, which I owed to my friend, now Sir G. Darwin, allows me to picture the scene. I was struck, as were others, with his wonderful modesty. On my propounding some difficulty in connection with colour vision and the theory which attributed the colours of flowers to the preference of insects, I remember that he asked time for consideration before making a reply. His enthusiasm also impressed me much. This characteristic must have remained. Commenting on it only a short time before the death of both of them, Frank Balfour, himself a strenuous and sympathetic worker, remarked to me that he wished he could be as much interested in his own subject as Darwin was in other people's subjects.

During the last generation Cambridge has been active in biological work. We have the men and the ideas, but the difficulty has always been lack of funds. At the present time it is desired, among other things, to establish a chair of genetics, a subject closely associated with the name of Darwin and of his relative Francis Galton, and of the greatest possible importance, whether it be regarded from the purely scientific or from the practical side. I should like to think that the interest aroused by this celebration would have a practical outcome in better provision for the further cultivation in his own university and in that of his sons of the field wherein Darwin laboured.

At the conclusion of the Chancellor's address the presentation took place of the addresses by delegates from America, Austria-Hungary, Belgium, Denmark, Egypt, France, Germany, Greece, Holland, and Italy. Short speeches were then delivered by Prof. O. Hertwig and Prof. E. Metchnikoff.

Prof. Hertwig referred to the influence of Darwin's work upon German biology, particularly at Jena. It was through Haeckel, who hailed Darwinism with delight, and said that evolution was the key of man's destiny, that the theory became predominant in German science. It had been the starting point for all the researches of the younger men, and had entered into the life of the German people. Earlier this year festivals in commemoration of Darwin's work were held in Hamburg, Munich, Frankfurt, and other towns in Germany. The celebration at Cambridge was the acme of these festivals, and would give an immense stimulus to the scientific work of the delegates privileged to be present at it. The influence of Cambridge upon Darwin was great and beneficial, and particular mention must be made of the encouragement received from Henslow. Three bright stars had appeared in the scientific firmament of the University, the last being Darwin and the two others Harvey and Newton.

Prof. Metchnikoff in his address referred to the debt which medical science owes to the theory of organic evolution founded by Darwin. Diseases undergo evolution in accordance with the Darwinian law, and the recognition of this fact led to the science of comparative pathology. It is possible definitely to show that inflammation is an act of defence on the part of the organism against morbid agents, and that this reaction is effected by certain cellular elements, together with a complicated and wonderful nervous and vascular mechanism. The same elements play an important part in resisting disease. The preponderating influence of the cellular action in the mechanism of immunity is admitted by the great majority of observers. Recently experimental medicine has been investigating the phenomena of adaptation in pathogenic microbes, by virtue of which we are able to attack the organism in spite of its defensive powers, and this is most probably effected by the selection of individual microbes endowed with special properties. This has happened with the micro-organism of recurrent fever. With regard to cancer, the theory must be rejected that it is caused by stray embryonic cells, shut off and remaining latent, on the ground of evolution, because the lower animals, which also possess embryonic cells, never suffer from malignant growths except when they are provoked by external agents. It is therefore very probable that cancer in man is equally caused by some external agent, some virus which has been diligently sought, but has not yet been found.

Addresses were then presented by delegates from Japan, Norway, Portugal, Russia, Spain, Sweden, and Switzerland, and by delegates from the British colonies and the British Isles. After the English delegates had been presented, Sir Archibald Geikie, K.C.B., president of the Royal Society, said that the society desired to mark the importance of that occasion by having a special copy of the Darwin medal struck in gold for the acceptance of the University. It will be remembered that the medal owes its existence to the committee of the International Darwin Memorial Fund, which in 1885 transferred to the Royal Society the balance of the fund, in trust, to devote the proceeds from time to time toward the promotion of biological studies and research. The first award was made to Dr. Alfred Russel Wallace in 1890. Lord Rayleigh was the secretary of the society when the medal was cast. It was, therefore, Sir Archibald Geikie continued, a very great pleasure to the Royal Society to have it in its power to hand to Lord Rayleigh, for acceptance of the University, a copy of the Darwin medal.

The following address was then delivered by Dr. Henry Fairfield Osborn, the delegate of the American Philosophical Society:—

Prof. Henry F. Osborn.

Crossing the Atlantic in honour of Darwin and rejoicing in the privilege of uniting in this celebration of his birth, we desire, first of all, to render our tribute to the University of Cambridge.

To no other institution in any country may we turn with such a sense of filial gratitude. In ever widening growth has been the influence of the Cambridge heritage, as pictured more than four centuries ago in the generous mind of Sir Walter Mildmay, the founder of Emmanuel. "Sir Walter," remarked Queen Elizabeth, "I hear that you have erected a Puritan foundation." "No, madam," he replied, "far be it from me to countenance anything contrary to your established laws; but I have set an acorn, which, when it becomes an oak, God alone knows what will be the fruit thereof." Through John Harvard, of Emmanuel, Cambridge became the mother of our colleges. Did not Emmanuel beget Harvard, and Harvard beget Yale, and Harvard and Yale beget Princeton and other descendants to the third and fourth generation? We thus salute to-day the venerable but ever youthful ancestor of many of the American universities, academies, and institutes of science, national and State museums, represented here, and in large part guided by true sons of the true daughters of the Alma Mater on the Cam. Through the survival of the best our political guidance is also passing more and more into the hands of men trained in these same daughter colleges. A son of Yale succeeds a son of Harvard as President of the United States. If your university men are leading the Empire ours are leading the nation.

Noble offspring, too, of the many pious foundations of the old University, of Trinity, of Christ's, are the great men too numerous to name, among whom there especially rise in our minds Newton, Clerk-Maxwell, Balfour, and, above all, Darwin. Newton opened to us the new heavens and Darwin the new earth. Clerk-Maxwell, with Hertz, enabled us to converse across the sea through the blue æther. The well-beloved Balfour set forth Darwinism in embryology; would that his life had been spared for the more difficult problems of our day. If in our hours of struggle with the mysteries of nature these are our leaders and companions, so in our hours of ease and relaxation do we not turn again to sons of Cambridge for spiritual refreshment, to the verse of Milton, of Byron, of Wordsworth and Tennyson, all richly imbued with the nature spirit, or to the no less masterly prose of Thackeray and Macaulay?

Far away are the giant forces of our Republic, the roar of her machinery and her world of trade, yet more apparent than real is the independence of her development. There still prevails the potent unifying influence of mind and motive, bred in quiet places like this, ever creating new generations of leaders in science, in literature, and in government, and ever renewing the strong bonds of friendship and of union.

What can we add to the chorus of appreciation of the great pupil of Christ's, which has come from American college, Press, and pulpit, since the opening of this anniversary year? Only a few words of personal impression.

To us Darwin, more perhaps than any other naturalist, seems greatest in the union of a high order of genius with rare simplicity and transparency of thought. Dwelling on this lucid quality and on the vast range of his observation, from the most minute to the grandest relations in nature, does not the image arise of a perfected optical instrument, in which all personal equation, aberration, and refraction is eliminated, and through which, as it were, we gaze with a new vision into the marvellous forms and processes of the living world? With this wondrous lens our countrymen Cope and Marsh penetrated far deeper into fossil life than their predecessor Joseph Leidy—thus the arid deserts of the Rocky Mountains gave up their petrified dead as proofs of Darwinism. Through its new powers Hyatt, Morse, Packard, and Brooks saw far more than their master Louis Agassiz, and drew fresh proofs of the law of descent from the historic waters of New England. From the very end of the new world, where the youthful Darwin received his first impressions of the mutability of the forms of life, came a clearer vision of the ancient life of Patagonia.

The new vision opened upon a period of great men; and this again suggests a reminiscence. Thirty years ago two of the present delegates arrived in Cambridge as students. They heard Clerk-Maxwell developing his theories before the Cambridge Philosophical Society. Michael Foster was in his prime and lecturing in his inimitable manner. Francis Maitland Balfour had just completed his "Elasmobranch Fishes," and was working five hours a day on his "Comparative Embryology"; his lectures were brilliant and inspiring; his relations with students altogether ideal; in his rooms, among many others, one met Lankester and Moseley, and enjoyed a rare flow of conversation on all subjects except biology. Either as students or as young instructors were Sedgwick, Forbes, Shipley, Weldon, Haddon, Harmer, and others. In this Senate House Robert Browning, Spottiswoode, president of the Royal Society, and Huxley received their honorary degrees. Throughout the winter Huxley was delivering his remarkable lectures, "Darwinism in Comparative Anatomy," suggestive and with occasional flashes of humour, still strong and full of fire, but beginning to show the effect of years of overwork, of public service, and research. About once a week he came among his students. One day an unusual stir or thrill passed along the tables as with him entered Darwin, his first and only visit to a modern biological laboratory. Darwin paused for a few moments' conversation, and one received the strong impression of a ruddy face, benevolent blue eyes, very deep-set beneath the massive overhanging brow—a wonderful effect of kindliness and of the far-off world survey of a great naturalist.

What of Darwin's influence in the future? While it is doubtful if human speculation about life can ever again be so tangential or so astray on ultimate causes as in the pre-Darwinian past of fifty years ago, it is probable, in fact it is daily becoming more evident, that the destiny of speculation is less the tangent than the maze—the maze of several lesser principles, with as many prophets calling to us to seek this turning or that. There are those who, in loyal advocacy of his system, feel that we shall not get much nearer life than Darwin did; but this is to abandon his progressive leadership, for if ever a master defined the unknown and pointed the way of investigation, certainly it was Darwin. In the wonderful round of addresses in his honour of this centennial year and in the renewed critical study of his life and writings, the recognition that Darwin opened the way has come to many with the force of a fresh discovery. It is true that he left a system, and that he loved it as his own, but his forceful, self-unsparing, and suggestive criticisms show that if he were living in these days of Waagen, of Weismann, of Mendel, and of de Vries, he would be in the front line of inquiry, armed with inventive genius, with matchless assemblage of fact, with experiment and verification, and not least with incomparable candour and good-will. This bequest of a noble method is hardly less precious than the immortal content of the "Origin of Species" itself.

In conclusion, we delegates, naturalists, and friends, desire to present to Christ's College, as a memorial of our visit, a portrait of Charles Darwin in bronze, the work of our countryman William Couper, a portrait which we trust will convey to this and future generations of Cambridge students some impression of the rugged simplicity, as well as of the intellectual grandeur, of the man we revere and honour.

The speech next delivered by Sir Ray Lankester was an eloquent appreciation of Darwin's work and an unequivocal vindication of the theory of the origin of species by the preservation of minute variations favourable to existence under prevailing natural conditions.

SIR RAY LANKESTER, K.C.B., F.R.S.

I feel it a great honour to be called upon to speak here to-day, and to stand, on behalf of the naturalists of the British Empire, by the side of the distinguished men whose orations you have just heard.

I think that the one thing about Charles Darwin which the large majority of British naturalists would wish to be to-day proclaimed, in the first place—with no doubtful or qualifying phrase—is that, in their judgment, after these fifty years of examination and testing, his "theory of the origin of species by means of natural selection or the preservation of favoured races in the struggle for life" remains whole and sound and convincing, in spite of every attempt to upset it.

I am not stating more than the simple truth when I say that, in the judgment of those who are best acquainted with living things in their actual living surroundings, "natural selection" retains the position which Mr. Darwin claimed for it of being the main means of the modification of organic forms.

Our admiration for the vast series of beautiful observations and interesting inquiries carried out by Darwin during his long life must not lead us to forget that they were devised by him in order to test the truth of his theory and to meet objections to it, and that they were triumphantly successful. They, together with the work of Alfred Russel Wallace and many of their followers, have more and more firmly established Darwin's theory. On the other hand, no attempt to amend that theory in any essential particular has been successful.

The nature of organic variation and of the character of the variations upon which natural selection can and does act was not, as we are sometimes asked to believe, neglected or misapprehended by Darwin. The notion that these variations are large and sudden was considered by him, and for reasons set forth by him at considerable length rejected. That notion has in recent years been resuscitated, but its truth has not been rendered probable by evidence either of such an accurate character or of such pertinence as would justify the rejection of Darwin's fundamental conception of the importance of minute and ubiquitous variations.

Further, in regard to the important facts of heredity connected with the cross-breeding of cultivated varieties, especially in regard to the blending or non-blending of their characters in their offspring and as to prepotency, it seems to me important that we should now and here call to mind the full and careful consideration given to this subject by Darwin. We cannot doubt that he would have been deeply interested in the numerical and statistical results associated with the name of Mendel. Those results tend to throw light on the mechanisms concerned in hereditary transmission, but it cannot be shown that they are opposed in any way to the truth of Darwin's great theoretical structure—his doctrine of the origin of species.

It has often been urged against Darwin that he did not explain the origin of variation, and especially that he has not shown how variations of sufficient moment to be selected for preservation in the struggle for existence have in the first place originated. The brief reply to the first objection is that variation is a common attribute of many natural substances of which living matter is only one. In regard to the second point, I desire to remind this assembly that Darwin described with special emphasis instances of what he calls "correlated variability." In my opinion he has thus furnished the key to the explanation of what are called useless specific characters and of incipient organs. That key consists in the fact that a general physiological property or character of utility is often selected and perpetuated, which carries with it distinct, even remote, correlated growths and peculiarities obvious to our eyes, yet having no functional value. At a later stage in the history of such a form these correlated growths may acquire value and become the subject of selection.

It is thus, as it seems to me, and as, I believe, to the great body of my brother naturalists, that Darwin's theory stands after fifty years of trial and application.

The greatness of Charles Darwin's work is, and will be for ever, one of the glories of the University of Cambridge. It is fitting on the present occasion that one who speaks on behalf of English men of science should call to mind the nature of his connection with this great University and the peculiarly English features of his life-story and of that fine character which endears his memory to all of us as much as his genius excites our admiration and reverence. Darwin was not, like so many a distinguished son of Cambridge, a scholar or a fellow of his college, nor a professor of the University. His connection with the University and the influence which it had upon his life belong to a tradition and a system which have survived longer in our old English universities than in those of other lands. Darwin entered the University, not seeking a special course of study with the view of professional training, nor aiming at success in competitive examinations for honours and emolument. He came to Cambridge intending to become a clergyman, but blessed with sufficient means and leisure to enable him to pursue his own devices, to collect beetles, to explore the fen country, and to cultivate his love of nature. It was thus that he became acquainted with that rare spirit Henslow, the Cambridge professor of botany, and it is through Henslow and the influence of his splendid abilities and high personal character upon Darwin that Cambridge acquired the right to claim the author of the "Origin of Species" as a product of her beneficence and activity as a seat of learning.

As an Oxford man and a member of Exeter College, I may remind this assembly that in precisely the same way Darwin's dearest friend and elder brother in science, Charles Lyell, had a few years earlier entered at Exeter College, and by happy chance fallen under the influence of the enthusiastic Buckland, the University reader in geology and a Canon of Christ Church. The wise freedom of study permitted and provided for in those long-passed days by Oxford and Cambridge is what has given the right to claim the discovery, if not the making, of Lyell to the one and of Darwin to the other.

Darwin's love of living nature and of the country life are especially English characteristics; so, too, I venture to think, are the unflinching determination and simple courage—I may even say the audacity—with which he acquired, after he had left the University, the wide range of detailed knowledge in various branches of science which he found necessary in order to deal with the problem of the origin of the species of plants and animals, the investigation of which became his passion.

The unselfish generosity and delicacy of feeling which marked Darwin's relations with a younger naturalist. Alfred Russel Wallace, are known to all. I cannot let this occasion pass without citing those words of his which tell us most clearly what manner of man he was and add to his splendid achievements as an intellectual force—a light and a beauty of which every Englishman must be proud. When in old age he surveyed his life's work he wrote:—"I believe that I have acted rightly in steadily following and devoting my life to science."

To have desired to act "rightly" and to be able to think of success in life as measured by the fulfilment of that desire is the indication and warrant of true greatness of character. We Englishmen have ever loved to recognise this noble kind of devotion in our national heroes.

In connection with the celebration, several learned bodies conferred honours upon the Chancellor, and upon Mr. Francis Darwin, F.R.S., and Sir George Darwin, K.C.B., F.R.S. Among these marks of recognition were the following:—Lord Rayleigh (Chancellor), corresponding member of the Senkenbergische Naturforschende Gesellschaft, Frankfurt-am-Main, and honorary member of the University of Moscow; Mr. Francis Darwin, member of the American Philosophical Society, foreign member of the Société Hollandaise des Sciences, corresponding member of the Senkenbergische Naturforschende Gesellschaft, Frankfurt-am-Main, honorary member of the Soc. Cæs. Naturæ Curiosorum, Moscow, honorary member of the University of Moscow, and Fellow of the Kaiserliche Leopoldinisch-Carolinische Deutsche Akademie der Naturforscher, Halle; Sir George Darwin, corresponding member of the Senkenbergische Naturforschende Gesellschaft, honorary member of the Soc. Cæs. Naturæ Curiosorum, Moscow, honorary member of the University of Moscow, and Fellow of the Kaiserliche Leopoldinisch–Carolinische Deutsche Akademie der Naturforscher, Halle.

SPEECHES AT THE BANQUET.

At the banquet on June 23 Mr. Balfour and Prof. Svante Arrhenius proposed the toast which was drunk in silence to the memory of Darwin. In the course of his remarks Mr. Balfour said:—

Charles Darwin's performances have now become part of the common intellectual inheritance of every man of education wherever he lives or whatever his occupation or trade in life. To him we trace in the main the view which has affected, not merely our ideas of the development of living organisms, but our ideas upon politics, upon sociology, ideas which cover the whole domain of human terrestrial activity. He is the fount and origin, and he will stand for all time as the man who has made this great, and, as I think, beneficent revolution in the mode in which educated men can see the history, not merely of their own institutions, not merely of their own race, but of everything which has that unexplained attribute of life, everything that lives on the surface of the globe or within the depths of the ocean. He is the Newton of this great department of human research, and to him we look, as we looked to Newton, to measure out heavens or to weigh suns and their attendant planets. After all, the branch of research which he initiated is surely the most difficult of all. I talk of measuring heavens and weighing suns, but surely these are tasks incomparably easy compared with the problem that attracts the physiologist and the morphologist in dealing with the living cell, be it plant, or animal, or man. That problem of life is one which it is impossible for us to evade, which it may be impossible for us ultimately to solve, but in dealing with which in its larger manifestations Charles Darwin made greater strides than any man in the history of the world has made before or any man has made since.

Prof. Arrhenius then spoke as follows :—

Evolutional ideas are as old as human civilisation. We find traces of them in old Egyptian legends of the growth of mankind, in Hindu myths, as well as in the cosmogony of Herod and in Ovid's Metamorphoses. During the lapse of centuries they were developed by philosophers and astronomers, *i.e.* by the men of the oldest sciences; and in the eighteenth century, when most modern sciences took a distinct shape, those ideas formed important parts of the scientific work of Kant, and still more in the admirable theoretical speculations of Lamarck. But still the finalist school, founded on primitive and mediæval considerations, was in the highest degree preponderant; and the leading biologist at the end of that century, Cuvier, had no conception of evolutionism. Even in Kant's works we find the finalistic ideas prevailing.

To accomplish the now prevailing evolutionary ideas a great work was necessary, in order that these should be developed into a system embracing all the biological sciences with the strictest logic and severest criticism. The attempts made at the beginning of the nineteenth century by many scientific men, amongst whom the name of Charles Darwin's grandfather, Erasmus Darwin, may be recalled, were far from sufficient. The epoch-making work was delivered by Charles Darwin, who, with an unrivalled patience and diligence, as well as a rare impartiality, during nearly thirty years, collected and sifted the enormous material upon which is based his masterly work "The Origin of Species."

It must be said that the time was ripe for the triumph of the conception of evolution, as is clearly indicated by the simultaneous work of Wallace on biology and by the publication of Herbert Spencer's philosophical investigations. Charles Darwin was also immediately followed by enthusiastic and prominent adherers, such as Huxley and Haeckel, who propagated and worked out the new doctrines.

This rapid success also caused a strong reaction from the side of the representatives of the old finalistic ideas, grown strong through centuries. The battle fought between the two parties carried the new ideas into common life, far from the men of science and the philosophers' study. During the last decade of his life Darwin had the good fortune to see his ideas brought to definite victory and generally accepted, not only in the vast domain of biology, which has been spoken of so eloquently this morning, but even by scientific men in general, and by the enlightened public opinion.

Charles Darwin had a clear perception of the far-reaching importance of his ideas. He applied them in elaborate investigations concerning the development of the intellectual and reflective faculties, to the formation of primitive social ideas amongst animals and men, to the genesis of the most elementary moral and religious conceptions, as well as to the fundamental problems of anthropology.

The more these various questions have been discussed the more the doctrine of evolution has grown in strength, and the greater has been the extent to which science has been brought under its beneficent influence. Nowadays there is hardly a science which has not been affected and in many cases thoroughly permeated by it. The sociological and statistical sciences now rest on an evolutional basis; history, and especially the history of culture, has found through it new lines of development; the linguist tries to find the natural laws of development of languages; the lawyer sees the legislative work of past generations and foresees their future modifications from the standpoint of evolution; the criminalist seeks the sources of crime in the influence of heredity and environment; and even the theologian, who for so long a time rejected the new ideas, finds now in them essential points of high ethical charm which he seeks to reconcile with true religion. At the same time, the investigators in exact sciences, where the doctrine of evolution had been adopted earlier than in biological sciences, were inspired to new and successful efforts to use it, as is, for example, obvious from the researches of Sir George Darwin, who, as well as the other members of the family, is a brilliant example of the heredity of intellectual properties.

Science is international; and this momentous movement has been felt in every country in the civilised world. Therefore we, representatives of all sciences, have come from all parts of the world to join you in doing homage to the memory of the greatest of all evolutionists.

All of us are profoundly sensible that the great intellectual revolution which is due to the introduction of evolutionism is the most important event in the development of the human mind, since the mighty political movement which began with the storming of the Bastille 120 years ago. There is, however, this significant difference between that time and this, that whereas in such a period every mighty change in the social, political, and intellectual development of mankind was only effected by strife and horrors of war, to-day, thanks to the civilising progress, this change has been accomplished by reason and persuasion. "The pen has been mightier than the sword." How much may we not congratulate ourselves that we have lived in such a period? In reality, the doctrine of evolution is inconsistent with violence, and we may hope, therefore, that it will give a mighty impetus to the maintenance of peace and a good understanding between civilised nations.

In conclusion, let me say that in thus venerating Darwin's memory all men of science regard him, not only as an ideal man of science, but as a man of science whose power and influence have been enhanced by his integrity and moral worth.

In replying to the toast, Mr. W. Erasmus Darwin related some interesting incidents as to Darwin's kindly and considerate nature in his home life. The toast of "The University of Cambridge" was proposed by Prof. E. B. Poulton, F.R.S., who asked whether the comparative freedom enjoyed by Darwin in his college life would be possible in these days of examination pressure. The vice-chancellor, in responding to the toast, said it was hoped that Dr. Wallace would attend the celebration and receive an honorary degree at Cambridge, but his health would not permit him to accept the invitation. The suggestion had been made (we understand it came from Prof. Meldola) that a message should be sent to Dr. Wallace; and the vice-chancellor announced that the following telegram had been sent :—"The naturalists, assembled at Cambridge for the Darwin celebration, cannot forget your share in the great work which they are commemorating, and regret your inability to be present."

On Thursday, June 24, the concluding day of the celebration, honorary degrees were conferred upon twenty-one of the delegates, and Sir Archibald Geikie delivered the Rede lecture already mentioned. The

Public Orator, Dr. Sandys, spoke as follows in presenting the several distinguished recipients of the degree of Doctor of Science *honoris causa* :—

PRINCE ROLAND BONAPARTE.—Agmen honorum nostrorum ducit hodie imperatoris magni fratris natu minoris nepos, cuius avunculi insignes scientiarum e provinciis inter se diversis palmas plurimas tulerunt. Ipse, Francogallorum in Republica maxima, et Instituti celeberrimi socius et Societatis Geographicae praeses iure optimo est electus. Olim geologiae, botanicae, zoologiae, anthropologiae studiis non sine gloria deditus, non modo gentis suae incunabula, insulam Corsicam, sed etiam orientem versus solem insulas remotiores victor felix exploravit. Idem orbis veteris e scientiarum castris trans aequor Atlanticum pacis satelles est profectus, velut alter Caesar

"victrices aquilas alium laturus in orbem." [1]

EDOUARD VAN BENEDEN, PROFESSOR OF ZOOLOGY AT LIÈGE.—Ductori nostro proximus progreditur Belgarum e gente vicina, Leodiensium ex Universitate insigni, professor praeclarus, Biologiae Archivorum fundator, cytologiae hodiernae conditor, qui, in opere singulari de *Ascaride megalocephala* conscripto, utriusque sexus cellularum nucleos etiam in morphologia idem valere diligenter demonstravit. Idem de vespertilionum, rodentium, crustaceorum, tunicatorum embryologia, deque *Dicyemidorum* formis egregie disputavit. Atqui haec omnia nonnullis vestrum quam nobis notiora sunt; illud autem nobis non ignotum, zoologiae professorem tam illustrem Francisci Balfourii nostri amicum olim fidelem fuisse.

OTTO BUTSCHLI, PROFESSOR OF ZOOLOGY AT HEIDELBERG.—Zoologiae professorem Heidelbergensem ovi cellulae in auctu investigando plurimis praecursorem praeclarum exstitisse constat. Idem *Infusoriorum* de vita tota, cellularum binarum praesertim de coniugatione, opus egregium conscripsit; in aliorum et sui ipsius circa *Protozoa* laboribus recensendis, ceteros superavit; etiam bacteriorum ipsam structuram explicavit; porro, in *Protozois* et *Protophytis* illis quae nomine uno *Protista* appellantur, amylum quomodo conformatum, quomodo distributum sit, aperte demonstravit; olim denique, non sine labore multo et minuto, *protoplasma* non iam reticulatam sed alveolarem quandam formam spumeam habere comprobavit. Nonnullorum fama cito peritura, velut spuma in fluctibus summis evanescit; viri huius in rerum natura penitus explorauda virtutem, "merses profundo; pulchrior evenit." [2]

ROBERT CHODAT, PROFESSOR OF BOTANY AT GENEVA.—Genevensi in Universitate, abhinc annos plus quam centum, plantarum physiologiae chemicae scientiam condidit vir illustris, Horatius Benedictus de Saussure. In eadem doctrinae sede viri tanti vestigiis summa cum laude insistit botanicae professor insignis, quem hodie salutamus. Scientiae illius de principiis praeclare disputavit; experimentis plurimis adhibitis, plantarum cotidie crescentium leges explicavit; fermentorum denique in plantis naturam ipsam patefecit. Idem, florum in scientia universa sollertissimus, non modo herbario celeberrimo inter populares suos praefuit, sed etiam algas virides minutissimas illas, quae patriae pulcherrimae lacus immensos incolunt, arte eximia depinxit, libro egregio descripsit.

FRANCIS DARWIN, HONORARY FELLOW OF CHRIST'S COLLEGE.—Patris illustris e filiis insignibus adest unus, qui patris cum operibus consociatus ultimis, viri tanti vitam et litteras diei in lucem non sine laude protulit. Botanicae provincia physiologica et libris et experimentis suis inter nosmet ipsos praeclare propagata, patris a Collegio propterea honoris causa socius merito est nominatus. Nuper, in libro egregio patris sui in honorem a plurimis conscripto, ipse et patris et sua et aliorum de motibus plantarum inventa luculenter perlustravit. Idem in anno praeterito Societatis Britannicae scientiarum finibus proferendis disputationes oratione egregia auspicatus, plantarum in motibus explicandis, plantis ipsis annorum volventium in serie memoriam quandam tribuebat. Hanc potissimum ob causam, non modo patris, sed etiam proavi, Florae poëtae eximii, ingenium praeclarum utriusque in progenie revixisse crediderim.

KARL F. VON GOEBEL, PROFESSOR OF BOTANY IN MUNICH.—Bavaria ad nos misit Florae ministrum insignem Monacensem, qui, post peregrinationes longinquas in India, in Venezuela, in Australia toleratas, de studiis suis pulcherrimis cum oratore Romano potest dicere :—"haec studia delectant domi; haec studia nobiscum peregrinantur." [1] Florum de biologia universo, florum de formis inter se diversis et originis et loci e natura varia exortis, florum de partibus minutissimis accuratissime describendis, quam praeclare meritus est! Darwini nostri de florum scientia inventa insignia quam penitus perscrutatus est; etiam ipse rerum naturae provinciae illius pulcherrimae in penetralia intima quam feliciter penetravit!

LUDWIG VON GRAFF, PROFESSOR OF ZOOLOGY AT GRAZ.—Salutamus deinceps virum genere insigni natum, Academiae et Berolinensis et Vindobonensis socium, in Universitate Graecina zoologiae professorem iucundissimum, qui liliorum marinorum parasiti cuiusdam anatomiam impeditam primus explicavit; quique non modo opera tria egregia de *Turbellariis* conscripsit, sed etiam de animalium parasitis in universum praeclare disputavit. Hodie vero magis iucundum, immo magis opportunum est, orationem illam eximiam recordari, quam abhinc annos tredecim zoologiae post Darwinum nostrum fortunis describendis dedicavit. Quod autem ad annum proximum attinet, auguramur virum tanta benignitate, tanta comitate praeditum, gentium omnium zoologis in Universitatem suam convocatis praesidem fore sine dubio acceptissimum.

RICHARD HERTWIG, PROFESSOR OF ZOOLOGY IN MUNICH.—Zoologiae professorem insignem Monacensem deinceps contemplatus, protinus videor mihi ante oculos ponere "par nobile fratrum." [2] Cum fratre suo illustri Berolinensi consociatus, quem hodie praesentem honoris causa salutamus, *Medusarum* et *Polyporum* de nervis sensibusque, anemones marinae de embryologia et anatomia, cellularum in universum de morphologia et physiologia, animantium denique de corporis inferioris intervallo quodam interiore quod κοῖλον nominatur, plurima praeclare conscripsit. Ipse, non modo zoologiae studiosis encheiridion doctrinae variae plenum donavit, sed etiam peritiorum in usum de *Radiolariorum* morphologia, de *Actiniariis* a nostratibus e profundo mari reportatis, de *Protozoorum* denique structura vitaque tota, erudite disputavit. Per orbem terrarum totum nota est praeceptoris tanti schola zoologica Monacensis, ex qua, "tamquam ex equo Troiano," [3] tot milites optimi exierunt.

HARALD HÖFFDING, PROFESSOR OF PHILOSOPHY AT COPENHAGEN.—Philosophiae professorem insignem Hauniensem Darwini in honorem legatum esse missum nemo mirabitur, qui ex opere eius novissimo didicit inter philosophiam et rerum naturae scientiam prorsus distinguere perquam esse arduum. Philosophiae in historia sua in tot linguas reddita, quid potissimum spectet, fortasse requiritis. Respondeo :—philosophi cuiusque personam. Etiam in psychologiae studio, quid praesertim praesumit? Personam. Deinde, religionis in philosophia, et officiorum in finibus proponendis, quid demum magis indies ante oculos nostros positum esse existimat? Ordinis magis continui adpetitio, partim in unaquaque persona, partim inter se diversis in personis. Quid denique professorem ipsum, non modo Reginae nostrae, populari suae, sed etiam amicis suis omnibus, tam amabilem reddit? Ipsius persona. Videtis virum sagacem, qui caritate summa adversus omnes imbutus, "omnia sperat"; [4] quique ingenio bene temperato, animo bene librato praeditus, monitum illud Horatianum constanter conservat :—"aequam memento rebus in arduis servare mentem." [5]

JACQUES LOEB, PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF CALIFORNIA.—Oceani Pacifici a litore legatus ad nos advectus est Californiae in Universitate physiologiae professor, veritatis indagator pertinax, qui, experimentis exquisitis adhibitis, rerum earum, quarum in medio animalia versantur, effectus inter se diversos distinguere est conatus. Non modo de caloris sed etiam de coloris et luminis vi, de geminorum origine, echinorum denique de ovi maturitate aut sanguine iniecto aut sale infuso in maius exaucta, quam subtiliter disputavit! Etiam in alia rerum provincia, Horati in saeculo, Epicuri

[1] Lucan, v. 238. [2] Horace, *Carm.* iv. 4, 65.

[1] Cp. Cicero, *pro Archia*, 16. [2] Horace, *Serm.* ii. 3, 243.
[3] Cicero, *De Oratore*, ii 94. [4] S. Pauli *Ep. ad Cor.* 1, xiii. 7.
[5] *Carm.* ii. 3, 1.

(nisi fallor) sectator quidam tractabat "echinos, ut melius, muria."[1]

EDMOND PERRIER, DIRECTOR OF THE NATURAL HISTORY MUSEUM, PARIS.—Sequitur deinceps Francogallorum Instituti celeberrimi et Academiae Medicae socius insignis, qui historiae naturalis Museum Parisiense tutelae suae creditum optime ordinavit. Olim, in philosophiae zoologicae incrementis enarrandis, populari suo, Stephano Godofredo Saint-Hilaire, inter Darwini nostri praenuntios locum praeclarum vindicavit. Ipse postea zoologiae universae describendae opus eximium consecravit. Quid dicam de animalium coloniis ab eodem accuratissime examinatis? quid de vermibus terrenis, quid de maris Mediterranei liliis dilucide descriptis? Illud unum dixerim: mari profundo penitus explorando plus quam semel peregre praefuit, interque rerum naturae interpretes optimos exstitit, qui patriae in gloriam numquam perituram

> "referebant navibus altis
> occulta spolia, et plures de pace triumphos."[2]

GUSTAV ALBERT SCHWALBE, PROFESSOR OF ANATOMY AT STRASSBURG.—Anatomiae professor Argentoratensis, in Aegypto et in America Septentrionali orbis novi et orbis antiqui explorator, anthropologiae provinciam totam peragravit; sensuum humanorum rationem universam explicavit; hominum antiquissimorum capita et ossa hic et illic reperta accuratissime descripsit. Homo est; humani nil a se alienum putat.[3] Stilo perquam lucido praeditus, non modo *Hominem primigenium* sed etiam *Pithecanthropum erectum* litterarum monumentis mandavit. Atqui, si antiquas quoque litteras licet hodie recordari, non de hominis propinquo quodam paupere, non de simia quadam mentis sublimioris nescia, sed de homine ipso donis optimis divinitus donato poëtae antiqui verba illa dicta sunt:—

> "os homini sublime dedit, caelumque tueri
> iussit, et erectos ad sidera tollere vultus."[4]

HERMANN GRAF ZU SOLMS-LAUBACH, PROFESSOR OF BOTANY AT STRASSBURG.—Salutamus etiam botanicae professorem Argentoratensem, virum genere antiquo, genere per annos prope octingentos nobili oriundum, qui arborum et plantarum reliquias antiquissimas saxorum in latebris conservatas opere in illo eximio descripsit, quod etiam in Britannia palaeophytologiae ad studium aditus faciliores plurimis patefecit. Idem, non modo Actis Botanicis edendis iam per annos viginti feliciter interfuit, sed etiam ipse de geographiae botanicae principiis, de floribus parasitis, de fungis et algis, de sinus Neapolitani corallinis, de fragaria, de tritico, de tulipa, de ficu, de aliis denique hortorum nostrorum plantis plurima non sine gloria conscripsit.

> "Patriam obruit olim
> gloria paucorum, et laudis titulique cupido
> haesuri saxis cinerum custodibus, ad quae
> discutienda valent sterilis mala robora ficus";[5]

haec autem generis nobilis progenies, vir iucundus, lepidus, modestus, titulo nostro dignissimus, tot rebus ingenio summo penitus exploratis, omnium bonorum in laude "monumentum aere perennius" invenit.

CLEMENT TIMIRIAZEFF, PROFESSOR OF BOTANY IN MOSCOW.—Meministis fabulosum illum Collegiorum nostrorum unius alumnum, qui ad insulam *Laputa* peregrinatus, incolas eius omnes solis de salute cotidie sollicitos invenit, inque Academia celeberrima Lagadensi professorem quendam venerabilem vidit, qui solis radiis e cucumerum cellulis eliciendis annorum octo labores incassum impenderat. Consilium tam mirum non prorsus absurdum fuisse botanicae professor quidam Moscuensis coram Regia Societate nostra non sine lepore indicavit. Scilicet per longos labores ipse comprobavit non modo solis radios in cucumi esse inclusos, sed etiam fructuum frondiumque omnium partem viridem solis e lumine radios illos tremulos eligere, quorum auxilio carbonium (ut aiunt) in aëre toto diffusum in materiam quandam vivam permutat. Idem spectri (quod dicitur) e parte rubra radios illos exortos esse docuit, qui frondium in vitam mutati, omnium hominum, omnium animalium corpora per tot saecula aluerunt. Ergo de spectri illius exemplo pulcherrimo, de arcu caelesti, verba olim divinitus dicta saeculo nostro sensu novo denuo commendata sunt—"Erit arcus in nubibus, et recordabor foederis sempiterni quod pactum est inter Deum et omnem animam viventem universae carnis, quae est super terram."[1]

FRANTIŠEK VEJDOVSKÝ, PROFESSOR OF ZOOLOGY IN PRAGUE.—Bohemorum in Universitate Pragensi zoologiae professor praeclarus, patriae inter flumina lacusque, spongillarum vermiumque in varietate maxima, studiorum suorum argumenta plurima invenit. Idem, bacteriorum in structura investiganda, etiam nucleum secundum ipsam normam invenisse dicitur. Deinde, de nucleorum natura in universum, deque ovi fecundi reddendi ratione omni, nunc maxime inquirit. Denique, ne laudationis nostrae in fine aculeum quendam desideretis, ne scorpionum quidem genus intactum reliquit.

MAX VERWORN, PROFESSOR OF PHYSIOLOGY AT GOTTINGEN.—Goettingensis Universitas, vinculo antiquo cum Britannis coniuncta, legatum ad nos misit physiologiae professorem insignem, virum ingenio versatili et multiplici praeditum, qui non modo archaeologiae regionem antiquissimam, aevi medii artes, scientiam denique numismaticam temporis subsicivi in deliciis habuit, sed etiam ante omnia scientiae illi magnae quae vitam universam investigat vitam prope totam dedicavit. Peritis notum est (ne minora commemorem) opus illud ingens annorum quattuordecim in spatio iam quinquies in lucem editum, in quo a cellulis singulis exorsus physiologiae provinciam totam ita peragravit, ut non modo scientiae ipsius historiam, philosophiam, psychologiam ipse suo Marte tractaverit, sed etiam aliorum inventa praeclara ingenii sui lumine illustraverit.

HERMANN VON VÖCHTING, PROFESSOR OF BOTANY AT TUBINGEN.—Florae in sacerdote celeberrimo Tuebingensi Darwini nostri discipulum praeclarum agnoscimus, qui plantarum in motibus accuratissime examinandis felicissimus, docet libramento quam exquisito nutet tremulae flos violae, caput aureolum exserat narcissus; quanta sollertia herba quaeque viridis frondes suas ita explicet, ut solis lumen vitale quam plurimum accipiat. Idem, "polaritatis" secundum legem quandam, ostendit in arborum ramis amputatis quantum a parte summa pars ima discrepet; quot quaestiones subtilissimas sapientissimo cuique subiciat rusticus ille simplex, qui ex omni hominum memoria in perpetuum conservat,

> "quos ipse via sibi repperit usus:
> hic plantas tenero abscindens de corpore matrum
> deposuit sulcis, hic stirpes obruit arvo."[2]

HUGO DE VRIES, PROFESSOR OF BOTANY AT AMSTERDAM.—Darwini nostri in memoriam decoramus hodie botanicae professorem Amstelodamensem, virum a Societate Regia numismate aureo Darwini in honorem instituto donatum. Quam pulchre ostendit, quam varium, quam mutabile sit florum genus illud pulchrum quod primula vespertina vel potius *Oenothera* nominatur! Alii, inter quos honoris causa Raium nostrum[3] nominamus, aiunt; "Natura non facit saltus"; hic autem speciem unamquamque, non e fluctuatione tam tarda ut oculorum aciem effugiat, sed e mutatione subita censet exoriri. Natura saltus igitur nonnumquam facit.

CHARLES DOOLITTLE WALCOTT, SECRETARY OF THE SMITHSONIAN INSTITUTE, WASHINGTON.—Trans aequor Atlanticum alter ad nos venit legatus insignis, Instituti celeberrimi Washingtonensis administrator indefessus, Americanorum in Republica maxima explorationi geologicae universae quondam praepositus. Zonae Olenelli, rupium illarum antiquissimarum, in quibus vitae formae fossiles (ut aiunt) repertae sunt, de incolis extinctis praeclare disputavit. Idem Cambriae in saxis, non modo *Brachiopoda* subtilissime examinavit, sed etiam *Trilobites* illos, quorum in oculo uno saxi in caligine aeterna clauso radiorum lucidorum sex milia olim scintillabant. Rerum natura, in magnis magna, in minimis quam immensa!

EDMUND BEECHER WILSON, PROFESSOR OF ZOOLOGY IN THE COLUMBIA UNIVERSITY, NEW YORK.—Populari suo proximus adsurgit Novi Eboraci in Universitate Colum-

[1] *Serm.* ii. 8, 52 f. [2] Juvenal, viii. 106 f. [3] Terence, *Heaut.* 77. [4] Ovid, *Met.* i. 85 f. [5] Juvenal, x. 143 f.

[3] John Ray, *Historia Plantarum*, i. (1686) 50, "Cum enim *Natura* (ut dici solet) *non faciat saltus*, nec *ab extremo ad extremum transeat*, *nisi per medium* . . ."; cp. Linnaeus, *Philosophia Botanica* (1770), p. 27, § 77.

biana zoologiae professor, qui saltationes illas *karyokinesis* nomine nuncupatas descripsit, quas ovorum in cellulis dividendis nucleorum fragmenta certatim exercent. In insectis autem nonnullis, docente doctore nostro novo, determinatur sexus, prout nucleorum fragmentum unum aut adest aut abest. Genus femininum tot fragmenta efficiunt; fragmenta uno tantum minora masculinum. Videtis, Academici, discrimine quam tenui genus masculinum a genere feminino separetur, ne dicam superetur.

CHARLES RENÉ ZEILLER, PROFESSOR OF PALÆOBOTANY IN PARIS.—E tot doctoribus supremus adest Francogallorum Instituti celeberrimi socius, palaeobotanicae professor praeclarus Parisiensis, qui iam per annos triginta plantas fossiles (ut aiunt) accuratissime examinavit; Africae, Americae, Indiae, Asiae Minoris flores extinctos non sine summo iudicio, non sine summo ingenio, investigavit. Viri huius auxilio, Florae antiquae e monumentis non iam unum alterumve capitulum perbreve, non iam paginae cuiusque lineae paucissimae, sed novae paginae plurimae, orbis terrarum quasi vitae perpetuae ad catenam continuam anulos novos addiderunt.

> "Sic unumquicquid paulatim protrahit aetas
> in medium, ratioque in luminis erigit oras.
> namque alid ex alio clarescere et ordine debet
> *omnibus*, ad summum donec venere cacumen."[1]

Rerum naturae seriem aeternam claudit *Homo sapiens*: honorum nostrorum seriem hodiernam claudit vir in Flora antiqua sapientissimus, Carolus Renatus Zeiller.

[1] Lucretius, v. *ad finem*.

A NEW ANALYTICAL ENGINE.

THE April number of the Scientific Proceedings of the Royal Dublin Society contains an interesting and very original paper by Mr. Percy E. Ludgate on a proposed analytical machine. Of all calculating machines, the analytical machine or engine is the most comprehensive in its powers. Cash till reckoners and adding machines merely add or add and print results. Arithmometers are used for multiplying and dividing, which they really only accomplish by rapidly repeated addition or subtraction, with the exception alone, perhaps, of the arithmometer of Bollée, which, in a way, works by means of a mechanical multiplication table. Difference engines originated by Babbage produce and print tables of figures of almost any variety, but the process is one of addition of successive differences. The analytical engine proposed by Babbage was intended to have powers of calculation so extensive as to seem a long way outside the capacity of mere mechanism, but this was to be brought about by the use of operation cards supplied by the director or user, which, like the cards determining the pattern in a Jacquard loom, should direct the successive operations of the machine, much as the timing cam of an automatic lathe directs the successive movements of the different tools and feeding and chucking devices. However elaborate the mechanism of Babbage, if completed, might have been, the individual elements of operation would, so far as the writer has been able to understand it, have been actually operations of addition or subtraction only, and, with the exception of the method of multiplication created by Bollée, the writer does not recall any case in which mechanism has been used to compute numerical results except by the use of the processes of addition or subtraction, simple or cumulative. Of course, harmonic analysers and other instruments depending on geometry are not included in the category of machines which operate on numbers.

The simplicity of the logarithmic method of multiplying must have made many inventors regret the inherent incommensurability of the function to any simple base, or, if commensurability is attained for any particular number and its powers by the use of an incommensurable base, the incommensurability of the corresponding logarithms of numbers prime to those first selected. On this account the writer has always imagined that the logarithmic method was unsuited to mechanism, or, if applied at all, could only be so applied at the expense of complication, which would more than compensate for the directness of the process of logarithmic multiplication.

Mr. Ludgate, however, in effect, uses for each of the prime numbers below ten a logarithmic system with a different incommensurable base, which as a fact never appears, and is able to take advantage of the additive principle, or, rather, it is so applied that the machine may use it. These mixed or Irish logarithms, or index numbers, as the author calls them, are very surprising at first, but, if the index numbers of zero be excepted, it is not difficult to follow the mode by which they have been selected. The index numbers of the ten digits are as follows:—

Digit	0	1	2	3	4	5	6	7	8	9
Index number.	50	0	1	7	2	23	8	33	3	14

When two numbers are to be multiplied, the index numbers of the several digits are mechanically added to the index numbers of each of the digits of the other, and, the process of carrying the tens being carried on simultaneously, the time required is very small. For instance, the author gives as an example the multiplication of two numbers of 20 digits each, which will require 40 of these additions, which he shows will require $9\frac{1}{2}$ time units if a time unit is one-tenth of the time of revolution of a figure wheel.

Unfortunately, while the principle on which the proposed machine is to work is described, only the barest idea of the mechanical construction is given, so that it is difficult to judge of the practicability of the intended construction. Whatever this may be, the originality of the method of mixed commensurable logarithms to incommensurable bases seems to the writer so great and the conception so bold as to be worthy of special attention.

Division has hitherto always been effected by the process of rapid but repeated subtraction, following in this respect the method practised with pencil and paper. Having discovered how to harness the logarithm to mechanism, Mr. Ludgate would, it would be expected, have managed to effect division by a logarithmic method, and possibly he could have done so, but here again he has left the beaten track, and by his ingenuity has made division a direct, and not, as hitherto, an indirect or trial-and-error process. Starting with a table of reciprocals of all numbers from 100 to 999, which in a mechanical form is intended to be stored in the machine, he imagines both numerator and denominator of the required fraction p/q to be multiplied by the reciprocal A of the first three digits of q so as to become Ap/Aq. Aq must, then, in every case begin with the digits 100, and it may be written $1+x$, where x is a small fraction. Then $p/q = Ap(1-x)(1+x^2)(1+x^6)(1+x^8)$ . . . a highly convergent series of which five terms will give a result correct to twenty figures at least, and so division is intended to be effected by a process of direct multiplication.

Until more detail as to the proposed construction and drawings are available it is not possible to form any opinion as to the practicability or utility of the machine as a whole, but it is to be hoped that if the author receives, as he deserves, encouragement to proceed with his task, he will not allow himself to become swamped in the complexity which must be necessary if he aims at the wide generality of a complete analytical engine. If he will, in the first instance, produce his design for a machine of restricted capacity, even if it does no more than an arithmometer, he will, by demonstrating its practicability and advantages, be more likely to be enabled to proceed step by step to the more perfect instrument than he will if, as Babbage did, he imagines his whole machine at once. In the writer's opinion, the ingenuity required to arrange a complete analytical engine is really in great part misplaced. Such a machine can only be used and kept in order by someone who really understands it, and it would seem to the writer of this notice more practicable to allow the user's attention to replace the action of operation cards, and leave to the machine the more direct numerical evaluations.

C. V. BOYS.

PROF. D. J. CUNNINGHAM, F.R.S.

THE death of this eminent anatomist occurred on Wednesday of last week, June 23. It was known that Prof. Cunningham had been ill for several months, but the fatal nature of the illness was not at first recognised, and the news of his untimely death in the full vigour of his powers will have come as a shock to many of his friends, and their name is legion.

Daniel John Cunningham was born in April, 1850, at Crieff, where his distinguished father, who was later to become principal of St. Andrew's University, was then the minister. His school days were passed at Crieff Academy. At the age of seventeen he was sent to Edinburgh University, and began the study of medicine. Here he had a brilliant career as a student, and in 1874 took his M.B. degree with first-class honours. In 1876 he proceeded to the M.D. degree, the subject of his thesis being "The Anatomy of the Cetacea"; for this he was awarded a gold medal. His work on this subject was performed in the anatomical department of the university, where he was acting as assistant demonstrator to Prof. Turner; the influence of the master is apparent in the work of the pupil.

In 1876 Cunningham became principal demonstrator of anatomy, a position of much responsibility, as well as of great advantage to the holder from the experience in anatomical work and in teaching which it offers. Of this experience he took full advantage, and his high qualifications were recognised when he was appointed in 1882 to the chair of anatomy in the Royal College of Surgeons in Dublin. This appointment was not long held by him, for in the following year his services were transferred to the much more important chair of anatomy in Trinity College. Here he remained until 1903, when, on the retirement of Sir William Turner from the professorship of anatomy in the University of Edinburgh, it was felt that there was only one man worthy to succeed him, and the invitation which was tendered to him by the Curators of Patronage was, not without some hesitancy, accepted by him.

The hesitancy—even in view of the higher emolument and larger sphere of usefulness which the appointment to his Alma Mater involved—is not difficult to understand. For Cunningham had endeared himself to Dublin by many close ties; he was the centre of a large circle of intimate friends, and his influence and interests were in no way confined within the walls of the university, but extended to all circles of society. For several years he acted as secretary, and for some time as president, to the Royal Zoological Society of Ireland, and the effect of his work is apparent in the splendid condition of their menagerie, which is, for its size, probably the most successful in Europe. He was a constant attendant at the famous Saturday morning breakfasts of the council, and on leaving Dublin for Edinburgh was the recipient of a silver bowl engraved with the signatures of his fellow-members, a testimonial which he prized with pleasurable pride. During four years he was honorary secretary to the Royal Dublin Society. He was frequently consulted on scientific questions by the Viceregal Government, who in 1900 appointed him a member of the commission to inquiry into the condition of the inland fisheries of Ireland. In the same year he was sent out to South Africa as a member of the Royal Commission to inquire into the care of the sick and wounded in the war. He also served on a War Office committee to report on the physical standards required for candidates for commissions and recruits.

But the performance of these public duties was not allowed to interfere with his scientific work. Both before and after his appointment to Dublin his communications on anatomical subjects were numerous and important. His text-books on "Practical Anatomy" and on "Systematic Anatomy"—the latter edited and in part written by himself—have a large circulation. His "Memoir on Cornelius McGrath, the Irish Giant," which was published by the Royal Irish Academy in 1891, is a model of exact anatomical description, and was influential in pointing to the analogies between the conditions of gigantism and those met with in acromegaly, a disease to which attention had shortly before been directed by Marie, who was the first to associate it with tumour of the pituitary body. No less important is his "Memoir on the Surface Anatomy of the Cerebral Hemispheres," which was published in 1892. In 1902 he delivered the Huxley memorial lecture before the Anthropological Institute, the subject of the lecture being "Right-handedness and Left-brainedness."

On his transference to Edinburgh in 1903, Cunningham's activities were in no way diminished, and his influence was immediately felt both in the university and in scientific and medical circles of the city. His genial personality at once won the hearts of the students, who were no less attracted by his powers of exposition. The confidence of his colleagues was manifested by his early election to fill the position of dean of the faculty of medicine. This confidence proved well-merited, for, under his auspices, the scheme of reform of the medical curriculum which had been for years in a condition of suspended animation was re-invigorated, and before long passed through all its stages, which in a Scotch university are more complex and difficult than those of a Bill in Parliament. As a member of the council and as secretary of the meetings, he took an active part in the work of the Royal Society of Edinburgh, and was instrumental in improving the form and character of its published Proceedings. He effected a similar change in the *Journal of Anatomy and Physiology*, of which he became acting editor, and to which he had always, either personally or through his pupils, been in the habit of contributing articles. He continued to take a keen interest in the public services, and was prominent in the movement for the establishment of a medical equipment of the Territorial Force in the East of Scotland.

Cunningham's eminence in science has been recognised on many occasions. He was elected in 1891 to the Fellowship of the Royal Society, and in 1898 served on its council. The Universities of Dublin, Oxford, St. Andrews, and Glasgow conferred upon him their honorary degrees. He was president of the Anatomical Society and of the anthropological section of the British Association, and at various times was examiner in most of the universities of the United Kingdom.

Of Cunningham's personal character it is impossible to speak too highly. Of his fine, manly figure; his frank, open countenance; his clear, honest, kindly eyes; his disposition, genial but firm; his humour, devoid of cynicism; his loyalty to his friends; his gentleness even to opponents, all who had the privilege of knowing him will for ever retain a bright remembrance. As a writer in the *Scotsman* truly says:—"To the University and to science his death is nothing short of a calamity, while to his friends it has brought a sense of desolation."

He was interred on Saturday afternoon at Edinburgh. His remains were escorted from the Church of St. Cuthbert by a long line of students, colleagues, representatives of learned societies, and personal friends, the melancholy procession offering a strong contrast to the gaiety of the city, the traffic of which was arrested by its passage. He lies in the beautiful Dean Cemetery, than which few places contain more distinguished dust. *Requiescat in pace.*

DR. G. F. DEACON.

THE death of Mr. G. F. Deacon, a member of the council of the Institution of Civil Engineers, and eminent for his scientific work in engineering, was announced in last week's NATURE. Mr. Deacon, during his comparatively short life—he died at the age of sixty-six—obtained a considerable reputation as a water-works engineer, and is best known by his connection with the Vyrnwy Reservoir for the supply of Liverpool. In 1876 the need had arisen for an additional supply of water, and Mr. Deacon, who was then acting as municipal and water engineer, was instructed by the corporation to make an investigation as to the locality from which an additional supply could be obtained. After a survey of several sources he finally advised that this could be best obtained from the River Vyrnwy, a tributary of the Severn, situated in North Wales. Mr. Deacon's recommendation was submitted to Mr. Thomas Hawksley and Mr. Bateman, who approved this choice. The Bill promoted by the corporation having received the sanction of Parliament, Mr. Deacon was appointed joint engineer with Mr. Hawksley to prepare the plans and carry out the work. When the works were about half finished, Mr. Hawksley retired, and Mr. Deacon was left in sole charge.

The Vyrnwy works are remarkable as having the largest reservoir in England, and the first to have a high water-tight masonry dam. This dam was formed with blocks of clay slate from the Caradoc beds of the lower Silurian formation, some of which weighed 10 tons. These were set in mortar composed of Portland cement and slate stone crushed fine enough to pass through meshes of one-eighth of an inch. The dam is 1350 feet long, 136 feet high, and impounds the water in a reservoir 5 miles long and covering 1121 acres. The cost of these works was $2\frac{1}{2}$ million pounds, and they were carried out under Mr. Deacon's supervision without the aid of a contractor. A full account of the Vyrnwy works is given in a paper read by Mr. Deacon at the Institution of Civil Engineers in 1896, and contained in vol. cxxvi. of the Minutes of Proceedings.

Mr. Deacon was educated at the Glasgow University, which subsequently conferred upon him the honorary degree of LL.D. He served his time in Napier's shipyard, which led to his becoming one of Lord Kelvin's assistants on the *Great Eastern* when an attempt was made to lay an Atlantic cable. At the age of twenty-two he commenced practice as an engineer at Liverpool, and six years afterwards was appointed municipal and water engineer of that borough. One of the most important services he rendered during this time was the invention of the waste-water meter, by means of which it became possible to locate the place where leakage and waste were going on in the mains or from the service pipes, and thus a very great saving was effected in the quantity of water required. He also devised considerable improvements in the instruments used for measuring the velocity of the flow of water in rivers, and applied the use of electrical mechanism to current meters. He took keen interest in devising and improving the means of making the meteorological observations necessary for determining the yield of rain water.

In 1879 Mr. Deacon resigned his appointment as municipal engineer in order to devote his whole time to the Vyrnwy works. On the completion of these he commenced to practise at Westminster as a consulting engineer, and was connected with many important schemes of water supply, and frequently was engaged in giving evidence before parliamentary committees. In addition to his work as a water-works engineer, Mr. Deacon applied a considerable amount of attention to the application of scientific principles to the solution of problems arising out of the practical work of the engineer.

Mr. Deacon was president of the engineering section of the British Association at the meeting held at Toronto in 1897, also of the Municipal and County Engineers at their meeting in 1878. He was a Fellow of the Meteorological Society, and a member of the Institution of Mechanical Engineers.

NOTES.

THE list of honours announced on the occasion of the celebration of the King's birthday on Friday last includes the names of five Fellows of the Royal Society. Mr. Francis Galton, F.R.S., Prof. J. Larmor, F.R.S., Mr. R. H. I. Palgrave, F.R.S., and Prof. T. E. Thorpe, F.R.S., have received the honour of knighthood, and Dr. W. Schlich, F.R.S., has been appointed a Knight Commander of the Order of the Indian Empire (K.C.I.E.). Other men of distinction in the scientific world included in the list are:—Mr. Edgar Thurston, superintendent of the Government Central Museum, Madras, appointed a Companion of the Order of the Indian Empire (C.I.E.); Prof. W. J. R. Simpson, a Companion of the Order of St. Michael and St. George (C.M.G.); Sir Dyce Duckworth and Mr. Henry Morris, president of the Royal College of Surgeons, have had baronetcies of the United Kingdom conferred upon them; and Mr. James Stuart, who founded the system of university extension and the mechanical workshops at Cambridge, has been made a privy councillor.

ON Monday evening Mr. E. H. Shackleton delivered his first lecture since his return home on the results of his South Polar expedition at a special meeting of the Royal Geographical Society in the Royal Albert Hall. The main facts of the expedition have already been recorded in our own columns and elsewhere, but a large and brilliant audience assembled to hear from the explorer's own lips an account of the experiences of his companions and himself during their fourteen months' sojourn within the Antarctic circle. It is not always easy to realise the meaning of distances between places the position of which is only known in terms of latitude and longitude, and Major Leonard Darwin, who presided over the meeting, performed a useful service for his audience by indicating the extent of ground which would have to be covered by a party starting from London northwards on a journey of the same length as that which took Mr. Shackleton from his winter quarters to within 100 geographical miles of the South Pole. The party would have to march so far as Edinburgh before reaching Captain Scott's record, and onwards to a point 240 miles beyond John o' Groats before reaching the limit of the journey. Mr. Shackleton told his story in a simple and graphic manner, which revealed, without unduly emphasising, the hardships and dangers experienced by his companions and himself on the great southern journey, and by the party under Prof. David which reached the South Magnetic Pole. The Lloyd-Creak dip-circle, he mentioned, worked remarkably well under the severe climatic conditions. The lecture was illustrated by a number of very interesting photographs, while at the close there was a display of "living pictures"—the first ever taken in the Antarctic regions—which afforded a very good idea of the movements of penguins and seals. One scene, which Mr. Shackleton will be well advised to omit in future, illustrated the death of a seal shot by the explorers. After the lecture the Prince of Wales, on behalf of the Royal Geographical Society, presented to Mr. Shackleton a special gold medal, and to a number of other members of the expedition replicas of the medal in silver.

THE next meeting of the French Association for the Advancement of Science will be held at Lille from August 2–7. The secretary of the association should be addressed at 28, rue Serpente, Paris.

THE annual meeting of the Association for the Oral Instruction of the Deaf and Dumb will be held at the Portman Rooms, Baker Street, W., on Tuesday, July 13. Lord Avebury will preside.

MR. F. MUIR and Mr. J. C. Kershaw send home, under date March 12, a description of a Peripatus which they have recently found in Ceram. This is the first time that Peripatus has been found in the Moluccas. The specimens, sixty-three in number, were all females. "In the size of its eggs (0·05 mm.) and in its mode of development and birth it approaches the neotropical group." In its other characters it appears to resemble Melano-Peripatus (the New Britain species found by Dr. Willey). The authors name the species *Peripatus ceramensis*. A description of it, with illustrations, will be published in the forthcoming number of the *Quarterly Journal of Microscopical Science*.

THE issues of the *British Journal of Photography* for June 18 and 25 contain a detailed account of a noteworthy collection of apparatus intended for the easy demonstration of certain optical and visual phenomena specially interesting to photographers. The apparatus, which was designed by Dr. E. Goldberg, of Leipzig, and is now on view at the International Exhibition of Photography at Dresden, is arranged in forty-four small cabinets. Each cabinet is fitted with the requisites for a single experiment, and is accompanied by printed instructions briefly stating the result to be looked for, and indicating the necessary manipulation, which is in every case so simple that the merest tyro can hardly fail of success. The points illustrated include defects of the eye, such as irradiation, chromatic aberration, the blind spot, and Purkinjé's figures; various subjective phenomena of colour; some effects of intermittent illumination; elementary examples of reflection, refraction, dispersion, diffraction, and absorption; colour mixture, with special regard to the devices employed in the modern processes of colour photography.

DURING the course of the discussion on cable rates and Press intercommunication in connection with the Imperial Press Conference, Mr. Marconi gave some interesting information. He remarked it would be injudicious for the Governments concerned to enter into a scheme of State-owned cables without first having investigated the capabilities of a wireless connection between the two countries. In discussing these connections, he said, we should refer to electric communication instead of cable communication. The cost of two stations capable of communicating over distances which have proved practicable—3000 miles—would be about 50,000*l*. for each station. This estimate, of course, is subject to variation. He is, he continued, certainly of opinion that it may be possible in the near future to communicate over greater distances, perhaps 6000 miles, or even more. There is a very interesting theoretical point about communicating a distance of 6000 miles, which is that when the equator is passed the wireless waves may begin to converge again, and it may occur that at the Antipodes messages can be received much easier than half-way to the Antipodes. That remains to be proved. At present the Marconi Company is prepared to take a limited amount of Press messages across the Atlantic at $2\frac{1}{2}d.$ per word. When the stations are completed it is hoped to take a large amount—15,000 or 20,000 words a day. If the amount is considerable the company would be prepared to give a service at 2*d*. a word from Canada to England.

THE new buildings of the Victoria and Albert Museum, South Kensington, were opened in State by the King on June 26. Mr. Runciman, President of the Board of Education, read an address, in which, on behalf of the Board, he thanked the King and Queen for consenting to open the new buildings, and explained the numerous uses of the museum. The address showed that the first object of the founders of the museum was to encourage a high standard of excellence among the craftsmen, manufacturers, and designers of this country. For many years lack of space prohibited a systematic arrangement and classification of the collections. The completion of the new buildings now makes it possible to display the collections in a manner worthy of the ambition which prompted their formation. With this object in view the Board of Education has formulated a scheme for the future organisation and management of the museum. The collections are classified in eight departments. Each department will have its own expert staff, while a separate staff will have charge of the supplementary collections intended for loans to provincial museums and schools of art. In the course of his reply the King said:—"The placing of an expert staff in charge of each section of the museum will have the double advantage of maintaining and developing the more scientific arrangement which has now become possible, and also of bringing about a more accurate knowledge of the history and beauty of the individual exhibits, and of their educational value."

THERE has, so far, been an entire absence of summer weather, and June has proved wet, cold, and almost sunless over the United Kingdom. In England the weather has been especially bad, and the aggregate rainfall is largely in excess of the average. In London the total measurement of rain, not including yesterday, June 30, was 4·29 inches, whilst the average for the month is 2·21 inches. The duration of bright sunshine is only eighty-seven hours, the average for the month being 167 hours, and in some recent years June has had 240 hours of sunshine; in May the sun was shining brightly in London for 297 hours. At Greenwich there have only been three days with the shade temperature above 70°, and there is only one year, 1860, with so few warm days in June during the last sixty-eight years. In June last year there were seventeen days with the temperature above 70°, and in May of the present year there were ten such warm days, the thermometer exceeding 80° on three days, whilst in June the highest temperature was 74°.

The latest contribution of Prof. W. Trelease to the elucidation of the genus Agave, published in the Transactions of the Academy of Science of St. Louis (vol. xviii., No. 3), deals with the Mexican species yielding fibre known as "Zapupe." Although in three cases flowers were not obtainable, five botanical species with local names are distinguished primarily according to the characters of the spines. The species Zapupe, Lespinassei, Deweyana are only known in cultivation, but Endlichiana and aboriginum are indigenous. Bulbils are described for two species, and it is stated that all appear to be freely bulbiferous after flowering, thus affording "pole" plants as well as offsets.

The list of new garden plants for 1908, issued, according to precedent, as appendix iii. of the *Kew Bulletin* (1909), has only recently been received. It furnishes the correct names with brief diagnoses, gives the reference to the original publication and the introducer, and also indicates which plants are in cultivation at Kew and would probably be available for distribution in the regular course of exchange. About one-third of the entries refer to orchidaceous plants, many being garden hybrids, and others mere varieties or forms. Two natural and several garden hybrids are noted under the genus Saxifraga. Messrs. Sanders are credited with the introduction of three palms and the cycad *Encephalartos Woodii*.

An investigation of the medullary rays in the beech, the oak and *Aristolochia sipho*, with the object of tracing the contour of the rays, has been carried out by Dr. K. Zijlstra, who communicates his results in *Extrait du Recueil des Travaux botaniques Néerlandais* (vol. v.). The contours of the rays in the oak and beech obtained by a comparison of tangential sections are fairly regular, being interrupted in places by fibre layers. They show an irregular but distinct increase in height towards the cambium. The height of the rays in Aristolochia stems approximates to the length of the internodes, if, as is assumed, the separate overlying portions are regarded as part of one original ray.

Dr. P. Lowell contributes to the Bulletin of the American Geographical Society (May) the first portion of a description of the plateau of the San Francisco peaks with reference to its effect on tree life. The peaks, which are for the most part cones of volcanic origin, rise out of a plateau having an elevation of 7000 feet. The desert nature of the region has kept it free from human destruction and the dry climate has preserved in a remarkable manner the fossil remains. The altitudinal distribution of the trees forms the chief subject of the paper. The zones of vegetation are said to topographise the country as with contour lines. The yellow pine, *Pinus ponderosa*, dominates the slopes from 6500 feet to 8500 feet. Then the Douglas fir, the silver fir, *Abies concolor*, the curious cork fir, *Abies subalpina*, and the aspen share the ground up to an elevation of 10,300 feet. Higher still, the Engelmann spruce and fox-tail pine, *Pinus aristata*, ascend to the tree limit, about 11,500 feet.

Mr. J. Parkinson contributes to the last number of the Journal of the African Society a collection of folk-tales current among the Yoruba-speaking peoples, which form an interesting supplement to the classical account of this people by the late Major Ellis. Like the Basutos, Pondos, and races beyond the African area, lightning is associated with a bird, and the thunderbolt is the subject of a special cult. The tortoise as the wise, helpful animal here takes the place of the hare, jackal, or frog in Bantu and Basuto tradition, several tales dealing with his cleverness and supplying etiological myths to account for the various marks still to be seen on his carapace.

In the June number of *Man* the Rev. J. Roscoe describes a remarkable cult of the python at Uganda. The floor of its shrine was found to be carpeted with sweet-smelling grass, and on one side was the sanctuary of the serpent and its guardian, the latter being a woman pledged to a life of celibacy. A log and stool for the python, covered with a piece of bark-cloth, lay on the floor of the shrine, and a round hole was cut in the wall for the ingress and egress of the reptile. It had been trained to resort to this shrine, where it was regaled with milk, fowls, and small goats. The snake is supposed to control the river and its fish, and offerings are made to it to ensure success in fishing. During worship a medium is dressed in pieces of bark-cloth, a goat-skin apron, and a cloak of leopard skin. The spirit of the python then is supposed to enter him, when he wriggles about on the ground like a snake and utters prophecies, which are unintelligible to the worshippers, and are explained by an interpreter. The python is also supposed to confer offspring, and if he be neglected punishes his votaries by bringing sickness on their children. When a suitable offering is presented he prescribes the use of certain herbs, which effect a cure. The cult thus presents striking analogies to that of Æsculapius, who, according to Prof. J. G. Frazer, was originally a serpent, the anthropomorphic god provided with a serpent symbol being a later development of the cult.

Miss Nina Layard, already well known for her researches in the Saxon cemetery at Ipswich, describes in the June number of *Man* a series of flint implements discovered by her on the sea-coast at Larne, co. Antrim. This site had already been explored by Messrs. Du Noyer, Knowles, and Gray, whose discoveries have led to protracted controversy, and the age and character of the specimens are still matters of uncertainty. They do not correspond closely with either the palæoliths or neoliths of England, and though many acres of land are covered by these raised beaches, nothing in the shape of a ground weapon has been found. The presence of many flints in a rolled condition leads to the inference that they are older than the formation in which they were found, and the occurrence of these specimens, which many authorities hold to be Neolithic, at such enormous depths in gravel is subversive of all English experience. Miss Layard, in the circumstances, is content to designate them "the older series," because since they were dropped on this shore there must have occurred, not only a gradual sinking of the beach and the formation of gravels 20 feet in depth containing the worked flints, but also a subsequent elevation until the surface of the gravel stands no less than 20 feet above high-water mark. In the same connection, the account in the same number by Mr. Worthington G. Smith of a Palæolithic implement found near the British Museum in 1902 is interesting. It is remarkable in this specimen that an oval flint pebble forms part of the basis of the implement, the maker of the tool, by clever flaking, having designedly left this pebble intact.

The geological section of the Belfast Naturalists' Field Club organised on June 19 an excursion to Scawt Hill for the study of the volcanic neck there. The geological structure of the district is that common to the plateau basalts of County Antrim, and consists of basic lava flows covering Mesozoic beds, and at Scawt Hill occurs the "neck" of one of the volcanoes from which the lavas came. A few years ago one of the members of the section came unexpectedly on a basic dyke traversing the dolerite neck. The neck has been found to be a fine-grained ophitic dolerite. The dyke is a granitoid basic rock, and may be classed as a diabase without olivine. A section of the chalk taken two yards from the dyke showed it to be converted into a typical crystalline limestone with large crystals of calcite. The geologists of the Belfast Naturalists' Field Club made during the excursion the observation that even at a distance from the dyke the band of chalk in contact with the dolerite neck seemed to have undergone a similar change, and to have been converted into hornstone.

IN the *U.S. Monthly Weather Review* of January last references are made to interesting communications by Mr. R. F. Stupart, director of the Canadian Meteorological Service (dated March, 1909), relating (1) to the establishment of new stations in Newfoundland and Labrador, and the proposed extension of storm warnings and weather forecasts to Newfoundland, and (2) to the supply of a complete equipment to several stations in the north of Canada, extending as far as Fort Macpherson (lat. 67° 27′, long. 134° 57′ W.). In connection with the source of "cold waves" frequently experienced in North America, Mr. Stupart thinks that the study of the far north with trustworthy barometer readings will be most valuable. He remarks that the persistent high pressures found there in some seasons apparently owe their origin to upper currents from the equator coming to earth farther north than usual, and that "we may very probably in the future connect the situation in the equatorial regions and trade-wind belts with that in the high latitudes."

THE first complete account of the new method which has been adopted by the Gesellschaft für drahtlose Telegraphie to secure an almost undamped series of oscillations in the secondary circuit of the sender is given by Prof. Fleming in the *Electrician* for June 11. The primary spark is divided into eleven very short sparks of about 0·01 inch in length, which are formed between twelve discs of copper, which may be water-cooled. The damping is so great that not more than two or three oscillations occur in the primary circuit, and the oscillations in the secondary are therefore free oscillations, which are only slightly damped. The device evidently marks a distinct advance in wireless telegraphy.

LAST year in the *Comptes rendus* and in *Le Radium* M. J. Becquerel described experiments on the electric discharge through vacuum tubes which appeared to indicate that, in addition to the canal rays, there existed positive rays which could be deviated by a magnetic field by amounts comparable with those to be expected if the rays were composed of free positive electrons. In the *Journal de Physique* for June, M. A. Dufour describes his own work on the same subject. He has repeated and extended M. Becquerel's experiments, and comes to the conclusion that the observations do not warrant the statement that the deviable rays observed are due to free positive electrons.

MR. R. H. COLLINGHAM contributes an article in *Engineering* for June 18 dealing with Ilgner-operated winding-engines. The principle of the Ilgner system is the employment of a motor-generator set coupled mechanically to a heavy fly-wheel and electrically to the motor driving the mill or winding gear. The motor of the motor-generator is driven off the power mains, and the function of the fly-wheel is to minimise the variation in the load drawn from the source of supply. All the heavy loads which come on the mill are met from the store of energy in the fly-wheel. In order to obtain this result, an automatic slip-regulating device is provided in the rotor circuit of the induction motor driving the motor-generator set, which regulates the amount of slip on the induction motor according to the amperes taken by the stator, the slip-regulating device only coming into operation when the stator current has reached a certain fixed value. When this value has been attained the regulating device increases the slip of the induction motor, causing the speed of the set to drop; the fly-wheel then gives up energy corresponding to the given variation in velocity. By this means the load on the supply mains is kept much more steady than would be the case if no fly-wheel were employed. Mr. Collingham treats especially the mechanics of the problems involved with the view of finding expeditiously the weight of wheel, size of motor, &c., required in given cases.

IN our article upon the Astrographic Congress at Paris (June 10, p. 440) it was stated that Rome was represented by Signor Lias. We are asked by Dr. P. Emanuelli to state that this should have been Signor Lais, who is vice-director of the Vatican Observatory, and was the representative, not of Rome, but of the Vatican.

WE have received from Messrs. Flatters and Garnett, Ltd., of Manchester, a copy of their conveniently arranged catalogue of collecting apparatus, nature-study appliances, cabinets, museum glassware, glass-top boxes, pocket lenses, and so on. The list is well illustrated, and reference to its contents is made easily.

MR. JOHN MURRAY has published a second edition of Mr. R. H. Lock's "Recent Progress in the Study of Variation, Heredity, and Evolution." The first issue of the book was reviewed at length in NATURE of April 18, 1907 (vol. lxxv., p. 578), but it may be pointed out that several alterations and additions have been made in the present edition. A short list of references has been added at the end of each chapter; the different chapters have been revised and supplemented, and a new chapter has been added.

"A SHORT HISTORY OF ENGLISH AGRICULTURE," by Mr. W. H. R. Curtler, is announced by the Oxford University Press for early publication. As the agriculture of the Middle Ages has often been ably described, Mr. Curtler devotes the greater part of his book to the agricultural history of the subsequent period, especially the seventeenth, eighteenth, and nineteenth centuries.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JULY:—

July 3. 14h. 30m. Uranus in conjunction with the Moon (Uranus 2° 22′ N.).
7. 17h. Mercury at greatest elongation (21° 11′ W.).
8. 3h. 46m. Mars in conjunction with the Moon (Mars 1° 21′ N.).
11. 15h. Uranus at opposition to the Sun.
15. 14h. Saturn at quadrature to the Sun.
18. 17h. 50m. Venus in conjunction with the Moon (Venus 3° 5′ S.).
19. 18h. Mars at greatest heliocentric latitude S.
20. 17h. 39m. Jupiter in conjunction with the Moon (Jupiter 4° 22′ S.).
23. 5h. 17m. Mercury in conjunction with Neptune (Mercury 1° 6′ N.).
25. 19h. Mercury in perihelion.
30. 22h. 4m. Uranus in conjunction with the Moon (Uranus 2° 16′ N.).

Comet 1909*a* (Borrelly-Daniel).—Several observations of this comet are recorded, and an ephemeris for it is given, in No. 4333 of the *Astronomische Nachrichten*. Neither photographs nor eye observations show any remarkable features, whilst the ephemeris indicates that the brightness is declining; on July 16 the comet will be but about one-third as bright as when discovered. The distance from the earth is, at present, about 1·09 astronomical units, and is rapidly increasing.

The Shape of the Planet Mercury.—Referring to a recent statement by Mr. Levander, that the equatorial diameter of Mercury has been shown to exceed the polar diameter, M. R. Jonckheere, in No. 4333 of the *Astronomische Nachrichten*, expresses the belief that the opposite is the case. His observations, made during the most recent transit of Mercury, indicated that the vertical diameter was the greater, the values being, vertical = 9·46″, equatorial = 8·73″; this is supported by other observers, whose results he gives. At present the positions of the equatorial and polar diameters of the planet are not known, but M. Jonckheere contends that the statement that the greater diameter is the one parallel to the celestial equator is, in the face of the evidence to the contrary, inadmissible.

Observations of Sun-spots, 1908.—The results of the first year's regular observations of sun-spots at the Royal Observatory at Capodimonte (Naples) are given by Signor E. Guerrieri in No. 6, vol. iii., of the *Rivista di Astronomia* (Turin). The sun was observed on 304 days, and on five days was seen to be free from spots, whilst the mean daily frequency of spot groups for the year was 5·3. The first half of the year showed an excess of groups in the ratio 3/2, but the analogous ratio for single spots was 4/5; altogether, 1606 groups and 9262 individual spots were observed during the year. The observations are tabulated and discussed in several different ways, and, if continued regularly, will form a useful supplement to the work so ably performed by the other Italian observers.

Observations of Saturn and its Rings.—In No. 4331 of the *Astronomische Nachrichten*, M. Schaer records the observations of Saturn and its ring system made at the Geneva Observatory, with the 40 cm. Cassegrain reflector constructed by himself, during the period September 18, 1908, to January 24, 1909. The chief feature recorded is the discovery of the new dark ring announced on October 7, 1908. This ring was seen, but thought to be the shadow of the bright rings, on previous occasions, but on October 5 it was seen to extend to the right and left, and was therefore judged to be something more than shadow; on October 6 the dark ring was seen to be separated, and the planet, with its usual colour, was seen through the interstice, which was about 3″ to 4″ long and 0·5″ to 1″ broad. In January of the present year the new ring was seen more easily than during the preceding months.

M. Schaer's observations also suggest the presence of a cloudy, absorbing atmosphere, and the occurrence of slight changes in the white ring between the crape-ring and the Cassini division. The invisibility of the rings when their plane passes through the earth is probably due to the masking effect of the newly discovered outer dark ring.

Tables for the Reduction of "Standard Co-ordinates" to Right Ascension and Declination.—In No. 4329 of the *Astronomische Nachrichten* Herr A. Hnatek published a series of tables for the computation of α and δ from the standard coordinates given in the catalogues of the international *carte du ciel*. A few copies of these tables, printed on stout paper, have been prepared, and may be obtained from the publishers for one mark per copy.

The Transvaal Observatory, Johannesburg.—From the *Observatory* (No. 410, p. 262, June) we learn that from July 1 next the institution directed by Mr. R. T. A. Innes is to be known as the Transvaal Observatory, Johannesburg, South Africa. The instrumental equipment is to be increased by the addition of a large refractor for visual work, and a photographic astronomical telescope, the gift of Mr. Franklin Adams, so that this institution will now rank as an astronomical, as well as meteorological, observatory.

The Comets of 1907 and 1908.—In a brochure published by Prof. Kobold, comet observers will find a very useful summary of the cometary phenomena of 1907 and 1908. Observations of fifteen comets were made during those two years, and for each object Prof. Kobold gives a short summary of the observed phenomena, a set of elements where available, and a table of references to the publications in which the observations were severally recorded.

THE ROYAL SOCIETY CONVERSAZIONE.

The ladies' conversazione at the Royal Society is always a brilliant function, and last week the presence of delegates and other distinguished foreign guests from the Darwin celebration at Cambridge added to its interest. The conversazione was held on June 24 in the rooms of the society at Burlington House, and the guests were received by Sir Archibald Geikie, K.C.B., president. Many of the exhibits were also shown at the conversazione held in May, and were described in Nature of May 20 (vol. lxxx., p. 347). Summaries of the other exhibits are given below, based upon the descriptions in the official catalogue, related subjects being here grouped together for convenience of reference.

Dr. W. N. Shaw, F.R.S.: Representation of temperatures and pressures in the atmosphere up to a height of fifteen miles, on July 27 and 29, 1908.—*A. Fowler:* Photographs of the spectrum of scandium. The photographs show the varying intensities of the scandium lines in the arc flame, normal arc, and the arc in hydrogen. Corresponding differences are found in the spectra of sun-spots and prominences.—*Messrs. Zeiss:* Liquid crystals observed under high temperatures with polarised light by micro-projection apparatus.—*Dr. F. Edridge-Green:* Spectroscope for estimating colour perception. In the focus of the instrument are two movable shutters, either of which is capable of moving across the spectrum. By means of the two shutters any given portion of the spectrum can be isolated. Each shutter is controlled by a drum graduated in wave-lengths, so that the position of the edges of the shutters can be known.—*C. E. S. Phillips:* Permanently luminous watch dial and military night compass. The watch dial is transparent (glass), and the figures are painted upon its upper surface. The dial is backed with a compound containing a minute quantity of $RaBr_2$ (radium bromide), which renders it luminous, so that the time may be easily read in the dark. The compass is arranged upon the same principle. By means of a luminous disc and strip, direction may be determined at night.

W. M. Mordey: The effect of electrostatic condensers in preventing or extinguishing arcs. A suitable condenser placed in shunt to an arc, or in shunt to a resistance in series with an arc, will instantly extinguish the arc. If connected in shunt to the contacts before they are separated it will prevent the formation of an arc even in a circuit having considerable electromotive force.—*The Linolite Company:* Metallic filament "tubolite." The metal filament is held at each end by a zig-zag spring to take up the expansion, and is supported by anchors at two intermediate points. The lamp may be placed in any position, and can be run on an alternating current or direct current circuit.—*Hon. C. A. Parsons, F.R.S.:* (1) Model of leakage path device for regulating voltage of alternators. The apparatus depends on the following very simple fact, that while an alternating current cannot *directly produce* a unidirectional field, it can have a strong action in diminishing magnetic flux. When applied to an alternator, the field magnets of the exciter are provided with a leakage path, around which windings carrying alternating current are placed. (2) Some samples of the blades used in steam turbines of Atlantic liners.—*Hon. R. C. Parsons:* (1) "Panflex" spring wheel for motor vehicles. The "Panflex" spring wheel is an invention which has for its object the easy motion of a vehicle when run at low or high speeds. This ease of motion is due to the springs being capable of deflection in every direction. The wheel is not subject to bursts or punctures, prevalent in the case of wheels fitted with pneumatic tyres. The wear and tear is small, and, should a spring break, which is seldom the case in practice, another can be inserted in a few minutes at a very small cost. (2) Working model apparatus for recording the effects produced upon wheels of various descriptions when passing over obstacles. (3) Seismograph apparatus for registering the jolts felt by the body of a motor vehicle when run on "Panflex" or pneumatic wheels.

The Director, Royal Gardens, Kew: (1) Specimens to illustrate the wood *Lignum nephriticum*, and the fluorescence of its infusion. *Lignum nephriticum* is the wood of "Coatli" (*Eysenhardtia amorphoides*), a small leguminous Mexican tree. An infusion of the wood was used medicinally by the Aztecs. Soon after the conquest of Mexico the Spaniards brought the wood to Europe, where it was used for similar purposes, and excited remark owing to the blue fluorescence of the watery infusion of the wood. The phenomenon was first described more fully by Athanasius Kircher (1646), and J. Bauhin (1651), who used cups made of the wood. It was carefully studied by Boyle (1664). During the next century the wood itself was lost sight of; its origin remained unknown until quite recently. Plukenet (1696) suggested, and Dale (1737) and Linnæus stated, that it was the wood of the horse-radish tree (*Moringa pterygosperma*), which is, however, a native of the Old World. Another source that has been suggested is *Pithecolobium Unguis-Cati*, a native of the West Indies. (In charge of Dr. O. Stapf, F.R.S.) (i.) Wood of true *Lignum nephriticum* and cup turned from the same, and samples of infusions, presented to the Kew Museum as "cuatl." (ii.) Medicinal substitutes of *Lignum nephriticum*:—(*a*) wood of *Moringa pterygosperma*, from Scinde; (*b*) wood of *Pithecolobium Unguis-Cati*, from Florida; (*c*) wood of a tree, possibly a species of Imbricaria (Sapotaceæ), from tropical America, received from Paris in 1851 as *Bois néphritique*. (2) Plants of Ecanda (*Raphionacme utilis*), and sample of rubber prepared at Kew from a tuber of it.—*R. A. Robertson:* Photographs (for identification purposes) of the transverse surface of timbers.—*Prof. R. H. Yapp:* Photographs of tropical vegetation. The photographs were, for the most part, taken during the Skeat Expedition to the Malay Peninsula (1899–1900).—*Prof. F. E. Weiss:* (1) Some alien aquatic plants from the Reddish Canal, near Manchester; (2) some South African aquatics grown in the laboratory, University of Manchester.

R. I. Pocock: Warning coloration in some weasel-like Carnivora. Animals which are nauseous or poisonous or dangerous to meddle with commonly have some means of self-advertisement, such as conspicuous coloration or sounding organs, which appeals to the sense of sight or of hearing of their enemies, warning the latter to let them alone; but most mammals are coloured so as to be concealed either from their enemies or from the prey they feed upon. Such concealment is commonly effected by counter-shading, the upper side being dark to tone down reflected light, and the lower side white to counteract shadow, the result being obliteration of the shape and solidity of the body. Some of the weasel tribe, however, form an exception to this rule, being light above and black below, often with the white of the back, as in skunks, or of the head, as in badgers, emphasised by black stripes; and since these animals are known to possess glands which secrete fluids with a fœtid or suffocating odour, and since, also, they are known to be desperate fighters and fearless and extraordinarily tenacious of life, and to feed, for the most part, upon vegetables or upon animal food, for the capture of which concealment is unnecessary, there are strong reasons for believing them to be conspicuously and warningly coloured.—*H. F. Angus:* Stereoscopic photomicrographs. The series comprise eggs of butterflies, moths, and parasites; botanical objects, such as mycetozoa, leaf hairs, &c.—*F. Enock:* Living stick-insects (*Bacillus rossi*). The eggs of these stick-insects are less than one-eighth of an inch in diameter, and much resemble a minute vase. On emerging they are half an inch in length, and quickly stretch themselves along a green twig, which they exactly resemble. Most of the specimens have changed their skins five times, the old skin being generally *eaten*. When mature, these stick-insects attain a length of more than 4 inches, and become of a brown colour, which harmonises with the brown twig on which they rest. They are nocturnal feeders, and exceedingly amicable toward each other, treating each other as sticks, several often clinging together.—*Prof. George H. F. Nuttall, F.R.S., and Dr. Seymour Hadwen:* The discovery of a curative treatment for malignant jaundice in the dog and for redwater in cattle, with a demonstration of the effects of trypanblau upon the parasites. The disease known as malignant jaundice (piroplasmosis) in dogs is exceedingly fatal. It has hitherto resisted all forms of treatment. Both trypanblau and trypanrot injected subcutaneously will cure or prevent the disease. The effect of the drugs is exerted directly upon the parasites (*Piroplasma canis*) which cause the disease. The parasites may be observed to degenerate and disappear from the blood within a few hours after treatment. The parasite of redwater in cattle (*Piroplasma bovis*) is likewise affected by trypanblau.

Dr. C. D. Walcott, Secretary of the Smithsonian Institution: Panoramic views in the Rocky Mountains, U.S., and Canada.—*Dr. A. Smith Woodward, F.R.S.:* Skull of Megalosaurus from the Great Oolite of Gloucestershire. This is the first nearly complete skull of a carnivorous dinosaur found in Europe, and agrees with the skull of Ceratosaurus, from the Jurassic of Colorado, U.S.A., in exhibiting a bony horn-core on the nose. The specimen was discovered by Mr. F. L. Bradley near Minchinhampton.—*Dr. C. W. Andrews, F.R.S.:* Remains of rhinoceros and mammoth from the Thames alluvium under the offices of *Lloyd's Weekly News*, Salisbury Square, Fleet Street, E.C. The specimens exhibited were:—(1) a nearly perfect skull of a young individual of the woolly rhinoceros (*Rhinoceros tichorhinus*), in which some of the milk-teeth were still in use; (2) a maxilla and nearly complete mandible of a young mammoth (*Elephas primigenius*); the first and second molars were in wear, the third not yet having appeared.—*Dr. F. A. Bather, F.R.S.:* Sections of seasonal clay from Stockholm. This clay, which was deposited during the melting and retreat of the great ice-sheet in Sweden, may be described as fossil years and seasons. The alternating bands of dark and light can be easily seen, and Baron G. de Geer (from whom the specimens have been received) believes that each cycle represents a year, the lighter rock having been formed during the melting of the snows in spring. He has traced these bands for great distances, and has been able to map the changing limits of the ice-sheet from year to year through a long period. This is the nearest approach to a definite chronology by years that has yet been made by geologists, but it still needs to be linked up to the chronology of human history.—*Dr. Marie Stopes:* The microscopic structure of fossil plants from Japan. The nodules containing the plants were obtained in the river beds of the mountainous region of northern Japan. They are of Cretaceous age, and contain fossil plants with their tissues so well preserved that the cells can be seen in microscopic sections of the stony matrix. All the plants are new to science, and among them are several specimens of the first petrifaction of a flower hitherto discovered. The nodules contain ferns, gymnosperms, and angiosperms, which form an interesting mixed flora, the first of the kind to be described from specimens showing their anatomical structure.—*Prof. Flinders Petrie, F.R.S.:* Ancient modelled heads of various races. These heads were found in the foreign quarter of Memphis, the capital of Egypt, and represent the various peoples who were known there, 500 B.C. to 200 B.C. The Persian Empire, at that time, brought together all races between Scythia and India, and the Mediterranean peoples were familiar with Egypt before that. The modelling was probably done by Græco-Egyptians. Most of these were found in the excavations of the British School of Archæology in Egypt.

SOME PAPERS ON INVERTEBRATES.

COMMENCING with entomology, mention may be made of a paper on new and little-known North American Tipulidæ, by Mr. C. W. Johnson, published in vol. xxxiv., pp. 115–33, of the Proceedings of the Boston Natural History Society. In addition to the description of a number of new species, the paper contains the diagnosis of the new genus Aeshnasoma, proposed for a large tipulid with antennæ of the type of those of Longurio, but with a wing-venation differing from both that genus and Tipula.

To the March number of *Spolia Zeylanica* Mr. T. B. Fletcher communicates the first part of a monograph of the plume-moths of Ceylon, dealing in this instance with the members of the family Pterophoridæ. There are, it will be remembered, two families of plume-moths, the one already mentioned and the Orneodidæ, or 24-plumed group. Both are regarded by the author as very ancient types, but there appears to be little or no near relationship between the two groups, so that their mutual resemblance may probably be attributed to convergence. Although nothing definite is known in regard to the advantage gained by the splitting of the wings in these moths, the author suggests that when pace is not essential, a light framework of wing supplemented by cilia will be superior to the ordinary lepidopterous wing, in that it gives an equal measure of support with less expenditure of muscular force. In the same issue Mr. P. Cameron describes certain new Ichneumonidæ and Braconidæ reared by Mr. Fletcher from Ceylonese plume-moths.

Part v. of the second volume of Records of the Indian Museum is devoted to the revision, by Mr. E. Brunetti, of two groups of Oriental insects, namely, the flies of the families Leptidæ and Bombyliidæ; the latter paper containing a list of the known Oriental species, of which some are described for the first time.

To the Proceedings of the South London Entomological and Natural History Society for 1908–9 Mr. H. S. Fremlin contributes a paper on the results of experiments to show the effect of physical and chemical agencies on butterfly pupæ. The species forming the subject of the experiments were *Vanessa urticae* and *Abraxas grossulariata*, the total number of specimens treated being just over two thousand. Water and high temperature were the agents for the influence of physical conditions, while the chemical agencies employed were nitric and hydrochloric acids, chloride of lime, sulphur, hydrogen sulphide, and carbon disulphide. In the case of *V. urticae*, the death-rate was excessive when the pupæ were exposed to continuous high temperature, hydrogen sulphide, and carbon disulphide. The pupæ of *A. grossulariata* were in great measure destroyed in the water-laden atmosphere, and in the continuous high temperature failed to develop; hydrogen sulphide, on the other hand, was less harmful than in the case of the other species, although it crippled such adults as developed. Chlorine had a marked effect on the red colour of *urticae*, but showed little result in the case of *grossulariata*.

To the June number of the *Entomologists' Monthly Magazine* Mr. R. S. Bagnall contributes an account of four species of Thysanoptera new to the British fauna, among which *Megathrips nobilis* is also new to science. That species, the largest European representative of the group, was first obtained by Dr. D. Sharp in Wicken Fen during 1896.

Leaving insects for arachnids, we find in the April issue of the Proceedings of the Philadelphia Academy Mr. N. Banks cataloguing a collection of spiders from Costa Rica, with descriptions of new species. The new forms are about seventy in number, in addition to which there are about a score of species not mentioned in "Biologia Centrali-Americana." Of the web-making species, a considerable number are common to the United States, but of the other groups few kinds range so far north.

To vol. xxxviii., part iv., of the *Travaux Soc. Imp. Nat. St. Pétersbourg*, Mr. E. K. Suworow contributes an elaborate account of the anatomy of *Ixodes reduvius*, a tick exhibiting sexual dimorphism in a strongly marked degree. The much smaller males are, for instance, distinguished from the females by a peculiar system of divisions in the external envelope of the body, while there are also histological differences in the hypodermis of the males as compared with that of the females, as well as distinctive features in the mouth-organs.

Three papers published by the U.S. National Museum—two in the Proceedings and one in the Bulletins—are devoted to crinoids. In the first of these (Proceedings, vol. xxxvi., pp. 391–410) Mr. A. H. Clark describes a second collection of these organisms obtained by the S.S. *Albatross*, of which fifteen species, together with four left over from the first collection, are regarded as new, and duly named, one of these forming the type of a new genus. *Eudoxocrinus alternicirrus*, hitherto known only by *Challenger* specimens, has been re-discovered, and its habitat definitely determined, but several other *Challenger* forms have not been met with.

In the second of these papers (Bulletin No. 64) Miss Elvira Wood, of Columbia University, gives a critical summary of Dr. Gerard Troost's unpublished monograph of the fossil crinoids of Tennessee. Dr. Troost, who was born in Holland in 1776, settled in Philadelphia in 1810, where he became one of the founders, and the first president, of the Academy of Sciences. In 1827 he removed to Tennessee, where he became professor of geology and mineralogy in Nashville University, holding that chair until his death in 1850. Only about a month before his death the manuscript of the monograph of Tennessee crinoids was sent to the Smithsonian Institution for publication. After passing through various hands for five years, this manuscript came into the possession of Prof. Hall, in whose custody it remained for upwards of forty years. The long period which has elapsed since it was written rendered re-writing practically imperative, but certain portions have been printed direct from the original MS. Many of the original illustrations have been replaced by photographs or new drawings.

In the third paper of this series (Proceedings, vol. xxxvi., pp. 179–90) Mr. Springer describes, under the name of *Isocrinus knighti*, a new crinoid from the Jurassic of Wyoming.

The molluscs collected on the north side of the Bay of Biscay by the *Huxley* in the summer of 1906 form the subject of an article by Mr. A. Reynell in vol. viii., No. 4, of the Journal of the Marine Biological Association. Out of the seventy-five species collected, sixty-two have been recorded from the British area.

In No. 1678 of the Proceedings of the U.S. National Museum (pp. 431–4) Miss H. Richardson describes and figures a specimen of the curious spiny woodlouse (*Acanthoniscus spiniger*) of Jamaica. Although this isopod is stated to be common in its native island, the type-specimen in the British Museum and the one described by Miss Richardson are believed to be the only examples in collections.

THE RESEARCH DEFENCE SOCIETY.

THE speeches at the annual general meeting on June 25 of the Research Defence Society illustrated the wide and manifold interests of its work. It is, indeed, a national society for telling the truth about a matter of national importance. It defends the good name, the honour, of science against reckless and unscrupulous opponents, and we are not surprised at the welcome that it received. The list of its 2500 members includes a very powerful and thoroughly representative collection of great names. The society has already formed a dozen branch societies, has given many lectures, and has distributed much wholesome and honest literature; it has also published a volume of essays, written with authority, and pleasantly free from all controversy. Thus it has begun well; and the report of its committee is justly satisfied with the work of the past year. We note here two of the points made by speakers at the annual meeting.

Sir James Dewar emphasised this fact, that Germany is far ahead of us in the equipment of great laboratories for research in the "borderland between physiology and chemistry." Money is spent lavishly over the investigation of organic chemical bodies, the discovery and the preparation of new organic drugs. The services of a hundred expert and highly qualified men of science are at the command of a single firm. They receive large salaries, and are free to follow the bent of this or that special study. In the long run, their united work is immensely profitable. Here is commercial rivalry, and more; here is a better understanding of the right conditions of "applied science."

Lord Cromer, president of the society, took as a signal instance of the necessity for experiments on animals the recent discovery of a serum treatment in cases of epidemic cerebro-spinal meningitis, that ghastly disease which goes by the foolish name of "spotted fever." It is an acute septic inflammation of the membranes of the brain and the spinal cord. By experiments on animals it was proved to be due to special germs of the order of diplococci. Flexner and Jobling, working at the Rockefeller Institute, discovered a way of preparing, from immunised horses, a serum containing a direct antidote, and this serum was first used in the spring of 1907. Before that time there was no special treatment of the disease, and the mortality ranged from 68·4 per cent. to 80·5 per cent. The children —it was mostly children—suffered terribly, and died in a few days; and of those who survived many were left, from the intensity of the inflammation, imbecile, paralysed, or blind. By the use of the serum the mortality has been reduced to 36·7 per cent. In Belfast, of 275 cases treated before the use of the serum, 72·3 per cent. died, and of ninety-eight cases treated with the serum 29·6 per cent. died.

The Research Defence Society exists to keep the public informed of such facts as these, and we hope that it will have a long record of such victories over disease.

IS THE ASSOCIATION OF ANTS WITH TREES A TRUE SYMBIOSIS?

THE fact has long been known that some species of ants occur in constant association with certain kinds of trees. Thus members of the dolichoderid genus Azteca are often found inhabiting the interior of the stems of *Cecropia peltata*, and among the Pseudomyrmini *P. bicolor* forms its nests within the spines of the "bull's-horn" acacia. The view has been held by many naturalists, amongst others by Fritz Müller and Bates, that in these cases the benefit is mutual, the tree affording both shelter and sustenance to its occupants, and receiving in return protection from the attacks of the formidable leaf-cutting ants of the genus Atta and of other enemies. Doubts on this point have been expressed by several authorities, among them by Dr. David Sharp, in whose opinion "there is reason to suppose that a critical view of the subject will not support the idea of the association being of supreme importance to the trees."

A careful investigation of the relations subsisting between the arboreal species of Azteca and Pseudomyrma and the trees which they inhabit has lately been conducted in Paraguay by Karl Fiebrig, who has published his results, illustrated by numerous photographic reproductions, in the current volume of the *Biologisches Centralblatt*.[1] His conclusions may be summarised as follows:—

Azteca not only makes use of internodal cavities already existing in the stem of *Cecropia peltata*, but excavates fresh spaces or enlarges existing ones at the expense of living tissues of the tree. Fritz Müller described certain pits in the stem of Cecropia where the wall is much thinner. These spots, he says, are selected by the female ant for the purpose of gaining access to the interior of the stem. But, according to Fiebrig, the ants effect their entrance into new internodal spaces by perforating the partitions in the stem before they have gnawed through the thin bottoms of the pits; moreover, openings to the exterior are often made irrespective of the situation of the pits, and when the latter are perforated the boring is, in certain cases, effected from within, and not from without. Neither the internodal spaces nor the pits can therefore reasonably be considered as myrmecophilous adaptations. Again, the alleged protection against leaf-cutting ants must often be superfluous, since the Cecropia, with its inmates, is apt to be found in marshy situations where these enemies cannot reach it. Most of the trees in Paraguay are subject to the attacks of the leaf-cutting Atta, but, nevertheless, though unprotected by the presence of Azteca, they continue to maintain their existence, even if belonging to introduced, and not native, species. Cecropia itself is not tenanted by ants until it is some years old. The presence of colonies of Azteca does not prevent Cecropia from receiving much damage from the attacks of other insect enemies, and Fiebrig is of opinion that the constant loss suffered by the tree from the depredations of Azteca itself involves a more serious drain upon its vitality than the occasional raids of the leaf-cutters. Finally, the occupation of Cecropia by these ants not only fails to afford protection against enemies other than the leaf-cutters, but even encourages the assaults of such formidable foes as woodpeckers and internally feeding lepidopterous larvæ.

With regard to the association between *Acacia cavena* and *Pseudomyrma fiebrigi*, the author points out that this tree, in common with other species of Acacia, is protected against the ground-haunting Atta by the fact that it grows only in situations which are constantly liable to inundation. The thorns in which the ants take up their abode have frequently been already hollowed out and furnished with apertures of access by lepidopterous larvæ; moreover, the spaces tenanted by the ants are not confined to the thorns, but extend also to the stem. In neither situation do they occur naturally, but in both they are excavated, as in Cecropia, whether by ants or caterpillars, at the expense of the living tissues of the tree.

On these grounds Fiebrig concludes that, at any rate so far as the species observed by him are concerned, the benefits of the association between trees and ants are not mutual, but are enjoyed by the ants alone. There is no doubt that the reasons for his view adduced by Fiebrig are of great weight. At the same time, it cannot be said that these observations are sufficient of themselves to disprove altogether the existence of ant-plant symbiosis.

F. A. D.

[1] "Cecropia peltata und ihr Verhältnis zu Azteca Alfari, zu Atta sexdens und anderen Insekten. Ein kritischer Beitrag zur Ameisenpflanzen-Hypothese." By Karl Fiebrig (San Bernardino, Paraguay).

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The following is the text of the speech delivered by Prof. Love in presenting Dr. G. E. Hale for the degree of D.Sc., *honoris causa*, at the Encænia on June 24:—

Inter Astronomos qui ea quæ in æthere solem circumfuso geruntur investigant nemini cedit Georgius Ellery Hale. Qui vir duodeviginti abhinc annos primus omnium fabricatus est instrumentum illud, ad lucis e solis puncto quovis emissæ naturam cognoscendam aptissimum, quo hodie utuntur omnes fere solis observatores. Hoc subsidio fretus potuit flammas illas excurrentes, quæ solis defectu plerumque cernuntur, sole pleno quasi in pictura exprimere: mox plagas lucidissimo candore fulgentes, quas faculas vocant, eodem modo repræsentare. Idem nuper docuit procellis hunc æthera vexantibus tenuissimas materiæ particulas quasi turbine quodam agitatas vim magneticam miro modo gignere: quæ omnia nemo demonstrare potuit nisi excogitandi peritissimus, in observando patientissimus, in causis cognoscendis sagacissimus. Neque ei satis erat Naturæ arcana reserare, sed Observatoria duo in orbe terræ maxima fere et instructissima condidit atque ornavit: idem Ephemeridem, in qua recentissima de siderum natura ubique reperta pervulgantur, conscribendam curavit. Sodalicium denique maximum instituit quo omnes omnibus ex terris huius militiæ cælestis contubernales congregarentur.

ST. ANDREWS.—Dr. William Nicoll, who has for some years carried out important researches on the parasites of birds, fishes, and other forms at the Gatty Marine Laboratory, has just been elected to the Ernest Hart memorial scholarship.

Dr. J. C. Irvine, lecturer on organic chemistry in the University, has been appointed by the University court to the chair of chemistry in St. Andrews, vacant by the resignation of Prof. Purdie.

The Viscountess Falmouth will present the prizes at the Horticultural College, Swanley, Kent, on Thursday, July 15. Sir John Cockburn will take the chair at 4 p.m.

A distinguished American physicist, Prof. E. F. Nichols, of Columbia University, has been elected president of Dartmouth College, a leading New England institution with more than 1200 students. Dr. Nichols is a graduate of Cornell, and held chairs at Colgate and Dartmouth before being appointed to his present post at Columbia.

The issue of *The Record*, the magazine of the South-Western Polytechnic Institute, Chelsea, London, for May, contains an account of this year's prize distribution, when Dr. H. A. Miers, F.R.S., the principal of the University of London, delivered an address. The report of the principal of the institute, an abstract of which is printed in the magazine, shows that there were 2573 students under his supervision during 1907–8.

The King has consented to lay the foundation-stone of the new buildings of the Imperial College of Science and Technology, South Kensington, on July 8. The building is to accommodate the departments of mining and metallurgy of the Royal School of Mines, geology of the Royal College of Science, and the extension of the engineering department (City and Guilds College), and will be situated on the land in Prince Consort Road lying to the east of the Royal College of Music, and extending so far as Exhibition Road.

The fourth annual issue of the "Girls' School Year Book (Public Schools)" has now appeared. The book becomes year by year more complete, and certainly provides a useful directory for those interested in the education of girls. It is, however, still difficult to understand the editors' method of selection of schools for detailed treatment. Among new features this year are articles on domestic science, teachers' registration, the teaching of music in public secondary schools, and a list of lecturers suitable for schools. The volume is published by the Year Book Press, c/o Messrs. Swan Sonnenschein and Co., Ltd., and its price is 2*s*. 6*d*. net.

A fully illustrated description of the college of engineering of the University of Illinois is contained in the issue of the *University of Illinois Bulletin* for March 8. Descriptions are provided of the work and equipment of the eight departments of the college, as well as those of the engineering experiment station and the school of railway engineering and administration. The college has been organised to give such training to young men as will enable them to do efficient work in the branch of engineering or architecture they may select, to meet the demand for highly specialised instruction and research, and to conduct investigations of value to the industrial enterprises of Illinois and distribute the knowledge gained.

In the course of his recent presidential address to the Society of Chemical Industry, of which a short abstract appeared in Nature of June 3, Prof. Meldola made the following appreciative remarks on the modern methods of laboratory instruction in chemistry:—"It is unnecessary here to dwell at too great a length upon the general practical training, although I should like to add that if the level has been raised, and if our teaching has become more philosophical, we are mainly indebted to a former occupant of this chair, Prof. Emerson Reynolds, who is unquestionably the pioneer reformer in the laboratory teaching of chemistry. I am glad of this opportunity of acknowledging the indebtedness of teachers to Prof. Reynolds, because, amidst the later clamour, his share in the development of chemical teaching has been overlooked." This address is published in full in the current number of the journal of the society.

Evidence of the rapid development of the Chinese Empire will be found in an article in *Engineering* for June 18 dealing with the engineering and mining college at Tang Shan, North China. This college was founded in 1906 for the education of Chinese students, and is in connection with the Imperial Railways of North China, both being under imperial administration. The staff consists of a president (Mr. S. S. Young), four English professors in mechanical engineering, civil engineering, mining, and physical faculties respectively, two Chinese *literati*, and a clerical staff. A four years' course was prescribed, and there are now more than 200 students in regular attendance from various parts of the country. Residential accommodation is provided for 160 students, together with houses for the staff, dining hall, and three educational buildings. All technical lectures are delivered in English. While the equipment is as yet far from being complete, it is indisputable that the existence of such an institution is a factor which cannot be disregarded when considering the future position of the Empire.

Mr. David Boyle, the curator of the Provincial Museum of Toronto, had the degree of LL.D. of the University of Toronto conferred on him on June 12, for his eminent services in the cause of archæology and ethnology. Dr. Boyle has been incapacitated for some time, and as he was too ill to attend the regular Convocation, the authorities paid him the unique compliment of holding a special Convocation at his residence, and of conferring the degree while he was lying in bed. Dr. Boyle was presented by Prof. Galbraith, and in the absence of the president, who had sailed for England, the degree was conferred by the vice-president, Prof. Ramsay Wright. Dr. Boyle went to Canada in 1856, and in the face of great difficulties has built up the fine archæological and ethnological collections in the Provincial Museum of Toronto. He is best known to students as the editor of, and chief contributor to, the annual archæological reports of the museum. They were begun in 1898, and form a valuable record of Canadian archæology and ethnology. The later reports have been duly noticed in Nature. We congratulate Dr. Boyle on this academic honour, which crowns a life of self-sacrificing and poorly remunerated toil for the subjects he has so much at heart.

The proceedings at the inauguration of Mr. R. C. Maclaurin as president of the Massachusetts Institute of Technology have been reported at considerable length in the American Press. One of the chief speakers was Mr. Bryce, who greeted the new president as a fellow-Briton, a fellow-Scotsman, and a fellow-member of Lincoln's Inn. Mr. Bryce said that Englishmen and Scotsmen would naturally be sorry that Mr. Maclaurin was not serving their country "in one of the new institutions which we have lately founded to try to make up for lost time in the promotion of scientific instruction." Still, "a scientific inquirer and teacher helps the whole world by the work which he does anywhere in it." In his own inaugural address, President Maclaurin emphasised the following articles in his creed as an educator:—(1) that the end of education is to fit men to deal with the affairs of life honestly, intelligently, and efficiently; (2) that in the higher education of a large and increasing section of the community science should play a very prominent, if not a leading, part; (3) that science and culture must go hand in hand, science being studied and taught in such a way as to make for that broad and liberal outlook on the world that is the mark of the really cultured man; and (4) that "above all we must preserve in our students the freshness and vigour of youth, and see to it with all care that their natural powers of initiative are improved and not checked by our training."

In recent years there has grown up in connection with local education authorities in all parts of the country systems of scholarships providing for the education of boys and girls of varying ages and attending schools of different grades, and also for young men and women anxious to continue their education after school days are over. The report of the higher education subcommittee on the scholarship scheme of the London County Council, recently adopted by the Council, provides an exhaustive account of the educational facilities offered in London to the sons and daughters of parents of limited incomes who have sufficient ability, as tested by examinations, to profit by continued attendance at school and college. The report indicates that in London, as elsewhere, there has been a disposition to multiply unduly the number of scholarships offered for competition, with the result that in certain districts there has had to be a marked lowering of standard of efficiency so that the scholarships might be filled up. This danger, with others, has been under the consideration of the committee, and steps have been taken in the case of certain classes of scholarship to reduce the number available, so that an efficient standard may be maintained. In framing the regulations which will govern the award of scholarships and exhibitions during the next academic year, the committee has endeavoured to arrange that, so far as possible, "no child or young person shall be debarred by poverty from obtaining the kind of education which will prepare him for the career for which his talents and character best fit him, and that the pecuniary emoluments attaching to the scholarships shall be sufficient to enable students to obtain the kind of education, whether industrial, scientific, or literary, which is best suited to their needs and capacities, but not sufficient to induce them to undertake a particular course of study with the object of securing the pecuniary advantages attaching to the scholarship."

As indicating the wide scope of the London County Council scholarship scheme, which has recently been amended, it may be said that in 1905 the Council awarded (*a*) 2600 junior county scholarships to children between the ages of eleven and twelve, and that the annual cost of awarding one of these scholarships annually was 85*l.*; (*b*) 390 probationer scholarships, each costing 56*l.*, to children of thirteen to fourteen years of age; (*c*) 100 intermediate county scholarships, each costing 129*l.*, to boys and girls of from fifteen to seventeen years of age; (*d*) fifty senior county scholarships, each costing some 200*l.*, to students more than eighteen years of age; and (*e*) various scholarships in science, art, and technology, at an expenditure of more than 18,000*l.* To state the scholarships which are to be offered for competition this year will indicate some of the changes which have been made as the result of four years' experience. There are to be (*a*) 1800 junior county scholarships, costing each the same as in 1905, and 300 supplementary junior scholarships of lower value; (*b*) 300 intermediate county scholarships, but the value of each, for sufficient reasons, has been reduced to 72*l.*; and (*c*) 150 senior county scholarships, each as in 1905, costing 200*l.* But, whereas the total expenditure in 1905 was 283,940*l.*, the amount in 1909 has, notwithstanding the greater wisdom of the conditions of award in the scheme, been reduced to 263,080*l.* The report of the Education Committee gives very satisfactory evidence to show that the object the education authorities in London have in view is to secure a high quality in the results they obtain, rather than to spread an incomplete and rudimentary education far and wide.

A NUMBER of people interested in the teaching of housecraft and domestic science visited Battersea Polytechnic on June 29 to see the domestic economy training department. Since the department was opened in 1894 more than 400 students have obtained diplomas, and are now occupying responsible positions in leading institutions and schools; the present number of students above eighteen years of age in the department is 130. Students of the department attend, in their first year, a course in "science as applied to household work," which includes physics, chemistry, physiology, and hygiene. This course is taken in addition to the purely practical work of the domestic arts. During the second session the scientific basis of knowledge thus obtained is applied in the practice kitchens, laundries, and housewifery rooms and hygiene laboratories. In the third year's course the same subjects are treated in greater detail, special attention being directed to bacteriology and the examination of food-stuffs. The main objects of the science work are:—(*a*) to explain, so far as possible, the chemical composition and properties of the materials dealt with in household work; (*b*) to explain the principal chemical and physical changes taking place in the common household operations involved in cookery, laundrywork, &c.; (*c*) to give a training in the principles of scientific method. Special stress is laid on the fact that household work generally is really an application of a number of facts and principles in chemistry, physics, hygiene, bacteriology, &c., and that, in order to understand the *rationale* of the ordinary household processes, a knowledge of the general principles of the branches of knowledge just mentioned is necessary.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, May 27.—Sir Archibald Geikie, K.C.B., president, in the chair.—Notes concerning tidal oscillations upon a rotating globe: Lord **Rayleigh**.—The absolute value of the mechanical equivalent of heat in terms of the international electrical units: Prof. H. T. **Barnes**. It is pointed out that the Clark cells used by the author in his determinations of the mechanical equivalent of heat in terms of the electrical units were prepared according to the old specifications. The absolute measurements of the Clark cell now being carried on with such precision in the various standardising laboratories are expressed in terms of the new form of cell with specially prepared mercurous sulphate. There is an important difference between the cells, which Wolff and Waters have shown amounts to 0·03 millivolts. The author has compared a set of modern cells with cells set up according to the old specifications, and finds the same constant difference. Taking 1·4330 international volts at 15° C. as representing the modern cells, then the cells made by the old specifications must be taken as 1·4333 international volts at 15° C. The author's measurements of the mechanical equivalent at different temperatures were calculated on the basis of a value for the Clark cell equal to 1·4342 international volts at 15° C. Re-calculating on the new basis, the value of the mean calorie is found to be 4·1849 joules. This agrees with Reynolds and Moorby's directly determined mean, which, expressed accurately for an interval of temperature between 0° C. and 100° C., comes to 4·1836 joules. Rowland's mean value between 5° C. and 35° C. is 4·185 joules, while the author's value between the same limits of temperature is 4·1826 joules. Thus, assuming the variation of the specific heat of water to be correctly determined, the value of the Clark cell, equal to 1·4330 international volts, brings the electrically determined mechanical equivalent into excellent agreement with the same constant measured by mechanical means.—An approximate determination of the boiling points of metals: H. C. **Greenwood**. Although high temperatures can now be easily attained by means of electric heating, no general investigation of the boiling points of metals has yet been carried out. Moreover, such values as are available have in most cases been deduced indirectly, and are very discordant. In the present investigation apparatus was devised for directly measuring the temperatures of ebullition under atmospheric pressure of a considerable number of metals, allowing of use up to 2700° C. Heating was effected electrically, and the metal, when unaffected by carbon, was contained in a thin-walled graphite crucible on the outside of which the temperature was estimated by means of a Wanner optical pyrometer. The difference in temperature between the internal and external surfaces of the crucible walls was found to be negligible. Accuracy of the temperature measurements was secured by checking the pyrometer against the "black body" melting points of specially purified strips of platinum, rhodium, and iridium. The following values were found:—aluminium, 1800° C.; antimony, 1440° C.; bismuth, 1420° C.; chromium, 2200° C.; copper, 2310° C.; iron, 2450° C.; magnesium, 1120° C.; manganese, 1900° C.; silver, 1955° C.; tin, 2270° C. In dealing with the metals aluminium, chromium, iron, and manganese, which readily combine with carbon, considerable difficulty was experienced in avoiding contact with carbon at the high temperatures in question. This was finally accomplished by the use of graphite crucibles brasqued with previously fused magnesia. In the absence of this protective lining the boiling point was very greatly modified by carburisation. The temperatures indicated for aluminium and manganese were far below those hitherto supposed necessary for ebullition.—Some results in the theory of elimination: A. L. **Dixon**. The eliminant of two quantics $\phi(x)$, $\psi(x)$, each of the n^{th} degree, may be expressed as a determinant the elements of which are (a_s, r_t), where (a, r) is $[\phi(a)\psi(r) - \phi(r)\psi(a)]/(a-r)$, and $a_1, \ldots a_n, r_1, \ldots r_n$ are two sets of n arbitrary quantities. For three quantics $\phi(x, y)$, $\psi(x, y)$, $\chi(x, y)$, each of the form $\Sigma A_{rs}x^r y^s \,(r \lesseqgtr n,\, s \lesseqgtr m)$, the eliminant is a determinant the elements of which are $F(a_s, b_s, \alpha_t, \beta_t)$ where $F(a, b, \alpha, \beta) = (\phi(a, b),$

$\psi(a, \beta)$, $\chi(a, \beta)\}/(a-\alpha)(b-\beta)$, and $a_1, b_1, \ldots, \alpha_1, \beta_1, \ldots$ are two sets of 2 mn pairs of arbitrary quantities. The eliminant of two quantics $\phi(x)$, $\psi(x)$ may be expressed as a Pfaffian

$$\Sigma\pm[1, 2][3, 4][5, 6] \ldots [2n-1, 2n]$$

where $[r, s] = \{\phi(a^2_r)\psi(a^2_s) - \phi(a^2_s)\psi(a^2_r)\}/(a_r+a_s)$. The eliminant of three quantics $\phi(x, y)$, $\psi(x, y)$, $\chi(x, y)$ of the ordinary standard form $\Sigma A_{rs}x^ry^s$, $(r+s \eqslantless n)$ is given by the Pfaffian

$$\Sigma\pm[1, 2][3, 4][5, 6] \ldots [2n^2-1, 2n^2]$$

where

$$[r, s] = (\phi(a_rb_r, a_r+b_r), \psi(a_ra_s, a_r+a_s), \chi(a_sb_s, a_s+b_s))/(a_r-b_s)(a_s-b_r).$$

—The liquidus curves of the ternary system aluminium-copper-tin: J. H. **Andrew** and C. A. **Edwards.** The study of the constitution of alloys is of great theoretical interest, and of some practical value; in fact, it may be said that the heat treatment of a given series of alloys cannot be correctly accomplished without an accurate knowledge of the structural changes which occur with varying temperature and concentration. We are now in possession of accurate data bearing on the constitution of a large number of alloys containing only two elements, but very little work has been published on mixtures of three or more metals. The object of the present research was to throw some light on the properties of ternary alloys, and, incidentally, the effect of impurities on binary alloys. The metals from which the alloys were made had the following degree of purity:—

	Per cent.
Aluminium	99·57
Copper	99·98
Tin	99·98

Freezing-point determinations.—The freezing points of the alloys were determined directly after mixing by means of a platinum + 10 per cent. iridium thermo-junction. The free ends of the wires were connected by a mirror galvanometer and balancing arrangement similar to that described by Messrs. Carpenter and Keeling in their work on the iron-carbon alloys. In order to locate the position of the isothermal curves, more than 400 alloys and melting-point determinations were made. *Conclusions.*—The character of the liquidus curves indicates that no well-defined ternary compound is deposited from any of the liquid alloys. The affinity of tin for either aluminium or copper is not sufficient to overcome the affinity of the last two elements for each other. As a consequence of the above, curves of the melting points of alloys containing a constant percentage of tin bear a striking resemblance to the liquidus curve of the aluminium-copper alloys. Tin is insoluble in by far the greater number of the alloys.—Studies on the structure and affinities of Cretaceous plants: Dr. M. C. **Stopes** and Dr. K. **Fujii.** This paper is the first account to be published of the anatomy of Cretaceous plants petrified in calcareous nodules. As an introduction to the flora, eighteen plants are described, all of which are new. The age of these plants is Upper Cretaceous, as is determined from the ammonites which abound in the matrix of the nodules, and the locality of all the specimens described is Hokkaido, northern Japan. The plants include one fungus, three ferns, eight gymnosperms, and six angiosperms. These numbers seem to represent, roughly, the proportions of the flora of the nodules as a whole, of which many more specimens are in the hands of the authors than are described in the present paper. The most interesting of the plants are:—a new type of gymnosperm, Yezonia, of which the vegetative anatomy is different from that of any known genus; a gymnospermic fructification, also new, which there is good reason to believe belonged to Yezonia; an angiosperm which is included in the Sabiaceæ; an angiosperm of the family Saururaceæ; and the first petrified flower, Cretovarium, which has three carpels surrounded by the perianth. The names of the described plants are:—*Petrosphaeria japonica, Fasciostelopteris Tansleii, Schizaeopteris mesozoica, Niponophyllum cordaitiforme, Yezonia vulgaris, Yezostrobus Oliverii, Araucarioxylon tankoensis, Cedroxylon Matsumurii, C. Yendoii, Cunninghamiostrobus yubariensis, Cryptomeriopsis antiqua, Saururopsis niponensis, Jugloxylon Hamaoanum, Populocaulis yezoensis, Fagoxylon hokkaidense, Sabiocaulis Sakurii, Cretovarium japonicum.* The phylogeny and distribution of these plants is considered so far as possible.

June 17.—Sir Archibald Geikie, K.C.B., president, in the chair.—The nature of the hydrogen flocculi on the sun: Prof. G. E. **Hale.** Photographs of the Hα line in the spectrum of the solar disc, made on Mount Wilson with high dispersion, were shown on the screen. The line appears as follows:—(1) A broad dark line, differing greatly in intensity and width in different regions of the sun. Except in eruptive or rapidly changing phenomena, the differences in width are not very marked. (2) Within the boundaries of the dark line a narrow single or multiple bright line is photographed in many parts of the sun. Sometimes the appearance resembles that of the calcium lines K_2 and K_3—*i.e.* the bright line lying on its dark background is divided into two components by a central dark line. In other regions the bright line is divided into a larger number of components, varying in width and separation. The images of dark hydrogen flocculi, on spectroheliograph plates taken with camera slit about equal in width to Hα, appear to be due, in the main, to local increase in the intensity of the dark line. In some parts of the sun, particularly those where the line is distorted, variations in the width of the line may also play an important part. The increased intensity of the dark line is probably the result of increased absorption. Slides were shown to illustrate the fact that prominences at the sun's brink are frequently recorded as dark flocculi when photographed in projection against the disc. The possible effects of anomalous dispersion were discussed, and photographs were exhibited of the same region of the sun, taken simultaneously with light from the red and violet edges of Hα. The similarity of these photographs apparently indicates that anomalous dispersion is not the prime factor in producing the hydrogen flocculi. Certain minor differences suggest, however, that it may perhaps play a secondary part in modifying their form.—The origin of certain lines in the spectrum of ε Orionis (Alnitam): Sir Norman **Lockyer,** K.C.B., F.R.S., F. E. **Baxandall,** and C. P. **Butler.** The star ε Orionis (Alnitam) is of great importance as offering a possible transition stage between the helium and bright-line stars, and the only outstanding lines of unknown origin were those at 4097, 4379·8, and a conspicuous double at $\left\{\begin{matrix}4647·6\\4650·8\end{matrix}\right.$. In the case of 4097, the clue to the identification was obtained from a spark spectrum of chromium, showing local intensifications of certain lines at one of the poles. Two of these lines were found to be the previously known silicon (iv) lines, 4089, 4116, probably present as impurities in the fused chromium, while one of the remaining two lines was found to coincide with the ε Orionis line at 4097. These four lines are shown under various conditions in the plate, indicating the steps taken in tracing their origin to nitrogen. In the spectrum of nitrogen, under the special conditions which gave the above lines at 4097, 4103, another line was found at 4379·8, which was greatly strengthened in comparison with its intensity in the ordinary spark, and this line coincides with the unknown line in ε Orionis. During the work on the above lines, one of the photographs taken of an alcohol spectrum showed abnormal intensifications on either side of the oxygen line 4649·2, suggesting the presence of a new double. The wave-lengths of the components of this double were determined as 4647·6, 4650·8, coinciding with the wave-lengths of the components of the strong double in ε Orionis. By a series of comparison photographs of spectra under varied conditions, the origin of the double was traced to carbon, and one of the strips of the plate (carbon spark in hydrogen) shows it quite isolated as it appears in the stellar spectrum. Further evidence of the validity of the identification is afforded by the peculiar nature of the components of the double.—Electric induction through solid insulators: Prof. H. A. **Wilson.** This paper contains an account of a series of experiments on the variation of the capacity of ebonite and other condensers, with the time of charging and with the potential difference. It is shown that the capacity

C after a time of charging t is given by the formula $C=C_0(1+B\log(1+pt))$, where C_0 denotes the capacity when $t=0$ and B and p are constants. In the case of ebonite at 30° C. this formula represents the results obtained to within 1 part in 2000. The values of the constants have been found for several substances at different temperatures. The capacity is shown to be independent of the potential difference within the limits of error. It is shown that after the temperature of an ebonite condenser has been changed, then a very slow change in the capacity goes on which continues for more than 100 hours at constant temperature.—The effect of pressure on the band spectra of the fluorides of the metals of the alkaline earths: R. **Rossi.** It was shown by A. Dufour that the band spectra of the fluorides of the alkaline earths show a marked Zeeman effect, and it was thought interesting to see whether these particular bands would also be displaced by pressure, for it is known that the cyanogen bands, which, like most bands, do not show a Zeeman effect, are not displaced by pressure. The large 21½-feet concave grating spectrograph of the physical laboratory of the Manchester University was used, and the bands of the fluorides of calcium, barium, and strontium were found to be shifted by pressure. The order of magnitude of the displacement is about the same as for line spectra.—The components into which the bands are resolved are widened by pressure, and the linear relation between pressure and displacement found by former observers on line spectra seems to hold also for these bands. There does not seem to be any evident relation between the magnitudes of the Zeeman and pressure-shift effect in the case of these bands.—The ionisation produced by an α particle: Dr. H. **Geiger.** The aim of the experiment was an accurate determination of the number of ions produced by an α particle when completely absorbed in air. The most direct way to find the number of ions would be to measure the whole ionisation produced by the α particles from a known quantity of radium C. Since it is, however, practically impossible to obtain the saturation current due to the α particles at atmospheric pressure, it was necessary to adopt an indirect method. This method was briefly as follows: The ionisation due to the whole number of α particles expelled from a known quantity of radium C was measured at a low pressure, allowing only a small definite portion of the range of each α particle to be effective. The ratio of the ionisation produced within this small portion of the range to the ionisation produced along the whole path was then found from an accurate determination of the ionisation curve. It was found that the number of ions produced in air by an α particle from radium C along its whole path is $2{\cdot}37\times10^5$. Since the α particles from different radio-active products differ only in their initial velocity, it was possible by the aid of the ionisation curve of radium C to calculate the number of ions produced by the other products.—A diffuse reflection of α particles: Dr. H. **Geiger** and E. **Marsden.** It was observed that a diffuse reflection takes place when α particles are incident on a plate. The reflected particles were counted by the scintillations produced on a zinc sulphide screen. The effect was found to vary with different metals as reflectors, the amount of reflection being approximately proportional to the atomic weight of the reflecting substance. Using different numbers of thin gold foils as reflectors, it was found that the reflection was a volume effect, and thus similar to the reflection of β particles. Taking a measured quantity of radium C as source, and using a plate of platinum as reflector, it was found that, of the incident α particles, about 1 in 8000 suffers reflection.—The decay of surface waves produced by a superposed layer of viscous fluid: W. J. **Harrison.** An estimate is obtained of the effect of a thin layer of viscous liquid on the decay of waves at the surface of a slightly viscous liquid. The period equation for the motion is of the fourth degree, and has two real and two complex roots in the case of waves of less than a certain length, and four complex roots in the case of waves of greater length. The real roots correspond to dead-beat modes, the complex roots to propagated modes. No general expression of any use can be obtained for the damping, but the equation can be solved numerically in any particular case. In the paper the velocity of propagation and the modulus of decay are given for waves of length 2, 5, 10, 20 cm. at the surface of mercury on which is superposed a layer of glycerine 1 mm. in depth. An estimate is also obtained for the damping when the wave-length is small compared with the depth of the layer. Two other problems in the decay of surface waves are discussed.—The passage of electricity through gaseous mixtures: E. M. **Wellisch.** (1) An experimental method (based on Langevin's method) has been devised in order to ascertain whether there are two distinct mobilities for the positive or for the negative ions produced by Röntgen rays in a mixture of two gases, or of a vapour and a gas. (2) No evidence was found of the existence of the two distinct mobilities; accordingly it is necessary to conclude that the motion of the ion through the medium must involve a mechanism of a character such as to produce a statistical average. (3) Experiments were conducted with regard to the effect produced on the ionic mobilities in air by adding small quantities of vapours. The mobilities showed a marked decrease on the addition of alcohol and acetone, but were not sensibly affected by the addition of the heavier vapours of methyl iodide and ethyl bromide. (4) Experiments were performed with regard to the ionic mobilities in mixtures of a gas and a vapour, the ions being formed from the latter constituent only. As a result of the experiments, it was shown that there must be, at all events initially, a transference of the charge (both positive and negative) from the vapour to the gas molecule. (5) Experiments were performed with regard to the stability of the vapour ions in the presence of hydrogen; it was shown that the vapour molecules can accompany the charge to an appreciable extent, even in the presence of a considerable quantity of hydrogen. (6) The mechanism by which the transference of charge from one molecule to another is effected has been discussed; there is reason to believe that the transference takes place by the medium of a detachable unit of positive electricity. (7) From the experimental results a theory of the mechanism underlying the passage of electricity through gases at ordinary temperatures and pressures has been deduced.—A study of the use of photographic plates for the recording of position: Dr. C. E. K. **Mees.**—The coefficients of capacity and the mutual attractions or repulsions of two electrified spherical conductors when close together: Dr. A. **Russell.** The computation of the electrostatic energy of two spherical conductors when close together is an important problem in spark systems of wireless telegraphy. In this case the formulæ previously given for the capacity coefficients are very laborious to evaluate. By extending a mathematical theorem due to Schlömilch, an approximate formula is obtained for the sum of a certain infinite series. By using this theorem, it is shown that when the spheres are close together the ordinary series formulæ for the capacity coefficients can be written in forms which can be readily computed to any required degree of accuracy. The author has re-computed and extended in this way Kelvin's table for the capacity coefficients of two equal spheres when the least distance between them does not exceed half the radius of either. When the spheres are at microscopic distances apart, the formulæ become very simple. Kelvin's table also for the rates at which the capacity coefficients of two equal spheres alter with the distance between them, when this distance does not exceed half the radius of either, has been re-computed and extended. When the spheres are very close together the laws of attraction and repulsion are simple. Let the radius of each sphere be a, let x denote the least distance between them, and suppose that the ratio V_1/V_2 of the potentials of the two spheres is not nearly equal to unity, and that x/a is very small compared with unity. In this case the mutual force between the spheres is attractive, and is given by

$$\frac{a(V_1-V_2)^2}{8x}\text{ approximately.}$$

If the potentials of the spheres be equal, the repulsive force between them is, to a first approximation, given by Kelvin's formula for the repulsive force between two equal spheres when in contact. When the charges on the spheres are $+q$ and $-q$ respectively, and x/a is small compared with unity, the attractive force between them is given by

$$\frac{2q^2}{ax\{\log_e(a/x)\}^2} \text{ approximately.}$$

—The effect of previous magnetic history on magnetisation: E. **Wilson**, G. E. **O'Dell**, and H. W. K. **Jennings.** It is well known that if a piece of iron be subjected to a considerable magnetising force, and then be tested for permeability corresponding to a lower force, the permeability so obtained may differ widely from the permeability which would have been obtained had the material been previously demagnetised. The principal object of this paper is to examine the effect of previous history upon the dissipation of energy by magnetic hysteresis. A ring of iron was carefully demagnetised, and the hysteresis loop No. 1, corresponding to a force H, was obtained. The force was then increased to a value H_1 for the purpose of producing previous history, and removed. A hysteresis loop No. 2, corresponding to the force H, was then obtained. As is well known, this loop shows a reduced permeability. The ring was carefully demagnetised, and a hysteresis loop No. 3 obtained as follows. A magnetising force supplied by an additional coil was gradually increased, until on reversal of the original force H a change of magnetic induction exactly equal to that observed in the case of loop No. 2 was obtained. Two loops (Nos. 2 and 3) have now been obtained, each having the same change of magnetic induction and the same net change of force H. The change from loop No. 1 to loop No. 2 has been brought about by inter-molecular force, whereas the change from loop No. 1 to loop No. 3 has been brought about by the application of an externally applied constant force. If the effect of inter-molecular force were capable of being exactly equivalent to that of the externally applied constant force, one would expect to find that the energy required to perform a complete cycle would be the same in each case—that is, the area of loop No. 2 would be equal to the area of loop No. 3. The experiments show that within certain limits the area of loop No. 2 is greater than that of loop No. 3, the difference depending upon the magnitude of the reversed force H and the previous history.

Mineralogical Society, June 15.—Principal H. A. Miers, F.R.S., president, in the chair.—Carnotite and an associated mineral-complex from South Australia: T. **Crook** and G. S. **Blake.** The carnotite of Radium Hill, near Olary, South Australia, occurs in a definitely crystalline condition. The crystals are tabular and orthorhombic in symmetry. The carnotite of Colorado, though not so definitely crystalline, also contains tabular crystals which are orthorhombic in symmetry, and probably identical in mineral characters with those of South Australia. From the general characters of these crystals it appears that carnotite is a mineral belonging to the uranite group, and that it may be regarded as the vanadium analogue of autunite. The black lodestuff in which the Radium Hill carnotite occurs is heterogeneous in constitution. It consists essentially of ilmenite, which is impregnated with magnetite, rutile, carnotite, and a mineral which is possibly tscheffkinite. The evidence provided by a study of the complex does not necessitate the view that new minerals are present, such as that to which the name "davidite" has been given.—The species pilolite, and the analysis of a specimen from China: G. S. **Whitby.** The specimen examined is from a new source, and possesses the formula $Al_2O_3.2SiO_2,2(MgO.2SiO_2),7H_2O$, a formula which is simpler than those given by Heddle and by Friedel to the pilolites which they investigated. The author considered that, for the present, the term pilolite should be applied to those varieties of mountain leather and mountain cork which (1) cannot be referred to asbestos, on account of their large water-content; (2) cannot be identified with serpentinous asbestos, on account of the relatively small amount of magnesia which they contain; and (3) hold their water in such a way that, when it has been expelled by heating, it is gradually re-absorbed to its original amount from the atmosphere.—Phenakite from Brazil: Dr. G. F. Herbert **Smith.** Crystals of phenakite recently discovered at the gold mine, San Miguel de Piracicaba, Brazil, all display the new form $\{23\bar{5}2\}$ noted by other observers, and another, $\{45\bar{9}6\}$, lying near it. The tetartohedral character of the symmetry is clearly marked.—Preliminary note on the occurrence of gyrolite in Ireland: F. N. A. **Fleischmann.** The mineral gyrolite, though well known as occurring in the basalts of the western islands of Scotland, has not hitherto been recorded from Ireland. Specimens have now been found in the basalts and dolerites in the neighbourhood of Belfast. The mineral occurs in small spherical aggregates, forming a crust on faroelite; it is associated with apophyllite, and occasionally with chabazite. The chemical composition and the optical characters of the mineral agree with those of gyrolite. The mineral is found only in the harder and denser layers of the basalt, and never in the soft, highly amygdaloidal layers.

Zoological Society, June 15.—Dr. A. Smith Woodward, F.R.S., vice-president, in the chair.—The organ of Jacobson in Orycteropus: Dr. R. **Broom.** Orycteropus has a long narrow organ of Jacobson which opens into the naso-palatine canal. The arrangement of the cartilages is quite different from the type found in the higher Eutheria, and there is also a marked difference from the arrangement in Dasypus. The general structure comes nearest to that of the marsupials, though there are a number of striking differences.—Some points in the structure of the lesser anteater (*Tamandua tetradactyla*), with a note on the cerebral arteries of Myrmecophaga: F. E. **Beddard.**—Decapod Crustacea from Christmas Island, collected by Dr. C. W. Andrews: Dr. W. T. **Calman.**—An abnormal individual of the echinoid Amblypneustes: H. L. **Hawkins.**—The decapods of the genus Gennadas collected by H.M.S. *Challenger*: S. **Kemp.**—Notes on a young walrus (*Odobaenus rosmarus*) recently living in the society's gardens: Dr. P. C. **Mitchell.**—Notes on the viscera of a walrus (*Odobaenus rosmarus*): R. H. **Burne.**

Royal Meteorological Society, June 16.—Mr. H. Mellish, president, in the chair.—Interdiurnal variability of temperature in Antarctic and sub-Antarctic regions: R. C. **Mossman.** The author discussed the day-to-day difference in the mean temperature of successive days at a few places in the Antarctic regions for which the necessary detailed daily observations are available. The greatest mean annual temperature variability, viz. 5·9°, was recorded during the "drift" of the *Belgica* in the ice pack, this high value being closely followed by a mean of 5·3° at the South Orkneys. In the Victoria Land region, Ross Island and Cape Adare have a somewhat lower temperature variability of 4·5°, the values of the southern station being higher in summer and autumn and lower in winter and spring than at the northern station. South Georgia occupies an intermediate position between a continental and an oceanic climate in its curve of variability, the mean monthly values varying according to the proximity of the pack ice. At this station the seasonal values show a small variation, and this is also the case at Ushuaia, in Tierra del Fuego. The variability at the Falkland Islands and New Year's Island is very small, pointing to the conserving influence exerted by the insular conditions which prevail at these places. The maximum variability occurs in winter, and the minimum in summer, at the three Antarctic stations, as well as at South Georgia and the South Orkneys. The smallest variability at any season for any station occurs at the South Orkneys in summer, being only 1·4°. It is at this season that cloud amount and fog frequency are at a maximum, while, at the same time, rapidly moving cyclonic disturbances are of infrequent occurrence.—Temperature records during balloon ascents: E. **Gold** and Dr. W. **Schmidt.** The authors described experiments made with the view of ascertaining if appreciable errors could enter into the temperatures recorded in balloon ascents owing to errors in the alcohol-carbonic acid method of testing the apparatus.—The exposure of thermometers: L. C. W. **Bonacina.**

EDINBURGH.

Royal Society, June 7.—Prof. Crum Brown, vice-president, in the chair.—The anatomy of the Weddell seal: Prof. D. **Hepburn**. Dr. W. S. Bruce, leader of the Scottish National Antarctic Expedition, had been fortunate to catch a young male seal only two or three days old, and it was this young specimen of the Weddell seal the anatomy of which was described in detail. Attention was particularly directed to the abdominal cavity, and especially to the peritoneal arrangements and the organs of alimentation. The length of the animal was 51·5 inches, and the length of the intestine 50 feet.—Lower Palæozoic Hyolithidæ from Girvan: F. R. Cowper **Reid**. The description was based on specimens in Mrs. Gray's collection. Nearly all the species were new; ten well-defined species of Hyolithes were established, also three of its subgenus Orthotheca. Two other forms were referred to Ceratotheca, and five new species of Pterotheca were recognised. The affinities of these new species were found to be rather with the Scandinavian than with English members of the group. The rich development of the Hyolithidæ in the Girvan district as compared with other British areas was noticed, and a marked feature of their stratigraphical distribution was the abundance of species in the Blaclatchie beds.—The atomic weight of platinum: Prof. E. H. **Archibald**. The experimental feature of the paper was the extreme care taken to ensure absolute purity of the platinum salts of chloro- and bromo-platinic acids used in the determination. Assuming the values given by the International Committee for the atomic weights concerned in the calculation, the author found the atomic weight of platinum to be not far from 195·25.—Group-velocity and the propagation of waves in a dispersive medium: G. **Green**. The aim of the paper was to develop the idea of group-velocity contained in Kelvin's paper of 1887 on the waves produced by a single impulse in water, &c., and to remove difficulties raised by Kelvin in later papers as to the applicability of Osborne Reynolds's and Rayleigh's dynamical interpretation of group-velocity. The idea of group-velocity used was essentially the same as the principle of "stationary phase" used by Lamb in his investigation of ship waves, but applied in this paper to the Fourier trains which constitute any wave-disturbance. The whole investigation was useful in directing attention to the manner in which group-velocity was concerned in the modification of an initially regular group of waves, or of any disturbance initially confined to a finite portion of a dispersive medium, and in showing, thereby, that the idea of group-velocity contained the explanation of the *modus operandi* of dispersion.—The theory of Jacobians in the historical order of development up to 1860: Dr. T. **Muir**.—*Nematonurus lecointei*, a deep-sea fish first discovered by the *Belgica*, and found again by the Scottish National Antarctic Expedition: Prof. Louis **Dollo**. The one specimen obtained by Dr. W. S. Bruce was found in lat. 62° 10′ S. and long. 41° 20′ W. at a depth of 1775 fathoms, and it constitutes the first macrurid found in the Antarctic seas. The corresponding Arctic zone has yielded eight species in six genera. The results were regarded by Prof. Dollo as unfavourable to the theory of bipolarity.—An experiment with the spark gap of an induction coil: Dr. Dawson **Turner**. When the spark gap is just long enough to prevent the easy passage of the spark, a dielectric rod or plate brought near the positive electrode facilitates the discharge, but when brought similarly near the negative electrode it has no obvious influence on the passage of the spark.

PARIS.

Academy of Sciences, June 21.—M. Bouchard in the chair.—Dimethylcamphor and dimethylcampholic acid: A. **Haller** and Ed. **Bauer**. Camphor forms a sodium derivative when treated with sodium amide, from which the monoalkyl and dialkyl derivatives are readily obtained. The mixture of monoalkyl and dialkyl derivatives can be separated by taking advantage of the fact that only the mono-derivatives combine with hydroxylamine to form an oxime. Dimethylcamphor, heated with sodium amide, gives an amide, probably dimethylcampholamide, from which the corresponding acid has been obtained.—The strata of the island of Elba: Pierre **Termier**.—The new Daniel comet: M. **Javelle**. Observations of this comet were made at Nice on June 16, 17, 18, and 19. The comet was nearly circular, with a diameter of 1·5′. There was a faint nucleus of magnitude 11 to 12.—Observations at the Observatory of Marseilles of the comet 1909*a* (Borrelly): Henry **Bourget**. Nucleus scarcely perceptible, of about 10·5 magnitude.—Observations of the comet 1909*a* (Borrelly-Daniel) made at the Observatory of Besançon with the bent equatorial: P. **Chofardet**. Observations made on June 17 and 19. Diameter, 1·5′; nucleus, very faint; magnitude, 11 to 12.—A question of minimum: S. **Sanielevici**.—The series of Dirichlet: Marcel **Riesz**.—Flight and the shape of the wing: L. **Thouveny**.—An experimental method for aërodynamical researches: A. **Rateau**. The surfaces or models to be studied are placed in a very homogeneous air current moving with a definite velocity. The results of experiments on a thin rectangular plane are shown graphically, and it is shown that there is no possible angle of inclination of the plane between 29° and 36°. This discontinuity was quite unexpected.—The heat of polonium: William **Duane**. The sensitive differential calorimeter used in these experiments has been described in an earlier paper; 0·2 gram of polonium salt gave off 0·0117 calorie per hour. Polonium and radium in quantities which give the same ionisation currents give off practically the same quantities of heat. This fact is favourable to the hypothesis that the heat given off by these bodies is due to the kinetic energy of the α rays.—The ionisation of air by high-tension electric mains: L. **Houllevigue**. The observed case of a hailstorm following exactly the direction of a high-tension cable has been explained by the suggestion that the wire emits torrents of ions carrying large electric charges. Direct experiment fails to confirm this hypothesis. The number of ions, positive and negative, existing in the neighbourhood of a high-tension wire is sensibly *nil*. Indeed, the high-tension lines appear to reduce the number of ions in the immediate neighbourhood rather than increase them.—A new form of the characteristic equation of gases: A. **Leduc**.—A new application of the superposition, without confusion, of small electrical oscillations in the same circuit: E. **Mercadier**. The original experiments were carried out with a complete metallic circuit; similar experiments have now been successfully carried out between Paris and Lyons, using a single telegraph wire with earth return.—A galvanometer for alternating currents: M. **Guinchant**. The galvanometer described was designed to replace the telephone in Kohlrausch's method of measuring the resistance of electrolytes. The accuracy of the measurements is of the same order as when the telephone is used.—The action of some organo-magnesium compounds on methyl-2-pentanone-4: F. **Bodroux** and F. **Taboury**. The reaction is complex, as employing the reagents in molecular proportions there is always a considerable proportion of unaltered ketone in the reaction product, together with the ethylene hydrocarbon corresponding to the tertiary alcohol which should normally have been produced. The tertiary alcohol is formed with a yield varying from 40 per cent. to 60 per cent. of the theoretical.—Some derivatives of thioindigo: M. **Béchamp**.—Elateric acid: A. **Berg**.—Pseudomorphine: Gabriel **Bertrand** and V. I. **Meyer**. Cryoscopic methods indicate that pseudomorphine is derived from two molecules of morphine with the loss of two atoms of hydrogen, and its formula would thus be $C_{34}H_{36}N_2O_6$.—The crystalline schists of the Ural: L. **Duparc**.—The elaboration of the nitrogenised material in the leaves of living plants: G. **André**.—The influence of time on the anti-virulent activity of the secretions of vaccinated animals and the relative immunity of the tissues: L. **Camus**.—The influence of a prolonged stay at a very high altitude on the animal temperature and the viscosity of the blood: Raoul **Bayeux**. The body temperature and the viscosity of the blood, under the influence of high altitudes, undergo modifications which are proportional to the stay at the high altitude.—Hay fever: Pierre **Bonnier**.—The tectonic relations of the earthquake in Provence: Paul **Lemoine**.—A geological sketch of the regions situated to the east and north-east of Tchad: G. **Garde**.—The geology of the Peloponnesus: Ph. **Négris**.—The position of the localities which appear to have been most troubled in the earthquake of June 11, 1909: M. **Jullien**.—The oxydases of the waters of Chaldette (Lozère): F. **Garrigou**.

NEW SOUTH WALES.

Linnean Society, April 28.—Mr. C. Hedley, president, in the chair.—The geology and petrology of the Canoblas, N.S.W.: C. A. **Süssmilch** and Dr. H. I. **Jensen**. The Canoblas are a group of extinct volcanoes in the vicinity of Orange, N.S.W. The western tableland here has an elevation of about 3000 feet. The surface of the tableland is a peneplain, above which rise residuals of a still older plain. This peneplain was cut out of a series of folded Devonian and Silurian rocks, and has since been elevated to its present altitude (3000 feet). The Canoblas Mountains proper consist of lavas and tuffs, deposited upon the peneplain.—Observations on the development of the marsupial skull: Prof. R. **Broom**. A fairly complete series of the diprotodont *Trichosurus vulpecula*, and an interesting early stage of the polyprotodont *Dasyurus viverrinus*, have been studied.—Notes on the synonymy and distribution of certain species of Australian Coleoptera, with descriptions of new species of Tenebrionidæ: H. J. **Carter**. The paper comprises notes upon the synonymy and distribution of a number of species referable to the three families Buprestidæ, Tenebrionidæ, and Cerambycidæ, accumulated during a recent visit to Europe, and especially to the museums in Brussels, Paris, London, and Oxford, together with the descriptions of twenty-one species of Tenebrionidæ proposed as new.

CALCUTTA.

Asiatic Society of Bengal, May 5.—A Goniomya from the Cretaceous rocks of southern India: H. C. **Das-Gupta**.—Coptis: I. H. **Burkill**. The author endeavours to determine the source of the roots of Coptis sold in India. Three kinds are sold, one, as is well known, coming from the Mishmi hills, and being derived from *Coptis Teeta*, Wall, the other two imported over-seas, and possibly being, respectively, roots of *Coptis Teeta*, var. *chinensis*, Fine and Gagnep, and of *Coptis anemonaefolia*, Sieb. and Zucc. Plants of *Coptis Teeta* in cultivation at the Lloyd Botanic Garden, Darjeeling, have been studied, and figures drawn from them.—Morphological and physiological differences between Marsilea left on dry land and that growing in water: Nibaran Chandra **Bhattacharjee**. *Marsilea quadrifolia* does not fruit when growing in water, but only on dried earth.—Notes on the history of the district of Hughli before the Mohammedan period: Nundo Lal **Dey**.—The drug astukhudus, nowadays *Lavandula dentata*, and not *Lavandula Stoechas*: I. H. **Burkill**. It is probable that the importation of *Lavendula dentata* into India began with the Portuguese trade. Before that, *Lavendula Stoechas* from Asia Minor served as the drug astukhudus from the time when the Mohammedans introduced it.—The Manikyala tope: H. **Beveridge**.—First notes on *Cymbopogon Martini*, Stapf: I. H. **Burkill**. The two varieties, Motia and Sofia, are to be distinguished from one another by the absence or presence of the chemical body carvon, by the angle at which the leaves arise, and by different preferences in the matter of climate.

CAPE TOWN.

Royal Society of South Africa, May 19.—Dr. L. Crawford in the chair.—The possible existence at Kimberley of oscillations of level having a lunar period: Dr. J. R. **Sutton**. The outstanding seismic feature of Kimberley is the diurnal variation of level whereby the crust of the earth rises and falls once a day under the influence of some solar action as yet uninterpreted. This matter was discussed in a paper read before the Royal Society of South Africa last July. The present discussion is concerned more with variations of level depending upon the gravitational influence of the moon. The observations do not cover a sufficiently extended period to admit of an exhaustive analysis, but, so far as they go, they imply perhaps that when the moon is south of the equator its attractive force causes the whole of the enormous protuberant mass of the earth's crust forming South Africa to oscillate periodically east and west during the course of the lunar day. This oscillation tends to mask whatever true lunar tide there may be in the solid earth. Only when the moon is nearest to the earth does the pendulum move in such a manner as to suggest that there is such a tide.—The rainfall of South Africa. The possibility of prediction over the south-west: A. G. **Howard**. For this investigation, which extended over five complete years, three stations were selected, so as to secure a triangle of observations, and at each the rise or fall of the barometer in twenty-four hours was noted, together with the direction of the wind at L'Agulhas. From a consideration of the various conditions, which fell under twenty-six heads, and were worked out daily during five complete years, it was found possible to construct a table for prediction purposes. This was applied to the rainfall for the year 1908, and the element of error under each condition of barometer was:—(1) when the pressure was decreasing generally, 5·23 per cent., and (2) when the pressure was increasing generally, about 11 per cent., proving the argument that it is possible to predict rainfall over the district from the date suggested.

DIARY OF SOCIETIES.

MONDAY, JULY 5.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Captain Tilho's Explorations in the Lake Chad Region: Lieut. Mercadier.

WEDNESDAY, JULY 7.

BRITISH ASTRONOMICAL ASSOCIATION, at 5.

THURSDAY, JULY 8, 1909.

RUWENZORI AND CENTRAL AFRICA.

(1) *Il Ruwenzori: parte scientifica: risultati delle osservazioni e studi compiuti sul materiale raccolto dalla spedizione di S.A.R. il Principe Luigi Amedeo di Savoia, Duca degli Abruzzi.* Vol. i., Zoologia e Botanica. Pp. vii+603; 74 plates. Vol. ii., Geologia, Petrografia e Mineralogia. Pp. xxi+286; 40 plates. (Milan: Ulrico Hoepli, 1909.) Price, 2 vols, 50 lire.

(2) *Résultats scientifiques des Voyages en Afrique d'Édouard Foà.* Publiés sous les Auspices du Muséum d'Histoire naturelle. Avec Préface de M. Edmond Perrier. Pp. xli+742. (Paris: Imprimerie Nationale, and Plon-Nourrit et Cie., 1908.)

(1) IN 1906 the Duke of the Abruzzi, already famous for his exploration of the lofty mountains of Alaska, resolved to do what no other traveller had done—make a thorough examination of the range of snow mountains in equatorial Africa known as "Ruwenzori." The number of snow peaks, their altitudes, extent of glaciation, and exact position on the map remained still unknown, although Ruwenzori had been revealed to geographical knowledge for nearly twenty years. Although no previous explorers had had the monetary resources of this prince of the House of Savoy, and consequently been able to fit out such a perfectly organised expedition, yet it must be noted that most of the Duke's predecessors suffered from sheer bad luck in the way of weather, or difficulties arising from the disturbed condition of the natives. Otherwise the Duke of the Abruzzi might have been forestalled as conqueror of these virgin peaks. But in any case it is doubtful whether any previous traveller was so perfectly trained to make every use of his opportunities as the Duke of the Abruzzi, who, apart from his carefully chosen staff, selected to deal specially with geology, biology, and photography, was himself a highly trained surveyor, scientific geographer, and alpinist.

The result has been, of course, a complete settlement of the position, height, configuration, and petrological structure of these "Mountains of the Moon"—not, as we now learn, the highest point on the African continent—in that respect they are only third in rank—but surely the most impressive and remarkable among African mountains. The general geographical and meteorological results of the expedition were given in one large volume at the close of 1908 (published in English and Italian). In the two volumes under review, the geological and biological collections and observations of the Duke's expedition are dealt with by a large number of authors, the whole work being edited by Dr. Alessandro Roccati (who has also written on the geology and petrology) and published in Italian only. The volumes are magnificently produced, and are of the highest importance scientifically. They deal justly, even generously, with the work of previous explorers, or with the opinions and researches of British, French, and German authorities (*inter alios*); but why did not Dr. Roccati get some one to go carefully through the proof sheets with him before publication? The two volumes abound in the most ridiculous press errors, wherever the Latin, English, German, or French languages are employed. English is the worst maltreated. The English authors quoted are sometimes made to express themselves in a very puzzling manner.

Ruwenzori was shown by the Abruzzi expedition to be a mountain chain mainly of archæan, crystalline rocks (gneiss, mica-schists, granite, &c.), cut athwart by a curved band of Palæozoic volcanic greenstones (amphibolite, diorite, diabase, &c.). In the upper valleys of the Bujuku, Mubuku, Mahoma, and other streams, born from the snow peaks and the glaciers, there is a lacustrine alluvium (which ought to be interesting of exploration for possible Pliocene or Pleistocene fossils). There are two or three calcareous deposits. The lower stream valleys are bordered by ancient and recent moraines. At the southern base of the Portal Peaks (south-east of Ruwenzori) there are three small dykes of basalt. Elsewhere in the distant foothills to the east and south of Ruwenzori there are plain evidences of recent volcanic activity in the intrusions of basalt, the stratified tuff, the craters of dead volcanoes (often filled with lovely crater lakes), the hot springs and the frequent earthquakes. This volcanic belt links on with the still smoking and devastated region of Mfumbiro and Lake Kivu, and is no doubt synchronous in origin with the volcanic activities of equatorial East Africa and of North Nyasa.

The work under review has much that is interesting to record on the former extension of the Ruwenzori glaciers. The volumes confirm the observations of Scott-Elliott, Moore, the present writer, and other travellers as to the signs of glacier action at comparatively low altitudes (7000 feet and less). If these deductions be correct, similar signs ought to be present (and should be looked for) on the Abyssinian, North Nyasa, Mlanje, Rhodesian, and Drakensberg Mountains. But if these indications of a Glacial period or periods are found in tropical Africa, and if, moreover, they are proved to be coincident in time with the Glacial periods of Europe and North America, will this not tend to dispose of the idea now in vogue that there has been a gradual shifting of the poles of the earth's axis, carrying with it the more or less glacial conditions gathered round the poles to various parts of the earth's surface? This last theory certainly explained more easily the former existence of a vegetation in both the present polar regions sufficiently dense to become transformed in course of time into coal-measures, a vegetation which could not have flourished with a six months' winter-night in every year.

Dr. Roccati thinks that Ruwenzori was at one time a lofty island of archæan rocks rising up out of the waters of an immense fresh-water sea—the Victoria Nyanza, Ibrahim (or Kioga), Albert Nyanza, Albert Edward, Dweru, and Semliki combined. He attributes this idea in its inception to the studies of Mr. C. W. Hobley, a Commissioner in the British East African service who has done so much to increase our knowledge of Equatorial Africa.

The Duke of the Abruzzi established definitely the existence in the Ruwenzori range of six great *massifs* of snow-crowned, glaciated peaks. These are not placed in a continuous chain, but rather in a cluster, almost a broken amphitheatre, with Mts. Speke and Baker in the middle and the snowless Portal Peaks (11,000–12,000 feet) on the eastern side. It is from the south-east that the Ruwenzori giants are most broken down and most approachable. All the snow peaks are grouped within a few miles of one another, but beyond them, to the north, are lofty, snowless hummocks, perhaps rising to 9000 or 10,000 feet, which prolong the chain northwards in the direction of Lake Albert.

The loftiest of the snow-crowned *massifs* or mountains (Mt. Stanley) rises to 16,815 feet at its highest point (the Margherita Peak). The next highest *massif* is Mt. Speke (16,080 feet). After that Mt. Baker (15,988 feet), Mt. Emin (15,797 feet), Mt. Gessi (15,647 feet), and Mt. Luigi di Savoia (15,299 feet).

In possessing all these separate snow-crowned *massifs*, Ruwenzori differs from Kilimanjaro (with only two) and Kenya (only one), besides in the fact that its origin is due to a slow upheaval of the earth's crust, and not—as is the case with the other two great snow mountains of Africa, and their neighbours, Meru and Elgon—to an outburst of volcanic energy.

In the zoological collection made by the Duke was a fine specimen of a leopard obtained at Bujongolo (about 12,000 feet altitude), on the east side of Ruwenzori. It measured about 7 feet 2 inches in total length, and of this measurement the tail only occupied about 2 feet 3 inches. These are rather the proportions in tail and body of a jaguar than of a leopard. The markings, moreover, in the large size and completeness of the rosettes recall the jaguarine type, and still more the boldly marked leopards of Sinai, Persia, and China, and the Central Asian Ounce. The canine teeth in *Felis pardus ruwenzorii* are proportionately much longer than in other African leopards (except in one example from the Abyssinian Mountains). In this point (but not in skull peculiarities) the Ruwenzori leopard resembles the peculiar "*fontanieri*" leopard of China. Prof. Lorenzo Camerano, who describes *F. pardus ruwenzorii*, does not seem to be aware that Mr. Lydekker a year or so ago described a similar type from the Toro country at the north-east base of Ruwenzori. The present writer also saw a large leopard skin of this description in the possession of the Rev. Mr. Teggart (C.M.S.) in eastern Toro in June, 1900. This skin appears in the background of a seated man on p. 587 of the "Uganda Protectorate."

The second volume of "Il Ruwenzori" contains a good deal of interesting material on the subject of the Colobus monkeys (a group which seem to retain points of affinity with the Semnopithecines of Asia, the Archæolemurine forms of Madagascar, and even the Cebidæ of America); of Grant's zebra, and the classification of the "quagga" subgenus of equines; of the Central African buffaloes; and of the squirrels, dormice, mice, and crested rats (Lophuromys) of Ruwenzori. A few new birds are described, and numerous molluscs. A noteworthy contribution to "Il Ruwenzori" is Prof. F. Silvestri's essay on the Myriapoda—the Diplopoda especially—obtained by the Abruzzi expedition.

A very large and important collection was also made of earthworms and of parasitic worms, the latter derived from the intestines of beasts, birds, and reptiles.

The botanical section of this work is also of high interest, as it illustrates very conclusively the alpine and subtropical flora of Ruwenzori—the giant groundsels, strange lobelias, the heaths, junipers, and ferns—filling up many gaps left in the work of previous travellers.

(2) Not equally valuable in the scientific study of Africa is the work so sumptuously produced by the Paris Museum of Natural History. The results of M. Édouard Foà's journeys, to have acquired proper significance and reward from the public interested in African geography and ethnology, should have been published ten years ago. His remarks would then have been more apposite; his discoveries would not have been forestalled by later and more scientific travellers. As it is, M. Foà was at no time what might be called a trained observer, except in regard to astronomical and meteorological observations and records. His ethnology and his natural history strike the critical reader as hazy, inexact, too generalised, too little founded on direct personal observation, too much influenced by traditional opinions. His vocabularies of native languages are full of errors, and are, moreover, quite displaced in interest by the serious treatment of these Zambezian, Central African, and East Congo languages by a host of British, French, and Belgian missionaries and officials. Amongst inaccuracies, too (perhaps on the part of the editors), is the presentation of an obvious Bushman (pp. 142 and 143) as a Yao. [The original of this mis-named picture is in the possession of the Royal Anthropological Institute.] Some of the notes on the Bushmen would be interesting and valuable were they not so devoid of actuality, of names, places, and dates. Apparently M. Foà did encounter some of the mysterious "Vaalpens" in the valley of the northern Limpopo (though he does not give them that name—see pp. 113, 114), a race the existence of which (as a "pygmy" type distinct from the Bushman) has been asserted by Prof. Keane and denied by Mr. Selous. It is interesting to note that M. Foà comments on the complete absence of steatopygy among these north Limpopo Bushmen (? Vaalpens), and the rest of his description rather accords with what Prof. Keane has collected relative to the Vaalpens.

There are portions of M. Foà's essays on the lion and the African elephant which strike one as new, interesting, and derived from original observation, mixed up, however, with much unnecessary padding. He is able to supply two good photographs of the rare Angas's Tragelaph and some fresh information about that handsome creature. He discovered in Central Zambezia what is probably a new subspecies of Burchell's zebra (or, as Mr. R. I. Pocock would say, quagga), which seems in its narrow striping an intermediate form between the zebra and the quagga groups (see also on this subject "Il

Ruwenzori"). M. Foà made considerable collections of fish in Central Africa, of mollusca, insects, spiders, ticks, and crustaceans. He also brought back Medusæ from Tanganyika. These Medusæ serve as a text for a very interesting article by M. Charles Gravier on the Medusæ of the Victoria Nyanza, of Tanganyika, and of the Niger basin. Perhaps the most important contribution to this *recueil* is the treatise by M. Louis Germain on the molluscs of Tanganyika, notably those collected by M. Foà. M. Foà's own remarks on the tsetse fly are worthy of attention. H. H. JOHNSTON.

THE PLANET MARS, 1890–1901.

La Planète Mars et ses Conditions d'Habitabilité. By Camille Flammarion. Tome ii., Observations faites de 1890 à 1901. Pp. 604. (Paris: Gauthier Villars, 1909.) Price 12 francs.

IN the year 1893 we had the great pleasure of giving our readers some account (vol. xlvii., p. 553) of the very excellent and complete summary of the observations of the planet Mars, made between the epochs 1636–1890, compiled by the distinguished French astronomer, Monsieur Camille Flammarion. This work, containing no fewer than 604 pages, presented us with a most interesting survey of the progress made in enumerating and deciphering the markings observed on the planet's surface. It commenced with the earliest known observation of the planet, namely, that of the Neapolitan astronomer Fontana, on August 24, 1638, who wrote:—

"1636. Martis figura perfecte spherica distincte atque clare conspiciebatur. Item in medio atrum habebat conum instar nigerrimæ pilulæ.

"Martis circulus discolor, sed in concava parte ignitus deprehendebatur.

"Sole excepto, reliquis aliis planetis, semper Mars candentior demonstratur."

The volume concluded with the observations made in the year 1890, including the first photographs of the disc of Mars made by Prof. W. H. Pickering at Mount Wilson, California, on April 9.

In Martian cartography the year 1890 seems to-day a very long time ago. The pioneers did their work well, and the great tradition which fell on the shoulders of those who were busy with Mars up to 1890 was well maintained, and a great amount of new knowledge secured. Since that year the attack on the planet, to unravel the secrets of its visible features, has been no less severe, and to-day the knowledge gained is only a new incentive to further research.

If we were to be asked to state three or four of the more recent and most important discoveries in relation to the planet Mars, we should be inclined to say as follows:—

(1) That the dark areas on the planet which were considered to be seas have been shown to be traversed by permanent lines, and that, therefore, the water surface explanation had to be abandoned (Pickering and Douglas, 1892).

(2) The successive development of the canals according to the Martian seasons (Lowell).

(3) The photography of the canals themselves (Lampland, 1903–5).

(4) The photography of the spectrum of water vapour in the Martian atmosphere (Slipher, 1908).

While the above may be considered as four of the important results secured since 1890, there is a host of many other valuable advances which will be found recorded in the volume under review.

Monsieur Flammarion has done his work exceedingly well, and, with masterly instinct, describes, fits together, and discusses the observations, made between the years 1890 and 1901 by a very great number of workers, in a logical and interesting manner.

Before commencing to give in detail the observations of the first epoch, 1892, he rightly refers at some length to the fine memoir published in 1896 by the celebrated Italian astronomer, M. Schiaparelli, the discoverer of the canals. This memoir is devoted to a discussion of his observations of the Opposition 1883–4, while a sixth memoir, published in 1899 and here referred to, contains his observations made at the Opposition of 1888.

Space does not allow us, nor indeed is it necessary, to enter into any detail into the successive series of observations which are here marshalled together. The reader must be left to peruse the volume himself and form his own conclusions, but even he will be astonished at the wealth of matter which is brought together under one cover.

As in the previous work, there is a great number of illustrations accompanying the text, and these add materially to the understanding of the changes of Martian features.

At the end of the volume, M. Flammarion, with the help of M. Antoniadi, has constructed a key-map of the surface features of the planet, which gives us an idea of the complicated system of markings which is the result of the observations up to the year 1901.

As has been mentioned above, some important additions to our knowledge of Mars have resulted from observations of more recent date, and we can only suppose that M. Flammarion has in hand vol. iii., which will, we hope, in due course be published, and be as valuable a contribution to astronomical science as its two predecessors.

In conclusion, we may quote M. Flammarion's remarks with regard to the habitability of Mars, since the subject has recently been prominently brought forward:—

"Mais il me semble que, dans toutes ces interprétations, je suis moi-même un peu terrestre. Il y a sans doute là d'autres éléments, non terrestres, mais *martiens*, ou, tout au moins, des conditions toutes différentes de celles de notre habitation. Que cette planète soit actuellement le siège de la vie, c'est ce dont témoignent toutes les observations. Mais il nous est encore impossible de nous former aucune idée judicieuse sur les formes que cette vie a pu revêtir, formes assurément differentes de nôtres. Un mystère impénétrable enveloppe encore aujourd'hui ce passionnant problème, qui est, en définitive, quoi qu'on en passe, le but, peut-être inaccessible, de toutes les recherches de l'Astronomie planétaire. Mais ne désespérons jamais! Qui sait ce qui sommeille dans l'inconnu de l'avenir?"

WILLIAM J. S. LOCKYER.

THE GEOMETRY OF FORCES.

Geometrie der Kräfte. By H. E. Timerding. Pp. xii+381. (Leipzig: B. G. Teubner, 1908.) Price 16 marks.

In this admirable volume Prof. Timerding gives a systematic and original treatment of the geometry of forces and force-systems in which for the first time, so far as we are aware, an adequate knowledge of modern geometrical research has been utilised in a text-book of mechanics.

Ever since the great work of Plücker, that large and most attractive department of mathematics known as the geometry of the linear complex has been found to be intimately connected with the geometry of forces. It is sufficient to recall the fact that whenever six forces applied to a free body are in equilibrium, the forces must lie respectively on six rays of a linear complex. In chapters viii. and ix. of Timerding's book now before us we have an admirable treatment of the application of the theory of the linear complex to the theory of systems of forces. The many interesting matters set forth in these pages show how greatly the advancement both of the geometrical theory and the dynamical theory is promoted by their association.

The statical and dynamical significance of the linear complex is closely connected with the fact that each ray of the complex is reciprocal to that screw of which the axis is the axis of the complex, while the pitch of the screw is the parameter of the complex. Many of the geometrical properties of the complex follow directly from this general principle. For example, on p. 107 it is shown that four linear complexes have two real or imaginary rays in common. This is an immediate consequence of the fact that one cylindroid can always be found of which every screw is reciprocal to any four given screws. As there are two screws of zero pitch on the cylindroid, these lines are, of course, the two common rays of the four linear complexes defined as being reciprocal to each of the given screws. We congratulate Prof. Timerding on his recognition of the proper place for the linear complex in the forefront of a text-book on the geometry of forces.

The theory of screws has received in this volume a treatment even more ample than that which it has already received in the works of Fiedler, Schell, Budde, Minchin, and more recently in the "Encyclopädie der mathematischen Wissenschaften." The excellent work of Harry Gravelius, "Theoretische Mechanik Starrer Systeme," contains a complete account of the theory of screws up to the date of its publication in 1889. Much of the work done on the subject in the succeeding decade has been available for the "Geometrie der Kräfte." It may, however, be remarked that certain developments of the theory which have appeared since 1900 have not been included in Prof. Timerding's volume. The theory of screw-chains, by which the theory of screws has been extended to any material system, is also not discussed. A suggestive reason for this omission is given in the preface (p. vii), where Prof. Timerding says that, in his opinion, the theory of screw-chains would require a new and voluminous treatment of the whole of mechanics in which the rigid body would appear as the first element.

Observing that the laws for the composition of twists and wrenches are identical, the author, as others have done, uses the word *dyname* to signify either a twist or a wrench. For a large part of the subject the use of the abstraction signified by the word dyname is very convenient, and considerable use has been made of the important labours of Study on the geometrical theory of dynames.

In an interesting chapter on "Die Reyeschen Strahlencomplexe" the author brings into its due prominence the fundamental importance of the "Geometrie der Lage" in kinematics. This chapter contains many admirable theorems, and we could only wish that such instructive and beautiful ideas as are here set forth were more generally introduced into the teaching of mechanics. Due acknowledgment is made throughout the work of the important contributions to the geometrical theory of forces by the late Prof. Charles J. Joly.

The chapter on the cylindroid may be specially commended, and prominence is given to the theorem that the projections of any point on the generators of a cylindroid lie on an ellipse. We may, however, note that the proof here set forth is not that by which the theorem was discovered, as shown in the original volume on the theory of screws published in 1876.

A sufficient account is given of the various systems of screw coordinates, and, following the analogy of the resolution of forces, Prof. Timerding uses notation which divides the coordinates of a screw into two groups of three each. It is, however, often convenient to use the six symmetrical coordinates of a screw referred to six co-reciprocal screws.

We are glad, indeed, to commend this most excellent work to the attention of teachers and students of theoretical dynamics. We are sure that if the book were translated into English it would form a very valuable supplement to the existing English books. It would give the student an adequate idea of the extent to which modern geometrical theory and the theory of forces act and react on each other to the vast benefit of both.

Robert S. Ball.

THE DISTRIBUTION OF GOLD ORES.

Gold: Its Geological Occurrence and Geographical Distribution. By J. Malcolm Maclaren. Pp. xxiii+687. (London: *The Mining Journal,* 1908.) Price 25*s.* net.

Dr. Maclaren begins his preface with the remark that "the writer who would add one more treatise to the literature of the study of ore-deposits must needs show justification." Any apology for the publication of his useful book is, however, quite unnecessary, for the increase by four times of the gold yield of the world during twenty years has been attended by a voluminous and scattered literature. Students of mining geology will be grateful to any author who undertakes the great labour of compiling a summary of recent work on gold and its distribution.

The longest and most valuable section of Dr. Maclaren's book is occupied by an account of the geological structure and mining history of all the chief goldfields of the world. This part of the work occupies 514 pages. The goldfields are classified by continents. Those of Europe are described first, and in proportion to their economic importance receive longer notice than those of Australia and South Africa. The longest section is that on the goldfields of North America. Each field is noticed separately; the descriptions are necessarily short, but they are concise, and are accompanied by useful reference to recent literature. The minor fields are described at relatively greater length than the others; and thus Kalgurli, with its "Golden Nile," is dismissed in four pages, including a full-page map and another figure. This distribution of space is, however, probably the most useful, as the less-known fields are often very instructive and their literature is less accessible. The author has travelled extensively, and his accounts of many fields have the advantage of personal knowledge and original information. The descriptions of the fields are therefore inevitably of unequal merit.

Among the most interesting sections are those on the mines of New Zealand—though as a New Zealander, it is strange that the author places Reefton in Westland, and spells the name of the founder of the New Zealand school of mining geologists Uhlrich—of Queensland (the author was once on the staff of its Geological Survey), and of Mysore. The historical introduction to the Mysore gold mines is of especial interest, and the author rejects the view that the ancient mines there can have been those from which Solomon and the Phœnicians obtained their supplies of gold. Dr. Maclaren remarks that India was then a civilised State, which needed more gold than it produced; and the Israelites could only have obtained gold there by barter, for which they had nothing to offer. This conclusion, therefore, strengthens the view that the Ophir of the Phœnicians must be in southern Africa, and that the gold probably came from the prehistoric mines of Rhodesia.

Dr. Maclaren's account of the separate goldfields is preceded by an introduction on the chemical and physical properties of gold, on natural and artificial compounds of gold, and on the theories of the formation of gold ores. The speculative section of this introduction is remarkable for the author's advocacy of somewhat extreme positions. Thus he denies the origin of any important ore deposits by other agencies than meteoric waters. He admits that there may be some magmatic water; but even when he allows that the gold is due to magmatic emanations, he holds that the water in which it is dissolved comes from a superficial source. He also holds to the once popular view that alluvial gold and gold nuggets are formed by growth *in situ* in the gravels from percolating gold-bearing solutions. He defends this view especially on the ground of the crystalline character of much alluvial gold; he quotes competent authorities who deny this fact, but affirms it from his own experience. The author does not explain why, on this precipitation theory, nugget formation is so local, and why the nuggets are so constantly found just below the outcrop of reefs containing nuggety patches of gold. He admits that the nuggets of Western Australia are derived from gold-quartz veins, and the evidence for the similar origin of the nuggets from Victoria—which contains the most famous of nugget-yielding goldfields—seems to the writer overwhelming.

Another doubtful hypothesis advanced by the author is the absence of any undoubted, valuable pre-Cretaceous placer deposit. He rejects, or quotes with apparent approval those who reject, the alluvial origin of the gold in various Mesozoic, Palæozoic, and Archæan conglomerates and sedimentary deposits; and he then argues that the absence of pre-Cretaceous detrital gold is due to the rocks having been lowered into a zone saturated with alkaline waters which removed the gold in solution and re-deposited it in veins.

Though many geologists may be disposed to differ from the author in some of his conclusions as to the formation of gold ores, they will be no less grateful to him for this valuable and trustworthy summary of the voluminous gold literature issued during the past twenty years. J. W. G.

SWINE IN AMERICA.

Swine in America. A Text-book for the Breeder, Feeder, and Student. By F. D. Coburn. Pp. xv+614. (New York: Orange Judd Co.; London: Kegan Paul and Co., Ltd., 1909.)

JUST as it might be said of the British fat bullock that he has followed the turnip, so it might be said of the American fat hog that he has followed the corn, *i.e.* Indian corn. In the United States there are 56 millions of swine—there are only three and a half millions in the United Kingdom—and far more than half these are to be found in the great corn States which are drained by the Mississippi and its tributaries. Iowa comes first with $8\frac{1}{2}$ millions, and Illinois and Nebraska next with $4\frac{1}{2}$ and $4\frac{1}{4}$ millions. Altogether there are about eighty million pounds' worth of swine in the United States, the duty of which it is to convert corn and other crops and by-products into more marketable commodities, and eventually to feed, not only the Americans, but also some part of the industrial population and the armies and navies of the rest of the world.

An industry so vast can do with many a text-book, and Mr. Coburn has produced one for those who breed, rear, and feed the raw materials for the American packing houses. Many experiments have been carried out in the States on the rearing and fattening of swine, and the gist of these is embodied in Henry's "Feeds and Feeding," which, however, is a book dealing rather with principles than with the details of management, and a book, therefore, for the student rather than for the farmer. Mr. Coburn's is a farmer's book. He has collected Henry's and many other data, and set them forth in such a way that the nutritive effect and economic value of every important feeding stuff and by-product is dealt with, whether these foods are fed separately or with others. The effects of bulky and succulent foods and of concentrates, and of these consumed separately and jointly, are fully considered. Thus, for instance, a farmer having a lot of corn is told what proportion of alfalfa, or roots, ought to be fed along with corn to attain the best economic results. This part of Mr. Coburn's book is valuable.

In the earlier chapters Mr. Coburn deals with the various races and breeds of swine in the States, and also with the principles of breeding; but, as may be inferred from the following quotation, although he writes at some length, he does not get much beyond the current nebulous ideas held by stock-breeders on these subjects:—

"There exists in some sections of Old Mexico a type of 'hog' which is the product of crossing a ram and a sow, and the term 'Cuino' has been applied to this rather violent combination. The ram used as a sire to produce the Cuino is kept with the hogs from the time he is weaned. . . . The Cuino reproduces itself and is often crossed a second and third time with a ram."

A number of the illustrations are not accurate representations of the breeds they refer to, but are rather artist's ideals.

OUR BOOK SHELF.

A Text-book of General Pathology for the Use of Students and Practitioners. By Prof. J. M. Beattie and W. E. Carnegie Dickson. Pp. xvi+475. (London: Rebman, Limited, 1908.) Price 17s. 6d. net.

In the preface the authors state that this volume is based on the teaching of the Edinburgh school of pathology, where the first chair of pathology in the United Kingdom was founded, and as such we welcome its appearance. At the same time, we do not note any features particularly novel, either in the subject-matter or in its arrangement, and in some respects the book seems to be lacking as a text-book of general pathology. Thus the important factor of heredity in disease, and shock and collapse, are not even mentioned, and we do not understand why a discussion of the nature of gout and the chemistry of uric-acid metabolism "do not come within the scope of the present volume."

The opening chapter deals all too briefly with the cell in health and disease. An excellent summary of modern views on cell-structure and cell-division is presented to the reader, but the section on the chemistry of the cell is mainly occupied with the recommendations of the Chemical and Physiological Societies on protein nomenclature.

The chapters which follow deal respectively with general retrogressive processes, disturbances of the circulation, inflammation and repair, progressive tissue changes, animal parasites, and immunity.

An excellent account is given of fatty change, and modern views respecting it are succinctly stated. Lardaceous disease is similarly well treated, but we do not understand why authors will persist in employing the terms "waxy" and "amyloid" to designate it, for "lardaceous" has the claim of priority; it is official in the "Nomenclature of Diseases" of the Royal College of Physicians, and the material present is universally known as lardacein.

The chapter on inflammation and repair gives all essential details on this important subject. The classification of tumours, admittedly a difficult subject, adopted by the authors is that advocated by Adami. This seems to us unnecessarily complex for the medical student and practitioner. The structure of tumours is given at some length, and the chief views on the causation of tumours are summarised. As regards the latter, one or two points brought out by recent research have been omitted. For example, the occurrence of heterotype mitosis in malignant growths is referred to, but Bashford and Murray's criticism of Farmer, Moore, and Walker's work in this connection does not appear, and in discussing the supposed sarcomatous metamorphosis of carcinoma no mention is made of the fact, which now seems certain, that it is the connective tissue stroma of the carcinoma which is thus transformed, and ultimately overgrows the carcinomatous elements. The vegetable parasites are omitted, as these are dealt with in text-books of bacteriology, but an excellent and fairly full account is given of the animal parasites, protozoan and metazoan. Immunity is discussed in twenty-five pages, and the essentials of the subject are conveyed to the reader.

On the whole, the book may be regarded as a very useful text-book of general pathology. It is excellently got up, and a word of praise must be bestowed on the illustrations, 162 in number (also four coloured plates), the majority of which are the work of Mr. Richard Muir, and as a rule depict very clearly the subjects they represent, though it may be questioned whether so many are really necessary, as they tend to distract the student from an examination of the actual specimens themselves.

(1) *Der Bau des Weltalls.* By Prof. Dr. J. Scheiner. Dritte, verbesserte Auflage. Pp. 132. (Leipzig: B. G. Teubner, 1909.)
(2) *Die Planeten.* By Dr. Bruno Peter. Pp. 131. (Same publishers, 1909.) Price 1.25 marks each.

(1) The series "Aus Natur und Geisteswelt" is well known. It consists of a number of little treatises, in which men of science occupying prominent positions have attempted to explain in an accurate and comprehensive manner the results of past inquiries, and the position to which our knowledge has extended in various directions. In the former of the two specimens before us, Dr. Scheiner gives the substance of six popular lectures delivered in Berlin to a number of high-school teachers in the course of which he attempted to describe so much of the universe as comes within the range of our telescopes. He endeavoured to bring home to his audience the magnificent scheme of distances on which the planetary and stellar systems are planned; he traced the detection of proper motion of the fixed stars, and showed how the sun's movement in direction and amount can be determined. The phenomena of the sun are explained in some detail, preparatory to the examination of the spectra of stars, a subject which is discussed somewhat fully, as might be expected from a member of the staff of the Potsdam Observatory. Herein, as the author points out, he is on the sure ground of observation. But in his last chapter he approaches the more speculative subject of the origin and constitution of the universe. The subject is handled with skill, and, notwithstanding the limited space to which the author is restricted, he has succeeded in making his subject both clear and interesting. We do not wonder that the little work has passed through three editions, for, apart from that longing to satisfy an intelligent curiosity which appeals to so many, the material is put in a very attractive form, which should appeal to many readers.

(2) Dr. Peter has a simpler subject, in which the facts have been many times detailed, and he has little scope for either originality of treatment or lucidity of arrangement. As the planets extend in order from the sun, so he must follow them from Mercury to Neptune. A Vulcan is hinted at within Mercury's orbit, but the

hypothetical planet outside Neptune does not attract comment. Since the satellites of Jupiter and Saturn come under notice, more attention might have been given to the moon and to the phenomena of eclipses. The plan of the book, however, aims rather at the description of the surface than of the motion of the planets, though naturally the tale of the discovery of Neptune is told once again. It might seem that there is scarcely room for such a book, considering the number of popular works that are extant, but there is some difficulty in keeping even these works abreast of the time. As an example we may quote the sentence, "Bestimmt sieben, wahrscheinlich sogar acht Monde umkreisen Jupiter." Notwithstanding the recent issue, there is here opportunity for correction in the next edition.

Untersuchung und Nachweis organischer Farbstoffe auf spektroskopischem Wege. By J. Formánek, with the collaboration of E. Grandmougin. Pp. 252. Second edition. Part i. (Berlin: Julius Springer, 1908.) Price 12 marks.

THE first edition of this work appeared in 1901 in a single volume. In part i. of the new edition which is now before us, subject-matter to which only forty-two pages were devoted in the first edition has been elaborated and added to so largely that it occupies the whole of part i. The introduction deals with spectroscopic methods in general, but more particularly with absorption spectra of coloured solutions and the influence of solvents, concentration, reagents, temperature, &c., on the latter. Then follow chapters on the spectroscope, general observations on the relationship between colour, absorption, fluorescence, and constitution of coloured compounds and dyestuffs, and on the relationship between chemical constitution and absorption spectra of dyestuffs belonging to individual classes. The latter include di- and tri-phenylmethane dyestuffs, quinonimide dyestuffs, fluorindene and triphendioxazine, acridine dyestuffs, and anthraquinone dyestuffs. No mention is made in this part of the azo-dyes, or the dyes of the indigo group, while of natural dyestuffs only alizarin is mentioned. It is to be presumed, however, that these important classes will receive due consideration in part ii., which represents the practical part of the work.

Although a vast amount of work has been done by different observers on the absorption spectra of the organic dyestuffs, the information is so scattered as to be difficult of access to the ordinary individual, and this is probably the main reason why this important subject has hitherto not received the attention which it merits. There is, however, ample testimony that this particular application of the spectroscope is being more and more appreciated by the manufacturers of dyestuffs on the one hand, and the users on the other. This is borne out by the fact that such an eminently practical body as the Société industrielle de Mulhouse has made a pecuniary grant to the author to enable him to publish the new edition. Prof. Formánek has made a life-long study of his subject, and a comprehensive and up-to-date book on this particular application of spectrum analysis, such as the present edition promises to be, would be much appreciated. It is to be hoped that the completion of the work will not be long delayed.

On the Calculation of Thermochemical Constants. By H. Stanley Redgrove. Pp. viii+102. (London: Edward Arnold, 1909.) Price 6*s.* net.

THERE are a number of physical properties of substances, *e.g.* molecular heat of combustion, refractivity, &c., which are chiefly additive in character, so that their values can be calculated if we know the necessary fundamental constants. It is, however, also well known that these properties, while still remaining additive, involve factors depending on the constitution of the molecule, *e.g.* method of linking, ring-formation, &c., all of which should be taken into account in the calculation of the value of the particular property in the case of any given substance. It is the thorough-going application of this principle in the calculation of thermochemical constants, extended so as to include, not only the specific thermochemical values of double and triple bonds, but also the thermal value of the "strain" in ring-compounds and of the single bond in chain-compounds, that the book under review expounds. The author's method of calculation has already appeared in several articles published in the *Chemical News,* on which the present monograph is based.

The author's method will best be understood from the following:—Let H be the value of a hydrogen atom *plus the link joining it to a carbon atom.* Let C be the value of a carbon atom, *not* including the value of its valencies; let L_1, L_2, L_3, be the values of the single, double, and triple bonds respectively. Knowing the constants for four hydrocarbons, it is possible to calculate the value of the following:—$C+4H=\alpha$, $2H-L_1=\beta$, $4H-L_2=\gamma$, $6H-L_3=\delta$. These are the "fundamental constants" for carbon and hydrogen. Moreover, the formula of any compound can be written in terms of these fundamental constants, and the theoretical value so obtained can then be compared with the experimental number.

This method the author has illustrated by the calculation of a large number of heats of combustion of substances belonging to different groups of compounds, and, with comparatively few exceptions, excellent concordance with the experimental numbers has been obtained. In this fact the method has its justification.

In an interesting section the author discusses also the relation between heats of combustion of ring-compounds and von Baeyer's strain theory, and he shows that in general there is perfect agreement. No simple relationship, however, has been obtained between the angle of deviation and the thermal equivalent.

The book is one which deserves and will no doubt obtain the attention of all who are interested in the relations between the thermochemistry of compounds and their chemical constitution; and the method of calculation is, moreover, one which will not improbably find application in the case of other physical properties of an additive character. It is an important addition to the literature of thermochemistry. A. F.

An Angler's Season. By W. Earl Hodgson. Pp. xii+299. (London: A. and C. Black, 1909.) Price 3*s.* 6*d.* net.

A BOOK from Mr. Hodgson is always worthy of the angler's attention, and "An Angler's Season" is no exception to the rule. Dealing as he does solely with salmon and trout, and almost entirely with Scotch waters, the author's season begins in January and ends in October, and to each month a chapter is allotted; throughout there is much good reading, a deal of sage advice, and some controversy. Early in February Mr. Hodgson is already at issue with the dry-fly fisherman, and his attack on the "Hampshire method" waxes furious, but he says nothing of those who fish with the dry fly in Aberdeenshire waters and find the method successful. Fault is also found with some anglers for their "habitual indifference to the weight of a basket" and their love of nature; surely an angler is no worse for also being a naturalist, or at least taking an interest in the natural history of fishes. A study of what naturalists have written would have shown the danger of Mr. Hodgson's theory that taking large fish only, and restoring all of smaller size to the water, would have the effect of increasing the average weight of the stock of fish in three years' time, and would, we think, have prevented the red flesh of some trout being attributed to richer feeding rather than to a differently constituted *menu*. We think, too, that the theory set forth to account for the absence of a run of salmon in some rivers of the east of Scotland in May, June, and July is somewhat strange, and cannot be maintained in the light of our present knowledge of the salmon's life-history.

There are throughout the book numerous practical hints of value upon such subjects as flies and baits, and as to the time and place for fishing under various conditions of water and weather; in the last chapter there is also a most thrilling tale of a riverside adventure. The illustrations, reproduced from photographs, are excellent, but are almost invariably separated by many pages from the corresponding text, and there is a good index. L. W. B.

A New Departure in Seismology.

ON the photographic records obtained from British Association types of seismograph it has been noticed that when the films have been moving slowly (60 mm. per hour) there have been slight thickenings in the trace, while if the recording surface has been moving quickly (240 mm. per hour) the line which ought to be straight is slightly wavy. These irregularities, which have hitherto received but slight attention, are so small that they may be easily overlooked. When the thickenings were first observed it was supposed that their existence was due to a flickering at the source of light or to some irregularity in the movement of the record-receiving surface. When, however, it was observed that these markings frequently occurred at the same time at different stations, as, for example, at Shide and Bidston, the conclusion was that they were due to movements of the ground, and might be the surviving phases of large movements with origins at a distance.

A very good illustration of this is given by comparison of the times of occurrence of the after-shocks which followed the earthquake of January 14, 1907, in Jamaica, with the times at which suspicious irregularities were found on the seismographic traces at Shide and Bidston. Between January 14 and July 5, 148 shocks were noted in Jamaica. Forty-three minutes after the occurrence of fifty-one of these shocks irregularities were found on the films at the stations mentioned. As forty-three minutes is the time we should expect a "surface" wave to travel sixty-seven degrees, or from Jamaica to England, the inference is that the slight irregularities represent movements which had their origin in Jamaica. Corresponding markings, with the exception of one at Göttingen on July 5, do not appear in the registers from European stations, which are not more than six or seven degrees farther from Jamaica than Britain.

Another instance of the recording of after-shocks are the markings seen on seismograms after the disaster which, on December 28, 1908, ruined Messina and Reggio. Between December 29 and January 30 at Mileto, forty miles from Messina, 225 shocks were noted. Eight of these reached the Isle of Wight, while on January 1 and 13 at Göttingen, Hamburg, and Laibach, only two were noted. The reason that so small a number travelled a considerable distance indicates that the originating impulses were weak. That a larger number should be recorded in Britain than at comparatively near stations is not so clear.

With smoked paper recording surfaces, whether the multiplication of recording levers be 10 or 200, a certain slackness in joints and elasticity of pointers prevents any record of motion being obtained until a certain amplitude of ground motion has been reached. With photographic recording apparatus where a light source is far from a recording surface, a thick line may obscure any minute movement. These instruments are therefore unsuitable as recorders of very small movements. This, at any rate, has been my experience.

The British Association type of instrument, when properly adjusted and installed, does, however, pick up these neglected movements—a result which is shown very clearly in the registers for this year.

It seems to me that beneath observatories all over the world earth-messages may be passing every few minutes, but these are not recognised because instruments generally in use are not capable of recording the same. To investigate this possible new departure in seismology, old types of instruments will have to be improved or new ones adopted. JOHN MILNE.

Shide, Isle of Wight, July 2.

Tables of Bessel Functions.

A COMMITTEE of Section A of the British Association for the Advancement of Science, appointed to undertake the further tabulation of Bessel functions, is at present considering the advisability of unifying and completing the existing tables with the view of the publication of a complete table of Bessel functions.

The committee would be glad of information as to existing tables of Bessel and Neumann functions with a real or complex argument, in addition to the following, of which the members are already aware:—

(1) *Meissel's Tables* (reprinted in Gray and Mathews' treatise on Bessel functions) giving $J_0(x)$ and $J_1(x)$ from $x=0$ to $x=15\cdot5$ at intervals of 0·01 [12 places]; also a table of the first 50 roots of the equation $J_1(x)=0$ to 16 places.

(2) *British Association Tables* (1889, 1893, 1896 Reports) giving $I_0(x)$ and $I_1(x)$ from $x=0$ to $x=5\cdot1$ at intervals of 0·001 [9 places]; also $I_0(x)$ to $I_{11}(x)$ from $x=0$ to $x=6\cdot0$ at intervals of 0·2 [11 and 12 significant figures]; also a table of $J_0(x\sqrt{i})$ from $x=0$ to $x=6$ at intervals of 0·2 [9 places]. (Part of these tables are reprinted in Gray and Mathews.)

(3) *Tables of* $J_n(x)$ *in Gray and Mathews* from $n=0$ to $n=60$ and from $x=0$ to $x=24$ at intervals of unity [18 places].

(4) *B. A. Smith's Tables* giving $Y_0(x)$, $-Y_1(x)$, $(\log 2-\gamma)J_0(x)-Y_0(x)$ and $(\log 2-\gamma)J_1(x)-Y_1(x)$, from $x=0$ to $x=1\cdot00$ at intervals of 0·01 and from $x=1\cdot1$ to $x=10\cdot2$ at intervals of 0·1 [4 places: error not exceeding 2 in the last place]. (*Messenger of Maths.*, vol. xxvi., 1897, and *Phil. Mag.*, vol. xlv., 1898.)

(5) *Aldis' Tables* of $I_0(x)$, $I_1(x)$, $K_0(x)$, $K_1(x)$ from $x=0$ to $x=11$ at intervals of 0·1 [16 places]. (Roy. Soc. Proc., 1896 and 1899.)

(6) *J. G. Isherwood's Tables* of $K_0(x)$ to $K_{10}(x)$ from $x=0$ to $x=5$ at intervals of 0·2 [5 significant figures]. (Manchester Lit. and Phil. Soc., vol. xlviii., 1904.)

The committee will be grateful to be allowed, through the medium of NATURE, to invite any readers who are aware of the existence of tables of Bessel functions other than the above to make known this fact.

Communications should be addressed to the secretary of the committee, Dr. L. N. G. Filon, University College, Gower Street, W.C. M. J. M. HILL.

University College, Gower Street, W.C.

Baskets used in Repelling Demons.

IN the issue of NATURE published on May 27 Mr. Kumagusu Minakata inquires regarding the use of baskets in repelling demons in countries other than Japan. In Calcutta, and I believe in other parts of India, it is customary when a new building is being erected to set up on the highest part of the scaffolding a pole, to the top of which a round basket and a scavenger's broom are attached. The basket and broom are apparently recognised as emblems of the low-caste "sweeper," and therefore as being disgusting objects. They are supposed to ward off ill-luck from the building. Their use in this instance may thus be compared to the use in many countries of obscene objects or gestures as a protection against malicious spirits or the evil eye. N. ANNANDALE.

Indian Museum, Calcutta, June 13.

THE SINHALESE PEOPLE AND THEIR ART.[1]

TO many it will appear that in this work Dr. Coomaraswamy has attempted too much; certainly the three purposes for which he tells us the book has been written have so little in common that a book which even in measure shall satisfy all three cannot be otherwise than loosely knit and somewhat amorphous. This volume, we are told, is written "first of all for the Sinhalese people as a memorial of a period which at present they are not willing to understand. . . . Secondly it is meant for those in East and West who are interested in the reorganisation of life, and especially of the arts and crafts under modern conditions. Thirdly, an endeavour has been made to render it as far as possible of value to the anthropologist, and to students of sociology and folklore." It seems very doubtful whether the Sinhalese people, with the possible exception of a few of the "educated" of whom Dr. Coomaraswamy speaks with scant sympathy, will appreciate the effort made for their benefit, and though there is much of interest to the folklorist and anthropologist in this sumptuous volume, it is as a work of art done for art's sake that the work is most interesting and valuable, and certainly few will be found to imitate Dr. Coomaraswamy's example at a time when publishers tell us *éditions de luxe* do not sell.

Not only the contents of the book preach the gospel of art, but, as it has been printed by hand on handmade paper, it is itself an excellent example of the point of view which, since this is a pioneer work, the author has been free to express with the least possible constraint. It is, indeed, in the fact that so much new ground is broken that the high merit of this volume lies, for it is certainly the first time that a detailed account of the arts and crafts of a small area in the East has been given, and it is well to remember that the culture here described was really limited to some two million people, inhabiting, roughly, two-thirds of an island, itself about the size of Ireland.

The arts and crafts of Ceylon, as they exist at the present day, represent the result of the action of western influence on the mediæval conditions which prevailed until the British occupation of Kandy, less than a century ago. It is with the remains of this late-lasting mediæval culture that Dr. Coomaraswamy mainly deals, and we are thus given an account of the work of the craftsmen of a feudal period in which there was no great attainment in fine art, brought about by the genius of a few men, but in which there was a widely spread popular art largely based upon early Indian traditions, for "Sinhalese art is essentially Indian, but possesses this special interest, that it is in many ways of an earlier character, and more truly Hindu—though Buddhist in intention—than any Indian art surviving on the mainland so late as the beginning of the nineteenth century. The minor arts and the painting are such as we might expect to have associated with the culture of Asoka's time, and the builders of Barahat. . . . It was the art of a poor people, the annual income of whose kings did not in the eighteenth century amount to 2000*l*. in money, besides revenue in kind."

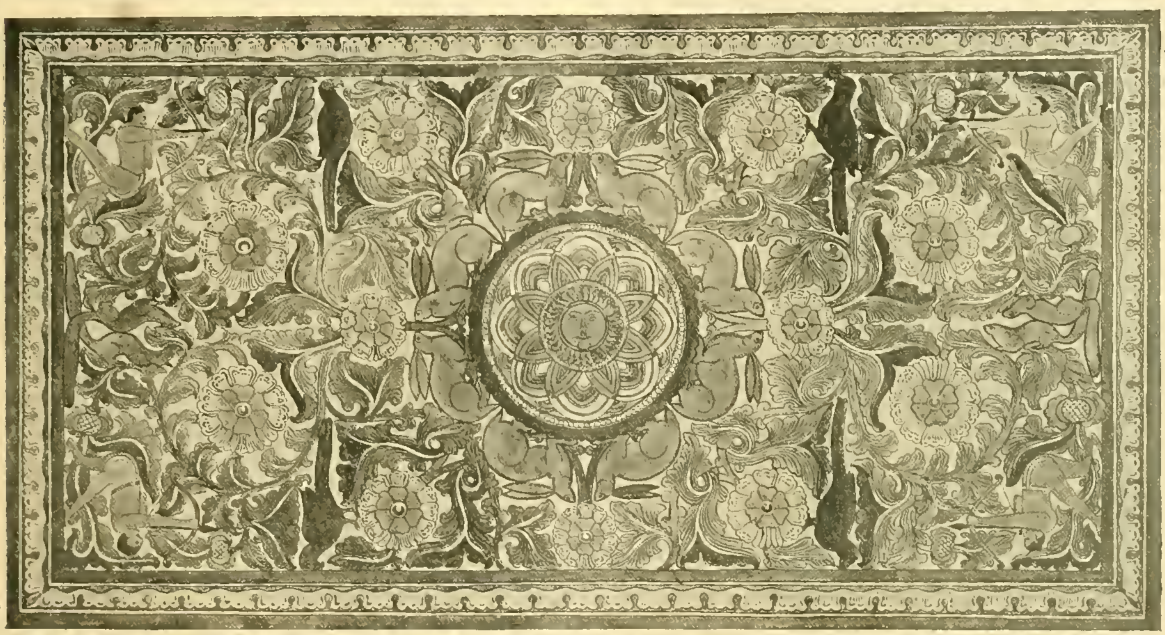

FIG. 1.—Verandah Ceiling Painting, Dalada Maligawa, Kandy. 19th Century. Now destroyed. From "Mediæval Sinhalese Art."

The first chapter of Dr. Coomaraswamy's book is devoted to the Sinhalese people and their history. The next chapters discuss the social organisation of Sinhalese society, and while the difficult question of caste is but lightly touched upon, considerable space is devoted to the personal services rendered to the king and his high chiefs. This account shows how true was Knox's narrative, and it is pointed out that Sinhalese villages were self-contained to such a degree as to be dependent upon the outside world for little but salt. The religion of the people is rapidly sketched, and certainly too little stress is laid on the large element of demonism—"devil-worship"—in the actual working religion of the Sinhalese. A most interesting account is given of the *nētru mangalaya*, or "eye ceremony," by which the image in a temple is dedicated. This consists essentially in the painting of the eyes of the image, when the figure, before this, "not accounted a god but a lump of ordinary metal" (Knox), becomes so full of power that in some cases

[1] "Mediæval Sinhalese Art." By Ananda K. Coomaraswamy. Pp. xvi+340; 53 plates. (Broad Campden, Glos.; Essex House Press, Norman Chapel, 1908.) Price 3*l*. 3*s*. net.

anyone interfering with it is smitten with sickness. In this ceremony a mirror was held to receive the first glance (*belma*) of the image while the eyes were being painted.

An account of the teaching of drawing as practised at the present day serves as an introduction to a consideration of the *motifs* employed in Sinhalese decorative art. Although there is an immense amount of new material in this section, it may be doubted whether it would not have been rendered more valuable to all, as it certainly would have been to the anthropologist, if greater attention had been paid to the history of the evolution of the individual elements of decoration; for instance, the *makara*, which bulks so largely in Sinhalese art, and which occurs on the Barahat Stupa, *circa* 200 B.C., is dismissed in rather less than half a page of print, while the *hamsa* fares even worse. These and many other conventional elements were most skilfully combined, and the beauty of the results attained is seen in plate xvi. (here reproduced in Fig. 1), of a nineteenth-century ceiling painting from the Dalada Maligawa, Kandy, representing a forest scene.

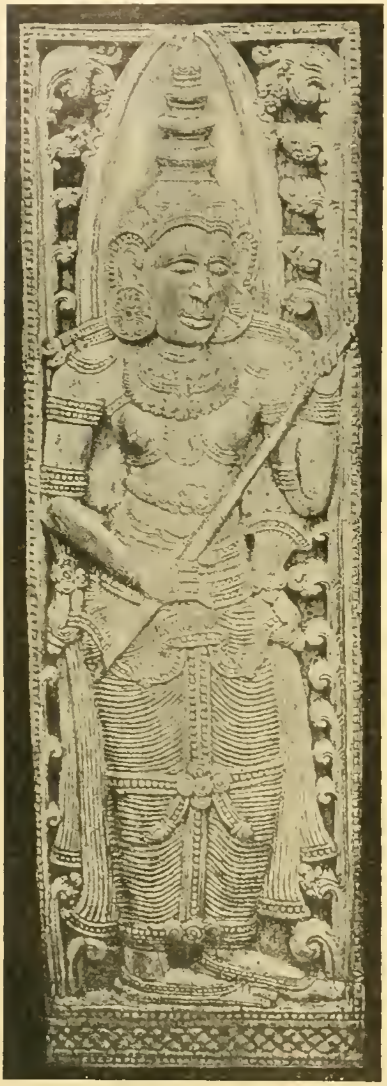

FIG. 2.—Guardian Deity from a Temple Door Jamb, Ivory. Height of plaque, 10¼ inches. Colombo Museum Collection. From "Mediæval Sinhalese Art."

There are chapters on architecture, woodwork, stonework, figure sculpture, and painting, the reduced colour plates of some of the wall paintings in Degaldoruwa Vihara, Kandy, being extraordinarily faithful reproductions of the originals, the spirit of which they have preserved to a surprising degree.

An interesting conjecture is made in chapter x., which suggests that ivory was comparatively little used in Indian art on account of the Hindu reluctance to use the products of dead animals; Buddhists had no scruples of this sort, and so ivory was always valued and used in Ceylon even in temples, with the result that ivory carvings are perhaps the most beautiful and pleasing fruit of the Sinhalese art impulse, rivalled only by some of the superb inlay metal work still existing on the temple doors. Fig. 2 represents an ivory carving in the Colombo Museum of a guardian deity from the jamb of a temple door.

In the last two chapters Dr. Coomaraswamy shows that, in the present stage of our knowledge, it is only possible to indicate the main sources which have influenced Sinhalese art. The most widely exerted influence in Indian art is that due to the Asokan Buddhist missions, the culture which these dispersed being early Indian; thus Sinhalese art is largely the result of the evolution of an early Indian art, in part sheltered by the geographical position of Ceylon from that Hinduism which overwhelmed it upon the mainland. But in post-Asokan and mediæval times this art was continually exposed to Indian influence; "indeed, until the close of the period of mediæval conditions, the relations between Southern India and Ceylon were similar to those obtaining in the Middle Ages between France and England." This leads to the suggestion that the famous rock paintings at Sigiri, the like of which are found only at Ajanta, are due to a school, representatives of which were to be found both in India and Ceylon. The fine bronzes recently found by Mr. H. C. P. Bell at Polonnarua and now in the Colombo Museum, though of a later date, point in the same direction, for the whole feeling of these is Hindu. To sum up, Dr. Coomaraswamy sees in Sinhalese art "an early stratum of indispensable barbaric decorative motives, . . . then a main stream of North Indian Buddhist influence; and thereafter the influence of continued reliance upon and intercourse with India, especially Southern India, accounting at every period for the strong admixture of purely Hindu with Buddhist *motifs*." With this conclusion few will quarrel, though Dr. Coomaraswamy says all too little concerning the earliest stratum. It remains only to direct attention to the number and excellence of the photographs by Mrs. Coomaraswamy, and to indicate that it is owing to her energy that the remains of the moribund art of Sinhalese embroidery have been brought together to form chapter xv.

C. G. S.

A DISCUSSION OF AUSTRALIAN METEOROLOGY.[1]

THE meteorology of the southern hemisphere presents a specially attractive field of study. The large area of water surface conduces to much simpler conditions than are to be found to the north of the Equator, and here, if anywhere, the meteorologist may hope to discover the fundamental principles underlying the general movements of the atmosphere. On the other hand, he has to face the relative paucity of data. The meteorological organisations of the three great land areas are still young, and our knowledge of what is happening over the sea is woefully small as compared with the completeness with which we are able to track down changes occurring over the great trade routes of the North Atlantic. The present discussion forms a recapitulation and a completion of work published from time to time from the Solar Physics Observatory, of which abstracts have appeared in previous numbers of NATURE (lxx., p. 177; lxxiv., p. 352). At the outset we congratulate Dr. Lockyer on his success in bringing together a vast amount of information and on the skill with which he has marshalled the facts deduced therefrom.

[1] Solar Physics Committee. A Discussion of Australian Meteorology, by Dr. W. J. S. Lockyer, under the direction of Sir Norman Lockyer, K.C.B., F.R.S. Pp. vii+117; 10 plates. (London: Wyman and Sons, Ltd., 1909.)

The opening chapters deal exclusively with Australian conditions. Pressure observations are considered first. The mean amplitude of the difference between a number of conspicuous minima and the succeeding maxima in the curves showing the annual variation, amounts to more than seven-hundredths of an inch. When the curves for those stations for which long records are available are compared, they all show a marked similarity, and the important generalisation is arrived at that simultaneous excess or defect of pressure in any one year is a marked feature of the whole Australian continent, and is not restricted to any one particular portion of this area. Coming next to the rainfall observations, an examination of the curves leads to a similar conclusion. Years of low rainfall are, broadly speaking, years of deficiency over the whole continent, and in years of excess the excess is also general. Moreover, a comparison of the rainfall and pressure curves suggests very strongly that periods of high pressure are periods of low rainfall, and *vice versa*. These are generalisations of great importance, for they introduce a great simplification, and correspondingly facilitate the further study of Australian weather conditions. In view of the few data available in proportion to the area considered, a meteorologist, arguing from analogy, might be disposed to regard these as hasty generalisations. The extraordinary variability of rainfall in other parts of the world is well known, and for its adequate study a large mass of information is essential. When the necessary figures are forthcoming we find that even within the narrow limits of our own islands there are very conspicuous differences between the north of Scotland and the south of England. Australian conditions are, however, different. As Dr. Lockyer points out, the weather of the continent is dominated primarily by anticyclones travelling from west to east. In years of high pressure these anticyclones are found to embrace a wider area, and thus the low-pressure systems which skirt their edges and bring rain to the northern districts in summer, and to the southern ones in winter, affect the land area to a smaller extent.

In discussing these questions of correlation, whether it be between variations of the same element at different places or between different elements, Dr. Lockyer uses the similarity between two curves as his standard of measurement. The points of resemblance to which he directs attention are, indeed, striking. At the same time, the reader feels a desire for a more definite expression of the relation between the elements under comparison. When we come to the correlation between the Australian curves and those for other parts of the world, which takes up much of the later part of the work, this becomes more imperative. Thus, on p. 72, after discussing the striking resemblance between the pressure changes at Adelaide and those of Bombay or Batavia, we read, "While the Cordoba curve is nearly the inverse of Adelaide—the curve for the Cape seems to be intermediate, being more inclined to be similar to the Australian type of variation than that of South America." The intermediate between two curves which are inverse to one another should be a straight line. If it is meant that the Cape curve follows now the variations of Adelaide and now those of Cordoba, it becomes a matter of importance to have some means of comparing the degrees of similarity in the two cases. Superpose any two arbitrarily drawn curves showing fluctuations of approximately the same amplitude, and we are sure to find that some of the maxima and minima agree. Can we say by how much the correlation between the curves we are discussing exceeds that between curves drawn arbitrarily?

The question of periodicity naturally comes in for discussion. After eliminating a variation of short period by taking means of groups of four years, Dr. Lockyer claims that the smoothed curves for Australia show a periodicity of nineteen years. It is true that there are conspicuous maxima in 1868 and 1897, and minima separated by about the same number of years, but this does not of itself prove a recurring periodicity, and the case is not advanced by drawing a "hypothetical" curve through the points of maximum in which an intervening secondary maximum is disregarded and replaced by a principal minimum. The occurrence of a similar interval between the maxima in the pressure curve for South America, but of other epoch, is suggestive, but the question of the connection between the two continents remains one for further study.

A highly suggestive and interesting chapter on the air movements over the three great land areas of the southern hemisphere points out some interesting similarities between the pressure distribution and the incidence of rainfall of the three continents. The volume also contains an interesting comparison of the flow of the Murray river with the rainfall, and of the frequency of southerly "Bursters" with the variations of pressure. The work thus ranges over a wide field. It offers much that is new, and brings together from a common point of view much information that has hitherto been scattered in a number of individual papers. R. G. K. L.

POSSIBILITY OF AN EXTRA-NEPTUNIAN PLANET.

M. GAILLOT has contributed an admirable note on this subject to the *Comptes rendus* (March 22). A summary of his calculations is set forth so clearly as to be easy to follow, and if we have one regret it is that he has not published the discordances between observed and tabular positions that necessarily form the basis of his work. We suppose that the *Comptes rendus* do not admit masses of tabular matter, and we wish to express the hope that M. Gaillot will publish this information somehow or other.

A review recently appeared in NATURE (June 17, p. 463) on Prof. W. H. Pickering's calculations. We there maintained that Prof. Pickering's supposed planet "O" could not possibly produce sensible perturbations in Uranus. Now, M. Gaillot and Prof. Pickering both locate their hypothetical planets in the same part of the sky. M. Gaillot's mass is five times that of the earth, or two and a half times that of Prof. Pickering's "O." A reader of the previous review will see that M. Gaillot's planet would, therefore, produce in Uranus inequalities exceeding a second of arc. We suspect that Prof. Pickering has made some numerical mistake in estimating the mass of his planet "O," and, if he can rectify this, we should then have two independent researches in practical agreement. M. Gaillot's result is, however, sufficiently confirmed by the analogy from inner planets developed in the previous review.

The important question now arises, "Are the observed discordances sufficiently large to point unmistakably to some unknown planet?" It is clear that an inequality with a coefficient of one second of arc appears to exist in the observations; but the elliptic constants of the orbit of Uranus are arbitrary, the observations are liable to small errors, and the theory of the action of known planets is not perfect. All this shows how unsafe it would be to assert the real existence of the inequality which would in its turn demonstrate the existence of an unknown planet. We may draw an analogy from the moon. The real existence of a term with coefficient nearly three seconds and period sixty-four years is now generally admitted in the motion of the moon. This term was first defined in 1904, and the case for its real existence was not a strong one until Prof. Newcomb arrived in 1909 at an almost identical conclusion from the totally different evidence of occultations. The term in the motion of Uranus must therefore be doubtful for the present. We are not entitled to do more at present than hope that it is real, and that a corresponding planet will reward M. Gaillot's admirable work. This doubt is fully admitted by M. Gaillot.

"Ces résultats ne doivent être acceptés d'ailleurs qu'avec une extrême réserve. En effet, les différences entre les positions observées d'Uranus et celles qui sont calculées a l'aide de nos Tables ne dépassent guère les limites des erreurs probables des observations augmentées de celles qui résultent des imperfections de la théorie. . . ."

It is noteworthy that, like Prof. Pickering, M. Gaillot bases his hypothetical planet upon Uranus and not upon Neptune. It appears, therefore, that the motion of Neptune is in good agreement with the tables, and that no extra-Neptunian planet can exist of a mass and epoch to produce sensible inequalities in the motion of Neptune since its discovery. This is an important negative result; in fact, if it be assumed that the unknown planet has a mass at least one-third that of Neptune, a considerable part of the ecliptic is excluded from the domain where this planet can possibly be found.

THE SORBY RESEARCH FELLOWSHIP.

IT will be remembered that the late Dr. H. C. Sorby, F.R.S., of Sheffield, bequeathed a sum of 15,000*l.* to the Royal Society of London to be held in trust for the establishment of a professorship or fellowship for original scientific research, the testator expressly desiring the professorship or fellowship thus founded to be associated with the University of Sheffield. Accepting this trust, the council of the Royal Society appointed a committee to confer with representatives of the University of Sheffield with the view of drawing up a scheme for giving effect to the intentions of Dr. Sorby's will.

A scheme, prepared by this committee for the establishment of a "Sorby Fellowship for Scientific Research" to be associated with the University of Sheffield, has now been approved and adopted by the council of the Royal Society, and by the senate and council of the University of Sheffield. This scheme provides for the administration of the income of the fund by a joint committee consisting of four persons appointed by the council of the Royal Society, one person appointed by the council of the University of Sheffield, and two by the senate of that University.

The object of the fellowship is not to train students for original research, but to obtain advances in natural knowledge by enabling men of proved ability to devote themselves to research; and in making an appointment the committee will pay special attention to the capacity for original work of a candidate, as shown by the work already done by him, and to the likelihood that he will continue to do valuable work. Each appointment will be in the first instance for five years, subject to the control of the committee, but may in special circumstances be prolonged for further periods if the committee is satisfied with the fellow's work.

The fellow will be required to carry out his research, when possible, in one of the laboratories of the University of Sheffield, and provision is made under the regulations for the setting aside of a sum not exceeding 50*l.* a year to form an apparatus fund, from which grants may be made from time to time to the fellow for the purchase of special apparatus and material required in his research. The stipend of the Sorby Research Fellow will probably be about 500*l.* per annum, and it is hoped that the committee will be in a position to make the first appointment to the fellowship early in the coming autumn.

PROF. T. W. BRIDGE, F.R.S.

WE regret to record the death, on June 30, of Dr. T. W. Bridge, Mason professor of zoology in the University of Birmingham. By his death the University is deprived of one of its oldest and most experienced teachers, and zoological science has lost one of those workers who, under the influence of Balfour and the Cambridge school, have contributed largely both by example and precept to our knowledge of vertebrate morphology.

Prof. Bridge was born in Birmingham in 1848, and after studying science at the Birmingham and Midland Institute, went in 1870 to Cambridge as assistant to Mr. J. W. Clark, then director of the Museum of Zoology. In 1872 he was elected to a foundation scholarship at Trinity College, and appointed demonstrator in zoology under the late Prof. Newton. After his graduation in 1875, he spent six months at Naples working in the zoological station, where, on the advice of F. M. Balfour, he carried out research into the "abdominal pores" of fishes. In 1879 he was appointed professor of zoology in the Royal College of Science at Dublin. In 1880 he became one of the original professors at the Mason College, Birmingham, holding the chair of biology; and when this chair was divided in 1882 he retained the title of Mason professor of zoology and comparative anatomy, and kept the same position when the Mason College became a University in 1900.

The original work carried out by Prof. Bridge dealt chiefly with the osteology of ganoid fish, the "poriabdominales" of vertebrates, and the air-bladder of Teleosts. The most important of these memoirs are undoubtedly those dealing with the last subject, and the large paper by Profs. Bridge and Haddon, published in the Philosophical Transactions in 1893, on the air-bladder of Siluroids, has become a classic. This work was the first thorough investigation dealing with the structure and physiology of this organ which had appeared since Weber's original discovery and fundamental treatise on the air-bladder published in 1820. In certain Siluroids, Weber found that extraordinary apparatus which still bears his name. He described in a few families the vertebral elements that link the air-bladder with the ear, and concluded that the apparatus subserved the function of hearing in these fish. What was now required was a systematic inquiry into the variation of this mechanism and into the use or uses of it; and it is this monographic treatment that we owe to Prof. Bridge and his collaborator. They investigated 100 species of Siluroids, and concluded that this highly specialised mechanism was employed, not for audition, but for the registration of varying hydrostatic pressures. These memoirs not only advanced our knowledge of this interesting structure, but threw light on many points of ecological interest in connection with other physostomatous Teleosts.

Prof. Bridge's most recent work was his article on fishes in the "Cambridge Natural History" (1904). This article has proved one of the most useful treatises on this subject both to teachers and students. The value of his work was recognised by his election into the Royal Society in 1903.

We must not conclude this short article without bearing witness to the great success of Prof. Bridge as a teacher. He excelled, to no common degree, in grounding his pupils in the elements of zoology. As examination candidates his students showed unusual accuracy, and, in the main, a wide knowledge. Those of them who were able to go further and undertake some piece of research found in him not only a stimulus, but an unwearied guide and a sagacious critic.

NOTES.

M. G. DARBOUX has been re-elected president of the Société des Amis des Sciences, MM. Aucoc and Picard vice-presidents, and Prof. Joubin general secretary. The society was founded in 1857 by Baron Thenard with the view of assisting unfortunate inventors, men of science, and professors and their families. Among the names of past-presidents of the society occur those of Thenard, J. B. Dumas, Pasteur, and others. Since its foundation the society has distributed in pensions and grants more than two and a half million francs. This year eighty pensions have been granted to old savants or their widows. The society has assisted the education of some seventy children, and made grants to thirty-five widows. The work of the society should appeal to all who benefit from the work of men of science. Information as to the society may be obtained from the treasurer, M. Fouret, 79 boulevard Saint-Germain, Paris.

WE learn from *Science* that the people of Honolulu have guaranteed already half the money asked for by the Massachusetts Institute of Technology for the maintenance of an observatory which the institute proposes to establish at the brink of Kilauea for the study of volcanic action.

THE Geologists' Association is arranging a long excursion to the Arenigs, from July 28 to August 7, under the direction of Mr. W. G. Fearnsides. The excursion secretary is Mr. E. Montag, 4 Queen's Road, Rockferry, Birkenhead.

THE Vienna correspondent of the *Times* announces that during excavations near Willendorf on the Danube by the prehistoric section of the Austrian Natural History Museum, a chalk figurine, 11 centimetres high, representing a female figure, was discovered in a stratum containing instruments and weapons characteristic of the Stone age.

THE maps of the cadastral survey of Egypt have just been used to determine accurately the area of land planted with cotton and its distribution. Each plot in which cotton was sown was marked on the maps (scale 1/2500), so that not only the area and position were recorded, but, since the land-tax has been recently re-assessed with the aid of these maps, the distribution of cotton on land of different degrees of fertility was also determined. The total area was 1,466,530 feddans, or 1,522,258 acres.

THE Naples Academy of Sciences (mathematical and physical section) offers a prize of 1000 lire for the best essay containing a systematic exposition of our present knowledge of the geometrical configurations of the plane and of spaces, considered in relation to the theory of substitutions, with, if possible, some new results. The memoirs are to be sent in anonymously not later than June 30, 1910.

IN *Travel and Exploration* for July Mr. H. Massac Buist discusses what the nations are doing in the progress of aviation, and refers to the annual prize offered by him to the Aërial League for the best essay by a member of that body dealing with the attention that is being devoted by the leading civilised nations to the advancement of aërial locomotion. The first competition is to close on January 31, 1910. In his article the author shows that while Governments are mainly devoting their attention to the construction of dirigibles, aëroplane machines are, to a large extent, being developed by private enterprise.

WRITING in the *Oxford and Cambridge Review*, with a foreword by Lord Montagu of Beaulieu, Mr. R. P. Hearne advocates the introduction of aviation as a form of sport at the older universities. It is pointed out that such a scheme would produce a school of skilled aviators whose experience would be of great value in future developments of aërial navigation. While the possibility of an Oxford and Cambridge flying race is suggested, we would point out that, in view of the fact that the great majority of Varsity men cannot afford to spend 1000*l.* on a motor-driven machine, the man of moderate means might participate in the sport by gliding down a suitable incline selected on the Gogmagogs, Madingley Hill, or Royston Heath.

THE number of records of earthquakes obtained at Shide, Göttingen, Hamburg, and Laibach between January 1 and April 30 this year were, respectively, 98, 65, 61, and 33. Each of these earthquakes extended over wide areas, and was recorded at more than one station. At Shide the instrument employed is of the type adopted by the British Association. At the other stations the records were made on smoked paper or by photographic arrangements with a high multiplication.

THE annual general meeting of the Royal Society of Arts, the 155th since the foundation of the society in 1754, was held on Wednesday, June 30, Sir William H. White, K.C.B., chairman of the council, in the chair. The Prince of Wales was re-elected for the ninth time in succession president of the society, and the council, with certain additions and alterations, was re-elected. The principal business of the meeting was the reading of the annual report, which recorded the proceedings of the society during the past year. Reference was made to the failure of the renewed attempt made by the managers of the London Institution to amalgamate with the society. The number of the society's members is now 3490.

THE *Times* announces that in July of next year there will be held in Brussels, in connection with the International Exhibition of 1910, the first International Congress of Administrative Sciences, under the direct patronage of the Belgian Government. The term "administrative sciences" is defined by the congress committee as meaning the sum of theoretical knowledge relating to the services, the organisation, the machinery, and the action of Governments, and to the most practical methods to be employed by them. The honorary secretary to the British committee of the congress is Mr. G. Montagu Harris, Caxton House, Westminster, S.W.

THE recent notices issued by the committee of the International Aëronautical Exhibition at Frankfort show that many valuable prizes, in addition to those we have already mentioned, have been placed at its disposal, including one by the German Emperor; three prizes are also offered for the best kinematographic films of natural flight. A series of scientific lectures will be delivered, the first being on July 12, by Major v. Parseval, who will describe his air-ship and its potentialities; many other well-known men of science have also fixed the dates of their lectures. The physics of the upper air will be discussed by Profs. Assmann, Hergesell, Süring, and others. A list of the lectures and prizes already arranged is published in the first number of the exhibition journal *Ila*, this title being a contraction of Internationale Luftschiffahrt Ausstellung.

WE are indebted to the author, Dr. K. J. Bush, for a copy of notes on the molluscan family Pyramidellidæ, published in the June number of the *American Journal of Science*. These notes may be regarded as in some degree supplemental to the article on the same group contributed by Mr. P. Bartsch to vol. xxxiv. of the Proceedings of the Boston Society of Natural History.

THE crinoids of the family Comasteridæ undergo revision at the hands of Mr. A. H. Clark in No. 1685 of the Proceedings of the U.S. National Museum, no fewer than five new genera, of which three are based on new species, being named and described in the course of the paper. The communication relates, to a great extent, to material collected by the *Albatross*.

POLYCHÆTOUS annelids from Monterey Bay and San Diego, California, are discussed by Dr. J. P. Moore in the June issue of the Proceedings of the Academy of Natural Sciences of Philadelphia, the collections on which the paper is mainly based having been obtained from San Diego in 1902 and 1903, and from Monterey Bay in 1903 and 1904. The total number of species mentioned is sixty-four, of which twenty-one are believed to be new to science. Many other forms doubtless remain to be described, as at both localities collecting was almost entirely restricted to inter-tidal limits, although a few hauls were made with the dredge.

DARWINISM looms large in the June number of *Neue Weltanschauung*, in which the opening article is devoted to a biography of Dr. August Weismann, accompanied by an excellent portrait of that distinguished biologist and evolutionist. There is also a notice of an interesting Darwin exhibition recently opened at Carlsruhe, and arranged by Prof. Walther May. The exhibits are divided into three sections, one historical and biographical, the second theoretical, and the third bibliographical. In the first are included a series of pictures illustrative of the life of Darwin and of the influence of the environment on the organism, while the second is devoted to pictures and specimens illustrative of Darwin's observations and teaching.

THE fresh-water crustaceans of Algeria and Tunis form the subject of the first paper in the June number of the Journal of the Royal Microscopical Society, this communication being based on the collections made by the author, Mr. Robert Gurney, in February and March, 1906. Although the Algerian fresh-water crustaceans have been better worked out than those of any other part of Africa, the author finds that even here our knowledge is far from complete, while still more remains to be done in Tunis, especially in the Tell, or coast-district. A very large number of species were collected, of which several are described by the author as new, the ostracods being omitted and reserved for a future communication. Perhaps one of the most interesting of the forms discovered during the visit is the malacostracan *Cirolana fontis*, described by the author in the *Zool. Anzeiger* for 1908 on the evidence of three examples found under stones at the mouth of a spring near Biskra.

As the result of a biological survey of the Belgian coast undertaken by the Royal Museum of Natural History of Belgium, Mr. G. Gilson, the director of that establishment, has been enabled to describe a new and interesting parasite which in autumn frequents the nursing-chamber of the females of the schizopod crustacean *Gastrosaccus spinifer*. Seeing that the schizopod occurs in great swarms at some distance from the shore, it is a matter for surprise that the discovery of the infesting parasite should have been so long delayed, especially as the latter is of relatively large size. The parasite is itself a crustacean, referable to the group of epicarids, a section of isopods which have become degraded in accordance with the requirements of a parasitic existence. Although nearly related to Dajus, Mr. Gilson is of opinion that the new species should represent a genus by itself, and accordingly proposes the name *Prodajus ostendensis*. The paper, of which we have received a separate copy, is published in vol. xliii., pp. 19–92, of the *Bulletin scientifique de la France et de la Belgique*.

A COPY of the Milroy lectures on disinfection and disinfectants, delivered by Prof. R. Tanner Hewlett, and reprinted from the *Lancet*, has been received. In these three lectures Prof. Hewlett decided not to deal with the details of the various methods of practical disinfection, for these are to be found sufficiently described in every text-book of hygiene; he has rather set himself to discuss the scientific principles embraced in the practice of disinfection. He first refers to the natural processes which reduce or destroy specific micro-organisms, such as dilution (by air, water, &c.), sunlight, desiccation, filtration (as in soil); he then turns to the defensive mechanisms with which nature has endowed the human body; and after making a brief reference to the application of internal disinfectants, he passes to a consideration of the disinfection of the infectious material outside the body. References are made to school disinfection, the requirements of an ideal disinfectant, the nature of the processes of disinfection, and the standardisation of disinfectants on the basis of their germicidal values. During the past few years much controversy has arisen upon the value of various methods of gauging the relative germicidal powers of disinfectants, and although advance has been made, we are still some distance from the goal of a satisfactory scientific method; it is important that this matter should be placed upon a sound basis, for, as Prof. Hewlett points out, the use of a disinfectant engenders a sense of security which, in the case of an inefficient one, is unreal, and may lead to disastrous results. The market is flooded with inefficient disinfectants, and there is at present no legal restraint upon their sale.

WE have been favoured with the report of the director of the Royal Botanic Gardens, Ceylon, covering the reports of the various subordinate officers connected with the gardens. Dr. Willis refers very hopefully to the introduction of American machinery for tilling the ground, owing to the success attending the trial at the experiment station in the north of the island. The growth there of Ceara rubber has been excellent, and in consequence nurseries of *Manihot dicholoina* have been formed. The Government chemist, Mr. M. K. Bamber, gives some particulars of analyses of young and old cacao leaves. In the young leaves potash and phosphoric acid accumulate to the extent of 35 per cent. and 10 per cent. respectively, but very small quantities are present in old leaves, which contain a large amount of silica combined with lime and magnesia.

MR. N. N. WORONICHIN, who has been studying the distribution of the algæ in the Black Sea, communicates a preliminary account to the botanical section (No. 7) of *Travaux de la Société impériale des Naturalistes de St. Pétersbourg* (vol. xxxvii., part iii.). Three vertical zones of distribution are distinguished. The littoral zone is narrow, as there is no appreciable ebb and flow; *Ralfsia verrucosa*, *Corallina virgata*, *Rivularia polyotis*, are the chief forms in certain bays, and in others species of Ulva and Enteromorpha are the most general. The second zone comprises depths from two to eight fathoms, where *Cystoseira barbata* is everywhere the dominant species. A third zone ranges from ten to thirty fathoms; *Polysiphonia elongata* is the chief formation down to twenty-five fathoms, then *Zanardinia collaris* is dominant, and lower *Antithamnion plumula*.

A SERIES of short papers by Dr. J. N. Rose relating to xerophytic plants of the unrelated but morphologically similar families of the Crassulaceæ and Cactaceæ is collected in vol. xii., part ix., of Contributions from the United States National Herbarium. A Mexican plant, formerly described from barren specimens as an Echeveria, is made the type of a new genus, Thompsonella. Another plant from Vera Cruz restores the species *Echeveria carnicolor*. Three new species of the same genus are recorded from Guatemala. The re-discovery of the Cuban species of tree cactus, *Cereus nudiflorus*, is interesting; other new species are an arboreal Pereskia, a remarkably spiny Echinocereus, and a Nopalea. Dr. Rose also describes a leguminous tree resembling a Cercidium, but sufficiently distinct to be placed in a new genus, Conzattia. The photographs illustrating the habit of these plants are admirable.

THE scenery of the Greater Antilles forms the subject of an interesting paper read by Sir H. H. Johnston at the Royal Geographical Society, and published in the June number of the *Geographical Journal*. The subject provides ample scope for the author's well-known powers of observation and description. Reference is made to the striking character of the royal palms, *Oreodoxa regia*, in Cuba, an avenue of which "looks like a column of white marble pillars crowned with a gerbe of glossy green fronds." The palmetto, *Sabal palmetto*, and two other palms with fan-shaped leaves, Thrinax and Coccothrinax, are prominent in the landscape of the plains and foothills. Tall cacti contribute largely to the scenery of eastern Cuba, especially on sandy flats. In the island of Haiti the agaves aroused the author's admiration. With regard to Jamaica, the author presents a sketch of the vegetation in January; he also offers a word of advice in the matter of retaining such natural beauty spots as Fern Gully.

WE have received revised editions of two useful little manuals:—(1) "Observing and Forecasting the Weather," by Mr. D. W. Horner; and (2) "Some Facts about the Weather," by Mr. W. Marriott. The first is intended for those who may wish to obtain some knowledge of the weather without the use of instruments. For such persons the work contains much useful information; the chapters on clouds and optical phenomena, from which successful forecasts may often be drawn, are especially interesting, as are also the sections on old weather proverbs and the popular fallacy of the moon's influence. The work is accompanied by some good typical illustrations. The second pamphlet gives "some of the results which have been obtained from present-day systematic meteorological observations in the British Isles," and is of special interest to those possessing instruments for an ordinary climatological station. It contains useful information referring to each of the meteorological elements, the use of synoptic charts, and particulars of average and extreme values; it also deals with special subjects, *e.g.* electrical phenomena and the investigation of the upper air, and contains many useful illustrations. The work will be acceptable to many who may wish to obtain accurate general weather knowledge without reference to more pretentious instructions and text-books.

THE *Electrical Review* for June 18 contains a list of the electric tramways, railways, and power companies of the United Kingdom. We note that the following towns head the list of those having electric tramways:—Manchester 105, Glasgow 95, London 86, Liverpool 59, Bradford 55, and Leeds 54 miles of track. The leading electric railways are:—the Liverpool and Southport with 35, the Newcastle and Tyneside with 30, the Metropolitan with 26, and the Metropolitan District with 24 miles of double track. The greatest power companies are:—the Newcastle-on-Tyne with a station capacity of 47,000 kilowatts, and the Durham Collieries with 11,000 kilowatts. One of the points which a study of the list brings out is the great popularity of electric traction in the northern towns as compared with the indifference in the south.

BY means of quotations from the "Atomistic" of 1862 and the "Weltleben" of 1881 of Robert Grassmann, Dr. F. Kuntze shows in the *Physikalische Zeitschrift* for June 15 that more than forty years ago the brothers Hermann and Robert Grassmann had worked out the details of an electronic theory to which the electronic theories of the present day bear some resemblance. According to the Grassmann theory, the smallest æther particle consists of a pair of entities to which symbols $+E$ and $-E$ are assigned. The pairs repel each other according to the inverse fourth-power law. When glass is rubbed with silk the $+E$ is attracted to the glass, the $-E$ to the silk, and the two bodies become electrified. Light is due to the oscillations of the pairs as pairs, electricity to the oscillation of the constituents of each pair. Heat is the oscillation of matter and the æther pair together. Matter in the same way consists of pairs of elements, and chemical combination of two substances is the attraction of the positive matter element by the negative part of the æther pair, and the negative matter element by the positive part of the æther pair. The positive and negative parts of a pair are supposed to keep apart owing to the motion of each round the other, as in a binary star.

AN interesting article on the mechanical testing of cast iron appears in the *Bulletin de la Société d'Encouragement pour l'Industrie nationale* for May. The author, M. Ch. Frémont, deals first with the historical aspect of his subject, giving drawings of early apparatus, and then proceeds to describe special machines of his own with which he has made many tests on small specimens for the determination of the coefficient of elasticity, the elastic limit, and the breaking strength. The results and plotted diagrams are given, and from these the author arrives at the following conclusions:—the testing under static bending of cast-iron samples of greatly differing strengths shows that the coefficient of elasticity varies considerably, from simple to triple proportion; the capacity for elastic bending of cast iron is inversely proportional to its strength; the elastic limit under static bending varies very greatly, being from 0·45 to 0·80 of the breaking strength.

MOST of the engineering and shipbuilding periodicals for the week ending June 26 contain reference to the new rules which are on the point of being issued by Lloyd's Register of British and Foreign Shipping. The revised rules are framed to include vessels up to about 680 feet in length, and they cover all the vessels previously classed by the society excepting the large Cunard steamers *Lusitania* and *Mauretania*. The most important modification in the new rules is in the basis for determining the "transverse number" and the "longitudinal number." The former number is now to be found by adding the breadth and depth only, and the latter by multiplying the length by the sum of the breadth and depth. It is also of importance to notice that all the sections in the tables conform to the standards of the Engineering Standards Committee. This is a very wise move, and is much to be commended. Another step in the right direction has been taken in the adoption of a unit for scantlings of one-fiftieth of an inch instead of one-twentieth as in the old rules. This not only conforms with the decimal system, but, as 0·02 inch is practically half a millimetre, a close connection with the metrical system is secured. As Lloyd's Register covers between 70 per cent. and 80 per cent. of the world's shipping for insurance purposes, the new rules cannot fail to influence the shipbuilding and steel industries in this and most foreign countries.

A note in the *Bulletin de l'Institut Pasteur* for May 30 (vii., No. 10, p. 453) announces the discovery by Carlos Chagas, of Rio de Janeiro, of a new human trypanosome parasite (*T. cruzi*), conveyed by a bug (Conorrhinus), and causing an often fatal illness among miners and others in the State of Minas.

The Bulletin of the Johns Hopkins Hospital for June (xx., No. 219) contains an interesting historical essay, by Dr. Gerster, on the life and times of Gerhardt van Swieten, physician to the Empress Maria Theresa, who was born in Leyden in 1700 and died in 1772 at Schönbrunn.

A comprehensive note on the cartography of the Philippine Islands is given by Prof. Guido Cora in *Bollettino della Soc. Geogr. Ital.* as a notice of the recent map of the islands compiled from original sources by Mr. C. W. Hodgson.

We have received from the Nottingham Free Public Library a copy of a simply arranged supplementary science catalogue of the central lending library dealing with books in most branches of science published between 1901 and the present year.

Mr. R. B. Henderson, assistant master at Rugby School, has written an introduction to the study of moths and butterflies for the Rugby School Natural History Society, entitled "The Scaly-winged." It will be published immediately by Messrs. Christophers.

We have received vol. vi. of "Contributions from the Jefferson Physical Laboratory." It consists of a reprint of twelve papers which have appeared in the Proceedings of the American Academy of Science or in other periodicals during the past twelve months. Five of these papers have already been noticed in these columns.

In the announcement in Nature of May 27 (p. 375) of the resignation by Mr. H. H. Clayton of his position at the Blue Hill Meteorological Observatory, it was stated that he had been in charge of the observatory since 1894. This statement does not express the position exactly. Mr. Clayton has served for many years as observer or meteorologist, and his researches have added to the reputation of the observatory, but the director is Prof. Lawrence Rotch, who founded the observatory in 1885, and provides for its material support.

The June number of the *Stonyhurst Magazine* contains an illustrated description of the Milne seismograph used in the National Antarctic Expedition in H.M.S. *Discovery* under Captain R. F. Scott, R.N., in 1904. The seismograph is now a permanent loan to the observatory at Stonyhurst from the Antarctic committee of the Royal Geographical Society. The instrument stands at Stonyhurst on a solid stone pillar fixed in 12 inches of concrete; its position is lat. 53° 50′ 40″ N. and long. 9m. 52·88s. W. of Greenwich. A new recording apparatus has been secured, and there is every reason to hope that useful observations will be made at the new station.

OUR ASTRONOMICAL COLUMN.

Comet 1909*a*, Borrelly-Daniel.—Further observations of comet 1909*a* have revealed no striking features either in its form or in its behaviour. In No. 4334 of the *Astronomische Nachrichten* M. Chofardet records the observations made at the Besançon Observatory, and states that on June 17 and 19 the comet was of magnitude 11·0 or 12·0, had a round, diffused head of 1·5′ diameter, and a vague condensation which could be seen occasionally by oblique vision.

A New Form of Comparison Prism.—In all spectroscopic work where a comparison prism placed over the slit is used, the dark band between the compared spectra, produced by the edge of the prism, constitutes an inconvenience which may prove a source of error. To remedy this defect, Prof. Louis Bell has employed a specially designed compound prism, in which the light from one of the sources is reflected from the fine edge of a thin layer of silver, whilst that from the other source is allowed just to miss the edge. Thus the line of demarcation is practically eliminated. The method of preparing such compound prisms is described, and illustrated by diagrams, in No. 4, vol. xxix., of the *Astrophysical Journal* (p. 305).

Halley's Comet.—No. 4330 of the *Astronomische Nachrichten* contains two search-ephemerides for Halley's comet. The first is by Dr. Holetschek, who discusses the probable date of perihelion and gives three ephemerides, one for May 16·45, 1910, and the others for thirty days before and after respectively. At the previous apparition, in 1835, the comet was discovered 102 days before the perihelion passage, when its distances from the sun and earth were 1·9 and 2·4 astronomical units respectively; the corresponding distance from the sun will occur, according to Dr. Holetschek's data (T = May 16·45, 1910), on February 3, 1910. The second ephemeris has been computed by Herr L. Matkiewitsch from the data given in the essay which won the Astronomische Gesellschaft prize; the positions now given vary considerably, at different epochs, from those previously referred to in these columns (Nature, No. 2046, January 14, p. 320).

The Polarisation of the Solar Corona.—In the June number of the *Bulletin de la Société astronomique de France* M. Salet discusses at length the photographs obtained at the 1905 eclipse with a polariscopic camera. These photographs show the coronal radiations to be strongly polarised right down to the moon's edge, thereby indicating that reflected light is being dealt with; but the spectroscopic observations indicate that radiations directly from a light-source are in question. M. Salet suggests that the apparent contradiction may be explained by the theory that the bright radiations observed spectroscopically are due to metallic vapours rendered fluorescent by the intense solar radiation. In this condition metallic vapours give band spectra, and the superposition of these might, if small dispersion were employed, produce the appearance of a continuous spectrum such as has been observed. In support of his theory M. Salet quotes the observation of Sir Norman Lockyer at the eclipse of 1882, that the coronal spectrum appeared to be formed of superposed bands, and directs attention to the discovery of magnetic fields by Prof. Hale, which, with a rotating sun, afford the conditions necessary for his theory.

THE SOLAR CONSTANT AND THE APPARENT TEMPERATURE OF THE SUN.—In a note published in No. 7, vol. lxix., of the Monthly Notices (p. 611), Dr. Féry discusses the measurement of the solar constant and of the sun's mean temperature. One of the greatest difficulties in these researches is to evaluate the atmospheric absorption, which in published researches has varied from 1·5 to 4; it is generally accepted now as having the value 2·4.

Having designed an instrument for measuring terrestrial high temperatures, MM. Féry and Millochau applied it to the determination of the solar temperature by Stefan's law. More than 750 observations were made at different altitudes, and at the summit of Mont Blanc the zenith transmission was found to be 0·91; with this correction the temperature at the centre of the sun's disc was found to be 5550° absolute, and the mean temperature 5360° C. Before dispatching it to India, this instrument was restandardised at the National Physical Laboratory, and, on a clear, dry day, gave eight concordant readings, from which the temperature at the centre of the disc was found to be 5153° absolute; on this day the zenith transmission at Teddington was, therefore, 0·74, or the absorption was 26 per cent.

Employing the accepted value of the constant (2·4), the recent researches give 5920° as the mean temperature of the sun; but Dr. Féry thinks this is too high, and, therefrom, deduces that the accepted value of the solar constant is too high. The Mont Blanc measures would indicate 1·65 as the value.

THE NATIONAL CONSUMPTION OF WATER.

AN important paper on the increase in the national consumption of water was read by Mr. W. R. B. Wiseman before the Royal Statistical Society on April 27. The paper is of considerable interest, and must have entailed a large amount of time and thought on the part of the author. The historical part, which deals with the early history of water supply in England, treats the question, not only from the general point of view, but gives many interesting details of the early methods adopted and the difficulties met with in many individual towns; in fact, it is not too much to say that the early beginnings of the water supply of all the principal towns in England are reviewed shortly in the paper. It is obvious that, as the object of the paper is to deal with the more modern questions which arise in connection with this subject, the author could not devote very much space to historical details. We can, however, judge that on this subject he has only touched the fringe of the information he has acquired, and it may perhaps not be too much to hope that he may return to this part of his subject at a future date.

The life of Sir Hugh Myddelton and the description of the work carried out by him of bringing the water from the springs of Chadwell and Amwell, in Hertfordshire, by means of the New River, for the supply of London are well known to most of us, and possibly the author of this paper may have material for the making of a story as interesting and romantic in connection with other towns.

The author says he was "tempted" to investigate the estimates of the population in the pre-censal period in order to determine whether the great increases in the population in the nineteenth century were abnormal or otherwise, as upon the answer to the query one must be guided in the provision of water supplies for future populations. As was to be expected, he found such an inquiry not of great value. He has, however, put together some interesting information as regards the growth of many towns, and has dealt with the reasons for the very rapid growth of several of them. From a general review, the conclusion arrived at is that "the nineteenth century was in no wise abnormal, and that a steady increase in the already considerable population may be expected throughout the twentieth century."

The author describes at some length the methods adopted for checking the waste of water in early days, and particularly the system adopted in Liverpool in 1868 of localising the waste by metering the supply in various districts.

Of course, the supply of water per head of population is the important question when dealing with the amount of water required, and the tables given of the supplies in a large number of towns show the variations which exist, and which extend from about sixty gallons as a maximum to below ten gallons as a minimum, leaving out one special case with small population which runs up to 124 gallons per head. The numbers all relate to total supply, which includes domestic, trade, and municipal demands. The statistics given show much greater uniformity of supply in the different towns than would have been anticipated, and it is evident from them that waste of water is carefully looked after in England, and all possible precautions taken to avoid it. If the consumption is compared with what is common in many of the large towns in the United States, where the water supply goes up to 200 gallons and more per head, it will be evident that the precautions taken in England have given very satisfactory results. The opposition to the use of water meters in the United States is probably the reason why leakage and waste continue on a large scale. This opposition is principally due to the view that, on sanitary grounds, it is not well to restrict the supply of water, but, as Mr. F. P. Stearns stated in his presidential address to the American Society of Civil Engineers, "no one has yet demonstrated the sanitary advantages of a leaky faucet or a defective ballcock."

Table No. 5 is a valuable one. It gives, first, the population of more than 120 cities, towns, or districts in England for two or three years, with intervals, sometimes large and sometimes small, between the years. It then gives the total supply in each of these water areas during the years mentioned, dividing it up under the heads of domestic, trade, and municipal, the daily supply per head of population then following under the same heads.

Considerable space is devoted to the reasons which have caused an increase in the supply of water per head for domestic, trade, and municipal purposes. As regards domestic, it is, of course, well known that the displacement of old methods of sewage disposal by the introduction of the water-carriage system was the first cause of the great increase of the water supply. The increased and increasing use of fixed baths must also largely augment the consumption, as the water used for a bath by one person may vary from thirty to one hundred gallons. The author gives various other reasons for the increase in the domestic supply. As regards municipal supply, attention is directed to the increase in consumption due to the public baths, wash-houses, street conveniences, &c. The author states that he has endeavoured for some time past to collect data which will give some idea of the relative proportion of the water supply needed for particular works or industries, but the results have been too meagre to justify definite conclusions. He, however, deals in a general way with the amount of water used in a large number of industries, among which are breweries, distilleries, paper works, textile industries, and many others, and the information given is of an interesting character. The conclusion is that, on the whole, the rate of increase of water supply is greater in recent times than in those more remote. There probably would have been no doubt about this conclusion in anyone's mind, but, although this may be the case, it does not detract from the value of the information which has been collected in this paper to prove it.

The moral drawn is that, with the increasing amount of water required, there will be an increasing competition for the remaining first-class upland reservoir sites, which will become fewer and fewer as time goes on, and it is therefore desirable that steps should be taken at an early date to create some central authority "which should be charged with the duty of water conservancy in its widest application, and for that purpose should engage in a close and exact study of the water resources of the country." The author then goes more fully into the details which ought to be dealt with by such a body.

This proposal is, of course, not new, although of great importance. It was dealt with by Mr. E. P. Hill in a paper which he read at the Institution of Civil Engineers on November 27, 1906. In the beginning of that paper he said, "the water supply of the country is really a national matter, and it should be considered as a whole, and a town should not be allowed to appropriate a particular area unless it can be shown that in a general survey of available sources of supply that area can economically, from a water point of view, be allotted to it."

The value of the paper would have been increased if some information had been given as regards what is being done in other countries in connection with systematic investigation of water resources. There is no doubt that such an investigation is of more value and of greater necessity to the United Kingdom, where the population per acre is large, than to some of those countries which are at present rather sparsely inhabited, but which, at the same time, spend money on proposals such as have been suggested. In the United States this work was undertaken as a national one some years ago, a beginning having been made in 1894–5 by a grant of 12,500 dollars. This amount was gradually increased, until the grant in 1905–6 was 200,000 dollars. Since then there has, we believe, been some variation in the amount voted for this purpose.

Considering the large amount of work which the author must have gone through to prepare this paper, it may seem almost ungracious to suggest that he should add anything further to it as regards other countries, but he has shown such a large capacity for putting information together that we hope he may be tempted to even further research in connection with this subject.

MAURICE FITZMAURICE.

THE WAR AGAINST TUBERCULOSIS.

THE National Association for the Prevention of Consumption and other Forms of Tuberculosis was well advised to open its exhibition or collection of object-lessons in the Borough of Stepney. It may safely be said that the Whitechapel Art Gallery never had any company of more interested sightseers than the thousands who, at this exhibition a few weeks ago, examined and discussed death-rates, ventilation, graduated labour and the apparatus used in performing it in the treatment of consumption, apparatus for the treatment of tuberculous diseases, playgrounds, pathological specimens, back-to-back houses, overcrowding, food-stuffs and the principles of nutrition, methods of disinfection, and the like.

Any interested onlooker would have seen at once that the official conferences and set discussions constituted, after all, but a small fraction of the educational work that was being carried on. Here was an exhibition of which the main object was not to direct the attention of the public to any patent medicine or "all curing" nostrum, but how to regulate their daily life, how to avoid disease, and how to get the best food value out of their weekly wages, be these great or small. Nevertheless, the promoters of this exhibition, realising what an opportunity they had, also gathered together a number of medical and municipal delegates interested in the matter, to discuss the best means of preventing and curing tuberculosis.

Even those dropping in casually found an enthusiastic band of demonstrators, nurses from dispensaries and hospitals, attendants from graduated labour homes, from sanatoria and similar institutions, all hard at work explaining to small groups of interested men and women the meaning of the exhibits of which they were in charge. It was interesting to see the keenness with which both teacher and listener tackled the subject; and that these demonstrators were doing their work well was apparent from the numerous and intelligent questions that were put at the end of the demonstrations. Even to the sharp, shrewd Londoner the importance of ventilation, of cleanliness, of light, of suitable feeding, have been small, but a few exhibitions and demonstrations such as those seen and heard in Whitechapel Art Gallery will soon change all that; and the President of the Local Government Board has done nothing better for some time than in giving his countenance and support to what promises to be a really living movement.

What is the object and what are the lessons insisted upon at these conferences? Anyone visiting the exhibition would have it brought home to him in some way or other that between 1858 and 1907 there had been a fall in the annual death-rate due to tuberculosis from 2700 per 1,000,000 living to 1150 per 1,000,000 living. He would also see that, were the fall to continue at the same rate, tuberculosis would be an extinct disease early in the 1940 decade. Although this is too favourable a state of things to look forward to, as there will always remain a certain substratum of tuberculous patients and foci that it will be almost impossible to reach, tuberculosis should undoubtedly be an almost negligible quantity in our death-rate by that time.

How has this fall been brought about? In the first place, even before Koch was able to prove the presence of the infective agent, the tubercle bacillus, in tuberculous lesions, it was realised by those who were studying the disease most closely that it could be transmitted from one person to another, and that crowded and badly ventilated rooms were, therefore, fruitful centres of infection. This was a very great step forward, the full effect of which, however, was not felt until Koch gave his wonderful demonstration of the presence of the tubercle bacilli. He isolated the infective agent—this tubercle bacillus; its life-history was studied, and its relation to the tissues of the animal body during the course of the development of the disease, demonstrated. In the history of the treatment of any infective disease little progress has been made in fighting against it until the causal agent has been demonstrated. Once this stage has been reached, however, the fight waged against infective disease of all kinds has become more and more effective. In the case of tuberculosis, the attack can now be delivered along many parallels. Every patient is looked upon as a possible centre of infection, and before setting about the cure of the patient those dealing with the case have set themselves the task of attacking the bacillus from every quarter and at every point. It is realised that the first thing to be done is to secure it, or kill it, if possible, immediately it leaves the patient, especially, of course, in the sputum, as it comes from the lungs.

In the case of tuberculosis, isolation, in the ordinary sense of the term, is out of the question, but although the patient cannot be segregated from his fellows—and in many cases it would be both unwise and cruel so to do—he should be carefully trained to isolate himself, so far as the tubercle bacillus is concerned, by taking every precaution to prevent any undisinfected material from getting beyond his immediate vicinity. More is necessary, however, than the mere killing of the bacillus as it leaves the human body; some attempt must be made so to build up the strength of the patient that his tissues may be capable of carrying on war with the bacillus either on fairly level terms or on terms in favour of the patient. This can only be done by ensuring good hygienic conditions—plenty of fresh air, light, good food, work enough with plenty of rest. Given these conditions, and the tubercle bacillus has a bad time of it; remove the conditions, and the bad time falls to the patient. It has been stated above that it is often unnecessary to segregate consumptive patients; it must be remembered, however, that in the late stages of the disease, when the patient is weak and when the various discharges from the body, sputum and other excreta, may contain enormous numbers of the infective bacilli, it may be advisable, and even necessary, in the patient's own interests as well as of those who daily come in contact with him, to keep him in hospital, to make his last days, or even weeks or months, as easy and as pleasant as possible for him. Moreover, under these conditions the destruction of the enormous number of tubercle bacilli coming from the body is a comparatively easy matter.

Those interested in the treatment of tuberculosis have for long been convinced that good feeding and fresh air are factors of prime importance in such treatment. Up to a few years ago, however, the results obtained, though very much better than any obtained under the old methods of treatment, were in certain respects extremely disappointing. The patients were not properly classified for treatment, and many died who apparently ought to have lived. Those who went to Whitechapel to learn would find that the treatment of consumptives under Dr. Paterson at

Frimley is a very different thing from the treatment carried on in the early days of sanatoria. Patients are no longer stuffed and rested indiscriminately. They are given work, rest, and food on a carefully graduated system; they are taught how to treat themselves—what to do and what to avoid. The sanatorium treatment, however, deals with but a small proportion of the cases; tuberculosis must be tackled on a much more extensive scale. Calmette in Lille and Philip in Edinburgh, seeing the importance of bringing the treatment of tuberculosis to the working classes and even the very poor, have organised what is now known as the dispensary system, in which are combined an intelligence department, an ambulance service, a training school, an out-patient and in-patient hospital service, and a sanatorium department. In Edinburgh the result has been a fall in the death-rate beyond that of other cities equally or more favourably situated, except in that they have not been provided with this well-organised system.

It is recognised that prevention of tuberculosis is certainly more important than its cure, and all interested in this question must realise what enormous impetus has been given to the whole movement by the energetic action taken by the President of the Local Government Board. His keen interest in the Milk Bill, in the Washington Congress on Tuberculosis, and in the Whitechapel Exhibition, his grasp of principles and the wealth of detail contained in his opening address at that exhibition, gave evidence of complete conviction and determination to act up to his conviction. All this marks a great advance in the public treatment of the question in this country. Medical men have long suspected that tuberculous milk was a prolific cause of abdominal consumption amongst their little patients. They have known how readily delicate children recovering from measles, whooping cough, inflammation of the lungs, and similar conditions, have been infected, sometimes from tuberculous patients, at other times, however, under conditions where infection from the human subject appeared to be impossible, and they now welcome with enthusiasm any legislation that will render impossible the spread of tuberculosis by the milk from infected cattle. Medical officers of health, aware of the insanitary conditions under which a large proportion of the population, not only urban, but rural, live, hail with satisfaction the idea that in any well-considered action they may take they will now, not only be commended, but helped. The National Association for the Prevention of Consumption has done well, not only to follow Ireland and America, but to improve upon the methods adopted in those two countries. Nothing but good can be the outcome of this movement, and we hope that the seventy thousand visitors to the Whitechapel Art Gallery will be followed by hundreds of thousands, who will have the opportunity of seeing this or a similar exhibition at the "White City" or on its tour through the large and populous centres of England, and perhaps even of Scotland.

VISION IN RELATION TO HEREDITY AND ENVIRONMENT.[1]

THE Francis Galton Eugenics Laboratory at University College, London, has already done much valuable work in many directions under the supervision of Prof. Karl Pearson. With the assistance of Miss Barrington, a useful inquiry has been made into the question of the inheritance of vision and the relative influence of heredity and environment on sight. The paper is a mathematical investigation of statistics culled from a variety of sources. Of these, two communications by Dr. Adolf Steiger, of Zürich, on the corneal curvature, and the report on 1400 school children issued by the Edinburgh Charity Organisation Society, afford the best material. Other contributory material of less value is taken from reports on the refraction of London elementary-school children by Dr. A. Hugh Thompson and the Education Committee of the London County Council, and on the eyesight of 500 Glasgow school children by Dr. Rowan. Throughout, the difficulty which specially besets such statistical investigations is present in the fact that all the material is intensely selected. There is no means of supplementing it by a knowledge of the distribution of astigmatism and other errors of refraction in the community at large. Thus, in dealing with percentage statistics of the heredity factor in myopia, the authors say that "the distribution of parents of the normal and the proportion of myopes to the normal in the general population (or at any rate in the 'universe under discussion') must be found before any appreciation of the effect of heredity can be made."

The first moot point which arises in dealing with the inheritance of refraction concerns the determination of the unit to be used to obtain a quantitative scale. It is now customary to measure the refraction in terms of the refractive power of the correcting lens instead of, as formerly, in terms of its focal distance. When the variations of the mean values in the population are small compared with the mean value in the individuals under discussion, it matters little which unit is adopted. This is true of corneal refraction (3 per cent.), but untrue of corneal astigmatism (75 per cent.). The difficulty is overcome by using, whenever possible, the method of contingency, fundamentally, or for purposes of control.

Investigation of the inheritance of corneal astigmatism leads to the conclusion that it is certainly inherited, as evidenced by minimum limits of 0·3 to the parental and of 0·4 to the fraternal coefficients, but the material is neither sufficient nor sufficiently classified to determine with any degree of certainty the accurate value of the inheritance coefficients. The authors point out that "there is a splendid field for a man who will measure the corneal astigmatism in a non-selected population." As this would be an easy and accurate task with the ophthalmometer there ought to be no difficulty in getting it carried out. Investigation of corneal refraction shows that it is inherited at the same rate as other physical characters in man. In dealing with the inter-relations of refraction, keenness of vision, and age, the results show how much more influence myopia has on visual acuity than hypermetropia, and that refraction defects contribute more than half the abnormality of keenness of vision. They further show that there is not the least doubt of a sensible relationship of age to each of the several categories of eye defect. It is probable that a great deal of hypermetropia, hypermetropic and mixed astigmatism disappears, probably owing to growth, between six and ten, thus swelling the number of emmetropic eyes, but that after this age there is not sufficient evidence to say whether these categories vary or not. Myopia and myopic astigmatism increase throughout, but this increase does not balance the total gain due to rectification by growth; it may be caused by continued action of some environmental factor, or by a growth factor.

The general conclusions derived from the slender data of this first study are as follows:—There is no evidence whatever that overcrowded, poverty-stricken homes, or physically ill-conditioned or immoral parentages are *markedly* detrimental to the children's eyesight. There is no sufficient evidence that school environment has a deleterious effect on the eyesight of children. Though changes of vision occur during school years, they are phases of one law of growth, a passage from hypermetropia to emmetropia and myopia of the eyes of "unstable stocks." There is ample evidence that refraction and keenness of vision are inherited characters, and that the degree of correlation between the eyesight of pairs of relatives is of a wholly different order to the correlation of eyesight with home environment. Intelligence as judged by the teacher is correlated with vision in only a moderate manner (p. 16). We scarcely think that the data justify so strongly worded an *ex cathedra* statement as that made by the authors in conclusion:—"The first thing is good stock, and the second thing is good stock, and the third thing is good stock, and when you have paid attention to these three things fit environment will keep your material in good condition. No environmental or educational grindstone is of service unless the tool to be ground is of genuine steel—of tough race and tempered stock."

CHILD EMPLOYMENT AND EVENING CONTINUATION SCHOOLS.

ANOTHER appendix volume, No. 20, to the report of the Royal Commission on the Poor Laws and Relief of Distress has been published (Cd. 4632), and incidentally indicates the directions which educational effort should take in this country in order to ensure the provision in future years of better educated workmen in the various industries on which the success of this country depends.

The report is by Mr. Cyril Jackson, chairman of the Education Committee of the London County Council, who acted for the commission as a special investigator to inquire and report on the main occupations followed by boys on leaving public elementary schools in certain typical towns; the opportunities of promotion in such occupations or of training for other occupations; and the extent to which such boys subsequently obtain regular employment (skilled or unskilled) as adults. Mr. Jackson was given power to make any feasible suggestions of a remedial character indicated by the facts, and he limited his investigations to a consideration of the prospects of permanence and educative value for adult industry of the occupations entered upon by the boys with whom he was concerned.

As regards the methods of inquiry adopted, it may be said that Mr. Jackson was able, from the sources of statistical information he found available, to obtain an idea of the various occupations in which there was an apparent excess of boys who could not when adults be absorbed in the same branch of industry. He afterwards, by interviews and by the distribution among employers of special forms to be filled up, obtained some further information as to these occupations; but he met with many difficulties, and only a small proportion of the forms were returned to him. In addition, a form of industrial biography for young men was issued to obtain direct evidence of the length of time boys remain in particular occupations and the age at which they were displaced if they have been in boys' work which does not lead to permanent employment as adults; but a third only of the forms circulated were filled up and returned—"Lads are always suspicious of anything which they think is prying into their affairs, and they believe there must be 'something behind,'" says Mr. Jackson.

There has been a steady diminution in the number of boys employed under fifteen during the last quarter of a century. With the recent stimulus given to secondary education, and counting on the zeal of new education authorities, there is reason to believe the decrease may be even more marked in the next census return. There are, however, exceptions to this decrease. The census general report of 1901 states, "while owing to the restriction of child labour, the total number of boys under fifteen years, returned as employed, showed a decrease of 12·9 per cent. on the numbers enumerated in 1891, the number of messenger boys at the same ages declined by only 5·1 per cent." It is, however, satisfactory to note how few are the trades in which an actual or a proportional increase in the number of boys is shown. As Mr. Jackson says, messenger boys have a very short life as such, and this form of occupation ceases as soon as the boys begin to require higher wages. It is unfortunate, therefore, that it should be just in this class that the decrease in boy employment is least marked.

The problem presented by the results of Mr. Jackson's inquiry is very grave in character, and the various statements of it collected in the present volume may be commended to the careful consideration of those who administer our educational affairs. Similarly, the opinions here collated of schoolmasters, of men working in boys' clubs, &c., of trades unionists, of distress committees, and others, deserve earnest study.

The analysis of the numerous forms received by Mr. Jackson proved a long and difficult task, and he is to be congratulated upon the important facts he has been able to gather together. The information respecting the capacity of boys, the wages they are able to earn, and the precise conditions regulating boy labour in specially selected industries, will repay careful deliberation, and may with advantage occupy the time and immediate attention of the members of education committees throughout the country.

Of especial interest are the conclusions arrived at and the suggestions which Mr. Jackson makes at the end of his report. The following excerpts will serve to show the vital importance of early legislation to ensure some efficient system of further education for all boys and girls during their adolescent years, whether they themselves desire it or not.

The evidence as to the difficulty boys find in getting into permanent work of a satisfactory kind seems overwhelming. Every inquirer gives the same impression.

The work of an errand boy or a telegraph messenger is bad for the boy, so is the work of a boy in a warehouse or factory who is employed to fasten labels to bottles, to fill packets of tea, or the like. It is not so much a question of a skilled trade not being taught as of work which is deteriorating, absorbing the years of the boy's life when he most needs educational expansion in the widest sense.

Mere skill of hand or eye is not everything. It is character and sense of responsibility which requires to be fostered, and "not only morals, but grit, stamina, mental energy, steadiness, toughness of fibre, endurance," must be trained and developed. Work which is monotonous kills development, and work which is intermittent destroys perseverance and power of concentration. The waste of boys' brains, character, and strength is ultimately not only destructive of the individual, but a serious economic loss to the community. It is probable that boy labour is not really cheap at all, owing to the undeveloped responsibility and carelessness of the young, but if the unskilled men who spring from them have been mentally and physically stunted, the loss to the employers is enormous, for they cannot earn a sufficient wage to live properly, and their output is below that required from an adult citizen.

In the large industries there should be a readjustment of conditions, but probably the initiative must come from an extension of State regulation of boy labour. This can be most easily effected by further raising the age of school attendance, or by a system of compulsory continuation schools. It must be recognised that much boys' work is wholly uneducative, and deteriorates instead of developing the man, and that this must be prevented. One of the largest industries—the textile—is still partly based on half-time child labour. It is probable that the operatives are really more to blame for this than the employers, many of whom are not very satisfied as to the advantages of child labour. The old contention that the manipulative skill required compelled the employment of children of twelve, because after that age their fingers lose suppleness, is not now heard so frequently.

One thing which appears likely to be of far-reaching benefit to the boy is increased education. Thus Mr. Kittermaster gives as his remedies:—

(1) Boys should be kept at school until the age of fifteen instead of fourteen.

(2) Exemption below this age should only be granted for boys leaving to learn a skilled trade.

(3) There should be school supervision until sixteen, and replacement in school if not properly employed.

Prof. Sadler and the Rev. Spencer Gibb suggest compulsory half-time schools, or, at any rate, some compulsory school until sixteen or seventeen. Mr. Gibb would like to see further amendments of the Shop Hours Acts so as to avoid the possibility of excessive hours of labour on certain days of the week. He points out, also, that the present Acts need to be more thoroughly enforced.

This inquiry seems to show that these reforms are necessary. The raising of the age of exemption would strengthen the boy, and he would be kept longer under discipline, and would become both steadier in character and more intelligent. It can hardly be seriously contended that the boy of the working man is really more fit for life than the public-school boy at the age of fourteen who is admittedly unready at that age.

It must not, however, be supposed that the present education given in the schools is all that can be desired.

There is a widespread feeling that it is too academic, and must be made more practical. In any case, it must aim at developing character and intelligence rather than merely imparting book knowledge.

If it is urged that further time for schooling is commercially impossible, it must be remembered that our great trade rivals, the Germans and the United States, have compulsory continuation schools or a higher exemption age. In Germany it is the custom for parents to put their boys to a skilled trade, and apprenticeship is as flourishing there as ever it was. "The Imperial Law on the 'Regulation of Industry' of 1891 decreed that the masters in any branch of industry were bound to allow their workers under the age of eighteen to attend an officially recognised continuation school . . . for the time fixed as necessary by the authorities." The local council might make such attendance obligatory for all male workers under the age of eighteen. Every raising of the school age or Factory Act limiting child labour has been in turn objected to as fatal to industry, but the community has very quickly adapted itself to the new conditions.

The removal of the supply of cheap boy labour under fifteen would probably lead to very useful readjustments of industry and to the substitution of mechanical labour for some of their work and for a greater employment of adult labour. It is, of course, true that to start boys at fifteen instead of thirteen or fourteen will not prevent a period of transition from boys' to men's jobs, but it will give a better chance of skill to the boy. A better and longer education should give the boys firmer and more disciplined characters and a greater power of adapting themselves to new work. Increase of efficiency, even in unskilled labour, means increased wage to the mutual benefit of employer and employed. It is the over-supply of unskilled labour which is not worth a good wage which is the real difficulty.

Again, in skilled trades proper there is little doubt that there is room for more boys, and they are not supplied now with the best material available. It is probable that labour exchanges for boys leaving school would be of very great value in securing that all the more intelligent and able boys had a chance of securing good openings. It is the ignorance of the boy which so often leads him into employment which is not suited to him.

Further, some better grading of wages is most desirable. At present, comparatively high initial wages are often paid to tempt boys into an unprogressive occupation. The value of the old apprenticeship scales lay in their attempt to make the wage increase with the capacity, but the low initial earnings have been the reason of the unpopularity of apprenticeship with the more needy and less far-sighted. It is quite possible that the boy leaving school at fifteen will still not earn more than he now does at fourteen. There is little doubt that in that case the employer would gain, because he would get a better article, but the boy would also gain, because he would be a better article and more fit to develop into a still higher efficiency, commanding better wages later. It is better that he should be paid less in his early years and be worth more as an adult. Under existing conditions he is bribed by large wages to spend his time on uneducative work which gives him no opportunity afterwards, and he is unfit to spend wisely the large wages which he receives. The present system demoralises the boy. The temptation to leave one job to get higher wages in another is almost irresistible, and the resulting instability is detrimental to himself and not economical to his employer, who is perpetually trying to train new boys.

EVOLUTION IN APPLIED CHEMISTRY.[1]

EVERY chemist, to be worthy of the name, should in his own work be a specialist; but there are few amongst us to whom it has been given to produce in their own particular line of research results of deep general interest. Our distinguished president, Sir William Ramsay, is one of the privileged few; I am one of the many, whose scientific results are like the grains of sand, the importance of which lies in their aggregation.

But a chemist, to be worthy of the name, should also be able to step forth from his own small sphere of activity and to look upon his science and allied domains of human thought as a whole, to contemplate its history and its future, its aims and progress, and to glean a few useful truths from such considerations. This is what I shall try to do.

The simple daily wants of mankind in a primitive condition are all supplied by nature. It is the progress of civilisation which led to the necessity of transforming her gifts, and thus created a chemical industry. Human chemical work supplements the chemical work of nature, and is therefore subject to the same governing laws. It is strange that no attempt has yet been made to trace the many coordinated points which exist between biology, the science of life, and chemistry, the science of molecular changes, without which life is an impossibility.

The subject is extensive enough for a book. I cannot hope to do justice to it in a short lecture, but I shall try to point out some of the relations existing between the results of biology and applied chemistry.

Biology as a science is of very recent date. The manner in which our forefathers tried to gain an insight into the overwhelming variety of the vegetable and animal kingdoms was purely systematic. Linnæus, de Candolle, Cuvier, and others, enabled us by their systems to classify nature, but they did not teach us to understand it. Hardly a century ago the dawn of a deeper insight began to rise on the horizon of science, and just fifty years have elapsed since that memorable meeting of the Linnean Society in which the flaming truth of evolution was given to humanity by one of the greatest minds that ever stood up amongst men. Botany and zoology, the pedantic histories of plants and animals, became suddenly united in biology, the great science of life, itself a living thing, capable of development and evolution.

Evolution is no longer a working hypothesis of natural science; it has become a new way of thinking, a method of harvesting everlasting truth from the fleeting changes of passing life. It is not applicable to living plants and animals only, but to everything that is capable of growth, alteration and improvement. Why should this method not be extended to the study of human achievements, of science as a whole? Why not to applied chemistry, which is so full of changes, and more vigorous in its growth and development than many another discipline?

It seems to me that England, the country which has given to all the other nations the invaluable gift of evolution, is the classical soil on which an attempt might be made to apply it in a new manner. It may help us to understand, and therefore to forgive, the struggle for existence, which in chemistry and its applications is as rife as amongst the organisms of the deep sea or the tropical forest. Looking at that struggle with the calm soul of the man of science, we shall easily recognise the underlying promise of the survival of the fittest and of certain progress in coming days.

As a rule, one takes it for granted that anything applied must have existed before its applications. It is not so with applied chemistry. Chemistry as a science is, as we all know, a comparatively new creation. Its applications, on the other hand, have existed since times immemorial, and may be traced back to the very beginnings of human civilisation. The men who in the past devoted their thought and energy to problems which we now call chemical had to reach their ends with the help of sound empiricism. Though their progress was slow it was sure, so that to this day we have sometimes occasion to marvel at their successes. More than that, we may safely say that some of our best industrial methods would never have been discovered if we had had chemical theory only to guide us. Science itself stands on an empirical basis—we cannot draw general conclusions unless we have well-established observations to start from.

It is perhaps not superfluous to remember these facts at the present time, when the brilliant success of theoretical chemistry is apt to make us forgetful of the services derived from purely empirical methods of research. Empiricism investigates without foregone conclusions,

[1] Address to the combined sections of the Seventh International Congress of Applied Chemistry on Monday, May 31, by Prof. Otto N. Witt, of Berlin.

whilst theoretical science verifies logical deductions. Science forces nature to divulge its secrets; empiricism is quite content to pick up the treasures it may come across in its ramblings through unexplored regions. Nature is still full of unknown treasures. Why should we cease to search for them? Why should we expect success only from logical deduction?

It is true that the scientific method of invention is a quicker road to success. Rapidity is everything in our times. Whirling along in a motor carriage to a well-known destination is distinctly more agreeable than tramping on foot in the glaring sun of a summer's day; but you cannot pick the flowers blooming by the roadside or stumble over hidden treasures at the rate of sixty miles an hour. The two methods of progress have both their own peculiar advantages, and should both be followed. Now and then they will meet, and make success doubly certain.

One of the best combinations of empiricism and theory is the examination of old empirical industrial processes by the methods and in the light of modern chemical science. A great deal of valuable information has been obtained in this way; much more remains to be discovered. It is this conviction which led me to propose to the last congress at Rome that a special section should be established in these congresses for the history of applied chemistry. The history of chemical science, as it exists now, is almost entirely devoted to theoretical systems and to the life of those who created them. The history of industrial methods is not so complete as one might wish it to be.

So far as the history of our nineteenth-century chemical industry goes, the materials for studying it are not wanting. The patent literature of the various countries is in itself an inexhaustible source of information, which can be largely supplemented from text-books and endless files of periodicals; but it is not so if we begin to inquire into the applied chemistry of previous centuries. The mysterious communications of the mediæval alchemists have been frequently examined; but Pliny remains our almost exclusive source of information about the chemical arts of the antique world. Yet these arts were many and highly developed, and Pliny's information was distinctly superficial.

How much more might be gathered about the chemistry of past times has been shown by the researches of such men as Berthelot and Edmund von Lippmann, who combined the accomplishments of distinguished chemists with those of the Orientalist in the study of Arabic and Hebrew authors. Who knows what a host of information may yet be lying dormant in unread Egyptian papyri and palympsests?

But the sovereign means of discovering these lost secrets is in the careful study and analysis of the products which ancient times have fortunately left us as proofs of their skill and knowledge. How much has been done in that respect by that one great master, Marcellin Berthelot, who found in such work the recreation of the later years of his life? How much more remains still to be done?

Thus we may hope to know at some future time more of the accomplishments of past generations than we do at present; and we may also hope that some of the methods thus re-discovered will awake to fresh life like mummy wheat, which is said to take root and grow if you plant it in fresh soil. Have we not greeted with delight the *terra sigillata* of the Romans, when the process for its manufacture was re-discovered by Fischer, a Bavarian potter, and has not a considerable industry sprung from the resurrected use of lanolin, or wool-fat, which was a panacea of the Greeks two thousand years ago?

Yet such discoveries will remain inheritances from the dead, and the cases of their resurrection to life will not be numerous; but we have living empiricism at our doors, which we allow to die and to sink into oblivion, without attempting to study it and to learn the lesson it has to teach—a treasure of information of incalculable magnitude hoarded up in the course of centuries by the skill and patience of countless millions of men who were, and are, as keen in the study of nature as they are reluctant to draw general conclusions from their observations.

This great treasure is the industrial experience of the Eastern nations. It is an undoubted fact, and if it were not, a single visit to the South Kensington Museum would prove it, that the people of Persia, India, China, Japan, the inhabitants of Burma, Siam, Cambodja, and the innumerable islands of the Pacific, are possessed of methods for the treatment and utilisation of the products of nature which are in many cases equal, if not superior, to our own. These methods must be to a large extent based upon chemical principles. Is it not strange that we know so little about them, and that little generally only indirectly through the accounts of travellers who were not chemists? If all these peculiar methods were fully known and described by persons who have seen them applied and watched their application with the eyes of a chemist, it would certainly be, not only of interest, but also of the greatest utility to our own industry; for it is the elucidation of empirical methods which, in the new light that science sheds upon them, leads to new departures and to progress. Who can deny the advantage which the industry of cotton dyeing and calico printing derived from the study of the Turkey-red process, which a century ago was bought as an Eastern trade secret by the French Government and generously placed at the disposal of European dyers? Would the making of porcelain have been invented in Europe if the impulse for it had not come from the East? Is there no connection between the introduction of Chinese porcelain and the invention of Delft, the curious observations of Réaumur on devitrification, and even the work of that great and original genius, Josiah Wedgwood? And would that supreme triumph of the application of pure chemical science to industry, the synthesis of indigo, ever have been accomplished if indigo, as a natural dye-stuff, and its extraordinary method of application by vat-dyeing, had not come to us from the East? What a stir has been created, even in these very latest days, by the extension of this ancient Eastern method of dyeing to other shades than those of indigo!

We live in a period when the intellectual nations of the East wake up from their political sleep of centuries, when they issue from their seclusion and demand their share of Atlantic civilisation; but their awakening means going to sleep for their industrial methods. These methods, ingenious as they undoubtedly are, cannot compete with ours in being applicable on a manufacturing scale. So our processes are transferred to the coasts of the Pacific, and their own methods are abandoned and forgotten. The Eastern industries cannot keep pace with ours, not because they are inferior in their results, but because they toil on foot whilst ours are motoring. In this struggle for existence the fittest means the quickest and the cheapest.

Yet I am certain that many a new and good result might be obtained from the combination of Eastern and Atlantic achievements. Examples of such happy blending are not missing. See what that great and original English inventor, Lord Masham, the very type of an Atlantic genius, has made of the wild silks of India!

It seems to me that these international congresses ought to make it one of their important duties to watch over the intellectual wealth of the past and to collect it before it disappears for ever. Let the chemists of all countries who flock together in these gatherings entrust to their keeping the old indigenous industrial methods of their nations; let the reports of these congresses, which are distributed over all the world, become a treasure-trove of ancient motives for new development!

If we consider how our present chemical industry has been evolved from empirical processes such as our ancestors practised them, and as they still exist in the countries of the East, and even in some parts of Europe, we can easily observe a gradual transformation similar in many respects to the one that living nature had to go through in evolving the present types of plant and animal life. It is here that the parallels between biology and chemistry offer themselves. They are interesting, and not useless to consider. It would be strange indeed if we could not gather some acceptable hints from surveying the broad expanse of the human toil and thought of centuries.

One of the most characteristic changes that have taken place is the transformation of handicraft into manufacture.

We have replaced personal skill by division of labour in chemical work just as much as in all the other branches of human industry. In so doing we have certainly unconsciously copied nature. Do not her earliest creations, the unicellular organisms, in which one cell is made to fulfil all the functions of life, resemble the patient craftsman, who works at the object that he wants to turn out from the beginning to the end, and then, with a last loving glance, hands it over to his client? And are not our factories of the present day comparable to the complicated organisms of the later epochs of creation, with their many coordinated and subordinated organs that work in unison, and in their joint activity are much more powerful than their tiny unicellular ancestors?

One of the most interesting chapters in the evolution of animated life is the gradual transformation of aquatic organisms into those living in the air and on solid ground —a tremendous change, and one which could only be effected by many and varied attempts and by means of the most marvellous adaptations. Right into the midst of our epoch, when the conquest of land as a permanent dwelling-place for plants and animals is practically accomplished, reaches the perpetuation of intermediate forms, which can adapt themselves to land or water, as the circumstances may require.

Now what is the lesson we can learn from the study of this wonderful development in comparing it to what has happened in our own industry? I think it is obvious and of the greatest importance. It is this, that no industry, and especially no chemical industry, can be transplanted, such as it is, from the place in which it has been successfully developed, into any other without having to undergo a complete change, which taxes to the utmost the organising and inventive power of those who make the attempt.

This is a truth too often forgotten in our times, when the keenest struggle for success is rife everywhere, and people who have to suffer from the competition of factories established in other countries are apt to vent their grief in uncharitable accusations. Yet how frequent are the examples, when manufacturers, who have risen to great prosperity, suffer tremendously by transferring their own business into some new locality. In many cases it is merely a move in their own country, yet it means, generally, a far-reaching adaptation to altered conditions; but if it becomes a question of transplanting a manufacture from one country into another, it must be quite a new creation if it is to be a success. As a new creation it should command our respect, and though it may be inconvenient it should not be disparaged. It was the destiny of aquatic organisms to conquer land as a dwelling-place, and it is the destiny of the industrial countries of the present day to carry industry to the nations that are ready to receive it.

There are, fortunately, no two countries alike in this world, and most of them differ, from a manufacturing point of view, more than land and water for plants and animals. Whenever an industry leaves its native country it has to be re-modelled. Take, for instance, the gas industry, which was born in England, and has been carried by English enterprise over all the world. No sooner it crossed the channel and was established in France and Germany than it had to be materially transformed, not in its principle, but in the constructive details and the dimensions of the necessary plant. Our coal was different from yours, our fire-clay had to be prepared and worked differently for the production of the necessary retorts, our condensers and gas-holders had to be altered and encased to withstand the sudden and wide changes of temperature of a Continental climate, our yields proved lower, and the economy of the process was materially different. Still greater changes awaited the gas industry on the other side of the Atlantic. Though the United States are possessed of good gas-coal, the freights for it to the New England States proved to be too high. On the other hand, anthracite was incomparably cheaper there than it is with us, and the same was the case with mineral oils of a high boiling point. All this led to the successful substitution of carburetted water-gas for the illuminating gas of Europe. At present we try hard to acclimatise this American adaptation of the gas industry both in England and Germany. Brilliant as the work done by gas specialists in connection with these attempts undoubtedly is, the success is, to say the least, indifferent, and will remain so until the water-gas question will again have undergone so complete a transformation and adaptation to European industrial conditions that it will once more be paramount to a new creation.

Another example. Just at the present time a new country is about to join the concert of industrial nations. Norway, in the rocky solitudes of which the bear was wont to ramble and the elk and the reindeer to graze, the blue fjords of which knew no other craft than fishing smacks and occasional pleasure yachts, is beginning to develop a chemical industry of vast dimensions. Will that industry be similar to the one existing in this country or in Germany? Certainly not. Its factories will have no chimneys, no fires. They will be activated by the "white coal," the force of roaring torrents. Our engineers have pondered over the problem of economically transforming heat into electricity; the task of the Norwegian manufacturer is just the reverse. One of the fundamental problems of our German chemical industry is the utilisation of our overwhelming wealth of sodium and potassium salts; the Norwegians neutralise their synthetic nitric acid with limestone, because they have no cheap alkali. Many other points of the same kind might be mentioned, but I think these are sufficient to show that, whatever that new Norwegian industry may prove to be, when fully developed it must be different from what the world has seen so far.

The first activity which the human race develops in taking possession of wild districts is agriculture, and we know full well that no two countries are alike in their agricultural methods and results. An agricultural country has to develop a dense population, and, in its work, the peculiarities due to its soil and its climate, before it can attempt to create an industry. The blending of the old agricultural interests with the newly acquired industrial ones means in itself a convulsion. Is it then probable that so fundamental a change may be brought about by the mere importation of a miserable copy of what has been born and nurtured to maturity on other soil and under another sun?

If we study the life of plants and animals we are struck by the marvellous economy reigning everywhere. There are few physiological processes which can be called wasteful. Every bye-product of the more important chemical reactions that take place in the organisms of plants and animals is utilised and made to serve some purpose. In plants, for instance, the refuse of the chemical work of the protoplasm seems to be deposited as encrusting material in the enclosing cellulose. The encrusted cell is then made to serve as a mechanical support for the body of the plant, whilst new and more vigorous cells are formed to fulfil the functions of life. Some of the bye-products of the chemical work of the plant are transformed into dye-stuffs, others into perfumes, both with the object of attracting the insects which are necessary for fertilisation. Everywhere in animated nature we see the principle of storing up food, either to serve in cases of need or to provide for a future generation. Even in those cases where nature seems to be wasteful, as, for instance, in producing germs and seeds in far greater numbers than seem to be required for the continuation of the species, the seeming superabundance is merely a wise calculation of the probabilities for the development of the germs. More marvellous, perhaps, than any of these examples is the economical use of the energy required for sustaining the functions of life. So far as I am aware, there is not a single engine of human invention which can utilise the energy supplied to it in so perfect a way as, for instance, a horse utilises the calories contained in its food for the production of mechanical power; and though the mechanical equivalent of light as a form of energy is, so far as I am aware, yet an unknown constant, we may safely say that the perfection with which living plants utilise the energy of sunlight for carrying out the endothermic reactions upon which their nutrition and growth depends is far superior to the methods which we have so far discovered for similar purposes.

Are not these principles of economy which so universally pervade living nature also the very essence of all industrial chemistry? Are not such considerations as economy of energy in its various forms, high yields, and the avoiding, or, if unavoidable, the utilisation of bye-products the fundamental principles which we try to instil into the mind of the young chemist about to begin his career as a manufacturer? The history of applied chemistry is teeming with examples where the survival of the fittest means neither more nor less than a victory of economy.

We all know that that marvellous creation of human ingenuity, the closed ring of industrial chemical processes working in connection with Leblanc's method of producing soda, is practically extinct on the Continent and materially reduced in its importance in England. This fate it had to suffer, because it was a wasteful process—wasteful in its utilisation of material and wasteful in its consumption of energy. The skill and resource exerted in its invention and constant improvement will for ever be gratefully remembered; but they were unable to check the progress of the Solvay process, which is more economical in its use of energy, and of the electrolytic methods for splitting up the alkaline chlorides, which produce no bye-products.

The progress of industrial chemistry does not always depend on the introduction of more perfect, but also more complicated, machinery and plant into the factories. Of course, every chemical process requires thorough working out from a mechanical point of view, and many of the most brilliant successes of our modern chemical industry are mainly due to a clever adaptation of mechanical means to a chemical end; but, taken as a whole, the real progress of the chemical industry does not so much consist in the improvement of the apparatus as in the simplification of the fundamental chemical reactions. More than once a seemingly insignificant chemical alteration of an industrial process has produced the same or a better effect than the introduction of the most ingenious and costly plant.

That the great principle of economy is not only applicable to the material necessary for carrying out chemical reactions, but perhaps even more to the energy consumed by them, is a distinctly modern idea. It is not so very long since we have begun to have, if I may say so, a conscience for fuel. Previous generations took it for granted that industrial work consumed coal, and that the necessary coal had to be provided and to be paid for. We are now awake to the fact that the quantity of fuel required for an industrial process is very much dependent on the way in which it is made to do its work.

Of course, the calorimetric effect of any given fuel is a constant, and it is also true that we can never utilise more than a certain proportion of it; but this proportion may vary considerably. It was alarmingly small almost through the whole of the nineteenth century, and we may congratulate ourselves upon its present ascendent tendency. A striking example of the transformation of our views about fuel and its proper use is the history of the smoke question. There was a time, both in England and on the Continent, when smoke was considered a necessary evil which had to be suffered. After a while smoke began to be looked upon as a nuisance, and war was declared against it by those who suffered from its disagreeable properties; but now we know that smoke is a waste, and that nobody has better cause to wage war against it than he who produces it. A smoking chimney does not only carry visible unburned carbon into the atmosphere, but in nine cases out of ten also invisible carbonic oxide and methane, with all the latent energy they contain. Smoking chimneys are thieves, and their misdeeds should not rise unavenged to heaven.

But even chimneys that are innocent of incomplete combustion may be guilty of stealing energy if they allow the gases of combustion to escape into the atmosphere with a higher temperature than is necessary to activate the draught. The lost energy of such gases may be trapped and recovered by the regenerating and recuperating apparatus now so largely used by many industries. Regenerative gas-heating is not only a sure prevention of smoke, but also the most powerful means of economising heat, and therefore one of the greatest acquisitions of modern industry. It is perhaps not saying too much that the saving of national wealth effected by it may amount to a sum sufficient to pay the aggregate national debts of all the civilised nations. Uncivilised nations are blessed with neither national debts nor heat-regenerating appliances.

My last comparison between biology and applied chemistry I should like to choose from a chapter which one might call biological sociology, though I am not aware that that name is commonly given to it. It treats of the wonderful phenomena of symbiose and aggregation.

Symbiosis is, as we now know, of very frequent occurrence. Plants or animals of totally different nature and organisation, or even plants and animals, may combine for joint life and activity with the object of helping and protecting each other in the great struggle for existence. What neither of them would be able to fulfil or obtain by its own strength and power they can do with ease and certainty in their faithful allegiance. Gregariousness—the flocking together of organisms of the same kind—arises from the same spirit of mutual help and protection.

There is a great deal in human life and institutions, in our morals, politics, and science, which reminds us that the human race, as an intrinsic part of animated nature, has also inherited its all-pervading tendency for combining forces; and what is thus apparent in the doings of mankind in general cannot be absent in the special field of activity which forms the object of our exertions. The various forms of chemical industry are essentially symbiotic. They depend upon each other for their success and progress. A solitary chemical factory in a country otherwise devoid of chemical industry is a practical impossibility. Chemical works come in shoals if they come at all. The maker of acids and alkalis wants other chemical enterprises to use his products, and these, again, are constantly on the look-out for customers. The more varied and numerous the factories are, the more they prosper, in spite of their complaints of growing competition.

The chemists themselves are gregarious. They form societies and academies and institutes and syndicates by the score, and who can deny the fact that brilliant results have been achieved by such combinations of forces? If we remember, in terms of unmeasured gratitude, the great originators of our science and its applications, we cannot forget the help rendered to its progress by such institutions as the Royal Society and Royal Institution, the French, Italian, and German academies, the leading chemical societies, and the innumerable universities in all parts of the world, the rapid growth and extension of which is the true gauge of our progress.

Last, but I hope not least, in this list of brilliant aggregations stand our congresses as a new, but most successful, creation. They represent a modern form of symbiotic effort amongst chemists, which is the more remarkable because it is international. They proclaim the great truth that science knows no boundaries and frontiers, that it is the joint property of all humanity, and that its adherents are ready to flock together from all parts of the world for mutual help and progress. It is the great truth proclaimed by one of our past presidents, Marcellin Berthelot—"La science est la bienfaitrice de l'humanité entière"—which our congresses might write on their banner, for it expresses the spirit which led to their foundation and ensures their success.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. H. KOBOLD, professor of astronomy at the Kiel University, has been called to the similar post at Berlin.

MR. J. E. BARNARD has been appointed lecturer on microscopy in the department of general pathology and bacteriology, King's College, London.

DR. G. S. WEST has been appointed to the chair of botany and vegetable physiology in the University of Birmingham, rendered vacant by the retirement of Prof. Hillhouse.

PROF. W. W. PAYNE has retired from the chair of astronomy at Goodsell Observatory, which he founded at

Carleton College, Northfield (Minn.), in 1877, but retains the co-editorship of *Popular Astronomy*. Dr. H. Wilson, his co-worker, has been appointed to the professorship.

Dr. C. Gordon Hewitt has accepted the appointment as entomologist to the Dominion of Canada in succession to the late Dr. James Fletcher, and has resigned, in consequence, his post as lecturer in economic zoology in the University of Manchester. He will leave England in September to take up his new duties at Ottawa.

We learn from the *Westminster Gazette* that the heirs of the late Herr Heinrich Lanz, head of the Mannheim engineering firm, have given a million marks for the establishment of an academy of sciences at Heidelberg, which will stand in the same relation to the university as the similar institutions in Leipzig and Göttingen stand to the universities in those cities.

Lord Strathcona has just presented the sum of 100,000*l.* to the McGill University, Montreal, of which he is Chancellor. Of this amount, 90,000*l.* is needed to complete and equip the new medical buildings, the old buildings having been destroyed by fire in 1907. The remaining 10,000*l.* is intended as a subscription to the fund for increasing salaries throughout the University.

At the meeting on June 28 of the council of the University of Paris, the rector, M. Liard, announced, we learn from the *Revue scientifique*, a gift by M. Henry Deutsch of 500,000 francs, and an annual grant of 15,000 francs, towards a scheme for the creation of an aërotechnical institute. He also announced a donation from M. Basil Zakaroff of 700,000 francs for the foundation of a chair of aviation in the faculty of sciences of the University.

The Belfast University Commissioners have made the following, among other, appointments to professorships and lectureships in the Queen's University of Belfast:—professor of economics, Mr. Thomas Jones; professor of botany, Mr. D. T. Gwynne-Vaughan; lecturer in organic chemistry, Dr. A. W. Stewart; lecturer in physics, Dr. Robert Jack; lecturer in bio-chemistry, Dr. J. A. Milroy; lecturer in geology and geography, Dr. A. R. Dwerryhouse; lecturer on hygiene, Dr. W. James Wilson.

New buildings in connection with the Merchant Venturers' Technical College, Bristol, were opened by Lord Reay on June 24. The college will, for the future, provide the faculty of engineering in the newly established University of Bristol, and in consequence of this arrangement certain changes in the curriculum and time-table will in all probability come into effect at the beginning of next session. These probable modifications are outlined in a short illustrated prospectus of the day classes of the college which was published recently. There are departments for the study of many branches of engineering, including civil, mechanical, electrical, mining, and motor-car engineering, the last-named subject being in charge of a special professor.

A new departure has been made in connection with the faculty of engineering of the University of Liverpool. A special course on refrigeration has been introduced into the honours school of mechanical engineering. The general theory and actual testing of refrigerating machines is included in the course on heat engines, but, in the final year of an honours student's four years' work, a course of lectures and laboratory work on heat engines and refrigerators is provided. In addition, a special optional course has been arranged on refrigerating machinery and cold storages, comprising the design of refrigerating machinery, the construction of cold storages, ice-making plants, and the general practice of refrigeration. This experiment, which constitutes, it is stated, the first attempt in this country to establish special instruction on refrigeration, will be watched with interest.

The programme of the Summer School of University Extension Students, which is to be held this year at Oxford from July 30 to August 23, covers a sufficient range of subjects to appeal to the most diverse tastes. Pure science scarcely takes the prominent place accorded to it in previous years; we notice, however, that one section of the work arranged is entitled "Italy's Contribution to Science," and will include lectures on Galileo, Vesalius and others, by such well-known authorities as Prof. Osler, Prof. A. Macalister, and Mr. Marconi. In addition to the general course on Italy, lectures and classes have been organised for economic and political science, and a special class on practical map-making will be conducted by Mr. N. F. MacKenzie. Application for tickets, and all inquiries in connection with the meeting, should be addressed to Mr. J. A. R. Marriott, University Extension Office, Examination Schools, Oxford.

We learn from the *Pioneer Mail* that a vesting order relating to the Tata Research Institute has been issued. The order recapitulates the bequests of the late Mr. Tata, and enumerates other gifts which have been made for the purposes of the institute; it then proceeds to outline the scheme for the government of the institute. The Viceroy is to be an *ex-officio* patron, and the heads of local Governments of India are included as vice-patrons. There will be also a court of visitors, on which the Government of India and the Government of Mysore will be represented, and Messrs. Tata, the sons of the benefactor, will be members during their lives. The director-general of education, the directors of public instruction to local Governments, and professors of the institute will be *ex-officio* members. There will be a council of twelve, a senate, and a standing committee of the court of visitors. The council, on which four professors will serve, will be the executive body of the institute, its proceedings being subject, however, to review by the standing committee referred to. There are now, we learn from the same source, ample resources at the disposal of the governing body of the institute. The sum available for initial expenditure includes building grants of 5 lakhs and $2\frac{1}{2}$ lakhs respectively from the Mysore Durbar and the Government of India respectively, with $1\frac{1}{2}$ lakhs from the Madras Government to be spread over three years, and there are in all 13 lakhs practically in hand. As the endowment is on a liberal scale, the financial future of the institute is assured. It may be added that the actual buildings are estimated to cost Rs. 6,57,000.

The new buildings of the University of Birmingham were opened by the King and Queen yesterday as we went to press. The following message upon this development of university work has been sent by Mr. Chamberlain to the *Birmingham Gazette*:—"The University formally opened by their Majesties in person to-day is the crowning point of the work undertaken by our city, and endows us with an institution we have long contemplated. His Majesty's consent to perform the opening ceremony is one more example of his constant interest in all that concerns the welfare of his subjects. It singularly enhances the importance of the occasion and distinguishes with his Royal approval the work which has thus been accomplished. Nothing in the history of education in this country is more surprising than the recent growth of university institutions. Formerly our ancestors were satisfied with the three universities of Oxford, Cambridge, and Durham in the whole of England and Wales; now in the last twenty years we have added to them other universities to provide for the wants of the towns and districts which are of provincial importance, and we have found that with the growth of these bodies has come the demand for instruction of the higher kind. Accordingly in many towns a fully equipped university has been established, and higher education has been placed within reach of all. By the generosity of our citizens and the munificence of some personal friends we in Birmingham have been enabled to provide and equip the principal technical departments of our university on a scale which previously has been unattempted in this country; but what we have accomplished is only the beginning. Much still remains to be done. The buildings are complete, and the endowments are altogether inadequate; the foundations have been laid, but the building up of the structure lies with the citizens of Birmingham."

A scheme is being developed to provide an interchange of University students between the United Kingdom, Canada, and the United States. The object is to provide opportunities for as many as possible of the educated youth of these countries to obtain some real insight into the life and customs of other nations at a time when their own opinions are forming, with a *minimum* of inconvenience to their academic work and the least possible expense, with the view of broadening their conceptions and rendering them of greater economic and social value. Lord Strathcona has consented to become president for the United Kingdom. The list of vice-presidents includes the names of the Chancellors and Vice-Chancellors of many British universities, the Prime Minister, the Lord Chancellor, and other well-known men. A large and representative committee has also been appointed. Additional objects of the movement are to increase the value and efficiency of present university training by the provision of certain travelling scholarships for practical observation in other countries under suitable guidance. In addition to academic qualifications, the selected candidate is what is popularly known as an "all-round" man, the selection to be along the lines of the Rhodes scholarships. It is hoped to afford technical and industrial students facilities to examine into questions of particular interest to them in manufactures, &c., by observation in other countries and by providing them with introductions to leaders in industrial activity. It is proposed to establish two students' travelling bureaux, one in New York and one in London; to appoint an American secretary (resident in New York) and a British secretary (resident in London), to afford every facility to any graduate who wishes to visit the United States, Canada, or the United Kingdom for the purpose of obtaining an insight into the life of those countries. It is hoped to provide twenty-eight travelling scholarships, fourteen of these being available for universities in the United Kingdom, ten for universities in America, and four for universities in Canada. The total cost of the scheme, inclusive of the maintenance of two travelling bureaux and the provision of twenty-eight scholarships per annum, is estimated at 13,500*l.* for a period of three years, equivalent to an annual expenditure of 4500*l.*, the relative annual expenditure being estimated at 2400*l.* in the United Kingdom, 600*l.* in Canada, and 1500*l.* in the United States. Promises of support may be sent to the hon. secretary, Mr. Henry W. Crees, at the University Club, Birmingham, and it is hoped that all interested in promoting the success of an educational scheme of far-reaching significance in the English-speaking world will contribute financially.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 24.—Prof. J. Cossar Ewart, vice-president, in the chair.—Pressure perpendicular to the shear planes in finite pure shears, and on the lengthening of loaded wires when twisted: J. H. **Poynting.** When a solid is subjected to a finite pure shear the lines of greatest elongation and contraction are not the diagonals of the rhombus into which a square is sheared, but lines making, respectively, $\pm\epsilon/4$ with the diagonals of the square, where ϵ is the angle of shear, and these lines are at right angles to the order of ϵ^2. If we assume that a pressure P is put on along the lines of greatest contraction, and a tension Q along the lines of greatest elongation, we may put $P=n\epsilon+p\epsilon^2$, $Q=n\epsilon-p\epsilon^2$, where n is the rigidity and p is a constant to the second order of ϵ. For equilibrium a pressure $R=(\frac{1}{2}n+p)\epsilon^2$ is required perpendicular to the shear planes. This is zero only if $p=-\frac{1}{2}n$, a supposition for which there is no apparent reason. To keep constant volume a stress may be needed $S=q\epsilon^2$ perpendicular to the plane containing P and Q, a pressure if q is positive. Suppose that a wire is twisted by a torque with axis along the axis of the wire. To keep the volume constant at every point it would be necessary to apply the system of forces R and S from outside. If this system is not applied we may expect the wire to change in length and diameter by amounts calculable in terms of the elastic constants. The change in length should be an increase $dl=Sa^2\theta^2/l$, where S is a function of the constants, given in the paper, a is the radius, and θ is the twist in length l. Such a lengthening has been found to exist for piano-steel, copper, and brass wires when loaded enough to straighten out kinks. For the piano wires tested S was of the order 1, and for the copper and brass wires of the order 1·5. The lengthening of a steel wire 0·97 mm. diameter and 2·3 metres long for a twist of one turn in the length was about 0·0019 mm. This lengthening on twisting should be taken into account in accurate determinations of the rigidity.—The wave motion of a revolving shaft and a suggestion as to the angular momentum in a beam of circularly polarised light: J. H. **Poynting.** When a shaft of circular section is revolving uniformly and is transmitting power uniformly, a row of particles originally in a line parallel to the axis will lie on a spiral of constant pitch, and the position of the shaft at any instant may be described by the position of this spiral. The motion of the spiral onwards may be regarded as a kind of wave motion. Its velocity with a given speed of revolution will only be the "natural" velocity $\sqrt{(n/\rho)}$ of twist waves along the shaft for a certain torque on the shaft. For any other torque the velocity is "forced," and forces from outside must be applied to maintain it at every point where the twist is changing. The group velocity of waves of this kind is zero. Taking a uniformly revolving tube as a mechanical model of a beam of circularly polarised light, and assuming that the relation between torque and energy holding for the model holds also for the beam of light, the angular momentum delivered per second to unit area of an absorbing surface upon which the light falls normally is $P\lambda/2\pi$, where P is the pressure of the light and λ is its wave-length. In light-pressure experiments P is detected by the torque produced on a disc at the end of an arm about 1 cm. The value is therefore about 100,000 times as great as the torque on the same disc, due to the angular momentum. If the angular momentum of circularly polarised light only has this value, there does not appear to be much prospect of detecting it at present.—The effect of a magnetic field on the electrical conductivity of flame: Prof. H. A. **Wilson.** This paper contains an account of some experiments on the change in the conductivity of a Bunsen flame produced by a magnetic field. The current through the flame was horizontal, and the magnetic field was also horizontal, but perpendicular to the current. The ratio of the potential gradient in the flame to the current was taken as a measure of its resistance. The results show that $\delta R/R=AH^2+BH$, where H denotes the magnetic field, R the resistance, and A and B are constants. The velocity of the negative ions can be calculated from the term AH^2, and the result is 9600 cm./sec. for 1 volt per cm., which agrees with Mr. E. Gold's results obtained by an entirely different method. The term BH is presumably due to the upward motion of the flame gases, but its value is about fifty times greater than the value calculated from the ionic theory.—Studies of the processes operative in solutions; xi., the displacement of salts from solution by various precipitants: Prof. H. E. **Armstrong** and Dr. J. V. **Eyre.**—The thermal conductivity of air and other gases: G. W. **Todd.** The paper gives an account of a determination of the thermal conductivities of air and other gases at atmospheric pressure. The conductivity was obtained from observations of the steady flow of heat between two horizontal circular metal plates maintained at different temperatures, the upper one at the temperature of steam and the lower one at room temperature. The upper plate was fixed, and the lower one could be moved up and down so as to vary the distance between them. If the temperatures of the plates are kept constant, the quantity of heat passing per second from the upper plate to the lower, when the distance between them is x, is given by $Q=K/x+R+Ex$, where the constant K is proportional to the thermal conductivity, R is the heat radiated, and Ex is the effect due to the edge. The latter is negligible when x is small compared with the radius of the plates, so that the relation between Q and x is given by a rectangular hyperbola. Hence the relation between Q and $1/x$ is a straight line the slope of which gives K, from which the conductivity is determined. The intersection of this line with the axis of Q gives the value R of the radiation. The value of the conductivity so obtained was independent of the nature of the surfaces of the plates, and also independent of the dimensions of the plates, the latter proving that convection currents were absent or negligible. The conductivities of some gases other than air were determined by comparing the rates of flow of heat through them with the rate of flow through air when the plates were at a fixed distance apart. The paper concludes with a calculation of the "radiation constant," from a determination of the absorption coefficient of the surfaces of the plates when painted black, and the radiation R.—The possible ancestors of the horses living under domestication, part i.: Dr. J. C. **Ewart**. By some naturalists it is believed that domestic horses are the descendants of a Pleistocene species (*Equus fossilis*)—now represented by the wild horse (*E. przewalskii*) of Mongolia—by others, the horses living under domestication are said to be a blend of a coarse-headed northern species allied to Prejvalsky's horse, and a fine-limbed southern species which in prehistoric times inhabited North Africa, or a blend of a Prejvalsky-like northern species and a southern species closely allied to *E. sivalensis* of the Pliocene deposits of India. The examination of the skull, teeth, and limb bones of horses found at Roman settlements and in the vicinity of pile-dwellings indicates that domestic horses originally belonged to several distinct types, viz. (1) a type characterised by long limbs, by a long face, broad and convex between the orbits, and strongly deflected on the cranium, and by the crown of the fourth premolar being from before backwards about 2·5 times the length of the grinding surface of its "pillar"; (2) a type with slender limbs, a fine, narrow, slightly deflected face, and the crown of the fourth premolar about three times the length of its "pillar"; (3) a type with fairly slender limbs, a long, narrow, somewhat deflected face, and the crown of the fourth premolar about twice the length of its "pillar"; (4) a type characterised by short, broad metacarpals, a short face, broad and flat between the orbits, and nearly in a line with the cranium, and by the crown of the fourth premolar being twice the length of its "pillar"; and (5) a type with short, wide metacarpals, the face long and strongly deflected, and the crown of the fourth premolar about 1·5 times the length of its "pillar." Only the varieties characterised by molars with short "pillars" are dealt with in this communication. The possible ancestors of the short-pillared varieties are *Equus sivalensis* of Indian Pliocene deposits, *E. stenonis* of the Pliocene deposits of Europe and North Africa, and a new species, *E. gracilis*. Arabs, barbs, thoroughbreds, and other modern breeds with a long deflected face, broad and prominent between the orbits, and the limbs slender, seem to have mainly sprung from *E. sivalensis*, while certain unimproved breeds with a deflected face, but very short "pillars," are probably related to *E. stenonis*. Exmoor, Hebridean, Iceland, and other ponies of the "Celtic" type, as well as ponies found in the south of France, the West Indies, and Mexico, characterised by a fine narrow skull, slender limbs, and the absence of ergots and hind chestnuts, are regarded as the descendants of *E. gracilis*, which includes (1) the small species of the English drift described by Owen as a fossil ass or zebra (*Asinus fossilis*); (2) the small species of French Pliocene and Pleistocene deposits known to palæontologists as *E. ligeris*, and the small species of North African Pleistocene deposits known as *E. asinus atlanticus*, and hitherto believed to be closely related to, if not the ancestor of, zebras of the Burchell type. By crossing experiments evidence has been obtained of the wide distribution of horses of the *E. gracilis* type; that broad-browed Arabs and thoroughbreds, with the face nearly in a line with the cranium, are mainly a blend of a southern variety of *E. gracilis* (*E. caballus libycus*) and a horse of the "forest" or Solutré type, and that heavy breeds have not inherited their coarse limbs from a species closely allied to the wild horse of Mongolia.—The alcoholic ferment of yeast-juice; part iv., the fermentation of glucose, mannose, and fructose by yeast-juice: A. **Harden** and W. J. **Young**. (1) Mannose behaves towards yeast-juice, both in the presence and in the absence of added phosphates, substantially in the same manner as glucose. (2) Fructose resembles both glucose and mannose in its behaviour, but in presence of phosphate is fermented much more rapidly than these sugars, and the optimum concentration of phosphate is much higher. (3) Fructose has the property of inducing rapid fermentation in presence of yeast-juice in solutions of glucose and mannose, containing such an excess of phosphate that fermentation is only proceeding very slowly. No similar property is possessed by glucose or mannose. These properties of fructose indicate that this sugar when added to yeast-juice does not act merely as a substrate to be fermented, but bears some specific relation to the fermenting complex. All the facts are consistent with the supposition that fructose actually forms a part of the fermenting complex. When the concentration of this sugar is increased, a greater quantity of the complex would be formed, and, as the result of this increase in the concentration of the active catalytic agent, the juice would become capable of bringing about the reaction with sugar in presence of phosphate at a higher rate, and at the same time the optimum concentration of phosphate would become greater, exactly as is observed.—The electrical reactions of certain bacteria applied to the detection of tubercle bacilli in urine by means of an electric current: C. **Russ**. The aim of these experiments was to ascertain whether bacteria suspended in an electrolyte are transmitted during electrolysis to either electrode, with the view of the recovery of pathogenic bacteria from a pathological fluid by such means. During electrolysis of certain salts in which bacteria were suspended, the organisms were found to migrate to one electrode; in some instances there was no migration. The effect was noticed to occur with killed as well as with living bacteria. By testing certain organisms in the same (but a small) series of electrolytes some differences of effect were found, though this line of inquiry was not pursued. To utilise this bacterial movement, an electrolyte in which tubercle bacilli had shown marked kathodic aggregation was added to tuberculous urine, and the kathode arranged in the form of a bacterial trap. After electrolysis tubercle bacilli entered the trap, which was eventually withdrawn, and the organisms recognised in a stained film prepared from its contents. A series of such urines was tested in this way, and in each case tubercle bacilli were found in the trap. In the final experiment a number of tubercle bacilli (estimated at 500) were added to 100 c.c. normal urine, and their detection attempted by separate investigators by means of the centrifuge and current. By the centrifuge none were found, while the current recovered 128 bacilli. The results of this preliminary investigation may be summarised as follows:—Certain bacteria under the influence of a suitable current aggregate at one or other electrode. The aggregation varies with the nature of the electrolyte, and is probably due to affinity between the products of electrolysis and the bacteria. It occurs with killed as well as with living bacteria. The aggregation by electrical currents affords a means of collection and examination. The differences in behaviour of various bacteria are such as to suggest the possibility of utilising the method for purposes of specific discrimination, but in this particular the data hitherto obtained are not sufficient to warrant definite statements.—The effect of the injection of the intracellular constituents of bacteria (bacterial endotoxins) on the opsonising action of the serum of healthy rabbits: Dr. R. Tanner **Hewlett**. In this investigation the effect of the endotoxins of the *Bacillus typhosus*, *Micrococcus pyogenes aureus*, and *B. tuberculosis* on the opsonising action of the serum of normal rabbits has been studied. The endotoxins were prepared by the Macfadyen process, the rabbits were inoculated subcutaneously, and the specimens for counting the number of bacteria ingested by leucocytes were prepared in the usual manner. Human leucocytes were employed, and the counts were made on fifty cells. (A) *Typhoid Endotoxin*.—The results for this endotoxin are approximate only, as agglutination and bacteriolysis are complicating factors. The amount of endotoxin injected was 0·1 mgrm., prepared from an avirulent strain. One day after injection a decided negative phase had developed (opsonic index about 0·2), two days after injection the index was rising (1·4), and attained a maximum on the third day (3·3), after which it fell. Dilution of the serum to 1 in 5 and 1 in 10 tended to increase phagocytosis. (B) *Staphylococcus Endotoxin*.—Endotoxin prepared from an old laboratory strain in a dose of 0·1 mgrm. produced a rise in the opsonic index to 1·6, which persisted for some weeks. Endotoxin (0·1 mgrm.) prepared from a recently isolated strain produced a rise to 2·5. An equivalent dose of staphylococcus vaccine (1000×10^6 cocci) produced a rise of the opsonic index to

1·8, which fell subsequently to a point lower than that with either endotoxin. Estimations of the opsonic indexes made with the recently isolated strain gave results higher than those obtained using the old strain. With another endotoxin, varying doses (0·1, 0·01, and 0·001 mgrm.) all produced marked rise in the opsonic indexes, the rise corresponding with the dose. (c) *Tubercle Endotoxin.*—Injection of 0·002 mgrm. of endotoxin caused a rise in the opsonic index to 1·9 sixteen days after. A similar dose of German tuberculin R. produced hardly any effect. A large dose (1·0 mgrm.) of endotoxin caused a marked negative phase (index 0·5) forty-eight hours after injection, with a subsequent rise to 1·8. Endotoxin (1·0 mgrm.) prepared from tubercle bacilli previously extracted with ether also produced a negative phase, with a subsequent rise to 1·5. (D) *Keeping Power of Endotoxin Solutions.*—Experiments were performed with staphylococcus and tubercle endotoxin solutions which had been kept for seven weeks after preparation; there was little diminution in activity. Other experiments indicate that the solutions deteriorate but little for three to six months after preparation. (E) "*Negative Phase.*"—Experiments indicate that endotoxin produces decidedly less "negative phase" than a vaccine.—The occurrence of protandric hermaphroditism in *Crepidula fornicata*: J. H. **Orton.** *Crepidula fornicata* is a streptoneurous gastropod belonging to the family Calyptræidæ. Individuals of this species associate together permanently in linear series, forming "chains." The chains may consist of from two to twelve individuals. The sex relations of the individuals were noted in about 300 chains. It was found that the individuals which occur at the attached ends of the chains are always females, those occurring near the top of the chains are males, while those about the middle often possess the secondary sexual characters of both sexes. In intermediate positions in the chains occur forms which, in their secondary sexual characters, are intermediate between females and hermaphrodites on the one hand, and between hermaphrodites and males on the other. Thus the chains present a transitional series, beginning with the males, which are the youngest individuals, and ending with the females, which are the oldest individuals. Microscopical examination of the gonad has shown that there is as complete a transitional series in the primary sexual characters as occurs in the secondary ones. All the adults are sedentary, but the young are able to move about freely. One thousand young ones have been examined, and found to be all males. There is, therefore, no doubt that all the individuals begin life as males, and change gradually in the course of their life-history into females. It is highly probable, from known descriptions of allied species, and from observation on species of allied genera, that protandric hermaphroditism is common in the Calyptræidæ. Further, it seems probable that the family will present a series in the evolution of protandric hermaphroditism. If such a series be found there is little doubt that a study of the earlier stages would lead to the discovery of the nature of the sexes, *i.e.* in Mendelian terms, whether the male is heterozygous and the female homozygous, or *vice versâ*. Ten other streptoneurous hermaphrodites are known. It would seem, therefore, that one of the chief distinctions between the Streptoneura and the Euthyneura is beginning to break down.—Sensitive micro-balances, and a new method of weighing minute quantities: B. D. **Steele** and K. **Grant.**—The polarisation of secondary γ rays: Dr. R. D. **Kleeman.**—The absorption of homogeneous β rays by matter, and on the variation of the absorption of the rays with velocity: W. **Wilson.** The experiments were made with the view of determining the manner in which the absorption coefficient of the β rays varies with the velocity. Radium, which gives out rays the velocities of which vary between very wide limits, was used as a source of radiation. A beam of rays from the radium passed into a magnetic field, by means of which approximately homogeneous rays could be brought into an electroscope. The velocities of the rays could be determined from the strength of the magnetic field. Screens of metal of different thicknesses were interposed in the path of the rays, and it was found that the law of absorption was not exponential, but approximately linear, except for large thicknesses of absorbing material. Various experiments were made to show that this was not due to the experimental arrangement, but was a real effect. The fact that the β rays from uranium, actinium, &c., are absorbed by matter according to an exponential law is shown to be a proof, not of their homogeneity, but of their heterogeneity. Groups of rays can be built up which represent the properties of these rays with respect to absorption. Further experiments were made on the change of velocity of the rays after passing through absorbing material, and it was found that the velocity of the rays, contrary to the view expressed by H. W. Schmidt, is appreciably reduced as they penetrate matter. The law of absorption of the β particles when measured by the ionisation method involves a considerable number of factors, and, as might be expected, no simple relation could be found between the absorption of the rays and their velocity.—Experimental researches on vegetable assimilation and respiration; v., a critical examination of Sachs' method for using increase of dry weight as a measure of carbon dioxide assimilation in leaves: D. **Thoday.**—The reproduction and early development of *Laminaria digitata* and *Laminaria saccharina*: G. H. **Drew.** The processes of reproduction and early development in both *L. digitata* and *L. saccharina* are very similar. The plant is the gametophyte, and is monœcious. The reproductive areas occur as dark patches on the lamina, and consist of gametangia embedded among paraphyses. The gametangia contain small spherical gametes, 0·003 mm. in diameter, and a number of globules of an oily substance. When mature, the gametangia rupture at their distal extremity and liberate their contents. The liberated gametes develop two flagella of different lengths, which are inserted close together; they are phototactic, and move in the direction of the longer flagellum. Cultures from the reproductive areas were made in a culture solution consisting of various salts dissolved in sea water. The solution was sterilised by heat, and all flasks, pipettes, &c., were sterilised by boiling. Division cultures containing the planogametes were made, and eventually cultures free from growths of the Ectocarpaceæ and other algæ were obtained. In such cultures, stages of isogamous conjugation, resulting in a spherical zygospore, were observed. Later a process grew out from the zygospore, and expanded at its end, and then the cell contents passed along this process, forming a spherical mass at the expanded end. This became cut off by a cell wall, and the remains of the zygospore degenerated. The cell thus formed developed chromoplasts, increased in size, and divided, producing typically a chain of cells each having an outer and an inner cell wall. This stage probably represents the sporophyte (2x) generation. Any cell of the chain may then rupture its outer cell wall, and by repeated divisions give rise to the laminaria plant which emerges from the ruptured exosporium. The young plant consists of a flattened lamina made up of cubical cells, having at its base a number of colourless unicellular rhizoids. The stipe is developed from the basal part of the lamina. The disc-shaped expansion develops at the base of the stipe and partially envelops the primary rhizoids; the hapteres arise as outgrowths from this disc.—The germicidal action of metals, and its relation to the production of peroxide of hydrogen: Dr. A. C. **Rankin.**—Surface flow in calcite: G. T. **Beilby.**—A preliminary note on *Trypanosoma eberthi* (Kent)—(*Spirochaeta eberthi*, Lühe), and some other parasitic forms from the intestine of the fowl: C. H. **Martin** and Miss Muriel **Robertson.**—The spectrum of magnesium hydride: Prof. A. **Fowler.** The author has previously discovered that many of the band lines peculiar to the sun-spot spectrum are identical with lines composing the green fluting attributed to magnesium hydride by Liveing and Dewar. The present paper gives the results of a further investigation of this spectrum with high dispersion, together with details of wave-length determinations. The principal results may be briefly summarised as follows:—(1) No sufficient reason has been found for modifying Liveing and Dewar's conclusion that the spectrum is produced by the combination of magnesium with hydrogen. (2) Lines are shown at short intervals in all parts of the spectrum from the extreme red to λ 2300, and definite groups of flutings begin at 5621·57, 5211·11, 4844·92, 4371·2, and near 2430. (3) From photographs of the magnesium arc in hydrogen at low pressures, taken with a 10-feet concave grating, the positions of close upon 2000 lines, composing the three principal bands, have been determined. The wave-lengths were derived from the interference standards of Fabry and Buisson, but have been corrected to Rowland's scale to facilitate comparison with solar spectra. (4) Twelve of the series of lines which compose the green band have been traced, and it is shown that none of the formulæ which have been proposed is sufficiently general in its application to represent all of these series within the limits of error of measurement. For the longer series the closest approximation is given by Halm's equation. (5) The identification of magnesium hydride in the sun-spot spectrum has been fully confirmed, and is clearly demonstrated by photographs submitted for reproduction. (6) It is shown that many of the bright interruptions of the dark background of the spot spectrum are not bright lines, but merely clear interspaces between lines or groups of lines in the spectrum of magnesium hydride. (7) The presence of the magnesium hydride flutings, together with flutings of titanium oxide and calcium hydride discovered at Mount Wilson, accords with the view that spots are regions of reduced temperature, and that their darkness is at least partly due to absorption. (8) The investigation of the possible presence of lines of magnesium hydride in the ordinary solar spectrum is for several reasons inconclusive, but there is evidence that very few, if any, of the thousands of faint lines tabulated by Rowland are to be accounted for by this substance.—The discovery of a remedy for malignant jaundice in the dog, and for redwater in cattle: Prof. G. H. F. **Nuttall** and S. **Hadwen.**—The comparative power of alcohol, ether, and chloroform, as measured by their action upon isolated muscle: Dr. A. D. **Waller.**

EDINBURGH.

Royal Society, June 21.—Dr. Burgess, vice-president, in the chair.—The pharmacological action of protocatechyltropeine: Prof. C. R. **Marshall.** Like most other tropeines, this substance paralyses, but only for a short period, the so-called vagal endings of the heart; it also depresses the neuro-muscular junctions in voluntary muscle and the muscular tissue itself. Its most interesting action, however, is upon the respiration. Medium doses, intravenously administered, rapidly paralyse the respiration. This effect is generally transitory, and is not concomitant with other effects produced by the compound. Tappeiner and Pohl have observed similar transitory effects after intravenous injection of other derivatives, and Pohl's explanation, which ascribes the effect to paralysis of the respiratory centres, was shown to be the true one for protocatechyltropeine. The relation between chemical constitution and pharmacological action as exemplified in the tropeines was considered, and an attempt made to show that definite action could not with certainty be attributed to the two constituent groupings of the tropeines.—The toot poison of New Zealand; an investigation into its pharmacological action: Prof. C. R. **Marshall.** This poison, which includes three definite species of Coriaria, has proved a serious hindrance to the rearing of stock in New Zealand. The active principle, isolated by Easterfield and Aston, is a glucoside named tutin. The effects produced are chiefly stimulation of the medullary centres and epileptiform convulsions, which are mainly of cortical and pontine origin. Pontine convulsions are very susceptible to anæsthetics. A fall of temperature always occurs after the administration of tutin. The substance also depresses the sentient centres, and in man causes loss of memory. Coriamyrtin and picrotoxin have a similar action, but are more powerful, and in some respects more transient in action, than tutin.—Hydrolysis of salts in amphoteric electrolytes: Miss H. H. **Beveridge.** The two principal methods in general use for determining the degree of hydrolysis of salts—catalysis of methyl acetate and electrical conductivity—give results in the case of salts of amphoteric electrolytes which are not at all concordant. The hydrolysis of anthranilic hydrochloride was therefore investigated by several independent methods. Of these, the solubility, distribution between two solvents, catalysis of diazo-acetic ester, and electromotive force all pointed to the catalysis values being correct, while values obtained from depression of the freezing point and electrical conductivity differed widely from these. The divergence was due, not to any abnormality in the degree of ionisation of the salt, nor to the speed of the ions, but might be explained by the assumption of some association of molecules and ions.—Seismic radiations, part ii.: Dr. C. G. **Knott.** Following up results regarding reflection and refraction of seismic disturbances given twenty years ago (see also *Phil. Mag.*, 1899), the author calculated the surface disturbances which accompany the reflection of the various types of elastic wave at the surface of an elastic solid. When the incident wave is condensational there is always a reflected distortional wave as well as a reflected condensational wave, and a simple harmonic disturbance produces at the surface a simple harmonic disturbance along a line differing at most incidences by a few degrees from the direction of the incident disturbance. When, however, the incident wave is distortional there is, after a certain critical angle, no reflected condensational wave. For incidences greater than this critical value the original simple harmonic motion of the incident wave is not, in general, accompanied by a simple harmonic motion of each particle of the surface, but each point of the surface is thrown into elliptic motion of all degrees of ellipticity from circle to straight line. Details were worked out for certain assumed values of the elastic constants. The results indicate how misleading in certain cases is the phrase "emergence angle," much used by seismologists.

PARIS.

Academy of Sciences, June 28.—M. Émile Picard in the chair.—Integral equations of the first species: Émile **Picard.**—The gases of volcanic fumaroles: Armand **Gautier.** The gas samples were collected under experimental conditions designed to exclude the possibility of the admission of atmospheric oxygen, and to preserve gases alterable by water, such as carbon oxysulphide. Gas taken from fumaroles at Vesuvius near the top of the cone was found to consist of hydrochloric acid, carbon dioxide, hydrogen, oxygen, and nitrogen. No sulphur compounds could be detected, and carbon monoxide, oxides of nitrogen, hydrocarbons, and fluorides were absent. Gases collected from fumaroles on Vesuvius eighteen months after an eruption showed hydrochloric acid to be absent, and 0·5 to 2·0 of carbon monoxide present. It was noted that, although no halogen acids could be detected, the gases leaving the fumaroles rapidly attacked steel and copper.—Ordinary carbon: H. **Le Chatelier** and M. **Wologdine.** By modifying the graphitic oxide reaction, graphite has been proved to be present in carbon from acetylene and in other varieties of carbon produced at moderately low temperatures, hitherto assumed to be free from graphite. Carefully purified amorphous carbon from various sources has a density of about 1·8.—The existence of trachytes with quartz (bostonites) in the Mont-Dore *massif*: A. Michel **Levy** and A. **Lacroix.**—The polished stonework in the Haut-Oubanghi: A. **Lacroix.** The ornaments are made of worked and polished quartz; the process of manufacture is described in detail, and shown to be strikingly analogous with similar work in Neolithic deposits.—The origin and evolution of fresh-water shrimps of the family of Atyidæ: E. L. **Bouvier.**—The hydration of potassium carbonate: M. **de Forcrand.** A thermochemical paper.—The action of metallic oxides on methyl alcohol: Paul **Sabatier** and A. **Mailhe.** Alumina, at temperatures about 300° C., furnishes a large yield of methyl oxide; thoria and titanium dioxide at 350° behave similarly; oxides of chromium and tungsten give a mixture of methyl oxide and formaldehyde, the latter being partially split up into carbon monoxide and hydrogen. Other oxides give the latter reaction exclusively.—Observations of the comet 1909*a*, made at the Observatory of Lyons with the bent equatorial of 32 cm. aperture: J. **Guillaume.**—The variations of brightness of Encke's comet and the sun-spot period: J. **Bosler.** The graphical comparison of the variations in brightness of Encke's comet and the number of sun-spots shows that the two phenomena are clearly related.—Comparison of the spectra of the centre and the edge of the sun: H. **Buisson** and Ch. **Fabry.**—The physical and historical interpretation of some markings on the moon's surface; from the eleventh part of the photographic atlas published by the Observatory of Paris: P. **Puiseux.**—An extension of the theory of continued fractions: A. **Chatelet.**—The calculation of the roots of numerical equations: R. **de Montessus.**—Remarks on a note by M. Petit on a new wave detector for wireless telegraphy and telephony: E. **Tissot.** It is suggested that the arrangement of a fine metallic point resting on a crystal of natural pyrites is really one of the thermoelectric detectors.—Comparison between the α rays produced by different radio-active substances: Mlle. **Blanquies.**—The temperature of the oxyhydrogen flame: Edmond **Bauer.** This was found to be 2240° C.—The "initial re-combination" of the ions produced in gases by α particles: M. **Moulin.**—The magnetic transformation of lead: M. **Loutchinsky.** The coefficient of magnetisation is ten times greater in lead crystallised by fusion than in lead hammered out or drawn into wire.—The practical method for the simultaneous calculation of atomic weights: G. D. **Hinrichs.**—The bromide of dimercurammonium, NHg_2Br: H. **Gaudechon.**—The formation of oxygen compounds of nitrogen and their metallic combinations (iron and lead) in the production of ozone for the sterilisation of water: Ed. **Bonjean.** The amount of oxides of nitrogen produced in commercial forms of ozonisers is sufficient seriously to attack lead and iron pipes used in the construction. This has not been considered in the design of sterilisation apparatus on the commercial scale.—The separation of graphite in white cast iron heated under pressure: Georges **Charpy.** Carbon arising from the decomposition of iron carbide produced at temperatures between 700° C. and 1100° C., and under pressures rising to 15,000 atmospheres, separates in the form of graphite.—Contribution to the study of uranyl chloride: Œchsner **de Coninck.**—A new alkaloid extracted from the bark of *Pseudocinchona africana*: Ernest **Fourneau.** The crystallised alkaloid studied has the composition of quebrachine ($C_{21}H_{26}N_2O_3$), and resembles this alkaloid in many of its properties. They differ in rotatory power, quebrachine being dextrorotatory and the new base lævorotatory.—The formation of lactones from acid alcohols: E. E. **Blaise** and A. **Kœhler.** An ϵ-octolactone can be prepared from the acid $C_2H_5.CH(OH).(CH_2)_4.CO_2H$ by slow distillation in a vacuum, but the ζ-lactone could not be prepared from the next higher homologue in the same way. If the dehydration is attempted by heating with 50 per cent. sulphuric acid, a migration of the hydroxyl group takes place, a γ-lactone being formed in both instances.—Soluble starch: Ch. **Tanret.**—The action of hydrogen peroxide upon crystallised oxyhæmoglobin: J. **Szreter.**—The cholalic acids: Maurice **Piettre.**—Regeneration in species of Syllis: Aug. **Michel.**—The mechanism of the immunity of snakes against the salamandrine: Mme. Marie **Phisalix.**—Concerning a note of M. Devaux entitled "The Relation between Sleep and the Retention of Interstitial Water": Raphael **Dubois.** The author points out that this note confirms his results on the phenomena accompanying sleep in hibernating animals.—The metamorphosis of the splanchnic muscles in the Muscideæ: Charles **Pérez.**—The ratio of the weight of the liver to the weight of the body in birds: J. **de La Riboisière.**—The glacial origin of Loch Lomond and Loch Tay: Gabriel **Eisenmenger.**—The hydrology of the *Bracas* (Basse-Pyrénées) and of El-Torcal (Andalousie): E. A. **Martel.**—The earthquake at Corinth on May 30, 1909: D. **Eginitis.**

NEW SOUTH WALES.

Linnean Society, May 26.—Mr. C. Hedley, president, in the chair.—Metasomatic processes in a cassiterite vein from New England: L. A. **Cotton.** The vein examined lies some six miles south-west of Inverell. A transverse section, about 11 inches in width, was taken and cut into six pieces, in planes parallel to the plane of the vein. Sections were then cut, and a series of four analyses made. Of the latter, three were of the vein, while the fourth was of the country rock, an acid granite. Examination of the slides showed that the central part of the vein was highly siliceous. The remaining slides of the vein-material showed an abundance of a peculiar pale mica of a paragonite-sericite nature. This mica was found to replace the quartz, felspar, and biotite of the acid granite. Fluorite was also found as a secondary mineral, and it is possible that a small amount of topaz was present.—Note on the Guyra Lagoon, N.S.W.: L. A. **Cotton.** The Guyra Lagoon lies immediately to the west of the town of Guyra. It is surrounded by low basalt hills, except for a depression in these to the south-east. The lagoon, which, before 1902, had held water so far back as the oldest settlers in the district could remember, is now dry. There has been no diminution in the rainfall to account for this. It is thought that the changing of the limited catchment area from pastoral to agricultural country may account for the present dryness of the lagoon. Field observations seem to indicate that the depression is a crater-lake.—Note on diurnal variations in the temperature of camels: Dr. J. B. **Cleland.** During the examination of a certain number out of 500 camels in the north-west of Western Australia, a wide diurnal variation in their temperatures, sometimes of 7° F., was met with. This would seem to be due to the high temperature of the atmosphere during the day, coupled with the fact that camels only visibly perspire at the back of the neck over a small area, and the coolness of the nights. The wide diurnal range suggests a resemblance to cold-blooded animals.—Some rare Australian Gomphinæ (Neuroptera: Odonata), with descriptions of new species: R. J. **Tillyard.** The present paper brings up to date our knowledge of Australian Gomphinæ. Five new species are added to the list, and the male of *Austrogomphus risi*, Martin, of which only the female was known, is described.—Studies in the life-histories of Australian Odonata; i., life-history of *Petalura gigantea*, Leach: R. J. **Tillyard.** The species is one of the few remaining forms of a very ancient family.

THURSDAY, JULY 15, 1909.

REGENERATION.

Experimental-Zoologie. Part ii., Regeneration: Eine Zusammenfassung der durch Versuche ermittelten Gesetzmässigkeiten tierischer Wieder-erzeugung. By Dr. Hans Przibram. Pp. viii+338; 16 plates. (Leipzig and Vienna: Franz Deuticke, 1909.) Price 14 marks.

THE second part of Dr. Hans Przibram's "Experimental Zoology" has so far only been published in German, but it is to be hoped that an English translation will follow in due course. It will be a matter for regret if the efforts of the Cambridge University Press to provide English-speaking biologists with standard editions of works which are otherwise accessible only in a foreign language do not receive sufficient support to justify their continuance. The present volume, which is very considerably larger than the first (reviewed in NATURE, March 4, p. 2), deals with the secondary aftergrowth of lost parts, embracing the phenomena of morphallaxis and deformation. The allied subject of grafting, which finds a place in Prof. Morgan's work on "Regeneration," published eight years ago, is not systematically dealt with, but it may well be that this is reserved for special treatment in the final volume on function. The subject-matter of the part now under notice is divided into eight chapters, dealing successively with the different groups of the animal kingdom, from the Protozoa to the Vertebrata. To these is added a general summary, containing an account of the general laws which govern the regenerative processes and their development in phylogeny. There are sixteen coloured plates, which are bound at the end of the volume, but these are so overcrowded with figures as to tend towards confusion, and the execution is not good. The work is adapted for purposes of reference rather than for continuous reading, and is furnished with an extensive bibliography, in which few omissions are to be detected.

In dealing with the power of compensatory hypertrophy possessed by the generative glands, the author alludes to the fact that although unilateral castration is said to promote an increased growth on the part of the remaining testis, the number of spermatozoa found in the semen is very appreciably diminished, at least according to Lohde's observations. These statements, however, are not necessarily conflicting, since Ancel and Bouin and others have shown that in all probability the interstitial cells of the organs, and not the spermatogenetic tissue, are responsible for the normal testicular influence which is exerted upon the secondary sexual characters and the organism as a whole; and so it may perhaps be, in general, that it is the interstitial rather than the seminiferous portion of the testis which undergoes hypertrophy after one-sided castration. Moreover, the time which Lohde allowed to elapse after extirpating the single testis was probably too short to admit of definite conclusions being drawn regarding the power of compensation possessed by the remaining testis. Dr. Przibram notes the occurrence of thyroid regeneration following the partial removal of that organ, but he omits to state that in certain cases the parathyroids are capable of regenerating tissue containing colloid substance, and so resembling, if not identical with, normal thyroid tissue. Neither does he mention that in rabbits and other animals which can survive thyroidectomy the function of the thyroid appears to be taken over by the pituitary, in which the cells of the *pars intermedia* show an increased activity, as manifested especially by a greater secretion of colloid. Both these processes are probably to be regarded as instances of functional restitution in allied organs of the body.

The regeneration of the uterine mucosa after parturition and menstruation is alluded to, but there is no reference to Heape's papers, which deal more fully than any others with the nature of the post-menstrual recuperative processes. Futhermore, there are certain omissions in the literature dealing with teratological science. Nevertheless, the work, as it stands, contains by far the most comprehensive account of the subject of regeneration that has as yet been written, and, as such, it constitutes an important addition to the literature of experimental zoology.

FRANCIS H. A. MARSHALL.

A NATURALIST IN TASMANIA.

A Naturalist in Tasmania. By G. Smith. Pp. 151. (Oxford: Clarendon Press, 1909.) Price 7*s.* 6*d.* net.

TASMANIA is the smallest of the Australian States, and its scientific interest is out of all proportion to its size, while its magnificent scenery, picturesque lakes, rugged mountains, noble forests, and its combination of vegetation of tropical luxuriance with a temperate summer climate will always make it one of the most attractive of Australian tourist resorts. The State has still a small and scattered population; internal communication and railway construction are exceptionally difficult, so, though it was the second in date of Australian colonies, much of the island is still very imperfectly known.

Mr. Geoffrey Smith, of New College, Oxford, made an expedition to Tasmania in 1907–8, aided by a British Association grant, in order to investigate the primitive shrimps inhabiting its lakes. The short volume gives a charmingly written narrative of his journey, and it is illustrated by some of Beattie's beautiful photographs and excellent drawings of some Tasmanian animals, such as that of the Tasmanian Devil (Sarcophilus), by Mr. Goodchild. It is accompanied by a geological sketch-map based on Johnston's.

Mr. Geoffrey Smith is enthusiastic over the beauty of Tasmanian scenery. He deals especially with the districts near Hobart and around the Great Lake on the Central Plateau. He gives a short note on the aborigines, with illustrations both of their heads and skulls. On the vexed question as to the relation of the Tasmanians, he is emphatic (p. 28) that—

"Whether the Tasmanian race ever inhabited the mainland of Australia or not, it is certain that neither in their physical characters nor in their culture have they anything to do with the Australian blacks, whose

 D

relationship lies rather with the Veddahs of Ceylon and the other straight-haired Proto-Dravidian races that still exist sparsely in India and the Malay Islands."

He says we have a good deal of information as to their burial customs, which differ totally from those of the Australians, and their language "seems to have differed entirely from the Australian and to show remote connection with the Andamanese" (p. 31).

His last chapter discusses the biological relations of Australia and Tasmania, and the evidence for the connection of Australasia with Antarctica. He is convinced that the fauna and flora of Australia entered it from the south and not from Asia. As he truly remarks, the marsupials are most numerous and of the most primitive types in southern Australia, while they are comparatively rare and most specialised in northern Australia. If they had migrated from Asia the opposite arrangement would have been expected.

The author still accepts Galaxias as evidence of the recent connection of Australasia and South America; he admits that it visits estuaries, but considers that it can only have spread across the southern Pacific along the shelf around the Antarctic land. After Mr. Boulenger's letter (NATURE, 1902, vol. lxvii., p. 84), with its convincing evidence that Galaxias breeds in the sea, the distribution of that fish is no indication of a former land connection. One slip, in fact, is the statement that the tree Senecios are unknown in the tropics (p. 133). They are the largest trees in the alpine zone of Kenya and other east African mountains. The author represents Tasmania as not a biological appanage of Australia, as he holds that it acquired its present distinctive characters before its separation from the mainland. Although this view is probable, the striking differences which the author well describes between the faunas of the two areas indicate that the separation happened long enough ago for many of the Tasmanian mammals to have developed into new species. The most striking part of the book is Mr. Smith's valuable contributions to knowledge of the primitive Tasmanian fresh-water shrimps, of which he discovered a new genus. They are allied to those of the European Carboniferous Crustacea, and are one of the groups of archaic animals still living in Australasia.

PROPERTIES OF BUILDING MATERIALS.

Introduction to the Chemistry and Physics of Building Materials. By Alan E. Munby. Pp. xx+345. (London: A. Constable and Co., Ltd., 1908.) Price 6s. net.

UNLIKE many books intended chiefly as short cuts to success in examination, this work seeks to impart in a clear, concise, and accurate manner the scientific principles underlying the proper use of material in construction.

Part i. contains chapters devoted to natural laws, measurement, the air, heat, chemical principles, water, acids and bases, coal, and a useful outline of geology. In part ii. all the chief building materials are dealt with in detail. The origin and occurrence of each material are described, also the preparation for use, varieties met with, impurities and adulterants, defects, and tests for quality, including both laboratory tests and simple practical tests such as may be applied by the workman. In every case the author is careful to point out the application of correct scientific principles, and from his practical knowledge is able to suggest many useful tests not generally known.

The work is thoroughly up to date, from both a scientific and a practical point of view, and the latest results of investigation into such matters as the setting action of cement, the rusting of iron, and the micrography of metals are clearly and broadly stated in their bearings upon the practical use of material.

This book will prove of great value to students intending to take up architecture as a profession. The builder, also, and the practical man will be glad to take advantage of much of the information given. In fact, many teachers in the architectural and building departments of technical colleges will be glad to know of the book with the view of recommending it to their students.

This being the first edition, it is hardly to be expected that the book is entirely free from defects. The diagrammatic illustrations given seem to be the least satisfactory part of the work. While the work has been written so lucidly as to render numerous figures unnecessary, it would seem that more than nine illustrations might be legitimately employed to assist the reader in grasping the subject. There is room for some improvement, too, in the chapter on timber, several inaccuracies having escaped correction, *e.g.* on p. 295, what is described as decay due to worms should rather be ascribed to the larvæ of certain beetles, &c. Also, on p. 296, the Teredo, although popularly regarded as a worm, should really be classed with the mollusca. In dealing with dry rot on p. 294, the temperature conditions are not referred to, although these play an important part in the development of the fungus.

A few statements in other parts of the book seem to call for reconsideration or correction, *e.g.* p. 20, § 3:—"If two vessels containing the same liquid be connected, the level in each will become the same *whatever*[1] the form or distance of the connecting pipe." Again, the statement, p. 277, "Shearing and torsional stresses are identical, apart from the method of applying the force producing them," although true, needs explanation to the mind not trained in mechanics.

The explanation given on p. 323 as to the optical theory of the production of a green pigment from yellow and blue powders, will hardly explain fully how it happens that the same blue powder, mixed with a red one, will produce purple. Turning to the useful table on p. 63, the tyro may be puzzled again to know why, if the substance denoted by CaO_2H_2 is termed calcium *hydroxide*, the substance PbO_2H_2 is termed lead *hydrate*; or, if CO_2 is called carbon *dioxide*, why SiO_2 is called silicon *oxide*. On p. 18 the author correctly says, "To move a heliostat reflecting a beam of light requires no more effort than would be necessary in the dark," but the heliostat being

[1] Italics not author's.

unknown to most students of building materials, it might be advisable to substitute the more familiar "mirror."

However, in spite of a few minor points like these, the book as a whole is well written, and admirably adapted to the class for whom it is intended. It deserves to take a permanent place among the text-books upon the subject, and in future editions the points referred to will no doubt receive attention.

H. B.

ECONOMIC BACTERIOLOGY.

Bacteria in Relation to Country Life. By Dr. Jacob G. Lipmann. Pp. xx+486. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1908.) Price 6s. 6d. net.

WRITTEN in non-technical language, this book gives a good account of the activities of micro-organisms. It may therefore be recommended to all those who desire to obtain a general knowledge of the functions of bacteria and the important *rôle* they play in relation to daily life, while the intelligent agriculturist will find a large amount of information which should aid him in his work. After a brief survey of the form, structure, food requirements, and conditions of growth of bacteria, successive chapters deal with these organisms as met with in air, water, and sewage. The relation of water to health and disease is discussed, and the chief factors in connection with the contamination and purification of water are detailed. A readable account is given of the disposal of sewage and of bacterial systems of sewage disposal. Next follow the most important sections of the book, viz. the relation of bacteria to soil fertility and the influence of manures. We here find accounts of the sources of nitrogen in the soil, of nitrification and denitrification, of the action of leguminous crops in fixing nitrogen, and of soil inoculation with pure cultures of nitrogen-fixing organisms. The proper methods of storing farmyard manure are dealt with at some length, and it is shown that under different conditions of storage the losses of organic matter from the manure stack in three or four months may range from 15 to 20 per cent. to 40 to 50 per cent. of the initial quantity, and valuable suggestions are made on the best means of conservation of manurial constituents, both by proper methods of storage and by the use of chemical fixatives.

The chapters which follow on milk, its production and preservation, are also excellent. Details are given which show that *careful* hand-milking yields a better milk as regards bacterial contamination than any milking machine, unless *extreme* precautions are taken in the sterilisation of the latter. The subject of pasteurisation of milk is also critically discussed, and the following extract sums up the author's views on the advantages and disadvantages of the process, views with which we fully agree and which should be widely known:—

"Pasteurisation is effective for the destruction of disease bacteria in milk and for the improvement of its keeping quality. It is agreed that city children fed on pasteurised milk, properly heated and properly cooled, are less subject to intestinal disturbances than children fed on raw milk. At the same time, it must be admitted that the pasteurisation of milk already filled with bacteria, and the products of their aictivities, will not remedy its defects. The undesirable substances formed by the bacteria are not entirely destroyed by the heating, and may still cause injury to the person consuming the milk.

"By resorting to pasteurisation, a dealer may be able to dispose of milk that would otherwise quickly become unsaleable. Similarly, the failure to cool the pasteurised milk quickly and to keep it at a temperature of 50°, or below that, may lead to the rapid multiplication in the milk of germs producing injurious or poisonous substances. Hence, pasteurised milk should be consumed within twelve hours, or should be immediately cooled down to between 45° and 50°."

The subject of tuberculosis in relation to milk is fully discussed. It is pointed out that large numbers of tubercle bacilli may pass into the excreta of tuberculous cows, a fact which was fully confirmed by the experiments of our Royal Commission on Tuberculosis as contained in the last report, and it is concluded that

"Whatever difference of opinion there may prevail as to the extent of human tuberculosis caused by the consumption of milk and milk products, it is conceded by sanitarians that persistent efforts should be made to eradicate bovine tuberculosis."

Subsequent chapters deal with milk beverages, butter and cheese, canning, ensilage and fermented liquors.

The book is adequately illustrated and clearly printed.

R. T. HEWLETT.

FORESTRY.

(1) *Our Forests and Woodlands.* By Dr. J. Nisbet. New and revised edition. Pp. xxiii+348. (London: J. M. Dent and Co., 1909.) Price 3s. 6d. net.

(2) *Trees: A Handbook of Forest-Botany for the Woodlands and the Laboratory.* By the late H. Marshall Ward. Vol. v., Form and Habit. Pp. xi+308. (Cambridge: University Press, 1909.) Price 4s. 6d. net.

(1) THE first edition of Dr. Nisbet's well-known book, "Our Forests and Woodlands," appeared in 1902. The second edition has now been issued, and will doubtless be welcomed by a large circle of readers, not only on account of the interesting and important information it contains, but the price is such as to bring it within the reach of many who cannot afford the more expensive, though excellent, works on forestry at present available to the English reader. A very important, and probably the most outstanding feature of the new edition is the preface, in which the author has given a *résumé* of the progress which has been made in forestry since the appearance of the first edition. The doings of the various Governmental committees and commissions which have sat of late years are clearly set forth. There is also given a very striking table in the form of an abstract from the "Annual Statement of the Timber Trade of the United Kingdom" for 1906 and 1907. Here it is shown that the gross total imports of wood and timber, wood-pulp, and manufactured wood-pulp come to about 37,500,000*l*. To supply these

present demands, leaving out of consideration the increasing consumption, which will no doubt continue, the author points out that it would require 3,000,000 acres of conifer and other woodlands, or an annual cut of 50,000 acres of timber worked on a sixty years' rotation. Contrary to opinions held in other quarters, Dr. Nisbet anticipates the decrease in the supply, to this country at least, of pitwood. At present large supplies come from Bordeaux, but signs are not lacking that the quantity of suitable timber is decreasing, while the French collieries themselves show increasing demands. It would be a serious blow to all our industries dependent on coal should the supply of pitwood fail, and in any case the price is likely to increase, which will, other things remaining the same, raise the price of coal.

Another very important question to which the author directs attention is the wood-pulp industry. At the present time the United States dominate the paper market of the world, but there is an increasing shortage of suitable timber for the making of paper-pulp, which is, therefore, naturally increasing in price, and the recent large rise in the price of paper is due to the growing shortage in the supply of spruce. Since 1904, the cost of mechanical wood-pulp in this country has increased from 85*s.* a ton to 120*s.*, while in America during the past ten years the price has increased threefold. The demand for pitwood and wood-pulp is bound to continue; in other words, there is a sure market for such produce, and the author, who is a widely recognised authority on such matters, points out that our waste lands and poor pastures are to a very large extent capable of producing conifers and soft-wood crops which could be established at comparatively little cost, and would yield good returns to the owner, and at the same time supply pit-wood for our mining industries and therefore indirectly benefit all industries dependent upon coal; and, lastly, with a sufficient supply of raw material for the making of paper-pulp a new industry would be created in this country.

There are altogether eleven chapters in the book, with an index at the end. Some very fine illustrations are also included. The first two chapters are mainly taken up with historical matters, which provide extremely interesting reading. The next two chapters deal with the sylvicultural characteristics of the oak and beech. In chapter v. the remaining hardwoods are considered, while the soft woods, such as alder, birch, lime, and poplars, are dealt with in chapter vi. Coniferous plantations of pines, firs, and larch are treated in chapter vii. Chapter viii. is more arboricultural, as it deals with hedges and hedgerow trees. Chapter ix. is occupied with the consideration of high-woods, copses, and coppicewoods, while the last two chapters, viz. x. and xi., are devoted to woodlands, game and sport, and the improvement of British forestry respectively.

The book is full of sound and trustworthy information. Its price is moderate, and it deserves a hearty reception from all those interested, directly or indirectly, in our forests and woodlands.

(2) This volume dealing with the form of trees is the final one of its series. The volume, like the previous one, has been seen through the press by Dr. Groom, who informs us in the preface that he has reduced changes from the original to a minimum. The few alterations and additions which were found necessary have been indicated by enclosure within square brackets. Part i. deals in a general way with the habit or form of trees, and, in addition to the text, the form or habit of the tree is indicated in many instances by illustrations, while the form of the branch-system is also indicated diagrammatically. A series of Mr. Henry Irving's well-known photographs illustrating the outward appearance of the bark has been included.

In part ii. the trees are detailed according to their form and other external appearances. The system of tabulation adopted is similar to that employed in the previous volumes. At the end we have an appendix which contains a classification of trees and shrubs according to their seedlings, and here we have many excellent drawings by Miss E. Dale from actual seedlings, the scale of magnification or reduction being indicated in each case. No doubt this appendix, as Dr. Groom points out, is not so complete as the author evidently intended to make it, yet it is, including the drawings, valuable so far as it goes, and is well worthy of careful study.

Taking the whole work as it now stands, we have five volumes which deal respectively with buds, leaves, flowers, fruits, and form, and it will be admitted on all hands that the late Prof. Marshall Ward has left behind a monumental work which will long be considered a standard on trees.

NEW BOOKS ON ORGANIC CHEMISTRY.

(1) *Modern Organic Chemistry.* By Dr. C. A. Keane. Pp. xiv+503. (London: The Walter Scott Publishing Co., Ltd., 1909.) Price 6*s.*

(2) *Practical Organic Chemistry.* By Dr. J. J. Sudborough and T. C. James. Pp. xviii+378. (London: Blackie and Son, Ltd., 1909.) Price 5*s.* net.

(3) *The Elements of Organic Chemistry.* By E. I. Lewis. Pp. viii+224. (Cambridge: University Tutorial Press, Ltd., 1909.) Price 2*s.* 6*d.*

(4) *Abhandlung über die Glycole oder Zwei atomige Alkohole.* By Adolf Wurtz. Pp. 96. Ostwald's *Klassiker,* No. 170. (Leipzig: W. Engelmann, 1909.)

(1) To anyone possessing a sound elementary knowledge of organic chemistry we can strongly recommend Dr. Keane's book. It is not a text-book, for there is no systematic arrangement of the materials, and the properties of individual substances and the relations of different groups are not brought into relief. If, for example, the student wishes to learn something about ordinary phenol, he will find bits of scattered information in four different places. Systematic instruction is obviously not the object of the book. But although the treatment is unconventional, and frequent digressions are made into regions not usually embraced by organic text-books, this very fact rather enhances than detracts from the interest of the

volume. The subject is brought into touch with other branches of the science. Thus, under hydrocarbons, we read a little about thermochemistry; under aldehydes there is a reference to autoxidation; under acids there are a few words about steric hindrance; under ethereal salts (a rather antiquated term) a short account is given of mass action, and so forth. In addition to this there are separate chapters on laboratory methods, stereochemistry, the sugars, dynamic isomerism, heterocyclic compounds, and the physiological properties of organic compounds.

That the subjects are treated rather broadly than deeply seems no serious defect. They are sufficient for the general reader, who is provided with elaborate references if he desires to extend his knowledge. In conclusion, we would direct the author's attention to a few inaccuracies which have been noticed, and which might be modified or corrected in a future reprint. The two isomeric dimethylethylenes, which are stated to be known in only one form, have been prepared by J. Wislicenus (p. 310); the molecular weight of triphenylmethyl has been determined, and corresponds to the double formula (p. 423); Fischer and Slimmer were unsuccessful in effecting an asymmetric synthesis (p. 301); it is incorrect to state that propylene and hydrobromic acid give exclusively isopropyl bromide (p. 45).

We would also suggest the following:—Thiele's hypothesis requires amplification to be understood (p. 46); it is very questionable if the explosiveness of a compound depends upon its breaking up into stable molecules, for many silver salts share with silver oxalate this property, whereas a substance like platinic chloride does not explode; the statement that *ethyl* and *methyl* "cannot exist in the free state because they contain one of the carbon affinities unsaturated" (p. 27) is inconclusive, especially as triphenylmethyl is referred to later as possibly existing (pp. 36, 423); without some qualification it is misleading to say that Dumas's theory of types "was especially developed by Gerhardt," and "received the support of Williamson and Wurtz" (p. 17). In the first place, Williamson originated the idea of Gerhardt's types, which were simple inorganic compounds in which hydrogen could be replaced by radicals. They were intended to denote chemical behaviour and not relationships. Ether had no generic relationship to acetic anhydride, though they belonged to the same type. Dumas's types, on the other hand, were organic substances which were intended to show relationships produced by substitution rather than chemical behaviour.

(2) The "Practical Organic Chemistry" of Sudborough and James is rather a laboratory handbook or book of reference than a course of practical instruction. As stated in the preface, examples are given of different types of operations. These types are grouped together. Thus, there is a chapter on the preparation of hydrocarbons, one on alcohols, another on halogen compounds, acids, esters, nitro-compounds, sulphonic acids, and so forth. In addition, there is a preliminary chapter on organic analysis and molecular-weight determinations, and, at the end of the volume, a number of useful examples of analyses and the determination of physical constants such as are playing an increasingly important *rôle* in the study of structure. The descriptions are clear and full, and the photographic illustrations are masterpieces of their kind. Altogether the book is probably the most complete among those of home manufacture on the subject of practical organic chemistry that has yet appeared.

(3) This modest little volume, which is one of the University Tutorial Series, should form an excellent introduction to the study of organic chemistry, and if the process of practical instruction can be carried on concurrently with theoretical teaching, as the author does with his own class, nothing better could be desired. He takes a few of the commonest organic substances and uses them, as they can easily be used, to illustrate quite a large variety of chemical operations and products. If the substance of the book can be assimilated in the course of four school terms, as the author states, we think that both teacher and student should be satisfied with the result. May we suggest that the name of Würtz should be spelt without the diæresis and Senderens without an *a*?

(4) One turns from the intricacies of a modern treatise on organic chemistry to Wurtz's classical memoir on the glycols with the same sense of relief that one listens to the simple melody of an early composer after the confused sounds of a modern orchestral symphony. Short and simple though it is, it is difficult to overrate the far-reaching results of Wurtz's research. It was not merely the discovery of a new class of alcohols and organic oxides, or an extension of Williamson's water type. It afforded for the first time clear experimental evidence of the existence of what were then termed "polyatomic" radicals. To quote Wurtz's own words:—

"The main result, which, in my opinion, is derived from these synthetic experiments, is not the discovery of the new compound, glycol—there are enough new compounds in organic chemistry—it is not even the synthesis of glycerine nor the difficulties connected with its preparation which have been successfully overcome; but it is the manner of the formation of glycol and the antecedent reactions which made it possible; it is the conversion of the allyl compound by which the iodide passed into glycerine. All these experiments, which were directed to the same end, have shown that an organic group united to 2 atoms of chlorine or bromine can replace two atoms of silver, and are therefore equivalent to two atoms of hydrogen, and that an organic group united to three atoms of chlorine or bromine can replace three atoms of silver and is equivalent to three atoms of hydrogen."

The theory of polyatomic radicals, like ethylene and glyceryl, soon developed into that of the polyatomic elements or the theory of valency, upon which the whole fabric of modern organic chemistry rests. Wurtz himself held perfectly clear views on the different valency of the elements. In his address to the Chemical Society in London in 1862 on ethylene oxide, he points out that as ethylene oxide represents a diatomic radical united to oxygen, so many of the metals may be regarded as diatomic elements. The paper is well worth re-reading, and is not by any means the least interesting addition to the *Klassiker*.

J. B. C.

PHYSICS FOR THE LECTURE ROOM AND LABORATORY.

(1) *The Elements of Electricity and Magnetism. A Text-book for Colleges and Technical Schools.* By Prof. W. S. Franklin and Barry Macnutt. Pp. viii + 351. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1908.) Price 7*s*. net.

(2) *A Short University Course in Electricity, Sound and Light.* By Dr. Robert A. Millikan and J. Mills. Pp. v + 389. (Boston and London: Ginn and Co., n.d.) Price 8*s*. 6*d*.

(3) *Naturlehre für höhere Lehranstalten auf Schulerübungen gegrundet.* By Dr. Friedrich Danneman. Teil ii. Physik. Pp. vii + 204. (Hanover and Leipzig: Hahnsche Buchhandlung, 1908.) Price 3.50 marks.

(4) *The Elementary Theory of Direct Current Dynamo Electric Machinery.* By C. E. Ashford and E. W. E. Kempson. Pp. vii + 120. (Cambridge: University Press, 1908.) Price 3*s*. net.

(5) *Electrical Laboratory Course for Junior Students.* By R. D. Archibald and R. Rankin. Pp. vi + 95. (London: Blackie and Son, Ltd., 1908.) Price 1*s*. 6*d*. net.

(1) THE order in which the elements of electricity and magnetism are presented in the first volume under notice is:—(*a*) Electric current; (*b*) magnetism; (*c*) electrostatics; (*d*) electric waves. This order is one which does not make the exposition perfectly happy. Thus it does not seem natural when it is found necessary to refer provisionally to the measurement of currents by their magnetic effect (p. 7) prior to any statement as to how magnetic effects themselves are measured. Surely the natural order is to take magnetism before considering the electric current, even though it may be preferred to deal with both before considering the phenomena of electrostatics. The author passes naturally and easily to the exposition of the last-named phenomena, and as many prefer this order this portion may certainly be commended to them.

The author is convinced that "elementary science instruction must be made to touch upon the things of everyday life if it is to be effective." This sentence may be taken as the keynote to the entire book. Thus electric resistances are usually represented as electric lamps. Those who are accustomed to abstract thinking may smile at these concrete representations; but it must be remembered that this is only an elementary book, and it must be admitted that much of the difficulty which many junior students feel is connected with the unreality of the subject as it appears to them. We commend the book for endeavouring, in this and other ways, to make the subject more real than it usually is.

More attention is given than is customary in an elementary course to phenomena connected with recent discoveries, such as kathode rays, radio-activity, electric waves, &c. We conclude that in America a junior course is in some respects more advanced than with us. This remark applies most to the chapter on electric waves, and to the appendix on ship's magnetism. Both these portions are very well done, though we would have thought them fairly strong meat for those who are making a "first systematic study of the subject." However, whether a student takes them in completely in his first study or not, he will be very glad to find them here ready to hand when required.

(2) The second of the volumes under review "represents primarily an attempt to secure a satisfactory articulation of the laboratory and class-room phases of instruction in physics." Expressed otherwise, it consists of a description of laboratory work, each experiment being preceded by as much theory as is necessary to make a complete logical exposition of the subject under study. We think that this plan is an excellent one; and it has been very satisfactorily carried out. Of course, it will be understood that the theoretical part is not sufficient to replace a text-book dealing specially with the theory.

Although electrostatics is introduced in the first chapter, electric capacity is not defined until later, when it can be measured by means of a ballistic galvanometer. There may be something to be said for this, but we think that the course of experiments would be considerably improved and the student would get a more vivid idea of what capacity is if experiments were added on parallel plate condensers used along with a gold-leaf electroscope or an electrostatic voltmeter.

In sound, a series of experiments on diffraction is included. The experiments on light *begin* with diffraction, a fact which prepares us for the exclusive use of the wave-method in proving the general phenomena of reflection and refraction. The final chapter is on radio-activity, and contains some simple experiments on uranium and thorium salts. The book is altogether a most excellent manual.

(3) We find in our third volume a well-selected series of very elementary experiments in the whole round of physics suitable particularly for school use. Though the subject is dealt with satisfactorily as a rule, it is not beyond criticism. The diagram of the paths of rays in a microscope would be improved if the rays represented as passing through the eyepiece were the same as those transmitted through the objective. The experiment on the "velocity of electricity" would be best left out of such an elementary book; the statement that electricity travels with the velocity of light is, of course, absurd.

(4) We are in entire agreement with the authors of this book, that in the training of an electrical engineer there should be included a knowledge of the theory of the subject built up logically from first principles, each step being illustrated with the help of some piece of machinery or practical appliance of a general and simple rather than an elaborate or necessarily up-to-date type. The present volume is intended to be used only as a note-book accompanying a course of experimental lectures. The authors are to be congratulated on the excellence of their little manual. The diagrams in particular are very carefully designed.

(5) The last of this group of text-books covers an elementary first year's evening course and part of a

second year's course. The first method of proving the inverse square law for magnetic poles will not convince. However, putting aside an occasional criticism of this kind, we think that the book will well serve its purpose of replacing manuscript instruction sheets in a junior laboratory.

OUR BOOK SHELF.

Théorie des Corps déformables. By E. et F. Cosserat. Pp. vi+226. (Paris: A. Hermann et Fils, 1909.) Price 6 francs.

THE authors, who are well known by their writings on general elastic theory, here reprint in separate form an appendix contributed by them to M. Chwolson's "Traité de Physique." The kinematical and dynamical theories of the flexible line, the flexible surface, and the deformable three-dimensional medium are discussed in turn in great detail. The dynamical standpoint adopted is that of the principle of action, which forms, in the authors' opinion, the only satisfactory basis for the "deductive" exposition of the subject. In each case the most general form of the function representing the "action" is sought which is consistent with the necessary invariantive relations. This procedure is, of course, not altogether new, and an expert, turning over the pages, will recognise much that in one form or another is familiar to him. The treatment is necessarily somewhat abstract, and is mathematically very elaborate, Cartesian methods being followed throughout. To many readers the long train of general investigations, unrelieved by a single application, may prove deterrent; but the authors at all events claim that their procedure has never before been carried out so resolutely and completely, and may justly pride themselves on the mathematical elegance of their work. Apart from its other qualities, the treatise has a distinct value as a book of reference, and furnishes a whole arsenal of formulæ which may save trouble to future writers.

The book begins with a kind of philosophical introduction to which the authors attach great importance. This requires to be read in conjunction with a previous treatise, which has also appeared in the French edition of M. Chwolson's work. Those who adopt in its fullest extent the empirical view of mechanics will perhaps consider that too much weight is attached to discussions of this kind. The historical references are, however, interesting, and fairly complete. The authors are indeed exceptionally well read in the history of their subject, and admirably conscientious in their citation of authorities. In their preface they promise a subsequent treatment of the theories of heat and electricity from a similar standpoint.

Practical Physiological Chemistry. A Book designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and of Science. By Prof. Philip B. Hawk. Second edition, revised and enlarged. Pp. xvi+447. (London J. and A. Churchill, 1909.) Price 16*s*. net.

PROF. HAWK'S text-book falls into the front rank with the numerous additions and improvements which have been introduced into the new edition. It is not only a practical guide, and, as such, should be found in all physiological laboratories, but forms a very complete, readable, and up-to-date account of our present knowledge of the chemical side of physiology.

A special feature has been made of the illustrations, which are beautifully executed, and most of which will be new to workers in physiological chemistry. The crystalline forms of the many protein derivatives which the work of Emil Fischer and his colleagues has been instrumental in rendering familiar to the students of this branch of science will be found among them.

One small slip we notice in connection with the matter of protein nomenclature. The initiation of the new system of terminology which is now being adopted for the albuminous substances is wrongly attributed to the British Medical Association. It was really a committee of the Physiological and Chemical Societies of this country which set the ball rolling.

The mistake is, however, a pardonable one, seeing that it was at the meeting of the British Medical Association held at Toronto in 1906 that the opportunity of presenting the subject to our American colleagues was taken advantage of. The success that has attended this effort to secure uniformity of nomenclature amongst English-speaking people has been very gratifying; the American system, adopted under the auspices of the American Physiological Society and the American Society of Biological Chemists, differs in only small and unimportant details from our own. W. D. H.

Behind the Veil in Bird-land. Some Nature Secrets revealed by Pen and Camera. By Oliver G. Pike, with a number of pen sketches by E. R. Paton. Pp. 106. (London: The Religious Tract Society, 1908.) Price 10*s*. 6*d*. net.

SINCE the Keartons, some years ago, showed what splendid results could be achieved by an intelligent use of the camera as an aid to the study of natural history, a host of nature-photographers has arisen, but only a very few have attained the high standard of merit set by the founders of this branch of photography. Mr. R. B. Lodge and Miss E. L. Turner in this country, Schillings in Germany, and H. K. Job in America have in some respects even surpassed the Keartons; while in this display of resource and dogged persistence in the most trying circumstances they stand unrivalled.

Mr. Pike in this rather pretentious volume has given some very excellent photographs, but the "Nature Secrets revealed by Pen and Camera" which he promises in his title-page are conspicuous by their absence. His pages contain hardly one single new fact, but a great deal that is banal. He solemnly assures us, in writing of the kestrel, that "The first summer rose, a delicate pink amidst the surrounding green, is a greater picture of spring than ever the sunlit sea could be"—which statement contains a great deal of truth!—"and," he continues, "a kestrel hovering over a meadow, yellow with summer's flowers, tells us a deeper story than the eagle soaring over a wind-swept moor." We fail to grasp why this should be so.

"Bird-land's veil" is constantly being "lifted up" for him, like the drop-scene at the theatre, and on the stage appear blackbirds, which tell him "the story of the leaves and flowers," and wrens, which reveal "the secrets of the hedgerows," while skylarks, to complete the illusion, like the celebrated Grigolati troupe in the pantomime, fly to and fro across the stage, and sing "happy songs"! Perfectly charming! W. P. P.

An Account of the Deep-sea Asteroidea collected by the R.I.M.S.S. "Investigator." By Prof. René Koehler. Pp. 143; 13 plates. (Calcutta: Indian Museum, 1909.) Price 12 rupees.

THIS substantial contribution to the material of the echinoderm "system" consists of 126 pages of minute description, and nine pages of general remarks. It is a continuation of certain reports of a preliminary and incentive character published many years ago by the naturalists and pioneers of the Indian Marine Survey, but, except that some doubtful identifications are disposed of and some errors criticised, it does not incorporate that earlier work.

In the descriptive part of the memoir thirty-nine species are enumerated, of which thirty are regarded as new, and are exhaustively described. The general remarks refer to eighty-eight species—the thirty-nine species treated by the author, and forty-nine species dealt with in the earlier reports—and furnish the evidence of the author's main conclusions. These conclusions are that the deep-sea starfish of the Bay of Bengal and Arabian Sea are much more Phanerozonia than Cryptozonia, and that their geographical affinities, so far as they can be discerned at all, are exclusively Indo-Pacific, with a slight Hawaiian touch.

Of the new species described by Prof. Koehler, five are separated as types of new genera. These are Johannaster, which is placed with very justifiable hesitation among the Plutonasteridæ, for some of its characters suggest a pentagonasterid connection; Phidiaster, which seems scarcely distinct from Psilaster; Sidonaster, which agrees in all points with Porcellanaster, except that, as in other porcellanasterid genera, the elements of the cribriform organs are papillar instead of lamellar; and Circeaster and Lydiaster, both of which are Antheneids having the abactinal plates of the disk much smaller than those of the rays.

It may be thought that the limits of some at least of these genera are cut too fine to last; and of the descriptions of species it may almost be said that they are accurate expositions of specimens rather than impressive definitions of nature's products; but such is the way of systematic zoology nowadays.

The memoir is most bountifully and most beautifully illustrated by the author's own hand; the plates, which are thirteen in number, are quite above criticism.

Antimony: its History, Chemistry, Mineralogy, Geology, Metallurgy, Uses, Preparations, Analysis, Production, and Valuation; with complete Bibliographies for Students, Manufacturers, and Users of Antimony. By Chung Yu Wang. Pp. x+217; illustrated. (London: C. Griffin and Co., Ltd., 1909.) Price 12*s*. 6*d*. net.

Mr. Wang observes in his preface that a metallurgical work in English by a Chinese author is unusual. After reading the book, the conclusion is irresistible that English metallurgists would gain if Chinese authors were more numerous. Mr. Wang has treated his subject with the greatest respect, and has drawn up with methodical care a complete treatise which will be very useful to all students of the subject. The long and apparently exhaustive bibliography at the end of each chapter would alone give the book a right to a place on metallurgists' shelves, but in many cases the facts are sufficiently set forth in the present work.

The author carried out some practical tests of the latest volatilisation process of extracting antimony from its ores, which was patented last year by M. Herrenschmidt, and seems to have been much impressed by its merits. The account of these tests is, however, almost the only original matter in the book, which is mainly a compilation of previously published material, printed without comment. Its merits lie chiefly in the logical sequence and the accuracy of the extracts.

Étirage, Tréfilage, Dressage des Produits métallurgiques. By M. Georges Soliman. Pp. 164. (Paris: Gauthier-Villars and Masson et Cie., n.d.) Price 3 francs.

This interesting little work, one of the well-known "Aide-Mémoire" series, deals with its subject from a practical point of view. It is divided into five chapters, the first considering shortly the general mechanical properties of metals and alloys such as tensile, shock, bending, hardness, and torsion tests. Chapter ii. shows the influence of annealing and of cold work. Chapter iii. is devoted to "étirage," or drawing, defined as "an operation which has for its object the completing of work done by rolling and giving to the metal a cross-section which cannot be obtained by rolling," after the manner of wire-drawing ("tréfilage," chapter iv.), which is a special case of drawing where the cross-section is circular. Chapter v. gives a short account of methods of straightening ("dressage"). A. McW.

Nutrition and Evolution. By Hermann Reinheimer. Pp. xii+284. (London: John M. Watkins, 1909.) Price 6*s*. net.

This is an essay on the importance of nutrition as a factor in evolution, and the author is in good company. For was it not Claude Bernard who said, "l'évolution, c'est l'ensemble constant de ces alternatives de la nutrition; c'est la nutrition considerée dans sa réalité, embrassée d'un coup d'œil à travers le temps"? To have had this thesis worked out in a methodical manner would have been great gain, but the author is not strong in scientific method. He has gleaned far and wide to illustrate "the evolutionary aspects of nutrition," and while he has a crow to pick with most of his authorities, who have not the "central key of a uniform analysis," he uses them when they suit him to back up his conclusion "that in its silent effects nutrition is one of the most formidable factors in the shaping of individual and racial destinies." The conclusion is sound, but we cannot say this of many of the arguments.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Bessel's Functions.

I once stated that a good style of writing English is not a strong point amongst British mathematicians, and the justice of this remark is exemplified by Prof. Hill's letter on this subject (Nature, July 8), since it contains the phrases Meissel's tables, Smith's tables, Aldis' tables, Isherwood's tables, which are correct; and Bessel functions, British Association tables, which are wrong. It is not in general permissible in English to employ a proper noun as an adjective, for the rules of grammar require either the use of the genitive case, or the conversion of the noun into an adjective, as in the words Newtonian, Lagrangean.

The British Association is one of the most important societies in the British Empire; it long ago discarded the insularity of our ancestors, and has become cosmopolitan in its operations. It is therefore not too much to expect that it will conform to the rules of grammar in its publications, and employ its influence in encouraging a good literary style.

I do not understand what Prof. Hill means by Neumann's functions. I believe that Neumann was the first mathematician who studied the properties of zonal harmonics and allied functions of degree $n+\frac{1}{2}$, where n is zero or a positive integer; but the subject was afterwards taken up and greatly extended by Prof. W. M. Hicks in connection with circular vortex motion. Hicks calls these harmonics *toroidal functions*, which is a much better phrase, since it puts in evidence the fact that these functions are connected with the potentials of *anchor rings* or *tores*.

There is also another class of functions which are zonal harmonics of complex degree $m-\frac{1}{2}$. These have been studied by Hobson (*Trans. Camb. Phil. Soc.*, vol. xiv., p. 211), who calls them *conal harmonics*.

A. B. Basset.

Fledborough Hall, Holyport, Berks, July 9.

Musical Sands.

May I record the existence of musical sands along the shore at the Sandbanks, Poole Harbour?

Some years ago the Poole authorities erected a series of box groynes along this coast between Poole Head and the Haven, and these have considerably increased the natural accumulations of sand, so that it is "making" everywhere, and the growth of the marram grass on the dunes is in many places (independently of that recently planted) rapidly extending seawards.

The beach now, between each groyne, consists of wide and flat deposits of sand, shells, and flint pebbles, but about midway between the dunes and the sea, where the sand is comparatively free from these, musical zones are of frequent occurrence.

In walking along the shore in a westerly direction, starting from the first groyne, the sounding qualities of the sand notably increase. Thus between the first and second groynes there are no musical patches, between the second and third the sounds are very faint, and between each of the other groynes, until one reaches the last at the Haven Point, the intensity of the sound increases. In a small cove at the Point, formed by the last groyne (constructed of barrels of concrete and an old ship), the sand is remarkably musical.

The increase of sound observed when walking in a westerly direction is due, I think, to the fact that the prevailing westerly winds, and the littoral drift, separate the finer particles from the sand and carry them eastwards, and a microscopic examination of samples obtained from distances about a mile apart on this shore confirms this.

This musical sand is of the Studland Bay type, and near the Haven gives even better results than any I have found there. The occurrence of musical sands along this particular shore through the conserving influence of the groynes is an interesting fact, for their existence there previously was very unusual, being only once noted in very small quantity during the last twenty years.

Parkstone-on-Sea, July 4. CECIL CARUS-WILSON.

The Commutative Law of Addition, and Infinity.

Referring to the review of Hilbert's "Grundlagen der Geometrie," on p. 394 of No. 2066 of Nature (June 3), may I point out that the commutative law of addition can be proved without the help of any axioms at all, other than those of general logic? The method, indeed, used by Peano in 1889 ("Arithmetices Principia . . .," Turin, 1889, p. 4), which is only based on axioms of a general nature (such as the principle of mathematical induction), and not on such special laws as the distributive ones, appears in so far superior to Hilbert's; and, since all Peano's axioms were proved in Mr. Russell's "Principles of Mathematics" of 1903, Hilbert's proof seems quite superseded. Further, the difficulties arising out of Dedekind's proof of the existence of infinite systems can be avoided without the introduction of "metaphysical" arguments about time and consciousness (see Russell, *Hibbert Journal*, July, 1904, pp. 809–12), as, indeed, your reviewer seems to think possible. But the connection of the fact that the existence of an infinity of thoughts (which must be in time) with Hamilton's idea that algebra was interpretable especially in the time-manifold, just as geometry is in the space-manifold, is not obvious. PHILIP E. B. JOURDAIN.

The Manor House, Broadwindsor, Beaminster, Dorset, July 2.

Neither Dr. Hilbert nor the reviewer make any suggestion that the commutative law of addition is best proved as a deduction from the laws of multiplication. But the laws of multiplication are so often treated as deductions from those of addition that it is interesting to have a case of the converse procedure. The fact that both these operations and their laws have been treated independently and in a strictly logical manner by Dedekind, Peano, and others is, of course, perfectly well known to all who have paid any attention to this part of mathematics. Whether Dedekind's critics have really avoided metaphysical arguments without at the same time making metaphysical assumptions is a question on which a difference of opinion is permissible.

G. B. M.

THE THEORY OF CROOKES'S RADIOMETER.

I HAVE noticed that the theory of this instrument is usually shirked in elementary books, even the best of them confining themselves to an account, and not attempting an explanation.[1] Indeed, if it were necessary to follow Maxwell's and O. Reynolds's calculations, such restraint could easily be understood. In their mathematical work the authors named start from the case of ordinary gas in complete temperature equilibrium, and endeavour to determine the first effects of a small departure from that condition. So far as regards the internal condition of the gas, their efforts may be considered to be, in the main, successful, although (I believe) discrepancies are still outstanding. When they come to include the influence of solid bodies which communicate heat to the gas and the reaction of the gas upon the solids, the difficulties thicken. A critical examination of these memoirs, and a re-discussion of the whole question, would be a useful piece of work, and one that may be commended to our younger mathematical physicists.

Another way of approaching the problem is to select the case at the opposite extreme, regarding the gas as so attenuated as to lie entirely outside the field of the ordinary gaseous laws. Some suggestions tending in this direction are to be found in O. Reynolds's memoir, but the idea does not appear to have been consistently followed out. It is true that in making this supposition we may be transcending the conditions of experiment, but the object is to propose the problem in its simplest form, and thus to obtain an easy and unambiguous solution—such as may suffice for the purposes of elementary exposition, although the physicist will naturally wish to go further. We suppose, then, that the gas is so rare that the mutual encounters of the molecules in their passage from the vanes to the envelope, or from one part of the envelope to another part, may be neglected, and, further, that the vanes are so small that a molecule, after impact with a vane, will strike the envelope a large number of times before hitting the vane again.

Under ordinary conditions, if the vanes and the envelope be all at one temperature, the included gas will tend to assume the same temperature, and when equilibrium is attained the forces of bombardment on the front and back faces of a vane balance one another. If, as we suppose, the gas is very rare, the idea of temperature does not fully apply, but at any rate the gas tends to a definite condition which includes the balance of the forces of bombardment. If the temperature be raised throughout, the velocities of the molecules are increased, but the balance, of course, persists. The question we have to consider is what happens when one vane only, or, rather, one face of one vane, acquires a raised temperature.

The molecules arriving at the heated face have, at any rate in the first instance, the frequencies and the velocities appropriate to the original temperature. As the result of the collision, the velocities are increased. We cannot say that they are increased to the values appropriate to the raised temperature of the surface from which they rebound. To effect this fully would probably require numerous collisions. Any general increase in the velocity of rebound is sufficient to cause an unbalanced force tending to drive the heated surface back, as O. Reynolds first indicated. If we follow the course of the molecules after collision with the heated surface, we see that, in accordance with our suppositions, they will return by repeated collisions with the envelope to the original lower scale of velocities before there is any question of another collision with the heated face. On the whole, then,

[1] See for example Poynting and Thomson's "Heat," p. 150.

the heated face tends to retreat with a force proportional both to the density of the gas and to the area of the surface.

A calculation of the absolute value of the excess of pressure cannot be made without further hypothesis. If we were to suppose that the molecules, after collision with the heated face, rebound with the same velocities $(v+dv)$ as they would have were the temperature raised throughout, the pressure would be increased in the ratio $v+(v+dv):2v$ or $1+dv/2v:1$. On the other hand, if the temperature were actually raised throughout, the pressure, according to the usual gaseous laws, would be increased in the ratio $(v+dv)^2:v^2$ or $1+2dv/v:1$. On this hypothesis, therefore, the unbalanced increment of pressure on the heated face is one-quarter of the increment that would be caused by a general rise of temperature to the same amount. This estimate is necessarily in excess of the truth, but it is probably of the right order of magnitude.

The supposition upon which our reasoning has been based, viz. that the mean free path of a molecule is large in comparison with the linear dimension of the vessel, has been made for the sake of simplicity, and is certainly a very extreme one. It is not difficult to recognise that in the extreme form it may be dispensed with. All that is really necessary to justify our conclusions is that the mean free path should be very large in comparison with the *vane*. The magnitude and distribution of the velocities with which the molecules impinge will then be independent of the fact that the face of the vane is heated, and this is all that the argument requires. The repulsion by heat of a silk fibre suspended in a moderately rare gas was, it will be remembered, verified by O. Reynolds.

RAYLEIGH.

LIFE IN AN OASIS.[1]

ALTHOUGH the oases of the Libyan Desert have been frequently visited by travellers—Poncet in the seventeenth century, Browne in the eighteenth century, and Cailliaud, Drovetti, Edmonstone, Hoskins, Rohlfs, Zittel, Schweinfurth, Brugsch, and others in the nineteenth century—yet none of these authors enjoyed anything like the opportunities for the study of these remarkable districts which have fallen to the lot of the writer of the work before us. For nine years Mr. Beadnell, as a member of that active body the Egyptian Geological Survey, was engaged in the study of the Libyan Desert—including the four oases of Baharia, Farafra, Dakhla, and Kharga—while during the last three years, as director of the operations of a development company, he has resided in the last mentioned, and has carried out important observations and experiments in connection with the questions of water supply, the effects of moving masses of sand in increasing the fertility of some areas, while overwhelming and destroying others, as well as of many other problems of great historical and antiquarian interest.

Now that the opening of a railway from Qena, a little north of Luxor, to the village of Kharga has been completed, the long and tedious camel-journey of four or five days along very rough caravan routes is avoided, and excursions from the Nile valley to this typical oasis will doubtless become much more frequent. The appearance of the present work is, therefore, very opportune. The detailed topographical and geological survey of the Libyan Desert with its oases was undertaken in 1897–8. Mr. Beadnell carried out the mapping of the Farafra and Dakhla oases, while Dr. Ball was engaged in surveying that of Kharga, the work in the Baharia Oasis being shared between the two investigators. Dr. Ball's map of the Kharga Oasis, with the accompanying official report, is a work of great geological value and interest, and Mr. Beadnell's residence in the district has enabled him to add not a few important scientific details to the admirable sketch given by his colleague.

The whole Libyan Desert forms a plateau, having an elevation which, at its maximum, is but little less than 2000 feet above sea-level, yet with a fairly general slope towards the north. In this great expanse of rough limestone and flint-covered flats, with hillocks and troughs of drifting sand, the oases are deep depressions, the bottoms of which vary from 100 to 300 feet above sea-level, surrounded, for the most part, by steep escarpments, through which only a few passes can be found which are capable of being used as camel-tracks. The whole of the deserts are underlain by great beds of sandstone (the Nubian series), forming two divisions, the "surface-water sandstones," never more than 160 feet thick, separated by 250 feet of impervious grey shales, from a much thicker series of sandstones below, the "artesian-water sandstone," which has been penetrated by borings to the depth of 400 feet.

It is by the removal, through denudation, of great masses of Eocene and Upper Cretaceous limestones and shales that the "surface-water sandstones" have been exposed on the floors of the oases. These beds are the source of springs, and, since the districts have been occupied by human beings, a great part of the area of the Kharga Oasis was covered by shallow lakes, probably formed by the outflow from these springs. But these great lakes have been gradually dried up, and the constant drain on the limited supplies of water afforded by the "surface-water sandstones" has greatly reduced its importance as a means of irrigation. The accounts of the various deposits laid down in these old lakes, with their interesting contents of worked flint-flakes and pottery, are among the most novel and interesting portions of Mr. Beadnell's book.

Far more important, however, than the surface-water sandstones, as a source of irrigation water, are the "artesian-water sandstones," which, by means of borings, have been drawn upon from the earliest times, and constitute even now a practically inexhaustible means for promoting the cultivation of the oases. On all questions connected with the nature and amount of the yield of the different kinds of wells, the author of this book writes as an authority, and he is able to give the results of numerous ingenious experiments, carried on, in some instances, for many months. That the enormous quantities of water contained in the thick sandstones of the Nubian system have their source, in part in the highlands of Abyssinia, in part in the Sudan, and to some extent in the upper waters of the Nile, where it flows over these pervious sandstones, there can be little doubt, though as to the proportional parts played by these several factors of the supply there is still much room for doubt—a doubt which can only be removed by prolonged observations.

The manner in which the ancient wells have been made, kept open, and from time to time repaired, has engaged the author's attentive study. It is surprising to learn how much has been accomplished with the aid of very simple appliances; and the long subterranean aqueducts—tunnels driven for miles into the sandstones for the purpose of increasing the flow of water—with numerous manholes up to the surface,

[1] "An Egyptian Oasis: an Account of the Oasis of Kharga in the Libyan Desert, with special reference to its History, Physical Geography, and Water Supply." By H. J. Llewellyn Beadnell. Pp. x+248; with 28 plates and 4 maps and sections. (London: John Murray, 1909.) Price 10*s*. 6*d*. net.

are wonderful monuments of persevering toil. The introduction of modern boring machines and other labour-saving contrivances may probably do much towards increasing the productiveness of the land of these oases in the future. Very interesting information is given concerning the cultivation carried on in the Kharga Oasis, and its possible extension in the future. The chief crops at present are rice, date and doum palms, and lucerne, though grapes, oranges, and other fruits are produced to a small extent. Many of these fruits, with cotton and other useful vegetable products, may be largely supplied from these districts, now that communication has been improved by the construction of the railway. In spite of the traditions concerning the existence of deposits of gold, silver, and other metals in the oases, it is probable, considering the geological structure of the district, that it is never likely to yield mineral products of greater value than the ochre, alum, and epsom salts, which the ancients obtained in small quantities as the result of an altogether disproportionate expenditure of labour and pains.

The author, being evidently a keen sportsman, is able to give many interesting details concerning the feral life in these singular depressions of the desert. The wild mammals consist of the Dorcas gazelle, with three species of fox, and occasional striped hyænas and jackals; the birds, of sand-grouse, rock-pigeons, turtle-doves, and quail. But British sportsmen must be prepared to find, among the primitive inhabitants of these lands, competing sportsmen, as enthusiastic and probably more experienced and persevering than themselves.

Although it is to the questions of water supply, and the dependent problem of agricultural development, that we look mainly for information to this work, yet its author has not been unmindful of many other points of general interest concerning the population of 8000 to 9000 souls and its distribution. They belong to Berber tribes, quite distinct from the fellahin of the Nile Valley, but with admixture from various other sources, and the author has been able, during his sojourn among them, to learn much that is of interest about their habits and customs. Their personal characteristics, peculiarities of land- and water-tenure, their taxation and commercial methods are well described, and the features of their villages and farms are admirably illustrated. Their modes of combating their great enemy the drifting sands from the north, which tend to form ever-advancing sand-dunes, receive especial attention. Some of the results attending this constant sand-drift are illustrated in the figures taken from the work.

The Egyptian kings, certainly from as far back as the eighteenth dynasty (1545–1350 B.C.), have claimed dominion over these oases. When Egypt fell under Persian rule, Cambyses sent an ill-equipped expedition to conquer the oases, but the whole army of 50,000 men, probably through the treachery of guides, perished miserably in the desert. The Romans long held sway in the oases, and many of the most remarkable of the monuments of the district must be referred to the period of their rule. The work before us indicates the great numbers of objects of archæological interest which are found in the district, including many Græco-Roman temples and a wonderful early-Christian necropolis, as well as very early flint implements and pottery. We learn that Mr. Pierpont Morgan has already had explorations commenced for the enrichment of American museums, and the completion of the railway may not improbably lead to excursions to Kharga and its temples becoming as popular as the trips to the cataracts and temples of the Nile are now. The book before us, which is dedicated to the memory of an old colleague of the author, Mr. Thomas Barrow, who fell a victim to the climate during explorations in the Sudan, ought to help to make known the points of interest attaching to these wonderful depressions in the great Sahara.

JOHN W. JUDD.

Encroachment of Sand-dunes at Meheriq. From "An Egyptian Oasis."

THE ISLE OF WIGHT.[1]

NOWHERE else in this country can the geologist find, along a coast line of only sixty miles, so many varied and magnificent cliff sections of the Cretaceous and Tertiary formations, and in no British area of equal size—a hundred and sixty square miles—can the botanist collect so many species of flowering plants, as in the "Garden Isle," which has long been a happy hunting-ground for field naturalists. Its rich flora and fauna, conditioned largely by its diversified soil, has already been dealt with in various works, notably in Venables' "Guide to the Isle of Wight" (1860), and in the Hampshire section of the "Victoria County History" series.

This new "Guide" contains a large number of new records, and will at least form a good basis upon which resident and visiting naturalists may build a complete natural history of the district. There can be no question as to Mr. Morey's qualifications for the editorship of this volume, since he has worked at the fauna and flora of the island for forty years, and in producing the "Guide" has obtained the services of a capable band of systematists in the various branches dealt with. One cannot but admire his industry, versatility, and enthusiasm. He tells us, "when, nearly three years ago, I decided to bring out a work which should fairly illustrate the fauna and flora and the natural history generally of the Isle of Wight, I did so, almost literally, with fear and trembling, fully realising the difficult task that I was undertaking"; and he expresses himself content to have served as a "horrible example" if by doing so those who come after him are enabled to profit by his mistakes of omission and commission. Such modesty disarms criticism, and Mr. Morey's energy and enterprise deserve the warm thanks and congratulations of all who are interested in the natural history of the Isle of Wight.

As is the case with all compilations, the book is unequal in quality, but we feel bound to point out two defects which, though common enough in works of this kind, detract considerably from its value and interest.

A book which attempts to compress into a comparatively small space an enumeration of the entire fauna and flora of a rich district, with an account of its geology, to say nothing of articles on palæolithic implements, meteorology, and even earthquakes, must necessarily consist largely of a census catalogue of species. Lists of species are undeniably useful, and not to be despised when compiled carefully, but the ideal to be aimed at in a real natural history is surely something that shall go beyond, and in some respects be the antithesis of, a mere list. Beyond a few vague references to the bare fact that the distribution of species of flowering plants, mosses, &c., is affected by the characters of rocks and soils, we look in vain for any evidence of the scientific ecological spirit which animates such works as Baker's "North Yorkshire," Lees' "West Yorkshire," and Wheldon and Wilson's "West Lancashire," and has made them valuable contributions to the growing literature of plant ecology. The three books cited are, of course, limited

[1] "A Guide to the Natural History of the Isle of Wight." A Series of Contributions by Specialists, relating to the various branches of Natural History and kindred subjects. Edited by Frank Morey. Pp. xx+560. (Newport, I.W.: County Press; London: W. Wesley and Son, 1909.) Price 8s. 6*d*. net.

to the botany of each district, but a general sketch of the distribution of the flowering plants, at any rate, should have been given in this "Guide." The island would afford excellent scope for a botanical survey, on the lines of the well-known work done by Dr. Smith, Dr. Moss, and other ecologists, in various parts of Britain. It is greatly to be hoped that in a future edition of, or supplement to, this "Guide" it will be found possible to include a chapter on plant distribution, with a vegetation map of the island, and, for comparison and correlation, a geological map. This would, if carefully done, preferably by an ecologically-minded botanist residing in the district, undoubtedly enhance the value of the book and secure for it more than the local interest that attaches to a merely floristic work.

Photo.] [*H. F. Poole.*

FIG. 2.—White Stork—a rare visitor—captured at Shorwell in 1902. From "A Guide to the Natural History of the Isle of Wight."

The second suggestion we venture to make, with reference generally to books similar in scope to this "Guide," is that most of the systematists responsible for the various lists of plants and animals given in local naturalistic compilations would do well to obtain the cooperation of a biological botanist or zoologist when writing their prefatory remarks on the group of plants or animals they are dealing with. So far as this "Guide" is concerned, we refer chiefly, as examples, to the sections dealing with some of the cryptogamic plants. It would be far better for the average cryptogamic systematist to pass straight on to his list and say nothing whatever about the life-history and development of his group than to write a string of incoherent and inaccurate sentences, repeating and perpetuating long since exploded errors and mare's-nests. Lichenologists, we know, are a stiff-necked generation, but surely it is time they hesitated to record in print their refusal to recognise the dual nature of the lichen thallus, which has been fully and finally established. There can be no excuse, either, for the hepaticologist who tells us that the liverworts are "linked to the lichens" by means of their thalloid forms! The account of the relationship between the liverwort Frullania and the rotifer which sometimes occupies its pitchers is entirely imaginative. The list of hepatics (liverworts) is conspicuous by the omission of several species which are certainly found in the island, and often abundantly in places, such as *Anthoceros laevis*, *Scapania nemorosa*, and *Lepidozia reptans*.

The articles by Mr. G. W. Colenutt (geology), Mr. P. Wadham (fishes, mammals, &c.), and Mr. R. H. Fox (birds) stand out as refreshing oases in the arid desert of species lists, being written in a "nature-study" spirit which can hardly be said to characterise the work of the other contributors. The "Guide" is illustrated by twenty-six excellent plates, chiefly from photographs by Mr. H. F. Poole, two of which we are permitted to reproduce here. F. C.

SLEEPING SICKNESS.[1]

IT may be taken as definitely established that sleeping sickness is due to infection with a trypanosome (*Trypanosoma gambiense*), and that this trypanosome is conveyed by a tsetse-fly (*Glossina palpalis*). But if we proceed to analyse and extend this proposition we soon get into difficulties. We do not know for certain whether man is the only "reservoir" of this trypanosome, or whether monkeys and other mammals, especially native dogs, can also harbour it. Should this prove to be so—though the balance of evidence is against the supposition—it must materially affect prophylactic measures. If we consider next the mode by which the trypanosome is conveyed we find ourselves in the midst of the most conflicting evidence. It is still uncertain whether the transmission is mechanical or whether there is a cycle of development[2] of the trypanosome in the fly; facts appear to be all in favour of the first view, analogy all in favour of the latter. Nor is the question a purely academical one, for if the transmission is mechanical, then the flies are no longer infective after the infecting reservoir (man) is removed; if, however, there is a cycle of development, then it remains to be determined how long an infected fly can remain infective after the infecting source is removed.

If, again, we consider the question, Can sleeping sickness be conveyed by any other species of tsetse-fly than *Gl. palpalis?* we must confess our ignorance. The balance of evidence certainly seems to be against the possibility, but should it be shown that other species can convey the disease, then the question of prophylaxis would be even more difficult than it now is. These reports show that these are some of the questions that urgently need solution, but there are others of equal importance which arise in the immediate carrying out of prophylactic measures. They concern the fly itself, its habits, duration of its life, its breeding grounds, its food, its powers of flight, its likes and dislikes in regard to foliage, trees, shrubs, grass, &c. These questions are all important, and

[1] "Reports of the Sleeping Sickness Commission of the Royal Society." No. ix.

[2] The existence of such a cycle is now practically established by the recent work of Kleine confirmed by Bruce.

in our opinion it is imperative to appoint one or more officers with special entomological knowledge to study these points minutely. It is true that these reports afford evidence that the officers concerned in these investigations have made additions to our knowledge on these points, but the other duties of these officers are so multifarious that valuable time is being lost through this defect. It is true also that in the epidemic in Uganda the condition of things is so terrible that it is impossible to wait for the solution of all these questions, however important, before any action is taken, and we may now consider what, with the present available knowledge, is being done to check the epidemic. The means of prophylaxis may be considered under three aspects:—(1) Those directed against the fly; (2) those directed against the carrier of the trypanosome, *i.e.* man; (3) those directed against the trypanosome itself.

(1) With regard to measures directed against the fly. It has been found, and it is a matter of the highest importance, that the "natural range" of the fly, *i.e.* the distance to which flies follow from water in search of blood, is, as a rule, under 50 yards. The still more important fact has been determined that clearing and burning or removing the undergrowth for a distance of 100 yards in either direction, *e.g.* from a ferry for a strip 50–100 yards broad, has the effect of banishing the fly. It is this method, then, *i.e.* banishing the fly by clearing from its "normal fly range," that is the basis of the methods now being carried out in Uganda. It is not necessary to clear extensively around a village, but simply to clear comparatively small strips of the "fly range" frequented by man. Although flies may occur in the village itself, unless there is a "fly area" present these flies are those which have followed their victims beyond the "fly range" to the village. If the flies of the "fly range" are banished, then, *ipso facto*, the "following" flies also disappear. A typical fly area, though there are exceptions, consists of more or less open water with contiguous and especially overhanging shade and generally a fairly well-defined bank or shore. If, then, clearing can permanently banish the fly, and we believe that this will be found to be the case, because the fly still has plenty of uncleared area to frequent—though the fact that its human blood supply is at the same time removed may modify the result—it is an important measure of prophylaxis, though its value is perhaps restricted to somewhat small areas and special conditions.

If the fly cannot be removed by clearing, then the population must be deported from the vicinity of the fly. This measure has been extensively carried out in Uganda by the removal of populations from the lake to inland fly-free areas two miles away, to prevent traffic from the lake, which is responsible for the great bulk of the infection; but in many cases there are serious difficulties in the way. Further, the removal of populations still non-infected from a potentially dangerous fly area to a safe fly-free area would be of the greatest importance, and would form a more striking object-lesson to the native of the value of these measures than the removal of an infected population, because a certain, probably high, percentage of these latter will eventually die of sleeping sickness, although in a safe area; whereas this would not be the case if the population removed was non-infected.

(2) As the two measures, clearing and deportation, of the healthy, are undertaken with the object in view of preventing access of the fly to man, so segregation of the sick prevents fresh infection of the fly, and diminution of the infectivity of the fly in a fly area. This implies the removal of the sick of a village to another village or camp in a fly-free area, and it is important to note that such areas are numerous, and may often be only a few hundred yards away. Fresh infection of the fly is also avoided by preventing the removal of infected natives to uninfected fly areas. The applicability of this measure depends mainly upon the "attitude" of the native.

(3) Measures directed against the trypanosome itself, *i.e.* the treatment of infected persons, are bound up closely with the segregation of the sick. The treatment of the segregated in fly-free areas by atoxyl or other arsenic preparations is the only one that is at all effective, but it must be admitted that the results are disappointing, and that the good results of the drug are in many cases only temporary. The patient's blood becomes free from trypanosomes (and presumably non-infective, though this is not proved), and so the chance of infection of the fly, if patients come in contact with fly areas, becomes less.

Time will show how far these measures, the numerous important details of which we have to leave unconsidered, will be successful. Those engaged in carrying out these arduous and dangerous measures have hope that although sleeping sickness may not be eradicated or the fly totally annihilated, yet that the epidemic will soon be under control. It must be the sincere wish of everyone that this hope may be justified.

J. W. W. S.

THE CONTAMINATION OF MILK.

THE contamination of milk has been the subject of a detailed research by Dr. Orr, carried out on behalf of the councils of the county boroughs of Bradford, Hull, Leeds, Rotherham and Sheffield, and the administrative counties of the East and West Ridings of Yorkshire. Of previous investigations, Delépine concluded that though his results did not exclude the possibility of infection at the home of the consumer, or during transit from the farm, they did indicate that infection at the farm, or through vessels infected at the farm and used by the farmer for the storage and carriage of milk, was of paramount importance. On the other hand, Newsholme attaches little importance to infection at the cowshed. Dr. Orr's investigation was carried out in a systematic manner, and not only were the bacteriological examinations carefully performed, but, in addition, the condition of the cows and cowsheds and the effects of season and atmospheric temperature were noted. First, the bacterial content of the milk in the udder was estimated, and it was found that the fore-milk (that first milked) contained from 18,000 to 48,000 microorganisms per cubic centimetre, and the milk after the removal of the fore-milk 890 to 4800 per cubic centimetre.

It is generally agreed that the milk as secreted is sterile, the microorganisms in the milk as drawn being derived from lodgment and multiplication in the teats and cistern.

Dirt on the udder is a fruitful source of contamination, and, during milking, dust, &c., from the udder adds much to the bacterial content of the milk. Dust in the cowsheds, and the entrance of dirt during transit and delivery, further add to the contamination, so that the milk, when it reaches the consumer, may contain an appalling number of microbes. The chief conclusions derived from Dr. Orr's work are:—

(1) Of the total organisms in the milk used by the consumer, the greatest number are contributed by the farmer. During railway transit, at the retailer's premises, and in the consumer's house, smaller amounts are added, the amount in each instance being apparently about the same.

(2) Of the glucose-fermenting or intestinal organisms and the streptococci, by far the greatest number are added

at the farm. The retailer adds a certain number, the consumer none.

(3) The sediment or "dirt" gains entrance to the milk chiefly at the cowshed. In 86·8 per cent. of the samples examined there was no increase in the sediment when sold by the retailer, but a decrease in 68·8 per cent.

(4) The farmer was responsible for the *Bacillus enteritidis sporogenes* (Klein) in the milk consumed in 66·6 per cent. of the samples. In 11·1 per cent. of the samples these bacilli were added by the retailer or the consumer, while in 22·2 per cent. the source was doubtful.

Various suggestions are made for improving the milk supply, and the imposition of the following standards is advocated:—

(1) A bacterial standard of not more than 50,000 organisms per c.c.

(2) Milk not to contain glucose-fermenting bacteria in less than 1/10 c.c.

(3) A sediment standard (at first) not exceeding 40 volumes per million.

Altogether, this report on the milk supply is one of the most important that has appeared in this country, and should be brought to the notice of all producers and retailers of this important article of diet.

THE WINNIPEG MEETING OF THE BRITISH ASSOCIATION.

WE are now in a position to give some further details about the local arrangements for the British Association meeting in Winnipeg during the last week in August next, and also the provisional programmes of the sections.

The Drill Hall will be used as the reception room. The main floor is 147 feet by 87 feet, so that there is no fear of undue crowding. Arrangements will be made for free access to the Parliament building grounds adjoining.

On the opposite side of Broadway are the University building and grounds. The University is a small and by no means beautiful structure. It resembles, in fact, in size and general style the public elementary schools of the city. But it must be explained that the University at present only teaches scientific subjects. Arts, medicine, and agriculture are taught in "affiliated" colleges which are scattered in various parts of the city. Thus, the classics and modern languages are taught in the four "affiliated" denominational colleges, St. Boniface (Roman Catholic), St. John's (Church of England), Manitoba College (Presbyterian), and Wesley College (Methodist); medicine is taught in the Manitoba Medical College, and agriculture in the Manitoba Agricultural College (Provincial Government) at Tuxedo Park. The University of Manitoba (also a Government institution) has been a teaching institution for five or six years. Founded in 1871 as an examining board, the University itself at present undertakes instruction in mathematics, chemistry, physics, botany, physiology, pathology and bacteriology, and civil and electrical engineering. But chairs in English history and political economy have been recently established, and these new departments will commence work next October. The government and organisation of the University is undoubtedly in an unsatisfactory state, and is, in fact, the subject of a Government Commission at the present time. There is a widespread feeling that the province ought to have a provincial university of the type provided in many States of the Republic to the south, and entirely free from any denominational influences.

Five of the sections (B, D, G, I, K) will meet in the University building. Section A will find its temporary home in Wesley College, where three rooms will be set aside for the meetings. Section E will be placed in the Convocation Hall at Manitoba College, and Section F in a class-room of the same institution. Section L will have the honour of sitting in the Legislative Chamber of the Provincial Government, while agriculture (subsection of K), and Sections H and C, will meet in the Alexandra, Carlton, and Isbister Schools respectively.

All these meeting places are conveniently near the reception room.

The local sectional secretaries are as follows:—A, Prof. F. Allen, professor of physics, University of Manitoba; B, J. W. Shipley, assistant to the professor of chemistry, University of Manitoba; C, R. T. Hodgson, Brandon Collegiate Institute, Brandon; D, C. A. Baragar, University of Manitoba; E, Alex. McIntyre, Normal School, Winnipeg; F, W. Manahan, Winnipeg; G, Prof. E. Brydone-Jack, professor of civil engineering, University of Manitoba; H, not yet appointed; I, Dr. Wm. Webster, demonstrator of physiology, University of Manitoba; K, Prof. A. H. Reginald Buller, professor of physiology, University of Manitoba; Principal W. J. Black, Manitoba Agricultural College; L, D. M. Duncan, registrar of the University of Manitoba.

University of Manitoba. (For Sections B, D, G, I, and K.)

A few hints to travellers may not be out of place. For the ocean voyage, heavy coats and wraps and a travelling rug would be great comforts, if not absolute necessities, as it is never very warm on the North Atlantic route. These, however, should be packed away for the overland journey, otherwise they will give rise to considerable inconvenience.

Travellers from Europe are specially warned not to carry with them in the train more baggage than is absolutely necessary for the journey. Each person ought, indeed, to be content with a suit-case and perhaps a small handbag. All kit-bags, gladstone bags, and such like are quite out of place, as there is no space provided for these, and they may be a great nuisance to everybody. An elaborate toilet, at any rate, is not possible during the railway journey, but the railway companies' sleeping cars are provided with sufficient lavatory accommodation. Everything except the suit-case and hand baggage should be *checked through* to destination.

To any American, or indeed to anyone who has ever travelled on the North American continent, such advice may seem quite superfluous, but it is rare that one travels across the country or witnesses the departure of trains without noticing some Englishman struggling to convey huge piles of luggage into a railway car; he is usually prevented from so doing by the porter, but if he succeeds his belongings soon become a trouble to himself and a nuisance to his fellow-travellers.

In regard to clothing, for Winnipeg during the week of the visit travellers should be provided with the same sort of selection as would be desirable at a meeting in Great Britain. The days in the latter part of August are usually hot, and the nights pleasantly cool. Those undertaking the excursion to the Pacific coast should be provided with some warm clothing for the mountains.

Manitoba College. (For Sections E and F.)

Those intending to visit Winnipeg for the meeting have been provided with postcard forms to fill in, giving various particulars of use to the local committee. These may be obtained from the assistant secretary in London, and should, with any other communications with regard to the meeting, be addressed to the local secretaries, University of Manitoba, Winnipeg.

In connection with the meeting, arrangements have been made by Mr. M. B. Cotsworth, of the Natural History Society of British Columbia, Victoria, B.C., on behalf of some of the members of the Association, to make a trip northward along the Pacific coast from Victoria or Vancouver to Alaska. The journey to Prince Rupert, Skagway, and back occupies ten days, costs about 14*l*., and may be made either before the meeting at Winnipeg or from September 10 to 19. An extension to Dawson (Klondike) and back brings the total time up to three weeks, and the cost to about 32*l*., while the round trip from Vancouver to Dawson, thence down the Yukon river to Nome and back by the Bering Sea and Aleutian Islands, occupies about a month, and costs 40*l*. Climatic considerations, however, make it desirable to carry out such extended trips before the meeting, and it is understood that some members have already arranged to do this. The excursions are not among the official arrangements of the Association, but further particulars may be obtained from the London office, Burlington House, W.

We are informed that Sir Joseph Thomson, in his presidential address to the Association, will touch on the following subjects:—The importance of original research as a means of education; the advantages and disadvantages as a training for work in science of the systems of education now in force in our schools and universities; the light thrown by recent investigation on the nature of electricity; on the relation between matter and æther, and the part played by the æther in modern physics; and a discussion of some problems raised by the discovery of radium.

SECTIONAL PROGRAMMES.

SECTION A (MATHEMATICAL AND PHYSICAL SCIENCE). President, Prof. E. Rutherford, F.R.S.—The arrangements for the meetings of this section are at present very provisional. After the address of the president of the section, the most important items in the provisional programme are two discussions, one on positive electricity, to be opened by Sir J. J. Thomson, F.R.S., and the second on earth tides, to be opened by Prof. A. E. H. Love, F.R.S. The papers promised include the following:—photographs of recent comets, Prof. E. Barnard; new photographs of Jupiter taken at Flagstaff Observatory, Percival Lowell; on sun-spots and magnetic effects, Dr. L. A. Bauer; the structure of the stellar system, G. C. Comstock; the asymptotic expansions of Legendre functions, Dr. J. W. Nicholson; on a continuant expressed as the product of linear factors, W. H. Metzler; luminosity and persistence-of-vision curves, Prof. Frank Allen; variation of the specific heat of mercury at high temperatures, Prof. H. T. Barnes; the effect of temperature-variations on the luminous discharge in gases for low pressures, R. F. Earhart. This list includes only those papers for which definite titles have been received; many others are promised. Friday morning, August 27, will be set aside for papers of interest to chemists, and the section will meet in joint session with Section B (Chemistry).

SECTION B (CHEMISTRY). President, Prof. H. E. Armstrong, F.R.S.—The provisional programme is as follows:—Joint sitting with the Section of Botany and Subsection of Agriculture to discuss "wheat" from several points of view, including requirements of the wheat crop, influence of external conditions, review of the chemical work on strength, the miller's requirements, wheat breeding, the history of the wheat plant, and the economics of the subject. (See programme of the Subsection of Agriculture.) Joint sitting with the Physiology Section to discuss food. Combustion, Prof. W. A. Bone, F.R.S.; chlorophyll, Prof. Willstätter; papers dealing with the physical chemistry of sulphur, Prof. Alex. Smith; (1) rotatory dispersion, (2) the cadmium arc, Dr. T. M. Lowry; (1) mercurous sulphate for standard cells, (2) on the constancy of the hydrogen gas electrode, Dr. C. J. J. Fox. Reports of committees:—(*a*) hydroaromatic substances; (*b*) aromatic nitroamines; (*c*) electroanalysis; (*d*) dynamic isomerism. This report will be presented in such form as to initiate discussion.

SECTION C (GEOLOGY). President, Dr. A. Smith Woodward, F.R.S.—Dr. Woodward's presidential address will be on the evolution of the vertebrates. There will be reports of research committees on:—the erratic blocks of the British Isles, Dr. A. R. Dwerryhouse; the fauna and flora of the Trias of the British Isles, which will be supplemented by an account of the progress of this investigation, illustrated by lantern slides, H. C. Beasley; and the fossiliferous drift deposits of Kirmington, Lincolnshire, and the East Riding of Yorkshire. This is the final report of the Committee. The papers will include:—the composition and origin of the crystalline rocks of Anglesea, E. Greenly; the faunal succession in the Carboniferous Limestone of the British Isles, Dr. A. Vaughan, which will be supplemented by an account of the progress of these researches, illustrated by lantern slides, by Prof. Sidney H. Reynolds, of Bristol; critical sections in the Palæozoic rocks of Wales and the west of England, W. G. Fearnsides; the microscopical and chemical composition of Charnwood Rocks, Prof. T. T. Groom; the igneous and associated rocks of Glensaul and Lough Nafovey areas, co. Galway, Prof. S. H. Reynolds; geological photographs, with illustrations of British scenery in relation to geology, Prof. S. H. Reynolds; the Glacial Lake Agassiz, Prof. Warren Upham; the advances in the knowledge of the glacial geology of South Wales, Dr. Aubrey Strahan; unconformities in limestone and their contemporaneous pipes and swallow-holes, E. E. L. Dixon; on new faunal horizons in the Bristol coalfield, Herbert Bolton; on the Permian succession in the north of England, Dr. D. Woollacot; a mineralogical paper, A. Hutchinson. Prof. J. W. Gregory, F.R.S., and Dr. Tempest Anderson are now making extended tours in Australia and the South Seas, and it is expected that they will have valuable and interesting communications to make to the section. An extended tour for four days has been arranged to the mining districts of Corall and Sudbury, under the direction of Prof. W. G. Miller, and Dr. J. W. Spencer will lead a party to Niagara and the glacial outlet of Lake Erie.

SECTION E (GEOGRAPHY). President, Sir Duncan Johnston, K.C.M.G.—The following are among the papers to be brought before the section:—some characteristics of the Canadian Rockies, A. O. Wheeler; the evolution of wheat culture in North America, Prof. A. P. Brigham; water routes from Lake Superior to the west, Lawrence J. Burpee; Yellowhead Pass and Mt. Robson, the highest point in the Canadian Rockies, Prof. A. P. Coleman; the influence of traffic or transportation upon the framework of cities, with an introductory reference to the influence of geography in the same direction, G. E. Hooker; the cycle of Alpine glaciation, Prof. W. H. Hobbs; the teaching of geography in secondary schools in America, Prof. R. E. Dodge (to be read at a joint meeting with Section L); the formation of arroyos in the south-west of the United States, Prof. Dodge; the development of Nantasket Beach, near Boston, Mass., Prof. D. W. Johnson; floods in the great interior valley of America, Miss Luella A. Owen; the precious metals as a geographical factor in the settlement and development of towns in the United States, Prof. Hubbard. Mr. J. Stanley Gardiner, F.R.S., will give a lecture, illustrated by lantern slides, on his work in the Seychelles, and there will probably be papers also by Prof. Goode, Dr. C. H. Leete, and Prof. Hoke.

SECTION G (ENGINEERING). President, Sir W. H. White, K.C.B., F.R.S.—In addition to Sir W. H. White's presidential address, a report will be presented by the committee on gas explosions, and a paper on the some subject will be contributed by Mr. Dugald Clerk. Other papers are as follows:—Skimming boats, Sir John Thornycroft; the Isthmian Canal, Col. Goethals; the work of the International Electrotechnical Commission, Ormond Higman; torsion tests on materials, C. E. Larrard; dielectric stress in three-phase cables, Prof. W. M. Thornton. Papers on grain handling and transportation in Western Canada, on the navigation of the St. Lawrence, and on high-tension overhead lines are in preparation.

SECTION K (BOTANY). President, Lieut.-Colonel D. Prain, F.R.S.—The following are some of the communications to be brought before the section:—*On Thallophyta:* On the production, liberation, and dispersion of the spores of Hymenomycetes, Prof. Buller; numerical determinations of the bacteria in the air of Winnipeg, Prof. Buller and Mr. Lowe; the nuclear phenomena of Ascomycetes in relation to heredity, Miss H. C. I. Fraser; the nucleus of the yeast plant, H. Wager, F.R.S., and Miss Peniston; some problems connected with the life-history of *Trichodiscus elegans*, Miss E. J. Welsford. *Ecological papers:* The fundamental causes of succession among plant associations, Prof. H. C. Cowles; some observations on *Spiraea Ulmaria*, Prof. Yapp. *Other papers:* A paper on the anatomy of the Osmundaceæ, Prof. Gwynne-Vaughan; (1) the evolution of the inflorescence, (2) the rubber industry, J. Parkin. The annual semi-popular lecture will be given by Mr. Harold Wager, F.R.S., on the perception of light in plants. In addition to the above, there will be a joint sitting with Section B and the Agricultural Subsection of K for a discussion on "wheat." Dr. O. Stapf, F.R.S., will contribute a paper towards this discussion, on the systematic history of wheat. Several other papers have been promised by prominent American botanists, but the titles are not yet to hand.

SUBSECTION K (AGRICULTURE). President, Major P. G. Craigie, C.B.—*Joint meetings:* (1) With the Economic Section, Thursday afternoon, August 26. The future possibilities of extending the food production of Canada, Prof. Mavor. (2) With the Chemical and Botanical Sections, Monday morning, August 30. Subject, wheat problems. Papers:—the miller's requirements; a review of recent chemical work on the strength of wheat, Dr. E. F. Armstrong; factors determining the yield of wheat, A. D. Hall, F.R.S., and Dr. E. J. Russell; milling properties of certain Canadian wheats, Prof. R. Harcourt; Canadian wheats, F. T. Shutt; wheat breeding in Canada, C. E. Saunders. Papers also by Dr. W. Saunders and by C. A. Zavitz. *Ordinary meetings:* Presidential address, Major Craigie; methods of crop reporting in different countries, E. W. Godfrey; the experimental farm system in Canada, Dr. W. Saunders; the fruit industry of British Columbia, R. W. Palmer. *Prairie soil problems:* Geography of the prairie soils, R. W. Brock; chemical characteristics of the prairie soils, F. T. Shutt; soil moisture and crop production, Prof. F. H. King; soil moisture as related to dry farming, Prof. F. J. Alway. Papers by A. D. Hall, F.R.S., and Dr. E. J. Russell. *Live-stock problems:* Paper by Prof. W. Somerville; the evolution of a breed of cattle, Prof. J. Wilson; some special features of the Danish system of cattle breeding, P. A. Morkeberg; paper by J. G. Rutherford. *Forestry problems:* Paper by Prof. W. Somerville; Canadian forest resources, R. H. Campbell; the insect pest problem, Prof. Lochhead; some forestry problems of the great plains of North America, C. E. Bessey.

SECTION L (EDUCATIONAL SCIENCE). President, Dr. H. B. Gray.—After the president's address on August 26 a discussion on moral instruction in schools will be opened by Prof. L. P. Jacks, editor of the *Hibbert Journal*. He will be followed by Mr. Hugh Richardson, and it is hoped that American and Canadian educationists will also take part. On Friday, August 27, there will be a discussion on practical work in schools, which will be opened on behalf of the subcommittee of the association which is now considering the question by Mr. W. M. Heller. Dr. C. W. Kimmins will contribute some account of the London trades schools, Miss Lilian J. Clarke will speak on practical work in girls' secondary schools, and Mr. W. Hewitt on practical work in evening and continuation schools. On Monday, August 30, there will be a joint meeting with the Geographical Section of the association for the discussion of geography teaching. Prof. R. E. Dodge, of Columbia, and Mr. G. G. Chisholm, of Edinburgh, are expected to open the discussion. There will also be a discussion on the relations of universities and secondary schools, with special reference to the accrediting and examining systems. On August 31 the president of the section will open a discussion on education as a preparation for agricultural life, with special reference to Canadian conditions. Should time permit, it is also intended to discuss the subject of consolidation schools. The organising committee of the section is in correspondence with educationists in Canada and America, and it is hoped to arrange that each subject shall be opened by representatives of American, Canadian, and British education.

NOTES.

We announce with deep regret the death of Prof. Simon Newcomb, Foreign Member of the Royal Society, on July 11, at seventy-four years of age.

The next international congress of mining and metallurgy is to be held in June, 1910, at Dusseldorf. The last congress was in 1905, and the place of meeting Liége.

At an audience on July 10, the King conferred upon Mr. E. H. Shackleton the Insignia of a Commander of the Royal Victorian Order in recognition of his work in the Antarctic.

It is stated by the St. Petersburg correspondent of the *Globe* that a Bill for the substitution of the new style for the old style of date reckoning in Russia will be brought before the Council of the Empire and the Duma in the autumn. There is at present a difference of thirteen days between the Russian calendar (old style) and the reformed Gregorian calendar introduced in 1582 and used in our country since 1752.

Another exhibition, arranged in connection with the *Model Engineer*, on similar lines to that which proved successful in 1907, will be held at the Royal Horticultural Hall, Westminster, S.W., in October next. The exhibits will include engineering models, electrical and scientific apparatus, lathes and light workshop appliances, model aëroplanes, and technical education equipment. An attractive feature will be the exhibits in the competitions for model and scientific apparatus making, several classes for both amateur and professional workers having been arranged, for which valuable prizes are being offered. Full particulars may be obtained from the organisers, Messrs. Percival Marshall and Co., 26–29 Poppins Court, Fleet Street, London, E.C.

The first Gustave Canet lecture was delivered by Lieut. Trevor Dawson at the twenty-fifth anniversary meeting of the Junior Institution of Engineers on June 30. The lecturer is the recipient of the first gold medal, which is to be awarded every fourth year by Madame Canet in memory of her husband, the award being made through the council of the institution. In his lecture, Lieut. Dawson gave many instances of the increased power and accuracy of guns. One photograph showed six 100-lb. shots striking the water, having been fired as a volley from 6-inch guns on a British cruiser at a range of 7300 yards. The total space embraced by the six shots was only 88 yards. Towards the end of the lecture the question of airship attack was dealt with, and the special ordnance to be used against these vessels described.

The British and Irish Millers' Convention was held at Chester on July 7, when a paper was read by Mr. A. E. Humphries, of Weybridge, on "Ideal British Wheats." Mr. Humphries pointed out that the British farmer no longer grows what the miller wants; instead of producing a strong wheat, capable of making large, shapely loaves, he produces a weak wheat, the flour from which is usually a drug in the market. The home-grown wheat committee of the British Millers' Association has been investigating the question of improvement, and is very hopeful about the future; it is believed that wheats will be produced of better quality, with better straw, less susceptibility to disease, and greater cropping power than those now available. The committee asks for a national cereal-breeding station, and commends this to the Board of Agriculture and the Chancellor of the Exchequer as one important means of agricultural development.

At the end of last year we observed with regret the report that Mr. James Parsons, principal mineral surveyor of Ceylon, had disappeared in the jungle, and his death was presumed. It seems that on the morning of December 29 last Mr. Parsons left his hotel at Nuwara Eliya for a walk in the open country, intending to return in time for lunch. About noon he was seen traversing a certain tea-estate, but from that date he was never seen alive. We now learn that, after three months' search, his remains were found in the jungle on April 11. Death was probably due to exposure. Mr. Parsons went to Ceylon in 1902 as assistant to Dr. A. K. Coomaraswamy to undertake a mineralogical survey of Ceylon. On Dr. Coomaraswamy's retirement he took his place in 1906. His last writings were two papers in *Spolia Zeylanica* on fluor-spar in Ceylon and votive offerings of weapons.

The recently issued account of the income and expenditure of the British Museum for the year ended March 31 last, and the return of the number of persons admitted to visit the Museum and the Natural History Museum, South Kensington, in each year 1903 to 1908, both years inclusive, provides much information of interest. The number of visits made by the public to the Natural History Museum during 1908 was 517,043, as compared with 497,437 in 1907, showing an increase of 19,606. The attendance on Sunday afternoons showed a slight falling off, the figures being 65,986, as against 66,367 in the previous year. The average daily attendance for all open days was 1420·4. The total number of gifts received during the year by the several departments was 2259, as compared with 2105 in 1907. Among other donors may be mentioned Mr. F. D. Godman, valuable collections of insects from Central America and other localities, and a series of water-colour drawings of butterflies of the family Hesperiidæ; the Hon. Walter Rothschild, mounted specimens of a male and female Californian sea-elephant, from the island of Guadeloupe, and a male sea-lion from California; the trustees of the Percy Sladen Fund, a large collection of reptiles, batrachians, and fishes from the Seychelles, Chagos Islands, and the Indian Ocean; Mr. C. D. Sherborn, a valuable collection of specimens of the handwritings of naturalists, consisting of some 8000 letters and other documents; and Mrs. R. P. Murray, the extensive herbarium made by the late Rev. R. P. Murray, comprising about 15,000 sheets.

According to the curator's report for 1908–9, the Otago University Museum at Dunedin has been augmented by a new wing—the Hocken wing—which will shortly be opened to the public, and is mainly devoted to art and literature. A living tuatara lizard has been kept alive for some time on the museum premises.

The report of the Rhodesia Museum at Bulawayo for 1908 shows continued progress on the part of that comparatively juvenile institution, despite the fact that one source of revenue has been cut off, while the Government has declined to be responsible for an annual subsidy to the funds. The largest increase to the collection has taken place in the entomological section.

The most important additions to the Giza Zoological Gardens, as we learn from Captain Flower's report for 1908, were the hippopotamus and the Nubian bustard. The curator finds it necessary to take special precautions to protect the smaller mammals and birds from nocturnal four-footed marauders, of which the worst is the jungle-cat, although jackals, dogs, and foxes also do much harm. During the year a jungle-cat killed a pelican. The pro tective measures rendered necessary by these raids have given rise to protests from European visitors ignorant of the true facts of the case.

Naturwissenschaftliche Wochenschrift for June 27 includes an illustrated article, by the Rev. E. Wasmann, on the origin of slavery and social parasitism among ants, in which it is urged that, before these can be properly understood, it is essential that we should acquire a knowledge of a series of independent developmental histories of different species, genera, and subfamilies, which commenced in past geological times. Only with such histories before us will it be possible to construct anything like a true working hypothesis of the origin of the phenomena in question.

To Mr. G. Gilson, director of the Royal Museum of Natural History of Belgium, we are indebted for a copy of an address read before a conference held in the apartments of the Royal Zoological and Malacological Society of Belgium on June 12, on the subject of the proposed establishment of an educational museum in Brussels. The address is chiefly concerned with the aims and objects of such a museum and the manner in which the scheme should be carried out. A teaching museum, it is urged, should be kept entirely apart from museums of the ordinary type, and run on totally different lines. As regards the selection and installation of the objects to be shown in the museum, it is pointed out that this task should be entrusted, in the first instance, to scientific experts, but that after this the collections should be handed over to the actual teaching staff.

To the July number of the *Century Magazine* Mr. R. W. Yerkes contributes an article on "imitation in animals," a considerable portion of which is devoted to an account of the behaviour of three Manx kittens, which had never previously seen mice, when confronted with one of these rodents. When the first introduction was made the kittens were five months' old, and the mouse was uninjured. Six weeks later the experiment was repeated, when the kittens were hungry, but still no attempt was made to devour the mouse. Later on the parent cat was introduced into the cage, when the mouse was killed by her, and, little by little, the kittens eventually learnt to follow their mother's example. The experiments, in the author's opinion, serve to show that these particular kittens had no instinctive propensity to kill and eat mice, and that they only learnt to do so by the force of example. Whether this holds good for kittens generally remains to be proved.

UNDER the title of *Technitella thompsoni* (after Prof. D'Arcy Thompson) Messrs. E. Heron Allen and A. Earland describe in the Journal of the Quekett Microscopical Club a new species of arenaceous foraminifera which constructs its enveloping test entirely out of regularly arranged calcareous plates of echinoderms. Of this foraminifer two specimens only have been found from dredgings in the North Sea. It possesses no oral aperture, the perforations in the echinoderm plates furnishing a sufficient outlet for the pseudopodia. Other species of the genus make their tests out of sponge spicules, but it is believed that the present species stands preeminent in its selective power of building material.

THE annual address to the Armstrong College Agricultural Students' Association, by Mr. A. Tindall, has been printed in the Proceedings of that body, and will be interesting to students of agricultural economics. It deals with the history and development of the Newcastle cattle market, and includes a number of valuable statistics, such as prices of cattle, &c., as well as accounts of sale customs. In the same publication will be found a short article on milk production and milk products by Mr. John Anderson.

THE United States Department of Agriculture Bureau of Entomology has issued a circular (No. 42) on the control of the San José scale. This pest has, in the past, proved a serious menace to the fruit-growing industry, but experience both in California and in the eastern States shows that it can be controlled. Seven methods have proved successful when properly carried out, viz. :—(1) the lime-sulphur wash; (2) soap wash; (3) pure kerosene; (4) crude petroleum; (5) mechanical mixtures of either of these two oils with water; (6) petroleum emulsion and soap; (7) miscible oils. Instructions are given for carrying out each of these methods.

BULLETIN No. 166 of the Maine Agricultural Experiment Station contains a discussion, by Messrs. Raymond Pearl and Frank M. Surface, of the inheritance of fecundity in poultry. The daughters of "200-egg" hens (*i.e.* hens laying 200 or more eggs in twelve months) were kept under observation. It is, as yet, too soon to draw general conclusions, but no evidence was obtained to show that a good winter layer necessarily produces another good winter layer, as is said to be assumed by practical poultry-breeders. On the contrary, the exact opposite happened here: the mothers, on the whole, were exceptionally good, and the daughters unusually poor, as winter layers.

RECENT bulletins from the Colorado Agricultural College include three on strawberry growing, dewberry growing, and the pruning of fruit trees, one on animal diseases, and one on bacterial diseases of plants. A disease of lucerne, first described by Paddock in 1906, and shown to be bacterial, is dealt with at some length. The bacteria seem to come from the soil and work up the stem, giving rise to a "watery, semi-transparent brownish appearance of the tissue, which turns black with age." Blisters are present, containing a sticky, yellow liquid swarming with bacteria. Other diseases dealt with are pear blight, soft rot of sugar beet, black rot of cabbage, bacterial blights of the potato family, of beans, and of cucumbers; specific organisms have in several of these cases been isolated.

THE endoparasites of Australian stock and native fauna form the subject of two papers by Dr. Georgina Sweet, of the Melbourne University. The work, which is still going on, aims at making a systematic and thorough inquiry into the nature of the internal parasites infesting Australian animals, both native and domesticated, and then into the life-history and conditions of increase and spread of these injurious forms. The work is both of scientific and practical importance; species exist in Australia that have not been recorded elsewhere, and it is desirable that their life-histories should be worked out; methods of control are also necessary, since Australia is largely dependent on its livestock, and suffers great losses of revenue as a result of parasitic diseases. In part i. the author gives a census of forms recorded up to date, in which the work of Dr. N. A. Cobb in New South Wales and others has been drawn upon; part ii. contains the new and hitherto unrecorded species.

WE are in receipt of the *Journal of Agriculture of South Australia*, a publication which is devoted almost exclusively to practical matters of local interest. The statistics for 1907 are discussed in one of the articles. The area under crop was 2,265,017 acres, nearly one-fourth of the whole area of the State, and 100,000 acres more than in the previous year. South Australia was at one time the granary of Australia, but here, as elsewhere, there is a strong tendency for other branches of husbandry to be taken up, and for wheat to lose in relative importance. The exports of wool were nearly 51 million pounds, again a considerable increase on the previous year. The acreage under barley and oats is the highest on record, while the fruit industry has made very rapid progress. Perhaps the best indication of improvement in method is found in the increasing use of artificial manures. Not many years ago the use of artificial manures was practically unknown. In 1897 it is estimated that 3000 tons were used for cereal crops; the consumption then steadily increased, and has been uniformly greater every year; in 1906 no fewer than 59,000 tons were used. In another article there is an account of the Roseworthy Agricultural College, an institution which not only provides instruction for those intending to be farmers, but also conducts investigations in the area it serves.

A friendly, and for the most part favourable, criticism of forest practice is provided by an American forester, Mr. B. Moore, in an article on the forests of northern India and Burma, published in the April and May numbers of the *Indian Forester*. He expresses a very decided opinion in favour of a regulated fire policy for forests of young teak and sal where the forests are situated in a moist climate, as in Assam. He also agrees with those who consider that Indian foresters in training should gain their practical experience in India.

A series of papers by Dr. B. L. Robinson, Miss A. Eastwood, and Mr. H. H. Bartlett, describing chiefly new or little-known Mexican and Central American plants, are collected in vol. xliv., No. 21, of the Proceedings of the American Academy of Arts and Sciences. The most important is the synopsis of Mexican species of Castilleja, with diagnoses and clavis compiled by Miss Eastwood; seventeen new species contribute to a total of fifty-four species for the genus. Dr. Robinson furnishes a revision of the genus Rumfordia with six species, and diagnoses of various tropical American phanerogams. New identifications are presented by Mr. Bartlett in a synopsis of American species of Litsæa and other articles.

Mr. G. Massee is responsible for two articles in the *Kew Bulletin* (No. 5), the one being a list of exotic fungi, the other a note on witches' broom of cacao. The latter is produced by a Colletotrichum receiving the specific name *luxificum*. Both vegetative and flowering branches are attacked, with the consequent production of hypertrophied shoots and flowers and diseased pods. The fungi are all new species of Boletus—except one Strobilomyces—collected by Mr. Ridley in Singapore. Another article in the bulletin is devoted to notes, by Richard Spruce, on the vegetation of the Pastasa and Bombonasa rivers, providing a description supplementary to chapter xvii. of the second volume of "Notes of a Botanist on the Amazon and Andes."

We have been favoured with a copy of the address delivered by Prof. J. W. Moll before the members of the Koninklijke Akademie van Wetenschappen te Amsterdam when presenting the dissertation of Dr. K. Zijlstra on the transport of carbon dioxide in leaves. Prof. Moll presents an excellent summary of the investigations, which prove that, to a limited extent, the transport of carbon dioxide is possible through the intercellular spaces; but it is obvious that such transport, if it takes place under natural conditions, is of no appreciable advantage to the plant, and could not enable the plant to absorb carbon dioxide from the soil. Thus the primary conclusion of Prof. Moll's original investigations is confirmed.

The prosperity of Egypt depends largely on the successful cultivation of the particular types of cotton known as "Egyptian." During the last twelve years, however, the yield of cotton has steadily and appreciably diminished, the loss amounting at current rates to about 5*l.* per feddan (1·109 acres). Many causes have been suggested as contributing to this result, and in "Cotton Investigations in 1908" (*Cairo Scientific Journal*, February, 1909) Mr. W. Lawrence Balls puts forward the view, for which there is some direct evidence, that a rise in the water-table in Egypt has been an important factor. Owing to improvements in irrigation, the supply of water in Egypt is greater than formerly, whilst the natural loss remains more or less constant. Artificial drainage is lacking, and in his view Egypt is in danger of becoming water-logged, in which condition the soil is rendered impervious to the roots of most plants. The remedy advocated is extension of the drainage system, an expensive proceeding, but justifiable if the reduced yield is due to the rise in level of stagnant water. Another important matter dwelt on in Mr. Balls's paper is the depreciation of cottons grown in Egypt owing to the hybridising of the Egyptian varieties by the less valuable "American Upland" races, cultivated because of their heavy yield. To combat this he proposes the breeding of a cotton bearing flowers in which the stigma is buried deeply amongst the stamens, thus reducing to a minimum the risk of natural crossing. The report is accompanied by a photograph of a section of such a synthesised flower. Egypt is leading the way in the practical application of Mendel's discoveries, for 1909 has seen the establishment by the Khedivial Agricultural Society of a Mendelian experiment station.

In the June number of *Folk-lore* Mr. T. C. Hodson, author of a valuable monograph on the Meithei tribe in Manipur, describes the custom of head-hunting among the hill tribes of Assam. The custom is, in the first place, ancillary to and a part of the funeral rite, which is affected by the social status of the deceased and the manner of his death. The funeral of a Kuki chief is incomplete without the head of a victim. The corpse is placed within the trunk of a tree, where it remains until it is sufficiently desiccated to allow of the preservation of the bones. The heads, again, are presented before piles of stones, the abode of the Lai, a powerful, mysterious entity, not always or necessarily anthropomorphised. The rite of deposition of the head of the victim is thus partly piacular, intended to propitiate the spirit of the deceased; partly religious, inasmuch as it is devoted to the vaguely conceived tribal spirit. The custom has also its social side, as success in a raid is held to be a proof of manliness, marking the transition from adolescence to maturity. It is also protective, because the spirit of the owner of the head becomes guardian of the village; and hence, as a necessary corollary, the head of a stranger is most highly valued, because, being ignorant of its surroundings, it is less likely to escape from the village of which, perforce, it has become protector.

An account of the life and philosophical doctrines of Henri Poincaré is given in the *Revue des Idées* for June 15 by M. Jules Sagret.

Prof. Garbasso, writing in the *Atti della Società italiana per il progresso della Scienza* (Rome: G. Bertero, 1909), discusses the structure of the atom, and gives a brief account of the theories of Briot, Kirchhoff, Bunsen, Helmholtz, Hertz, Lockyer, Kayser and Runge, Rydberg, Puccianti, Stoney, and J. J. Thomson.

IN the *Sitzungsberichte* of the Vienna Academy, cxvii., 8, 9, Dr. Philipp Forchheimer discusses certain mathematical solutions of the problem of underground flow of water in a homogeneous stratum bounded by a plane impervious floor, the equation of continuity in this case being the ordinary two-dimensional form of Laplace's equation, with the square of the depth as the dependent variable.

THE theory of the polar planimeter is treated in a novel way by Dr. Gabriele Torelli in the *Rendiconto* of the Naples Academy, xiv., 8–12 (1908). The author finds that the treatment of the subject given in text-books is far from convincing, and he proposes an alternative treatment based on the use of Jacobians. Those who have worked with planimeters in this country will fully agree with the author as to the need of a more satisfactory investigation of their principle, and if such a need exists in the case of the polar planimeter it is still more necessary for the so-called "hatchet planimeter," which is usually worked by rule, with little attempt, if any, to explain its principle.

AN important contribution to our theories of wave-propagation in wireless telegraphy is given by Prof. A. Sommerfeld in the *Annalen der Physik*, xxviii., pp. 665–736 (1909). The investigation, while taking account both of surface waves and of waves distributed in space, tends to support the view that we have to deal with waves propagated along the surface of the earth in accounting for the transmission of Marconi signals. Prof. Sommerfeld, further, in his analytical results obtains analogues of properties associated with electrodynamic waves in wires and certain optical phenomena (Brewster's law).

IN the *Rassegna contemporanea* for May, 1908, Mr. Gino Cuchetti discusses the project for anti-seismic houses, due to Prof. Giuseppe Torres, of Venice. This project is based on the view that circular structures are the best calculated to withstand earthquake shocks, and in the designs shown in the illustrations each building consists of several circular turrets of different diameter communicating with each other, an arrangement having considerable artistic merits, though wasteful of space. In the succeeding number of the *Rassegna* Dr. Enrico Pantano discusses the problem of "internal colonisation" as applied to Italy, and we note with considerable interest the important bearing on this problem of the campaign against malaria.

A REPORT on the resistance of rivets is presented by M. Ch. Fremont to the *Bulletin de la Société d'Encouragement* for April. It is pointed out that the resistance of riveted plates to statical forces or shocks should be borne as much as possible by the adhesion of the plates and as little as possible by shearing of the rivets themselves, and the author emphasises the necessity of standardising the heads of rivets and of regulating the maximum temperature during the process of heating, so as not to destroy the elastic qualities of the rivet. The increased efficiency obtained by the application of continued pressure during the riveting is also mentioned.

IN a paper on the most general problem of optics, published in the Proceedings of the Turin Academy of Sciences, Prof. Antonio Garbasso and Guido Fubini point out that little has been done in solving problems of propagation of light waves in a medium which is neither homogeneous nor isotropic. The authors propose a theory for the special case of a medium in which the ellipsoids of elasticity are of revolution having their axes parallel, and the lengths of these axes are the same at all points in a plane perpendicular to the axis of revolution. An illustration of such a medium is afforded by a stratum of gelatin placed in contact with a solution of zinc chloride and subjected to pressure; the colours seen in such a medium under polarised light are shown in a plate accompanying the paper.

WE have received part iii. of "Klimatographie von Oesterreich," issued by the Meteorological Office of Vienna, in which the climatology of Styria is fully and ably discussed by Dr. Robert Klein. The treatment of the subject follows closely along the lines laid down by Hann in his "Handbuch der Klimatologie," and is, indeed, similar to that adopted by that author in the earlier parts of the work which deal with Austria proper. The book is a model of what the treatment of the special climatology of a restricted area should be. It gives for each region the probabilities of the occurrence of phenomena such as frosts of different degrees of intensity, heavy rainfall, and others. At the same time, the underlying principles are not lost sight of. Styria presents many features of special interest, as the altitudes included in its boundaries vary from about 200 metres to 4000 metres above sea-level. The cultivated region extends up to about 1500 metres. We have thus a great variety of meteorological conditions brought before us in the records from the stations of the second order which are discussed in the volume.

IN the April number of *Meteorologische Zeitschrift* Mr. E. Alt gives an interesting account of the double daily oscillation of the barometer over the globe, especially with reference to the Arctic regions. He preludes his paper by a *résumé* of the efforts hitherto made to elucidate this intricate problem by harmonic analysis, by Lamont, Angot, Hann, and others, and gives useful explanations of the several terms of the series. The theory now generally accepted is that referred to by Lord Kelvin (Proc. Roy. Soc. Edin., 1882) and developed by Prof. Margules (*Sitzungsber.* Vienna Acad., 1890). Mr. Alt has discussed a large number of observations both on land and at sea, and has exhibited the synchronous distribution of the double wave of air pressure by a series of charts. With reference to the Arctic regions, observations taken mostly from the *Challenger* report show that the maxima of the oscillations occur, on an average, about 11h. 20m. a.m. and p.m., and of the minima, on an average, about 5h. 20m. a.m. and p.m. (G.M.T.). The amplitude is small, amounting, on the average, to about 1/10 mm. The investigations of several physicists, including Prof. Margules, point to the view that the synchronism of the oscillation in the polar region is due to the existence of a second half-daily oscillation of the atmosphere which occurs in the direction of the meridians.

WE direct attention to a very laborious and important work by Dr. H. Fritsche entitled "The Mean Temperature of the Air at Sea-level exhibited as a Function of Longitude, Latitude, and Period of the Year" (Meteorologische Publication I.). The author has, *inter alia*, calculated from the constants of the harmonic formula the resulting values of mean temperature for the whole surface of the earth, for each 10° of longitude and 5° of latitude, for twenty-four equidistant epochs of the year, and for the whole year, with maxima, minima, and phase times. But this general description in no wise gives an idea of the immense work covered by some 184 closely printed tables; these are rather difficult to follow, being, with the explanations in German, printed in facsimile lithography. The calculations are based mostly on Buchan's monthly and yearly isothermal charts ("Atlas of Meteorology," by Bartholomew and Herbertson). The mean yearly temperature of the globe is given as 14·6° C., and the amplitude as 4·2°; the coldest period is at the end of January, 12·5°, and the warmest in the middle of July, 16·7°. The mean temperature of the northern hemisphere, 15·3° C., is nearly $1\frac{1}{2}$° higher than that of the southern. The work includes seven isothermal charts between 30° and 90° S. latitude for the year, for mid-January, and each alternate month.

The *Halbmonatliches Literaturverzeichnis* of the *Fortschritte der Physik*, issued under the auspices of the German Physical Society, still continues to furnish more promptly than any other periodical a list of the papers dealing with topics of interest to physicists which appear in the various journals and proceedings of societies. As instances of the promptness with which titles of papers are published, we may mention that the number for June 15 contains the titles of several papers read at the meetings of the Royal Society and of the Physical Society of London in April and May.

The prestige of the "principle of relativity" as a basis for our treatment of electrodynamics in moving media has been increased by a preliminary communication made to the German Physical Society by Dr. E. Hupka, an account of which is given in the *Verhandlungen* of the society for June 15. Three or four months ago Dr. A. H. Bucherer announced that the results of his experiments on the inertia of the negatively charged particles of the β rays from radium were distinctly in favour of the principle as against its most formidable rival the "sphere theory." Now Dr. Hupka, working with the electrons produced when light falls on negatively charged bodies, has shown that when these electrons are accelerated by the action of an electric field, and then deflected by passing through a magnetic field, the deflections observed are again in favour of the principle, which may be stated as follows:—The electrodynamic phenomena exhibited within two systems moving with respect to each other in a straight line will follow the same laws, provided that in each system the unit of time be so chosen that the velocity of light is expressed by the same number.

"Supplementary Investigations of Infra-red Spectra," by Prof. Wm. W. Coblentz (parts v., vi., vii.), has been received from the Carnegie Institution of Washington. This publication contains supplementary data on the doubtful points which arose in the author's preceding work, and also some additional observations on the emission spectra of metal filaments and insulators, thus rounding up the subject as completely as possible at the moment. Although, as Prof. Coblentz goes on to say, the programme of investigation is completed, the subject is not exhausted—not even thoroughly initiated. The value and importance of the author's work in the infra-red region of the spectrum are too well known to need any further diploma of merit at this time; moreover, it is impossible to deal in detail with the account of the many new observations described in the present monograph. There are three separate lines of work, namely, infra-red reflection spectra, transmission spectra, and emission spectra. To these is added a valuable chapter on the instruments and methods used in the work. Two points of special interest may be noted, one of which is the relation between the maxima in the reflection spectra of the carbonates and the atomic weight of the metal, where the maxima steadily shift towards the red with increase in molecular weight. The second point of interest is the infra-red spectra of the colloidal metals in relation to the coloured glasses. There is no doubt that, quite apart from its general importance, Prof. Coblentz's work, owing to the range of spectrum dealt with, will have considerable bearing upon the relation between absorption and chemical constitution.

A new form of gearing, which has been invented by Mr. Jules Lecoche, and is being introduced by the Anglo-Foreign Inventions Syndicate, Ltd., of 10 Camomile Street, E.C., is illustrated in *Engineering* for July 2. The gearing essentially consists of two wheels having spiral or helical teeth which run out of contact, a mechanical clearance of about 1/32-inch separating the tops of the teeth on the two wheels. One of the wheels is provided with field magnets in such a way that a magnetic flux is generated between its teeth and the corresponding teeth on the other wheel. The mechanical drive is obtained entirely by means of the magnetic flux, the form of the teeth being such that, when the wheels are running together, the tops of any two teeth in magnetic mesh lie immediately one over the other, and follow each the same path. As two teeth leave each other, the magnetic flux will be transferred from the leaving teeth to the approaching teeth, thus ensuring continuity of drive. As there is no contact there can be no friction; and as the power consumed in the field coils is only about 3 per cent. of the power transmitted, a gearing efficiency of about 97 per cent. is attainable. Another advantage lies in the high speed of transmission possible. Ball bearings are used for the spindles, an example at present being shown in London by the Albany Engineering Company, of Ossory Road, S.E., having a gearing loss of 1·79 per cent. and an over-all efficiency of more than 90 per cent. The advantages of this gear should open a wide field for its applications.

We have received a copy of the report of the Indian Association for the Cultivation of Science for the year 1907. The association arranges courses of lectures upon scientific subjects, maintains a laboratory and library, and conducts an annual examination of candidates for prizes and medals. Interesting speeches were given at the annual meeting held last November, and altogether the association appears to be doing useful work in spreading a knowledge of and interest in science.

The July number of the *Fortnightly Review* contains an article by Dr. Marie C. Stopes entitled "An Expedition to the Southern Coal Mines." Dr. Stopes was sent by the Royal Society for special palæobotanical work to Japan, where she spent a year and a half in close touch with the Japanese. In addition to devoting a large part of her stay to research work in the Imperial University, Dr. Stopes travelled widely on tours of inspection and investigation. She entered a great many of the coal mines in Japan, and penetrated to the heart of the country searching for interesting specimens. Her article is in the form of a diary, not written for scientific workers, but intended to supply a series of pictures of life in many parts of Japan.

OUR ASTRONOMICAL COLUMN.

Radial Motion in Sun-spot Vapours.—Referring to some comments and queries, by Mr. Buss, in the May number, Mr. Evershed gives further details of the radial motion discovered in sun-spot vapours, in No. 411 of the *Observatory*. He has found that when the slit of the spectroscope does not bisect the spot symmetrically, but crosses the penumbra on the side of the spot nearer to the centre of the sun's disc, the lines are always convex towards the violet; whereas if the slit crosses the opposite side of the penumbra they are convex towards the red. That the line displacements are due solely to motion is shown by the change in position angle of the maximum shift as the spot traverses the disc. The maximum displacement is always such as to indicate that the maximum motion is along the radius, but the observations are not yet sufficiently delicate to disprove the existence of a superimposed, relatively slow spiral motion; on the other hand, there is no direct evidence that such an outward spiral motion exists.

Recent work shows that the radial motion is confined to the lower chromosphere—the "reversing layer." In the higher chromosphere the absorption lines H_3, K_3, and probably $H\alpha$, are usually twisted in the opposite direction to the other lines, thus indicating an inward movement of the vapours. This apparently agrees with Prof. Hale's observation of a dark flocculus moving towards the centre of the spot. There is still an apparent discrepancy between this radial movement and the vortex motions invoked by Prof. Hale to explain the Zeeman effect in sun-spot lines, and, according to Mr. Evershed's results, the vortex, if it exists, either above or below a sun-spot, does not affect the absorbing gases of the "reversing layer" in the penumbræ of spots.

BINARY STAR ORBITS.—In No. 4, vol. xxix., of the *Astrophysical Journal*, Father Stein discusses the photometric observations of the binary star *RZ* Cassiopeiæ on the assumption that it is an Algol variable. Assuming that the orbit is circular, and that the mean densities of the two components are equal, he finds that the mass of the system is 1·002 the sun's mass, the mass of the bright body, the primary, being 0·040 sun's mass; the radius of the bright body is 1·43, and that of the satellite 1·17 the sun's radius, the mean density of each body being 0·222 that of the sun's density. The centres of the two bodies are separated by 0·022 astronomical unit.

No. 13, vol. i., of the publications of the Allegheny Observatory, contains a discussion of the orbits of the spectroscopic components of 2 Lacertæ, by Mr. R. H. Baker. In spectrograms of this star taken on fine-grained plates, the lines of the components are, at certain epochs, separated, and it is interesting to note that the "blend" curve differs considerably from various parts of the primary curve, thus suggesting that for all spectroscopic binaries having a large range of velocities it is desirable that spectrograms should be taken on the finest-grained plates obtainable at the epochs of maximum velocity. The measurement of such plates might, supposing the lines to be separated, considerably modify the results obtained from coarser-grained plates on which the component spectra are inseparable. Mr. Baker finds the period of this star to be 2·6164 days.

MICROMETRIC MEASURES OF DOUBLE STARS.—In No. 4336 of the *Astronomische Nachrichten*, Mr. Phillip Fox publishes the measures of a number of miscellaneous double stars made with the 12-inch and 40-inch refractors of the Yerkes Observatory. The 40-inch is not used regularly for this work, but is employed when conditions are not suitable for securing parallax plates. Mr. Fox's observing-list is mainly made up of Holden double-stars, about half of which have now been observed, but these measures are reserved until the complete list is ready. The present publication includes the measures, made during 1907–8, of about 130 multiple systems.

THE IDENTITY OF COMETS 1908*a* AND 1908*b* (ENCKE).—In No. 4332 of the *Astronomische Nachrichten*, Dr. Ebell discusses the question of the identity of comet 1908*a* with Encke's comet. It will be remembered that when 1908*a* was first discovered by Prof. Wolf, it was announced as being Encke's comet, but the latter was not discovered until May, 1908, when it was found by Mr. Woodgate at the Cape Observatory. Dr. Ebell finds that both the motion and the brightness of comet 1908*a* are against the theory of identity with Encke's, for the latter was, theoretically, much fainter, about 3·5 magnitudes, than the observed object. There still remains the question as to whether 1908*a* was a fragment of Encke's, split off by some accidental encounter or explosion, and this question is being investigated at Pulkowa.

COMET 1909*a*.—Photographs of comet 1909*a* (Borrelly-Daniel) were obtained at the Greenwich Observatory, with the 30-inch reflector, on June 22 and 30, and the resulting positions are published in No. 4337 of the *Astronomische Nachrichten*. The same journal also contains a set of elements computed by Prof. R. T. Crawford, and elements and ephemeris calculated by Prof. Kobold.

THE KING ON INCREASED PROVISION FOR ADVANCED SCIENTIFIC INSTRUCTION AND RESEARCH.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY.

THE King laid the first stone of the new buildings of the Imperial College of Science and Technology on Thursday, July 8. The plans exhibited were those of the Royal School of Mines and an extension of the City and Guilds of London Institute, which will occupy the block of ground at the corner of Exhibition and Prince Consort Roads, South Kensington, and extend as far west as the Royal College of Music. The Imperial College of Science and Technology consists at present of the Royal School of Mines, the Royal College of Science, and the City and Guilds of London Institute, and is administered by a Board of governors appointed by Royal charter, and under the presidency of Lord Crewe.

It is interesting to note that the first building to be erected by the governors of the Imperial College is the much-needed one for the Royal School of Mines, and that the funds for the purpose have been provided chiefly by the late Mr. Alfred Beit and Sir Julius Wernher, of the mining house of Messrs. Wernher, Beit and Co.

The life of the Royal School of Mines has been one of many vicissitudes. Even from the time of its foundation in 1851, difficulty has been experienced in providing adequate accommodation. The move from Jermyn Street to South Kensington, which began in 1872, and, as was stated by Lord Crewe in his address to his Majesty, was not completed until 1880, furnished better accommodation for subjects such as chemistry, physics and mechanics; geology was probably in but little worse position than in Jermyn Street, and metallurgy had better laboratories than before, but mining, which was the last to move, has had but poor quarters. The demand for scientific education, however, has grown so rapidly that even the laboratories for chemistry and physics soon became too small, and the fine buildings in Imperial Institute Road, in which the Royal College of Science has its chemical and physical laboratories, have for the past two years received the students. The buildings now to be erected will comprise well equipped laboratories, museums, lecture- and classrooms, and drawing offices for the mining, metallurgical, and geological sections, and, in a one-storied building, 250 feet by 120 feet, under a separate roof, ore-dressing testing works and an experimental metallurgical laboratory are to be erected, the equipment being provided by the Bessemer Memorial Committee.

The extension of the City and Guilds of London Institute will include a laboratory for the study of hydraulics, equipped by Mr. G. Hawksley, but the extension is chiefly necessary on account of the number of students having already outgrown the space available, and the introduction of advanced courses on special subjects requiring more room. Here, again, top-lighted courts will allow the extension of the mechanical laboratories of the institute. The Goldsmiths' Company has provided a large sum towards this work.

In the course of his reply to the address delivered by Lord Crewe on behalf of the governors, professors, students, and staff of the Imperial College, the King said:—

"The concentration of various associated colleges into one institution, which was effected by our Order in Council of July, 1907, has always seemed to me to be an admirable scheme for the furtherance of scientific instruction, which my dear father had so much at heart; and the names which appeared in the first list of the members of the governing body were sufficient in themselves to give the college a very high status in the educational world.

"The purposes of the college, as stated in the charter, are to give the highest specialised instruction and to provide the fullest equipment for advanced teaching and research in various branches of science, especially in its application to industry. In recent years the supreme importance of higher scientific education has, I am happy to say, been fully recognised in England; and as time goes on I feel more and more convinced that the prosperity, even the very safety and existence, of our country depend on the quality of the scientific and technical training of those who are to guide and control our industries. The rapid growth of knowledge makes it necessary for the teacher of any branch of applied science to be a specialist of a high order, and the most accomplished specialist cannot impart the full advantage of his knowledge without that complete provision of apparatus for research and instruction which this college will supply.

"The college has already given admirable results, and we may well look for a steady increase in the number of students and in the efficiency of the instruction provided.

"The thanks of the country are due to those public-spirited donors through whose generosity a large portion of the funds have been provided for this great work, and I join in your appreciation of their munificence. I think it is especially fitting that the great discoveries of the late Sir Henry Bessemer, to which the remarkable development of the engineering industries in the last half-century is largely due, should be commemorated by the equipment of the new laboratories of this institution."

University of Birmingham.

On July 7 the King and Queen, accompanied by the Princess Victoria, performed the opening ceremony of the new buildings of the Birmingham University. Inasmuch as the founding of the University on the initiative of Mr. Chamberlain has been effected almost entirely by means of money subscribed by the inhabitants of the Birmingham district, the occasion was appropriately made to partake largely of the nature of a civic function.

The characteristic note of the proceedings may perhaps best be given by some quotations from the King's speeches. In replying to the address from the Corporation, after warmly commending the public spirit of the citizens, His Majesty said:—"Great schemes such as that for providing your city with pure water have been undertaken in the past, and have been brought to a successful issue; but none is worthier of support or more far-reaching in its scope than the establishment and extension of the great University in which you have taken so important a part." Later, in reply to an address from the Chamber of Commerce expressing the recognition by the commercial and mercantile classes of the value of the advancement of higher education, his Majesty said:—"I am glad to learn that the commercial community have been faithful and generous supporters of the University. I feel assured that your expectations of advantages to be derived from the Faculty of Commerce in training the future captains of industry will be realised."

After a luncheon at the Council House, their Majesties drove, through roads lined with enthusiastic spectators, to the new buildings at Bournbrook, a distance of about three miles. The opening ceremony took place in the great hall of the University, which was occupied largely by members of the University and representatives of other educational bodies.

The University address was read by Sir Oliver Lodge, and the following characteristic passage may be quoted:—"Guided by our Chancellor, whose inability to be present on this memorable occasion we deeply regret, we have made no attempt to give an appearance of finality to our present undertaking. Rather do we regard it as capable of indefinite expansion. Whilst the field of scientific research is ever widening, and its discoveries demand yearly a fresh application to the facts of life, the claims of the humaner studies become none the less imperative; and in both these branches of human activity, which can only flourish side by side, we realise the need of continual development. But we believe that the work which we have begun, upon which this day your Majesties set the seal of your Royal approbation, can confidently be entrusted to the generosity and to the devoted service of the generations that are to come."

His Majesty, in replying, after paying a tribute to the Chancellor, proceeded:—"For the wonderful progress of higher education in the country we have largely to thank the great universities established in our principal cities. No nobler object for munificence can be found than the provision for the necessary equipment for such education; an equipment which, in view of the diverse and elaborate requirements of the modern schools of instruction, must be costly; but without which these schemes, however carefully designed, will prove fruitless. Such institutions as this are of paramount importance in enabling students to obtain in their native city instruction in science and technology, in art and mathematics, which in former days they were compelled to seek in places far distant from their homes, at an expense which in some instances they could ill afford. The universities also foster a wholesome rivalry, and encourage the growth of the highest form of public spirit. A man educated at this University will be a better citizen of Birmingham, and a better subject of the Empire."

At the close of the opening ceremony, their Majesties inspected a part of the departments of civil and electrical engineering.

THE SCIENCE COLLECTIONS AT SOUTH KENSINGTON.

THE question of the worthy housing of the science collections at South Kensington has been brought before the Government on several occasions during the last thirty years or so. The object of a deputation which waited upon Mr. Runciman at the Board of Education on Tuesday was again to endeavour to obtain an assurance that the Government will provide the money for the building of a museum in which the science collections can be exhibited as satisfactorily as are those of art. The deputation included distinguished representatives of the leading scientific societies and institutions, and the memorial which was presented was signed by the president and officers of the Royal Society, all its living past-presidents, and 128 of its Fellows distinguished in physical science; the Chancellors of the Universities of Cambridge, London, Glasgow, and St. Andrews; the Vice-Chancellors of the British universities; the presidents of scientific societies and institutions; professors of chemistry, physics, mathematics, astronomy, and engineering in all the British universities, university colleges, and principal technical schools and polytechnics; the directors of the chief polytechnics in London and in the provinces; and a very large and distinguished body of persons eminent in and interested in British science and desirous of its promotion.

There can be no doubt, therefore, as to the opinion of representatives of physical science upon the urgent need of satisfactory provision for the housing of the science collections. As Sir William Anson said in introducing the deputation, "the museum, which represents the application of science to material, should be placed in the same position as art and natural history by the Government of the country."

The collections should be in a suitable building, with room for rearrangement and expansion. A site is available at South Kensington if the Government will come forward with the offer of funds for the actual building; but in spite of the memorial and the deputation, Mr. Runciman did not give an assurance that the money will be forthcoming. He was sympathetic, and promised to place the matter before the Prime Minister and the Chancellor of the Exchequer, and with this result we must be satisfied for a while. A useful purpose has certainly been served by bringing the subject into public view. We can now only hope that the Government will rise to the opportunity and offer to the physical sciences, which are closely connected with the industries of this country, the same advantages for its collections as are already possessed by natural history and by art.

From a full report of the deputation in Wednesday's *Times* we make the subjoined extracts.

The memorial presented by Sir Henry Roscoe was as follows:—

"We, the undersigned, being deeply interested in the practice and progress of British science, desire to bring before you the importance of the proper housing of the Science Collections at South Kensington. The permanent buildings now erected provide accommodation for art collections only; to complete the scheme a suitable building for the science collections is a necessity. The formation of a science museum representative of all branches of physical science, both pure and applied, has long engaged the attention both of the Government and of British scientific men. So long ago as 1874 the Duke of Devonshire's Commission on Science strongly recommended the establishment of such a museum, and in their fourth report the Commissioners state:—'While it is a matter of congratulation that the British Museum contains one of the finest and largest collections in existence illustrative of biological science, it is to be regretted that there is at present no national collection of the instruments used in the investigation of mechanical, chemical, or physical laws, although such collections are of great importance to persons interested in the experimental sciences. We consider that the recent progress in these sciences and the daily increasing demand for knowledge concerning them make it desirable that the national collections should be extended in this direction, so as to meet a great scientific requirement which cannot be provided for in any other way.' Since these words were written a National Science Museum has been established, and the collections in it have been steadily enriched by many important acquisitions. These collections are at present housed in the old buildings at South Kensington known as the Southern Galleries and the Western Galleries. They now include models and copies of historical and modern philosophical apparatus of the greatest value to all interested in the progress of British science, and a large number of machines, instruments, and models of great interest as illustrating the origin and development of our most pregnant British inventions, together with such special collections as the unique series of models illustrating the history of shipbuilding.

"In 1876 the Royal Commissioners of the Exhibition of 1851 offered to the Government of the day a sum of 100,000*l.*, together with a site on the Commissioners' ground, for the proper housing of this collection, under the condition that the Government should undertake its maintenance. In 1878 the Commissioners repeated their offer, and in 1879 this was declined by the Government. In 1888 the land to the south of Imperial Institute Road, reaching to that conveyed to the Government in 1864 for the erection of the Natural History Museum, and containing 4½ acres, was sold to the Government for 70,000*l.* This land has now been in part permanently allocated to the main section of the new buildings of the Imperial College of Science and Technology and to the building in course of erection for the Meteorological Office and a post office. The remainder of the site is at present occupied partly by temporary buildings and partly by the old buildings—the "Southern Galleries"—which now afford accommodation for the machinery and naval architecture collections of the Science Museum. This portion of the site, adjoining as it does on the north the Imperial College and on the south the Natural History Museum, is well regarded as an ideal position for the long projected Science Museum, which would complete the magnificent group of museum buildings already erected at South Kensington.

"The cost of acquisitions for the current growth of such a science museum, it may be noted, is far less than that of a corresponding art museum. The value of art products increases rapidly with age, whereas the scientific implements, machinery, and apparatus, interesting from an historical point of view, have rarely any great commercial value. The art collections of the Victoria and Albert Museum are now in possession of splendid buildings. If the buildings provided for the science collections were equally worthy of the interests which they should serve, the objects now in the museum could be exhibited to much greater advantage. Moreover, those *lacunae* which mark sections of recent activity in discovery and invention would be more readily filled than they can be while the obviously temporary character of the accommodation suggests to those who hold objects of interest in the history and advance of science that the authorities have but little appreciation for such things.

"Other countries, notably France and Germany, have recognised the importance of preparing suitable buildings for their National Science Museums. In Paris the Museum of the École des Arts et Métiers has a world-wide renown; and a National German Science Museum is now being built in Munich at the cost of 300,000*l.* England, the mother of so many great inventions that have proved to be pioneers in industrial arts, stands alone in having made no adequate provision for exhibiting and arranging in proper order her unique collections. The undersigned venture to urge upon you that the time has now arrived for action. Land sufficient for the purpose is in the Government's hands, and the Royal Commissioners of '51 if approached by the Government with a definite building scheme would doubtless give it due consideration. The need is great, and the mass of British science workers will hail your favourable decision with gratitude."

In his remarks, Sir Henry Roscoe said that what is needed is a building adequate to the proper exhibition of the present collection, and one worthy of British science. The grant for science purposes is 1800*l.*; that for art 11,260*l.* The fact that with so small a grant the national science collections have reached so important and in many respects so unique a position has been partly due to the fact that the cost of acquisitions for the current growth of such a science museum is far less than that of the corresponding growth of an art museum. Land sufficient for the required purpose is in the hands of the Government, and the Royal Commissioners of 1851, so long ago as 1878, offered to contribute 100,000*l.* towards a building for the Science Museum. Sir Archibald Geikie said that the council of the Royal Society desired him to express its keen sense of the importance of the collections and the need for better housing for re-arrangement and expansion. Sir David Gill said that, confining his remarks principally to the astronomical collection, he was much impressed with its extreme value, as it included apparatus of all periods, from the earliest days down to the present time. Mr. Alexander Siemens, expressing the view of the Institution of Civil Engineers, said that in the interest of students of engineering it is of the utmost importance that the collections should be housed with plenty of space, and should be as complete as possible. Sir Hugh Bell, as president of the Iron and Steel Institute, said his national pride was hurt when he went through the building at South Kensington and saw the collections housed in a place erected about fifty years ago as refreshment-rooms or something of that sort. Paris, Munich, and Berlin are very much in advance of London in that matter. Dr. R. T. Glazebrook, director of the National Physical Laboratory, said that the physical collection at South Kensington is very inadequately housed and quite fails to represent the growth of that science in England. Mr. W. M. Mordey, president of the Institution of Electrical Engineers, said there is at present no adequate representation of their work in this country. Sir William Ramsay said it is practically impossible to gain any notion of the progress of chemistry from a visit to the collection. Sir George Darwin said that in going over the museum he was struck by two or three things—first, the great interest of the collection; secondly, the overcrowding of it; and, thirdly, the extreme deficiency of the buildings in which it is housed.

Mr. Runciman, in the course of his reply, said:—The memorial which has been presented to the Board of Education and to me on the subject of this museum is one of the most weighty memorials that I think has ever been received by any Minister. We not only provide, or intend to provide, an exhibition for the exposition and demonstration of the principles of science, but we provide illustrations of the applications of science and arts to industry, including models and actual examples of outstanding inventions which are of historical importance, and, as Sir Henry Roscoe has said, are absolutely irreplaceable. We have the greatest desire to maintain historical industrial processes, and we have special collections, such as those in which I myself am enormously interested—namely, naval architecture, models of machines, and astronomical instruments. The whole of these are of priceless value. But I quite recognise that they are in many respects incomplete; and I am also impressed with the fact, as indeed everybody is who knows the building in which that collection is housed, that the housing has a great deal to do with the collection in the buildings in their present state. I recognise that the collection, even at the present day, is dreadfully overcrowded. The best illustration of that lies in the fact that in the cases now erected in the museum we have found it necessary to provide for what may be called a basement exhibition. When one passes through the exhibition one sees a considerable number of persons kneeling down on the floor in order to see what is in the basement of these cases. Anyone who is responsible for the museum can hardly avoid being ashamed of that condition of things. It is true that some parts of the galleries were put up as temporary buildings. They were part of the exhibition, I think, of 1862, and it is remarkable that they have lasted so long. The whole difficulty is the very prosaic difficulty, I fear, of money and land. The South Kensington area, which now contains some of the most remarkable collections and some of the most valuable buildings in the world, has been very rapidly occupied. We cannot go south because of the Natural History Museum, and we are blocked on the north by the Imperial Institute, the Royal College of Science, and some of the other buildings, and I cannot at the moment see in what direction it will be possible for us to expand. The magnificent work which has been done in the direction of art on the other side of the road certainly sets the pace, and I recognise with you that it is pressingly necessary that we should have a new building for our great science collection at the earliest possible date. The question of funds is affected to some extent by the hint thrown out by Sir Henry Roscoe of assistance from the 1851 Commissioners. I cannot imagine any better work to which the Commissioners could devote their funds than in giving assistance in the construction of new buildings. For the moment I will say no more than that I will transmit to my colleagues and lay before the Cabinet, the Prime Minister, and the Chancellor of the Exchequer the very valuable statement which you made, and I will use my own personal influence, for whatever it may be worth, to impress on them the necessities of the case.

ESKDALEMUIR OBSERVATORY.[1]

WE have received the annual report of the observatory department of the National Physical Laboratory for the year 1908, which is noteworthy as being the first report issued since the establishment of the new magnetic and meteorological observatory at Eskdalemuir. Readers of NATURE will be aware that the advent of electric tramways to the neighbourhood of the observatory at Kew has greatly interfered with magnetic work there. The new establishment in Dumfriesshire is far removed from all industrial undertakings, and will thus be free from disturbing effects due to artificial causes.

So far as Eskdalemuir is concerned, the past year has been one of installation and experiment, and the report contains no results of observations. The superintendent, Mr. G. W. Walker, went into residence on May 11, 1908, and was followed shortly after by his staff, comprising observer, computer, mechanic, and mechanic's assistant. The first instruments to be set up were the Elliot unifilar magnetometer and the Dover dip circle, which were given to the laboratory by Sir Arthur Rücker. They are the instruments which were used by the donor and Prof. Thorpe in their magnetic survey of the British Isles in 1890. The first absolute measurements of horizontal force, declination, and inclination were made on May 29, and were continued for eight weeks, when some changes became necessary. Observations, made three times a week, were resumed in October, and have since formed part of the routine work of the observatory. The final determination of the azimuth of the fixed mark awaits the completion of the arrangements for the time signal.

The recording apparatus consists of a set of Eschenhagen magnetographs and a set of Kew pattern magnetographs made for the observatory by Mr. P. Adie. The former belong to the Admiralty, and are those used at the *Discovery's* winter quarters in 1902–4. Owing to damp, the magnetic house could not be used immediately, and the instruments had to be accommodated elsewhere. The Eschenhagen recorders were set up temporarily in the seismograph room. The Adie instruments were accommodated in the general laboratory, but the warping of the wooden supports has made satisfactory compensation for temperature changes impossible, and the point will have to be taken up again when the instruments are removed to their permanent positions.

For seismological work a twin-boom Milne seismograph is in use. Regular records have been obtained since September 24. Provision has also been made for carrying on the work of a meteorological observatory or station of the first order. The photographic barograph and wet- and dry-bulb thermograph have been lent by the Meteorological Office. They are the identical instruments which were formerly in use at Fort William Observatory, the base station of Ben Nevis. A Dines pressure-tube anemometer, a Beckley autographic rain-gauge, a Campbell-Stokes sunshine recorder, and barograph and thermograph of Richard pattern complete the outfit of ordinary meteorological instruments. Provision has, of course, been made for the usual control readings and for eye observations of weather phenomena. An Ångström compensation pyrheliometer has also been set up, and preparation has been made for recording the atmospheric electrical potential.

At Kew the usual observing and testing work has been continued. Summaries of the magnetic and meteorological work are given in the appendix. The results of measurements of solar radiation with an Ångström pyrheliometer, and of the temperature of the soil at depths of 1 foot and 4 feet, are given for the first time. The examination of the apparatus to be used at Eskdalemuir has formed an important part of the year's work, and we note also that Mr. W. Dubinsky, of the Pavlovsk Observatory, spent some time at Kew for the purpose of making comparisons between the Kew standard magnetometers and barometer and the standards in use in Russia. These comparisons were carried out in accordance with a general scheme for the international comparison of standards approved by the last International Meteorological Conference. The report concludes with the usual summaries of the magnetic results obtained at the observatories at Falmouth and Valencia.

[1] The National Physical Laboratory. Report of the Observatory Department Richmond, Surrey, and of the Observatory, Eskdalemuir, Langholm, Dumfriesshire, for the Year 1908, with Appendices. Pp. 53. (Teddington, 1909.)

THE IMPERIAL CANCER RESEARCH FUND.

THE annual meeting of the general committee of the Imperial Cancer Research Fund was held on July 9 at Marlborough House, when the Prince of Wales, the president of the organisation, took the chair.

The following are extracts from the report, which was adopted at the meeting:—

During the past year further correspondence took place with the authorities of the International Society for Cancer Research in Berlin, in which it has been suggested that the executive committee should re-consider the attitude hitherto adopted and join the International Society; and offering that the first International Congress should be held in London. The executive committee is of opinion that the decision arrived at is in the best interests of the scientific investigation of cancer, and accordingly it adhered to its position. At a subsequent date a petition was presented by the International Society for Cancer Research in Germany to the King, as patron of the Imperial Cancer Research Fund, asking that the decision might be reviewed, but His Majesty, after considering the facts submitted to him through the Foreign Office, expressed the view that the Imperial Cancer Research Fund has cooperated freely in the past, both with German and other foreign workers, and will continue to do so in the future.

It may be well to recall in this connection the extent to which the Imperial Cancer Research Fund has encouraged the investigations of independent workers both at home and abroad. As is well known, the material for experimental research is difficult and costly to obtain, and is beyond the reach of many who, but for the help given from this fund, would be debarred from participation in this branch of the research. Recognising that such help must be of the first importance, it has been the aim of the general superintendent, Dr. E. F. Bashford, with the entire concurrence of the executive committee, to distribute to all applicants who possess the necessary credentials the material accumulated with much labour and expense.

A satisfactory feature of the past year has been the recognition of the work of the fund by foreign investigators, as is shown by the number of applicants for permission to work under the general superintendent. It has been found impossible to concede all the requests, but gentlemen from Italy, Bukarest, New York, and Munich have been accorded full liberty to pursue their researches in the laboratories supported from the fund, and every facility has been given them. Special arrangements have also been granted to other workers to pursue certain specific investigations, and to certain foreign medical men to study the methods during a short visit to this country.

Reviewing the results of seven years' work on the comparative and experimental investigation of cancer, says the general superintendent in his report, one is struck by the difference between the nature of the problems before us seven years ago and of those now being considered, as well as by the freedom one feels in investigating the problems presented to-day, without the incubus of having to consider them from the standpoints of the many hypotheses now proved to be untenable. I do not think that too much is claimed by asserting that the arduous labour of the past seven years is gradually effecting, and in several respects has actually effected, a complete revolution in many aspects of the cancer problem. But it has done still more in opening up new vistas in biology. Seven years ago no one conceived it possible that portions of the mammalian organism could be kept growing for a period four times the length of life of the whole animal. But to-day the number of different kinds of tissues now being propagated separately make it theoretically possible that the majority of the tissues may be so grown and segregated. In other words, a living animal can be analysed into many of its living component tissues. The finer relations of various kinds of tissues to one another have been revealed by the application of the new methods. The biological alterations which living mammalian cells may undergo suddenly, as well as gradually, under the influence of experimental conditions, can now be studied. These and many other achievements in the field of general biology are the most important practical fruits which have accrued from the experimental study of cancer, upon which they have only indirect bearings. Ultimately they are bound to be of far-reaching general biological importance, although to-day they are merely the weapons that have been forged to attack cancer. Their further development and their utilisation for the solution of purely biological problems will probably precede the solution of many of the problems surrounding the nature and causes of cancer.

While some chance opportunity may yield results of immediate practical moment, the outlook on therapeutics in the meantime is in the direction of preventing dissemination or metastasis. The means of explaining why inoculated cancer can undergo spontaneous cure have been greatly enriched by the acquisition of fresh strains of propagable tumours behaving in a variety of ways in this respect, and presenting all gradations from some growing progressively in every animal inoculated, to others which, while developing for a time in every animal, are ultimately got rid of in all cases by the active resistance which the tumours induce against themselves.

In acknowledging a vote of thanks, the Prince of Wales said, during the course of his remarks:—"When presiding over this committee on previous occasions I have expressed the view that immediate results in regard to the cure of cancer must not be counted upon, but that rather we must look forward to steady and consistent progress in accordance with the experience of all scientific investigation. There can be no doubt, however, that the seven years' work already accomplished by the fund has brought about a complete change in the standpoints from which cancer should be studied. The many and varied lines of research are being pursued with the utmost perseverance, and every development, as it occurs, is followed up with the minutest care. During the past year an important work—the third scientific report—has been issued from our laboratories, and has been received with appreciation by all those at home and abroad who are competent to express opinions on these highly technical researches. This of itself marks a steady and valuable advance, and one of which we have every reason to be satisfied.

SCOTTISH EXPEDITION TO SPITSBERGEN.

Dr. William S. Bruce, of the Scottish Oceanographical Laboratory, is conducting another expedition to Prince Charles Foreland and other parts of Spitsbergen. One of the chief objects of the expedition is to complete the survey of Prince Charles Foreland which he began in association with H.S.H. the Prince of Monaco in 1906 and continued in 1907. He will also connect this survey with the mainland of Spitsbergen across Foul Sound, thus joining up the work of H.S.H. the Prince of Monaco, the late Captain Guissez, Captain Bourée, and Captain Isachsen in the north-west of Spitsbergen.

In 1907, Dr. Bruce brought back geological collections which have been described by Dr. G. W. Lee, of H.M. Geological Survey of Scotland, in a paper read to the Royal Physical Society, Edinburgh. These rocks and fossils entirely change previous opinions of the geology of Prince Charles Foreland, which was thought to be Silurian, whereas the rocks of Prince Charles Foreland consist, first, of a series of metamorphic crystalline schists, quartzites, and non-fossiliferous shales and hard grey limestones; secondly, of the fossiliferous limestone, probably permo-Carboniferous; and, thirdly, of grey shales containing the remains of dicotyledonous plants of Tertiary age. This time Dr. Bruce will carry with him a specially strong geological staff, and he hopes to clear up definitely the whole geology of Prince Charles Foreland and the neighbouring coasts of the mainland.

A special study of the botany of the Foreland will be made, Dr. Rudmose Brown carrying on that special part of the work. Dr. Bruce's staff consists of Mr. J. V. Burn Murdoch, who accompanied him to Prince Charles Foreland in 1907; Mr. John Mathieson, of H.M. Ordnance Survey of Scotland, who will take entire charge of the survey work; Dr. R. N. Rudmose Brown, late botanist of the *Scotia*, at present lecturer on geography, Sheffield University; Mr. Ernest A. Miller, who accompanied Dr. Bruce in 1906, and has since been attached to the meteorological and magnetical service of the Argentine Republic, having wintered at Scotia Bay, South Orkneys, during the last year. Mr. H. Hannay and Mr. A. M. Peach are the geologists, and Mr. Alastair Geddes will also accompany the expedition.

Dr. Bruce has chartered the steamer *Conqueror*, which is being specially re-fitted for the purpose, and has selected as master of the ship Captain Francis Napier, who has been kindly lent by Messrs. James Currie and Co., Leith. The expedition will leave Leith on Monday next, July 19, and is expected to be absent about two months.

We understand that this expedition, which will be Dr. Bruce's ninth visit to the polar regions, in no way interferes with his future Antarctic plans.

BIRD NOTES.

To the May number of *Naturen* Mr. O. J. Lie-Pettersen contributes an account of the life-history of the icterine tree-warbler (*Hypolais icterina* or *H. hypolais*) in Norway, where it is known as the "bastard nattergale." The dates of arrival in the neighbourhood of Bergen during a period of eleven years range from May 16–20 inclusive; birds of the year take their departure about the middle of July, and old birds some weeks later. By the middle of August nearly all have vanished, although an occasional straggler may be seen up to the end of that month, and one specimen was so late as September. Among the trees haunted by this species the hazel is the favourite; nesting takes place at the end of May or early part of June, and the period of incubation is thirteen days.

The April number of the *Emu* contains the minutes of a conference on Government bird-protection in Australia, held at Melbourne in November, 1908. A large number of species and subspecies were recommended for total protection, among these being lyre-birds, coachwhip-birds, emeus, and cassowaries. Owing, however, to the conference being unable to prepare a protection Bill, on account of the relations existing between the Commonwealth and its constituent States, it was eventually decided that the list of species and groups recommended for protection should be submitted to each State for favourable consideration. The urgent need for efficient legislation in this direction is made evident by a statement on another page of the same issue with regard to a recent wholesale slaughter of emeus.

To Mr. L. J. Cole we are indebted for a copy of a paper from the April number of the *Auk* on the importance of "tagging," or marking, birds as a means of studying their movements. It is pointed out by the author that we are still nearly as much in the dark as regards the true "inwardness" of migration as was the case a century ago, and that practically all our information on this subject is connected with mass-movements, so that we are ignorant of the wanderings of individual birds. The acquisition of a knowledge of such individual movements will, it is urged, aid, not only in the study of the general migration of species, but will assist in analysing the factors connected with migration as a whole. Active measures are being taken to inaugurate a system of bird-marking in the United States.

A similar movement has been started in this country by Mr. H. F. Witherby, the editor of *British Birds*, the details of which will be found in the June issue of that serial. The rings used for marking are extremely light, and do not in any way interfere with the bird's power of flight; each is stamped "Witherby, High Holborn, London," and bears a distinctive number, which in the smaller sizes is stamped inside the ring, and it is hoped that anyone into whose hands should fall a bird so marked will send the bird and the ring, or, if this is not possible, then the particulars of the number on the ring, the species of bird, and the locality and date of capture, to the address given.

Yet another centre for bird-marking is to be established at Aberdeen, as announced in the June number of *British Birds*.

The history of the rise and progress of ornithology in South Africa is presented in concise and popular form by Mr. A. Haagner in Popular Bulletin No. 2 of the South African Ornithologists' Union, recently published at Pretoria.

To No. 1670 of the Proceedings of the U.S. National Museum Mr. E. A. Mearns contributes a paper on new and rare birds from the Philippines, while in No. 1683 of this serial the same author gives a list of birds recently collected in the Philippines, Borneo, and certain other Malay islands.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Dr. E. Knecht has been appointed professor of technological chemistry in the University of Manchester.

From the *Observatory* we learn that Mr. J. Lunt, astrophysical assistant at the Cape Observatory, has been given the honorary degree of D.Sc. by the University of Manchester.

The annual meeting of the Midland Agricultural and Dairy College will be held on Monday, July 26, when the report on the year's work will be presented. The Duke of Rutland will address the meeting, and present the diplomas and certificates gained during last session.

Merely to mention the titles of four of the six articles contained in the February–March issue of the *Southern Educational Review* is to demonstrate the importance its editor attaches to the education of the negro. These articles are those on "Results of Attempts at the Higher Education of the Negro of the South," "The Essential Requirements of Negro Education," "Negro Rural Schools," and "Relation of the State to the Education of the Negro." The review is published at Chattanooga, Tenn., U.S.A., by the editor, Mr. H. Elmer Bierly.

It is proposed to establish in connection with the Paris University a system of exchange between French and foreign professors on similar lines to that which has for some time been in vogue between Berlin and America. M. Liard, rector of the university, has made an appeal to the friends of the university to create a fund for the purpose. M. Albert Kahn has placed at the disposal of the rector an annual grant of 30,000 francs for five years. The *Revue scientifique* states that two million francs are necessary for the success of the scheme.

It is announced by the New York correspondent of the *Times* that Mr. John D. Rockefeller has celebrated his seventieth birthday by giving 2,000,000*l.* to the General Education Board, which he founded in 1907 for the purpose of endowing American colleges and universities. The Board had already received 8,600,000*l.* from him. Some forty institutions of higher education have benefited by this trust, including Harvard and Yale Universities. The correspondent states that the Board's policy is governed by the belief that every city of more than 100,000 inhabitants should possess a college. The annual income of the Board is said to be 200,000*l.*

The accounts of the London Polytechnics for the year ended July 31, 1908, have been printed by the London County Council. The council's comptroller points out that the total ordinary receipts of these eleven institutions amounted to 212,495*l.*, an increase of 8,543*l.* over the previous year. The council's grants amounted to 80,503*l.*, or 37·88 per cent. of the total receipts. Grants from the Board of Education amounted to 38,229*l.*, or 17·99 per cent.; the sums received from the City Parochial Foundation were 27,704*l.*, or 13·04 per cent., and from City companies, &c., 6,929*l.*, or 3·26 per cent. The total ordinary expenditure on revenue account of all the polytechnics amounted to 211,950*l.*, an increase of 4,431*l.* over the previous year. Taking the results as a whole, so far as ordinary income and expenditure are concerned, there was a surplus of 545*l.* on the institutions, as compared with a deficit of 3,567*l.* in 1906–7. The amount expended on teachers' salaries reached 99,286*l.*, or 47·84 of the total expenditure; other salaries accounted for 25,509*l.*, or 12·30 per cent.; rent, rates, and taxes absorbed 11,586*l.*, or 5·58 per cent.; and apparatus and other educational appliances and furniture cost 18,327*l.*, or 8·83 per cent. of the total expenditure.

Teachers at agricultural schools and colleges in this country will be interested in the full and detailed syllabus issued by the Colorado State Agricultural College. The requirements for admission strike an English teacher as severe, and we can only congratulate the Colorado College if it is in a position to insist on the high standard they imply. The student is expected to have a certain acquaintance with English literature, gained by reading specified classics, and to be "familiar with the essential principles of rhetoric," including the following:—"choice of words, structure of sentences and paragraphs, the principles of narration, description, exposition, and argument." History is another essential subject, and the teacher who is preparing pupils for the college is informed that "the mere learning of a text will not give the preparation that the colleges desire. Effort should be made to cultivate the power of handling facts and of drawing proper deductions from data, to develop the faculty of discrimination, to teach the pupils the use of books, and how to extract substance from the printed page." The other subjects—mathematics, chemistry, physics, "other languages"—are to be taught in a similar spirit. Students so trained would form admirable raw material, and could have no great difficulty in taking the fullest advantage of the college course.

The Board of Education has issued [Cd. 4736] its regulations for technical schools, schools of art, and other forms of provision of further education in England and Wales which will come into force on August 1 next. No changes of special importance have been made as compared with those of last year. It is satisfactory to note that the amount of each of the royal exhibitions, &c., tenable at the Royal College of Art and the Imperial College of Science and Technology, South Kensington, has been raised from 50*l.* to 60*l.* per session. The old royal exhibitions and national scholarships tenable at the Imperial College of Science and Technology, have been combined as royal scholarships, the competition for which is to be conducted on the lines hitherto adopted for the award of national scholarships. In place of the former studentships-in-training in science, the Board of Education has established special studentships for teachers of science and technology who are qualified to enter on the third or fourth year of the course provided at the Imperial College. We notice that in future such teachers-in-training are not to be permitted to continue for more than two years in all at the Imperial College, a change which, in view of the need for highly qualified teachers in our provincial schools of science and technology, seems of doubtful wisdom.

THE new laboratories of St. Paul's School, built to celebrate the quatercentenary of the foundation, were opened on Wednesday, July 8, by Lord Curzon. In his address, Lord Curzon said he noticed how the school had kept pace with the spirit and reforms of the day, how during the last hundred years its numbers had increased from 153 to 600; how the modern side had grown to equal the older side in numbers and importance; and he told how great had been the achievement of the school under the late high master, Dr. Walker, one of the great school-masters of the nineteenth century. Lord Curzon went on to say that we lived in an age of self-depreciation, of a too great self-depreciation. Foreign critics were always coming to our public schools to learn how, having their superior equipment and their excellent organisation, they might obtain also "that training in character, that sense of moral responsibility, that spirit of civic patriotism, that ordered sense of personal liberty which were among the chief and most honourable characteristics of our public school system." So while content to learn from others we were not to forfeit that in our educational system which had done so much in the civic government of the country and the empire. The Bishop of Manchester referred to the conditions, so different from those obtaining now, under which he had learnt at St. Paul's School; yet he had learnt there that most valuable of lessons, to think. The high master, Dr. Hillard, said that St. Paul's had taken its full share in all those changes in educational method which began with Arnold's life at Rugby.

SOCIETIES AND ACADEMIES.

LONDON.

Geological Society, June 16.—Prof. W. J. Sollas, F.R.S., president, in the chair.—The Carboniferous Limestone of County Clare: James A. **Douglas**. The district forms the westernmost limit of the central Carboniferous Limestone plain of Ireland. The area, for the purposes of description, is divided into two main districts. The northern region is formed by an elevated plateau of Viséan Limestone, which rises on the north and east in terraced cliffs, but to the south-west dips below the "Coal-measure" series. The surface is of bare rock, devoid of vegetation. The southern district is not formed of limestone; the high ground on the east is of Old Red Sandstone and Silurian rocks, that on the west of Coal-measures. The older formations appear as two anticlinal flexures, forming the mountains of Slieve Aughty and Slieve Bernagh. The margin of the syncline is formed by Tournaisian shales and limestone, while the Viséan limestones occupy the core. The limestone fauna show that the Geological Survey boundary between the Upper and Lower Limestones corresponds with the transition from a Tournaisian to a Viséan fauna, and the Middle Limestone contains a fauna distinct from that of the Upper, although they are not separable on lithological grounds. The Old Red Sandstone is succeeded by a series of sandy shales containing brachiopods characteristic of the Cleistopora zone; at the base are found modioliform lamellibranchs. The Zaphrentis zone is well developed. The most remarkable portion of the whole sequence is included in the Syringothyris zone. These beds show evidence of deposition in shallow water. The fauna is compared with that of the Waulsortian phase of Belgium. The incoming of a Viséan fauna is well marked at the base of the Seminula zone; in the middle of this zone occurs an important bed of oolitic limestone, with abundant gasteropods. The Dibunophyllum zone attains a thickness equal to that of the Midland area.—The Howgill Fells and their topography: J. E. **Marr**, F.R.S., and W. G. **Fearnsides**. The Howgill Fells form a monoclinal block, from which the Carboniferous rocks have been denuded. The northern slope probably corresponds with the sloping plane of unconformity between the Carboniferous rocks and Lower Palæozoic strata. On the south the slope to the Rawthey is along a block-fault. The chief drainage was originally north and south from the watershed at the summit of the block. The tract was glaciated by its own ice, but "foreign" ice was conterminous with the local ice on all sides. The rocks are, from the point of view of erosive effects, nearly homogeneous. The chief erosive effects of glaciation were the truncation of spurs, the formation of conchoidal scoops in the concavities of the valleys, a general widening of the valleys, and but slight deepening. A feature of interest is the contrast in this small area between these glaciated valleys and others of V-shaped cross-section, which are typical water-carved valleys unaffected by glacial erosion.—A new species of Sthenurus: L. **Glauert**.—Some reptilian remains from the Trias of Lossiemouth: D. M. S. **Watson**. The fore-limb of *Ornithosuchus woodwardi* is shown in a specimen in the Manchester Museum. Ornithosuchus is restored as an animal walking on all fours, with the head carried rather low. The proportions are identical with those of Ætosaurus. A description is given of the skeleton of a very small reptile, interesting as recalling Ætosaurus in its armour.—Some reptilian tracks from the Trias of Runcorn (Cheshire): D. M. S. **Watson**. Four types of tracks which occur on the slab of sandstone from Weston Point, described in 1840 by Dr. Black, are discussed in this paper. It is suggested that some of these prints may quite well belong to such thecodonts as Ornithosuchus.—The anatomy of *Lepidophloios laricinus*, Sternb.: D. M. S. **Watson**.

Linnean Society, June 17.—Sir Frank Crisp, vice-president, in the chair.—The growth of a species of Battarea: J. G. Otto **Tepper**.—The deposits in the Indian Ocean: Sir John **Murray**.—The *Sealark* Penaeidea, Stenopidea, and Reptantia: L. A. **Borradaile**.—The *Sealark* Lepidoptera: T. B. **Fletcher**.—Report on the Porifera collected by Mr. C. Crossland in the Red Sea, part i., Calcarea: R. W. H. **Row**.—The African species of Triumfetta, Linn.: T. A. **Sprague** and J. **Hutchinson**.—New species of Malesian and Philippine ferns: Dr. H. **Christ**.—The acaulescent species of Malvastrum, A. Gray: A. W. **Hill**.

DUBLIN.

Royal Dublin Society, June 22.—Dr. J. M. Purser in the chair.—The fossil hare of the ossiferous fissures of Ightham, Kent, and on the recent hares of the *Lepus variabilis* group: M. A. C. **Hinton**. The paper describes the fossil remains of *Lepus variabilis*, Pall., obtained from the rock fissures at Ightham, and deals with the osteology of the recent and fossil hares of the *L. variabilis* group. The Pleistocene hare of England is referred to a new subspecies, *L. variabilis anglicus*, which is to be regarded as the immediate ancestor of *L. variabilis hibernicus*, its relationship with the existing Scotch form not being so close. The subspecies *anglicus* and *hibernicus* are shown to be the most primitive members of the *variabilis* group. The most important conclusion reached is that, contrary to the prevalent view, the *variabilis* group of hares has originated in temperate latitudes, and not in the high north.—The value of benzidine for the detection of minute traces of blood: Prof. E. J. **McWeeney**. The author began by explaining the chemical nature of benzidine, which is a di-*p*-diamino diphenyl. This substance, when dissolved in acetic acid and brought into contact with blood in presence of H_2O_2, at once undergoes oxidation with formation of a brilliant blue colour. The reaction is in principle the same as that with guaiacol, the old-fashioned Van Deen's or Schönbein's guaiacum test. The colour base from guaiacol differs from the benzidine colour-base in the same way as an amine (aniline) differs from a phenol, or an aurine from a rosaniline dye. The test is ten-fold more delicate than that with guaiacum, and detects blood in solution as weak as 1/500,000; but for medico-legal purposes it is preferable to bring particles of the suspected matter into contact with the reagent, when each granule, if blood, at once strikes a most brilliant blue. The reaction can be observed under the microscope. The test worked well with blood-stains many years' old, and seemed to be independent of the nature of the substratum. Controls, and a time limit of about a minute, were essential, and the sensitiveness of each batch of benzidine had to be worked out beforehand. Of all the substances tested, none gave the typical blue colour so speedily as blood, save fresh vegetables and fruit, which at once struck an intense blue, at first limited to the fibro-vascular bundles. Boiling deprived them of this power, owing to the destruction of the oxydase, whereas blood solutions gave the blue reaction at once after five minutes' boiling. The author recommended this test to the attention of medical jurists.

Paris.

Academy of Sciences, July 5.—M. Émile Picard in the chair.—Some new trialkylacetophenones and the trialkylacetic acids derived from them: A. **Haller** and Édouard **Bauer**. It has been shown in a preceding communication that dialkylacetophenones can be converted into trialkylacetophenones by treatment with an alkyl iodide in benzene solution in presence of sodium amide. These trisubstituted ketones, when further heated with sodium amide in toluene give a nearly quantitative yield of the amide of the trialkylacetic acid, together with benzene. In the present paper alkyl groups of high molecular weight are introduced. It has been found that on treatment with sodium amide these trialkyl ketones always give the fatty amide, the expected change into benzamide and the trialkylmethane not being effected. The preparation and properties of several new ketones are described.—The tectonic relations of the island of Elba with Corsica, and the situation of the latter in the Alpine chain: Pierre **Termier**.—The new *Recueil* of levellings of Russian railways as a basis for the hypsometry of the country: J. de **Schokalsky**.—Central Asiatic Russia and the level of the lake basins: J. de **Schokalsky**. There is evidence that the levels of the Siberian lakes are slowly rising. This is connected with the fact that the annual rainfall for the last twenty years has been slowly increasing. It is possible that there are alternate dry and wet periods in Siberia, and that at the present time the wet period has passed its maximum.—M. J. C. **Kapteyn** was elected a correspondant in the section of astronomy.—Occultations of stars observed at the Observatory of Lyons with the Brunner 16-cm. equatorial during the eclipse of the moon of June 3: J. **Guillaume**.—The summation of Dirichlet's series: Marcel **Riesz**.—The singular integrals of certain algebraical differential equations: B. **Gambier**.—Linear differential equations and uniform transcendentals of the second order: René **Garnier**.—Some inequalities having a bearing on the theory of elastic vibrations and electrical vibrations: A. **Korn**.—The conductivity of a gas at atmospheric pressure under the influence of a high alternating voltage: A. **Chassy**. The conductivity of a gas increases continuously with the voltage, and it is only for the highest voltages well above the critical voltage that the capacity of the gas condenser is the same as that which would be obtained if the gas were replaced by a liquid conductor. It is possible that under these conditions the gas is a true conductor and follows Ohm's law.—The radio-activity of potassium salts: Émile **Henriot** and G. **Vavon**. The minute radio-activity shown by potassium salts would appear to be a property of the potassium atom, since all attempts to concentrate the radio-activity by a series of fractionations failed. This confirms the results of Campbell and MacLellan. The rays have been identified with the β rays.—Tautomeric changes elucidated by means of the magnetic rotatory power: P. Th. **Muller** and M. **Thouvenot**. A differential method was employed to increase the sensitiveness of the measurements. Experiments were made with methyl cyanacetate and its sodium salt and with acetoacetic ester and its sodium derivative. The results indicate a change in the internal structure when the molecule passes into the sodium derivative.—The chlorides of silicon: A. **Besson** and L. **Fournier**. THE DRESSING OF MINERALS.

The Dressing of Minerals. By Prof. Henry Louis. Pp. x+544. (London: Edward Arnold, 1909.) Price 30*s*. net.

THE author says, in his preface:—

"The object of the present work is to give an account of the theory and practice of the dressing of minerals, which will, I hope, prove useful to the miner or metallurgist who desires to understand the principles upon which this art is based, as also to the manufacturer who supplies the necessary appliances, and above all to the student who is preparing for either of the above professions." . . . "I have disregarded the time-honoured division which would make separate branches of the dressing of ores, and the cleaning of coals."

The first impression produced on reading this statement is that the new departure is warranted; that there are many points in common in the two branches, and that the comparison of practice under the different conditions would be of an illuminating character. The further perusal of the book, however, seems hardly to bear out this promise, and the joint treatment of the two branches rather tends to confusion, for the cleaning of coal involves the use of so many methods that are inapplicable to ores and *vice versa* that, if the two branches are to be treated in the same book, they should at least be dealt with under different sections.

Difficulties, inherent to the method adopted of dealing with the subject, are found throughout the book, and it is practically only in the chapter on general construction of dressing works that any clear differentiation between coal and ore dressing appears. It may be that the manufacturer should be acquainted with the machines used in both classes of work, and even that the student should acquire a knowledge of, and be able to draw comparisons between them, but that coal-miners should be called upon to study the various forms of rock-breakers, stamps, and other crushing mills and fine grinders seems unnecessary.

The book is well written and interesting, more especially, perhaps, in those parts that deal with theoretical considerations which relate to the construction of the machines. The designs of various machines are illustrated by excellent plates, and leading dimensions are often given, as well as the cost of the machines and manufacturers' figures regarding capacity. The latter are sometimes apt to be high; for instance, it is stated on p. 140 that a pair of Krom rolls 26 inches diameter by 15 inches face will crush about two tons of average ore per hour to about 30 mesh.

Relatively little information, however, is given as to setting up machines, their adjustments or running, the general conditions that have to be fulfilled or the general care of a dressing plant. Early forms of machines and historical references have received a good deal of attention, possibly more than they deserve, while in many cases modern forms have been passed over with brief mention, and a statement that they have not been long enough in use to enable an opinion to be formed regarding their value.

The treatment of the subject is divided into general considerations; volumetric sizing; sorting and washing; comminution; separation by specific gravity; appliances depending essentially on vertical fall; jigs; horizontal current separators; shaking tables; pneumatic, magnetic, and electrostatic separation; separation by surface tension; accessory appliances and general construction of dressing works.

It is, perhaps, in the chapter on volumetric sizing that the treatment of coal and ores together is most objectionable. It is sometimes difficult to gather whether the machine spoken of is used for coal or ores, and although, of course, many of them could be used for both, there is a more or less clear line of distinction between the two. To find a Wilfley impact screen described between the Klein screen and Zimmer conveyor screen seems curious. Trommels are said to be satisfactory to $\frac{1}{16}$-inch mesh. In the chapter on comminution such varying machines as rock breakers, rolls, Huntingdon mills, ball mills, tube mills, and disintegrators have been dealt with all too shortly. The Griffin mill is passed over in one paragraph, in which it is described as "like the Huntingdon mill with a single large roller which is caused to revolve on its spindle by means of gearing," but the construction, mode of action, and causes of crushing are so different in the two machines that the Griffin certainly merits a fuller description.

It seems questionable whether vanners should be included under the title of shaking tables, and no distinction is made between the condition of a pulp adapted for a vanner and that for a shaking table. The number of discussions that have taken place, and tests that have been made to prove whether it is better to classify the pulp or not before treatment on vanners, do not appear to be mentioned, while an authoritative pronouncement on the subject would have been of interest.

The subject of pneumatic separation has been treated more fully than it appears to deserve, and machines described which have certainly not warranted their existence. Magnetic separation has also received a good deal of attention, and many machines are figured which are used both for strongly and feebly magnetic substances.

In dealing with separation by surface tension, the author says it is impossible to offer correct or satisfactory explanations of the observed phenomena. He, however, presents an historical account of the development of the processes which depend upon this property, and briefly refers to several of the flotation processes. He has, however, only described the Elmore oil process and the Elmore vacuum process in any detail, from which it would seem that, in his opinion, they only are worthy of consideration. The chapter on accessory appliances passes from tipplers to various ore bin gates, then comes back to creepers, and returns to various conveyors of the belt, bucket, scraper, and screw types. Car and bucket elevators and tailings-wheels are dealt with, as well as ore feeders, and the chapter is finished with a few words on weighing and sampling.

There is a great deal of varied information contained in the book, but it would have been better to confine the subject to one or other of the branches referred to in the opening paragraph.

DUSTLESS ROADS.

Dustless Roads. Tar Macadam: A Practical Treatise for Engineers, Surveyors, and Others. By T. Walker Smith. Pp. xi+225. (London: Charles Griffin and Co., Ltd., 1909.) Price 10*s.* 6*d.* net.

THE growing use of motor-cars, and the destructive action due to the rapid speed at which they are driven, and the sucking action of the indiarubber tyres on the surface of the roads, has rendered a change in their management necessary.

It is the almost unanimous opinion of road experts that, in order to preserve the surface of the roads in good condition, it is necessary that some kind of bituminous material must be used for binding the stones of the macadamising, which, while cementing them together, will also give a waterproof and comparatively dustless surface.

The book under notice has, therefore, been published at an opportune time, as the method of repairing roads described in it, which has been more or less successful, has been so far only of a tentative character, the work not being carried out on any scientific basis, but very much by the rule of thumb.

The author, who was borough engineer at Barrow-in-Furness for several years, had under his charge many miles of macadamised roads subject to motor traffic, and devoted his attention to experimenting and trying to find out the best means of solving the difficult problem of keeping these roads in good order, and preventing the creation and spreading of dust, at a reasonable outlay. The results of his experience are given in the book under notice. The author, however, not content with his own experience, has also collected the opinions of a large number of road surveyors throughout the country as to the advantages and disadvantages, and cost of tar macadam, the answers to the queries submitted being given in the tables contained in the book.

The subjects dealt with are divided into fifteen chapters relating to tar macadam as a remedy for dust nuisance; the necessity for standardisation in construction; tar; aggregates for tar macadam; preparation and laying; mechanical mixing; effect of wear and tear; scavenging, watering, and maintenance; camber, gradient, noiselessness, and hygienic advantages; tractive effort; statistics of road mileage; cost of maintenance; and tar spraying. There are twenty-four illustrations and a tabulated analysis of the replies to queries.

The author shows that the binding material used in the making or repair of macadamised roads is the crux of efficient road maintenance and the prevention of dust. His opinion is that it is absolutely necessary, if macadamised roads are to meet the needs of present-day traffic with the searching demands that motor traffic makes on the surface of the road, that a bituminous binding or matrix should be employed. He points out that so far, although this fact is fully recognised, no scientific study has been made to standardise the materials used, and the proportion and quality of this material:—

> "Thus the matrix is usually prepared as it seems best to the individual in charge of the tar boiler who uses anything that comes from the local gas works; who boils it as long as he thinks necessary, and adds to it whatever he thinks may improve it in the way of pitch or creosote. It is a subject in which the personal factor has entered to an exceedingly great extent, and each man acts more or less as it seems best to him in his own mind."

The aggregates for tar macadam are also fully dealt with. The author points out that as the tar binding cements the stones together, the abrasion caused by friction in water-bound macadam is thus absent, the properties of noiselessness, elasticity, and resilience being secured. The only portion of the road material which is subject to any considerable wear is the surface, which has to bear the friction due to the rolling of the wheels, and also the impact of the horses' feet. It is, therefore, contended that the use of granite or other similar expensive material is not necessary for the lower coat, which consists of from 80 to 85 per cent. of the whole; but that where the road is only subject to moderate traffic the lower layer may consist of hard limestone or slag, either of which material holds the tar better than granite; the upper layer, which has to bear the surface wear and tear, being composed of granite. The author's experience leads him to the conclusion—

> "that it is an absolute waste of money to put such good material as granite in the bottom when a less costly material will do perfectly well when armoured with a good coating of tarred granite."

The patent processes known as "Tarmac" is described. The makers of this road material have expended upwards of 20,000*l.* in the construction of works and plants at Wolverhampton. The aggregate used is slag, the tar is distilled before using, and the mixing is done by machinery. The author, however, does not seem to think that it has any special advantage over ordinary tar macadam mixed locally when this is done in a proper manner. In the tables the cost of the materials and of mixing and laying is given for a great number of localities. As an average this may be taken as from two shillings to half a crown per square yard for a coating of 3½ inches of slag and hard limestone for the bottom layer, and half an inch of tarred granite for the surface coat. The general opinion appears to be that there is a saving in the cost of maintenance of roads where tar macadam is used in place of water-bound macadam, in some cases amounting to as much as 75 per cent., the average, however, being put at 37½ per cent.

With occasional tarring and sanding of the surface, a tar-macadam road, so far as the lower layer is concerned, is practically everlasting. The surface where there is much traffic requires re-covering about once in four years. Instances are given from the author's own experience where roads having a fair amount of traffic "have been as good at the end of six years as when first covered, and so far as can be seen will need very little for another six years."

This book ought to be carefully studied by all surveyors having charge of roads subject to motor traffic.

VECTORIAL GRAPHICS.

Vectors and Vector Diagrams applied to the Alternating Current Circuit. By W. Cramp and C. F. Smith. Pp. xvi+252. (London: Longmans, Green and Co., 1909.) Price 7*s*. 6*d*. net.

NOT many years ago a certain type of journalist used to compare and contrast the theorist and the practical man, to the demolition of the former and the apotheosis of the latter. Fortunately, such an attitude of mind is no longer possible. The merely practical man could never have constructed the Forth Bridge, nor launched the *Mauritania* on her record-making career. Innumerable examples might be given of the necessity of true theory in the economical designing of all kinds of machinery; but probably there is nothing that better proves how much mathematical science lies at the foundation of modern methods than electrical applications, especially those that have to do with the alternating current. The whole history of the development of the transformer and the alternating-current motor is simply the realisation of the solution of a differential equation given long ago by Maxwell. In this realisation the first great steps were taken by Heaviside, who introduced the terms impedance, admittance, reluctance, &c., giving a new precision to the ideas involved. By a mathematical extension of meaning the symbols which entered into the electrical equations of steady currents became applicable to the corresponding cases of sinusoidal currents. Stated in purely mathematical language, this transition depended on the properties of the complex variable.

Thus, to take the simplest case, Ohm's law $RC=E$ for steady electromotive force becomes Maxwell's expression $(R+L d/dt)C=E$ when E is variable. Representing a sinusoidal electromotive by the exponential of the imaginary ipt, we get the solution in the form $(R+iLp)C=E$, where C and E now stand for the amplitudes of the varying quantities. This complex quantity which operates on C may be treated analytically like the real quantity R in Ohm's law. Multiplication by the conjugate gives

$$(R^2+L^2p^2)C=(R-iLp)E.$$

In the end, after all analytical transformations have been effected, the real part of the expression must be picked out. A little experience will make the average student quite efficient in this kind of algebra, especially if it is combined with numerical and practical work.

But the value of the method does not stop here. Following familiar paths, we may give a geometrical form to the expressions, and obtain graphical representations of important relations. Thus the complex quantity $RC+iLpC$ may be laid down as a vector in a plane, RC being the component along a chosen direction and LpC the component at right angles to this direction, while the ratio Lp/R measures the tangent of the angle between the vector and the chosen direction of reference. Again, if we regard C as a complete vector, the complex operator may be considered to be a versor rotating C through the angle just named. Can we utilise these fundamental vectorial and versorial conceptions to construct a graphical representation of real value to the electrical engineer? The answer has been given in the affirmative; and among those who have worked up the method along these lines, no one holds a higher place than C. P. Steinmetz. The method has been presented in more or less detail in most of the recent books on the alternating current, and now we have an extremely valuable addition to the literature of the subject in "Vectors and Vector Diagrams applied to the Alternating Current Circuit," the joint work of William Cramp and Charles F. Smith, both lecturers in the electrical engineering school of Manchester University. The authors, for reasons given, depart somewhat from Steinmetz in their development of the method, but the foundation is essentially the same. Once the fundamental propositions are admitted and grasped, the whole treatment is a model of lucidity and self-consistency. One unusual feature of the book is that it assumes a certain fairly advanced knowledge at the start. This is a good feature, which might well characterise more of our text-books. The authors are careful at the same time to indicate exactly what knowledge the student must possess before he is in a position to make effective use of their methods—he must know the fundamental laws of the alternating-current circuit very thoroughly. Nevertheless, it would have been of advantage to have indicated in a few preliminary sections the manner in which the method originally took shape as a synthesis of the symbolic solutions of Maxwell's differential equations. There also seems to be a certain looseness of argument in the way in which the properties of vectors are stated. For example, having defined in the usual geometrical way the meaning of the "vector product" of two vectors, and having so named it, they remark, "This product must itself be a vector product, since it has already been shown to possess a definite sense." This is no proof, but mere statement. The defined product must be shown to obey the vector law of addition before it can be called a vector product.

These imperfections do not, however, affect the purpose of the authors, who are to be congratulated on having enriched our technical literature with a clear and systematic exposition of the vectorial graphics of alternating-current phenomena. After a discussion of the more purely geometrical character of the method, illustrated throughout by reference to familiar electrical phenomena, a succession of chapters follows on self and mutual induction, the transformer, motors of the induction type, and alternating-current commutator motors. A chapter is then thrown in on the product of two vectors, and the two concluding and longest chapters deal respectively with locus diagrams and examples of the application of locus diagrams. The book is amply illustrated by more than a hundred diagrams. Everything is concise and to the point, and the student who *works* through its pages will find himself equipped with a valuable weapon of research.

THE RECONSTRUCTIONAL ANATOMY OF THE KIDNEY.

Untersuchungen über Bau und Entwickelung der Niere. Edited by Prof. Karl Peter. Erstes Heft. Inhalt I., Karl Peter, Die Nierenkanälchen des Menschen und einiger Säugetiere. II., Michio Inouye, Die Nierenkänalchen des Rindes und des Tümmlers. Pp. viii+447. (Jena: Gustav Fischer, 1909.) Price 30 marks.

THE editor of this monograph holds with Koelliker that a knowledge of the morphological characteristics of the renal tubules is an important groundwork for the study of the physiology and diseases of the kidney. This ground plan he has laid down in a bulky volume, profusely illustrated by numerous and well-executed drawings. By means of maceration with concentrated hydrochloric acid and subsequent isolation of the urinary tubules, as well as by reconstruction models and serial microscopic sections, he has studied, along with his pupil, Michio Inouye, the structure of the kidney in various mammalian families in great detail. For the benefit of those who desire to ascertain his results without reading the whole of the text, he condenses a summary of his work into seventy-five pages of this volume.

Prof. Peter has worked out the structure of the kidney of the mouse, rabbit, sheep, cat, man, and pig, while Inouye has studied the organ in the seal and ox. They have given a minute description, perhaps too minute, of the organ in the various animals without adding, to any great extent, to our knowledge of the subject.

As a result of his study, Prof. Peter divides the medulla of the kidney into an inner and an outer zone, and the latter into an inner and an outer area. The cortex he divides into a *pars convoluta* and a *pars radiata*. These, to some extent, can be recognised with the unaided eye or by means of a lens, and each is composed of certain definite parts of the tubules, each zone or area being composed of the same parts in the same species. In fact, with some slight exceptions they are composed of the same parts throughout the whole of the mammalia. A summary of the zones and their contents is given.

These researches of Prof. Peter—minute and accurate as they are—have particularly little in them that will interest those who seek to elucidate the functions and diseases of the kidneys. The author himself states that as regards the significance of the Malpighian bodies his investigations have produced nothing new. Concerning the first convoluted and zigzag tubules which he includes under the name of the "Hauptstück," certain observations have been recorded with regard to variations in the amount of fat contained in the cells, and from the fact that these vary in their affinity for eosin in different parts of the convoluted tubule, the deduction is made that the functions of the latter are not the same throughout its length. The facts adduced by these investigations have very little bearing on the two rival theories of the manner in which the kidney removes the urine from the blood—whether by a process of secretion or one of filtration.

The function of the narrow, clear part of the loop of Henle is concluded to be the resorption of the water which has been thrown out of the glomerulus. This is deduced from a ratio which Prof. Peter has found to exist between the relative length of this part of the tubule and the specific gravity of the urine in various mammalia with the exception of some of the smaller ruminants. In this matter his observations support the experiments of Ribbert and H. Marger, and of Hausmann. These experimenters removed the whole of one kidney and the medulla of the second in a rabbit, with the result that the urine was doubled or trebled in amount. As the narrow, clear part of the loop of Henle is contained in the medulla, it is inferred that the increase in the amount of urine is due to the removal of the resorbing part of the tubule. So many factors have to be considered in a case like this that the author's deductions must be regarded with a certain amount of reserve. While one must admire the industry and accuracy manifested by this work, it must also be admitted that even those specially interested will find it very tedious reading, and it is to be hoped that it may be possible to confine the other promised volumes within a more modest compass.

R. D. K.

GREEKS AND HITTITES.

Ionia and the East. Six Lectures delivered before the University of London by D. G. Hogarth. Pp. 117. (Oxford: Clarendon Press, 1909.) Price 3*s*. 6*d*. net.

THE author of this book aims at solving the interesting problem of the origin of Hellenic civilisation in the Grecian colony of Ionia, in western Asia Minor. He utilises, in a masterly manner, the results of the extensive archæological researches that have been carried out within the last thirty years in south-eastern Europe. The excavations of Schliemann, Evans, and numerous other workers in this field have completely revolutionised our ideas about the origin of that early Grecian culture to which modern European civilisation owes so much.

Mr. Hogarth's conclusions are, that in Attica the home country of the Ionians, the population, before the migration to Asia Minor, was mainly Ægean, but mixed with a northern element of invaders from the Danubian area. At this date there survived in Attica a vigorous bloom of Ægean culture affected to an unusual degree by some eastern influence, so that the colonists who settled on the west coast of Asia Minor in the early centuries of the first millennium B.C. were by no means barbarians. In Ionia the Greek settlers came in contact with a highly developed Asiatic civilisation—namely, that of the Hittites—and one of the most original features of Mr. Hogarth's book is the demonstration which he gives of the powerful influence of the Hittite civilisation in the development of the Hellenic culture in Ionia. The Hittites were predominant in Asia Minor from 2000 B.C. to 800 B.C., and, besides being possessed of a highly developed culture of their own, acted as intermediaries for the transmission of Mesopotamian culture to the Greeks. Of both these influences there is distinct evidence in the few excavations that have been carried out in Asiatic Greece.

There appears to be a rich field awaiting the archæological excavator both in Ionia and in other parts of Asia Minor. In Lydia, which was apparently a Hittite satrapy, very little excavation has been done, and in the Hittite country on the upper Euphrates hundreds of buried cities are known to exist, in some of which, it is almost certain, as Mr. Hogarth points out, bilingual inscriptions connecting the Hittite script with the Assyrian will be found. We may, then, expect discoveries equalling, if not excelling, in importance those that have recently been made in Mesopotamia, in Egypt, and in Crete.

Another iconoclastic view of Mr. Hogarth's is that the Phœnicians played an insignificant part in the development of Greek civilisation. He reduces "the part played by the Phœnicians among the Greek Isles and coasts to that of mere huckstering traders who followed seaways long ago opened by others."

Mr. Hogarth considers that the Hittites were not a maritime people, but were confined strictly to their continent by the Ægean command of the sea. In view of the migration from Lydia to Umbria related by Herodotus, and of the existing population of broad-headed races in the Balkans, which, judging from its present distribution, must apparently have landed on the eastern shores of the Adriatic, Mr. Hogarth's views on the non-maritime character of the Hittites will, we venture to think, be considerably modified by future discoveries. The one weak point in Mr. Hogarth's admirable little book is his disregard of the evidence of physical anthropology. No explanation of the ethnological evolution of the East will be satisfactory which fails to account for the transition of the primitive dolichocephalic peoples of the Balkan peninsula into the strongly brachycephalic population of the present day, and in this respect Mr. Hogarth's otherwise admirable work completely fails. J. G.

SOME NEW CHEMICAL BOOKS.

(1) *Naturgeschichte einer Kerze von Michael Faraday.* Herausgegeben von Dr. R. Meyer. Pp. viii+172. (Leipzig: Quelle und Meyer, 1909.) Price 2.50 marks.

(2) *Junior Chemistry.* By R. H. Adie. Pp. viii+266. (Cambridge: University Tutorial Press, 1909.) Price 2s. 6d.

(3) *Chemistry.* By Prof. W. A. Tilden, F.R.S. Dent's Scientific Primers. Pp. ix+108. (London: J. M. Dent and Co., n.d.) Price 1s. net.

(1) FARADAY'S six lectures on the chemical history of a candle were, it may be remembered, delivered to a juvenile audience at the Royal Institution during the Christmas holidays of 1860–1, nearly half a century ago.

In reading them we are impressed not merely by the delightful simplicity and freshness of their style, and by the variety and ingenuity of the experimental illustrations, but more especially with the completeness of the story he had to tell. There is little that has been modified or extended in this branch of knowledge during these fifty years; there is scarcely a single sentence which might not be uttered without comment or correction to a similar audience to-day.

It is not surprising, therefore, that a fresh edition of Dr. Meyer's excellent German translation should be in demand among young people in Germany, and it speaks well for their appreciation of Faraday and his charming "chemical history" that the translation has reached its fifth edition.

The book is attractively bound, and contains a very pleasing portrait of the author, together with a short biography.

(2) Mr. Adie justifies the production of another elementary chemistry on the ground that the average first-year student shows a lack of intelligent understanding of chemical aims and methods, for which, we infer, the other books are mainly responsible. We are inclined to think that this want of intelligent understanding is due neither to the character of a particular book, nor altogether to the teacher, but to the kind of chemistry done in schools and fostered by the scholarship system of the older universities.

If the systematic study of chemistry at the university or college were founded on a good general knowledge of mechanics and physics, and an elementary notion of those chemical processes applicable to everyday phenomena, the path of the college professor or lecturer would be made much smoother. But schools are not content with this modest programme, and insist upon a standard of knowledge beyond the grasp of the average schoolboy. The result is that the college teacher has to build upon a muddy foundation of confused ideas, which are so familiar to examiners and so difficult to eradicate later. What commends Mr. Adie's new book is not so much the disastrous effects of its predecessors as the long teaching experience of the author. The results of fifteen years' experience of a thoughtful teacher are always valuable, and, as one might have anticipated, the book offers a thoroughly sound course of practical instruction.

The arrangement of the exercises is clear and logical, the examples are thoroughly typical, well selected, well illustrated, and carefully described. Many of the experiments, without being exactly new, are modified and arranged in a convenient form, and the quantitative examples, which are numerous and varied, furnish a sound basis for that most difficult part of chemistry, the understanding of quantitative laws and the theories drawn from them. In reference to the quantitative part, it would be interesting to know what sort of errors the author obtained in determining such things as the gravimetric composition of water, the weight of steam, and the analysis of the oxides of nitrogen, of which no actual examples are given. If the two oxides of nitrogen give anything like correct results by the method described, that much-quoted example of multiple proportion would lose something of its elusive character.

(3) In the editor's preface to Dent's Scientific Primers, in which the one under review is included, we are told that the great advances in knowledge during the last thirty years necessitate a re-statement of the theories of the different sciences.

This may be true of chemistry if it were a question of publishing a new treatise or even a students' text-book; but when we consider that this miniature volume of a hundred pages is intended for a student possessing no previous acquaintance with the subject and without the leisure to study it systematically, we cannot be surprised that the advances in knowledge are not very apparent. We might even go further and state that, except for a passing reference to radium and the noble gases, and the use of the words "stereochemistry" and "polypeptides," the book might just as well have appeared thirty years ago.

With the very limited space at his disposal, Prof. Tilden has made good use of his materials, and has compressed into a small compass a very readable and suggestive account of the elementary facts and theories of chemistry.

J. B. C.

OUR BOOK SHELF.

Histoire du Développement de la Chimie depuis Lavoisier jusqu'a nos Jours. By Prof. A. Ladenburg. Traduit sur la 4e édition allemande. By Prof. A. Corvisy. Pp. v+388. (Paris: A. Hermann et Fils, 1909.) Price 15 francs.

Forty years ago, the first German edition of Ladenburg's "Lectures on the History of the Development of Chemistry during the past 100 Years" was published. This was a relatively small book of 320 pages, which presented, in the course of fourteen lectures, a carefully drawn and evenly balanced sketch of the progress of chemistry subsequent to the time of Lavoisier. At the date of its publication it was unique in dealing, in a logical and consistent manner, with the progress of the atomic theory in its application both to inorganic and to organic chemistry, and in serving at least as an introduction to the particularly difficult and complicated period in the history of organic chemistry which began in the 'thirties and extended to the late 'fifties or early 'sixties of last century. It was not until about four years later that this period was dealt with, a good deal more elaborately, by Kopp in his "Development of Chemistry in Recent Times" (1873). A specially valuable feature of Ladenburg's lectures was the abundance of references to the literature, which tended to encourage the reader to extend his knowledge of particular branches of the subject by consulting the original papers of the various authors. A second German edition was called for in 1887, when the original book was revised, and was extended by the addition of a fifteenth lecture.

In 1900 an English version of Ladenburg's "History" was published, which was translated from the second German edition, but included various corrections and minor additions by the author, and also a sixteenth lecture, specially written for this translation. A revised English edition appeared in 1905. The third German edition (1902) was merely a reprint of the second edition with the sixteenth lecture added to it, but in 1907 a thoroughly revised and very considerably enlarged German edition appeared, which extended to more than 400 pages, and contained seventeen lectures, the subject-matter being brought up to date as fully as possible, and including accounts of the progress of discovery in connection with such recent subjects of extended investigation as radium, asymmetric nitrogen, the proteins, and the colloid substances. It is from this fourth German edition that the French translation which is before us was prepared, and the fact that a French version is now published may be taken as in itself a tolerably satisfactory indication, not only that Ladenburg's book has established itself as a work of permanent value in the estimation of chemists irrespective of nationality, but also that it is free from national bias, such as is frequently met with in historical works. The translation bears every evidence of having had much careful attention bestowed upon it, and it gives a faithful representation of the original. The book is produced in a creditable style typographically.

(1) *Biologisches Praktikum für höhere Schulen.* By Dr. Bastian Schmid. Pp. vi+71. (Leipzig and Berlin: B. G. Teubner, 1909.) Price 2 marks.

(2) *Biologische Experimente nebst einem Anhang mikroskopische Technik.* By Walther Schurig. Pp. xi+180. (Leipzig: Quelle und Meyer, 1909.) Price 2.40 marks.

(1) This is an attempt to compress into seventy-one octavo pages a practical introduction to the study of the comparative anatomy of plants and animals, together with a certain amount of experimental physiology. There are seventy-five text-figures and nine plates. A considerable number of types, ranging from bacteria to mammals, are dealt with in a very scrappy and superficial manner in the text. A large proportion of the illustrations are borrowed from the works of well-known authors. They are well reproduced, but the text and explanations of the figures are very inadequate. A plate containing figures of the skeletons of a frog, a dog, and part of the skeleton of a bird (apparently there was no room for the skull, which is omitted), without a single bone labelled, is not likely to be of very much service even to the most elementary scholar. Doubtless, however, there are people who are gratified by observing a resemblance between an actual specimen and a book illustration, and they may even think that they have learnt something by comparing the two. It is only fair to the author to mention that the book is intended to be used in conjunction with the instruction of a teacher, who, no doubt, would be able to supply many of the deficiencies.

(2) This little book is addressed to school teachers and students of nature, and is intended to serve as a guide to a large number of simple experiments in animal and vegetable biology. It is very suggestive, but the style is rather too much that of a cookery book, and the work suffers greatly from over-condensation. A good practical course on general physiology, in itself a very desirable thing, might be founded upon it by an experienced and well-read teacher of biology, but it would take a very long time to carry out all the experiments in a satisfactory manner.

Inborn Errors of Metabolism. The Croonian Lectures delivered before the Royal College of Physicians of London in June, 1908. By Dr. A. E. Garrod. Pp. vi+168. (London: Henry Frowde, and Hodder and Stoughton, 1909.) Price 3*s.* 6*d.* net.

Dr. Garrod delivered before the Royal College of Physicians in June, 1908, his Croonian lectures under the above title, and the present little book is a welcome re-publication of these lectures in a rather more extended form than those actually delivered. The author is well known for his researches on nutrition, metabolism, and the urine, and has always had a special bent in the unravelling of those rarer anomalies which in so many cases are transmitted from generation to generation. It would lead one too far into strictly medical matters to attempt anything in the shape of even a condensed account of the matters specially selected by Dr. Garrod, and so one need only mention that the anomalies treated at length are albinism, cystmaria, alkaptonuria, and pentosuria.

It must not be supposed that the examination of these comparatively rare conditions is devoid of general interest, for it is often just these curious accidents of perverted tissue change which form the opportunity of the keen observer in unravelling the perplexities of the normal state. The natural sequence of study is physiology first, pathology next. But very often an inversion of this order leads to important accessions to knowledge. Dr. Garrod is to be congratulated on having been successful in such an experiment, and those interested in metabolism cannot do better than study his lucid and bright exposition of the subject. W. D. H.

Practical Testing of Gas and Gas-meters. By C. H. Stone. Pp. x+337. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1909.) Price 15*s.* net.

THIS is a laboriously complete compilation of the various methods of testing gas for illuminating power, purity, chemical composition, and calorific value, and of proving the accuracy of the indications of gas-meters. The subject is one mainly of technical interest only, and very specially so even for that, and hardly suitable, therefore, for detailed consideration in these columns. An examination of the book shows how great a diversity of apparatus has been devised and thrust upon the innocent gas-producing world, and how gratuitous some of the diversity is. Where apparatus has been designed for official testings, the objection to protecting the manufacture by patents has given the constructor liberty to alter and "improve" or spoil an instrument, as the case may be.

The American has a great opinion of the English official ten-candle lamp designed by Mr. Harcourt, but he will not take it as he finds it, and so he makes an American pattern. The English official calorimeter, too, judging by the observations made, has also gone through a metamorphosis in crossing the Atlantic. As is to be expected, the book is well got up and illustrated, and its value is increased by the inclusion of a number of tables of value to those whose business is to test and examine gas.

A Compendium of Food-microscopy. By E. G. Clayton. With sections on Drugs, Water, and Tobacco. Compiled, with additions and revision, from the late Dr. A. H. Hassall's works on Food. Pp. xxxix+431. (London: Baillière, Tindall and Cox, 1909.) Price 10*s.* 6*d.* net.

THIS book, written by an ardent disciple of the late Dr. Hassall, is largely based on Dr. Hassall's works on food and its adulteration. An account is given of the microscopical characters of all the principal vegetable food-stuffs, beverages such as tea and coffee, fruit preserves and condiments, and of tobacco, opium, and a few other drugs, together with those of the chief adulterants of these substances. In addition, chapters are devoted to foods of animal origin and the parasites which may infect them, milk, cream, butter, and cheese, and to the microscopical flora and fauna of water. The book is profusely illustrated with line drawings to scale, which usually reproduce very clearly the characteristics of the substances they are intended to depict, though occasionally there is an irritating want of systematic arrangement of the figures, Fig. A, for instance, sometimes being on the right, sometimes on the left, of the page. Though the botanical terminology is not always that used nowadays, on the whole the book should form a useful addition to the library of the analyst and microscopist.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Molecular Scattering and Atmospheric Absorption.

SINCE Lord Rayleigh discussed the question of molecular scattering, and its bearing on the explanation of the blue colour of the sky, our experimental and observational data have become much more trustworthy. While our knowledge of the number of molecules in a gas allows us now to calculate with sufficient accuracy the amount of direct sunlight which is diverted by scattering, Mr. Abbot's series of measurements at Washington and on Mount Wilson gives us the actual observed opacity of the air for different wave-lengths.

Lord Rayleigh showed that, on the hypothesis of the elastic solid theory of light, small particles of matter, which act simply by adding inertia to the æther, scatter light and retard the passage of a wave passing over them in such a way that the relation

$$k = \frac{32\pi^3(\mu - 1)^2}{3N}$$

holds, where k is the coefficient of extinction of energy, μ the refractive index, and N the number of molecules per cubic centimetre. He showed, further, that the same equation may be deduced from the electromagnetic theory if the particles locally affect the inductive capacity of the medium. In the forthcoming new edition of my "Optics" it will be proved that the equation is independent of theory, provided μ is nearly equal to unity; the limit of its applicability is only reached when there is a retardation of phase at the origin of the scattered light the square of which is appreciable, and it can be shown that this is actually the case except within the region of anomalous dispersion. The range of the formula may be further increased if $\frac{1}{4}(\mu^2 - 1)^2$ is written for $(\mu - 1)^2$.

For N I have used Rutherford and Geiger's value $2{\cdot}72 \times 10^{19}$, and with the known value of the refractive index of air, k may be calculated. If h is the height of the homogeneous atmosphere above the point of observation, e^{-kh} is the fraction of light which would reach the observer if no light were lost in any other way than by molecular scattering. In the following table the transmitted light calculated in this manner is compared with Abbot's observed figures. The first column gives the wave-length, the second column contains the observed values of the transmitted energy for Washington, taking all observations into account, while the third column gives the number calculated from the observations on February 15, 1907, when the air was exceptionally clear. The calculated values are entered into the fourth column. The last three columns give the corresponding numbers for Mount Wilson. The selected clear day in this case was October 11, 1906.

	Washington			Mount Wilson		
Wave-length	Observed mean	Observed clear day	Calculated	Observed mean	Observed clear day	Calculated
4×10^{-5}	0·55	0·72	0·71	0·73	0·76	0·76
5	0·70	0·84	0·87	0·85	0·89	0·89
6	0·76	0·87	0·94	0·89	0·92	0·95
7	0·84	0·90	0·96	0·94	0·96	0·97
8	0·87	0·94	0·98	0·96	0·99	0·98
10	0·90	0·96	0·99	0·97	0 99	0·99

The close agreement between the two last columns shows that on a clear day on Mount Wilson atmospheric absorption is practically accounted for by molecular scattering. There is a slight indication of selective absorption in the red, but otherwise the columns are in complete agreement. On the average day there seems an additional absorption of about 2 per cent. It is remarkable that, even at Washington, the calculated absorption for blue light should so nearly agree with the calculated value; this means that even at the sea-level the greater part of the absorption on a clear day is due to scattering by the molecules of air. The large diminution in the intensity of blue light at Washington on the average day seems to indicate that there is a substantial amount of scattering by small solid or liquid particles.

The figures for Mount Wilson give us confidence in the trustworthiness of Mr. Abbot's determination of the solar constant, because it is clear that the total effect of the atmosphere can be eliminated with greater certainty if it is mainly due to the permanent constituents of the atmosphere, and not to matter which is variable in amount. As the top of Mount Wilson is less than 1800 metres above sea-level, we may conclude that at high elevation the blue colour of the sky is completely accounted for by molecular scattering.

That the scattering sets a limit to the transparency of gases must be kept in mind in discussing problems of solar and stellar physics. We may feel confident, for example, that what is called the reversing layer can only have a small thickness, for otherwise we should not be able to observe so far into the ultra-violet as we do.

The scattering may profoundly modify the character of the spectrum, as I have explained in a paper on "Radiation through a Foggy Atmosphere" (*Astrophysical Journal*, vol. xxi., p. 1), in which it is shown how increased thickness, without change of temperature, may convert an absorption line into a bright line. It seems to me probable that the bright and dark flocculi shown in spectroheliograph pictures may find their explanation chiefly in variation of thickness in the absorbing layer, the bright patches being due to increased thickness.

The transparency of interstellar space has recently received a much needed critical discussion at the hands of astronomers, and Prof. Turner has applied the law of scattering to explain certain discrepancies between visual and photographic magnitudes. The value he gives for the opacity allows us to calculate the average density of the matter which is diffused through space on the supposition that it is gaseous. If the value of $(\mu-1)/D$ (where μ is the refractive index and D the density) be taken to be approximately equal to that of air, I find that the number of molecules per cubic centimetre in space would have to be of the order of a million, and the mean free path of the order of 3000 kilometres.

Although not directly connected with the subject which forms the main part of this communication, I would like to point out that the same analysis which gives the coefficient of extinction in terms of the retardation of phase at the source of the scattering also gives a resultant force acting on the molecule in the direction in which the light is passing. When summed up for all the molecules this force is found to be identical with what is generally called the "pressure of light," for if E represents the energy density, the force acting per unit volume on the scattering molecules is found to be kE, where k is the coefficient of extinction.

There is a widespread impression that light pressure only acts on particles the linear dimensions of which include several wave-lengths of light, but this is not correct. The determining factor is the extinction of light, whether by scattering or by absorption, as indeed appears if we take the view adopted in Prof. Poynting's work on the subject that a propagation of momentum accompanies the transmission of light. The momentum is destroyed equally whether the molecules act as scattering or as absorbing centres. The extinction by scattering near the surface of stellar bodies does not, however, appear to be sufficient to cause any measurable effects comparable with their gravitation.

ARTHUR SCHUSTER.

The Fixation of Nitrogen by Soil Bacteria.

MAY I be allowed through the columns of NATURE to ask Prof. W. B. Bottomley a few questions with regard to his paper on "Some Effects of Nitrogen-fixing Bacteria on the Growth of Non-leguminous Plants" (Proc. Roy. Soc., B, lxxxi., 1909, 287), abstracted in NATURE of May 13 (vol. lxxx., p. 327), as I had not the opportunity of being present when the paper was read?

Prof. Bottomley bases his conclusions on experiments to show that Pseudomonas, the bacterium associated with the leguminous plants, will fix more nitrogen in an artificial culture, when Azotobacter is also present, than when alone. He quotes the following results:—

Control	0·48	mgm. N. per 100 c.c. culture solution
Pseudomonas alone	0·91	,, ,, ,,
Pseudomonas and Azotobacter ...	1·24	,, ,, ,,

These differences would almost seem to be within the range of experimental error, but in any case, does not the demonstration require a further statement of how much nitrogen Azotobacter alone would fix? Other observers are accustomed to get fixations by Azotobacter alone of from 5 to 20 mgm. of nitrogen per 100 c.c. of such a culture solution, the maximum being about 10 mgm. of nitrogen fixed per gram of mannite. The only conclusion that could be drawn from Prof. Bottomley's figures would be that Pseudomonas injuriously affects the power of Azotobacter to fix nitrogen, supposing that a reasonably active culture of the latter had been used.

Turning to the field experiments, in which Prof. Bottomley claims to get an increase of crop by adding cultures of Pseudomonas and Azotobacter to soil which presumably already contains both organisms, data for estimating the probable experimental error are again lacking. From the Rothamsted experiments, where we may assume the conditions are more than usually favourable to exactitude, the mean error of a pair of similarly treated plots in a single year is about ± 10 per cent., which would more than cover the differences observed by Prof. Bottomley's experiment with oats.

In another experiment with barley, Prof. Bottomley obtained a higher percentage of nitrogen in the corn from the treated strip than in the corn from the rest of the field, 1·76 against 1·55 per cent. (I presume that "milligrammes of nitrogen per cent." is a clerical error). In view of the comparatively small changes in the composition of the grain of a cereal which are usually effected by large variations in the supply of nutrient, I should like to know from Prof. Bottomley if duplicate samples were taken from different parts of the untreated section of the field, and what range of variation they showed in their nitrogen content.

Coming to the next experiment, it is difficult to judge how far a bulbous plant like *Galtonia candicans* is suitable for experiments on nutrition, but it is rather necessary to know what relation the weight of the bulbs planted bore to those harvested. Prof. Bottomley only says that 250 bulbs "of equal size" were planted in each bed. Can he let us have the weights in each case? Moreover, he tells us that the treated bed was twice watered with the culture solution, the control bed being given pure water at the same time; was the same amount of water given to each, and how much of the culture solution was applied, for it contained monopotassium phosphate, sodium chloride, &c., which may well have been a considerable factor in any beneficial effect experienced?

Prof. Bottomley will perhaps forgive me if these questions may seem somewhat critical of his conclusions, but any communication appearing in the Proceedings of the Royal Society must be taken into account, and one therefore wishes to have the data necessary for determining the weight to be attached to the results.

A. D. HALL.

The Rothamsted Experimental Station, July 12, 1909.

Occasional Unexplained Ringing of House-bells.

AN observation sent me by Mr. Alexander Sinclair, of Swansea, to the effect that during a thunderstorm drops of water leaking through the ceiling "assumed a pear shape and jumped 9 inches almost horizontally to the curtain rings above the window," suggests that house-bells of the ordinary non-electric type may occasionally be rung by this means. I picture the process as follows:—The bell wires collect atmospheric electricity, by induction or otherwise, which the walls are insufficiently conducting to carry off freely; consequently the bells get charged, are attracted to a neighbouring wall or pipe, and released suddenly by a spark. This little lateral jerk rings the bell.

I put the simple suggestion on record because I sometimes hear of an inclination to attribute the phenomenon to less familiar causes.

OLIVER LODGE.

Musical Sands.

IN an interesting letter Mr. Carus-Wilson gives us the results (NATURE, July 15) of further observations made by him on a phenomenon on which he has written from time to time. I believe I have suggested to him in years gone by—if not, perhaps you will allow me to suggest now—the possibility of the musical ring of certain sands in motion being due to their consisting largely of grains of *hyaline* quartz. That fact, if ascertained, would account for the ring of the grains in motion, while the smoothness of their glassy surfaces would facilitate their motion, and so increase the force of their mutual impact, tending to raise the pitch of the note produced. I have never had an opportunity myself of making a microscopic examination of such sands, but I venture to commend such an examination to Mr. Carus-Wilson's consideration. The assortment of the sands by the wind into possibly more rounded and more angular grains may also throw some light upon the matter.

A. IRVING.

Bishop's Stortford, July 19.

Wych Elm Seedlings.

THE prolific flowering of the Wych elm, *Ulmus montana*, this year must have been followed by the formation of unusual numbers of fertile seeds. At present the ground beneath these elms in my garden is covered with hundreds of their seedlings, many of which have already developed a second pair of serrated leaves.

The elms themselves seem to have suffered from the strain of producing so large a crop of fruits, for their leaves, though now of the usual size, were very late in appearing, and are sparsely distributed on the branches.

ROSAMOND F. SHOVE.

26 Blessington Road, Lee, Kent, July 13.

POPULAR NATURAL HISTORY.

MR. LEA'S "Romance of Bird-life,"[1] a handy and fully illustrated volume published at a marvellously low price, covers the whole life-history of the bird, from the egg upwards, the twenty-one chapters containing a summary of the observations of a great many writers on ornithology arranged in a masterly and most attractive form. One of the concluding chapters deals with the birds of the past and vanishing species, and is illustrated with a reproduction of a curious old wood-cut published in 1601, representing early voyagers knocking down dodos and other birds with sticks on the island of Mauritius. In that upon "Wisdom and Folly" we have anecdotes bearing on the intellectual capacity of birds. There are many instructive passages in the book, which is quite a mine of information. It is stated that in more than one instance, if when a chick was cheeping while still in the shell the mother uttered a note of warning, the cheeping stopped instantly; and it is pointed out that this teaches us that the simple language of call-notes is instinctive, for the chick cannot possibly have learnt their meaning by experience. Nestlings the food of which is placed in their mouths by their parents cannot be taught to pick it up from the ground like chicks until they are much older. Young moorhens, however, which are fed from their mother's beak at first, will peck upwards at anything that is offered to them, but not downwards. So far as the author is aware the frigate bird is the only species which ever carries on fishing in mid-air, waiting until the flying-fish are startled from the sea by some large fish which preys on them below the surface; other fishing birds follow them into the water. The romantic story of the ospreys at loch-en-eilein (which should be written eilean) is told and illustrated.

Possibly the "romance" is a little overstrained in places, and ordinary incidents in a bird's general life habits sometimes magnified or transfigured into something more wonderful. For instance, it is a common custom with snow buntings (and with some other quick-footed birds which feed in flocks) for the rear ranks to fly to the front over the backs of the others, a manœuvre repeated by the others in turn. This simple desire (and its expression) to have first turn at whatever food is going is here advanced as "a boisterous little game of their own" in the section on sport and play. The combats of ruffs are much milder and much less important affairs than is here represented; and it seems really unlikely that nuthatches could drive out squirrels from their nest, or would want to take possession of it. Unlike most of the popular bird books published in recent years this one fills a vacant place.

Almost anyone seems to feel capable nowadays of writing a book on British birds, and, in good truth, there is material enough to compile from. Time was when to write an account of British birds was an undertaking attempted by few, and those only who had made the subject their main study for many years, and were on all hands accounted authorities. Now almost anyone does it, and there is a perfect stream of books on this subject. They come out so frequently that, although the title has been turned and twisted in a great variety of ways, it has even been found impossible to discover fresh and original names to distinguish them by. Most of them put forward some special claim upon the public. Many of them purport to cater for the ignorant and the beginner; one, indeed, made a point of picking brains without acknowledgment. Here is one[1] "with a new method of identification." This book has been written with the exclusively practical object of enabling persons unacquainted with British birds to identify them by their most obvious characteristics. By the grouping of birds, as here carried out, under such headings as "Black-and-White Birds," "Ruddy-breasted Birds," "Trunk-climbing Birds," it is claimed that the birds are presented to the beginner as he himself sees them. Where necessary, notes are appended to the descriptions indicating those birds with which the one described is most likely to be confounded, and the chief characteristics by which it is to be distinguished from them. Before proceeding to observe birds, however, the user of this book need do no more than read through the list of group-headings. The book is, in fact, another attempt at a royal road to a knowledge of our birds. The idea has been tried over and over again in some shape or form, both here and in America, but we do not think it will ever be successful. In the present case the difficulties of grouping begin to be apparent very shortly. "Skuas" as a group heading will convey nothing to the beginner without good pictures. In the end the author is left with three birds, the jay, the goldfinch, and the white wagtail, which do not fall into any groups. The two first are so conspicuous that perhaps they do not want grouping; but, really, after some of the grouping, *e.g.* putting the hedge sparrow and some others among those which are "brown above and white below," it seems rather like straining at a gnat not to have dropped the third in among the black-and-white birds. We are glad to read that there are a few breeding pairs of kites in the Midlands of England, and hope

[1] "The Romance of Bird Life." Being an Account of the Education, Courtship, Sport and Play, Journeys, Fishing, Fighting, Piracy, Domestic and Social Habits, Instinct, Strange Friendships and other interesting Aspects of the Life of Birds." By John Lea. Pp. 376; illustrated. (London: Seeley and Co., Ltd., 1909.) Price 5*s*.

[1] "British Birds and their Eggs, with a New Method of Identification." By J. Maclair Boraston. Pp. x+301; 136 coloured illustrations. (London and Edinburgh: W. and R. Chambers, 1909.) Price 6*s*. net.

it is the case. There is a classified list of the birds contained in the book, and an index, so that every facility is given to those who try to learn birds' names in this way. Illustrations of the eggs of *all* British-breeding birds appear in the sixteen plates devoted to that part of the subject. Some of the plates of birds are pleasing. But in the great majority of cases the three-colour process has probably played sad tricks with the colours, and some of the pictures are misleading. Others make the bird-lover shudder; for horrible and appalling crudeness of colour their equal would be hard to find.

Young egg-collectors are also provided with a simple guide to identify their finds.[1] A part of a larger work, "The Young People's Nature-study Book," it is in the form of a pocket-book, with blank leaves at the end for making notes on the spot. The system of this key is as follows. The nests are grouped under the headings according to their locality and position. Turning to the particular section to which a nest belongs we find additional characteristics of the nests and eggs described, which it is hoped should lead by process of elimination to a correct result. The eggs figured on the four coloured plates are those most generally confused. They can hardly be expected to be very good, but will be useful. The introductory remarks are instructive, and there are some photographs of nests.

Mr. Vos has issued[2] the second and third parts of a description (illustrated) of the rambles of two friends in search of birds' nests near London, comprising the results of two seasons. They seem to have been exceptionally fortunate in finding many interesting birds and nests, and some which would not have been expected. For instance, a snipe's nest almost within earshot of Bow Bells seems wonderful. But even more so in some respects, perhaps, is "a little colony of three pairs" of carrion crows on a small island; for in our experience, even where crows are common, it is most unusual for these unsociable birds to nest in close proximity to one another. The situation of one nest, in the top of an elder-tree, about twenty-five feet from the ground, seems unusual in a country where big trees are to be found, and the egg described as about an inch long was very small, an average crow's egg measuring an inch and three-quarters. The third part concludes with a grouping of the birds mentioned to aid in their recognition; a description with figures of the eggs; a synopsis, an alphabetical index of some of the birds mentioned, and a general index. A number of nests have been nicely photographed for the book, but the photographs of *stuffed* birds are open to criticism, as is usual.

Some of our best and really competent ornithologists have from time to time considered the possibility or advisability of editing Johns's classic,[3] but they have feared to tread. With regard to the present edition we can only regret that a good old book has been spoilt to some extent. Fortunately, not much has been done to it, for although the editor claims to have rectified statements as to the local distribution of various species which, with the progress of time and local changes, no longer apply, and to have added facts here and there which he considered of some value, this has been done so inadequately that it might as well have been omitted altogether. There are some birds, the Lapland bunting and shore lark, for instance, the status of which on the British list has entirely altered since Johns wrote; yet the articles on these species are left just as he wrote them. The editor has also brought the scientific arrangement of the species up to date. If this was to be done, more care should have been taken, when the order and sequence of the species was altered, to avoid absurdities consequent upon careless revision of the articles. As it is, we are told that the black tern is scarcely less aquatic than the whimbrel; that the name laughing gull is often given to the common gull; that the snow-bunting does not confine itself so closely to the Arctic regions as our homely reed-bunting, and various other absurdities, all of which are due to the fact that the use of the expression "the preceding species" has not been revised. Harmless as are these misstatements to the seasoned ornithologist, they might easily confuse the beginner. A large number of species included in the older editions of Johns's work have been omitted from this edition, presumably because of their rarity. But this weeding out, if done at all, should have been done consistently, and on some definite plan. Here we find that while the whole of the rarer herons, including the little bittern (which is believed to have bred with us), have been left out, the black stork, a very rare casual visitor, has been retained. The spotted eagle, which has only occurred on a very few occasions, is included, while the blue-throated warbler, an annual visitor, sometimes in some numbers, has been cut out. Then why include the little crake and not Baillon's crake? Why the Pomatorhine skua and not Buffon's skua? The black-necked grebe (which has bred in this country) is not included in the text, though it is figured. But it is needless to go further through the list, except to say that one very rare bird, the lesser grey shrike, has been inserted. The statement that the green sandpiper breeds probably in wild parts of Surrey, Sussex, and Hampshire has been added to Johns's account of this bird because "the Son of the Marshes considers that it does so." More definite information would have been very desirable. There is a glossary of provincial names and of technical terms, and an index. The old (and often unsurpassed) wood-cuts with which we have been so long familiar no longer appear, and we cannot but regret them. Instead we have sixty-four original coloured plates, comprising 256 figures. Many of these are absolutely charming and excellent portraits of birds, and altogether they are by far the best coloured pictures of our birds we have seen in a book published at anything like so low a price as this. The colour reproduction has been much more successful than usual, for which the artist may well be pleased and the publishers congratulated.

The account of the principles and measures which Baron von Berlepsch advocates[1] for the exercise of a rational protection of birds as carried out at Seebach will be read with interest and profit by the many people who like to feed the birds in winter and get them to breed in boxes. The main features of the protection here treated of are the provision of shelter woods and plantations, pruning bushes and trees in such a way as to provide nesting situations, winter feeding, and making up for the loss of natural nesting-places of the breeders in holes consequent upon the removal of old and decayed trees. With planting for birds we are not so much concerned in England as

they are on the more open plains of the Continent; nor is feeding so necessary in our usually more open winters; but the chapter on bird-boxes will be sure to interest those who have been in the habit of hanging up boxes in their gardens and woods. Baron Berlepsch came to the conclusion that the nesting-boxes in use in his boyhood served no purpose, and that the only chance of success lay in the boxes being made to imitate nature. He has now succeeded in getting proper boxes made, most of which are exact imitations of woodpeckers' holes. They are here figured and fully described, and the manner of fixing and hanging them. They are now to be bought in England. Other illustrations show sections of woodpeckers' holes, correct and worthless boxes, plans of shelter woods for birds, the woods before and after cutting, pruned bushes, &c. A useful calendar of operations concludes this very practical little volume.

The first volume of the "Book of Nature-study"[1] covers animal life from mammals to insects, spiders and worms, &c., and is educational in character, written chiefly for the education of those who have to teach natural history to the young. The editor points out that one of the causes of teachers failing with their students of natural history is their ignorance of the subject; and one of the main objects of this book has been to place the necessary information in such a form as to be accessible to the teacher. It is also most truly pointed out that in teaching natural history a principal object which should never be lost sight of is the stimulation of the powers of independent inquiry and observation on the part of the children themselves. The introductory chapter expounds certain general themes which must form part of the intellectual background of successful nature-study in the field of animal life, and the subsequent sections contain an excellent and clearly written introduction to the various forms thereof, their structure and life-history. A useful bibliography of works dealing with the subject, and in which it can be followed up, is appended to each section. The matter dealt with is so extensive that space cannot here be found to indicate more than the general character of the work, and it must suffice to say that it serves its purpose admirably. The illustrations are exceedingly fit and suitable for the purpose in view. The book is well printed on good paper, and the six coloured plates are simply delightful, as well as most instructive, and are some of the best and most successful efforts at colour printing we have seen.

THE ADAMELLO GROUP.[1]

THE Adamello group is a conspicuous though distant feature in the panoramic view of snow-clad giants which greets us on reaching some lofty peak of the Pennine Alps in the neighbourhood of Zermatt. It rises like an island above a sea of lower mountains, almost untouched by snow—a vast tabular mass covered with glaciers, "a huge block," to quote Mr. Douglas Freshfield's graphic description, "large enough to supply materials for half-a-dozen fine mountains. But it is, in fact, only one. For a length and breadth of many miles, the ground never falls below 9500 feet. The highest peaks (about 11,600 feet) . . . are merely slight elevations of the rim of this unlifted plain. . . . Imagine an enormous white cloth unevenly laid upon a table and its shining skirts hanging over here and there between the dark massive supports" ("The Italian Alps," p. 202).

One huge mass of intrusive igneous rock, now laid bare by denudation, practically forms the Adamello. On the east it is defined by the great Judicaria fault; on the west by the Val Camonica; on the north the narrow neck crossed by the Tonale Pass alone separates the waters running to the Lagò d'Iseo from those which flow either to the Lago di Garda or to the Adige. Thus it seems indicated by nature as a subject for a monograph, and Dr. W. Salomon accepted her challenge nearly twenty years ago. From time to time he has published papers on important details, and now gives us the fruits of his studies in one of those massive memoirs which only a national institution can afford to publish. We have but to glance at his route-map, in parts of which the red lines showing his track cross and recross like a mass of wriggling worms, to see that he has done his work with Teutonic thoroughness, leaving hardly any accessible place unvisited, while in order to ascertain how the rocks are related to those of neighbouring regions he has extended his investigations to the Val Tellina and to the lakes of Iseo and Idro.

Selection from so great a mass of details is impossible, and criticism of them demands a knowledge of the district comparable with that of the author, so that we can only indicate his main conclusions and comment on one or two which have a more general character. The igneous holocrystalline rock, to which Von Rath, about half-a-century ago, gave the name tonalite (from the Tonale Pass) consists of quartz, plagioclase felspar (probably andesine), biotite, and hornblende. It varies a little in coarseness and in composition, especially in the relative abundance of

[1] "Die Adamellogruppe, ein alpines Zentralmassiv, und seine Bedeutung für die Gebirgsbildung und unsere Kenntniss von dem Mechanismus der Intrusionen." Von Wilhelm Salomon. i. Teil: Lokale Beschreibung, kristalline Schiefer, Perm, Trias. Pp. xiii+433. (Wien: Abhandlungen der k.k. Geologischen Reichsanstalt, 1908.) Price 30 kr.

the last two minerals, the second of which is often fairly idiomorphic. It is, in fact, a variety of quartz-diorite, for which some petrographers use the name. Enclosures of a darker, more basic rock are not unfrequent, which in some cases much resemble included fragments, but in others may have a concretionary origin. The tonalite is cut by dykes of a more aplitic character, and apophyses from it penetrate the neighbouring sedimentary rocks. The percentage of silica is rather lower than in an average granite, that of ferro-magnesian constituents is higher, while in the alkalies the soda much exceeds the potash. The monzonite of the Fassathal differs from it in being poorer in silica and richer in alkalies; the granite of that valley and of the Cima d'Asta exceeds it in both respects; but, as we see from the neighbourhood of Predazzo, these early Mesozoic ejections indicate much differentiation of any original magma. But for these interesting questions it is enough to refer to Prof. Brögger's classic memoir [1] on that district.

If this tonalite *massif* represents the supply basin to one or more volcanic orifices, all traces of the latter have completely disappeared. The blood-red "porphyries," so characteristic of a broad region east of the Adige, above and below Bozen, can also be seen west of that river, at no great distance from the Adamello, and can be traced south of it to beyond the Sesia. These were erupted in Permian times, but the tonalite, like those other holocrystalline masses already mentioned, is later than most of the Trias. On that point evidence has been accumulating since 1846, but it is made more than ever certain by Dr. Salomon's exhaustive examination of the relations of the tonalite and the various stages of that system from the Werfener Schichten (Bunter) to the Haupt Dolomit (lower part of the Rhætic). The usual proofs of intrusion can be seen in many places, and a zone of contact metamorphism traced for a considerable distance outwards from the margin of the invading rock. It can also be seen breaking into Permian sediments and into the older crystalline schists.

These schists Dr. Salomon divides into three groups: the Edolo Schiefer, the Rendena Schiefer, and the Tonale Schiefer. The first, which occur on the north and in the northern part of the west of the Adamello *massif*, are said to be phyllites, sometimes anthracitic, with quartzose-banded phyllites and quartzites; the second, consisting of phyllitic gneisses and mica schists, occur occasionally on the west, but are more developed on the east; and the third, specially characterised by bands of saccharoidal marble, often rich in silicates, and associated in one part with a zone of augen gneisses, occur on the north, on the other side of the Edolo Schiefer. Dr. Salomon regards the Rendena Schiefer as early Cambrian or late Archæan, but refers some of the Tonale Schiefer to the Mesozoic, considering the marbles to be infolded Triassic limestones, metamorphosed by intense pressure. It may seem presumptuous for one who has merely traversed this district, and that not at all recently, to express any difference of opinion, but, as Dr. Salomon supports his views by references to other parts of the Alps which the present writer has carefully and continuously studied, he has no hesitation in saying that the identification of those Alpine marbles with the acknowledged Triassic limestones is very like that of Monmouth and Macedon, and that the asserted Mesozoic age of the crystalline schists, to which most of the so-called phyllites belong, and with which these marbles are associated, is supported by no better evidence than mistakes in elementary mineralogy and the neglect of important facts, such as the presence of fragments of those crystalline schists in indubitable Triassic rock. So we venture to think that the last word has not yet been said on the subdivisions and the ages of these crystalline schists.

[1] "Die Eruptionsfolge der triadischen Eruptivgesteine bei Predazzo," 1895.

As dolomitic limestone occurs in the neighbourhood of the Adamello, the author discusses the relation of these rocks to coral reefs. Here we are surprised at not finding any direct reference to the Royal Society's memoir on the borings at Funafuti, and the author is apparently satisfied with the following quotation (p. 417):—"Die Bohrung auf Funafuti erscheint in demselten Licht; die dort erreichte grosse Dicke wurde wahrscheinlich in der Grunlage einer alten Kalksteines erreicht, so dass die erlangten Resultate keinesweg die Annahme der Senkungstheorie nötig machen." We can only suppose that Dr. Salomon has never seen the conclusion of Dr. C. J. Hinde's study of the cores (Memoir, p. 334):—"The evidence appears to me to indicate a continuous formation of reef rock, without any abrupt break, from the depth of 1114 feet to the present time"; while Prof. J. W. Judd (p. 175), after stating that specimens of Tertiary limestones from reefs in Indian and Pacific seas had been carefully studied for purposes of comparison, expressly states:—"The same recent forms of foraminifera, corals and other organisms occur from the top to the bottom of the series of cores. On this point the evidence appears to be conclusive, and we are justified in stating that no basis of old Tertiary limestone was reached in the deep boring at Funafuti."

But these two defects, for such we deem them, do not blind us to the many merits and great value of this memoir. The facts will remain, even if, in a few cases, Dr. Salomon's interpretation of them be ultimately set aside. The book is the outcome of years of patient toil, and, when completed by the petrographical and palæontological studies of his collections, will be a permanent monument to his scientific energy, zeal, and acumen.

T. G. B.

TIDAL PROBLEMS.[1]

THE authors of the planetesimal theory have in this volume made a further important contribution to the discussion of the problems of cosmogony. In their endeavours to establish their own theory on a sound footing, much work has necessarily to be done in the way of criticising earlier theories. The classical nebular hypothesis of Laplace has already been discussed in a series of papers by Profs. Chamberlin and Moulton, and found wanting in many respects. To them in part is due the general abandonment of this hypothesis in anything like its original form by most astronomers of the present day. The present volume of papers is directed mainly against the tidal theories developed by Sir George Darwin, and more particularly against the view that at some far-distant epoch the moon separated from the earth.

Prof. Chamberlin's paper on "The Former Rates of the Earth's Rotation" opens with an attack on the theory of centrifugal separation of the heavenly bodies. We are compelled to admit the force of many of his criticisms with regard to the separation of the planets from a parent sun, but the similar criticisms levelled against the formation of the planetary sub-systems are lacking in weight. In particular, the argument from a comparison of the present orbit of Phobos with the ring system of Saturn fails if a change in the dimensions of the orbit of Phobos, assumed negligible, is allowed for. Also the mere statement

[1] "The Tidal and other Problems." By Profs. T. C. Chamberlin, F. R. Moulton, and others. Pp. iv+264. (Washington: Carnegie Institution, 1909.)

that the recently discovered retrograde satellites complicate the centrifugal hypothesis is no serious argument against this hypothesis. They can be made to fit into a general modified scheme. With regard to the earth-moon system, the criticism based upon the irregularity of present-day ocean tides seems irrelevant to the main issue. In the past, at any rate, we must look to regular body tides in the earth as the main factor in tidal evolution; of these tides, as mathematical analysis shows us, a natural result is a retardation of rotation. There are several further criticisms of interest in the paper, notably the reminder that the moon, if brought down to the surface of the earth (assumed to be of its present size), would be inside the limit given by Roche's criterion of stability, and would split into fragments. This point has already been considered by Sir G. Darwin (NATURE, 1886). In his discussion of it he abandons any idea that his theory explains the actual method of genesis of the moon, while he claims that it is of importance in dealing with the moon's later history.

The dynamical arguments of the paper are reinforced by geological arguments. It is shown that there is no geological evidence supporting the view that in earlier times the earth's rotation was much more rapid, and consequently the earth itself much more oblate than at present. The greater part of the changes must have taken place before the earth had solidified and its surface had become a book for the geologist to read. Only on such terms will the geologist accept the tidal theory, and on this particular point he has the support of Kelvin. In view of recent discoveries of unsuspected sources of heat and energy, it seems that the necessary extension of time involved in this requirement of the geologist may be granted by the physicist, and that the theory need not be abandoned by the mathematician at the bidding of the geologist.

Prof. Moulton's line of attack is quite distinct from that of his colleague. By considerations of energy and momenta alone he traces back the earth-moon system under various simplifying assumptions to the time when day and month were equal. He obtains in all cases a distance between the centres of the two bodies of more than 9000 miles. This result is very much the same as that originally found by Sir G. Darwin, but the latter suggested, without examining the point very closely, that a consideration of the sun's tidal effect would greatly diminish this distance. Prof. Moulton proves that the actual difference due to this cause is very slight, and his conclusion strongly reinforces the view that fission must have taken place, if at all, at a time when the earth was much less dense than at present. The further contention that the fission could not have been the result of increased rotation alone has already been recognised as valid by Sir G. Darwin. The latter's suggestion that the coincidence of a solar tide with a free period of oscillation of the earth might have led to a condition of instability has been examined by Prof. Love (Phil. Mag., March, 1889), who showed the idea to be quite feasible.

Of the remaining papers in the volume, which deal mainly with special points discussed by Chamberlin or Moulton in relation to the wider problem, the most interesting is an examination by Dr. Lunn of the heat which would be developed in the building up of a planet according to the planetesimal theory. A general qualitative agreement with the known requirements of facts is reached. More could, perhaps, hardly be looked for. Perhaps the following general criticism of the planetesimal theory may be made at its present stage of development. In many respects it gives a general *qualitative* agreement with observed facts, while its supporters are criticising older theories on the ground that they lack at times a close *quantitative* agreement with observed facts. It remains to be seen whether the newer theory will come up to the standard by which the older theories are being judged.

F. STRATTON.

PROF. SIMON NEWCOMB.

BY the death of Prof. Simon Newcomb science has sustained one of the most severe blows of recent years. America has lost her most eminent man of science, and not since the death of Adams has the world been deprived of so illustrious an investigator in theoretical astronomy. Newcomb's career up to 1899 was described by Loewy in the article on "Scientific Worthies" in NATURE, vol. lx., p. 1, and his activity and marvellous powers of work continued up to the date of the illness that has just terminated fatally. Since 1899 he has given us his interesting book entitled "The Reminiscences of an Astronomer" (1903), in which he described the early incidents of his life and related the extraordinary circumstances by which his steps were guided into the career which led him to such eminence.

Newcomb commenced his reminiscences with the words:—"I date my birth into the world of sweetness and light on one frosty morning in January, 1857, when I took my seat between two well-known mathematicians (Winlock and Runkle) before a blazing fire in the office of the 'Nautical Almanac' at Cambridge, Mass."

Though born at Wallace, in Nova Scotia, March 12, 1835, Simon Newcomb was of almost pure New England descent. His father was, he tells us, the most rational and the most dispassionate of men, who, when he had reached the age of twenty-five, set forth to search for a wife who possessed the qualities most suitable in a helpmeet. His search had extended nearly a hundred miles before, in the village of Moncton, he found in Emily Prince what he desired, and his son says the marriage was "in all respects a happy one, so far as congeniality of nature and mutual regard could go." . . . "My mother was the most profoundly and sincerely religious woman with whom I was ever intimately acquainted, and my father always entertained and expressed the highest admiration for her mental gifts, to which he attributed whatever talents his children might have possessed. The unfitness of her environment to her constitution is the saddest memory of my childhood. More I do not trust myself to say to the public, nor will the reader expect more of me."

How Newcomb's early years were passed may perhaps be conjectured from the fact that the autobiographical chapter in which he records them bears the title of "The World of Cold and Darkness." He had, however, from his earliest years a keen desire for knowledge, and read whatever books were available. His first introduction to the intellectual career he desired was not promising. In those days there was a so-called physician, Dr. Foshay, living near Moncton, who was reputed to have effected cures of sick persons given up by other doctors. As Newcomb says, "Diomeds of the medical profession before whose shafts all forms of disease had to fall were then very generally supposed to be realities." By the intervention of an aunt, young Newcomb agreed to live with the doctor, rendering him all assistance in preparing medicines, while the doctor, on his part, undertook to supply Newcomb's bodily needs and teach him "the botanic system of medicine." After a little experience it began to dawn upon Newcomb that Dr. Foshay, notwithstanding his boasted medical skill, was no more than an ignorant pretender, and that the time of his assistant would be utterly wasted instead of being, as he expected, expended on studying botany and scientific medicine. So on September 13, 1853, Newcomb determined to run away after leaving a letter for the doctor, in which he explained that, as the doctor had shown no indication of fulfilling his promises, his assistant felt that the arrangement was annulled. Newcomb was on the road before daybreak, and walked until late at night, ever fearing pursuit from the doctor. It appears that the doctor did actually attempt a pursuit, but, by good fortune, Newcomb eluded recapture, and at last reached a house where he was hospitably entertained. "Thus ended," he says, "a day which I have always looked back to as the most memorable in my life."

After a week of hardship, which Newcomb says he will not harrow the feelings of the reader by describing, he arrived at Calais, where he found a boat bound for Salem. The little money that he had in his pocket was less than the price of the passage, but he undertook to supplement the deficiency by working his way. A few months later we find him engaged as a teacher in a school at a place called Massey's Cross Roads, in Kent County, and devoting every spare hour to reading whatever mathematical books he could obtain. His first appearance as an author was in refutation of a Mr. Eveleth, who doubted the Copernican system, and Newcomb published in the *National Intelligencer* an exposition of the fallacies in the paradoxer's essay. In 1856 he was teaching in the family of a planter, near Washington, and on a visit to the library of the Smithsonian Institution he was delighted to see among the mathematical books the greatest treasure that his imagination had ever pictured, a work that he had thought of almost as belonging to fairyland—Laplace's "Mécanique Céleste." Shortly afterwards he summoned up enough courage to seek for an interview with Prof. Henry, who suggested that he should look for some position in the Coast Survey, and his reception by Mr. Hilgard was such that Newcomb writes:—"I found from my first interview with him that the denizens of the world of light were up to the most sanguine conceptions I ever could have formed." Mr. Hilgard introduced him to Prof. Winlock, of Cambridge, Mass., and thus in 1857 he entered "the world of sweetness and light" by becoming one of the computers in "The American Ephemeris and Nautical Almanac."

From this time the progress of Newcomb to the height of astronomical fame was unchecked. Dr. Gould, the well-known astronomer, wrote to tell him that there was a vacancy in the Corps of Professors of Mathematics attached to the Naval Observatory at Washington, and suggested that he might like the post. Newcomb at first was disinclined to consider the proposition. Cambridge seemed to him the focus of the science and learning of his country. He also rather shrank from what he called the drudgery of night work in the observatory, for he considered that it would interfere with the mathematical investigations in which he was specially interested; but he finally decided to apply, and a month later, September, 1861, was much gratified in receiving the appointment duly signed by Abraham Lincoln. Newcomb accordingly settled in Washington, where he married, in 1863, Mary Caroline, daughter of Dr. C. A. Hassler, U.S. Navy, and three daughters were the issue of the marriage.

In the winter of 1870 Mr. Cyrus Field, of Atlantic cable fame, had a small dinner-party at the Arlington Hotel, Washington. A young son of Mr. Field's was present, who had spent the day in seeing the sights of Washington. The youth described his visit to the observatory, and expressed his surprise in not finding any large telescope. The guests were at first incredulous, but, finding that the statement was true, a senator who was present declared that this must be rectified, and in due course Alvan Clark and Sons were entrusted with the manufacture of a great objective of 26-inches aperture.

Newcomb was specially interested in this enterprise, because, as he says, "the work of reconstructing the tables of the planets, which I had long before mapped out as the greatest one in which I should engage, required as exact a knowledge as could be obtained of the masses of all the planets. In the case of Uranus and Neptune, the two other planets, this knowledge could best be obtained by observations on their satellites. To the latter my attention was therefore directed." In 1875 the instrument was given over to Prof. Asaph Hall, and of course it has become for ever famous as the means by which Hall made his beautiful discovery of the two satellites of Mars.

In Newcomb's "Reminiscences" we find, in a chapter on "The Author's Scientific Work," a most interesting sketch of the great problems to the solution of which his life's work was devoted. It appears that the first important investigation on which he entered in his early years at Cambridge, Mass., related to the orbits of the asteroids. This particular investigation discussed the theory that these bodies originated as fragments of a large planet broken up by some cataclysm. It involved an extended examination of the secular perturbations of the orbits of the asteroids to determine whether at any epoch even hundreds of thousands of years ago all the orbits passed through one point, though by the influence of perturbations they have now ceased to do so. The investigation seems to show that no such cataclysm as that looked for ever occurred, and that each of the asteroids has been a separate body since the solar system came into existence.

Another problem which shows the lines of thought habitually present to Newcomb may be thus stated. Do the mutual attractions of the sun, planets, and satellites completely explain all the motions in the solar system? or, as he expressed it, "Does any world move otherwise than as it is attracted by other worlds?" This opens up two great researches: first, in bringing the labours of astronomers together so as to determine with the utmost accuracy the actual movements of the heavenly bodies, and, second, in securing all attainable perfection in the mathematical methods employed in their examination. A very important branch of this inquiry is presented by the movements of the moon. Such an investigation as Newcomb sketched out had a stimulating effect on the discussion of old and valuable observations of the positions of the moon deduced from ancient eclipses, and much of Newcomb's best work was done in connection with the lunar theory.

In 1875 Newcomb was offered the position in Harvard University which is now filled with such distinction by Prof. Pickering, but he declined this offer after careful consideration. On September 15, 1877, he was appointed editor of "The American Ephemeris and Nautical Almanac." He tells us that "the change was one of the happiest of my life. I was now in a position of recognised responsibility where my recommendations met with the respect due to that responsibility, where I could make plans with the assurance of being able to carry them out." He approached the duties of this office in the loftiest spirit, and devoted his energies to the task of improving the fundamental constants employed. With this object in view, extensive investigations in various parts of dynamical astronomy had to be undertaken. His efforts were unremitting to improve at every point the processes of calculation, as well as the materials on which the calculations were based. Among the greatest of Newcomb's labours, measured by their value to science, are, undoubtedly, those done in connection with this office. Astronomers all over the world recognise "The Astronomical Papers of the American Ephemeris" brought out under Newcomb's guidance as works of classical value. In this great task he had the good fortune to obtain the assistance of many eminent men, among whom was Mr. George W. Hill, who, in Newcomb's generous words, "will easily rank as the greatest master of mathematical astronomy during the last quarter of the nineteenth century." Newcomb's important "Compendium of Spherical Astronomy," published in 1906, should also be mentioned in connection with the "Astronomical Papers." After his term of service in the office of the American Ephemeris had expired in 1883 by the age-limit, Newcomb became professor of mathematics and astronomy in Johns Hopkins University in Baltimore, and this post he held until 1893.

As in the case of other men who have risen to a foremost position in science, Newcomb was wonderfully versatile. He was, as we have seen, a leader among mathematical astronomers, he did good work on various occasions in practical observation, and that he was a skilful experimenter when occasion required is shown by his beautiful investigations of the velocity of light; but Newcomb also wrote a number of books intended more for the general public than for technical astronomers. His "Popular Astronomy" is universally recognised as an admirable work full of lofty thought and luminous suggestion. It is remarkable for its literary grace no less than for its scientific accuracy, and those who had the privilege of enjoying Prof. Newcomb's friendship will recognise throughout "Popular Astronomy" indications of that quaint humour which was so characteristic of the author. He wrote many other books; he was recognised as an authority on economics and life assurance, and he even wrote a novel, though I do not know whether this particular venture was sufficiently successful to encourage a repetition of the experiment. All the honours which his own country or other countries could bestow on a man of science were liberally showered on him with universal approval.

It need hardly be said that for a self-taught man to become one of the most consummate mathematicians of his day, and one of the great leaders of science, not only great abilities, but indomitable industry were necessary. Newcomb was an indefatigable worker. From morning until night he was at his desk, and yet such was the kindliness of the man that when a demand on his time and friendship was made by a brother astronomer or mathematician, his books were laid aside, and he would devote himself assiduously to a day of gracious offices for his visitor. Newcomb had a serious illness about fifteen years ago, but he made a remarkable recovery, and until the last few months he was still hard at work. He died after a long illness on July 11, 1909.

Thus passes from the world the most conspicuous figure among the brilliant band of contemporary American astronomers. His inspiring example will long be treasured by those who were acquainted with his work. His habitual loftiness of thought, nobility of character, dignified courtesy, and ever-ready helpfulness endeared him to his many friends on both sides of the Atlantic. His private acts of quiet kindness and goodness of heart will be affectionately cherished by those fortunate persons to whom they are known.

ROBERT S. BALL.

NOTES.

THE first attempt to cross the Channel by aëroplane was made by M. Latham on Monday, July 19. The machine, which is a monoplane, started from Sangatte, and was about 600 feet above sea-level when it left the land. This altitude was increased to about 1000 feet, and a speed of between forty and forty-five miles an hour was attained. After travelling about eight miles from the shore in the direction toward Dover the engine stopped, and the monoplane glided steadily down in a straight line to the water, where it floated until the destroyer *Harpon* came up about five minutes later. M. Latham was then taken on board, and his monoplane towed into Calais harbour.

THE death is announced of M. Henri de Parville, who was for several years editor of *La Nature*, and more recently a contributor to *Cosmos*. M. de Parville did much useful work in the direction of instructing and interesting the French public in the achievements of science. Primarily an engineer, he was well versed in other branches of pure and applied science, and for many years devoted the greater part of his energies to work for the scientific Press.

THE Institute of Metals has just completed the first year of its existence, during which period the membership has increased from barely two hundred to well over five hundred. The autumn meeting of the association will be held at Manchester on Thursday and Friday, October 14 and 15. A series of about half a dozen papers will be read and discussed at the two morning sessions of the institute. The afternoon of the first day will be devoted to a visit to the University of Manchester, where members will be received officially, on behalf of the University, by Vice-Chancellor Alfred Hopkinson, K.C. The new engineering laboratories will be open for inspection, and facilities will also be given for inspecting the Municipal School of Technology. In the evening a reception will be held by the Lord Mayor at the Town Hall. During the afternoon of Friday, October 15, members will have the opportunity of visiting works of metallurgical interest in the neighbourhood of Manchester.

THE committee nominated by the Paris Academy of Sciences for the distribution of the Bonaparte fund (25,000 francs) for 1909 has received thirty-five applications, only nine of which are considered to conform with the regulations laid down by the committee of 1908. It is proposed to allocate the fund as follows:—4000 francs to M. Cayeux, to enable him to pursue his researches on the fossils of the Oolitic iron deposits in the United States; 4000 francs to M. Chevalier, to assist him in carrying on his geographical and ethnographical researches in the French colonies in tropical Africa; 4000 francs to M. Pérez, to assist in the publication of his memoir entitled "Recherches histologiques sur les Métamorphoses des Muscides"; 3000 francs to M. Houard, to enable him to proceed to Corsica, Algeria, and Tunis to collect material for his anatomical and physiological studies; 2000 francs to M. Berget, for the construction of an apparatus for the study of the distribution and intensity of gravity; 2000 francs to M. Bernard, to continue his studies of the variation of the solar radiation and the illumination of the sky in the immediate neighbourhood of the sun; 2000 francs to M. Blaringhem, for the continuation of his experimental researches on the variation of species; 2000 francs to M. Estanave, for the continuation of his researches on stereoscopic projection by direct vision, stereoradiography, and autostereoscopy; 2000 francs to M. Mathias, to enable him to continue in the cryogenic laboratory of Leyden his researches on liquids and on the law of corresponding states at low temperatures.

THE seventh annual meeting of the South African Association for the Advancement of Science will be held at Bloemfontein during the week ending on Saturday, October 2, under the presidency of Sir H. Goold Adams, K.C.M.G. The work of the association will be divided into three sections, as follows:—section i. will include mathematics, physics, astronomy, meteorology, geodesy, geography, engineering, mining, and architecture; section ii. will include chemistry, metallurgy, mineralogy, geology, botany, zoology, agriculture, forestry, bacteriology, physiology, and hygiene; section iii. will include education, philology, psychology, history, archæology, economics, statistics, sociology, anthropology, and ethnology. Papers on any of the subjects enumerated will be welcomed, and should be submitted to either of the secretaries. A strong reception committee has been formed under the chairmanship of the Mayor of Bloemfontein (Mr. C. L. Botha), who is taking active steps towards making the visit to Bloemfontein a success. The joint honorary secretaries at Bloemfontein are Dr. Geo. Potts, of the Grey University College, and Mr. Arthur Stead, 40 Victoria Road, Bloemfontein. Further details regarding this meeting of the association may be obtained from the assistant general secretary, P.O. Box 1497, Cape Town.

THE provisional programme of Section H (Anthropology) of the British Association, for the Winnipeg meeting, has now reached us. In arranging the proceedings of the section an attempt has been made, so far as possible, to cover the latest developments in anthropological science. Dr. T. Ashby, director of the British School at Rome, will deal with archæology in the western Mediterranean; Mr. R. M. Dawkins, director of the British School at Athens, with archæology in the eastern Mediterranean; and Mr. D. G. Hogarth with the archæology of Asia Minor, with special reference to the Hittites. Miss Breton will review the present state of our knowledge of the arms and armour and of the physical type of the ancient inhabitants of Central America. It is hoped that the first results of an expedition which Dr. Haddon is now conducting among the natives of the western coast of North America may be available for the meeting. A number of prominent anthropologists of the United States have promised to contribute to the proceedings of the section. Among these may be mentioned Dr. F. Boas, who will deal with anthropological problems in Canada; Miss Fletcher, who will read a paper on her work among the Omaha people; papers will also be contributed by Dr. Gordon, of Pennsylvania, and Dr. Clarence Moore. Dr. Harry Piers, of Halifax, Nova Scotia, will deal with our present knowledge of the natives of Nova Scotia, and Mr. C. Hill-Tout will present his final report on the natives of British Columbia. The valuable reports which have been presented to the association from year to year by Mr. Hill-Tout are the results of work undertaken under the auspices of the Canadian Ethnographic Survey Committee of the British Association, now defunct. In this connection it may be mentioned that papers dealing with the urgent necessity for an ethnographic survey of Canada will be contributed by Mr. E. S. Hartland and Dr. F. C. Shrubsall.

IN the *Revue scientifique* for July 3 is published the discourse delivered by Dr. Edmond Perrier, Director of the Paris National Museum of Natural History, on the occasion of the inauguration, on June 13, of the statue of Jean de Lamarck. In this oration, which is characterised by eloquence and insight, M. Perrier does full justice to the extraordinary industry of Lamarck, and to the merits of his work on the systematics of invertebrates and plants In dealing with his speculative treatises on meteorology and kindred subjects, while allowing that his imagination was apt to get the better of his judgment, M. Perrier pertinently asks what would become of science if its professors never permitted themselves to attack questions which current opinion pronounces insoluble. On the subject of organic evolution, the author brings out in an interesting way the contrast between the influence of Lamarck and that of Darwin upon scientific opinion. M. Perrier does not concern himself to defend Lamarck's view of the method of evolution against objections, but points out that while Lamarck was himself thoroughly convinced of the truth of the general principle which is everywhere accepted to-day, his work met at the time with almost universal neglect. On the other hand, it fell to Darwin's lot to secure the general assent of his scientific contemporaries. After discussing the opposition to Lamarck offered by Cuvier, M. Perrier concludes with the observation that the great anatomist, in the pride of his assurance, was alter all mistaken, and once more it is the *pêcheur de Lune* who was right.

THE Torquay Natural History Society has started a journal of its own, of the first number of which we have received a copy. This opens with an account of the history of the society, which is followed by a series of short papers, several of them dealing with local subjects.

WE are indebted to the Conchological Society for a copy of the July number of the *Journal of Conchology*, in which special reference is made to the need of further workers in Scotland to assist the "census" of British land and fresh-water molluscs now being taken.

THE July number of the *Popular Science Monthly* contains two articles on Darwinian subjects, one, by Prof. F. H. Giddings, dealing with Darwinism in the theory of social evolution, while in the second Prof. Dewey discusses Darwin's influence on philosophy.

THE July number of the *Museums Journal* deals largely with American topics, one article being devoted to the tariff on certain objects of art, a second to exhibits in the Brooklyn Institute illustrative of evolution and the preservation of animals, and a third to the history and collections of the Chicago Academy of Sciences.

To vol. xxvi. (pp. 283–331) of the *Bulletin of the American Museum of Natural History*, Mr. A. Hermann, the chief preparator to the museum, contributes an interesting account of the methods now in use in preparing vertebrate fossils. The plates accompanying this paper illustrate the newest American systems of mounting fossil skeletons for the combined purposes of exhibition and study.

DR. G. STEINMANN has sent us a copy of a paper entitled "Zur Abstammung der Säuger," published in vol. ii. of the *Zeitschrift für induktive Abstammungs- und Vererbungslehre*, in which he further elaborates his remarkable views as to the polyphyletic origin of mammals. The extent to which he carries his views will be apparent when we state that while he derives Glyptodon from the dinosaurs of the Ancylosaurus group, its relative Panochthus is considered to be descended from Polacanthus.

ACCORDING to the July number of the *Selborne Magazine*, the Brent Valley Bird-sanctuary is yearly proving more and more successful, nightingales being numerous, while nuthatches and nightjars have made their appearance in the preserve. At least one pair of nuthatches is known to have nested, and it is not improbable that the nightjars may have laid in a recently made clearing. The Selborne Society desires to make it known that its work is by no means limited to birds, but that antiquities, as well as many other subjects, come within its purview.

THE New York Zoological Society has recently issued a special "Wild-Life Preservation Number," dealing with the efforts that have been recently made, alike in the States and in British Columbia, to preserve a remnant of the big-game fauna of the country. The year under review is a notable one, on account of marking the establishment of no fewer than five new game-reserves on the North American continent. By special enactment, the prongbuck, of which it is estimated that above 5000 head still remain, has been placed on the totally protected list; but it is a question whether the law will be obeyed in remote districts. If not, the only course is to form a reserve in the special habitat of this remarkable and interesting species.

IT is surprising how long it takes to acquire a complete knowledge of the structure even of an animal so thoroughly investigated as the frog. It is not many months since the existence of Reissner's fibre in the *canalis centralis* of the central nervous system of this animal was first announced by Nicholls, and now we learn that the frog also possesses a *nervus terminalis*, morphologically similar to that of fishes. For this information we are indebted to Herrick, who contributes a short paper on the subject to the May number of the *Journal of Comparative Neurology and Psychology*. The nerves in question, for they are, of course, paired, are extremely short and slender, and may be observed in transverse sections lying beneath the olfactory bulbs, but they appear to be quite distinct from the olfactory nerves. They are composed of non-medullated fibres. In the next paper in the same journal, R. E. Sheldon records the occurrence of the same pair of nerves in the carp.

STUDENTS of embryology will find much to interest them in two recent numbers of the *Zeitschrift für wissenschaftliche Zoologie* (vol. xcii., parts iii. and iv.). A memoir by Erwin Taube on the development of the Euphausidæ deals with the segmentation of the egg up to the time of gastrulation, and constitutes an important contribution to our knowledge of cell-lineage in the earlier stages of ontogeny. A kindred topic is ably handled by E. Martini in a study on the constancy of the histological elements in *Oikopleura longicauda*. The author maintains that in many species certain cell-individuals in every specimen come to occupy exactly the same position in the body, always show the same relations to their surroundings, and can also be recognised as homologous by their histological characters. He refers to Goldschmidt's recent work on the central nervous system of Ascaris as one of the best examples of such constancy, and finds a similar condition of things in the nervous system, notochord, and certain other organs of Oikopleura, while the endostyle does not conform to the general rule.

IN the May number of the *Journal of Experimental Zoology*, Raymond Pearl sketches out a comprehensive scheme for the study of the physiology of reproduction in the domestic fowl, and makes a commencement with a biometrical investigation of the shape of the eggs laid by a particular pullet. The first egg was very abnormal in shape, but the normal form was ultimately attained by a progressive regulatory change which is shown to follow a logarithmic curve. The author concludes that the shape of the egg is determined by the muscular activity of the walls of the uterus. The physiology of nematocysts is dealt with in the same journal by O. C. Glaser and C. M. Sparrow, whose investigations support Grosvenor's view that the discharge of the thread-cells is brought about by osmotic pressure. They also afford further proof of the fact, recently demonstrated by Toppe, that the threads are capable of penetrating the tissues of other animals; but it appears that in order to do this they must make their punctures before eversion is complete.

WE learn from the *Transvaal Agricultural Journal* (No. 27) that *Phylloxera vastatrix* has appeared in the Transvaal vineyards, and may be expected to spread and do a considerable amount of damage. Fortunately the Transvaal possesses an excellent Agricultural Department, and all proper steps to cope with the pest will be taken. In an article in the journal Mr. Davis, the Government horticulturist, describes phylloxera-resistant vines that would be suitable for the country and should in future be planted.

THE *Agricultural Journal* of the Cape of Good Hope recently directed attention to the ravages caused by the *Antheraea tyrrhea* caterpillar in certain districts, and published an appeal from the Government entomologist, Mr. Lounsbury, for material. The caterpillar comes as a plague, but between its intervals of abundance it appears to be held in check by some parasitic enemy. Two parasites are known, and others are being looked for as the simplest and most effective way of getting rid of the caterpillar.

THE necessity for looking after fruit trees properly is well brought out in a Bulletin (No. 253) recently issued by the Michigan State Agricultural College. Upon many Michigan farms there are said to be mature apple orchards that have been neglected for many years, and have produced no income beyond an occasional small crop of apples of uncertain quality. A detailed account is given of the methods, chiefly involving pruning and spraying, by which three such orchards were improved and made to yield an average net profit of 104 dollars per acre per annum for a period of five years.

THE results of field experiments in Shropshire and Staffordshire, and at the Harper Adams Agricultural College, have just been issued by the Staffordshire Education Committee. They include manurial trials on grass land, potatoes, mangolds, and swedes, and are on the lines generally adopted in such cases. Unfortunately, no analyses of the soils are given, nor any descriptions sufficient to enable anyone to apply the results to any other case. However, if the intention was simply to show that artificial manures increase crops the experiments have been a success. The experiments carried out at the college are fuller, and some interesting notes are added from the various departments on black scab of potatoes, by Mr. Malthouse; black leg in cattle, by Mr. Wilson; and agricultural chemical analyses, by Mr. B. F. Davies.

IT has always been recognised in England that an agricultural college should have its own farm, but in Scotland the conditions have hitherto been rather different, and it has been held that the college could do without one. We now learn, however, from the *North British Agriculturalist*, that the Glasgow College of Agriculture has decided to acquire a farm at Kilmarnock, to be used both for teaching and experimental purposes. The sum of 3000*l*. will be needed for equipment, but the Scotch Education Department has promised to contribute one half, on condition that the other half can be raised locally. The experiment is attracting a good deal of attention among agriculturists in Scotland.

EXPERIMENTS made in Cape Colony, and reported in the *Agricultural Journal* of the Cape of Good Hope, show that Turkish tobacco of good quality can be grown in certain districts. Irrigation was not found necessary, excepting when planting was to give the crop a good start; indeed, the crop will stand drought quite as well as vines when once it is established. The price realised in 1907 was 1s. 11*d.* per lb., being 5*d.* in excess of the previous year's price; nearly three times as much was grown in 1908 as in 1907, and there has also been a great improvement made in the method of curing. Although the labour required is somewhat special, it has not been found impracticable to train women, girls, and boys to do the finer work.

THE removal of charlock from corn crops was formerly a costly matter when it had to be effected by hoeing, but has become much more simple since chemical methods were devised. Experiments carried on at various centres are reported by Mr. G. F. Strawson, and confirm the results obtained by other investigators. They show that young charlock can be destroyed in growing corn crops without injury to the latter by spraying with fifty gallons of a 3 per cent. solution of copper sulphate per acre. If the charlock is older a stronger solution must be used; early spraying is therefore economical. The crop—whether corn, tares, beans, or peas—increases considerably when the competing weeds are killed, and young grass seeds and clover sown in with the corn are not injured by the copper sulphate because their leaves are too smooth for the solution to remain on.

A WELL-ILLUSTRATED description of the Polish Miocene species of Turritella is given by M. W. Friedberg in the *Bulletin international* of the Cracow Academy, 1909, 2. The author finds that the genus is well represented, and contains a number of varietal forms differing from those ordinarily described. This applies specially to *T. Turris* and *T. pythagoria*, of each of which M. Friedberg describes five varieties.

THE probable origin of the white Florentine iris forms the subject of a note by Drs. R. Pirotta and M. Puglisi in the *Atti dei Lincei*, xviii., 10. Forms have been observed with blue spots variously arranged, and it is found that these are not peculiar to individual plants, but may occur on different plants in different years. From this, as well as from geographical considerations, the authors propound the view that *Iris florentina* is a variety of *I. pallida* which has become permanent.

BY the publication of a well-arranged catalogue, the authorities of the Bradford Public Libraries have shown in the most practical way their appreciation of a large collection of scientific books and pamphlets acquired from the library of the late Dr. F. A. Lees, the author of the "Flora of West Yorkshire." The collection is especially rich in local floras of the British Isles. The herbarium of 25,000 specimens collected by Dr. Lees was acquired at the same time, and is arranged in the Cartwright Memorial Hall.

AN account of the black wax of Burma known in the vernacular as "pwê-nyet" is provided by Mr. D. Hooper in the *Agricultural Ledger* (No. iii., 1908). The wax is stored by a small bee, *Melipona laeviceps*, which forms its hive generally in a hollow tree, and constructs a peculiar trumpet-shaped entrance. The bees commonly swarm in the kanyin-tree, *Dipterocarpus turbinatus*, because in tapping for resin large holes are made in the trees which furnish suitable cavities for the construction of the hives. Incidentally, Mr. Hooper publishes analyses of resins from various species of Hopea, Shorea, Dipterocarpus, and Canarium for comparison with the wax. The chemical tests point to the wax being similar to the resins of Dipterocarpus and Hopea, while the substance forming the vestibule is almost certainly the resin of Dipterocarpus.

A FOURTH article on the sylva of Colorado dealing with forest formations and forest trees is contributed by Prof. F. Ramaley to vol. vi., No. 3, of the University of Colorado studies. There is a well-differentiated forest region in the river valleys, where cotton woods and willows predominate; two mesophytic formations are the canyon and aspen forests of the foothills; the higher montane and sub-alpine formations are composed of pines, firs, and Douglas spruce. The flora contains a number of interesting trees. The pinyon, *Pinus edulis*, yields large edible seeds; the rock pine, *P. scopulorum*, is recommended for planting in semi-arid districts; the Colorado blue spruce, *Picea parryana*, is a fine ornamental tree. The genus Populus includes the aspen, the balsam poplar, broad-leaf cotton-wood, *P. Sargentii*, narrow-leaf cotton-wood, *P. angustifolia*, and lance-leaf cotton-wood, *P. acuminata*. *Rhamnus purshiana* furnishes the drug "cascara sagrada."

THERE are differences of opinion as to the best method of improving the Indian cottons, but there can be no doubt as to the advisability of testing the possibilities of improvement by the hybridisation of native varieties. The problem, which furnishes a capital opportunity for disciples of the Mendelian school, has been broached by Mr. P. F. Fyson, who records his experiments in the Memoirs of the Department of Agriculture in India (vol. ii. No. 6). His object was to test the stability of certain characters as a preliminary to more definite investigations. Colour of flower, shape of leaf, and fuzziness of seed were selected as likely characters. With regard to colour, yellow appeared to be dominant over white, and since the colour in Gossypium is a sap colour, this conforms to general experience. The pointed leaf characteristic of *Gossypium neglectum* (*arboreum*) was dominant over rounded *herbaceum*, but the segregation of "fuzzy" and "naked" seeds was not distinct.

IN the July number of the *Reliquary*, Mr. E. H. Goddard continues the useful series of articles dealing with local collections of antiquities, his subject being Roman objects discovered in Wiltshire. Though the county possesses no Roman sites ranking in interest and importance with those of Dorchester, Silchester, Bath, or even Lydney or Woodchester, it contains Cunetio near Marlborough, villas at Box, Colerne, and Wraxall, and, in particular, Old Sarum, which will remain a sealed book until the excavations now projected are taken in hand. But besides these there are numerous smaller sites, of which only one, Rotherley, has been properly investigated. The best collection of late-Celtic pottery is that gained from the Westbury Ironworks. Mr. Goddard figures and describes a number of interesting objects—pottery, bronze rings and fibulæ, kitchen utensils, the sole of a Roman lady's shoe, and a curious bronze plaque with a figure of Minerva, the last from the downs above Lavington. On October 21, 1638, the Devil visited Widdecombe Church, a fine building on the river Webburn, in Dartmoor, a full account of which remarkable event is recorded on a tablet in curious versification, the work of the village schoolmaster, which is preserved in the church. As a matter of fact, the place was the scene of a terrible thunderstorm, which caused the loss of several lives, damaged the tower, and caused such consternation that it was attributed to demoniacal agency. The original tablet, a curious instance of the popular beliefs current at the time, is reproduced by Mr. Le Blanc Smith in the July number of the *Reliquary*.

THE seventh annual report of the director of the Bureau of Science, Manila, shows what the Americans are accomplishing in the Philippines. One of the most pressing needs has been to obtain a sufficient medical staff to cope with the infectious and epidemic diseases and the pernicious superstitions of the natives relating thereto. At present there is but one doctor to every 430 square miles of territory in the Philippines, and many towns even of some importance have no resident medical man. In these circumstances the medical school is training intelligent natives, and is making efforts to secure sufficient numbers of students to remedy the deficiency. Anthropomorphic measurements of Filipinos and of Igorots are made, and other studies have been undertaken to throw light on the histories of the natives. In addition, a large amount of work is recorded on the natural resources of the island—sugar, fibres, essential oils, &c. It is stated that the fruit of *Pittosporum resiniferum*, Hemsl., commonly known as the petroleum nut, yielded on distillation 7 per cent. of heptane.

"A SHORT Guide to the Museum of Practical Geology, Jermyn Street, London, S.W.," has been issued anonymously at the price of one penny. It seems strange that the names of the curator and director are not attached, but we may take it for granted that they are responsible, as the guide is "sold only at the museum." It will undoubtedly prove of great service to visitors in directing attention to the many objects of scientific interest and practical importance that are exhibited, and in giving so far as possible within the compass of forty-eight pages a good deal of explanatory information. The last handbook to the museum, prepared by Mr. Rudler, the former curator, was issued in 1896, and since that date many alterations and improvements have been made. The removal of the fine collection of British pottery and porcelain, though lamented by many students, was necessary for the proper display of further raw materials in place of manufactured articles. Thus the exhibition of British minerals has been considerably extended, and the practical applications of geology have been more fully illustrated by examples of brick clays, road stones, &c. The map department has received special attention, and illustrations are displayed of the mode of preparation of the Geological Survey sheets on the scales of six inches and one inch to a mile. Instructive models of the Isle of Purbeck and of the complicated district of Assynt, in Sutherlandshire, have also been introduced. Plans showing the arrangement of the specimens on the several floors of the museum form an exceedingly useful feature in this new guide.

WE have received from the Philippine Weather Bureau reports by the Rev. J. Coronas of two severe typhoons experienced in 1908. The first, called the Hong Kong typhoon of July 27 and 28, resembled in its leading characteristics the destructive storm of September 18, 1906. The Manila Observatory was able to announce its appearance to the north of Luzon on the morning of July 26; it increased in speed in the China Sea, where its velocity of translation was about $8\frac{1}{2}$ miles an hour, and about $14\frac{1}{2}$ miles when it struck Hong Kong, but once in China it began to fill up, as is generally the case. The Hong Kong Observatory carefully watched the progress of the storm, and gave timely warning of its approach. The second storm, called the *Tarlac* typhoon of September 18 to 27, from the wreck of the ship of that name, was first announced on the morning of September 20, being then near the Western Carolines. When it reached the Philippines its velocity was about fifteen miles an hour. The storm was most violent at Borongan (Samar), and reduced that town to a heap of ruins; it reached the northern part of Indo-China on September 27. An eye-witness at Borongan states that the roof of the town church was "blown up like a huge kite," while the convent was "simply crushed down" soon afterwards, showing that there were ascending and descending currents on the same side of the centre, the winds being in both cases from the same direction. The area of destructive winds had an average radius of about fifty miles. The full reports, with diagrams, are published in the bulletins of the Weather Bureau.

WE have received a reprint of the article "London by Night," by Mr. H. Wild, which appeared in *Photography and Focus* in March last. It contains four very realistic reproductions of photographs of London streets taken at night by means of the illumination provided by the ordinary artificial lights. The photographs were taken on rapid quarter plates of several makes by means of a portrait lens (Dallmeyer's 2B) with an exposure of about half a second, and they will bear enlargement up to 15×12 inches. They open up a field in photography which was undreamt of a few years ago.

THE June number of *Le Radium* contains an article by M. Moulin on the most probable value of the atomic charge e of electricity according to the most trustworthy of the observations made up to the present time. The three methods which M. Moulin discusses are:—First, the condensation method adopted by Sir J. Thomson and his pupils, and by Profs. Millikan and Begeman in America; second, the direct measurement of the charge on the particle, by Prof. Rutherford and Dr. Geiger; and third, the calculation of the number N of molecules in a gram molecule, based on the measurements of the Brownian movements by Prof. Perrin. The first and third of these methods agree in giving for e the value $4 \cdot 1 \times 10^{-10}$ electrostatic units, while the second gives 4·6, a high result which M. Moulin attributes to the want of uniformity in the layer of radium C with which Messrs. Rutherford and Geiger worked. His final conclusion is that the most probable value of e is $4 \cdot 1 \times 10^{-10}$ electrostatic units, and of N 7×10^{23}.

IT is well known that reaction steam turbines have a lower efficiency at the high-pressure end than at the low-pressure end. This is caused by the relatively small area of blades at the high-pressure end and the proportionally high percentage of clearance which permits of excessive leakage of steam round the blades. Published tests of a large marine turbine show an efficiency ratio of the high-pressure turbine of 55 per cent. at full power, as against 63 per cent. for the low-pressure turbine, in spite of the adoption of lower steam and blade speeds in the high-pressure turbine, thus securing a higher ratio of blade area to clearance area for the purpose of reducing leakage. In the Melms-Pfenninger turbine, illustrated in *Engineering* for July 9, a successful attempt is made to combine the advantages of the impulse type for the high-pressure end with the reaction type for the intermediate and low-pressure sections. An important feature of this turbine is the adoption of a drum construction for the impulse section, in which it differs from the wheel construction usual in turbines of the Curtis type. The remainder of the turbine is of the well-known Parsons type. The makers say that they have found it practicable to work with a clearance of but 10 mils. between the nearest points of the opposed fixed and moving surfaces.

THE steamer *Tortuguero*, which was launched from the shipbuilding yard of Messrs. Alexander Stephen and Sons, Ltd., at Linthouse, on the Clyde, on March 24, and sailed on April 22, represents the latest practice in the transport of bananas from the West Indies. A full description of the vessel appears in the *Engineer* for July 9, from which we note that she is of 5000 tons gross, having insulated space of 220,000 cubic feet, the capacity of the fruit bins being 175,000 cubic feet. Granulated cork is used for the insulating material, the average thickness of the cork being from 7 inches to 8 inches, and the bins are so constructed that the bunches of fruit do not come into contact with metal surfaces during transit, all such being protected by wood gratings and battens, or by hemp-rope coverings. An elaborate arrangement of air passages enables cooled air to be supplied throughout the cargo, the cooling of the air being effected by a Hall's CO_2 refrigerating plant. An even temperature of 55° F. is maintained, and the fruit is inspected frequently so as to ensure its arrival at Manchester in proper condition for the market. In loading, the fruit is stored without covering of any kind, the lowest bunches are arranged with stems vertical, and the final layer placed horizontally, an arrangement which economises space and ensures freedom from damage.

A SECOND edition of Mr. Arturo Massenz's "Lavorazione e Tempera degli Acciai" has been published by Mr. Ulrico Hoepli, of Milan. The price of the volume is 2 lire.

SOLUTIONS of the exercises in their "Modern Geometry" have been prepared by Messrs. C. Godfrey and A. W. Siddons, and are published in volume form by the Cambridge University Press at 4s. net.

MESSRS. DAWBARN AND WARD, LTD., have published a fifth edition of the 1909 "Photographic Annual, incorporating the Figures, Facts, and Formulæ of Photography." This year-book is edited by Mr. H. Snowden Ward, and the present issue has been extended, largely re-written, and revised to June, 1909.

MR. BERNARD QUARITCH has just issued a catalogue of books on natural history which he is offering for sale. Particulars are given of works on zoology, geology, palæontology, mineralogy, and botany. Among other interesting items we notice the original drawings of Hubner's European butterflies, an example of Jacquin's Selectarum Stirpium Americanarum Historia, and a few important herbals.

WE have received in two volumes parts A, B, C, and D of the quarterly bulletin of the results for the year 1907–8 secured during the periodical cruises and in intermediate periods in connection with the Permanent International Council for the Exploration of the Sea. The parts in order deal with the temperature and salinity of the surface water; the temperature, salinity, density, &c., of sea water at different depths; the oxygen, nitrogen, and carbon dioxide dissolved in sea water; and plankton tables for August and November, 1907, and February and May, 1908. The first three parts have been prepared with the assistance of Mr. Martin Knudsen, and the last with the help of Mr. Harry M. Kyle. The volumes are published by Andr. Fred. Høst et Fils, of Copenhagen.

OUR ASTRONOMICAL COLUMN.

STATIONARY METEOR RADIANTS.—Since Mr. Denning announced the existence of stationary meteoric radiants in 1878, many observers have endeavoured to explain, and account for, them, hitherto without much success. The apparent radiant of a meteor depends almost as much on the true direction of the earth's motion as it does on the true motion of the meteor itself, therefore it seems almost impossible that these bodies should appear to stream from the same point of the heavens for months at a time. In an article appearing in No. 5, vol. xxix., of the *Astrophysical Journal* (June, p. 365), Prof. W. H. Pickering shows, however, that this apparently puzzling phenomenon is only what is to be expected, arguing from our present knowledge of meteor-orbits. Briefly, he shows by diagrams and tables that the attracting force of the earth's mass is, at different times, capable of deflecting or accelerating the smaller bodies, so that the apparent change of the longitude of the radiant counterbalances the variation produced by the earth's motion; thus the radiant appears to be stationary, or nearly so. Prof. Pickering also produces arguments against the prevalent idea that meteors are generally of infinitesimal mass.

COMPARISON OF THE SPECTRA OF THE CENTRE AND EDGE OF THE SUN'S DISC.—Previous observations having indicated that in passing from the centre to the edge of the sun's disc the spectrum suffers modification, MM. Buisson and Fabry recently repeated the observation, using their interferometer method, in which each wave-length is examined independently of those of the other lines. Their observations, which are published in No. 26 of the *Comptes rendus*, confirm the earlier ones of Hale and Adams, and Halm.

The latter showed that the wave-length of a line in the spectrum at the limb was a little greater than when the centre of the disc was observed. From the study of fourteen lines in the region of λ 4400 MM. Buisson and Fabry find that the increase of wave-length varies from 0·004 to 0·006 Ångström; to this rule the two vanadium lines, λ 4379·4 and λ 4406·8, are exceptions. The observations also show that in the spectrum at the limb the same lines are a little broader than in the spectrum at the centre, the increase of breadth amounting, in the mean, to 0·010 Ångström.

MM. Buisson and Fabry suggest that these two phenomena, displacement and broadening, are due to the same cause. The only modification a line really undergoes is a displacement, amounting to 0·010 Ångström, of its red edge, the more refrangible edge remaining invariable. In the exceptional case of vanadium the broadening is apparently symmetrical. They suggest, further, that the asymmetrical broadening may be caused by pressure—an increase of seven atmospheres would be sufficient to produce the observed effect—but only becomes apparent at the limb where a greater thickness of the denser layers is traversed by the radiations.

CHANGES OF FORM IN SUN-SPOTS.—Some interesting results of detailed observations of sun-spot forms are discussed, and illustrated by drawings, by M. A. Amaftounsky in No. 4332 of the *Astronomische Nachrichten*.

He shows that whilst, in general, the outline of the penumbra roughly follows the form of the nucleus, tremendous changes may take place in the former, whilst the latter is apparently undisturbed. This is what would be expected on the hypothesis that the nucleus of the spot is a depression, a hole, and the penumbra is produced by the ascending and descending of incandescent vapours. The appearance of bright spots in the nucleus, sometimes followed by the bridging and disintegration of the latter, is explained by the supposition that the nucleus is at a higher temperature than the photosphere, and constantly re-vaporises the filaments and tongues of the penumbra by the expulsion of hotter vapours.

MUTUAL OCCULTATION OF JUPITER'S SECOND AND FOURTH SATELLITES.—In No. 4338 of the *Astronomische Nachrichten* M. Pidoux describes the conjunction and mutual occultation of J ii. and J iv. observed by him at the Geneva Observatory on June 17, 1908. Plotting the various measures, he finds that the conjunction took place at 8h. 33·4m. (G.M.T.), the shortest distance between the centres of the satellites being 1·9″. Whilst the latter quantity agrees exactly with that calculated and published by Oudemans, the time is 4·6 minutes in advance of the ephemeris.

According to calculation, satellites iii. and iv. should have been in conjunction at 7h. 58·5m. on July 3, 1908, but when first observed by M. Pidoux, at 7h. 52m., the conjunction was already complete and the satellites appeared as one. At 7h. 59m. the system was elongated, and at 8h. 2m. the two images were distinctly separated. It therefore appears that the observations prove the calculated times to be several minutes too late.

THE YERKES OBSERVATORY.—From the University of Chicago we have received a brochure in which Prof. E. B. Frost gives a brief, detailed account of the establishment, equipment, and work of the Yerkes Observatory. Fourteen excellent reproductions of photographs of instruments, spectroheliograms, nebulæ, &c., illustrate the twenty-four pages of the booklet, and give the reader a very fair idea of the enormous activities and possibilities of the institution. One point which attracts our attention is Prof. Frost's emphasis of the necessity for having, in a modern astronomical observatory, well-equipped workshops wherein repairs and modifications of existing instruments may be executed, and new instruments constructed.

PROMINENCE OBSERVATIONS.—No. 6, vol. xxxviii., of the *Memorie della Società degli Spettroscopisti Italiani* contains Prof. Riccò's periodical summary of the Catania prominence observations, dealing with the first six months of 1908. Prominences were observed on ninety-three days during the six months, and 170 in the northern, and 247 in the southern, hemisphere were measured. The mean latitude for the two hemispheres was 27·5°, but, dividing the latitude, N. and S., into 10° steps, there were two maxima (lat. 10°–20° and 50°–60°) in the northern hemisphere and only one (20°–30°) in the southern.

SCIENTIFIC WORK IN INDIA.

THE annual report of the Board of Scientific Advice for India for the year 1907–8 has lately been issued by the Superintendent of Government Printing, Calcutta. The Board was constituted in 1902, and consisted originally of the heads of the meteorological, geological, botanical, forest, survey, agricultural, and veterinary departments, but the Government of India invites from time to time to serve upon it other men of science in the service of the imperial and provincial Governments. The Board is a central authority for the coordination of official scientific inquiry, intended to ensure that the work of research is distributed to the best advantage and the prevention of useless duplication of inquiries and lack of inter-departmental cooperation. The advice of the Board is given with the view of aiding the Government of India in prosecuting practical research into questions of economic and applied science on the solution of which the progressive prosperity of the country depends. The Board discusses annually the proposals of the head of each of the great departments in regard to the programme of investigation in his department, and submits each year a general programme of research to the Government. Its reports and programmes are communicated through the Secretary of State for India to the Royal Society, which has appointed an advisory committee to consider them.

The present report opens with a summary of the proceedings at the three meetings held during 1908, two at Calcutta and one at Simla. As indicative of the scope of the labours of the Board, some of the subjects discussed at the first meeting may be mentioned. The Board had under consideration the remarks of the Royal Society committee on the Board's report for 1905–6 and its programme for 1907–8. The subjects discussed included, among many others, the preparation of a hand-list of the species of the flora of India, economic and industrial chemistry, and the limits of the imperial mycologist's research work, the relations of the zoological section of the Indian Museum to other departments engaged in zoological research, and proposals for a special report on the progress of the Geological Survey.

The conclusions arrived at by the Board in these matters were as follows:—that, as regards the preparation of a hand-list of the flora of India, although its importance was recognised, lack of staff and the existence of more immediately necessary work precluded its preparation forthwith; that the consideration of economic and industrial chemistry and the work of the imperial mycologist should await the results of the discussion of the subjects by the Board of Agriculture for India; that reference should be made, so far as possible, to the zoological section of the Indian Museum by other departments engaged in zoological research; and that no officer was available for the increase of work that the preparation of a special report on the progress of the Geological Survey of India would necessitate.

Very full reports upon the work of the various scientific departments during the year 1907–8 then follow. Dr. J. W. Leather and Mr. D. Hooper deal with the work on industrial and agricultural chemistry, and Mr. Puran Singh with forest chemistry; Dr. G. T. Walker, F.R.S., with solar physics, meteorology, and terrestrial magnetism; Sir Thomas H. Holland, F.R.S., with geology; Colonel S. G. Burrard, F.R.S., with geodosy and geography; Messrs. W. W. Smith, A. Howard, E. J. Butler, and R. S. Hole with various branches of botany; Mr. A. M. F. Caccia and A. J. Gibson with forestry; Dr. N. Annandale and Messrs. H. Maxwell-Lefroy and E. P. Stebbing with zoological subjects; and Colonel H. T. Pease with veterinary science.

The programmes of work of the various scientific departments for the year 1908–9, as approved by the Board, constitute the next section of the volume, which concludes with an appendix by Dr. W. R. Dunstan, F.R.S., director of the Imperial Institute, describing the economic investigations conducted for India at the Imperial Institute during the year ended September 30, 1908.

The detailed programmes of work teem with particulars of investigations of great interest, but since the bare enumeration of the researches to be undertaken runs to twenty-seven large pages, it is possible here only to give an example or two. In meteorological work, a special endeavour is being made this year to secure meteorograph records of temperature and humidity up to great heights by means of small balloons. At four nearly equidistant periods between April and December batches of registering balloons have been, and are to be, liberated at some place in the west of the Punjab, and organised efforts made to recover as many as possible on descent. Each batch was to comprise, perhaps, ten complete units, the adjustment and liberation of which takes between a week and ten days. It was hoped to reach heights of 25,000 feet in the earlier experiments, and later in the year it is hoped to increase the heights at which the balloons are caused to descend until 50,000 feet has been reached. It is important to reach this height in order to see whether the isothermal zone, which has been almost invariably found at or near that level by sounding balloons in Europe, is to be encountered over India.

The new work to be undertaken by the Geological Survey provides another typical instance of the activity of scientific workers in India. The mapping of previously unsurveyed areas in the Amherst district of Lower Burma is being proceeded with, the geological map of the Raniganj coalfield is being revised in conjunction with a committee appointed by the Mining and Geological Institute of India, and the following pieces of work are in hand:—a survey of the ossiferous deposits of the Siwaliks and the Salt Range; an examination of copper-ore and associated sulphide-ore deposits in Sikkim; a survey of certain glaciers in Sikkim; and a study of the palæontology of (*a*) the Cretaceous rocks of Tibet, (*b*) the fossil fishes of the East Coast Gondwanas.

POSITION FINDING WITHOUT AN HORIZON.

WHEN about three years ago the first Gordon-Bennett balloon race was held, and several of the aëronauts descended precipitately on the north coast of France, believing they were approaching the Bay of Biscay, it seemed to me worth while to consider the possibility of designing an instrument by the aid of which observations could be taken so as to obtain even a rough idea of position. For this purpose the observation of the altitude and azimuth at any moment of a single star or of the sun will be sufficient to establish the locality, or the altitudes of two stars not in the same vertical plane with the observer will do as well.

If the observation is such that the error is as great as the diameter of the sun or moon, the resulting uncertainty of position will be a little more than thirty miles, and so in proportion. The observer will be, of course, on a circle on the earth described round the point where the star is in the zenith, the radius of which in nautical miles is equal to the zenith distance of the star expressed in minutes.

A search at the Patent Office library showed that a large number of inventors had for nautical purposes, rather than for use in balloons, imagined instruments which, for various reasons, would be impracticable. In some an attempt has been made to combine a sextant and a pendulum, but even if the observer were not expected to watch the star and the pendulum at the same time, the pendulum was made so short and of such quick period that the inevitable trembling of the hand would give rise to angular relative movement of the pendulum represented by several diameters of the sun. The beauty of the sextant is the property it possesses of gluing the two objects, *e.g.* the sun and horizon or moon and star, which are being observed together, so that with all the spasmodic movements which the magnification of the telescope and the unsteadiness of the hand make inevitable, the eye, nevertheless, can follow them and see if there is continuous close contact or not, whereas if the apparent position of one of the objects only depended upon the steadiness of the hand, no observation worthy of the name would be possible. It is therefore essential, if any approach to accuracy is required, that the star or sun should be seen in the same field with, and glued to, the mark, whatever form that may take, which determines the altitude, and also that the angular variation in the position of this mark should hardly be affected by the trembling of the hand. I tried at the time to interest one or two instrument makers, but unsuccessfully; now, however, that the subject is attracting attention in Germany, as shown by Dr. Lockyer's (vol. lxxx., p. 29) article in a recent number of NATURE, perhaps my design may be worth bringing forward. I would only remark that an instrument of the kind would be useful on board ship when the sun or stars may be visible while the sea horizon is obscured, provided only that, as is usual in fog, the ship is not rolling seriously. These worse conditions can only be met by the more complicated gyroscopic horizon perfected by Admiral Fleuriais.

The instrument depends essentially upon the use of a vertical collimator suspended on gimbals, and top-weighted like a metronome, so as to have a period of swing either way of as much as one second. The collimator has at its focus a scale of, say, tenths of a degree in transparent divisions upon an opaque ground, and above its lens a clear or half-silvered glass mirror set at 45° with the axis of the collimator. The collimator is suspended in a tube, which is the handle of the instrument, and which carries also the parts of a small sextant.

Figs. 1 and 2 are vertical sections through the axis of the instrument, the latter partly in elevation. *a* is a box frame to which are attached the tubular handle *b*, the telescope *c*, and other sextant parts. The telescope is carried by means of a slide *d* and pin *e*, so that it may be moved sideways or be hinged downwards when not in use. Inside the handle is mounted a gimbal ring *f*, on which the collimator *g* is supported on knife-edges *h*; *i* is the scale already described; *k* is the unsilvered mirror attached to the collimator, by means of which the scale *i*, illuminated by the mirror 7, may be seen in the telescope; *l* and *n* are the horizon and index glasses respectively of the sextant, but made as prisms for convenience, though, of course, the usual mirrors might be used; *r* is the top weight of the collimator; and *t* a correcting weight running on a screw to bring the zero of the scale *i* apparently on to the true horizon. A conical damper *u*, lined with velvet, is made to slide within the handle, being pressed upwards by a spring *v* so as to steady or even to lift the collimator off its *v*'s and against the pins 1, and capable of being moved downwards by the thumb-lever *x* and fork *y*. An exterior sleeve 5 carries a cap 8, which serves as a protector to the translucent window at the base of the handle, and as a holder also for the illuminating mirror 7; 3 is a quadrant carrying three dark or tinted glasses.

When the telescope is directly opposite the mirror *k* and the reflectors *l*, *m* of the sextant, the star will be seen by double reflection projected upon the scale, of which one half is marked + and the other −. The arm of the sextant being therefore set to any position to bring the star on to the scale, a series of scale readings may then be made, which, added to or subtracted from the vernier reading, give the series of altitudes. If the telescope is slid sideways so that half its field is to the right of the mirror *k*, it may be made to look into the object-glass end of a surveyor's level or even at the sea horizon with a known dip, and the zero of the scale tested and so adjusted by means of the moving weight *z*. At any time when a sea or artificial horizon is available, observations may be made as with an ordinary sextant with the telescope laterally displaced, and by this means also the index-glass may be adjusted.

I have experimented with a collimator and telescope mounted as described, and found that, without the top

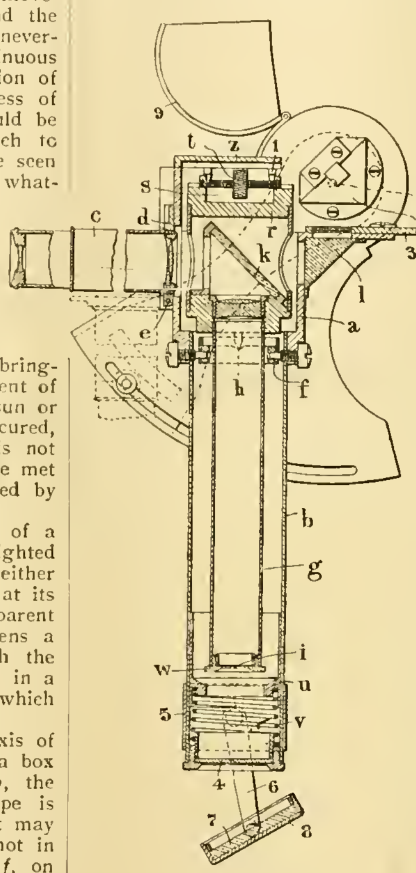

FIG. 1.

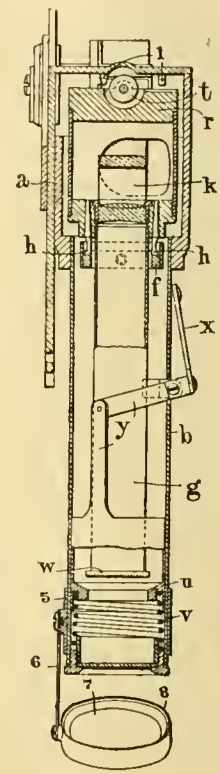

FIG. 2.

weight, the angular movement due to unsteadiness of the hand is far too great for accurate observation, but that when the period is increased to about one second by top-weighting, the angular movement is so far reduced that, when sitting at a table and holding the instrument in the hand, an accuracy of 1′ is possible. Of course, with the trembling of the hand the collimator turns about its centre of oscillation, and so with the period named a sudden movement of 1/100 inch will correspond to 1′ about, while if the period is two seconds the angular accuracy will be four times as great.

If used on a ship with any appreciable rolling it would be best to get down to the neutral axis, and observe zenith stars through a hatchway, so as to avoid the horizontal acceleration which is so pronounced on the bridge, for, of course, the collimator will hang, not in the true vertical, but at an angle equal to $\tan^{-1}\frac{\text{horizontal acceleration}}{g}$. If this is small the star may be observed to move a corresponding degree upon the scale in time with the rolling of the ship, and the successive elongations may be read off.

In a balloon, owing to the extreme quiet, I believe useful observations could be taken, more especially at those times at which it is not turning. I do not think it would be of any use on a flying machine in motion.

C. V. BOYS.

THE POSITION OF HIGHER EDUCATION.

THE higher education subcommittee of the education committee of the London County Council has had under consideration the relations which it is desirable should subsist between the University of London and other institutions of university rank in the metropolitan area and the London County Council. The subcommittee's report was presented to the education committee towards the end of May, and contains, not only a valuable *résumé* of the various steps taken by the late London Technical Education Board and by the Council itself to improve the supply of higher education in London, but also an important collection of statistics concerning the financial aid given by municipal and other authorities in the great provincial centres of population.

The subcommittee's report includes tables of grants made by other local education authorities to university education, the grants made by the Treasury in London and the provinces, and those provided by the London County Council. In London the grant from the Council is 48·6 per cent. of the Treasury grant, and in other towns the grant from the local authorities is 75 per cent. of the Treasury grant.

Grants mode by Provincial Local Authorities to Universities and University Colleges.

	Treasury grant	Grants from Local Authority
Universities:	£	£
Birmingham	11,000	7,010
Leeds	11,000	14,456
Liverpool	13,050	14,650
Manchester	15,200	5,950
Sheffield	5,700	11,744
University Colleges:		
Bristol	4,750	532
Newcastle-upon-Tyne	6,750	2,890
Nottingham	5,800	4,340
Reading	3,950	1,800
Southampton	3,250	2,113
Aberystwyth	4,000	—
Bangor	4,000	—
Cardiff	4,000	4,712
Dundee	1,000	80
Total	£93,450	£70,277

London County Council Grants to University Education.

	Treasury grant	Council grant
	£	£
Bedford College	4,000	800
King's College	8,700	2,000
University College	10,000	1,500
London School of Economics	1,150	1,200
East London College	—	1,000
Imperial College of Science and Technology	20,000	5,000
University of London	8,000	10,000
Extra Grants	—	3,720
Total	£51,850	£25,220

It is pointed out in the report that the various universities and university colleges have been successful in obtaining great assistance from generous donors, and that in such cases the receipt of State aid and financial help from the local authority does not seem to affect the flow of private benevolence. Thus Birmingham has received more than 256,000*l.* in this way; Leeds 380,000*l.*; Liverpool more than 188,000*l.*; Manchester more than 192,000*l.*; and Sheffield more than 229,000*l.*; while, in London, University College had received up to the date of the latest Government report 453,000*l.*; King's College 206,000*l.*; and Bedford College more than 29,000*l.* from private benefactions.

The subcommittee has given careful and sympathetic consideration to the applications received from certain London institutions of university rank for grants during the present year, and has come to the conclusion that more might be done in London for university education in consideration of the amount of the grant received from the Treasury, and having regard to the rateable value of the county of London. In this connection the following table, abbreviated from one included in the report, is instructive:—

Town	Rate in £ necessary to raise grant to local University or University College	Amount obtainable from a similar rate in London
		£
Birmingham	0·498	92,672
Leeds	0·638	118,724
Liverpool	0·6027	112,162
Manchester	0·227	42,203
Sheffield	0·646	120,228
Bristol [1]	0·070	12,946
Newcastle-upon-Tyne	0·173	32,129
Nottingham	0·851	158,360
Reading	0·6033	112,288
Southampton	1·00	186,111
Aberystwyth	—	—
Bangor	—	—
Cardiff	0·977	181,840
Dundee	0·019	3,604
London	0·135	25,220

The table shows very clearly that if London made the same proportional provision for higher education that Cardiff does, the annual grant would be 181,840*l.* instead of 25,220*l.*; or 158,360*l.* if it applied the same fraction of the rate as Nottingham does for higher education.

It is of interest to pass from the comparison of rate-aid and State-aid for higher education in England and Wales made in this and the preceding tables to some facts relating to the position of the subject in other countries. By a fortunate circumstance, an exhaustive article by Prof. Guido H. Marx in the issue of *Science* for May 14 shows remarkable growth and spread of interest in higher education, and the consequent great increase in the number of young men and women pursuing advanced studies, and receiving higher scientific and other training, in various countries.

It is natural to look to Germany for significant educational movements, and Prof. Marx, dealing with the combined attendance at the twenty-two German universities, shows that prior to 1870 this attendance was fairly uniform, keeping regular pace with the population. Immediately after 1870 the increase of attendance grew much more rapidly than the population, and there is not the slightest tendency for the increase to fall off. At the beginning of the period of rapid development in 1870 there was in Germany one student in the institutions of higher education for every two thousand inhabitants, while in 1907 there was one such student to every thousand inhabitants.

In the case of the United States of America, the combined attendance at all the colleges, universities, scientific, technical, and professional schools—omitting preparatory departments—up to the year 1885 showed a condition of practical stability, but beginning with that year the ratio of these students to the population increased year by year, and at present indicates no signs of falling off. In 1885 there was one such student for every seven hundred inhabitants, and twenty years later one for every four hundred of population.

Several important deductions can be made from the following table, drawn up by Prof. Marx:—

[1] The Bristol Town Council has decided to devote the produce of 1*d.* rate (about 7 000*l.* a year) to university education.

Number of Students in Higher Educational Institutions in different Countries.

Country	Population	Total number of students	Population per student
United States	84,000,000	210,333	400
Switzerland	3,500,000	6,500	530
Germany	61,000,000	61,267	1,000
Sweden	5,300,000	5,000	1,060
France	39,000,000	32,000	1,200
Roumania	6,000,000	5,000	1,200
Italy	33,000,000	24,000	1,400
Belgium	7,100,000	5,000	1,400
Holland	5,600,000	4,000	1,400
Austria-Hungary	47,000,000	30,000	1,570
Spain	19,000,000	12,000	1,600
Great Britain	44,000,000	25,000	1,750
Russia	147,000,000	23,000	6,400

Russia, it is seen, is the only western country of prominence which has not passed Germany's figure of the year 1870, namely, one student for two thousand inhabitants. "Perhaps," says Prof. Marx, "the most striking fact displayed by this table is the way Great Britain has lagged in this vast movement of the democratisation of the advantages of higher education—and, scarcely less significant, the strong leading position of the United States."

Too much importance must not, however, be attached to the table here reprinted with slight modifications, or to Prof. Marx's conclusions. The total number of students of higher education in the case of the United States includes students of both sexes in colleges, universities, technical and professional schools (exclusive of preparatory departments), in the session 1905–6, and in the case of Germany, too, the students of technical and professional schools above gymnasial rank are included in the total. But Great Britain's 25,000, and the totals assigned to all the remaining countries except Russia, deal only with their universities; their technical colleges and professional schools being ignored, apparently. It is not by any means contended that higher instruction in science and letters receives anything like the consideration it should in this country, but it is desirable, in making a comparison such as that Prof. Marx has instituted, to eliminate as many sources of error as possible, and to confine attention rigidly to matters which are really comparable. The article upon "The Supply of Secondary Education in England and Elsewhere," which appeared in NATURE of June 17, supplements to some extent the information brought together by Prof. Marx and summarised in the foregoing tables.

ASSOCIATION OF ECONOMIC BIOLOGISTS.

THE eighth annual meeting of this steadily growing association was held in the new School of Forestry at Oxford on July 13–15. The outstanding features of the meetings were the extremely interesting, and in many cases important, papers that were read and the discussions which followed, signs alike of the increasing importance of the application of biological science.

The president, Dr. A. E. Shipley, F.R.S., opened the meeting with a paper on the relations of certain cestodes and nematode parasites to bacterial disease. He argued that the piercing of the wall of the alimentary canal by parasites carries with it bacterial infection. In the case of the "disease" of the grouse, the piercing of the wall of the cæcum by the tapeworm *Trichostrongylus pergracilis* was followed by an intrusion of bacteria into the submucous layers. It is found that there is a definite relation between the number of worms in the alimentary canal and the number of bacteria in the body of the host. This perforation of the intestinal wall and subsequent invasion of the lesions by bacilli is of importance in such diseases as peritonitis and appendicitis. Such worms as Oxyuris, &c., are frequently associated with peritonitis, and other entozoa with appendicitis. He strongly advocated the greater use of vermifuges, which are used less than heretofore, and in this he was supported by Prof. Osler in the discussion that followed.

One of the most important papers was that of Prof. G. H. F. Nuttall and Dr. S. Hadwen, who gave an account of their successful curative treatment of piroplasmosis. This "tick-fever" is very fatal. In severe cases 80 per cent. to 85 per cent. of the red blood-corpuscles are infected, and the escape of the parasites into the blood gives rise to the characteristic hæmoglobinurea. The life-cycle, which was described, bears a definite relation to the treatment, and the double pyriform and large rounded forms of the parasite are dominant in the blood. It was found that if trypanblau was injected subcutaneously or intravenously all the pyriform parasites disappeared, and the remaining parasites degenerated two hours later. The animals (dogs) showed no symptoms. The parasites returned in very small numbers after about ten to twelve days, but the animals appear to be quite well, and the parasites disappear. One injection was sufficient, and nearly all the animals injected were cured, while the uninjected controls all died; a 100 per cent. mortality which occurred in this disease in dogs was converted into an 85 per cent. recovery. The drug has the same effect on the Piroplasma causing "red-water disease" in cattle. Further investigations of a thorough character are necessary before the drug can be put to practical use, but its discovery is of the greatest importance.

Mr. C. Warburton gave a very interesting account of his experiments on the life-histories of the human Pediculi, the clothes and head lice. Great difficulties were encountered at first, but finally, by allowing them to feed on the back of his hand two or three times a day, the author was able to fill a very important blank in the knowledge of these insects. He found that the female of *P. vestimenti* laid 124 eggs in twenty-five days. The eggs began to hatch in eight days, and continued to do so for about a month. The larvæ feed as soon as they are hatched, and after moulting three times became imagines in eleven days. Great trouble was experienced in breeding *P. cervicalis* (*P. capitis*), but patience and discomfort were rewarded with success, and it was found that a single female deposited forty-eight eggs, which hatched in seventeen to eighteen days, and the later stages were correspondingly lengthened compared with those of *P. vestimenti*.

The actual and possible applications of recent discoveries in heredity to biological problems of an economic character were discussed by Mr. A. D. Darbishire. He showed how important were such Mendelian principles as segregation and the breeding true of organisms bearing the recessive character. The recessive character may be a resistance to the rust fungus, as Prof. Biffen discovered in wheat. He was inclined to believe that resistance to the attacks of the beetle Bruchus might be dealt with according to Mendelian principles, and also the increase of the saccharine contents of peas by the selection of the absorptive character, which is different in round and wrinkled peas.

Mr. S. A. Neave gave an interesting account of his observations on the distribution and habits of the tsetse-fly *Glossina palpalis*, which were made in the Congo Free State and North-east Rhodesia in the years 1907–8. It would appear that the high plateau country forming the watershed between the basins of the Congo and Zambezi rivers forms a barrier against the southward extension of the distribution of the fly. He was of the opinion that, on the whole, *G. palpalis* will not be found to occur in the Zambezi basin, an important fact in view of the possibility of the spread of sleeping sickness into South Africa entertained by some authorities.

The results of observations and investigations on other insects of economic importance were communicated to the association. Dr. C. Gordon Hewitt has continued his investigations on the large larch saw-fly *Nematus erichsoni*, and finds that the natural enemies are increasing in number. The percentage of parasitic ichneumons has increased, as also the attacks of the small vole *Microtus agrestis*. A parasitic fungus (Cordyceps) has been found attacking the pupal stage, and the insectivorous birds are being encouraged. In spite of all these he was of the opinion that the results of the attack would be of a grave character, an opinion which was shared by Prof. Somerville in the subsequent discussion. A number of successful experiments on the breeding of the house-fly during the winter months (February) under favourable conditions of temperature, &c., were described by Mr. F. P. Jepson, who has thus been able successfully to confirm the observations of previous investigators. Mr. Walter E. Collinge described the part played by the Collembola, or "springtails," in the destruction of such plant life as developing seeds, bulbs, orchids, and hops. The structure of the rose-aphid *Siphonophora rosarum* was described by Mr. A. J. Grove, and Prof. E. B. Poulton exhibited a collection of predaceous insects and their prey.

The disappearance of the fresh-water crayfish from the Thames valley and other localities in this and European countries owing to the so-called "plague" is a problem of great interest to biologists. Mr. Geoffrey Smith's paper on some of the work that he has been carrying on in cooperation with Prof. Dreyer on the pathogenic bacteria of *Carcinus moenas* was of especial interest to economic biologists, as this work is connected with the question of the relation of the so-called plague bacillus to other pathogenic bacteria living on the outside of crabs, lobsters, and crayfishes.

Prof. William Somerville exhibited an interesting collection of injurious fungi and the injuries caused by the same, and a paper on the blossoming and pollen of our hardy cultivated plants, by Mr. C. H. Hooper, was communicated to the association.

On July 14 a very enjoyable excursion to the School of Forestry's arboretum at Tubney and to Bagley Woods was made. It was also resolved to accept the invitation to hold the meeting next year at the University of Manchester.

THE MUSEUMS ASSOCIATION.

THE twentieth annual conference of the Museums Association, which opened at Maidstone on July 13, attracted a fair number of members from the more southern towns, though the northern districts were not very generally represented.

Preceding the conference there was a council meeting on the evening of Monday, July 12, when the secretary and editor, Mr. E. Howarth, resigned those offices, after being editor of the *Museums Journal* since its first issue in 1901, and secretary for many years prior to that date. The formation of the association was first advocated in an article written by Mr. Howarth and published in NATURE in 1877. From that time the idea gradually extended, and in 1889 the association was duly organised at York, where it will very fitly hold its twenty-first anniversary next year.

The president, Mr. Henry Balfour, curator of the Pitt-Rivers Museum at Oxford, opened the proceedings with an extremely interesting address, which dealt cogently with the question of a national folk-museum, one of the phases of museum work that has been strangely neglected in these islands. While the ethnology of most regions of the world is illustrated in museums with profusion, the mediæval and post-mediæval life of our own country has received quite inadequate attention. Even the British Museum is everything except British so far as ethnology is concerned. The president instanced two museums, however, where praiseworthy efforts were made to illustrate local folk-culture, viz. the Museum of the Society of Antiquaries in Edinburgh and the Guildhall Museum, London. "What is required is a national folk-museum dealing exclusively and exhaustively with the history of culture of the British nation within the historic period, and illustrating the growth of ideas and indigenous characteristics. Others have, indeed, a perfect right to criticise us, for in most European countries a folk-museum is a prominent and patriotic feature of very many of their cities and towns," Berlin, Budapest, Sarajevo, Moscow, Paris, Helsingfors, Copenhagen, Bergen, Christiania, and Stockholm being cited as a few examples.

Mr. Balfour then described with some detail the Nordiska museum in Stockholm as a model upon which to base a national folk-museum of our own, and said, "I feel sure that a well-organised and carefully arranged folk-museum standing in grounds which could be adapted for an open-air exhibition would be as much appreciated by students and as popular with the masses as any institution in the country." If a strictly national collection develops as it should, and is treated upon broad scientific lines, there will be no lack of lessons that may be learnt from it. The development of culture within the geographical region would be illustrated by chronological series depicting the general life and habits of the people at successive periods. An open-air exhibition in connection with the main museum would enable obsolete types of habitations and other large structures to be erected, and admit of the exhibition of many features of the older domestic and social economy; and, further, it would supply a permanent centre for the performance of the folk-dances, songs, and old-time ceremonies of the British people.

It was rather singular that the special subject of the "arrangement of mammalia in museums," which had been selected by the council, was completely ignored, not a single paper with any reference to it being submitted, while ethnology received a large amount of attention. Mr. H. L. Braekstad supported the president's plea with a bright, descriptive paper on open-air museums in Norway, Mr. F. W. Knocker discoursed on the practical improvement of ethnographical collections in provincial museums, and Mr. W. Ruskin Butterfield offered some suggestions for loan exhibitions of local antiquities. Art museums were dealt with in thoughtful papers by Benj. I. Gilman, of the Museum of Fine Arts, Boston, and Dr. A. H. Millar, of the Albert Institute, Dundee. Other papers comprised the Maidstone Museum, by J. H. Allchin; the relation between libraries and museums, by F. Woolnough; mounting and displaying coins, by R. Quick; life-history groups of injurious insects, by H. Bolton; and a very serviceable description by Sir Martin Conway of his ingenious and convenient method of dealing with photographs.

The annual report, read at the business meeting on July 15, recorded the uninterrupted growth of the association, which now possesses a cash balance of 250*l.*, as well as a stock of publications that are constantly in demand. The ballot papers showed that Dr. Tempest Anderson had been elected president, Mr. E. E. Lowe secretary, and Mr. F. R. Rowley editor. It was decided to publish a directory of all the museums in Great Britain and the colonies, the work to be proceeded with at once by Mr. H. M. Platnauer and Mr. E. Howarth.

ADAPTATION IN FOSSIL PLANTS.[1]

THE Darwinian theory of the origin of species by variation and natural selection only fulfils its *rôle* in so far as the distinctive characters of organisms are, or have been, adaptive, *i.e.* beneficial to the species. Purely "morphological" characters (if any such exist) and non-adaptive characters in general are not explained by the Darwinian theory (or only indirectly with the help of correlation). I therefore make no apology for having a good deal to say about adaptations in what follows.

That the great bulk, if not the whole, of organic structure is of the nature of an adaptive mechanism or device cannot be seriously doubted.

The origin of species by means of natural selection does not, as has sometimes been imagined, involve a constantly increasing perfection of adaptation throughout the whole course of evolution. Darwin expressed his belief "that the period during which each species underwent modification, though long as measured by years, was probably short in comparison with that during which it remained without undergoing any change."[2]

During the long periods of rest, adaptation to the then existing condition of life must have been relatively perfect, for otherwise new variations would have had the advantage and change would have ensued. It thus appears that, as a rule, a state of equilibrium has existed in the relation of organisms to their environment, only disturbed when the conditions were changing. That such long periods of evolutionary stability have actually occurred is shown, for example, not only by the familiar case of the flora of Egypt, unaltered during a long historic period, but still more strikingly by the absence of any noticeable change

[1] Abridged from the presidential address delivered before the Linnean Society on May 24. By Dr. D. H. Scott, F.R.S.

[2] "Origin of Species," sixth edition, p. 279.

in the plants of our own part of Europe since Glacial or pre-Glacial times.

The conclusion follows that at any given time, apart from the relatively short critical periods when changed conditions had to be met, we must expect to find organisms in a state of complete adaptation to their surroundings. When physical, and especially mechanical, conditions are in question, such as have practically remained constant through all geological time, we may reckon on finding the corresponding adaptive structures essentially the same at the earliest periods as they are now.

Hence the attempt to support the Darwinian theory by the detection of imperfect mechanical adaptations in Palæozoic plants is wholly futile, as was well shown by the late Prof. Westermaier. This author's own point of view was not that of a Darwinian, but, nevertheless, his conviction that efficient adaptation has always been characteristic of living organisms is a perfectly sound one, thoroughly in harmony both with the principles of Darwin and Wallace, and with the observed facts, as far back, at any rate, as the palæontological record extends. In particular, Westermaier's contention that the construction of the Carboniferous plants followed the laws of mechanical stability and economy of material, just as is the case in plants of our own day, is completely confirmed by accurate observations on their structure, while an opponent's supposed detection of Palæozoic constructions "in direct contradiction to the principles of the engineer" merely showed that the critic had failed to distinguish between the supporting and conducting tissues of the plant. It appears to have been characteristic of Palæozoic plants that their mechanical tissues were, to a great extent, independent of the wood and concentrated in the outer cortex—the most advantageous position on engineering principles. For example, the extremely prevalent "Dictyoxylon" type of cortex, in which bands of strong, fibrous tissue, united to form a network, alternate with the living parenchyma enclosed in their meshes, was an admirable mechanical construction for stems which did not attain any great thickness by secondary growth.

In the Calamites we find, in young stems, the same alternation of fibrous and parenchymatous bands in the cortex, which is so familiar to physiological anatomists in the stems of our living horsetails.

The great tree-ferns of the later Carboniferous (if ferns they were) evidently depended for their mechanical strength on a stereome or supporting tissue quite distinct from the vascular system, and for the most part peripherally disposed, as it should be. Their power of resistance to bending strains was no doubt greatly increased by the dense external envelope of strongly constructed adventitious roots, imbedded in the cortex, a mode of support which we meet with in some monocotyledons such as Kingia (Liliaceæ) and species of Puya (Bromeliaceæ) at the present day.

When we come to the most highly organised of the Palæozoic plants, the Cordaitales, constituting the characteristic gymnosperms of that epoch, we find that the young stems had the same "Dictyoxylon" construction of the cortex as was so common among the contemporary fern-like seed-plants. The cordaitean wood, however, often assumed a dense structure, and in many cases (as also sometimes occurred among the pteridosperms) there were tangential bands of narrow fibre-like wood-elements, suggesting, though not identical with, the autumn wood of recent coniferous trees, and no doubt subserving a special mechanical function.

The exigencies of secondary growth, when occurring on a great scale, ultimately demand that the mechanical tissues should be seated in the wood, on the inner side of the growing zone, though this is not the best position on engineering principles. The old plants were, on the whole, more correct in their methods; their successors have more often had to adopt a compromise, which sacrifices a certain degree of mechanical efficiency in order to facilitate construction.

In the leaves of the Cordaiteæ we meet with remarkably perfect types of mechanical construction showing various applications of the I-girdle principle, with utilisation of the "web" for the protection of the conducting vascular strands. The construction is on the same lines as that of many of the monocotyledonous leaves investigated by Schwendener in his classical work. It will be remembered that the cordaitean leaves were originally classed as those of monocotyledons, which they closely resemble in form and mechanical requirements. Here there is no secondary growth to disturb the lines of a rational construction; the leaves were of great length and borne on lofty stems, requiring a strong mechanical system for their support, and hence we find that they present admirable illustrations of engineering principles.

Without pursuing the subject further, it may be added that other Palæozoic leaves show essentially the same types of mechanical construction as are found in leaves of corresponding shape and dimensions in the living flora.

These few illustrations may suffice to show that, from an engineering point of view, the plants of the Palæozoic were just as well constructed to resist the strains to which their organs were exposed as are their recent successors.

I have elsewhere dwelt on the gradual change in the construction of the wood, correlated with the on-coming of secondary growth, and have traced the slow extinction of the old, "cryptogamic," centripetally developed wood, as the newer, centrifugal wood, derived from a cambium, more and more effectually took its place.[1] In the former we have to do with a structure becoming vestigial, but it is interesting to note how the doomed tissue was not always left in its old age to be a mere pensioner on its more active neighbours, but was often employed, while it survived, on such work as it was still able to do. We find, in quite a number of cases,[2] that the central wood had changed its character, and shows by its structure that it had become adapted to the storage rather than to the transmission of the water-supply, its earlier function now being more conveniently left to the external parts of the wood. Such utilisation of vestigial structure appears to be a good mark of a high standard of adaptation.

Another interesting case of adaptive specialisation in an organ which may be regarded as of an old-fashioned type is to be found in the rootlets of Stigmaria. The nature of these appendages has been much disputed; last year we had an interesting discussion on the subject, opened by Prof. Weiss. I have used the word "old-fashioned" because there is some reason to suppose that these organs were not yet quite sharply differentiated as roots; at any rate, there are certain points in which they rather resemble modified leaves, though in my opinion the root-characters predominate. Though they may thus be "primitive," from the point of view of our current morphological categories, these organs, as Prof. Weiss has discovered, show a remarkable adaptive mechanism in the presence of strands of water-conducting elements running out from the central vascular bundle, and terminating in plates of tracheæ placed in the outer cortex. The whole constitutes an absorptive apparatus more elaborate than anything found in recent roots, if we except a few highly specialised haustorial roots of parasites. This example seems to me instructive, for it shows how a very high degree of adaptation may co-exist with characters which suggest a somewhat archaic type of organ.

As an example of adaptation to more special conditions, I may instance the xerophytic characters shown by various Carboniferous plants, especially in the structure of their leaves.

Though there is no question of absolute perfection in nature, it appears that, under given conditions, adaptation is and was sufficiently perfect to make it very difficult to put one's finger on any defect. When we think we can do so, it generally turns out that the defect is in the mind of the critic rather than in the organism criticised. We will take a particular case, where the history seems to give some justification for our fault-finding.

The late Palæozoic family Medulloseæ were in some respects the most remarkable plants, from an anatomical point of view, that we know of. Most of them were plants of great size, with rather sturdy stems bearing immense fern-like fronds; the habit altogether must have been something like that of a tree-fern, but their reproduction was by large seeds, borne on the fronds. To

[1] Scott, "The Old Wood and the New" (*New Phytologist*, vol. i., 1902).
[2] Megaloxylon, Zalesskya, *Lepidodendron selaginoides*.

adapt the vascular system of the stem to the supply of the large and compound leaves, the polystelic type of structure was assumed, *i.e.* the single vascular cylinder (still to be recognised in some of the earlier members of the group) became broken up, in various ways, into a number of distinct cylinders, only connected at intervals. So far the change was in the same general direction as in the evolution of the higher ferns; the fossil family, however, was not content with a complex primary vascular system, but must have secondary growth as well. Now if you have a number of vascular columns in the same stem, each growing continuously in thickness on its own account, it is evident that very special arrangements will be necessary to avoid overcrowding. The difficulty was overcome, and the Medulloseæ for some time flourished among the dominant families—the Permian formation represents their Golden age. But one is tempted to think that the system was too complicated to last; at any rate, it seems not to have lasted, for these elaborate stems have not been found in any later rocks. Either, as Mr. Worsdell supposes, the medullosean stem became reduced and simplified to form the cycadean type of stem of later days, or, as I am more inclined to believe, the family died out altogether. Even here, though we seem to have an instance of a cumbrous mechanism, over-reaching itself in elaboration, yet it worked well enough for a time, and it would be difficult to say exactly what the conditions were that led to its being superseded.

The hypothesis of "a gradual development from the simpler to the more complex" is not borne out by the facts of palæobotany—the real course of events was infinitely more involved. On a general view, as Darwin himself recognised, "the geological record does not extend far enough back to show with unmistakable clearness that within the known history of the world organisation has largely advanced."[1] This wise saying has been too often overlooked by those who have tried to popularise evolution—it is eminently true of the geological history of plants. Though there is no doubt a balance on the side of advance, due chiefly to the increasing complexity of the inter-relations among the organisms themselves, the general progress since Palæozoic days is by no means so great as has often been assumed, and we may be sure that as our knowledge of the older plants increases we shall come to form a still higher estimate than we do now of their adaptive organisation.

It has been alleged that it is the fact of the gradual appearance of higher forms which enables us to determine the relative age of strata by their fossils. So far as plants are concerned, this statement is only true to a very limited extent. A fossil angiosperm, no doubt, would be evidence of an age not earlier than the Cretaceous, but, on the other hand, a lycopod of much higher organisation than at present would establish a strong presumption of Palæozoic age; so would the higher forms of the equisetales; a cycadophyte with a fructification far more elaborate than that of recent Cycadaceæ would afford sure proof that the bed containing it belonged to the Lower Mesozoic.

Of course, much depends on the meaning we give to the words "higher" and "lower." If by "higher" we mean nearer to the recent types, then it is merely a truism to say that the higher forms are characteristic of the later rocks; but if by "higher" we mean more elaborately differentiated, then the statement quoted is, in any general sense, untrue. If, again, we imply by the word "higher" more perfectly adapted to the existing conditions, then it would be very difficult to prove any advance, for, as I have endeavoured to show, adaptation has in every age been fully adequate in relation to the then conditions. If organisms have grown in complexity, it is only where the conditions of their life have become more complex. The most striking examples of high organisation in relation to organic environment are presented by the characteristic modern subkingdom, the angiosperms, in the evolution of which, as Saporta pointed out, insect fertilisation has been the chief determining factor, leading to an infinite variety in the special adaptations of the flower, and no doubt indirectly affecting the mode of life of the whole plant. The advent of the angiosperms seems to have been almost simultaneous with that of the higher families of insects, which now, at all events, are chiefly concerned in pollination. It would be difficult to overestimate the importance of these relations in their effect on the flora of the world. If the vegetation of our own epoch appears, on the whole, definitely more advanced than that of earlier geological periods, this is probably due in a greater degree to the contemporary insect life than to any other cause.

[1] "Origin of Species," sixth edition, p. 308.

I have discussed the subject of reduction in evolution elsewhere,[1] and will only briefly allude to it here. In many groups (lycopods, equisetales, cycadophytes) there has been a lowering of the standard of organisation, partly due to direct reduction, partly to the extinction of the higher forms in each group. There are, however, many other cases in which the simplification of particular organs means a real advance.

Taking into account all the causes which make for simplification, the question suggests itself whether, when we find a simple type of structure existing at the present day, there is any presumption in favour of its primitive nature. It has sometimes been urged that such a presumption exists (except when direct evidence of reduction can be adduced) on the ground that the general course of evolution must have been from the simpler to the more complex, a rule, as we have seen, subject to so many exceptions that, within the limited period to which the palæontological record extends, it has practically no validity. My own conviction is that in such cases there is no *presumption* of primitiveness at all, and that we should demand very strong evidence before admitting that a given simple structure is primitive. Of course, it may happen that a primitive simple type, or at least an old simple type, may have survived to our own day; this may have been the case in decaying families, where the less advanced members have had the best chance of evading the competition of ascendant races; but, on the whole, it is very unlikely that, among all the changes and chances of the world's history, a really primitive simplicity should have been preserved. "The eternal ages are long," and there has been time enough for many ups and downs on every line of descent.

The subject of reduction, so essential a clue in any attempt to trace the course of evolution, suggests a reference to the question of the simpler angiospermous flowers. While the older morphologists were wont to interpret such flowers (*e.g.* those of Aroideæ, Piperaceæ, Cupuliferæ) as reductions from more "perfect" types, there has been a tendency in more recent times to accept the simpler flowers as primitive structures from which more elaborate forms have been evolved. Quite lately, however, a reaction has set in, due to the discovery by Dr. Wieland of the wonderful bisexual flowers of the Mesozoic cycadophyta, which are constructed on the same plan (though, of course, with many differences in detail) as the more perfect angiospermous flowers, such as those of Magnoliaceæ. If the angiospermous flower was derived from a source allied to the Bennettiteæ, its evolution, as suggested by Wieland, must have been essentially a process of reduction. I only wish to point out that this view is not inconsistent with the great relative antiquity of simple and, *ex hypothesi*, reduced forms, for which, in the case of the Amentiferæ, there seems to be good geological evidence. Reduction appears to have often been a rapid, indeed a comparatively sudden, change, as shown by the frequent occurrence of much-simplified forms in the same family in which the prevailing structure is typically complete. It appears quite probable that some groups with very simple flowers, though not "primitive," may be very ancient, tracing their origin from forms which in quite early days underwent reduction (as a means of specialisation) from the highly developed flowers which probably characterised the first autonomous angiosperms.

The tentative and somewhat fragmentary observations which I have here stated tend to the following conclusions:—

(1) That at all known stages of the past history of plants there has been a thoroughly efficient degree of adaptation to the conditions existing at each period.

[1] "Darwin and Modern Science." XII. The Palæontological Record. II. Plants. (1909.)

(2) That the characters of plants, having always been as highly adaptive as they now are, natural selection appears to afford the only key to evolution which we at present possess, for all periods covered by the palæontological record.

(3) That this record only reveals a relatively short section of the whole evolution of plants, during which, though there has been considerable change, there has not been, on the whole, any very marked advance in organisation except in cases where the conditions have become more complex, as shown especially in the floral adaptations of angiosperms.

(4) That simple forms existing at the present day are, as a rule, of a reduced rather than a primitive nature, but that such reduction may have often set in at a relatively early stage of evolution, and is, therefore, consistent with a considerable degree of antiquity in the reduced forms.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. C. G. BARKLA, demonstrator and assistant lecturer in physics at the University of Liverpool, has been appointed professor of physics in King's College, London, in succession to Prof. Harold A. Wilson, F.R.S., who has accepted an appointment in McGill University, Montreal. Mr. P. H. Kirkaldy has been appointed an assistant professor in chemistry in the same college.

HARVARD has this year conferred only one honorary doctorate of science. The recipient is Mr. S. F. Emmons, of the U.S. Geological Survey. The University has conferred upon its late president, Dr. C. W. Eliot, not only the honorary LL.D., but the honorary M.D. "It has not been our custom," said the new president, Prof. Lowell, "to confer the degree of Doctor of Medicine *honoris causa*, but an exception is fitting in the case of one who, in the opinion of professors of medicine, has accomplished more for the progress of medical education in this country than any other living man, Charles William Eliot. Not in its buildings alone, but also in the instruction and research within its walls, he found our medical school brick and left it marble." At Yale the honorary D.Sc. has been conferred on Profs. E. W. Morley, W. T. Sedgwick, and E. H. Moore—a chemist, a biologist, and a mathematician respectively.

A FOURTH series of lectures on scientific microscopy is to be held at the institute for microscopy of the University of Jena from October 11–16 next. Prof. H. Ambronn will give two lectures, the first on Abbe's theory of the formation of the microscopic image, and the second on the method of testing objective systems. Dr. H. Siedentopf also will lecture twice, dealing with dark-ground illumination and ultramicroscopy. Dr. A. Köhler's two lectures have for their subjects photomicrography: (*a*) projection of the image on the plate, (*b*) illumination of the object with transmitted and incident light, and photomicrography with ultra-violet light. In connection with each lecture suitable practical work has been arranged, and demonstrations also will be provided. Application for admission to the lectures should be made to Dr. Ehlers, Jena, Beethovenstr. No. 14. A fifth series of lectures will be held from March 7–12, 1910, in the anatomical institute of the Leipzig University.

THE first volume of the report on attendance, compulsory or otherwise, at continuation schools, prepared by the Consultative Committee for the Board of Education, was published (Cd. 4757) a few days ago. The evidence on which the recommendations of the committee have been based will be issued later as a separate volume. The committee was instructed to consider, among other matters, "whether any means, and if so what, can be devised, in respect of rural areas and of urban areas respectively, for securing (i.) that a much larger proportion of boys and girls should on leaving the public elementary school commence and continue attendance at evening schools than at present do so, and (ii.) that employers and other persons or bodies in a position to give effective help shall co-operate in arranging facilities for such attendance on the part of their employees, and in planning suitable courses and subjects for the schools and classes." The witnesses examined by the committee included representatives of employers of labour, of labour organisations, the Public Services, local education authorities, teachers of all grades, inspectors of schools, and persons specially interested in philanthropy. The volume available, with its careful consideration of every aspect of the problem, brings home forcibly to the reader its complexity and importance, and we hope to deal more fully with the whole question in a future issue. Here we will only express satisfaction that the views of enlightened educationists are being brought prominently into public view by reports such as that before us. The resolutions as to leaving age and continuation schools contained in the report of the Education Committee of the British Science Guild (NATURE, January 28, vol. lxxix., p. 382) receive substantial support from the Consultative Committee's conclusions, and it may be hoped that action will be taken before long in the direction indicated by them. Most of the German States have compulsory continuation schools, and Scotland was placed in the same position by its Education Act of last year. It remains for England to adopt a like standard of educational efficiency for its children.

ON the vote of 13,648,792*l.* for the expenses of the Board of Education, Mr. Runciman, President of the Board, made a statement in the House of Commons last week reviewing the state of education in the country. Dealing with technical education, the Minister spoke hopefully. It has been, he said, the object of the Board of Education to make technical education more practical, with a closer bearing on the duties likely to be required from the young men and women who pass through technical classes. In agriculture there is one remarkable fact, namely, that garden classes in elementary schools have been enormously on the increase, and during the last few years the number of these classes which are now carried on in these schools has been trebled. There has been considerable development in technical classes which can be attended by those who intend to enter on an agricultural career, by young farmers and young labourers who at the present time have to spend long and laborious days in the fields or farmhouses, but who are prepared to devote one or two evenings a week to the specialised training which can be provided in technical classes. The cumulative effect of technical training on the young men and women of our country must show itself sooner or later. The great employers have been giving help, said Mr. Runciman, in many parts of the country to those who organise the technical schools. Messenger boys, for instance, are induced more and more to take advantage of the classes in the evening. Some great employers, like the General Post Office, not only give direct inducement to their messenger boys, but put a certain amount of pressure on them to take advantage of classes, and many employers all over the country have made it a condition of service in their works or their great business establishments that the boys should attend a certain number of classes every week. The inspectors of the Board are not only taking a keen interest in the curriculum, but they are also acting as missionaries in what is one of the most useful forms of educational work initiated during the last few years. In concluding his speech, Mr. Runciman pointed out that we still have nothing but an old, temporary building in which our valuable science collection is housed, and he expressed the hope that it may be possible in the near future to give this great collection a better building in which it may be exhibited, and to give to those who have lent or given to that museum some security that the objects which they have given will be well preserved and well exhibited.

THE new engineering buildings of the University of Manchester were opened by Sir Alexander Kennedy on July 15. The general scheme comprises four adjacent buildings; the main block, a three-storied building, contains the lecture rooms, tutorial rooms, drawing offices, private rooms, and research room. The hydraulic and testing laboratory covers the space at the back of this building, and connected to it by a covered way are the thermodynamic laboratories and the workshop. Principal Hopkinson presided at the opening ceremony, and in the course of his remarks pointed out that the example set by the Owens College in 1866, in providing for the professional education of engineers, has been followed by all the important universities in the country. During his speech Sir Alexander Kennedy made it clear that the old system of apprenticeship has become inadequate. The function of the laboratory, he said, is to try to let a man learn by handling, experiment, and measurement the nature of the materials with which he will have to deal later. The extraordinarily rapid progress which has been made in mechanical and electrical engineering during the last generation has been largely due, Sir A. Kennedy thinks, to the good training all over the country of the men who have to carry out the details of the work. On the part of colleges and universities, he continued, there is a tendency to attempt to make students do a great deal too much. While it is necessary that an engineer shall have a knowledge of a great many things before he gets to his profession, he cannot acquire much knowledge in three years. It may be hoped that a strong university with a strong man at its head will draw a very distinct line in some common-sense fashion in defining what knowledge shall be imparted to the students. Sir William Mather proposed a vote of thanks to Sir A. Kennedy, and expressed his disappointment at the neglect displayed by the large engineering firms of the Manchester district in connection with the higher development of engineering science among young men. The success of engineering in the future will depend almost wholly on elements quite different from those which have distinguished it in the past. The next generation of engineers must be trained carefully by methods enabling them, above all things, to combine economy with efficiency. The technical school must perforce stop short of what may be called the practical part of applying machinery in the best possible way. To ensure success, there must, he continued, be a certain number of young students devoting themselves to laboratory work, and this extension of Manchester University must prove of great usefulness.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, June 25.—Dr. C. Chree, F.R.S., president, in the chair.—A transition point in zinc amalgam: Prof. H. S. **Carhart**. The paper gave the preliminary results of an investigation which has for its primary object the determination of the heat of dilution of zinc amalgams. This heat of dilution is negative, that is, the dilution of zinc amalgam by the addition of mercury absorbs heat. In the course of the experimental work, which was conducted by Dr. W. D. Henderson, phenomena so extraordinary were encountered that the concentration at which they occur was called a transition point in zinc amalgam. The method employed was electrical, by means of a concentration cell, the only difference between the two legs of the cell of H-form being in the concentration of the amalgam composing the electrodes.—A method of producing an intense cadmium spectrum, with a proposal for the use of mercury and cadmium as standards in refractometry: Dr. T. M. **Lowry**. Of the twenty-six wave-lengths that have been used in the study of rotatory dispersion (Proc. Roy. Soc., lxxxi., p. 472, November 19, 1908) the following seven have been found to be the most suitable for general use:—

Li	Cd	Na	Hg	Cd	Cd	Hg
6708	6438	5893	**5461**	5086	4800	4358

In refractometry it has been customary to use the series:—

Hα	Na	Hβ	Hγ
6560	**5893**	4861	4341

This series has the disadvantages (1) that the chief standard Na 5893 is a doublet, and (2) that the other three lines are of such weak intensity that they are useless for the majority of optical measurements. It is therefore urged that—in view of the readiness with which the mercury and cadmium spectra can now be produced—the mercury green line should be generally adopted in place of sodium as chief standard in optical work of all kinds, and that the hydrogen lines should be abandoned even as secondary standards in favour of the series of wave-lengths set out above.—The measurement of wave-length for high-frequency electrical oscillations: A. **Campbell**. The experiments had for their object the calibration of wave-meters for the measurement of the high frequencies (200,000 up to 1,000,000 ~ per second) used in wave-telegraphy. Two wave-meters (A and B) were tested, both being of the type consisting of a series of self-inductance coils used singly (L) in series with a variable air-condenser (K) and a thermo-ammeter, the reading of K being obtained by altering the capacity until the circuit shows resonance with the working circuit. The coils of wave-meter (A) were wound with solid wire, those of (B) with stranded wire (7/36s), each strand being separately insulated. The absolute value of the frequency was determined by photographing spark-trains in the primary circuit by means of a rotating mirror running at a constant and accurately measured speed. The value of the frequency deduced from the measured values of K and L with wave-meter (B) were in close agreement with the actual frequency deduced from the spark-photographs. With wave-meter (A) the agreement was naturally not nearly so close, but was much improved when the values of the self-inductances of the solid wire coils were corrected to the high-frequency values by the formulas of Heaviside and L. Cohen.—An electromagnetic method of studying the theory of and solving algebraical equations of any degree: Dr. **Russell** and Mr. **Alty**. The problem of finding the roots of an algebraical equation of the nth degree is identically the same as that of finding the positions of the "neutral points," that is, the points where the resultant force due to the earth and definite currents in n long vertical wires is zero. The n wires are arranged at any convenient distances apart in a plane which is at right angles to the magnetic meridian. The currents in the wires are then adjusted to certain values which are readily found by the methods of partial fractions. If x_1 and y_1 be the coordinates of one of these neutral points measured with reference to certain definite axes, $x_1 \pm y_1\sqrt{-1}$ is a pair of roots of the original equation. All the real roots lie on the axis of X which cuts the wire at right angles. The positions of the neutral points thus determine all the roots, real and imaginary, of the given equation. The peculiar advantage of the method is that it is easy to see, in many cases almost at once, what effect varying the value of the coefficient of any power of x will have on the roots of the equation.—The sine condition in relation to the coma of optical systems: S. D. **Chalmers**. The condition for the correction of coma in a centred optical system is the well-known sine condition. This has been proved by Clausius, Helmholtz, Hockin, and others, and the importance of this condition in the design of optical systems has been pointed out by Abbe, Steinheil, Conrady, and others. The present paper shows how to obtain the relation between the coma of a system and the errors in the sine condition.—A new Féry thermo-electric calorimeter: Dr. C. V. **Drysdale**. This form of calorimeter can be used continuously, and permits the value of the gas produced in a gas-works or producer-plant to be watched from time to time.—An instrument for measuring the strength of an intense horizontal magnetic field: F. W. **Jordan**. The method consists in measuring directly the transverse force on a conductor traversed by a current in a direction at right angles to the field.—A method of determining the sensibility of a balance: Prof. **Poynting**.—The balance as a sensitive barometer: Mr. **Todd**.

Challenger Society, June 30.—Dr. A. E. Shipley in the chair.—Colour changes in tropical sea perches from the Bermudas: C. T. **Regan**. In one case an individual specimen exhibited successively the coloration of three so-called "species."—Recent observations of Prof. Otto Pettersson on tide-like movements in deep water: Dr. H. R. **Mill**. Daily observations on temperature and salinity were made at close intervals from surface to bottom in the Gullmar Fjord, when covered by ice, between January 30 and March 25 of this year. The effect was that of an invasion of sea water from the Skagerack twice in a lunar period, followed by a withdrawal of the sea water and the filling up of the upper part of the fjord with brackish land water in rhythmical succession, and Prof. Pettersson inclined to the belief that these movements were of tidal origin. Dr. Mill pointed out that Sir John Murray and he had shown that similar effects of a non-periodical kind were produced in sea- and fresh-water lochs of Scotland by the action of wind, and that he had shown analogous effects on the Atlantic coast of the Hebrides.

PARIS.

Academy of Sciences, July 12.—M. Émile Picard in the chair.—The nature of the change undergone by crystals of heptahydrated sodium sulphate in contact with crystals of the decahydrate: D. **Gernez.** From an examination of the phenomena occurring with supersaturated solutions of sodium sulphate, sodium chromate, acetate, and hyposulphite, it is concluded that the opacity of the lower hydrated crystals in contact with the higher hydrate is due to penetration of crystals of the higher hydrate into the crystalline network of the lower. There is no evidence for any change in the proportion of water in the crystals first formed.—Observations on the nature and origin of the gases which form in volcanic fumaroles or which emerge from the craters of old volcanoes: Armand **Gautier.** The gases from the old crater of Agnano, near Naples, consist almost entirely of carbon dioxide (96 per cent. to 98 per cent.), together with traces of methane and a little more than 1 per cent. of nitrogen. The latter contains argon, neon, and helium, and possibly the other argon gases.—The influence of anæsthesia on the decomposition of certain glucosides in plants: L. **Guignard.** Plants of black mustard, submitted to the action of chloroform vapour, produce the mustard essence; cooling to the temperature of boiling methyl chloride produces the same effect. Similar observations have been described by M. Mirande regarding the formation of hydrocyanic acid.—A hæmogregarian of *Pituophis melanoleucus*: A. **Laveran** and A. **Pettit.**—The neutral carbonates of rubidium and cæsium: M. **de Forcrand.** A thermochemical paper.—The theory of functions: Henri **Lebesgue.** A correction of a previous paper.—The singularities of uniform analytical functions: D. **Pompeiu.**—Systems of reservoirs: Edmond **Maillet.**—Orthoscopic telescopes: M. **Tscherning.**—Chemical reactions and ionisation: G. **Reboul.** The apparatus described is capable of measuring ionisation over a wide range; details are given of the results obtained in numerous chemical reactions.—Remarks on the preceding paper: A. **Gautier.**—A new method of separating uranium X, and on the relative activity of this substance: B. **Szilard.** The method is based on the addition of ferric acetate, ammonium acetate, and acetic acid to the uranium solution, and the precipitation of the iron by heating; uranium X is concentrated in the precipitate.—The chemical action of the penetrating rays of radium on water: Miroslaw **Kernbaum.** Radium rays that had passed through glass decomposed water in accordance with the equation $2H_2O = H_2O + H_2$, both the hydrogen and hydrogen peroxide being determined quantitatively. An attempt to obtain a similar reaction by allowing Röntgen rays to act upon water for 100 hours gave negative results.—The diffusion of ions through metals: Georges **Moreau.** The passage of ions through heated plates of platinum, nickel, iron, and brass has been studied. A theory of the diffusion has been developed, and an experimental confirmation given.—The action of the α rays on solid dielectrics: Tcheslas **Bialobjeski.** A study of the alteration in the conductivity of sulphur produced by the α rays of polonium.—The hydrolytic decomposition of bismuth bromide: René **Dubrisay.** There is only one bismuth oxybromide produced in this reaction; a rise of temperature does not appreciably affect the hydrolytic dissociation of bismuth bromide.—A proposed solution for the equation of condition relating to the calculation of atomic weights: G. D. **Hinrichs.** The author points out that his equation of condition is diametrically opposed to that given by L. Dubreuil.—The cementation of iron by carbon in a vacuum: Léon **Guillet** and Ch. **Griffiths.**—The extraction of lutecium from the gadolinite earths: G. **Urbain,** MM. **Bourion** and **Maillard.** For the final purification from thorium and scandium, the oxides were converted into the chlorides by heating them in the vapour of sulphur chloride. This method of fractional sublimation of the chlorides promises to be of service in the separation of the rare earths.—The condensation of isopropyl alcohol with its sodium derivative: formation of methylisobutylcarbinol and dimethyl-2: 4-heptanol-6: Marcel **Guerbet.**—The iso-indogenides: A. **Wahl** and P. **Bagard.**—The production of peat on the rocks of tropical Africa: Aug. **Chevalier.**—The ferment of belladonna: C. **Gerber.**—The influence exerted by certain vapours on plant cyanogenesis. A rapid method for testing plants for hydrocyanic acid: Marcel **Mirande.** Any cyanogenetic plant, submitted to the action of chloroform vapour, at once gives off hydrocyanic acid. The latter can be detected by the use of Guignard's picrate paper.—The action of urohypotensine on the arterial pressure: J. E. **Abelous** and E. **Bordier.**—The proof of alimentary glycosuria in epileptics: MM. **Florence** and **Clement.**—The hypotensive action of serum from a dog which had been deprived of its suprarenal capsules: Jean **Gautrelet** and Louis **Thomas.**—The chemical composition of ox bile: N. A. **Barbieri.**—The life of yeast after fermentation: E. **Kayser** and A. **Demolon.**—The action of the ultra-violet rays on cider in fermentation: MM. **Maurain** and **Warcollier.**—Experimental reproduction of exanthematic typhoid in the ape: Ch. **Nicolle.**—The chemical effects of immersion in water of the quartz mercury-vapour lamp: J. **Courmont,** Th. **Nogier,** and A. **Rochaix.** No ozone is produced which would account for the observed bactericidal effects, and no other chemical change of importance could be detected.—Symmetry of organs in some species of Syllis: Aug. **Michel.**—The reactions of some mitochondria: E. **Fauré-Fremiet.**—The ichthyological fauna of Lake Victoria: Jacques **Pellegrin.**—The Silurian of Nova Zembla: V. **Roussanof.**—The earthquake of Provence, June 11, 1909: Louis **Fabry.**—The earthquake of July 7, 1909: Alfred **Angot.**

HOW TO DIAGNOSE GENIUS: A STUDY OF HUMAN ENERGETICS.

Grosse Männer. By Prof. Wilhelm Ostwald. (Leipzig: Akademische Verlagsgesellschaft, 1909.)

THIS book is a study in comparative biography, and may be said to point the way to a new field of investigation. Prof. Ostwald was prompted to write it, as he tells us in his first sentence, by an ingenuous question put to him by one of his Japanese students as to how budding geniuses could be recognised. Much money, his student went on to say, is spent by various Governments in attempting to discover those people whose thorough education may be expected to bring in a return of value to the State, and the question how best to discover latent genius is an eminently practical one. After cogitation, Prof. Ostwald came to the conclusion that it is those students who cannot be kept on the rails—that is, who are not contented with methodical teaching—who have within them the seeds of genius; and the writer's experience would lead him to the same conclusion.

But in order to lay a basis for such a deduction, vague, to some extent, because derived only from personal impressions, a careful comparison has been made of the lives of six men, all of whom had a great influence on the thought of their time. These are:—Davy and Faraday; Julius Robert Mayer, who shares with Joule the honour of having shown the equivalence of heat and work; Liebig; Gerhardt, who, in his day, contributed to the revolution in chemical thought; and Helmholtz.

These names belong to men of science, exclusively; the reason for the choice is perhaps to be found in words penned by Liebig:—

"The history of the nations teaches us of the futile efforts of powers, political and ecclesiastical, to maintain spiritual and bodily slavery over mankind; future history will deal with the conquest of liberty, gained by the investigation of the reason of things, and of truth; a conquest gained by weapons unstained with blood, and on a field in which religion and morals take part only as feeble allies."

This, it may be remarked, is prophecy, and, as such, is at present beyond criticism; it may, however, be pointed out that to some of us, at least, the prospects held out by the remarkable conquests over what used to be called "the forces of nature" do not at present point to a speedy millennium. However, the retort is open that it is not the spread of the teachings of science, but a disregard for such teachings, which is the reason that our moral progress does not keep pace with our material progress.

Be that as it may, Prof. Ostwald has given, in his masterly style, delightful sketches of the lives of these undoubtedly distinguished men. The biographies differ somewhat from the usual "lives," inasmuch as the failings, as well as the virtues, of the subjects have been touched on. No character is perfect, and, without ample knowledge, it is impossible to attempt to draw just conclusions.

One notable characteristic of men of genius is that it is rare for them to have come from either a high or a low grade of society. Exceptions are confined practically to England and France, as witness Boyle, Cavendish, and Lavoisier; Faraday might perhaps be instanced as an example—almost the sole example—of the second class.

Another characteristic is the very early age at which such men develop. Goethe was twenty-four years old when he electrified the German nation by his "Sorrows of Werther"; Schiller was twenty-two when he published "The Robbers"; Newton had invented the calculus, discovered the law of gravitation, and had completed his analysis of light before his twenty-fifth year; Linnæus had evolved his sexual system of plants at the age of twenty-four; and the list might be extended indefinitely, to Carnot, Clausius, Scheele, Berzelius, Vesalius, the reformer of the science of anatomy, the physiologists Ludwig, Helmholtz, and Du Bois Reymond, to, last, though not least, Kelvin. Youths who make their mark at a later age, as already remarked, show a distaste for the formal instruction which is still given in the public schools of Germany and England. In this connection it is interesting to note the saying of a writer on English public schools, himself once a distinguished headmaster, that, while a classical or mathematical master does not fall off, indeed improves, with age, inasmuch as he perfects himself in methods of teaching practically unprogressive branches of learning, the science masters cannot but deteriorate, unless they keep abreast with the progress of science by increasing its bounds by their own efforts. Prof. Ostwald takes a strong view of the inutility of the training to be acquired from a linguistic, especially a classical, education, and believes that the usual duration of school life is far too great. In this the writer heartily concurs.

"Had Kelvin or Leibnitz been so unfortunate as to have come into the world in our days, and in Germany, their early development would have been of no avail; they would have sat on the school benches till their eighteenth year—an age at which they had gained a prominent position in science."

The temperaments of the men whose lives are chronicled may be divided under two heads, "Klassiker," or "phlegmatic," to quote an old classification, and "Romantiker," or "sanguine." To the former class belonged Faraday, Mayer, and Helmholtz; to the latter Davy, Liebig, and Gerhardt. These temperaments correspond to the rate of reaction to external stimulus. The romantic type is eager, alert, impatient, and impulsive; the classic type painstaking, conscientious to a fault, self-criticising, and accurate. It is remarked on as curious that most men who have achieved greatness belong to one or other of these classes; it would appear that average minds, who occupy a mean position, being neither very impulsive nor very critical, have not the qualities which raise them above their fellows.

The "yield" of such minds, to use an expression borrowed from chemical manufacture, depends, according to Ostwald, on their "economic coefficient." To transform one kind of energy into another implies the "degradation" of a portion; this is the second law of thermodynamics. Born into the world with the usual amount of energy, *i.e.* capacity for work, some minds are so constituted as to transform a large portion of it so that it is of service to humanity, while a comparatively small portion is, as it were, wasted. The sum of the action of such minds constitutes human progress. It is necessary that the progress of the individual genius should be hindered as little as possible by artificial and unnecessary obstacles, and it would appear that in some countries the path is made easier than in others. Taking the membership of national academies as a test, if only a rough one, of scientific eminence, the proportion of distinguished men to the inhabitants, reckoned in millions, is in Saxony 0·2, in Baden and Norway 0·25, in Switzerland 0·33, in Holland and Bavaria 0·41, in England and Prussia 0·49, in France 0·79, in Italy 2·17, in Austria 2·7, in the United States 3·08, and in Russia 16·3; that is, for example, there is in Russia only one member of international academies to 16·3 million inhabitants. It can hardly be doubted that this low number is due to the hindrances which stand in the way of the progress of youths who might, in Russia, display genius, and enrich the world by their efforts.

It is impossible to review such a book as this satisfactorily in a short article. It teems with interest, not only on account of the intrinsic attractiveness of the subject, but also because of the masterly grasp of it displayed by the author. Whatever Prof. Ostwald writes is sure to interest, owing to the originality of his mind and his lucid and attractive method of presentment. On every page there occurs some saying which excites attention, even although the reader may sometimes be disposed to challenge the conclusions drawn. The questions discussed are well worth the most careful consideration of all who have the welfare of humanity at heart. The problem considered is an eminently practical one—perhaps the most practical problem which exists—and we owe the author a debt of gratitude for having introduced it to us in such a charming manner. W. R.

SOME MEN AND MATTERS IN CHEMISTRY.

Essays, Biographical and Chemical. By Sir William Ramsay, K.C.B., F.R.S. Pp. vii+247. (London: Constable and Co., Ltd., 1908.) Price 7*s.* 6*d.* net.

IT is good to read about the pioneers of science, their trials and their triumphs. Even it is good for the student who has to "grind" up facts about scientific worthies and serve them up hot to a voracious examiner; albeit in such a case it smacks strongly of "turning old heroes into unworthy potions," as Sir Thomas Browne remarks in discussing the medicinal virtues of mummies. At any rate, such a student would get some of the facts about his heroes pleasantly enough in reading what Sir William Ramsay has to say in the present volume concerning Boyle and Cavendish, Davy and Graham, Black, Kelvin, and Berthelot.

The essays are a collection of lectures and magazine articles published, the author tells us, at various times during the last twenty-five years. It follows that they are of a popular character in the sense that little or no special knowledge on the part of the reader is assumed. They are somewhat unequal in scope and treatment, as may be inferred from the fact that the organs in which they first appeared included such diverse publications as the *Youth's Companion* and the Proceedings of the Royal Society.

Of the biographical essays, those upon Berthelot and Lord Kelvin seem to the present writer to show the author at his happiest. Perhaps that is because there is the personal note in them; for Sir William Ramsay was acquainted with the French *savant* as well as the English one. He gives us an attractive glimpse of the happy home life of the Berthelots. There was a touch of romance, too, about the meeting of young Marcellin Berthelot with his future wife, which is described in the essay, and which we may venture to quote almost in the author's words. Mademoiselle Breguet was beautiful and well-dowered, but presumably beyond Berthelot's reach. However, one day she was crossing the Pont Neuf in the face of a strong wind, wearing a charming Tuscan hat.

"Behind her walked her future husband; suddenly she turned round to avoid having her hat blown off, and practically ran into his arms. A case of love at first touch," says Sir William.

The stories of Boyle and of Cavendish will always appeal to chemists. The author describes and contrasts the work and character of the two men in an interesting little sketch. "Each was in advance of his age"; Boyle by reason of his calm philosophical spirit and clear judgment, Cavendish in his power of refined quantitative experiments and deductions. Neither was married; and the author, after reflecting that Boyle was too many-sided and Cavendish too reserved, remarks:—"It is perhaps legitimate to draw the conclusion that man's nature does not culminate in its best without the influence of a helpmeet." It may be so; but another conclusion, perhaps equally legitimate, is that if there had been a Mrs. Boyle and a Mrs. Cavendish there might have been no "Sceptical Chymist" and no "Experiments on Air." Black also, it may be noted, remained unmarried, though a particular favourite of the ladies. Perhaps they missed much, these three distinguished chemists, both in personal happiness and in perfection of character; but it may well be that their loss was mankind's gain, and that chemical science has cause to bless the circumstances which enabled them to pursue their researches with singleness of aim, undistracted by either the joys or the troubles of matrimony.

A sketch of the careers of Davy and Graham completes the essay on the "Great London Chemists." Space allows only a brief mention of the author's comparison of the four. Graham, with his philosophical mind, more resembled Boyle than Cavendish or Davy. While Cavendish carried his devotion to science so far that it deprived him of the ordinary pleasures of a human being, and while Davy, in relation to fashion, could not escape the accusation of playing to the gallery, Graham pursued a happy mean, beloved by his friends, esteemed by all. "Of him, as of Faraday, it might have been said with no shade of misgiving, 'He was a good and a true man.'"

The second half of the volume is devoted to essays on various chemical topics. A few titles will indicate their nature; thus there are "The Becquerel Rays," "What is an Element?" "Radium and its Products," and "The Aurora Borealis." This last is an interesting discussion of the evidence for regarding krypton as a noteworthy constituent of the aurora. An oration upon "The Functions of a University," delivered some eight years ago at University College, concludes the work, and ends with the remark:—

"As it exists at present, a University is a technical school for theology, law, medicine, and engineering. It ought to be also a place for the advancement of knowledge, for the training of philosophers, and of those who love wisdom for its own sake. . . ."

Surely; and if examples were wanted of men who loved wisdom for its own sake, who "scorned delights and lived laborious days" in pursuit of it, yet by whose labours was wrought incalculable material benefit to posterity, what better instances could be found than those of the pioneers of chemistry?

With two or three exceptions, neither the biographical nor the chemical essays pretend to be more than popular presentations of their several subjects, and if here and there they seem perhaps a trifle superficial and jejune, it is only fair to remember the circumstances of their production, and to recall the fact that some were written when their distinguished author's powers were less mature, by a quarter of a century's growth, than they are to-day.

C. SIMMONDS.

EXPERIMENTAL PSYCHOLOGY.

A Text-book of Experimental Psychology. By Prof. C. S. Myers. Pp. xvi+432. (London: Edward Arnold, 1909.) Price 8s. 6d. net.

THIS book supplies a want which has been long felt by both students and teachers. Until now there has been no text-book to meet the special needs of those attending a course of instruction in experimental psychology. There have been books on psychology written on an experimental basis which have differed little, if at all, from others not so characterised, and there have been handbooks for the laboratory, notably that of Titchener, but there has been no book which attempted to give in reasonable compass a general account of experimental methods and of the results which have been gained by the experimental movement in psychology. Such a book was needed for two classes of persons, for those definitely committed to the study of the subject, and for the large class of people who know that experimental psychology exists but do not know what it means.

It may be said at once that for each Prof. Myers's book will be of the greatest service. It gives a concise and yet clear account of what has been done by means of experiment in psychology, and it is surprising to find so vast an amount of information in a book of the size. At the same time, there has been admirable judgment in the selection of the material and in the discussion of the many thorny topics in which the science at present abounds. The only fault to be found is that its conciseness will make it difficult for the beginner, but this has been anticipated by the author, who has distinguished the more difficult parts by means of brackets to indicate that they should be left by the beginner for a second reading. Further, the last eighty pages are devoted to an illustrated description of laboratory exercises, and the performance of these will go far to remove any difficulty due to the conciseness of the main body of the text.

To pass to detail, the earlier chapters are devoted to the senses, and those on hearing are especially full. There is no other book in which a summary of the very important researches of recent years on this subject can be found. The accounts of the psychophysical and statistical methods, given under these titles and in the chapter on identity and difference, are admirably clear, though, perhaps, not enough stress has been laid on the use of the psychophysical methods for purposes other than threshold determination. These methods were devised with the idea that by their means sensation and other psychical states might be measured. They are, however, coming to be used more and more for the exact comparison of the effects of different conditions on mental processes in which there is no question of the actual determination of a threshold, either absolute or differential, and the attention of the student might have been more forcibly directed to this aspect of the use of the methods.

The subject of memory is very fully treated, it might be thought a little out of due proportion. The space devoted to it is, however, fully justified, for we have in this branch of the subject what is, perhaps, the greatest achievement of the experimental method in pure psychology apart from those advances which are rather physiological than psychological.

In a short chapter on muscular and mental work an excellent account is given of modes of research which are now taking a very important place in applied psychology and especially in pedagogy, and the author rightly insists on the difference between the mental work of laboratory methods and that of ordinary life. There is at present a great danger that the value of this line of work will suffer depreciation owing to premature application to practical problems. The last two chapters chiefly serve to show how little the experimental method has so far accomplished in the study of such subjects as attention and feeling.

It is to be regretted that want of space has not allowed the author to deal with the comparative and pathological sides of psychology so far as these can be studied by the methods of experimental psychology. The result of the perusal of this book, in which the accomplishments of the science have been so ably portrayed, is to confirm an impression that the experimental study of the developed mind will not take us very far, and that it is in the study of the developing mind and of the dissociations and destructions produced by disease that there lies the chief prospect of advance. It is to be hoped that the author will be able to deal with these subjects, either in another book or in a future expansion of the present volume.

Although this country has been very late in recognising the experimental movement in psychology, the subject has at last succeeded in making a position for itself, and its existence is recognised in the chief universities of England and Scotland. Its further progress will certainly be assisted by this able account of the methods and accomplishments of the science.

SPEECH.

The Science of Speech, an Elementary Manual of English Phonetics for Teachers. By Benjamin Dumville. Pp. xii+207. (Cambridge: University Tutorial Press, Ltd., 1909.) Price 2s. 6d.

THIS is a concise, accurate, and interesting little manual, written by one who is evidently a master of the subject of phonetics, and knows how to communicate information. Nowhere have we seen so good an account of the muscular movements and the positions of the articulating apparatus. The book is intended for teachers, who often, in these days, are required to teach the elements of phonetics, or, at all events, to train children in the art of correct pronunciation and good reading. It is not a book to be read hastily. It requires a careful experimental study of the movements described, with the aid of a mirror, but the descriptions are so clear and the methods so simple and convincing that the accurate knowledge acquired will well repay all the trouble. The nature of vowels, consonants, diphthongs, digraphs, the distinction between voice and whispering, the various kinds of whispers, and the nature of the aspirate are fully explained.

There is an interesting chapter on the sounds in connected speech, such as accent, emphasis, intonation, assimilation, and variations in pitch. The author, perhaps, scarcely attaches the importance to pitch, or rather to variations in pitch in the words or syllables of a spoken sentence, which we are inclined to do, and which is brought out in a striking way when the vibrations of the sounds of a sentence are recorded on a rapidly moving surface. We are much interested in the chapter on "The Organic Basis of English," which must appeal to physiologists, the point being that, by repetition, during the early period when speech is acquired, a kind of habit is imposed on the articulating organs, and, we would add, on the nerve centres involved; this will be determined by the sounds the child imitates, or is taught to pronounce. There will thus be a kind of organic habit for each language, a consideration that may explain how difficult it is for one trained from early days in the English language to acquire, in later life, the true intonation of good French. The author gives a striking illustration, p. 141, of the difference between the English *t* and its French equivalent, so that an Englishman uttering the sentence *Ton thé t'a-t-il ôté ta toux?* (Has your tea taken away your cough?) would probably not give the *t* the peculiar softness or quality that can only be obtained by pronouncing the *t*, as the French do, by starting with the tip of the tongue from the back of the front teeth, instead of a little behind, as is done in English speech (see Fig. 27).

The last two chapters deal with spelling reform and with the important pædagogic question of whether a phonetic training is helpful to children who are learning to read. We will not follow the author here, but be content with stating that he presents his arguments forcibly but with fairness. Children must at first be taught by the ear alone, and by frequent repetition; sounds that are distinctly bad, like the peculiar tone of many resident in London or in the south, or the nasal drawl of the west of Scotland, must be got rid of; and the ear of the child must hear, at all events during school hours, the tones of pure English. In not a few cases, probably, the work of the teacher may be undone by the sounds of the child's home. The author refers briefly to the use of the phonograph. The intonation of the gramophone is far superior, and we would advise that the Gramophone Company should be induced to take, say, a dozen records from highly trained and correct voices, illustrating the tones of pure and undefiled English. These would be of immense service to teachers. The Gramophone Company has a record of the voice of the late Canon Fleming, uttering some of the prayers in the Morning Service of the Church of England, which fully illustrates what we mean.

It is a pity that a better set of symbols for phonetic speech sounds has not been invented. Some are very grotesque, but, still worse, with a weak eyesight, some of the symbols are difficult to discriminate. The symbols of Graham Bell seem to us to be better than those mostly in vogue, and it is only right to mention that these are used by so high an authority as Mr. Sweet in his "Primer of Phonetics." Mr. Dumville is to be congratulated on having produced an excellent book on what is truly the *science* of speech.

John G. McKendrick.

A TEXT-BOOK OF OTOLOGY.

Lehrbuch der Ohrenheilkunde für Ärzte und Studierende. By Dr. Paul Ostmann. Pp. viii+533. (Leipzig: Verlag von F. C. W. Vogel, 1909.) Price 18 marks.

THE name of Dr. Paul Ostmann is well known to otologists, not only in Europe, but in the British Islands and the United States. A text-book upon diseases of the ear from his pen is, therefore, welcome, even though it be disappointing. Like all text-books which hail from the German Empire, however, it is marked by that peculiar German conceit which, whilst giving ample prominence to the work of compatriots, ignores, or, at the most, dismisses with curt comment, that of equally prominent scientific labourers of other countries. Dr. Paul Ostmann's text-book abounds with references to German aural surgeons, but in all its 533 pages only some seventeen British or American otologists receive mention, and the names of some of these are spelled incorrectly. Picking out, from motives of curiosity, the names quoted from among those surgeons who belong to our own country, we find that Handfield Jones, Toynbee, Hinton, Ogston, Macewen, Walker Downie, Dundas Grant, and Yearsley alone receive acknowledgment for their work, whilst Cheatle, Pritchard, Barr, and many other names of equal lustre in the domain of diseases of the ear are ignored completely. In a work issued at the present time, when so much that is of lasting value has been done for the advancement of otology, one expects to find mention at least of that which fairly may be described as epoch-making. Yet the pioneer work of Lake, Marriage, Armour, and Yearsley in operations upon the labyrinth for the relief of distressing and incurable vertigo and tinnitus receives no attention, whilst the still more recent researches of Bárány are barely noticed, and those of West, Scott, Crum-Brown, and Alexander are passed over in silence.

For the work as a text-book we can speak with moderate approbation. There is no dissertation upon anatomy to swell the book, but the author plunges straightway into methods of examination and diagnosis. This portion is not too much padded with unnecessary pictures of instruments, and the diagrams are adequate, with the exception of Fig. 13, which is exaggerated and wholly unnatural. A considerable number of pages is devoted to the functional testing of the ears, and this appears to be treated very fully and exhaustively. In dealing with anomalies of the hearing, a series of useful charts is given from actual cases. In treating of the various diseases of and operations upon the ear, we can find no mention of the use of the hand-gouge in place of the chisel and mallet in performing operations upon the mastoid, an improvement in technique which we owe to British surgery. We fully approve of the classification of otosclerosis with diseases of the bony labyrinthine capsule. This is a distinct advance upon those text-books which continue to describe it as a middle-ear condition.

An excellent section deals with the effects of general diseases upon the ear, and another is devoted to the toxic effects of quinine, the salicylates, iodide of potassium, arsenic, aspirin, chloroform, tobacco, alcohol, mercury, silver, carbon dioxide, and phosphorus. Sections such as these are so rarely met with in the works of specialists that they deserve unstinted praise.

It is disappointing to find so important a subject as deaf-mutism dismissed in four pages.

The volume is an average text-book, and deals with its subject in an average manner, but it does not add markedly to the now voluminous literature of otology. As a guide for the student and junior practitioner, it will, no doubt, find a useful place.

OUR BOOK SHELF.

Zenographical Fragments, II. The Motions and Changes of the Markings on Jupiter in 1888. By A. Stanley Williams. Pp. xiii+104; 9 plates. (London: Taylor and Francis, 1909.)

MR. WILLIAMS has been known for about thirty years as a very painstaking planetary observer, and, considering the small sizes of his telescopes ($5\frac{1}{4}$-inch and $6\frac{1}{2}$-inch reflectors), his results have been remarkable in their comprehensiveness and importance. To Jupiter especially Mr. Williams has devoted attention, and, as a continuation or supplement to the "Zenographic Fragments" which he published twenty years ago, and dealing with his observations in 1887, has now issued a similar contribution for 1888. The individually observed transits of the various spots are given, and the periods of rotation are derived and compared with the results of 1887 and subsequent years. In 1888 the number of spots followed with sufficient fulness and accuracy to enable their rotation period to be well determined was 76. Of these, 48 were equatorial markings, and 15 were north tropical spots. The power used on the telescope was 150, and consisted of a single plano-convex lens. The planet was badly situated for observation, its meridian altitude only slightly exceeding 20° even in the south of England.

Notwithstanding the difficulties encountered, however, Mr. Williams succeeded in securing a mass of useful observations, the number of spot-transits recorded being 888. These are carefully discussed, and the results presented in a series of tables. The rotation periods deduced during the opposition of 1888 are included with many others by Mr. Williams and other observers in later years in summaries exhibiting the changes of relative velocity from year to year. It is by comparisons of this character extending over a long period of time that we may hope finally to unravel the problem offered by the changing scenery of Jupiter's vaporous envelope and by the remarkable series of different currents circulating in various latitudes. A number of painstaking observers, including Mr. Williams, Prof. Hough, Major Molesworth, Rev. T. E. R. Phillips, Mr. Bolton, and others, have accumulated extensive materials, to this end, during the past quarter of a century, but much more remains to be done.

The comparisons which Mr. Williams has instituted at the end of his volume are not so valuable as they might have been in consequence of omissions in quoting the results of various observers. Thus, in the table of rotations of spots in the south equatorial current, Mr. Phillips's values for 1898 and 1906–7 are given, but similar figures for the intervening years are not mentioned at all. Similarly the writer's rotation periods for 1905–6 (*Monthly Notices*, vol. lxvi., p. 434) are altogether omitted. On the whole, however, Mr. Williams's new contribution to zenographic study is very valuable and ably executed. There are few typographical errors, and the volume is well got up, while the illustrations are excellent, though the differences between the light and dark markings are intensified, perhaps purposely, to assist the eye in noting the details more readily.

W. F. D.

Introduzioni Teoriche ad Alcuni Esercizi Pratici di Fisica. By Alfonso Sella. Edited by A. Pochettino and F. Piola. Pp. viii+133. (Firenze: Successori Le Monnier, 1909.) Price 2.50 lire.

THIS is a short treatise on a few selected subjects of practical physics. They comprise the testing of a balance and calibration of a thermometer tube, the measurement of specific heat by the method of mixtures, the determination of the constants of a ruled grating, the measurement of magnetic field-intensity and its horizontal component, and the use of the Wheatstone bridge and the quadrant electrometer. The various problems involved are treated very fully, but in a purely theoretical manner, evidently intended to point out to the instructor the difficulties and limitations likely to be encountered. Thus, in the determination of a magnetic field, the lack of uniformity is dealt with at exceptional length, and the mathematical reasoning is given in full at every step. In the measurement of the magnetic quantities M and H, account is taken of such sources of error as the rigidity of the suspending fibre, and the variation of the magnetic moment and the moment of inertia with the temperature. In adding the dimensional equations, the author unfortunately adheres to the old practice of expressing them in terms of M, L, and T only. That $M/H = L^3$ (*recte* L^5) implies that it has something to do with a volume, but conveys no information concerning the physical constitution of the quantities in question.

The whole of the work dealt with belongs to the second term of the physics course in the University of Rome. The author compiled it while yet Prof. Blaserna's assistant. His untimely death after succeeding to the chair prevented him from publishing it himself, but that duty has been admirably carried through by his two able disciples.

Azimuth. By G. L. Hosmer. Pp. v+73. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1909.) Price 4s. 6d. net.

This work is avowedly not a text-book; it is a handbook for the practical surveyor, and, as such, should prove very useful. Prof. Hosmer gives just the ordinary methods for checking the angles of a survey by observation of the sun and stars, but the book is removed from the commonplace by the conciseness of its instructions and the numerous practical hints given at all the necessary points. The tables for computing the results are given in the latter part of the book, and the examples are worked out on specimen forms calculated to obviate clerical errors.

The book is nicely printed, illustrated with useful diagrams, and well bound. These features, combined with its handy size, make it a very useful work for the practical surveyor to carry with him as a pocket-book for easy reference. W. E. R.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Notes on a Stone Circle in County Cork.

In view of several references made in NATURE lately to stone circles in Ireland (vol. lxxix., p. 488, February 25), the following notes on one situated at Drumbeg, near Glandore, County Cork, may prove of interest, especially as this circle contains the characteristic "recumbent stone" of the "Aberdeenshire" type in the south-western half of its circumference, a feature not hitherto met with outside that locality.

Drumbeg Circle. Recumbent stone and supporters, viewed from centre of circle, showing notch in hills (solstitial sunset line).

The accompanying photograph shows this stone and its supporters, of which the following dimensions may be given:—recumbent stone, 7 feet long, 1 foot 8 inches deep, 2 feet 6 inches high; right supporter, 4 feet 8 inches high, 1 foot 9 inches deep, 3 feet wide; left supporter, 5 feet high, 1 foot 6 inches deep, 3 feet wide.

The circle stands on a hill-side facing the sea, upon an artificial plateau with a well-defined edge, 160 feet long, on the southern (seaward) side. This edge, otherwise straight, is indented by a "cove" 20 feet in length, directed towards the centre of the circle, which it almost touches externally on its southern side.

A row of four small ovals, and mounds of stones (probably burial-sites), lie in a line a short way outside the plateau to the south-eastward. The remains of (?) a hut-circle of rough stones occur at a distance of 170 feet westward from the main circle, and there is a large solitary outlying boulder situated on a small eminence 100 feet to the north-eastward.

The following astronomical features (sight-lines) are observable in the above remains:—

(1) From the recumbent stone; solstitial summer sunrise over one of the two most important stones of the circle; sky-line elevated 3° 40′. (This line passes almost over the outlying boulder.)

(2) From the same position, May sunrise over the second of the two important stones; hill-line elevated 2° 20′.

(3) From same position (or from centre of circle, see photograph), solstitial winter sunset over a conspicuous gap in the hills, distant one mile.

(4) Edge of the plateau lies in the line of May sunrise or November sunset.

(5) Side of the cove is directed to the solstitial summer sunset over centre of circle, nearly.

(6) Line of stone ovals, outside plateau, is practically that of May-sunrise.

(7) From centre of (?) hut circle, over the northernmost stone of circle (a slab with a rounded profile, thus differing from the remainder, which are of "pillar" form), to the outlying boulder, is the May-sunrise line.

There are no indications of a burial-mound in the centre of the circle. BOYLE T. SOMERVILLE.

Admiralty Survey Office, Tenby, S. Wales.

Musical Sands in Chile.

The interesting letter of Mr. Carus-Wilson, dealing with the existence of musical sands, suggests to me that some fact in my experience relating to this subject may be worth putting on record, and may, through the courtesy of your columns, possibly lead to the elucidation of an occurrence which has hitherto lacked explanation, at least in my mind.

Some few miles to the west of the town of Copiapo, in Chile, and, so far as my recollection of the locality carries me, about half a mile to the southward of the railway line, there is a tailing off of a ragged hill-range, which runs about north and south. In a ravine—it is too small to be called a valley—the sand which covers the greater part of that portion of Chile has, blown doubtless by the sea-breeze, been carried up the gully to which I refer, and lies there at a slope equal to the flowing angle of dry sand. The place is locally known by the name of "El Punto del Diabolo," as, given conditions of wind and weather, which time did not allow me to study, a low moaning sound, varying in intensity, can be heard for quite a quarter of a mile away. Amongst the superstitious natives the place is avoided. Thinking it worth a visit, I went there with the late Mr. Edwards, who was then the British Consul in that district. On our arrival we found that the sands were quite silent, but on making a glissade down the slope a gradually increasing "rumble" was heard, which increased in volume as the sand slid away before us. As the sound increased we were subjected to an undulatory movement, so decided that it was difficult to keep one's balance, and as we both had heard that this sand had swept over an old silver mine, there was a clear impression on the minds of both that the vibration might break in the roof of the old workings. I write of this experience for what it is worth. I do not know whether the ground under the sand was hollow or solid, and although I have ventured to theorise on the subject, as yet I have found no satisfactory solution of this, to me, quite unique experience. M. H. GRAY.

Lessness Park, Abbey Wood, Kent.

The Æther of Space.

As one who has read with the greatest appreciation the work recently written by Sir Oliver Lodge on this subject, I take it that the following statements represent fairly well the condition of scientific opinion at the present time:—

(1) The fundamental units of which matter is composed are probably individualised regions of the universal æther, neither condensations nor rarefactions, but distinguished by some kinetic structure from the unmodified æther surrounding them.

(2) The æther, as a whole, is stationary, there being nothing of the nature of æther currents, but it possesses an exceedingly fine-grained circulation in closed curves, its elasticity being of kinetic origin.

(3) So far as the motion of a mass of matter is concerned, there is no ætherial viscosity, and, consequently, the earth carries no æther with it in its motion. We therefore live in an æther stream due solely to the earth's motion in space, and having the full value due to its velocity, the failure of Prof. Michelson's delicate experiment being due to a lessened cohesion (of electromagnetic origin) in any length of matter carried at right angles to the æther stream.

The question arises as to whether the æther which forms any mass of moving matter remains the same. Assuming the above statements, there appear to be two alternatives. Either the æther, distinguished by special structure, which composes the ultimate units of which matter is built up, has a bodily transfer through space, or the æther in the line of approach must be rapidly caught up in the advancing vortices (or whatever the structure may be), fused into their being, and as rapidly liberated along the line of recession.

If the former supposition be correct, there must be a region of slip in the æther surrounding the ultimate units (electrons); if the latter, we have the very interesting conception of matter being incessantly made and unmade as regards its fundamental units with a speed proportional to the velocity of motion. All the physical properties of a given mass of matter would remain constant, while the æther, the substratum of its existence, was changing.

If this reasoning be not in error, I shall be glad if Sir Oliver Lodge or any other physicist will indicate which of these views obtains acceptance.

CHARLES W. RAFFETY.

Botanical Surveys.

REFERRING to the review, in NATURE of July 15, of Mr. F. Morey's "Guide to the Natural History of the Isle of Wight," in which it is suggested that the Isle of Wight affords wide scope for a botanical survey on the lines followed by Dr. W. G. Smith and his school of plant-ecologists, it may be of interest to the reviewer and others to state that already the primary survey of the district has been completed and maps made by the writer, in association with the Central Committee for the Study of British Vegetation.

As suggested by "F. C.," a bare species list, even if complete, can do but scant justice to the variety of the vegetation of the Isle. Though in some types it is second in interest to the opposite mainland of South Hampshire, as, for example, in the calcareous grasslands and dry and wet heathlands, yet the almost full development of maritime associations and the diversity of the woodland formations do much to restore the balance.

The island has been under a long-continued civilisation, yet there still remain, almost untouched by man, several station-associations which, according to the plan of Prof. Conwentz, would be among the first to be scheduled as "natural monuments." In this last respect the island is but typical of much of Britain, and the regret expressed by your reviewer that the makers of county floras are not animated even by the spirit of Baker's "North Yorkshire" is shared by all who know the standing of British plant-ecology. To such it is sad that the period which saw the publication of Wheldon and Wilson's "West Lancashire" saw also the publication of the arid lists of many of the Victoria county histories, as of Lancashire itself. W. MUNN RANKIN.

Storey Institute, Lancaster, July 19.

The *Acarus Crossii*.

SOME months ago (NATURE, February 4) a correspondent directed attention to the account of Crosse's remarkable experiences when experimenting with electric currents, and the appearance of quantities of an acarus in the solutions treated, as fully narrated in Chambers's "Vestiges of the Footsteps of Creation," and the question was asked whether any explanation of such strange phenomena had ever been heard of. No reply seems to have been made, and, presumably, no recent attempts to investigate the mystery have taken place. It may be of interest to note that Chambers's account is fully corroborated in the "National Dictionary of Biography," and it appears that Crosse, though he did not make any suggestions as to "spontaneous generation," but merely related the facts and left explanations to others, found himself the victim of such a shower of abuse that he thenceforth entirely abandoned all research work and retired into obscurity. His experiments would probably have been forgotten but that they were repeated with complete success by another worker. Considering how much more easily prolonged electric action can nowadays be applied, would it not be well if someone would have the patience to repeat once more the exact conditions so amply described by Chambers, and so, if possible, clear up what is undoubtedly a very mysterious occurrence? CHARLES E. BENHAM.

28 Wellesley Road, Colchester, July 7.

Barisàl Guns in Australia.

IN NATURE of June 4, 1908 (vol. lxxviii., p. 101), under the title of "Barisàl Guns in Western Australia," you published a note from me describing a peculiar, loud detonation heard by my companions and myself while on the Strelley River, in the north-west of Australia. In reading Captain Sturt's "Two Expeditions into the Interior of Southern Australia during the Years 1828, 1829, 1830, and 1831," I find that, when camped on the newly discovered Darling River, near what is now the town of Bourke, in New South Wales, in February, 1829, a very similar sound was heard by the explorers. Sturt's words are as follows:—"About 3 p.m. on the 7th Mr. Hume and I were occupied tracing the chart upon the ground. The day had been remarkably fine, not a cloud was there in the heavens, nor a breath of air to be felt. On a sudden we heard what seemed to be the report of a gun fired at the distance of between five and six miles. It was not the hollow sound of an earthly explosion, or the sharp cracking noise of falling timber, but in every way resembled a discharge of a heavy piece of ordnance. On this all were agreed, but no one was certain whence the sound proceeded. Both Mr. Hume and myself had been too attentive to our occupation to form a satisfactory opinion; but we both thought it came from the N.W. I sent one of the men immediately up a tree, but he could observe nothing unusual. The country around him appeared to be equally flat on all sides, and to be thickly wooded: whatever occasioned the report, it made a strong impression on all of us; and to this day, the singularity of such a sound, in such a situation, is a matter of mystery to me" (2nd edition, 1834, vol. i., p. 98).

J. BURTON CLELAND.

Bureau of Microbiology, Sydney, New South Wales, June 19.

THE STONE CIRCLES OF KESWICK AND LONG MEG.[1]

IT has frequently been shown that the site on which a stone circle was erected was chosen with reference to the elevation of the northern horizon. At Keswick and Long Meg it appears that a further choice was exercised, in that, when possible, natural features were utilised in place of outlying stones or circles. In each case Arcturus rose in a well defined gap between two hills, whilst at Keswick, where the Pleiades were used for the May warning, the alignment passes over the crest of Great Mell Fell.

At Keswick the circle consists of thirty-eight unhewn stones with an internal diameter of about 50 feet. The rectangle or chapel involves ten additional stones, and there is a single outlying stone. These are all shown on the plan accompanying the paper, those which appear to have fallen being indicated by cross-hatching. The stones range from 2 to 7 feet in height.

As the result of a preliminary survey, the following alignments were carefully measured:—

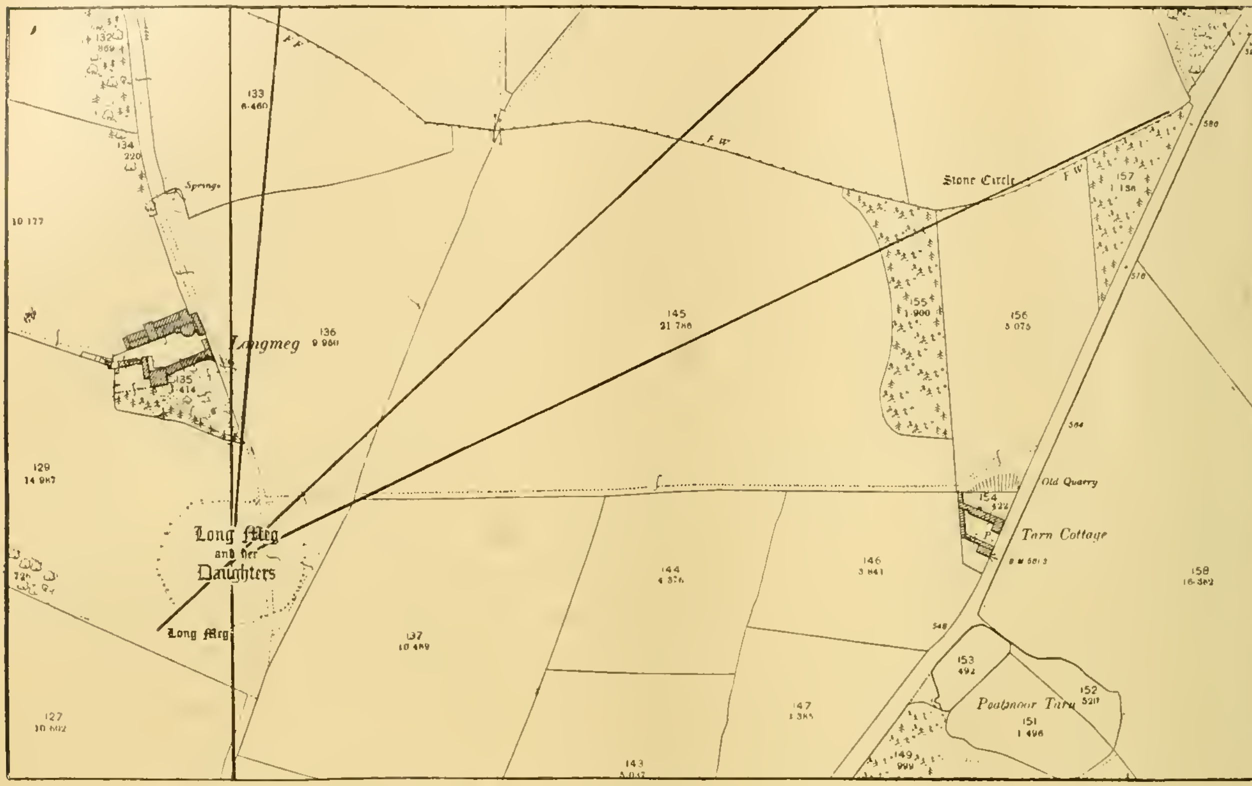

FIG. 1.—Portion of Ordnance Map—Long Meg. From the Proceedings of the University of Durham Philosophical Society.

(1) From the centre of the circle over the tip of the pointed stone, No. 1, to the gap on the horizon between Blencathra (Saddleback) and Skiddaw; (2) from the eccentric centre along the centre line of the chapel, over the tip of the pointed stone, No. 10, to the crest of Great Mell Fell; (3) from the outlying stone to the centre of the circle, proceeding along the valley of the Greta.

FIG. 2.—The Chapel or Rectangle, Keswick Circle. From the Proceedings of the University of Durham Philosophical Society.

The observed altitudes and azimuths and the calculated declinations are given in Table I.

[1] Abstract of a paper on "Sun and Star Observations at the Stone Circles of Keswick and Long Meg," by Dr. John Morrow (Proceedings of the University of Durham Philosophical Society, vol. iii., part iii, 1908–9).

Table I.—*Keswick Circle* (*Lat.* 54° 36′).

Alignment	Altitude	Azimuth E. of N.	Decl. N.	Object
Circle to Gap (Saddleback-Skiddaw)	2° 38′	8° 25½′	37° 19′	Arcturus rising.
Centre line of chapel to Great Mell Fell	1 42	79 38½	7 6	Pleiades rising.
Outlying stone to centre of circle	−0 29	64 45½	13 25	May and August Sun.

The Pleiades and Arcturus were the warning stars for the May and August festivals respectively. Of these, the Arcturus alignment is the better preserved, and this gives the date of erection of the circle as about 1400 B.C.

The stones known as "Long Meg and her Daughters" are in the neighbourhood of Little Salkeld, a few miles from Langwalby. There are sixty-eight stones in the circle, and at least one other is buried. The 25-inch Ordnance map gives a fairly accurate plan. The diameters are about 350 feet in an east and west direction, and 305 feet north and south.

Between six and seven hundred yards to the north-east there is a small circle of some 15 feet diameter composed of eleven good-sized stones.

The only shaped stone, Long Meg, is to the south-west of the main circle. It is more than 12 feet in height, and is deeply notched at the top.

The alignments taken were:—

(1) From the centre of the large circle, over a stone which is now recumbent, to a well defined gap on Newbeggin Fell (the only well defined gap on the horizon); (2) from the centre of the large circle to that of the small outlying circle; (3) from Long Meg to the centre of the large circle.

These are dealt with in Table II., and we here also get the date from the Arcturus alignment. This date is 1130 B.C., showing that Long Meg was probably erected after the Keswick circle had fallen into disuse.

Table II.—*Long Meg* (*Lat.* 54° 43′ 20″).

Alignment	Altitude	Azimuth E. of N.	Decl. N.	Object
Circle to Gap (Newbeggin Fell)	1° 11′ 20″	4° 52′ 20″	35° 36′ 35″	Arcturus rising.
Large circle to small circle	3 12 0	64 24 40	16 44 35	May and August Sun.
Long Meg to centre of large circle ...	2 40 0	49 37 20	23 53 40	Summer solstice.

Fuller descriptions of the circles, and details of the alignments and the degrees of accuracy to be expected, are given in the original paper in the Proceedings of the University of Durham Philosophical Society. An appendix contains the results of a geological examination of the stones made by Dr. Woolacott. These circles are now brought into line with, and render an additional verification (if such were needed) of, the theories first formulated by Sir Norman Lockyer.

THE FLORA OF SOUTH AFRICA.[1]

While ostensibly forming a part of the scientific results of the *Valdivia* expedition of 1898–9, the present volume is in reality much more than this. Indeed, it represents the results of many years of work and experience of the flora of South Africa. For an account of this flora, the editor of these memoirs has been singularly fortunate in securing the cooperation of Dr. Marloth. The author has given to botanists an excellent and comprehensive survey, which for many years must form a standard reference work on the plant-geography of South Africa. The volume contains a full historical summary of the work of previous investigators and travellers, adds much that is new, and supplies a series of vivid descriptions of the peculiar vegetation of this quarter of the globe.

After giving an account (accompanied by a series of maps) of the various floral regions as suggested by earlier plant-geographers, the author proposes a scheme of his own. This resembles, on the whole, that proposed by Dr. Bolus in 1905, but differs in several essentials from any previous scheme. The following are the larger divisions now suggested:—

(A) The Cape Province of the South-west.

(B) The Southern Palæo-tropical Provinces, which include:—

(1) The grass steppes of Rhodesia, the Northern Transvaal, part of Natal, &c.

(2) The South-eastern Littoral.

(3) The forests of the South Coast.

(4) The Central Region, including the Karroo, the Karroid uplands, and Little Namaqualand.

(5) The Western Littoral.

The essential differences between Dr. Marloth's scheme and earlier ones consist in (*a*) the more accurate delimitation of the Cape Province, (*b*) the separation of the forest region of the South Coast from the Cape Province, and (*c*) the smaller subdivisions which he proposes for the above provinces. Though brief descriptions are given of the others, the only regions treated in detail in this volume are the Cape Province, the South Coast forests, and the Central Region. Each of these may now be briefly noticed.

The Cape Province.—The peculiar systematic character of the Cape flora is, of course, well known. It is exceedingly rich in species, many of which have a very limited range, and includes numerous endemic forms of the orders Proteaceæ, Thymelæaceæ, Ericaceæ, Restionaceæ, &c. The dominant vegetation is a "Macchia," composed of sclerophyllous evergreen shrubs, with small, entire, xerophytic leaves. Mixed with the shrubs, but subordinate to them, are many xerophytic dicotyledonous herbs, together with bulbous and succulent monocotyledons, and many Restionaceæ. This Macchia (see Fig. 1), which somewhat resembles that of the Mediterranean region, forms the real climatic type of vegetation of the Cape region. Other ecological types, *e.g.* those found in marshes, or on rocky ground, sand dunes, &c., are due to local edaphic influences. The Macchia is typical only where the original vegetation has not been destroyed, and Dr. Marloth is of opinion that if the land were freed from the influence of bush fires and of grazing herds of domestic animals, in fifty years' time it would become entirely covered with a dense, impenetrable Macchia.

Dr. Marloth has explored many of the mountains outside the area of the Cape Province proper, and finds that outliers of the Cape flora occur as "islands" on the higher mountain ridges, both in the Karroo and also in Little Namaqualand. The occurrence of these Cape "islands" is, he considers, largely due to the fact that the ridges are sufficiently high to experience the effects of the rainy south-east winds. Their climate thus more nearly resembles that of the Cape than that of the dry desert plains below them. Besides this, wherever edaphic and other factors permit, there is a reciprocal invasion between Cape and Karroid forms. For instance, even those parts of the Cape region which have the greatest rainfall are not entirely devoid of succulent immigrants from the Karroo. Comparatively few succulents, however, can survive the effects of an exceptionally rainy winter.

[1] "Wissenschaftliche Ergebnisse der deutschen Tiefsee-Expedition auf dem Dampfer *Valdivia*, 1898–1899." Edited by Prof. Carl Chun. Zweiter Band, Dritter Teil. Das Kapland, insonderheit das Reich der Kapflora, das Waldgebiet und die Karroo, pflanzengeographisch dargestellt. By Rudolf Marloth. Pp. 436; with 20 plates and 8 maps. (Jena: Gustav Fischer, 1908.) Prices 100 marks and 81.50 marks.

The Forests of the South Coast.—Though formerly more extensive, the true forests of South Africa are now practically confined to a small strip of coast-land in the Knysna district. Floristically, the Knysna forests are so distinct from the Cape Province that Dr. Marloth has classed them (for the first time) as a separate region. In this district, where the annual rainfall amounts to some 36 inches, the woodland has all the characters of a typical temperate rain-forest. Epiphytes are common, and lianes are not infrequent. Westwards the forests become more dwarfed, and finally pass into the Macchia of the Cape Province.

The Central Region.—Passing northwards from the South Coast the rainfall rapidly diminishes, and in consequence the country becomes increasingly arid and desert-like. Thus the Central Province (including the Karroo, the Karroid uplands, and Little Namaqualand) forms a vast area, over which semi-desert conditions prevail. But the only true desert in South Africa is the narrow strip of coast-line known as the Western Littoral. Elsewhere, the streams arising in the mountains somewhat lessen the severity of the conditions, and even in the "Gouph" we can only speak of a stony semi-desert. The term "Gouph," a word of Hottentot origin, signifying barren, empty, void, is employed to denote the most arid and desert-like part of the central Karroo. The vegetation, for the most part, consists of dwarfed, rounded shrubs, with reduced, often ericoid leaves, and numerous succulent herbs scattered between the shrubs. Here and there, one or the other type of plant is so dominant as to render it possible to distinguish a succulent steppe from a dwarf-shrub steppe, but in general they are mixed. Eastwards the Karroo passes into grass steppes, and to the south and west into the richer vegetation of the Cape Province.

The Karroid uplands, which occupy large tracts of the northern part of Cape Colony, are still comparatively little known botanically, except from the collections of Thunberg, Lichtenstein, and Burchall, made more than a hundred years ago. In fact, according to Dr. Marloth, many parts of this region have never yet been visited by botanists.

Ecology.—The chief value of Dr. Marloth's work is on the floristic side of plant geography. He has travelled extensively, and, although many parts of South Africa are still incompletely known botanically, he has considerably advanced our knowledge of plant distribution in this part of the world. But, in addition to this, Dr. Marloth has not lost sight of the ecological point of view. Throughout the work the dependence of vegetation on rainfall (which is nowhere better seen than in South Africa) is emphasised, and rainfall and temperature tables are introduced wherever possible. One very interesting point brought out is the importance, especially at higher altitudes, of moisture deposited on the vegetation from the thick clouds which so often cover and obscure the mountain tops. An apparatus for collecting the moisture precipitated from clouds has been employed on Table Mountain. On one occasion, during a period of six days, this instrument registered a precipitation of 152 mm., while an adjacent rain-gauge only recorded an actual rainfall of 4 mm. The author devotes a special section of more than fifty pages to the "General Ecology of South African Plants." Under this heading are discussed the various growth-forms found in different plant formations, such as annuals,

FIG. 1.—Macchia from the North side of Table Mountain, showing Protea, Leucadendron, Brunia, &c. Reproduced from "Das Kapland," by Dr. R. Marloth.

tuberous and bulbous plants, shrubs, &c. Epiphytes (as is to be expected in a climate of such general dryness) are few, but parasitic phanerogams are abundant. A good deal of attention is paid to the various contrivances for storing water and reducing transpiration. Other matters discussed are insects and birds as agents of pollination, the influence of wind, light, &c. Several curious instances are adduced, especially in the genus Mesembrianthemum, of so-called protective resemblance. Though supposed cases of mimicry in the plant kingdom should be received with caution, it must be admitted that the resemblance, both in colour and form, between some of these curious plants and the stones and rocks amongst which they grow is exceedingly striking.

The closing chapters of the volume are occupied by a useful discussion on the affinities and origin of the South African flora in general, and that of the Cape Province in particular. The older theories of Hooker and Wallace, as well as those of later authors, to account for the resemblances between the floras of South Africa, Australia, and temperate South America, are given at some length, and discussed in the light of what is known of geological and climatic changes since the Cretaceous period.

Not the least interesting feature of the volume is a series of short, posthumous sketches of the vegetation of various districts, by the late Prof. A. F. W. Schimper, who was botanist to the *Valdivia* expedition. These sketches, which are marked by Prof. Schimper's usual lucidity, supplement Dr. Marloth's descriptions in many respects.

On p. 188 is a photograph, taken in the Knysna forest district, in which both Prof. Schimper and Dr. Marloth appear. The latter, however, with characteristic modesty, has omitted his own name from the description of the figure. The volume is copiously illustrated by line drawings and photographs. Some of the latter take the form of particularly beautiful heliogravures. There are also a number of useful maps, illustrating the rainfall, geology, and phytogeographical regions of South Africa. Karte 6 would be improved by a clearer method of indicating the regional boundaries.

To sum up, the work presents a most useful account of the present position of geographical botany in South Africa. Its very limitations, particularly in the ecological sections, afford a graphic indication of the enormous (and in many directions practically untouched) field which awaits future investigators.

R. H. Y.

PALÆOLITHIC MAN.[1]

RECENT discoveries have filled up to a great extent the gaps in our knowledge of Palæolithic man. The skeleton find in the lower grotto of Le Moustier (Dordogne) in the main confirms Klaatsch's conclusions, based on a comparison of the face-skeleton of the Neanderthal race with that of the present Australians. *Homo mousteriensis* belongs to the older Diluvial race, that is, to the Neanderthal type, not to *Homo sapiens* found in more recent Diluvium. The subject was about sixteen years old probably a male. That *Homo mousteriensis* belongs to the Neanderthal type is further shown by the character of the femur and radius (of which the length is estimated at 195 mm., while the upper arm measures 210 mm.). The Neanderthal race had short extremities, in which fact Klaatsch sees an approximation to the present Arctic races of Mongoloid relationship.

[1] "Recently discovered Fossil Human Remains and their Bearing upon the History of the Human Race," by Moritz Alsberg (*Globus*, vol. xcv., No. 17, May 6, 1909).

Mention must also be made of the extraordinarily massive proportions of the absolutely chinless lower jaw. The knobs on the backs of the incisors recall the Krapina find. All the upper front teeth have much curved roots adapted to the round arching of the upper jaw-bone.

The position of the skeleton at Le Moustier, like that of the find at Grimaldi, proved that Diluvial man buried his dead with care. The posture is that of sleep, with the face turned to the right, and the right arm under the head, which was surrounded by flint flakes. Beside the skeleton were found, in addition to flint implements of the Mousterian type, some of the Acheulean type, among them a splendidly worked "hand-wedge." A mark on the right femur is traceable to burning, but there is no sign of the cannibalism ascribed by Kramberger to Krapina man.

Another important find in France is that of a male skeleton, brought to light by the Abbés A. and J. Bouyssonie and Bardon near La Chapelle-aux-Saints (Corrèze), in an absolutely undisturbed archæological stratum. The subject is an old man of about 1·60 m. in height. The skull is actually 208 mm. long by 156 mm. broad, that is to say, dolichocephalic, with an index of 75. The height from basion to bregma is only 116 mm. The breadth-height index is 62, far outside the variation in living man. The huge, almost round orbits and very wide nasal aperture agree with what has been noted as very remarkable in skulls of the Neanderthal type. Though the face is defective, its prognathous nature is clear. The mandible is of great dimensions, and in so far as senile atrophy has not produced changes, exhibits a formation which agrees in the main with those of lower jaws from Spy, Krapina, La Naulette, &c. Here, too, we have absence of chin, "negative chin-formation" (Klaatsch). The occipital and temporal regions have Neanderthal characteristics. The old man's grave contained no tools of the Acheulean stage. This fact, and the predominance of reindeer-bones in the grave, would lend some degree of probability to the supposition that La Chapelle man belongs to a rather later cultural phase than Le Moustier man. Both are to be taken as representatives of the Neanderthal type, and as belonging to the Middle Diluvium.

P. Adloff has in several publications dealt with the question as to whether the above physical characteristics comprised under the term "Neanderthal race" represent an absolutely fixed human type, or whether they were subject to variations. As regards differences of dentition in different specimens of the Neanderthal type, he comes to the conclusion that by no means insignificant differences do exist; Krapina man especially exhibits a form sharply distinguished from other representatives of the genus Homo. Obviously, in a type like the Neanderthal, scattered over a vast area, and doubtless existing for many thousands of years, certain variations must arise by way of adjustment to different climatic conditions, food, mode of life, &c.

Dr. O. Schoetensack has recently made a notable find at Mauer, near Heidelberg, of a fossil human lower jaw, which he has called *Homo heidelbergensis*. It unites two at first seemingly contradictory qualities: (1) massiveness of the body of the jaw, combined with entire absence of chin-projection, breadth and thickness, and special form of the ascending rami—phenomena usually taken as indicating a development little advanced, so-called pithecoid qualities; (2) a set of teeth agreeing with that of present man in all essentials, the size of the teeth not surpassing the scale of variation in some still extant primitive peoples (*e.g.* Australians). No doubt, as Adloff says, the teeth of man are in many respects more primitive than those of anthropoids, and the pithecoid characteristics met with in human dentition are actually primitive features. A glance at the lower jaw of a young gorilla or of a South American howler shows a remarkable resemblance of the mandible to that of *Homo heidelbergensis*. Dr. W. Wright has given an account and illustrations of this jaw in Nature of June 3, p. 398.

In determining the exact position of *Homo heidelbergensis* in the human pedigree, it must always be borne in mind that a huge difference in time exists between *H. heidelbergensis* and the members of the Neanderthal race. Fossil remains of Neanderthal man belong to the Middle Diluvium, coinciding in general with the Mousterian culture period; whereas the remains (of *Elephas antiquus, Rhinoceros etruscus*, Falc., and *Equus stenonis*, Cocchi) were found undisturbed in the same stratification with *H. heidelbergensis*, which points to earliest Diluvium or to the transition period from Diluvium to late Tertiary age (Pliocene). The long periods intervening between Neanderthal man and *H. heidelbergensis* are shown by Penck's climatic curve of the Glacial periods (Ice ages), mainly coinciding with the Quaternary age, with warmer inter-Glacial periods between and the Palæolithic culture periods introduced into his diagram. The culture epoch, called Mousterian by the French prehistorians, corresponds, according to Penck, together with the subsequent divisions of Palæolithic culture (Solutrean, and perhaps partly Magdalenian), to the Ice-age divisions, comprising the inter-Glacial epoch, which falls between the Riss- and Würmeiszeit. On the other hand, Penck makes the oldest divisions of Palæolithicum correspond: Acheulean and the preceding Chellean, to the warm intervening epoch of specially long duration between the Mindel- and Risseiszeit. Obviously, the late Palæolithic age (of successive Mousterian, Solutrean, and Magdalenian cultures) lies very much nearer to the present than that earlier division of the Palæolithic age (of Acheulean and Chellean cultures).

The supposition that a very long interval elapsed between Middle Diluvium (with Neanderthal man in Europe) and that earliest Diluvium (of *H. Heidelbergensis*) receives indirect confirmation from recent excavations by R. R. Schmidt (Tübingen). He devotes himself chiefly to later divisions of the Palæolithic age, and, working back from the Neolithic age, shows the relatively long duration of the culture-sections which he calls late, high, and early Magdalenian; later and earlier Solutrean; late, high, and early Aurignacian; and late Mousterian. However, the slow and gradual earliest cultural progress of the human race leads one to attribute to those oldest divisions of the Palæolithic age, commonly called Chellean or Acheulean, a still longer duration than to all those later divisions.

Thus an enormously long period must have elapsed between Neanderthal man (generally coinciding with Le Moustier culture) and *H. heidelbergensis* (of earliest Diluvium, or Pliocene-Diluvium transition). No fundamental objection stands against the view of Rutot, Klaatsch, Verworn, and others that the first beginnings of human cultural development reach far back beyond Diluvium into the middle division of the Tertiary period (Oligocene, according to Rutot), and that the much debated eolith is to be regarded as the primitive implement of man at the lowest cultural stage. It is obvious that an extremely long period of slow development must have preceded the production of the "hand-wedge," the characteristic implement of the Chellean age.

Neanderthal man, then, is of slight antiquity as compared with *H. heidelbergensis*. Klaatsch has for years upheld the theory that to discover the roots of the human race we must go very far back, perhaps even to the roots of the mammalian genealogical tree, and additional probability is lent to this idea by the Heidelberg find. The teeth of the Heidelberg jaw undoubtedly prove that no anthropoid stage preceded that to which the Heidelberg mandible belongs, so that to explain the similarity of human and anthropoid forms we must go back to the remote ancestor from which there branched off on the one side the genus Homo and on the other the genera of anthropoids and perhaps of other ape-species. The fact that the origin and development of anthropoids reaches back to the Middle Tertiary age (Miocene) prevents the assumption that the Heidelberg mandible is itself the stage of development at which the anthropoids branched off from the genus Homo; this is also rendered improbable by the discovery of eoliths in Middle Tertiary beds. There is nothing to preclude the supposition that the Heidelberg fossil, as regards formation, stood fairly near the point of separation. The line of descent Pithecanthropus–Neanderthal man–recent man has to a certain extent been shaken by the recent researches, which attribute less antiquity to Pithecanthropus than was hitherto supposed to be the case.

At the conclusion of the paper is a brief discussion of the genealogical tree of the phylogeny of man and the anthropoids, recently published by Prof. G. Bonarelli, of Perugia. According to this table *Pithecanthropus erectus, Homo heidelbergensis*, and Neanderthal man may be regarded either as successive stages in the direct line of descent of Hominidæ or as offshoots from those stages.

A. C. Haddon.

THE ORIGIN OF THE PLANETARY SYSTEM.

Dr. See contends that the planets and satellites of the solar system were captured and their orbits made remarkably circular by a resisting medium. In his view, therefore, Laplace's nebular hypothesis is altogether wrong, whereas the current view is that it is in the main right, though in need of considerable modification and extension.

Dr. See's paper contains a single table, the object of which is to show that, when the sun and planets are expanded to fill the orbits of the bodies revolving about them, their rotations must have been so slow that it is inconceivable that they could have flung off planets or satellites. As an extract from the tables we may quote that, assuming the law of internal distribution remains unchanged, the principle of conservation of angular momentum implies that the sun, when it filled the orbit of the earth, rotated in 3192 years instead of in 25·3 days, as at present. It is no doubt inconceivable that the matter which now forms the earth was being carried round as an integral part of a nebulous sun at one instant, and shortly afterwards revolving as a planet with 3000 times its former velocity; but Dr. See's figures involve the assumption that the law of internal distribution remains unchanged. He probably regards 3000 as a sufficient factor of safety.

A precisely similar point is made with regard to thirty-three other bodies in the solar system. Dr. See then continues that, as detachment has been disproved, capture is the only other alternative. This is not a proof. There are more things in heaven and earth than Dr. See has dreamed of in his philosophy. Capture is a possibility, but Dr. See has done nothing to raise his theory beyond a mere conjecture, even though he points out, in addition, that a resisting medium would diminish the mean distance and the

[1] "On the Cause of the Remarkable Circularity of the Orbits of the Planets and Satellites and on the Origin of the Planetary System." By T. J. J. See.

eccentricity of an elliptic orbit, and that in the case of Jupiter's satellites the outer orbits are highly eccentric, and the inner orbits nearly circular. It may be mentioned that Mercury is an exception to his rule.

Suppose that Laplace had not thought of the possibility of capture. Then Laplace would have been as much entitled to say detachment was the true explanation, because no other was possible, as Dr. See is now entitled to say that capture survives as the only possible explanation. Laplace, of course, would not have reasoned in this way. His theory explains many features of the solar system, in fact so many that when new discoveries showed that his theory was incomplete, there has been a nearly universal reluctance to say that it was altogether wrong. We do not see that Dr. See's hypothesis explains anything. Why, for instance, on the hypothesis of capture are the vast majority of orbits near the plane of the ecliptic and their motion direct?

STATE AID FOR UNIVERSITY EDUCATION.[1]

THE grant in aid of university colleges originated in the demand for advanced education in 1889 arising from the university extension movement, and was intended to help university colleges in providing suitable courses. In twenty years conditions have changed, and some of the university colleges have become universities, but they are still claimants for the aid. The members of the University Colleges Advisory Committee had a difficult task before them, and they submitted a report dated July 24, 1908. On this a Treasury minute, June 3, 1909, has been founded which lays down the conditions for participation in the grant. The conditions are summarised thus:—

(1) Any institution to secure a share of the grant must be prepared to afford satisfactory instruction of university standard, which should normally include English, classics, French, German, history, philosophy, mathematics, physics, chemistry, biology.

(2) The courses of instruction must be attended by a reasonable number of students capable of profiting by the education afforded.

(3) The buildings and initial equipment must be adequate for the courses established.

(4) The aggregate income of the institution, whether derived from grants or otherwise, must be sufficient to maintain all the departments in a state of efficiency, and to provide a superannuation scheme.

(5) The grants should be confined to institutions serving great centres of population, and no new institution should be admitted unless it serves a district not already adequately provided with instruction of a university standard.

(6) Due regard must be paid, not only to the standard and the efficiency of the teaching, but also to the spirit animating the institution and its influence as an intellectual centre.

These are the conditions, and it must be agreed that they appear very just, except number five, concerning the admission of new institutions to the privileges, as there may be two or more institutions in a great centre which afford equal or identical advantages, one, however, receiving the grant to the exclusion of the other. This is the case in London, where there are two large institutions fulfilling the conditions, but excluded because certain other colleges are sharing already in the grant. Both Birkbeck College and East London College more than satisfy all the conditions, and there are several other institutions and polytechnics which fulfil, or come very near to fulfilling, the qualifications.

It will naturally be asked why the grant in aid is to be limited to certain favoured institutions in some centres, and the answer must lie in the miserable inadequacy of the grant. The advisory committee had before them, not the difficulty of the standard of the colleges, but how to make quite too small a meal satisfy the demands of a large, hungry, and rapidly increasing family. In domestic affairs the difficulty has to be met by the father increasing the family allowance, and it would be more logical for Parliament to increase the allowance. The solution of allowing part of the family to starve is indefensible. We have alluded to the condition of affairs in London particularly because London has come off worse in amount than any other city in proportion to its population. London, too, has suffered from want of civic spirit. In the lesser cities strong civic spirit pushes their claims on Parliamentary notice.

It must be noted that the advisory committee is fully alive to the fact that many of the universities and university colleges are drawing grants from several sources, *i.e.* Board of Education, Board of Agriculture, Parliamentary grants, and local rates, and there is danger of their being paid twice over for the same work; but the advisory committee does not suggest at present any way out of this difficulty other than getting a return made to them from each of the granting authorities.

It has been suggested before that all higher institutions should receive their grants from one authority, which should be able to take a survey of the whole kingdom. At present many higher institutions have to depend largely on the local education authority, which secures neither breadth of treatment nor sufficient continuity. The institutions find that there are fat and lean years, and it is not likely that the best educational results will be obtained when there is so much uncertainty. In an article which appeared recently in this journal it was suggested that the control of the higher technical institutions throughout the country should be under a central authority, for prosperity in trade is a national affair, and not local. The same view must be taken in regard to the university colleges and universities. They should be as free from local restraint as possible. This is foreshadowed in the report in the following words:—

We trust, however, that it may be found possible to regard such a scheme as being merely transitional, and to replace it in the near future by one on the more simple lines we have indicated. . . . a scheme that would comprise in a single vote the whole aid granted by Parliament to universities and university colleges for education of university character and standard. The coordination of the institutions which provide higher education in the country in accordance with the principles of administration embodied in the Education Act, 1902, is proceeding apace, and the universities and university colleges have taken the initiative in connecting themselves with the local education authorities most closely related to them by locality and communications. Universities, however, are non-local as well as local institutions, and it is of importance that this two-fold aspect should be appreciated by the central administration, which has to dispense the State subvention for higher education by way of grants to this or that locality, and which must at the same time pay due regard to the interests and necessities of the country as a whole.

[1] University Colleges (Great Britain). Grant in Aid. Parliamentary Paper 182. (London: Wyman and Sons.) Price 1½d.

NOTES.

THE present summer promises to be one of the coldest on record, but for rainfall it is likely to be several inches short of the measurement in 1903, when at Greenwich the total fall for the three months, June to August, was 16·16 inches. So far, the highest temperature at Greenwich since the commencement of June is 77·7°, on July 18, whilst at the observing station of the Meteorological Office, in St. James's Park, the highest temperature is

75°. The Greenwich records only show three days in June with the thermometer above 70°, and the observations since 1841, a period of sixty-eight years, only show one June, 1860, with an equally small number of warm days; but as recently as 1907 June only had five days with the thermometer above 70°. For the first twenty-seven days of July there have been only fifteen days with a temperature above 70°; this is precisely the same number as during the whole month in 1907, whilst in 1879 there were only eight equally warm days, and in 1888 only twelve. In 1907, the summer of which approximates somewhat to that of the present year, there were twenty days in August with a temperature of 70° and above. In 1868, which is about the warmest summer on record, there were in the three months seventy-seven days above 70° and thirty-three days above 80°, whilst in the coldest summer, 1860, there were only twenty-three days with 70° or above, and the sheltered thermometer on no day touched 80°. Taking England as a whole, the temperature this summer has been largely deficient of the average, and the rainfall has been generally in excess, but not to any great extent, whilst the sunshine is everywhere deficient.

M. Blériot accomplished a flight across the English Channel in his monoplane in the early morning of Sunday, July 25. He started his flight at 4.35 a.m. from Baraques, near Calais, and, having travelled across the Channel, he landed in safety in a field near Dover Castle. According to M. Blériot's own account of the flight, his engine at the time of starting made 1200 revolutions—almost its highest speed—to enable him to get over the telegraph wires along the edge of the cliff, but as soon as this was accomplished the speed was reduced. The monoplane travelled at a height of about 250 feet, and at the time of passing the *Escopette*, the destroyer in attendance, in the Channel the rate of travel was at least 42·5 miles an hour. Twenty minutes after leaving the French coast M. Blériot was able to make out Dover Castle, and, heading the monoplane westward, he followed the coast-line to Dover. Eventually catching sight of his friend, M. Fontaine, waving a large French tricolour to guide him to a suitable place of descent, the monoplane was brought to earth with little damage. The flight represents an achievement of great interest in the history of aërial navigation. On being informed of this notable feat, M. Quinton, president of the Aërial League, remarked, "Before five years are out England will have ceased to be an island. The sea is no longer a barrier. Relations between nations will undergo a change. The strategic and political situation of certain peoples will be transformed." The *Times* gives the following particulars of M. Blériot's monoplane, *Blériot XI.* The area of its sustaining surface, which was at first 14 square yards, was increased last February to 17 square yards. Its spread is 8½ yards. Under these conditions the small monoplane left the ground very easily, but could not stop in the air more than two minutes. Its motor was then replaced by a three-cylinder Anzani of 105 mm. (4·13 inches) bore and of 22–25 horse-power, weighing 132 lb. in working order. With this modification the *Blériot XI.* has made some very successful flights, including one on July 4, when the aëroplane stopped in the air for 50m. 8s., and another on July 13, when it flew from Étampes to Chevilly, a distance of twenty-six miles. It then went to Calais, where it underwent a few tests, with the present result. The framework of the *Blériot XI.* is of ash and poplar stiffened with piano strings. It weighs 45 lb., and is about 23 feet long; it can easily carry a load of 660 lb. placed at its middle point. The landing *châssis*, including the wheels and springs, weighs only 66 lb. The inclination of the tail of the machine, and the warping of the wings, ensuring lateral stability, are effected by means of a hand-lever, whilst the vertical rudder is moved by a bar pressed down by the foot of the aviator. The propeller, which is a Chauvière one of the type known as "Intégrale," is placed in front of the machine, and is so designed that the air it throws back does not meet the framework of the aëroplane. It has a diameter of a little less than 7 feet, and working the *Blériot XI.* it has an efficiency of 85 per cent.

The Civil Service Supplementary Estimates of sums required to be voted for the year ending March 31, 1910, include 6500*l.* to the Royal Society, as grant in aid of the expenses of the aëronautical section of the National Physical Laboratory. The grants under the Irish Universities Act, 1908, amount to 28,150*l.*, namely, Queen's University, Belfast, 4700*l.*; University College, Dublin, 16,000*l.*; University College, Cork, 5700*l.*; and University College, Galway, 1750*l.*

Mr. H. Garrett, writing from Greensted Rectory by Ongar to the *Times* (July 28), says:—"During the severe thunderstorm on the 13th inst. a meteoric stone fell in the stable yard here with a terrific explosion when within a few feet of the ground, embedding itself in the gravel about 8 inches, the ground around for several feet being perforated with small holes caused by the fragments. The main part and fragments which we could collect weighed 1 lb. 13 oz. The fall was witnessed by my daughters, who were sheltering about eight yards away."

A Reuter message from Melbourne states that it is proposed to invite the British Association to meet in Australia in 1913. The University of Melbourne is communicating with the different Australian universities with the view of formulating definite proposals. It is suggested that the invitation should proceed from the Commonwealth.

The local secretaries for the forthcoming British Association meeting at Winnipeg desire it to be known that the proposed excursion up the coast of British Columbia to Alaska, now being organised in connection with the Natural History Society of Canada, is unofficial, and is not part of the local committee's arrangements. Those desiring, therefore, to make this journey before the meeting should communicate with Mr. M. B. Cotsworth, Victoria, B.C.

The death is announced of Prof. G. Arth, professor of industrial chemistry in the University of Nancy. Prof. Arth's first researches were concerned with organic chemistry, his work on menthol and its derivatives being well known. For some years Prof. Arth had been engaged in perfecting methods of metallurgical analysis.

We notice with regret the death, at Naples, of Dr. V. R. Matteucci, instructor in geology in the University of Naples, and director of the observatory on Vesuvius. It will be remembered that during the eruption of Vesuvius in 1906 Dr. Matteucci followed successfully every phase of the eruption at grave risk to his own safety.

Mr. P. W. Stuart-Menteath desires to direct the attention of our geological readers to the instructive sections to be seen in the neighbourhood of Gavarnie, in the Pyrenean region. The subject has been fully discussed in a paper on the Gavarnie overthrust, and other problems in Pyrenean geology, by Mr. E. E. L. Dixon, with an appendix by Mr. Stuart-Menteath (*Geol. Mag.* for August and September, 1908).

By the will of the late Miss E. S. Wolfe, who died on June 10, leaving estate of the gross value of 71,520*l.*, with net personalty 60,295*l.*, the sum of 1000*l.* is to be given to each of the following societies among other institutions:—the Royal Anthropological Institute, the Royal Archæological Society, and the Royal Geographical Society. Subject to the payment of duties on the estate, the residue is left to King Edward's Hospital Fund, the Royal Institution, and the Royal Society.

The National Trust for Places of Historic Interest or Natural Beauty makes an appeal for upwards of 1000*l.* to purchase the central portion of the Cheddar Cliffs with the view of preserving the beauty of that natural monument of scientific interest. There is grave danger that the beauty and grandeur of the gorge may be obliterated before long if the extensive quarrying operations, which have been in progress during the last seven years, are not discontinued. Donations may be sent to the secretary of the trust at 25 Victoria Street, London, S.W.

The French Association for the Advancement of Science will meet this year at Lille on August 2–7, under the presidency of Prof. Landouzy, dean of the faculty of medicine in the University of Paris. The gold medal of the association, which was instituted last year, is to be awarded to Prof. H. Poincaré, who will deliver a lecture during the course of the meeting. In addition to minor visits to the industries of the neighbourhood, three more extended excursions have been arranged in connection with the meetings. The first of these will be to Douai, where demonstrations by the best-known aviators are to be given; the second excursion will be to the mines of Sessevalle, Aniche, and Gayant, and the third to Gand, Ypres, Bruges, and Furnes. A large number of papers will be read at the meetings, among them being communications from Prof. Poincaré, on integral equations; Prof. A. Gautier, of Paris, on the existence of water vapour in volcanic gases and the origin of thermal springs; Prof. A. Bertillon and Dr. A. Chervin, on metrical anthropology; and Dr. Lewkowitsch, on a new refractometer. The secretary of the association may be addressed at 28 rue Serpente, Paris.

An important paper on the determination of the bovine or human origin of tuberculosis in the human subject is contributed by MM. A. Calmette and C. Guérin to the current number of the *Comptes rendus* (July 19). They have found that tubercle bacilli of bovine origin can be readily cultivated on a glycerinated ox bile; tubercle bacilli from human beings or birds refuses to grow on this medium, whilst developing readily on human bile or bile from the bird respectively. Another distinction is afforded by the fact that injection of the infected matter into the mammary gland of a goat causes grave mammitis, leading to the death of the animal, if the tubercle bacilli are of bovine origin, whilst cultures of human origin produce a very mild and non-fatal infection. The method has been applied to the diagnosis of a fatal case of acute tuberculosis in a child, aged five months, which had been bottle-fed, and both of whose parents were healthy. The result of applying both the above tests was to show that the tuberculosis was of bovine origin. The authors point out the importance of being able to determine with exactness the relative frequency of tuberculous infections of bovine and human origin.

Fifty years of Darwinism forms the subject of an article contributed by Dr. W. Breitenbach to Nos. 4 and 5 of *Neue Weltanschauung.*

A list of the birds, by Dr. G. M. Allen, forms the eleventh part of the "Fauna of New England," now in course of issue in Occasional Papers of the Boston Society of Natural History.

The dragon-flies of the Mississippi valley collected during the pearl-mussel survey of that river in 1907 are catalogued by Mr. C. B. Wilson in No. 1692 of the Proceedings of the U.S. National Museum.

The fresh-water sponges in the collection of the U.S. National Museum are in course of description in the Proceedings of that institution by Dr. N. Annandale, the first instalment (No. 1690) dealing with those from the Philippines and Australia.

In vol. v., part vii., of the Annals of the South African Museum, Mr. E. Meyrick describes a number of new local Microlepidoptera, while Mr. L. Peringuey discusses new or little-known Hymenoptera of the family Mutilidæ from South Africa.

In the *Irish Naturalist* for July Dr. R. F. Scharff describes and figures a speckled otter from Lough Sheelin, recently acquired by the Dublin Museum. Although albino specimens are known, this appears to be the only speckled otter on record.

In the July number of the *Entomologist's Monthly Magazine* Mr. G. H. Verrall announces that he is attempting to re-introduce the large copper butterfly (*Chrysophanus dispar*), in the shape of its Continental phase *rutilus*, into Wicken Fen, where he has turned out a number of the larvæ.

New fishes from Japan and the Liu-kiu Islands are described by Mr. J. O. Snyder in No. 1688 of the U.S. National Museum Proceedings, while two new electric rays from the South Atlantic coast of the United States are named and described by Messrs. Bean and Weed in No. 1694 of the same publication.

We have recently had occasion to notice several papers on crinoids published by American workers, and we have now to add to the list two by Mr. A. H. Clark, published respectively as Nos. 1691 and 1693 of the U.S. National Museum Proceedings, the first of these dealing with seventeen new species belonging to various genera, while the second is devoted to four new species of Rhizocrinus.

The absence of aquatic forms among the mammals of the Miocene beds of Nebraska has led Dr. F. B. Loomis to the conclusion that these deposits are of aërial rather than lacustrine origin, and this view is confirmed by the study of the tortoises, or turtles, as the author calls them, in American fashion, from the Harrison beds, of which several new species are described by him in the July number of the *American Journal of Science.* All these are land-tortoises of the typical genus Testudo.

The thorax and the articulation of the wings of insects form the subject of an important memoir, by Mr. R. E. Snodgrass, published as No. 1687 of the U.S. National Museum Proceedings. In this paper, which amplifies conclusions reached in earlier communications, the author attempts to show the uniformity of thoracic structure prevailing throughout all orders of insects, and urges that in no case is there evidence that any of the constituent elements of any one thoracic segment have an origin apart from that particular segment. In his study of the wings he adopts the venation-nomenclature proposed by Comstock.

The determination of the ages of eels inhabiting the fresh-waters of Sweden and the deductions to be drawn therefrom form the subject of No. 46 of the *Publications de Circonstance* issued at Copenhagen by the Conseil Permanent International pour l'Exploration de la Mer. As the result of these investigations it has been found that the great majority of the five-year-old eels collect at the mouths of the rivers discharging into the Gottland and Botten lakes, where they remain in a barren condition from five to seven years, after which they make their way, as ten- to twelve-year-old fishes, *viâ* the Kattegat, the Skagerack, and the North Sea to the Atlantic for the purpose of spawning.

The mystery so long shrouding the young of the sanderling has at length been solved, and in the June number of Witherby's *British Birds* Dr. Eagle Clarke gives an excellent coloured plate of four of the long-sought chicks. This brood was discovered by Dr. Bruce on August 3, 1906, in the north-eastern portion of Prince Charles's Foreland, Spitsbergen, and the chicks and their parent are now mounted in the Royal Scottish Museum. Other chicks were subsequently obtained, in 1907 or 1908, by the Danish expedition to N.E. Greenland. In ground-colour the chicks are greyish-buff, variegated with black and deeper buff, and flecked with white, longitudinal stripes being absent. There is a collar of uniform buff on the back of the neck, and the under-parts are nearly white.

The July number of the *Journal of Economic Biology* is devoted to three papers on injurious insects and their relations. In the first of these Mr. R. S. Bagnall describes certain new British species of thrips (Thysanoptera), with notes on injurious kinds. In the second Mr. H. H. King has notes, with plate, on a boring beetle of the family Buprestidæ, referable to the genus Sphenoptera, the larvæ of which are doing considerable damage in the Sudan by attacking the stems of cotton. The third paper, by Messrs. W. E. Collinge and J. W. Shoebotham, is devoted to the description of a new genus and species (*Amerus normani*) of Collembola, based on specimens taken in a greenhouse in the garden of the Rev. Canon Norman at Berkhampstead, Herts. A second species of the group, *Neelus murinus*, typically from Cambridge, Mass., U.S.A., has likewise been taken at Berkhampstead.

The much-discussed problem of the nature of the "ciliated funnels" of the leeches is dealt with at length, and in a very interesting manner, by Rudolf Loeser in the first part of the ninety-third volume of the *Zeitschrift für wissenschaftliche Zoologie*. The author has investigated these organs in three species of Gnathobdellidæ and four of Rhynchobdellidæ. He concludes that in no case can the ciliated funnels be regarded as nephrostomes, their connection with the nephridium being entirely secondary. They are to be compared with the "ciliated urns" of Gephyreans, and, like the latter, are primarily blood-purifying organs, in the "central mass" of which phagocytosis, and also the formation of new amœbocytes, takes place. In the Glossiphonidæ the "capsules" are the phagocytic organs, connected with the body-cavity through the funnels, and giving off their products by osmosis to the nephridia. In Herpobdella (Nephelis) and in the Hirudinidæ the ciliated organs are the places where blood corpuscles develop, while the excretory products are conveyed to the nephridia through botryoidal vessels. The author has also investigated, by injection methods, the relations of the various blood-containing spaces, and his observations tend to support the conclusions of recent authors, such as Oka, on this subject. He regards it as certain that the lateral blood channels of the Gnathobdellidæ are not true vessels, but merely parts of the body cavity with muscular walls.

An illustrated pamphlet of forty-seven pages, describing how Rio de Janeiro has been freed from yellow fever, has reached us; its title is "Comment on assainit un Pays. L'Extinction de la Fièvre jaune a Rio de Janeiro," by Nerêu Rangel Pestana. The pamphlet is issued by La Mission Brésilienne d'Expansion économique, and is published in Paris by MM. Aillaud et Cie. The deaths from yellow fever in Rio de Janeiro were 1078 in 1898, whereas in 1908 there were only four. The sanitary budget has risen from one million to seventeen million francs. Sanitary works on a large scale were carried out, such as port works, canalisation of marshes, construction of new avenues and roads, with proper alignment through the old unhealthy parts, re-construction of drainage, fumigation of houses, oiling of pools, introduction of pipe water-supply, and so on, and, perhaps as important as anything, a sanitary code, rigorously enforced against obstinacy, ignorance and ridicule, the usual means employed for resisting such measures. As illustrating the activity of the sanitary staff, more than 153,000 breeding-places of mosquitoes were dealt with in 1906. In 1907 the death-rate was 19·2. The general mortality is now no greater than that of Vienna. It must be remembered that occasionally yellow fever disappears quite independently of an attack on the mosquito, but it can hardly be doubted that these splendid triumphs of tropical medicine in Rio de Janeiro, in Santos, and in other places have been entirely due to the war without mercy waged against *Stegomyia fasciata*, and that soon yellow fever will be a disease of the past.

An account of the American mistletoe, *Phoradendron flavescens*, dealing with the anatomy and some of its biological aspects as a hemiparasite, is presented by Mr. H. H. York in Bulletin No. 120 of the University of Texas. Dissemination is attributed to the agency of birds that eat the seeds. The commonest host plants are hackberry, mesquite, elm, and osage orange. The seedling first forms an attachment disc on the outside of the host, then sends in a primary haustorium which spreads in the cortex; from the haustorium sinkers are developed, which penetrate the wood along the medullary rays. The growth of the parasite is very slow, but it may attain a length of 3 feet in about twenty years. The host plants become misshapen, but are not seriously injured, unless indirectly by wood-boring insects, which first attack the mistletoe.

The expectation that many striking new plants would be discovered in the collection made by Mr. E. Ule in the State of Bahia is fully borne out by the first list of diagnoses published in Engler's *Botanische Jahrbücher* (vol. xlii., part ii.). Two xerophytic bromeliads from the mountains furnish the types of new genera, Sincoræa and Cryptanthopsis, allied to Fascicularia and Cryptanthus; new species, chiefly rock-inhabiting, are added to Encholirion, Hohenbergia, and other genera. Two root-climbing parasites are additions to the genus Struthanthus, and a new bushy Phoradendron was taken on a Cæsalpinia. Dr. H. Harms, one of the collaborators with Mr. Ule, describes a number of new species for the Leguminosæ, notably species of Calliandra, Mimosa, and Cassia. Under Euphorbiaceæ, new species of Euphorbia, Jatropha, and Manihot are recorded, and Dr. I. Urban distinguishes a new species of Loasa.

A highly interesting number of the Proceedings of the Boston Society of Natural History (vol. xxxiv., No. 7) is devoted to the flora of the islands of Margarita and Coche, lying off the mainland of Venezuela. The author, Mr. J. R. Johnston, has twice visited the islands, and has made a close study of the flora of Venezuela. The list comprises about 650 species, of which two-thirds are common to tropical America, thirty-seven are west Indian, and eighty-two are confined to South America, of which one-half are endemic. The Leguminosæ is the predominant family, and supplies many of the common plants, such as species of Cæsalpinia, Cassia, and Calliandra. The family of Cactaceæ is individually, although not specifically, well represented, and the species of Bromeliaceæ are conspicuous on account of their striking colours and appearance. The paucity of species in comparison with the number of genera is marked, the proportion being 1·6 to 1; the specifically largest genus is Croton, with eleven species; Capparis provides nine species.

MESSRS. BAUSCH AND LOMB, Thavies Inn, the makers of the high-class Minot microtomes, have issued a new catalogue of their various patterns to indicate recent improvements. Additional features are noted for the well-known Minot automatic rotary microtome; the knife can be moved to and fro, from side to side, or can be rotated, owing to its insertion in a special knife block; split nuts with releasing lever allow of rapid adjustment, and the feed wheel is provided with a guard. The new model Minot automatic precision microtome, a powerful and rigid type designed for heavy work, although equally efficient for light cutting, has been re-modelled; the gearing between fly-wheel and crank produces an exceptionally smooth feed. A freezing microtome for fixing on the nozzle of a cylinder containing carbon dioxide is a new instrument, intended to provide surgeons with an apparatus for preparing sections that can be examined on the spot.

WE have received the *Studi e ricerche di chimica agraria* for the years 1906–8 from the agricultural chemistry laboratory of the University of Pisa. The volume includes a paper by the director, Prof. Italo Giglioli, on the stimulus to plant growth occasioned by small quantities of manganese salts, &c., and studies by A. Quartaroli on certain properties of phosphates of agricultural interest.

A SUBJECT of great practical importance and scientific interest is discussed in a recent issue of the *Cairo Scientific Journal* (No. 29). For the past twelve years there has been a steady fall in the average yield of Egyptian cotton per feddan, and the loss now amounts to five pounds per feddan per annum at current prices. The late Mr. Gibson, in 1906, attributed the loss to the rise in level of the subsoil water, which is a direct consequence of the canal system now being introduced. One case was noted on the State Domains where a high-level canal raised the water-table of the adjoining land by seepage from a depth of 3 metres to $1\frac{1}{2}$ metres, and the yield of cotton fell off considerably. The remedy appears to lie in a great extension of the drainage system.

ATTENTION has recently been directed in the pages of the *North British Agriculturalist* to the use of soya beans as cattle food. The bean is well known in America and in Asia, but has hitherto not been used in the British Isles. After removing some of the oil, the residue is made into oil-cake containing about 7 per cent. of oil and 40 per cent. of "albuminoids" (*i.e.* 6·4 per cent. of nitrogen, albuminoid being defined as nitrogen × 6·25), and is at present cheaper than other foods of like composition. During the spring of this year about 50,000 tons of beans have been imported, it is understood, from Manchuria, and at present prices the cake promises to form a very useful addition to the list of cattle foods.

MR. E. S. THOMAS contributes to the May number of the Journal of the Cairo Scientific Society a useful article summarising the facts of the early mining industries of Egypt. The gold of the desert has been worked from a very early period, an ingot having been found buried with a corpse of the first dynasty, while gold-handled flint knives and stone jars, the mouths of which are ornamented with gold, testify to the artistic skill of the people of the same period. The earliest direct references to expeditions in search of gold date from the twelfth dynasty. Western Asia drew large supplies of gold from Egypt during the period represented by the Tel-el-Amarna letters, and the records of tribute paid in the precious metal by subject races show that immense treasures were at the disposal of the Pharaohs. Silver was also received in large quantities from Crete, Attica, and probably from Cilicia. The first systematic scheme for gold-mining under Egyptian management dates from the nineteenth dynasty, and it continued to be carried on until it became impossible to protect the workers from Bedouin marauders. Large workings in the quartz reefs at Um Rus and Haimur show the vast extent of these operations. Altogether about ninety old workings in search of gold have up to the present been identified in the eastern Egyptian desert, and twenty more known to exist remain to be traced. Exclusive of workings in the Sudan proper, all these lie between lat. 22° and 28°, that is, between Minia and the Sudan border, and east of long. 33°. Many others will probably be discovered in the more remote desert area.

THE Director-General of Indian Observatories has issued a memorandum (dated June 8) on the meteorological conditions prevailing before the south-west monsoon of 1909. Past experience shows that the most important indications regarding monsoon rainfall are afforded by the pressure conditions in South America and the Indian Ocean, and these for the past two months have been decidedly favourable, being above the normal in the former and below in the latter regions. Late and excessive snowfall is unfavourable to the monsoon, especially in north-west India, but since April none of any significance has occurred. From these and other data referred to in the memorandum Dr. Walker draws the following useful inferences:—(*a*) the general conditions are such as have, in a decided majority of years, been followed by a total monsoon rainfall of more than the average amount; (*b*) the indications regarding the geographical distribution are by no means well marked, but suggest that the outlook for the plains of north-west India during the earlier part of the season is somewhat less favourable than that for the field of the Bay current.

ALTHOUGH much work has been done on the relation between the magnetic qualities of steels and their composition, we are still far from being in a position to state what it is exactly which confers on a steel the property of magnetic permanence. The most recent work in this field is that of Mr. T. Swinden, described in the June number of the Journal of the Institution of Electrical Engineers. Mr. Swinden, after examining a number of steels containing 3 per cent. tungsten both magnetically and microscopically, comes to the conclusion that magnetic permanence depends more on the constitution than on the state of crystallisation of the steel.

THE July number of the *Journal de Physique* contains Dr. Hale's address to the Société française de Physique on the magnetic fields of sun-spots. By means of a very careful and detailed comparison of the intensities and polarisations of the doublets and triplets obtained in the Zeeman experiment in the laboratory with the corresponding effects obtained in the spectra of sun-spots by the help of the Snow telescope at Mount Wilson, California, at an altitude of 1700 metres, Dr. Hale shows that sun-spots consist of columns of ionised vapours circulating in opposite directions in the two solar hemispheres, the axis of rotation being, in general, inclined at a considerable angle to the normal to the solar surface. There appears to be evidence of connection beneath the solar surface of the vortices observed north of the solar equator with those south of that line. The whole of the observations afford strong support to the theory that sun-spots are the normal products of the convection currents which occur in the sun.

THE *Bulletin international* for 1907 of the Bohemian society, L'Académie des Sciences de l'Empereur François Joseph I., was published in 1908, and a copy has just reached us. Drs. B. Kučera and B. Mašek write in English on the radiation of radio-tellurium, and continue a description of their researches, which have led them to the following conclusions among others. The absorption of the α rays from radio-tellurium in metals and gases investigated by Bragg's method is manifested similarly as with α rays of radium and its first transformation products by lowering of the ionisation curve. The atomic stopping power is very nearly proportional to the square root of the atomic weight, and possesses almost the same values as Bragg found for radium C. It is probable, though, that the proportionality constant increases slightly with atomic weight. For the same gas (air) the ranges corresponding to the α rays of the same velocity are inversely proportional to the pressure (density) of the gas. The ranges for the rays of the same velocity in different gases (air, oxygen, carbon dioxide) are inversely proportional to the mean square roots of their atomic weights. The existence of a secondary radiation of α rays which ionises air at ordinary pressure cannot be taken as ascertained.

FROM the account, published in *Engineering* for July 16, of the trials conducted recently by the Scottish Automobile Club, it is evident that electric ignition can be made perfectly trustworthy if well carried out. Fifty-eight cars were fitted with high-tension magnets, four used accumulators only, and three low-tension magnets. Only one car fitted with high-tension magnets had any stops at all, except for cleaning or changing sparking-plugs, a matter which often depends more on the lubrication than on the ignition apparatus. Of the other systems, there was only one small stoppage in any of the cars having accumulator ignition, and two considerable stops in cars fitted with low-tension magnets. The Albion car, fitted with low-tension magnets, went through without an ignition stop, as it has done on previous occasions, and it may be taken for granted that the low-tension system, like the high-tension, can give completely satisfactory results.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN AUGUST:—

Aug. 3. 23h. Mercury in superior conjunction with the Sun.
5. 4h. 15m. Mars in conjunction with the Moon (Mars 0° 13′ S.).
,, 23h. Saturn stationary.
6. 9h. 45m. Saturn in conjunction with the Moon (Saturn 1° 32′ N.).
10-12. Perseid maximum.
11. 19h. 2m. Venus in conjunction with Jupiter (Venus 0° 12′ N.).
13. 8h. Mars in perihelion.
17. 11h. 36m. Jupiter in conjunction with the Moon (Jupiter 4° 17′ S.).
18. 0h. 13m. Venus in conjunction with the Moon (Venus 4° 15′ S.).
23. 3h. Mars stationary.

A LARGE GROUP OF SUN-SPOTS.—During the past week a group of sun-spots, of abnormal size for this period of the sun-spot cycle, has been visible on the solar disc—even to the naked eye. This large group has developed from a few scattered, small nuclei which came round the eastern limb on July 18, and now includes a leading spot of large dimensions and two separate trails of smaller spots. In addition to the large group there was another, preceding, group of medium size and two smaller ones to be seen on the disc on Saturday last. This outburst still further emphasises the extension, in time, of the sun-spot maximum of 1905–6.

PHYSICAL INTERPRETATION OF LUNAR FEATURES.—In presenting the eleventh fascicle of his photographic map of the moon, M. Puiseux placed before the Paris Academy of Sciences some ideas as to the nature and history of the lunar landscape, suggested by the study of the photographs. From the absence of any appearance of division into parallels of the dark and light areas, M. Puiseux argues that the moon certainly has not polar regions of ice and snow such as those seen on the earth and Mars. Then, considering the probable presence or absence of water, it follows that the moon's surface must either be glaciated completely or shows no trace of water areas.

Against the former suggestion, which, it will be remembered, is the one upheld by Herr Fauth, the noted selenologist, there is the relatively low albedo, comparable to that of the terrestrial volcanic and siliceous rocks, but certainly much less than that of snow or ice, and there is also the fact that extremely bright and extremely dark areas are mixed up indiscriminately in small areas. M. Puiseux promises a further communication dealing with the subject of the form and distribution of the dark lunar spots seen on the same photographs (*Comptes rendus*, No. 26).

DOUBLE-STAR MEASURES.—No. 158 of the Lick Observatory Bulletins contains the fourteenth list of double stars discovered and measured by Prof. R. G. Aitken with the 36-inch refractor of the Lick Observatory. All the pairs measured are separated by distances of less than 5″, and in eighty-two cases less than 2″. The present publication contains the measures of 100 double stars, and brings the total number discovered by Prof. Aitken to 2000, 74 per cent. of which are separated by distances of less than 2″.

A discussion of the available data of 7500 known pairs leads Prof. Aitken to the conclusion that, among the stars down to the ninth magnitude, the number of doubles having separations of less than 2″ is greater than those separated by distances exceeding 2″, but less than 5″, in the proportion of 3/1. Hence follows a strong confirmation of the probability that practically all the closer doubles are in reality binary systems, not merely optical pairs.

No. 4338 of the *Astronomische Nachrichten* contains the measures of a number of double stars made by Mr. E. D. Roe, jun., with the 6½-inch refractor of his observatory at Syracuse.

MAXIMUM OF MIRA IN 1908.—Observations of the brightness of *o* Ceti were made by M. Luizet, at St. Genis-Laval, between September 18 and November 28, 1908, and show that the maximum brightness, 3·6 mag., occurred on October 12; this agrees within one day with the epoch given in the *Annuaire du Bureau des Longitudes* (*Astronomische Nachrichten*, No. 4340, p. 332, July 16).

OBSERVATIONS OF JUPITER'S FIFTH SATELLITE.—Although finding it a difficult object to measure, Prof. Barnard succeeded in obtaining measures of Jupiter's fifth satellite during 1908 and 1909 sufficient to determine the times of, and distances at, elongation, and to give a new value of the satellite's period. Western elongations took place at 1909 February 21 14h. 25·4m. (central standard time) and 1909 March 14 12h. 29·6m., and the apparent distances were 56·47″ and 56·00″ respectively; taking $\Delta = 5{\cdot}20$, the latter become 48·08″ and 47·93″. Combining these values with those determined in 1892, the period becomes 0·49817906d., which agrees within one-thousandth of a second of time with that previously determined. It therefore appears that the period is now quite accurately known, and has suffered no sensible change during the seventeen years that the satellite has been under observation (*Astronomische Nachrichten*, No. 4339).

THE FEEDING HABITS OF MŒRITHERIUM AND PALÆOMASTODON.

THROUGH the discoveries in the Oligocene[1] of the Fayûm Mœritherium and Palæomastodon have become famous as two of the earliest, and more or less direct, stages in the ancestry of the elephants. In restorations by various authors each of these animals has been provided with a proboscis of less or greater length, as would befit a more or less remote ancestor of an elephant. As first announced by Dr. C. W. Andrews, to whom we are chiefly indebted for our present knowledge, Mœritherium does anticipate the Palæomastodon type in the enlargement of the second pair of upper and lower incisors and in the general pattern of the grinding teeth. Since the wish is always father to the thought, and nothing is more to be desired than a primitive progenitor of the Proboscidea, it was altogether natural to place Mœritherium in or near the line of ancestry of the elephant, and in such ancestry, as a member of the Proboscidea, the animal has gone into general literature.

A first more cautious note was sounded by Dr. Andrews in his memoir of 1906,[2] p. xvii, in which he observes:—"As already mentioned, Mœritherium was probably an amphibious, shore, or swamp living animal, and it was no doubt owing to the continuation of the conditions favourable to its mode of life that it persisted into the Upper Eocene period. In the meantime, however, either from this or some closely allied type, there had arisen another animal more adapted to terrestrial life and showing a great advance in the direction of the typical Proboscidea: to this creature the name Palæomastodon has been given." Elsewhere (p. xxi) Dr. Andrews notes that Mœritherium favours the view, first put forward by de Blainville, of an original relationship between the Proboscidea and Sirenia. Later on in the same work (p. 119) the same author, in commenting on the similarity between the pelvis of Mœritherium and that of the Eocene sirenian Eotherium, observes:—"Then it may fairly be suggested that Mœritherium and Eotherium, both occurring in the same region (one the most primitive Proboscidean, the other occupying the same position with regard to the Sirenia), are, in fact, closely related, and had a common ancestor in early Tertiary times, probably in the Lower Eocene." On p. 105 we find a comment on the remarkable likeness between the brains of Mœritherium and the Sirenia.

Since these suggestive comments were written other materials have been secured, including a nearly perfect skull and jaws of Palæomastodon by the British Museum and a skull of Palæomastodon and two partly preserved skulls of Mœritherium by the American Museum.

The question of habits and of affinity seems so important and interesting that the writer has taken it up afresh with these additional materials. The inquiry was suggested by the general resemblance which the skull of Mœritherium bears to that of a Sirenian as seen from above and in palatal view. The method of comparison adopted is that of making life-size models of the skulls of Mœritherium and Palæomastodon, then placing the sense organs and the mouth parts in position, guided solely by comparison with existing mammals showing more or less analogous modifications and by the actual condition of the hard parts themselves. This work was done by Mr. E. Christman under the writer's direction.[1] Palæomastodon itself in all probability had not developed a proboscis, although there is no question as to its being in the direct line of proboscidean ancestry. Mœritherium not only had no proboscis, but was totally different from Palæomastodon both in its appearance and habits, and only very remotely related to this animal, if at all. The study shows, further, that Mœritherium is closer to the Sirenians and less close to the Proboscidea than has hitherto been supposed.

A profound difference between these animals is brought out in comparing the top and side views of the skull, when it is seen that, whereas the eyes of Palæomastodon are in the typical mammalian position above the first permanent grinder, those of Mœritherium are very far forward, well raised in the front part of the head, and of very diminutive size, as shown by the shallowness of the sockets. All these are also characters of the Sirenian head. As indicated by the auditory meatus, the ears are relatively in a more elevated position than in Palæomastodon. Both these peculiarities are adaptations to aquatic life to protect the sense organs and bring them near the surface of the water in swimming, so that they will emerge first and disappear last.

FIG. 1.—Side view of the head of Palæomastodon modelled by Mr. E. Christman under direction of the author.

The cutting teeth and mouth parts of Mœritherium are also opposed in an entirely different manner from those of Palæomastodon, so that it may be said safely that there was not the most remote resemblance either between the mouth parts or the feeding habits of these two animals. In the former the nasal bones do not greatly recede, and there was consequently little or no free retractile power of the upper lip, which is always the rudimentary condition in the evolution of a proboscis, as witnessed in the living tapirs. Comparison with Hyrax, the beaver, and other animals with an enlarged pair of front teeth tends to show that the upper and lower lips were heavy and fleshy, somewhat similar in form and function, that is, in prehensile power, and that the blunt tusks may have been covered when the mouth was closed, somewhat as in the hippopotami. These tusks were feeding rather than fighting weapons, probably because Mœritherium was protected from attack by its aquatic habitat. The conclusion is that Mœritherium was a confirmed and continual river-living animal, feeding mainly under water and on the banks, more specialised for aquatic life than the hippo-

[1] These Palæomastodon beds were at first regarded as Upper Eocene, but closer comparison with those of Europe has shown that they should be rather considered as Lower Oligocene.

[2] "A Descriptive Catalogue of the Tertiary Vertebrata of the Fayûm, Egypt." (London, 1906.)

[1] The models have been reproduced and copies presented to the British Museum. The writer is indebted to Mr. W. K. Gregory for many valuable suggestions.

potami, as indicated by its feeble pelvis, but less specialised than the Sirenians. It would not be far from the truth to say, from our present knowledge of the animal, that Mœritherium is an offshoot of the Proboscideo-Sirenian stock, with *slightly* nearer kinship to the elephants than to the Sirenians.

The distinctive peculiarities of Palæomastodon are that its eyes are in the position typical among mammals, that is, above the first true grinders. The reason that they appear to be so far back is that the lower jaw is extended unusually far forward. The upper jaws, on the other hand, recede, practically terminating at the sides in the very sharp, laterally compressed tusks, which at this stage were chiefly developed as fighting or defensive weapons, while only indirectly of value as feeding organs. It is noteworthy that when the upper and lower lips are restored in such a manner as to enable the animal to close the mouth, the upper tusks are so largely covered that they are not especially prominent.

In contrast with Mœritherium, the nasal bones and openings deeply recede; thus a very wide space is left to be filled by a large retractile upper lip, which could undoubtedly be raised or lowered. The question now arises, How far had this lip begun to transform into a proboscis? Was there a free projecting proboscis as represented in several previous restorations? A negative answer appears to be furnished by the structure and mode of wear of the lower incisors. Together these form a broad, protrusive, spoon-shaped feeding organ, which is invariably greatly worn on the upper surface and somewhat less at the ends. This worn upper surface seems to prove that in the prehension of food the edge of the upper lip was constantly pressed downward against these teeth, thus, with the aid of fine particles of grit and sand, which were occasionally taken in, causing wear. In brief, the food appears to have been seized between the upper lip and the spoon-shaped lower teeth. Palæomastodon was a browser, and this lip could be turned up and retracted effectively to pull down smaller branches, but there is no reason to suppose that it had the free curling and independent prehensile power which characterises a true proboscis. If we critically consider the theory of the animal possessing a proboscis of considerable length, we find it rests upon the idea of kinship with the elephant rather than upon careful study of the mouth parts themselves.

If, now, we consider the elephant, we find that one of its many unique features is entire loss of the prehensile power of the anterior portion of the lower jaws, these parts having receded and disappeared. The elephant thus presents the widest possible contrast with Palæomastodon, in which the most prominent part of the face is the projecting lower teeth and jaw. It is obvious that the development of a proboscis took place step by step with the recession and loss of prehensile power in the lower jaw. If Palæomastodon had possessed an independent prehensile proboscis extending beyond the line of the mouth for the seizing of food, we cannot assign any function to these large and much worn lower incisors. A more probable view, therefore, seems to be that here presented in the model of the head and mouth parts, which were made directly upon a model of the skull itself. In the stages between Palæomastodon and the *M.* (*Trilophodon*) *angustidens*, the Lower Miocene elephant of Europe, the lower incisors have begun to transform into tusks to be employed in uprooting plants and smaller trees, just as the upper tusks are used by elephants now. With this change their prehensile function was gradually abandoned and assumed by the upper lip, which thus began its slow evolution into a freely projecting and prehensile proboscis.

All restorations contain a large element of conjecture; we shall certainly never know how these most interesting animals of the Lower Oligocene rivers of the Fayûm actually appeared, but the first rule of restoration is not to be too much influenced by kinship, but to adhere to the evidence afforded by the hard parts themselves. This rule has evidently been broken by the writer in attributing a small elephantoid ear to Palæomastodon. Unfortunately, there is no means of even conjecturing the shape of the ear of this animal, except to exclude the small aquatic type of ear which may be attributed to Mœritherium.

H. F. OSBORN.

FIG. 2.—Side view of the head of Mœritherium with the eye and ear in position. The form and position of the nostrils is somewhat conjectural. Modelled by Mr. E. Christman under the direction of the writer.

THE HEALTH CONGRESS AT LEEDS.

THE Royal Sanitary Institute and the Royal Institute of Public Health combined this year, for the first time, to hold under the auspices of the Corporation and University of Leeds a joint session.

No more fitting person than Colonel T. W. Harding could have been selected to fill the presidential chair, who fills at the present moment the important office of chairman of the Royal Commission on Sewage Disposal. It is difficult within the space of a few paragraphs to present a comprehensive review of the varied topics which came up for discussion in the different sections, and embraced anything from the treatment of tuberculosis to that of trade effluents, and from the ventilation of cowsheds to the hygiene of the mouth.

Although many of the views expressed, especially in the recently formed child-study section, were of a tentative nature and the result of incomplete experience or of individual opinion, a striking feature of the congress was the earnestness displayed by those participating in it, a remarkable fact when one considers how much of the work connected with sanitary matters is self-imposed, largely unofficial, and purely disinterested.

It seemed appropriate that the president, an old Leeds citizen, should have referred in his opening remarks to the sanitary improvements of the town, which had nearly halved the death-rate in fifty years; but the greater part of his address was devoted to a general survey of the growth of public interest in and control of sanitation, and the present-day problems of urban life. Among the present-day problems he referred to the continued high mortality from phthisis, pneumonia, and diphtheria, and the heavy death-rate among children. Although the president pointed to the great advances which have been made in sanitary reform in nearly every direction, he raised the important question as to whether the present system of elementary education is wholly good. "We are spending," he said, "large sums in elementary education; would it not be well to pause awhile and see if we are moving on right lines? We are cramming young minds in frail and half-fed bodies with all the information we can get into them, and most of it will soon be forgotten. By all means let us teach what we can, but without impairing physical development, which is much the most important work to be seen to."

In Mr. J. T. Quinton's (Liverpool) address to the conference of sanitary inspectors we were introduced to the inner working of the local sanitary machine and to the difficulties encountered by sanitary inspectors by the self-interest of those in the council whom they serve. He further touched on the subject of alcoholism, welcomed the introduction of systematic instruction in public elementary schools on its effects, and deprecated the view advanced by some that alcohol constitutes an article of food. He demanded further State interference in the matter of alcoholism, and the repeal of the exemption of patent and proprietary goods from the Food and Drugs Act.

One of the most thoughtful and comprehensive of the sectional addresses was that delivered by Dr. Newsholme (principal medical officer of the Local Government Board) to the preventive medicine section on some conditions of social efficiency in relation to local public administration, which can only be appreciated by a full perusal. Dr. Newsholme began by showing how closely interrelated are the social and sanitary problems, and how a more accurate knowledge and wider outlook will enable social problems to be seen more nearly in their correct perspective. By way of illustration he pointed out that "if the avoidable loss of life and health from communicable diseases were realised by the members of the sanitary authority, they would be less likely to build extravagant town halls while the water supply of the town is impure, or to provide municipal Turkish baths while backyards and streets remain unpaved. . . . And this more accurate knowledge and wider outlook means the abandonment of the old hand-to-mouth and empirical method of dealing with social evils. The conception of poverty and destitution as an element when it is, in fact, a complex compound will disappear, and with it will disappear administration which supplies doles to relieve the symptoms of destitution, without making efficient efforts to investigate its varying causation and to initiate preventive measures against its recurrence." "We have to realise the close interdependence of social evils, which often form a vicious circle where evil effects become, in their turn, sources of evil." As sickness is one of the main causes of sickness, poverty is one of the most potent causes of poverty. The growing tendency is to stop disease, whether communicable or not, at its source, the prompt and early treatment being one of the chief means of securing social efficiency, and the better organisation for the treatment of the sick, from whatever disease, must be regarded as a chief object of the preventive medicine of the future. The monetary value of lives lost, including cost of sickness, through phthisis, enteric fever, and other diseases, is so large that measures of prevention may be regarded as the best possible investment for the community. In the latter part of this suggestive address Dr. Newsholme pointed out the insecurity of tenure of medical officers, who are re-elected for periods of one to five years, and, unlike district medical officers, relieving officers, and vaccination officers, can be removed without the consent of the Local Government Board. He further referred to the overlapping and waste produced by the great variety of authorities dealing with closely related conditions.

In the presidential address to the engineering and architectural section, by Mr. G. F. Bowman (Leeds), reference was made to the question of back-to-back houses, and a strong case was made out for the erection of buildings of the modern type already existing in Leeds; but whether in this connection the working classes "should be the best judges of what is best for themselves" is a dictum open to grave criticism.

Dr. Newman (principal medical officer of the Board of Education) chose for the subject of his address in the child-study section child mortality. He began by pointing out that, of the annual half-million deaths in England and Wales, one-third occur under the age of fifteen years, and of this third 85 per cent. are under five years of age.

Whereas the death-rate at all ages above one year shows a steady decline, there is no such indication below that period. The first two years of life "form a veritable fire through which we pass the vast majority of the children of the nation, losing in the process approximately 150,000 of them every year, and marking many of the survivors with the signs of the flame." The three primary causes, then, are the physique of the mother, infant mismanagement, and exposure. "It is idle," said Dr. Newman, "to patch up children at school age if we first make them all pass under damaging and devitalising conditions at the beginning of their lives."

In the industrial hygiene section Dr. Whitelegge (London), as president, gave an address on the relation of health to industry. He began by referring to the improvements in industrial conditions brought about by the combined action of employers and employed, and to the responsibilities thrown upon local authorities in respect to initial construction of buildings. He pointed out the difficulties which attend an investigation into the causes affecting health in certain complex trade processes unless the different operations are separately grouped, and he further emphasised the importance of keeping safety appliances in an efficient state. In this connection he mentioned the importance of permanent local exhibitions of safety appliances, such as exist abroad, especially in textile centres, in metal and mining localities, and in the Potteries. Thus, in the removal of dust, as in metal grinding, there is no source of information, and unless expert advice is taken costly mistakes may result. There are standards of ventilation, of humidity, and of soluble lead in which employers and employed should have opportunities for instruction. Lead poisoning from glazing has been reduced by three-quarters in the last twelve years, but phthisis, or "potters' rot," from dust inhalation is still prevalent. Clearer definitions as to factory lighting and temperature in reference to humidity are required, and further information should be obtained in reference to fatigue in different arduous employments. The welfare of operatives in certain industries is affected by demands on the part of consumers. A large section of the public had grown accustomed to phosphorus matches, and it was not until the match manufacturers agreed unanimously to the prohibition of phosphorus, coupled with prohibition of import, that the Government was able to put an end to this needlessly dangerous branch of industry.

In his presidential address to veterinary surgeons, Mr. H. G. Bowes (Leeds) welcomed the recognition accorded by the President of the Local Government Board to the necessity of proper veterinary inspection of dairy cattle, though, he continued, "why the farce of the M.O.H. inspecting the cows, accompanied by a veterinary surgeon, should be kept up I don't know," nor why the inspection of cowsheds and byres should not be done by the same inspector. He further advocated the appointment of a veterinary adviser to the Local Government Board, whose advice in dealing with bovine tuberculosis would be invaluable. He emphasised especially the necessity for more rigorous treatment of this disease, which, it is unanimously agreed, is transmissible to, and a recognised cause of, disease in human beings. In view of the wide-spread nature of the disease at present, the slaughter of all tainted cattle would be impracticable, but a gradual weeding out of the worst cases as centres of infection might be initiated. A most important step has been taken in the Tuberculosis Order which comes into force on January 1, 1910, which requires compulsory notification and slaughter of all cattle obviously affected. He claimed further attention to the condition of cowsheds throughout the country, as exercising an important effect in diminishing the disease. In the conclusion of his address Mr. Bower referred to the abuse of tuberculin by the indiscriminate sale.

The treatment of sewage was among the subjects which came up for discussion at a joint meeting of the engineering, bacteriology, and chemistry sections, when interesting papers were contributed by Messrs. E. J. Silcock,

A. J. Martin, J. T. Thompson, and G. A. Hart. Mr. Silcock dealt with a new method now at work at Rothwell, in which, after removing grit, the sewage is pumped on to a revolving fine-mesh screen, then taken to deep percolating bacteria beds, then through sand filters, and discharged.

In the section of preventive medicine an important paper was read by Dr. Robertson (Birmingham) initiating a discussion on tuberculosis. He pointed out that more human suffering is due to tuberculosis than to any disease, that it was produced by infection derived from cases of phthisis, from milk, and possibly from meat, and developed slowly after the germ is taken into the system. He emphasised the importance of milk and meat in carrying infection, and pointed out that more than 30 per cent. of dairy herds are infected. In this connection more attention should be given to the ventilation of cowsheds. Dr. Woodcock (Leeds) followed with a paper on the physique of the phthisical as a means of diagnosis, whilst Dr. Trevelyan (Leeds) discussed the methods of preventing infection from those already suffering from the disease. An interesting discussion followed, and a resolution was passed "that the Health Congress wishes to direct the attention of agricultural societies to the great assistance which they might render to the community by making it one of their conditions in offering prizes for dairy cattle that the animals should be free from tuberculosis."

Subsequently papers were read on the protection of the food supply. Imported and canned foods were dealt with by Dr. H. Williams (London) and Dr. W. F. Dearden (Manchester), whilst Dr. Savage (Colchester) discussed the administrative measures for examining food supply in general, Mr. W. G. Barnes (London) advocated measures for eradicating tuberculosis from the milk supply, and Dr. Stedman explained methods of administering the "Dairies' Order." In the bacteriology section papers were contributed by Mr. J. Johnstone; on the significance of leucocytes in milk as indicating a need for detailed examination, by Dr. Savage (Colchester); on the catalase of milk as an indicator of disease, by C. Revis (London); and on the growth of the bacillus tuberculosis, by Dr. Moore and R. S. Williams (Liverpool). In the latter the important observation was made that the bacillus will only grow between certain definite limits of oxygen pressure, being equally stopped by absence of oxygen or by more than 60 per cent. To stop and kill the organisms completely about 70 per cent. of oxygen must be present, which does not interfere with the majority of other organisms tested. In the same section a joint paper was read by Prof. Grünbaum and Dr. M. Coplans (Leeds) on the selective action of preservatives, in which they discuss the effect of different preservatives on the growth of organisms. Papers were also contributed by Mr. J. C. G. Ledingham (Aberdeen), on the bacteriology of summer diarrhœa; by Dr. S. G. Moore (Huddersfield), on the advantages derived from its notification to the authorities; and by Dr. Buchan (St. Helens), on administrative measures for its reduction.

An interesting series of papers was read in the engineering and architectural section on water supply and treatment of trade water, and in the section on industrial hygiene lead poisoning, its pathology and prevention, abstracts of which, from want of space, cannot be given.

Sir Charles Cameron gave an attractive popular lecture on underground and overground air.

During the congress the University of Leeds took advantage of the occasion to confer degrees *honoris causa* on the president of the congress, Colonel T. W. Harding, and on Sir James Crichton-Browne, F.R.S., and Major Ronald Ross, F.R.S.

LANCASHIRE FISHERY INVESTIGATIONS.[1]

THE report of the Lancashire Sea-fisheries Laboratory at Liverpool for 1908 gives evidence of sustained investigation into problems that demand several years' work for their solution. The articles are in almost every case continuations of those contributed to the report of 1907, and it is therefore unnecessary in a brief review to do more than summarise the findings of the several workers on the fishery questions with which they have been so long occupied.

Prof. Herdman gives a further instalment of results obtained by tow-netting with modern nets in the Irish Sea. This method of obtaining the floating or drifting organisms is now becoming more delicate, and the catching power of the nets is more accurately known than was formerly the case. The object in view being an exact determination of the distribution and fluctuation of the "plankton," no trouble is too great and no determinations are too laborious to deter the director of the fisheries work. Accordingly, this paper contains an immense amount of data both as to methods and results with regard to the seasonal and local variations in this fauna, and also with reference to the influence of conditions upon its abundance and behaviour. The statistical work involved in such a report is very great, and the credit of these laborious tables is due to the zeal of Mr. Andrew Scott. On the whole, the results of 1908 show the correctness of the conclusions arrived at in the previous contribution to this "intensive study" of plankton round the Isle of Man, but they also demonstrate some seasonal divergences which are in all probability of considerable importance to fishermen, as affecting the arrival of spring or autumn migrants. The only criticism that we feel justified in making upon such a heavy and valuable undertaking is the absence of any analysis of the light-factors that influence plankton, but we hesitate to press this criticism, as Prof. Herdman has not published the whole of his results.

Of the more striking fishery papers, attention may be directed to Mr. Johnstone's important experiments on quarantining mussels. Mr. Johnstone has determined the degree of bacterial pollution in a number of shell-fish taken from Welsh and Lancashire bays, and finds that the contamination, though, as a rule, not serious, is probably due to general contamination of the water or sea-bed in these districts. In some cases, however, the pollution is more serious, and, by transferring these heavily infected mussels to cleaner open water, Mr. Johnstone finds that in four days' quarantine the maximum amount of sterilisation is effected. The bare fact, of course, has long been known, for oysters infected by typhoid, for instance, but this report is a continuation of that more extended investigation which is needed in order to enable fishermen themselves to increase a healthy supply of shell-fish near the larger towns. Mr. Johnstone also contributes papers on the temperatures of the Irish Sea, on the growth and migration of plaice, on parasitic growths in flat fish, and a joint paper with Capt. Weigall on the outfit of the fine new boat, *James Fletcher*, which the Lancashire Sea-fisheries Committee commissioned recently. In addition to these papers, the wider aspects of biological investigations are not overlooked, and we are glad to see that Dr. Bassett has continued his hydrographical study of the Irish Sea by a further analysis of its salinities. It is to be hoped that aid will be forthcoming to provide the Lancashire committee with a member of staff specially devoted to such work.

Lastly, reference must be made to an excellent *résumé* of the method for finding the coefficient of plankton-nets (in regard to catching power) by Mr. Dakin. This gentleman's elaborate study of Pecten, forming an appendix to this report, has been noticed already in these columns (May 6, p. 273), and we may merely, therefore, refer to it as an example of the good results obtained by bringing different methods to bear upon the study of an organism.

[1] Report for 1908 on the Lancashire Sea-fisheries Laboratory at the University of Liverpool and the Sea-fish Hatchery at Piel, No. xvii. Pp. 366+9 plates. Drawn up by Prof. Herdman, F.R.S., assisted by Andrew Scott and J. Johnstone. (Liverpool, 1909.)

ORIGIN AND RITES OF GYPSIES.

IN the *Journal of the Gypsy-lore Society* for April Miss D. E. Yates publishes a translation of a paper by Prof. R. Pischel, originally published in the *Deutsche Rundschau* for 1883, on the home of the Gypsies. Reviewing various references to the origin of this race, he comes to the conclusion, on the evidence of philology, that the Gypsy dialects are closely connected with those of Dardistan, and he accordingly fixes this region as the original Gypsy home. This view is based largely on materials collected by Drew, Biddulph, and Leitner. It is unfortunate that this opportunity was not taken to utilise the results of Dr. Grierson's linguistic survey, which now supplies ample glossaries and grammars by which the problem may be solved. Pischel's view is accepted by Dr. Grierson in his chapter on the languages of India in the first volume of the Report on the Census of India for 1901. He regards the Indian origin of the Gypsies as fully established, and while it is doubtful from which Indian tribe they really sprung, he believes that they spoke one of the non-Sanskritic Indo-Aryan tongues, which are by him grouped under the heads of Shína-Khowár, Káfir, and Kalasha-Pashai. The work of Sir G. Robertson on the Kafirs of the Hindu-Kush also supplies materials which might have been utilised in re-editing Prof. Pischel's paper.

Mr. E. O. Winstedt contributes to the same number of the journal an interesting paper on the Gypsy rites connected with birth, marriage, and death. It is a good collection of material, much of which has been gathered from comparatively obscure sources, but it is to be regretted that before publication it did not pass through the hands of a competent student of comparative ethnography. Among birth rites, he notes the customs of laying the child on the ground, the passing of the mother and baby through fire into which, among some of the subtribes, drops of the father's blood are allowed to fall. In connection with marriage, we have references to the customs of exchanging wives; the use of the broomstick and tongs as marriage symbols; the lifting of the bride over the doorstep; the exchanging of vows over a dead horse or hen; the blood covenant; the dance upon layers of sweetmeats; the custom of placing lighted candles, eggs, and apples in a stream; a custom, probably misinterpreted, of so-called marriage by capture; methods of divorce; and the curious custom, which has Indian parallels, of the father-in-law cohabiting with his daughter-in-law during the youth of his son. Among death rites, he mentions that of burning the clothing and other property of the dead man at the time of his burial, a custom of which various interpretations are suggested; interment without a coffin; disinterment of the dead; and the pouring of liquor on the grave. The variance of custom among the different Gypsy groups points to the conclusion that they have assimilated much from the races with whom they successively came into contact. It is now probably too late to fix the exact provenience of customs such as are described in this paper. If this could be done it might furnish valuable material for the investigation of the origin of this mysterious people.

CLIMATOLOGICAL REPORTS.

THE climate of the island of Norderney (lat. 53° 43′ N.) forms the subject of part iii., vol. xxxi., of *Aus dem Archiv der deutschen Seewarte*. The observations were very carefully made several times a day for nearly ten years (between 1880 and 1890) by the late Mr. O. J. Ommen; the instruments and exposure were not all that could be desired, but Dr. R. Assmann, of Lindenberg, has taken great pains to correct these defects, as regards temperature, by comparisons with hourly observations at Hamburg, Bremen, &c., the result being that the paper becomes a very useful contribution to the meteorology of the coast of East Friesland. The moderating influence of the sea upon the air temperature is plainly shown; the autumn and winter months have higher, and the summer months lower, temperatures than the Continental stations; the yearly variation at Norderney is only 17·1° C., while at Berlin it is 19·2°. It is interesting to note that the equinoctial gales maintain their old reputation at Norderney, the stormiest months being March and October.

The year-book of the Austrian Meteorological Service for 1907, which has recently been published, contains, as in previous years, hourly (1) readings or means at observatories possessing self-recording instruments; (2) daily observations and monthly summaries at a number of selected places; and (3) temperature and rainfall tables for all stations. Many of the stations are situated at great elevations, and the data are consequently of especial interest. The observations at purely rainfall stations are not included in the year-book, but are published separately by the hydrographic department. With the aid of the Academy of Sciences, the Austrian Meteorological Society and other bodies, the investigation of the upper air by means of balloons has been regularly continued, and the detailed observations are published in the *Anzeiger* of the academy. The reports of earthquake phenomena at various stations are also published in the *Anzeiger*, and, in addition, a weekly report is issued. This special service was taken over during the late Prof. Pernter's administration, and to it the office owes its present name, "Zentralanstalt für Meteorologie und Geodynamik." In connection with its system of weather telegraphy, forecasts are sent by wire daily, free of charge, from April to November, to all post and telegraph offices in Austria; to south Tyrol they are sent all the year round.

The report by Captain H. G. Lyons, director-general of the Survey Department, Egypt, on the rains of the Nile basin and the Nile flood of 1907, contains valuable statistics of the monthly and mean rainfall at a large number of stations in and near the Nile basin, with particulars of the lake- and river-levels of 1907 and previous years. The rainfall at Lake Victoria was 20 per cent. to 30 per cent. in defect, and caused famine in parts of Uganda, while on the Bahr el Jebel, the White and Blue Nile, the rains were mostly weak and irregular; the basin of the Atbara alone had a fair amount. The Nile flood was late in commencing, and very weak throughout the year; the volume of water which passed Wadi Halfa and Aswan respectively, between July and October, was only 0·65 and 0·60 of an average flood. That a flood which was so complete a failure should not have had a disastrous effect on Egyptian agriculture, Captain Lyons remarks, is due to improvements in the irrigation system of recent years and to rains on the Abyssinian tableland in the early part of the year. The investigation of the rainfall of Abyssinia is of great importance in estimating the supply of water, but there is at present an almost complete absence of trustworthy observations. The stations established by the Italian Government in Eritrea furnish most valuable results for understanding the meteorological conditions of the eastern Sudan; telegraphic rainfall reports sent daily from Addi Ugri in August and September rendered important assistance in connection with forecasts of the flood.

The year-book and rainfall report for 1908, issued by the Norwegian Meteorological Institute, have been received. These volumes contain:—(1) Hourly readings and means for Christiania, observations taken three times a day at selected stations, and monthly and yearly summaries at other places; (2) daily rainfall values at 200 stations, with monthly and yearly summaries and other details at 449 stations, and yearly amounts and averages for each year from 1867. The charts showing the yearly distribution of rainfall (isohyets) for each 200 mm. clearly exhibit the effect of the rugged land on the water-laden currents from the Atlantic. The isohyets on the western coasts show amounts of 2000–3000 mm.; these amounts rapidly decrease to 1000 and even to 400 mm. in the interior of the country. The weather forecasts issued by the institute are generally very accurate; those for the Christiania district show an average success of 88·3 per cent. This result is to some extent due to daily telegrams from Iceland and Færöe Islands, and to reports of weather at British stations, now received through the medium of the Deutsche Seewarte.

PROCESSES FOR THE FIXATION OF ATMOSPHERIC NITROGEN.

THE fixation of atmospheric nitrogen on a commercial scale has already been the subject of articles in NATURE (February 8, 1906; August 30, 1906; July 23, 1908). The method used by Birkeland and Eyde depends upon the well-known fact that an electric arc may be broadened out into a fan shape under the influence of a magnetic field. Through the arc thus formed air is driven. Since, however, only a small portion is raised to the temperature necessary for the reaction, while the greatest part serves for cooling, the gases escaping from the Birkeland furnace at a temperature of from 600° C. to 700° C. do not contain more than from 1 per cent. to 2 per cent. of nitric oxide. For further cooling, the gases are led under boilers or through a distilling apparatus, and, finally, at a temperature of about 50°, into an oxidation chamber, where further oxygen is taken up, forming nitrogen dioxide, which in turn is absorbed by water, and thus converted into nitric acid.

To facilitate shipment, not a pure calcium product, but a basic nitrate less hygroscopic was obtained. By a new process (German patent 206,949) the nitrous gases are absorbed by calcium cyanamide, forming a mixture of nitrate of ammonia and nitrate of calcium. When this solution is tested with sulphate of ammonia (Norwegian patent 18,029 of Birkeland) calcium sulphate is deposited, leaving a solution of an ammonium product. By testing this again with sulphuric acid, and distilling, nitric acid is given off, and sulphate of ammonia remains. By this means, therefore, concentrated nitric acid is also obtained from the nitrous gases. The furnaces, used in the Norwegian plants (the first at Notodden) for the production of nitric acid from the air, work with 500 to 700 kilowatts at a pressure of 5000 volts. The coefficient of reduction of these furnaces is 0·7 to 0·75.

The method of Schönherr (Badische Anilin- und Soda-Fabrik) is said to be much more economical in the use of electric energy. In this process a perpendicular tube is employed having at the lower end an electrode, between which and the walls of the tube or an upper electrode a long arc is maintained. The air rushes whirling through the tube, filling it throughout its length, which may be several metres, with a steadily burning arc. There are now three furnaces, each employing about 600 horse-power, and using an arc about 5 metres long. Single-phase current is used at high pressure.

Recently Birkeland has lengthened his furnace and considerably increased the distance between the electrodes. By means of the magnetic field a long arc is produced which takes the shape of a screw and rotates in the furnace; by this means the air, which enters in the direction of the arc, is set in violent motion (American patent 906,682, dated December 15, 1908).

Mention should also be made of the method of Haber and König (French patent 392,670), which may be regarded as a great step in the development of the processes just mentioned. Here the mixture of nitrogen and oxygen is led under a low pressure into the narrow tube in which the flaming arc burns, the tube being well cooled on the outside. By this means, it is stated, gaseous mixtures are obtained from the air which contain from $9\frac{1}{2}$ per cent. to $10\frac{1}{2}$ per cent. of nitrous oxide, whereas in the older Birkeland-Eyde furnace only 1 per cent. was obtained.

In a paper read at the recent International Congress of Applied Chemistry Mr. Bagley directed attention to the production of nitric acid and nitrate of ammonia direct from ammonia gas. A plant is working successfully in connection with a battery of coke ovens in Germany. Ammonia gas mixed with air is forced rapidly through a plug of platinum. Every seventeen parts by weight of ammonia produces sixty-three parts by weight of nitric acid of 36° Be. Nitrate of ammonia is also produced by neutralising the nitric acid with a further supply of ammonia obtained from crude gas liquor. By a modification of the Mond process ammonia is also obtained from the gasification of peat.

IMPROVEMENTS IN PRODUCTION AND APPLICATION OF GUNCOTTON AND NITROGLYCERINE.[1]

FOR centuries the only explosive known to the world was that mechanical mixture of saltpetre, charcoal, and sulphur called gunpowder. Chemical explosives may be said to date from the discovery of guncotton by Schönbein, and it is a fact worth noting on this occasion that the first sample of guncotton in this country was one which accompanied a letter of Schönbein from Basle, dated March 18, 1846, and addressed to Michael Faraday at the Royal Institution. Schönbein referred to guncotton in this letter as follows:—

"There is another point about which I take the liberty to ask your kind advice. I am enabled to prepare in any quantity a matter which, next to gunpowder, must be regarded as the most combustible substance known. So inflammable is that matter that on being brought in contact with the slightest spark, it will instantly be set on fire, leaving hardly any trace of ashes, and if the combustion be caused within closed vessels a violent explosion takes place. That combustible substance is, as I will confidently tell you, raw cotton, prepared in a simple manner, which I shall describe you hereafter. I must not omit to mention that water has not the least action upon my matter, that is, that it may be immersed ever so long in that fluid without losing its inflammability after having been dried again. A substance of that description seems to be applicable to many purposes of daily life, and I should think that it might advantageously be used as a powerful means of defence and attack. Indeed, the Congreveian rockets can hardly be more combustible than my prepared cotton is. What shall I do with that matter? Shall I offer it to your Government? I have enclosed a little bit of that really frightful body, and you may easily convince yourself of the correctness of my statements regarding its properties."

In a subsequent letter he gave this body the name of guncotton.

Attempts to manufacture guncotton in accordance with the method devised by Schönbein were made both in this country and abroad. Accidents which occurred, however, both in Great Britain and France in the early days of manufacture, led to the abandonment of attempts to produce it in these countries; it was only in Austria that its production was persevered with, and a system of manufacture worked out there by Baron von Lenk. Having succeeded in producing guncotton on the manufacturing scale, von Lenk turned his attention to adapting it for propulsive purposes, and although at one time his efforts appeared to have met with a certain amount of success, and batteries of field artillery in Austria were actually equipped with guncotton cartridges, the difficulty of moderating its rate of combustion was never satisfactorily overcome. While this question was still the subject of experiments, serious accidents, due to the spontaneous combustion of guncotton in store, led to its production being given up even in Austria.

In 1863 Sir Frederick Abel took up the study of the manufacture of guncotton in this country with the view of adapting it for propulsive purposes, and, at the same time, of improving its stability, so that its spontaneous combustion in store might be prevented.

He was not successful in the first object, but, as regards the production of guncotton of good stability, the modifications that he introduced into the von Lenk system of manufacture resulted in the production of stable guncotton.

The process of manufacture devised by von Lenk was briefly as follows:—

Skeins of long staple cotton yarn were immersed in a mixture of strong nitric acid of 1·52 sp. gr., one part, and sulphuric acid of 1·84 sp. gr., three parts, contained in iron pans. The skeins were stirred about in the acid bath for a few minutes, removed to a grating above it, and some of the acid squeezed out with a suitable iron tool. The cotton, while still thoroughly wetted with acid, was transferred to earthenware pots, in which it remained for forty-eight hours. The pots stood in cold water to prevent decomposition of their contents. At the end of two days the conversion of the cotton into guncotton was complete; the skeins were removed from the pots, and as much as possible of the acid removed in centrifugal wringing machines. After centrifugalling the skeins were drowned as rapidly as possible in a cascade of water, the object being to remove the rest of the free acid. The final purification was effected by immersing the skeins for about three weeks in running water, boiling for a few minutes in an alkaline solution, and finally washing for a few days in flowing water.

In all that concerned the actual process of nitration Abel followed von Lenk, but instead of using skeins of long staple cotton he introduced the use of cotton waste from the spinning mills, suitably cleaned, and after the free acid had been removed in the preliminary drowning the

[1] Discourse delivered at the Royal Institution on Friday, January 29, by Sir Frederic L. Nathan, R.A.

guncotton, still in the same physical condition as the cotton waste from which it had been produced, was reduced to a fine state of division in a beating-engine. The effect of this important modification was to remove the last traces of "free acid" and of unstable bodies, so that the prolonged washing in cold water could be dispensed with, and, at the same time, a much more stable product obtained.

Cotton fibre is of a tubular structure, and so long as these tubes exist in long lengths the impurities in the interior of the tubes, derived from the evaporated juices of the cotton plant, and more or less affected by the nitration process, are extremely difficult of removal. Not only is the cotton in the form of long tubular fibres, but these fibres are themselves matted and entwined to such an extent that the former process of washing in running water even failed to remove impurities from amongst the bundles of fibre.

The operation of pulping introduced by Abel breaks up both the bundles of fibre and the fibres themselves, reducing the latter to short lengths or destroying them altogether by crushing. In this fine state of division the removal of impurities is much more readily effected by washing.

The manufacture of guncotton by the von Lenk-Abel process was commenced in this country about 1865. Foreign countries took it up in quick succession, and the process was the one universally followed for the next forty years. Some modifications of the nitration process were made towards the end of that period, in one case in the direction of dipping larger charges of cotton waste, and of allowing them to remain in the original acid mixture until nitration was completed, and then transferring the whole contents of the nitrating pan into the acid centrifugal; in another case the nitration process was actually carried out in the centrifugal itself.

In 1905, however, an entirely new system of nitration, hereafter referred to as the "displacement process," was invented by Messrs. Thomson, of the Royal Gunpowder Factory, and this process has been perfected and has entirely replaced the pot system of nitration there, and at Nobel's Explosives Factory at Ardeer, in Scotland. It is also being adopted at other factories both in this country and abroad.

The nitration of the cotton waste is carried out in shallow, circular earthenware pans. These pans are grouped together and worked in sets of four. The bottom of the pan slopes downwards to a central hole, connected by suitable pipes and cocks to a pipe supplying the nitrating acid, and to other pipes through which the waste acid is removed on completion of nitration. The pans are covered with aluminium hoods connected to an exhaust fan, for carrying off fumes.

Nitrating acid is then run in up to a definite mark, and a charge of 20 lb. of dry cotton waste is immersed in the acid in each pan in small quantities at a time. An aluminium fork is used for the purpose. When the charge of cotton waste has been dipped, perforated earthenware plates are placed on the top of it to keep it all under the surface of the acid; a film of cold water is run on to the surface of the plates and serves as a seal to prevent fumes getting into the room, and the aluminium hoods are removed. The cotton waste remains soaking in the acid for two and a half hours; at the expiration of that time its conversion to guncotton is complete. The cock leading to the waste acid pipe is then opened, and the waste acid allowed to flow away from the guncotton at a definite rate, whilst cold water is allowed to flow on to the top of the perforated plates at an equal rate. The water follows up the acid through the guncotton without any appreciable mixing of the water and the acid taking place, and when the whole of the acid has been displaced in this way the water is allowed to drain away from the guncotton, which is then ready for the final purification process. This system of manufacture possesses many advantages over the systems which it is superseding. Foremost among them are:—

(1) Decreased cost of manufacture, due to the facts that for a given output very much less labour is required; that the plant is both very cheap and very durable; that no power is required to work it; that less acid is lost in the washing processes; and that, owing to the absence of fumes and spilt acid, the cost of maintenance of the buildings is reduced.

(2) Increased safety so far as personnel is concerned, because there is no escape or splashing about of acid, which in the old processes was a fruitful source of acid burns, and also because decompositions, which used to take place both in the digesting pots and in the acid centrifugals, with the consequent evolution of poisonous oxides of nitrogen, no longer occur.

(3) A better guncotton is obtained. It is freer from unconverted cotton, and as the whole of the nitration and preliminary washing operations are carried out in earthenware receptacles, it is freer from mineral impurities.

(4) An increased yield to the extent of about 7 per cent. is realised.

The manufacture of guncotton was not commenced at the Royal Gunpowder Factory, Waltham Abbey, until the year 1872. Shortly after that date an improvement was made in the purification process. It consisted in subjecting the guncotton, while still in the waste form, to a series of steam boilings in large wooden vats. In the early days of this process boilings of long duration were used throughout. Later, a system was introduced in which a large number of short boilings at the commencement was followed by a couple of final long boilings. With the introduction of the displacement process of nitration, a thorough investigation of the chemistry of the boiling process was undertaken at Waltham Abbey, and as a result it was ascertained that a more rapid purification was effected by means of two long boilings, each of twelve hours' duration, followed by a series of very much shorter ones.

It is very probable that the displacement system of nitration is itself responsible for the reduction in the amount of boiling required to produce a stable guncotton. Although there is no appreciable amount of mixing taking place between the displacing water and the waste acid, still, mixing at the surface of contact does occur to a slight extent, sufficient to produce a distinct rise of temperature. The zone of warm acid liquid produced passes very slowly through the whole of the guncotton, removing in its course various impurities. The purifying action of this liquid is no doubt due to the fact that it possesses strong oxidising and solvent properties.

The pulping process introduced by Abel is still universally employed, and although its value from a purification point of view is no longer of such great importance now that guncotton is boiled as it was in the early days of cold-water washing, it is, undoubtedly, still of use in effecting a final purification of the guncotton.

In the beating-engine the mechanical process of reducing the guncotton to a pulp is effected, but no actual removal of impurities takes place, because the water is not changed during the operation. The impurities still present in the guncotton at this stage are both mechanical and chemical. The mechanical impurities consist chiefly of particles of metal of various kinds, sand and fine grit, wood and similar substances, introduced originally in the cotton waste and during the processes of manufacture. The chemical impurities are bodies produced by the action of the nitrating acid on bodies other than cellulose; they are not entirely removed in the boiling process, but are set free in the pulping. To remove the mechanical impurities the guncotton pulp, in a large volume of water, is at Waltham Abbey run from the beaters over flannel laid on long shallow troughs, the troughs having pockets with baffle plates at intervals. The rough surface of the flannel retains the fine particles of grit, &c., and the larger particles settle in the pockets or grit-traps. In the last pocket an electromagnet is inserted to remove iron or steel particles which may have escaped retention in the grit-traps.

The guncotton thus freed from mechanical impurities runs into large oval iron tanks called "poachers," where it receives several cold-water washings. The contents of the poacher are agitated by means of a power-driven wooden paddle-wheel, and then allowed to settle. The washing water containing the impurities is drawn off from the surface of the guncotton by means of a large skimmer, in order that not only impurities in solution may be removed, but also any light solid impurities in suspension.

The finally purified pulp is passed to a moulding machine, where it is lightly compressed to remove the bulk of the water, and converted into a form in which it can be easily handled. If intended for use in mines or torpedoes, or for demolition purposes, the lightly compressed shapes are submitted to heavy hydraulic pressure, converting them into dense hard blocks.

The other high explosive of which I am to speak, viz. nitroglycerine, enters into the composition of many modern propellants. Nitroglycerine was discovered by Sobrero in 1847, but it remained for a long time a chemical curiosity only.

Alfred Nobel commenced its manufacture as a blasting agent about 1868, for which purpose he absorbed nitroglycerine with an infusorial earth known as kieselguhr, and gave the compound the name of dynamite; but, prior to this, nitroglycerine had been made on a large scale in America, where it was frozen after manufacture for purposes of transport, and used for blasting.

Nitroglycerine is a liquid, and is a much more violent explosive than guncotton, and whereas the manufacture of guncotton is absolutely safe throughout, that of nitroglycerine is dangerous. The risks attendant on the manufacture of nitroglycerine are due to the facts that the temperature resulting from the chemical reaction is not so easily controlled, and that nitroglycerine, being a liquid insoluble in water, the processes after nitration have to be carried out with a substance not rendered inert, as guncotton is, by admixture with water. For these reasons the nitration of glycerine in the early days of the production of nitroglycerine on a manufacturing scale was carried out in very small quantities.

With the introduction of dynamite, the small pots used for the nitration of glycerine, standing in vessels full of ice water, were replaced by lead tanks, in which considerable quantities of glycerine, amounting to several hundred pounds, were nitrated at one operation. In these vessels the temperature was controlled by means of cold water circulating through lead coils fixed in the tank, and the whole contents of the tank were kept in agitation during the nitration by means of mechanical stirrers or by compressed air escaping through small holes in lead pipes situated at the bottom of the nitrating vessel. On completion of the nitration it was the practice in the early days to drown the whole of the charge of nitroglycerine and waste acid in a large bulk of water, from which the nitroglycerine separated out and was removed for subsequent purification by washing with alkaline solutions in lead tanks. This system entailed the loss of the waste acid, and was superseded by a process in which the nitroglycerine and waste acid were run from the nitrating vessel into another vessel termed a separator, and allowed to separate in it. The nitroglycerine, being lighter than the waste acid, came to the top, and was run off into a third tank for preliminary purification, consisting of several water washings.

This preliminary purification removes most of the free acid adhering to and dissolved in the nitroglycerine, but in order to obtain a stable product a further and prolonged purification is necessary, as in the case of guncotton. This is effected in lead tanks by repeated washings with warm, dilute sodium carbonate solution. The alkali remaining in the nitroglycerine after this treatment is thoroughly removed by washing with purified warm water. As nitroglycerine is a somewhat viscous liquid, special care has to be taken that the washing solutions are brought into very intimate contact with every portion of the charge of nitroglycerine. For this purpose the method universally employed is to agitate the contents of the washing tanks by means of the escape of air under compression through small holes in the bottom of the tank. As a result of this very thorough agitation the nitroglycerine, even after the removal by skimming of as much as possible of the washing liquid, still contains a small proportion of water suspended in it in a very fine state of division. It also contains small quantities of flocculent impurities and mineral matter derived from the glycerine and acids. To get rid of these bodies filtration is resorted to; coarse crystalline salt is very usually employed as a medium, but at Waltham Abbey it has been found that a filter in the form of a mat of sponges is more efficacious and free from the objections salt filters possess.

After the removal of the nitroglycerine from the waste acid, which takes place in a comparatively short space of time, the waste acid was run out of the separator into large lead vessels, where it remained for days, in order to allow of the formation and removal of the last traces of nitroglycerine. This process is known as after-separation, and was necessary to enable the waste acid to be dealt with without risk, because so long as it contained any traces of nitroglycerine it could not be stored or handled without risk of violent decompositions, or even of explosions, taking place.

This system of manufacture, comprising nitration, separation, preliminary washing, final washing, and after-separation, all carried out in different vessels and in different houses, was the one which, with slight modifications in detail, was followed almost universally, and is still in use in many of the older factories in this country and abroad. Its disadvantages are several. In the first place, owing to the fact that it is unsafe to transport or to carry liquid nitroglycerine about, factories are always designed so that it may flow from process to process by gravity. The result, obviously, is that nitroglycerine houses must be built on the side of a hill, or, as this is not always possible, the alternative of building a nitrating house, and also, probably, a separating house, on artificial mounds, has to be resorted to, entailing a very considerable expense.

In the next place, owing to the corrosive nature of the mixture of nitroglycerine and waste acid, and to the acid nature of the nitroglycerine even when separated from the waste acid, the only material which can be used for the cocks necessary to allow the nitroglycerine and acid to run from vessel to vessel is earthenware. The use of earthenware cocks is attended with considerable risk, owing to the fact that there is friction in them between the key and the body of the cock, and there is always the risk in moderately cold weather of the nitroglycerine freezing and fixing the key; force, if used in these circumstances, would be very liable to cause accident. Again, the necessity of storing the waste acid under observation for long periods is a costly one, both as regards labour and plant required.

It was to overcome these disadvantages that the whole system in current use for the manufacture of nitroglycerine received very careful consideration at the Royal Gunpowder Factory some years ago.

The first step that was taken to improve matters was to abolish the use of earthenware cocks in the preliminary and final washing tanks. As the nitroglycerine when it was ready to leave these tanks was thoroughly free from acid, it was possible to get rid of the cocks on these tanks, and to replace them by rubber tubes. During the washing operations this tube is secured to a nozzle fixed to the outside of the tank at a point above the level of the liquid. To run off the nitroglycerine it is only necessary to slip the rubber tube off the nozzle and direct it into another vessel or into a lead gutter used to convey the nitroglycerine to the next operation.

Rubber, however, could not be used in the case of the separator or the nitrator, where either acid nitroglycerine or a mixture of nitroglycerine and acid had to be drawn off. To overcome the difficulty in this case an entirely new system was invented at Waltham Abbey. Instead of running the nitroglycerine and waste acid on completion of the nitration process into the separator, the separation is allowed to take place in the nitrating vessel itself. Nitroglycerine as it separates from the waste acid comes to the top, it being the lighter of the two liquids, and to remove it from the nitrator all that is necessary is to raise the liquid contents of the vessel gradually until the nitroglycerine reaches the top of the nitrator, where a pipe or gutter is fixed to lead the nitroglycerine away into the preliminary washing tank. This raising of the charge is effected by introducing into the bottom of the nitrator, through the same pipe by which the nitrating acid is admitted, the waste acid from a previous charge. The rate of inflow of the waste acid is regulated, so that the nitroglycerine displaced is as free as possible from acid in suspension.

The waste acid has still to be dealt with. It was discovered that the addition of a small percentage of water to this acid, after the nitroglycerine has been separated from it in the nitrator-separator, entirely prevents the further formation and separation of the small traces of the nitroglycerine, which the after-separating bottles were required to deal with.

The advantages of the Waltham Abbey plant and system of manufacture over others are briefly as follows:—

(1) *Increased Safety.*—By the abolition of all cocks through which nitroglycerine had to pass, the risks attendant on their use have disappeared. By the presence of cooling coils in the one and only vessel in which nitroglycerine and acids are in contact, any undue rise in temperature, always a possibility in the circumstances, can be at once checked. It was not usual to have cooling coils in the separator and after-separating bottles.

(2) *Reduction in Total Elevation for, and Area of a Factory.*—The abolition of the separator, and the running off of the nitroglycerine from the top of nitrator, effect a very material saving in the height required.

The after-separating house being no longer necessary, or the separator house when one existed as distinct from the nitrating house, the number of buildings, and therefore the ground area, is substantially reduced.

(3) *Reduced Cost of Production.*—This results from the fact that the capital outlay for a factory is much less, that fewer men are required for a given output, that there is less plant and fewer buildings to maintain, and that the plant itself suffers slower deterioration. Finally, the yield of nitroglycerine is increased by at least 5 parts for every 100 parts of glycerine nitrated.

The substitution recently of Nordhausen for ordinary sulphuric acid has further improved the yield of nitroglycerine, and whereas a few years ago a yield of 210 parts of nitroglycerine for every 100 parts of glycerine nitrated was considered excellent, the average yield at Waltham Abbey is now 230 per cent., a very high figure in view of the fact that the theoretical yield is 246·74 per cent. The use of Nordhausen sulphuric acid also permits of a considerable reduction in the proportion of nitrating acid to glycerine, so that a larger output is obtainable for any given sized plant.

(*To be continued.*)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Harvard University has recognised the growing importance of public health and preventive medicine by establishing in its medical school a department exclusively devoted to those subjects. It has appointed Dr. Milton J. Rosenau to the professorship of hygiene and preventive medicine, with the headship of the new department. Dr. Rosenau has lately been professor of bacteriology at the Washington Post-graduate Medical School.

The council of the Institution of Mining and Metallurgy is prepared to offer five scholarships for the current year (provided suitable candidates present themselves) of the value of 50*l.* each, to assist graduates in mining or metallurgy to take a practical course in mines or works at home or abroad. The scholarships will be awarded to graduates of the Royal School of Mines and other recognised British mining colleges or schools. Further information may be obtained from the secretary of the institution, Salisbury House, E.C.

The following doctorates have been conferred by the University of London upon internal and external students for the theses mentioned and other papers:—Miss Annie Abram, "The Effects produced by Economic Changes upon Social Life in England in the Fifteenth Century"; Mr. P. Hartley, "On the Nature of the Fat contained in the Liver, Kidney, and Heart"; Mr. E. T. Mellor, "The Geology of the Neighbourhood of Middelburg, &c."; Mr. J. Stephenson, "Studies on the Aquatic Oligochæta of the Punjab"; Mr. W. Makower, "On the Active Deposit of Radium"; and Mr. H. Stansfield, "The Echelon Spectroscope, its Secondary Action, and the Structure of the Green Mercury Line."

At a recent meeting of the council of the University of Bristol Dr. Lloyd Morgan tendered his resignation of the office of Vice-Chancellor, and in accepting the same the council placed upon record its sense of the distinguished services rendered by him to the cause of university education during the twenty-two years of his tenure of office as principal of University College, Bristol, and its hearty acknowledgment of the unsparing manner in which he has devoted his time and influence to the promotion of the scheme for the foundation of the University of Bristol, now brought to a successful issue. Sir Isambard Owen, principal of Armstrong College, Newcastle-on-Tyne, has been elected Vice-Chancellor of the University, and Prof. J. Michell Clarke Pro-Vice-Chancellor.

Many evidences of the numerous activities of the Association of Teachers in Technical Institutions are to be found in the July issue of the association's journal, which is published by the St. Bride's Press, Ltd. Addresses and papers read at the annual conference, of which an account appeared in Nature of June 10, are printed in the periodical, and, in addition, there are several contributions by members of the association on various branches of technological chemistry. Prof. A. F. Holleman, of the University of Amsterdam, writes on substitution in the benzene-nucleus, Mr. Frank E. Weston discusses thermic reactions, and Mr. E. B. Naylor describes a course of instruction in chemistry designed to meet the needs of a mining centre. Full particulars are given also respecting the administrative work both of the parent association and its branches.

Messrs. Cornish Brothers, Ltd., of Birmingham, have published in pamphlet form the address delivered last January by Sir Alexander B. W. Kennedy, F.R.S., in his capacity of warden of the Guild of Undergraduates, to the students of the University of Birmingham. The address is entitled "The Complete Student," and contains much wise and kindly advice to young men entering upon life. Early in the address Sir Alexander says:—"I am sure that the exclusive use of our mental apparatus for technical or professional or business matters, or equally for artistic or scientific matters, renders the large part of that apparatus which is adapted for far wider uses useless and inert. The owner of only half a mind—especially if it be only the money-making half—is a very poor person. Moreover, even the one used half tends to become smaller and less elastic as its owner grows older. As regards his friends, such a one grows every year duller and more stupid; as regards his profession, he becomes less and less able to appreciate its continually changing aspects; as regards himself, he has as deliberately thrown away half of the pleasure of existence as if he had chosen to shut himself up all his days in a tube railway, beautifully illuminated by arc lamps, but absolutely cut off from the light of the sun."

The London County Council Education Committee has had under consideration lately the question of the attendance of pupils residing outside the metropolitan area at secondary schools within the administrative county of London. The inquiry has led to some interesting comparisons as to the ratio existing between the gross cost per pupil of the education provided in London secondary schools and the amount of fees paid by the pupils. Taking the case of the seventeen secondary schools provided and managed by the committee, the gross estimated cost of education per pupil, apart from capital charges, varies from 12*l.* 14*s.* in the case of the Dalston County Secondary School for Girls to 27*l.* 1*s.* in the case of the Holloway County Secondary School for Boys. The Board of Education grant of 4*l.* 10*s.* is uniform throughout these schools, so that the net cost of education per pupil varies from 8*l.* 4*s.* to 22*l.* 11*s.* The fees charged to fee-paying pupils vary from 4*l.* 10*s.* to 12*l.* a year per pupil. In the great majority of the schools the fee charged is only about one-half that of the net cost, and nearer one-third that of the gross cost. In other words, London parents who send their children to these county secondary schools are called upon to pay only about one-third of what that education costs. It would be a wise policy for the Education Committee to take steps to bring this fact home to the parents, for at present evidences are not wanting that the facilities which London now enjoys for secondary education are insufficiently appreciated both by the parents and their children.

The second volume of the report of the U.S. Commissioner of Education for the year ended June 30, 1908, has been received from Washington. An important chapter, running to some 122 pages, provides exhaustive statistics relating to the universities, colleges, and technological schools of the United States. The total value of all gifts and bequests reported by the institutions, of which the Washington Bureau takes cognisance, during the year under review, amounted to 2,964,200*l*. Of this amount 1,029,600*l*. was given for buildings and improvements, 1,468,300*l*. for endowment, and the remainder for current expenses. Twenty-four institutions received 20,000*l*. or more during the year, the most fortunate of the universities being Chicago, which benefited to the extent of 419,700*l*.; Princeton, 200,850*l*.; California, 187,200*l*.; and Harvard, 138,400*l*. The statistics deal with 464 American universities, colleges, and technological schools. For the year 1907–8 these institutions received 3,448,500*l*. from students' fees, 811,000*l*. being for board and lodging. The grand total of the receipts of the institutions reached the large sum of 13,360,000*l*. In their libraries were 12,636,656 volumes. The value of their scientific apparatus, machinery, and furniture was 5,588,300*l*.; their grounds, 11,714,300*l*.; their buildings, 42,878,000*l*.; and their productive funds, 51,954,000*l*. The institution had a teaching force of 21,960, the number of men being 19,254. The number of students under the tuition of this large staff was 265,966.

On July 21 Lord Monk Bretton asked in the House of Lords what steps had been taken to define the spheres of the Boards of Agriculture and Education, respectively, in the matter of agricultural education. At the same time he referred to the memorandum recently issued by the Board of Education, which implied that a sum of 21,000*l*., in part at any rate, is available for agricultural education. He stated that he has been in communication with the university authorities and others, and can find no evidence that the money is used for this purpose. Similarly, the Treasury grants and the block-grant system of the Board of Education have not helped agricultural education; money from the latter source, indeed, goes to the relief of the rates. British agriculture, he pointed out, receives much less money than the amount granted in foreign countries, a result due to the absence of agreement and coordination between the Board of Education and the Board of Agriculture. Earl Carrington, in reply, stated that an understanding had that morning been arrived at by the two Boards as to the general lines of their future policy. There will be direct cooperation in regard to educational work, and in particular with the view of improving and extending specialised agricultural instruction. An inter-departmental committee of officers of the two Boards will consider the questions that may arise as to the correlation of work and of grants. Everything is working harmoniously between the two departments. Lord Belper strongly urged that any arrangement between the two Boards should follow the recommendation of the Agricultural Education Committee that agricultural education provided by colleges, farm institutes, and winter schools should be under the direction of the Board of Agriculture, while agricultural instruction given at evening classes connected with elementary schools should be under the Board of Education. The Marquis of Lansdowne emphasised the great importance of the subject. Quoting Sir Horace Plunkett's dictum, that what is wanted in these days is not merely economic holdings, but an economic system and an economic man to carry it out, he went on to say that we cannot get the economic man to carry out the economic system unless the Government takes some pains to give him a proper education.

The Staffordshire County Council Education Committee has issued its scheme of agricultural education, and a perusal of the circular shows that the committee is fully alive to the difficulties involved. Provision is made (*a*) for those already engaged in agricultural pursuits, and who therefore can only devote their evenings to study, or, at most, a few weeks during the slack winter time; (*b*) for boys and girls leaving elementary schools. The former class always proves difficult to get at. Lecturers in agricultural and horticultural subjects are provided, at a merely nominal cost to the locality, to give courses of six to twenty lectures. Practical demonstrations are also arranged in cooperation with the Harper Adams College. These include:—(1) Manurial experiments to show the effect of different manures on crops and to compare different varieties of crops; (2) hedge-layering and ditching courses, which are necessarily held in the day-time, and for which prizes are therefore given by way of recompense; (3) horticulture and fruit-growing. There are also scholarships for short winter courses, tenable at the Harper Adams College or the Midland Dairy College, which, however, have been very inadequately taken up in the past. Coming now to provision for children leaving school, we find:—(1) Minor scholarships awarded for the Brewood Grammar School (agricultural side); (2) major scholarships for the Harper Adams or Holmes Chapel College, or, in the case of women, the Swanley Horticultural College. Farmers are apt to grumble because boys who take up agricultural scholarships subsequently find something they are better fitted for. Such grumbling is, of course, wholly unreasonable, and shows a want of appreciation of the true meaning of education. We are therefore sorry to see a proviso that "candidates who accept Brewood scholarships are expected to take up agriculture on leaving school. No appointment as pupil-teacher in any elementary school under the county committee will be given to boys who have held Brewood scholarships." How can a boy of fourteen be expected to know just what career he will succeed at best? Why should he be penalised if he elects to go in for farming, and discovers, two years later, that his bent is for teaching? Does not the education committee know that to discover what a boy can do, and to set him at it, is one of the great objects of all education?

SOCIETIES AND ACADEMIES.

Edinburgh.

Royal Society, June 28.—Dr. R. H. Traquair, F.R.S., vice-president, in the chair.—At the request of the council Prof. Louis **Dollo**, of the Royal Museum at Brussels, delivered an address on the extinct gigantic reptiles of Belgium. The history of their discovery and the manner of their preservation were detailed in a most interesting and racy lecture, the peculiar skeletal arrangements of the iguanodon being specially dwelt upon.

July 5.—Prof. Cossar Ewart, F.R.S., vice-president, in the chair.—Notes on the skeleton of a Sowerby's whale (*Mesoplodon bidens*) stranded at St. Andrews, and on the morphology of the manus in Hyperoodon and in the Delphinidæ: Sir William **Turner**, K.C.B. This species of whale was first recognised in 1800 from a specimen cast ashore on the Moray Firth, and described by Sowerby. Not until 1872 were other specimens found on the Scottish coast. The present specimen led to some corrections of former conclusions, especially in regard to the differences of sex. Some interesting results were given in regard to the comparative anatomy of the hand in this whale and the allied genera of Hyperoodon and dolphins. The occurrence of five distal carpal bones in the Sowerby's whale disposed of the theory that this number did not occur in mammals.—Current and temperature observations in Loch Ness: E. M. **Wedderburn** and W. **Watson**. The observations were complicated, and at times conflicting, secondary currents and cross-currents being frequent, and evidently forming part of the circulation of the lake. Of the general conclusions the following may be mentioned. When the lake is of uniform temperature the direct current produced by wind is felt to considerable depths, and the return current is also felt in the deepest parts. When the lake has become stratified and the temperature discontinuity has appeared, the return current is almost always above the discontinuity. When the wind changes direction or follows a calm, the direct surface current is felt to considerable depths, but after the wind has been blowing for about twelve hours the return current asserts itself, and the direct current is restricted to a narrower zone.—Pettersson's observations on deep-water oscillations: E. M.

Wedderburn. In the Gullmar Fjord, off the Skagerack, Pettersson observed oscillations of temperature and salinity with a period of fourteen days. This he attributed to the action of the moon, although he admitted that he could not give any reason for the effect. Mr. Wedderburn suggested that it was due to a temperature seiche in the Skagerack. When a layer of depth h and density ρ floats on a layer of depth h' and density ρ' in a land-locked bay of length l, the period is given by the formula

$$T = 4\pi l \sqrt{g(\rho + \rho')/(\rho/h + \rho'/h')}.$$

With $l = 250$ metres, $h = 20$ metres, $h' = 100$ or 200 metres, $\rho = 1{\cdot}023$ and $\rho' = 1{\cdot}027$, the calculated periods are 13·9 days for $h' = 200$ metres and 14·2 days for $h' = 100$ metres.—A Carboniferous fauna from Novaia Zemlya: Dr. G. W. **Lee.** This was an account of a collection of fossils found by Dr. W. S. Bruce during a cruise with Major Andrew Coats in the yacht *Blencathra*. The fossils were found at Cape Cherney in 71° north latitude, and proved that the Carboniferous seas had extended some six hundred miles further north than had hitherto been supposed. The collection contained more than thirty species similar to the fauna of the lower limestone of the Scottish coal-fields and of the Yoredales of England.—Note on the flight of Nigerian arrows: Dr. C. G. **Knott.** These were unprovided with feathers, and rotation seemed to be given to the arrow by the action of the air upon the head, the asymmetrical form of which was probably originally occasioned by the manner in which the wings and barbs were forged. Experiments on the rotation were described.—The development of the auditory ossicles in the horse, with a note on their possible homologues in the lower Vertebrata: Ray F. **Coyle.** The malleus, stapes, and lucus were developed from an area which is originally homogeneous, and lying between the proximal ends of the first two visceral bars. Later the malleus and lucus are split off, bearing a close relation to the first bar. The stapes is related neither to the first or second bar nor to the auditory capsule, arising as an element peculiar to the Mammalia.

July 12.—Dr. Horne, F.R.S., vice-president, in the chair.—A further contribution to a comparative study of the dominant phanerogamic and higher cryptogamic flora of aquatic habit in Scottish lakes (Scottish Lake Survey): George **West.** The lochs studied were those of Kirkcudbrightshire, Wigtonshire, Fife, and Kinross. In north-west Kirkcudbrightshire the lochs are of highland character, but the flora, though resembling that of the Ness district, does not thrive to so great a depth. This is due partly to the comparative shallowness of the Galloway lochs and to the deposit of dead leaves of grasses over the floor of the loch. The lochs of south-east Kirkcudbrightshire are of lowland type, and have in many cases a rich and luxuriant flora. In Wigtonshire both types of lochs are found, those in the open moor being scanty in flora, while those within the zones of active agriculture are of lowland type and of rich and varied vegetation. The populous mining, manufacturing, and agricultural regions of Fife and Kinross are characterised by many lochs of the lowland type, some of them being very luxuriant in aquatic flora, because the non-peaty water contains a rich supply of food-salts, due in many instances to the activity of man in the surrounding district. The paper enumerated about 250 species of plants found in the lochs of the areas named.—Osteology of Antarctic seals (Scottish National Antarctic Expedition): Dr. R. B. **Thomson.** The seals brought home by Dr. Bruce numbered in all forty-four, and included all the Phocidæ except the elephant seal. The most interesting capture was that of two Ross seals, the dentition of which differs markedly from that of other Antarctic seals. The dentition is remarkably feeble. The chief food being soft-bodied cephalopods, the incisors and canines have developed into needle-pointed re-curved hooks of great delicacy, while the post-canines have been allowed to degenerate. Other anatomical peculiarities were described, one interesting anomaly being presented by the fifteenth dorsal or last rib-bearing vertebra. On one side there is the normal condition, an articular facet bearing a feebly developed rib; on the other there is a well-marked process representing the absent rib, showing that the costal processes in the lumbar vertebræ are the homologues of the ribs.—A negative attempt to detect fluorescence absorption: Dr. R. A. **Houstoun.** Results which seemed to indicate fluorescence absorption have been obtained by Burke, by Nichols and Merritt, and by Miss Wick, but, after careful experimenting and making every allowance for the uncertain nature of the phenomenon studied, the author is inclined to refer these positive results to systematic errors in the photometric arrangement.—The effect of internal friction in cases of compound stress: G. H. **Gulliver.** The minimum resistance to deformation and the inclination of the surfaces of sliding were given for any system of stress in a body, the internal friction being supposed to be operative. The application of the formulæ to experimental data did not yield very consistent results. With internal friction taken into account, the modified expression for the equivalent bending moment of a shaft under combined bending and twisting gives values intermediate between those given by the formulæ of Rankine and Guest.—A new experimental method of investigating certain systems of stress: G. H. **Gulliver.** The lines of maximum shear in a strained solid, as indicated by surface changes in the manner already described by the author, were compared, by superposition, with the stream lines of a viscous fluid in channels of definite shape obtained by the method of Hele Shaw. The comparisons were extremely satisfactory, and showed how analogous the equations of strain in the one case are to the equations of flow in the other.—Motion of Neptune's satellite: David **Gibb.** The calculations were made under Prof. Dyson's supervision, and were based upon the numerous observations which have been made in the American observatories since 1892, when Struve discussed all that had until then been made. From 650 equations of condition, twenty-two sets of normal equations were formed and solved. The results led to various corrections to be applied to Struve's elements. The eccentricity of the orbit of the satellite was found not to exceed 0·001. From the changes in the node and inclination, which are due to the spheroidal form of Neptune, the inclination of the orbit to Neptune's equator could be found—about 21°. The longitude of the node of Neptune's equator on the earth's equator was found to be about 205°, and the inclination of the two equations 132·8°. From these it was deduced that the pole of the satellite's orbit describes a small circle about the pole of Neptune in about 580 years, and that Neptune's equator is inclined at an angle of about 27° to the plane of its orbit round the sun.—The monsoons of the Chilian littoral: R. C. **Mossman.** The paper was a general discussion of the prevailing winds in this region of the southern hemisphere, showing how they are influenced by the circumpolar distribution.—The super-adjugate determinant and skew determinants having a univarial diagonal: Dr. Thomas **Muir.**—The illuminating power of groups of pin-hole burners: R. G. **Harris.** The variation of the illuminating power of symmetrical groups of two, three, and four burners with the distance between contiguous members of the groups was found to require somewhat complex equations for its expression. The graphs were of the same general form, and could be accounted for qualitatively on the assumption that the variation of illuminating power was due, for the most part, to a two-fold effect of the increase of distance between the burners on the supply of oxygen. The more open distribution of burners increased this supply, but the diminished draught attending such open distribution diminished it.—The life-history of *Hydrolius fuscipes*, L.: F. Balfour **Browne.** A complete and detailed monograph on this common and interesting form of life.

PARIS.

Academy of Sciences, July 19.—M. Émile Picard in the chair.—Researches on the movements of the upper layer of the solar atmosphere: H. **Deslandres.** Details of the spectroheliograph at the Observatory of Meudon are given, together with some of the results of a study of the calcium line K_3.—The determination of the displacements of the axis of rotation of meridian telescopes: Maurice **Hamy.**—The reduction of plant assimilation during cloudy weather: A. **Müntz** and H. **Gaudechon.** During direct exposure to sunlight the quantity of carbon fixed by plants is about five times as great as during cloudy or rainy weather.—The determination of the bovine or human origin of Koch bacilli isolated from tuberculous lesions in human beings: A. **Calmette** and C. **Guérin** (see p. 135).—The origin of the contrasts of colour and sudden changes of level which are found in the moon: P. **Puiseux.** The hypothesis of snow or ice being the cause of bright spots on the moon is considered and rejected, as is also the suggestion that the dark spots are caused by deposits of cosmic material.—Observations of the comet 1909*a* (Borrelly-Daniel) made at the Observatory of Marseilles with the comet finder: A. **Borrelly.** Positions are given for June 21, 26, and July 8 and 13.—Observations of the comet 1909*a* (Borrelly-Daniel) made at the Marseilles Observatory with the Eichens equatorial of 26 cm. aperture: M. **Coggia.** Positions are given for June 18, 20, 24, and 25.—Systems of differential equations: Edmond **Maillet.**—The existence, in the magnetic decomposition of the absorption bands of a uniaxial crystal, of dissymmetry of positions observed parallel to the lines of force, the field, and the optical axis of the crystal: Jean **Becquerel.** The author has repeated his earlier experiments on this subject with a more powerful magnet (field-strength, 34,000 Gauss). The unsymmetrical change of position, as also the changes in the intensities of the lines, are in accord with the theory of W. Voigt.—The relation between the electric double refraction of mixed liquids and the optical double refraction of the solid constituents of these solutions: J. **Chaudier.**—Harmonic analysis and resonance: Henri **Abraham.**—The application of the magnetic properties of metals to automatic coin machines: Antal **Fodor** and M. **de Büty.** The use of a permanent magnet in a coin slot machine is applied in such a manner that the machine only works when a nickel coin is used. Discs of copper, zinc, or tin drop through without affecting the mechanism: iron blocks the machine, and prevents it being further used.—Researches on the phosphates of thorium: A. **Colani.** A description of the preparation of thorium chlorophosphate and double phosphates of calcium and strontium with thorium.—The synthesis of papaverine: Amé **Pictet** and A. **Gams.** The steps in this important synthesis are as follows:—veratrol, acetoveratrone, amino-acetoveratrone hydrochloride, homo-veratroyl-amino-acetoveratrone, and homoveratroyl-oxy-homoveratrylamine. This last substance is dehydrated in xylene solution with phosphorus pentoxide, and the base thus obtained is identical in all respects with natural papaverine.—The catalysis of the fatty acids: J. B. **Senderens.** It has been shown in a previous paper that thoria and alumina, heated to a suitable temperature, convert the vapours of the fatty acids into the corresponding ketone. The properties of the oxides of chromium, calcium, zinc, copper, and cadmium have been investigated from this point of view, but none of these oxides is so advantageous as thoria in this reaction.—The presence of dimethoxy-2:3-methylenedioxy-4:5-allyl-1-benzene in the essence of *Crithmum maritimum*: Marcel **Delépine.**—Some reactions of anthranol: Robert **Padova.**—The di-iodine addition derivatives of the higher fatty acids of the series $C_2H_{2n-4}O_2$: A. **Arnaud** and S. **Posternak.** The fixation of two atoms of iodine is nearly instantaneous in acetic acid solution.—A new base extracted from rye containing ergot; ergothioneine: C. **Tanret.** The method of extraction and the chemical and physical properties of this new base are described; its composition is $C_9H_{15}N_3O_2S$.—The constitution of perseulose: Gabriel **Bertrand.**—Contribution to the study of cultivated oats: M. **Trabut.**—The influence of the radium radiations on the chlorophyll and respiratory functions of plants: Alexandre **Hébert** and André **Kling.** No direct effects on these two functions can be traced; some secondary effects appear to be due to the slight changes induced in the plant cells.—The muscular work electrically provoked in the cure of diseases by reduction of the nutrition, and in particular the cure of obesity: J. **Bergonié.**—The anti-rabic properties of the cerebral substance: A. **Marie.**—The action of the pancreatic juice on esters: L. **Morel** and E. **Terroine.** The action of the pancreatic juice on esters is very slight, but is considerably reinforced by the addition of bile salts.—A new endoparasite of insects: Louis **Léger.**—The instability of the Swiss plateau in post-Glacial times: E. **Romer.**

CALCUTTA.

Asiatic Society of Bengal, July 7.—Some notes on mineralogy: Prof. E. **Sommerfeldt.** (1) Measurement of angles in crystals. An apparatus is shown (devised by the author) which permits the use of a simple goniometer like a theodolite-goniometer. (2) Isomorphism between anhydrite and barites. The method of Ostwald for recognising isomorphism was used for answering the question, Are the sulphate of barium and calcium isomorphous? The answer is that one salt is not able to remove the supersaturation of the other, and that, therefore, no isomorphism exists between them.—The Shou (pronounced Siau) or Tibetan stag: Lieut.-Colonel J. **Manners-Smith.** A note on the distribution and habits of *Cervus affinis*, and on specimens living in captivity in Nepal.—The Loranthus parasite of the Moru (*Quercus dilatata*) and Ban (*Quercus incana*) oaks: E. P. **Stebbing.** Mistletoes are exceedingly abundant on these two species of oak in certain parts of the north-western Himalaya. They attack the trees about Naini Tal and throughout Kamaon so extensively as, with the aid of boring beetles which follow them, to cause at times their death. It seems that moss aids the mistletoe seeds in obtaining a lodgment.—Decomposition of ammonium platinichloride and platinibromide under the influence of heat: Prafulla Chandra **Ray** and Atul Chandra **Ghosh.**

THURSDAY, AUGUST 5, 1909.

WHAT THE ELECTRICIAN WANTS.

Modern Electric Practice. Edited by Prof. Magnus Maclean. New edition. In six volumes. Vol. i., pp. xii+302. Vol. ii., pp. vii+351. Vol. iii., pp. viii+340. Vol. iv., pp. vii+314. Vol. v., pp. vi+293. Vol. vi., pp. vii+362. (London: The Gresham Publishing Co., 1909.) Price, the six volumes, 54s.

A PUBLICATION of so ambitious a character as that which now lies before us courts severe criticism. Six handsomely bound volumes, which would adorn any bookshelf, beautifully printed on excellent paper, and copiously illustrated with still more excellent illustrations, should be, like Cæsar's wife, above suspicion. The indolent reviewer may well feel aghast when confronted with "a comprehensive treatise" which "no single writer could hope to issue," and which has consequently been compiled by "the cooperation of contributors, each of whom is an expert in his own department of study and practice"; and the editor may well comfort himself against the possibility of adverse criticism by the reflection that what no one man can write no one man can review—a comforting reflection and a true one; but therein lies the paramount necessity for being above suspicion; for, unable to criticise all, the reviewer must perforce base his judgment on selections, and if, perchance, those selections are unfavourable, good work runs the danger of being condemned merely on the strength of its association with bad, and the "experts" as a body stand or fall according as some amongst them have or have not proved worthy of their trust.

Let us, however, in the first place venture some criticism of the work as a whole. A publication such as this challenges comparison with a number of independent treatises, and in one respect at least it should be superior. Careful editorship should secure, not only no unnecessary overlapping, but also uniformity of treatment. When reviewing the first three volumes on their original appearance five years ago, the writer pointed out that the statement in the preface that the contributors had all been allowed to use their own units amounted simply to an admission of slipshod editing. We regret to find that statement still standing. But in our former review we directed attention to a more serious error, namely, that at different places different values were given to the same quantities. We have turned again to the two tables to which we referred, and find them unchanged, the editor being still apparently unable to make up his mind whether the conductivity of platinum is greater or less than that of iron. We pity the student or the engineer who consults such data as these for trustworthy information. It is a well-known rule of conduct when a number of people agree to disseminate incorrect information that the precise nature of the information is of less importance than that all should be agreed upon it; we think this rule should be borne in mind when the third edition is issued, if it is not found possible to obtain a correct table of conductivities.

Discrepancies such as these once discovered, suspicion is aroused, and one turns to individual articles to consider each on its merits. Here, as is naturally to be expected, one encounters varying degrees of merit. Some of the articles are well written, sound, and comprehensive monographs; others are exceedingly weak. We do not profess to have carefully read all, but can only judge the bulk by the average of those we have studied carefully, and it must be confessed the average is low.

Take, for example, the subject of primary batteries; the references in the index raised considerable hopes, but after they were traced we came to the reluctant conclusion that the index conveyed almost as much information as the articles. Primary cells are dealt with in section i., part i., chapter viii. Their treatment occupies five pages, about one-third beng woodcuts (Figs. 58 and 59, by the way, being crossed). The particulars given are most meagre; neither the E.M.F. nor the internal resistances are given, and one has no idea whether the Leclanché cell, for example, gives 1 volt or 100; no particulars of life or output are given, and there is no comparison between the efficiency of different types. Dry cells are referred to in half a line, which conveys no impression whatsoever as to what they are like. Primary batteries are, it is true, again referred to in vol. vi., in the article on electromedical appliances, but only incidentally, and though the E.M.F.'s are mentioned here in one or two cases, this is about the only additional information given. The most elementary five-shilling textbook with the same ground to cover gives more valuable information on this subject than this comprehensive treatise written by experts; and it cannot be claimed that the primary battery is of no importance, as it is still enormously used for telegraph and telephone work, the consumption in England running into several millions a year.

Or, turn again to wireless telegraphy: this is not quite so easy as it sounds, for the entries under this heading in the index are of no use. There are two, of which one draws a blank, and the other leads to a casual reference to the subject in the article on secondary batteries. Under telegraphy we fare no better, but the recollection of the somewhat unfamiliar name of radiotelegraphy eventually leads us on the right track, only to find a bare five and a-half pages allotted to the subject. It is needless to say that no adequate treatment can be given in this space, even though one-half of it is occupied by diagrams. It is difficult to reconcile this with the allocation of four-and-forty pages to the description of electric fittings.

There is one respect in which a publication such as this is liable to compare unfavourably with the individual treatise—it is more difficult to keep up to date. If one branch of electrical engineering shows specially rapid development, it is easy for a treatise which deals with that branch alone to be revised or rewritten; but a production such as this is not likely to be revised when only one or two of its sections call

G

loudly for revision. This is the always recurrent objection to the encyclopædia, which applies with special force to an encyclopædia of so progressive an industry as the electrical. If any real attempt is to be made to maintain such a publication in the front rank, it can only be done by very frequent and thorough revision. We have certainly no ground for complaint in the present instance on the score of frequency of revision—a new edition within four years of the original issue is as much or even more than could be expected—but some of the contributors do not appear to have taken the duty of revision with sufficient seriousness, and thus, whereas some of the articles have been entirely rewritten, others in which progress has certainly been no less marked appear to have been scarcely altered.

We need make no apology in this connection for referring to the articles on electric lamps. Probably in no other branch of the electrical industry has there been more startling progress during the past three or four years. Often though the expression is abused, it is true in this instance to say that both arc lighting and incandescent lighting are being revolutionised. The article on incandescent lamps has been brought well up to date, and the information given on metallic filament lamps, if not so full as some could hope, is as full as could be expected in relation to an industry still carried on with more or less secrecy; but the article on arc lamps appears to be untouched. We have the gravest suspicion that the author does not realise what the flame arc really is; if he does, he signally fails to convey a correct impression to his readers, and, at the best, his treatment of the flame lamp is grossly inadequate.

In reviewing one of the volumes on its first appearance we ventured to suggest that, in view of the generally inferior standard of the letterpress as compared with the illustrations, the latter should be published without the former. The publishers appear to have adopted this suggestion to the extent of attaching to the inside of the back covers of some of the volumes ingenious little folding paper models of electrical apparatus to which we have been unable to trace any reference in the text. Many a pleasant half-hour may be spent by the student of electrical engineering, unable to obtain access to real electrical apparatus, in unfolding these models and trying to fold them up again in the correct order.

We are at a loss what to say in conclusion; we suppose that, so long as there is a large number of engineers anxious to write, and several willing to read, there will be an output of treatises, good, bad, and indifferent; but, personally, we have a strong disposition against buying in bulk, taking the good with the bad, "as they come," in the phrase of the market.

The beneficent uncle anxious to make a suitable gift to a budding electrical engineer may find in these volumes a useful outlet for surplus wealth, but the discriminating student will be well advised to make other investments. We can well imagine that there will be many, when confronted with so imposing an array of information in so handsome a guise, who will be unable to believe that the matter can be less good than the manner; but we are loth to think that it is a comprehensive treatise such as this which really represents what the electrician wants.

MAURICE SOLOMON.

THE THERMODYNAMICS OF THE EARTH.

Radio-activity and Geology. By Prof. J. Joly, F.R.S. Pp. xi+287. (London: A. Constable and Co., Ltd., 1909.) Price 7s. 6d. net.

THOSE who are acquainted with Prof. Joly's presidential address to Section C at Dublin last year will not be surprised at the appearance of this volume from his pen. One of the most remarkable chapters the scientific historian has yet to write is the story of the rapid progress of research into the phenomena of atomic instability. In the spontaneous disruption of atoms, showing itself in the phenomena of radio-activity, we have learned of a store of energy of immense magnitude hitherto undreamt of. The fact alone that atoms are unstable systems has enlarged immeasurably the scope of our speculations regarding all inorganic evolution, while the knowledge of the forces locked up in them has still more directly affected almost every department of science. It is impossible that the geologist should long remain indifferent to this new phase of scientific inquiry, and it is Prof. Joly's endeavour to show him that already he must give heed to its teachings, and to point out where attention must be given. As being himself an active investigator, able both as physicist and geologist, no one better qualified for the task could be found, and his work must be carefully considered by every thoughtful geologist, however much any of his conclusions may be controverted.

The volume is wisely opened with a couple of chapters in which the fundamental principles and methods of radio-active inquiry are simply but accurately explained. These we would especially commend to the reader who may be inclined to a not unnatural scepticism as to the trustworthiness of conclusions based on the investigations of quantities of material habitually measured in billionths of a gram. It is of the utmost importance, too, for the geologist to realise to what degree the intra-atomic changes are independent of physical conditions, and that such changes do not affect the atoms of radium alone, but in varying degrees those of many substances.

In the chapter on radium in the earth's surface materials we are supplied with fairly ample data on which to judge of the general distribution of this element and its associates in the rocks. It is a significant fact that the rarer an element the more uniformly it appears to be distributed in nature. In spite of the natural variation of the quantities in different rock-specimens, and of considerable divergence among the averages of different investigators, we are still left with the conviction that the almost uniform presence of radium in fairly well ascertained quantity throughout the earth's crust is assured, and may be safely assumed as a basis of speculation. The demonstration at the end of the chapter, that the well-known pleochroic halos in certain minerals are due to the radio-active discharges from the minute inclusions forming their centres, will specially interest petrologists.

Thus assured of the general prevalence of radium, Prof. Joly proceeds to trace its effects as a factor in terrestrial thermodynamics. The variations in the temperature gradient below the surface naturally suggest investigation, and an attempt is made to connect the high temperatures met with in the Simplon tunnel, and that near one end of the St. Gothard, with local variations in the radium content of the rocks. In the succeeding chapter is worked out a very ingenious theory to account for the well-known fact that mountain chains arise on the sites where sedimentation has been most extensive, *i.e.* from the great geosynclines. Having shown that the rocks cannot retain the comparative richness in radium, which they possess normally at the surface, to a depth of more than ten or fifteen miles, and that detrital rocks contain almost the whole of the radium which was in their parent rocks, it is then pointed out that denudation results in the thinning of this radium-rich surface-layer in one locality and the piling up of such material in the area of sedimentation—it leads to "a convection of energy." Not only is a much larger quantity of radio-active material accumulated in the sedimental area, but—and this is still more important—the *thickness* of the radio-active layer is there greatly increased. As a result, the heating effect is there emphasised, and the area of sedimentation becomes an area of weakness; the geosyncline becomes a mountain chain.

In natural sequence comes an inquiry whether the same cause of instability may in any degree account for the more general movements of the ocean bed which were first referred to by Darwin. This involves a preliminary discussion of the probable depth of oceanic deposits. The radium content of globigerina ooze is found by numerous determinations to be four or five times that of normal sediments, but its efficacy will depend much more on its thickness. Such meagre data as are available in the few examples of upraised oceanic sediments are carefully discussed, and a thickness of 4 kilometres is assumed as probably not excessive. This is estimated to lead to local weakening to the extent of bringing the 800° C. isotherm 10 per cent. nearer the surface, even assuming the radio-activity of the ooze no greater than that of ordinary sediments. It is, therefore, concluded that the accumulations of ooze which surround all the great coral areas may well account for some at least of their instability.

Returning again to the mountains, some of their more specialised problems are dealt with—the great overfolds and the extensive metamorphism which appears in some cases to have been effected at depths of only a few kilometres.

Finally, the larger problems of earth-heat in general are considered. Kelvin's estimate of the comparatively short interval since the attainment of the *consistentior status*, on the assumption of the simple cooling earth, is taken as evidence against the truth of that assumption. It is well maintained that the known radio-activity of the surface rocks, even if continued to only very moderate depths, is sufficient to account for all the present heat loss; and, in view of the fact that some of the loss must be due to interior heat and to decay of the radio-active supply, a limiting depth of 10 to 15 kilometres is obtained for the rich surface layer. At the same time, it is shown that the low conductivity of the rocks allows the assumption of considerable quantities of interior radium, as the interior might rise in temperature for many millions of years without the surface being affected. The determination of the age of minerals by measurement of the quantity of helium evolved from their contained uranium concludes the work. The results of Strutt are strongly criticised on the ground of their disagreement with the ages determined from the rate of accumulation of sediments and of oceanic sodium, though hope is entertained that the method may yet give accurate results.

As a kind of appendix, a useful chapter is added, explaining in detail the methods of investigating the radio-activity of the rocks.

It is necessarily easy to criticise a work of this character. Almost all its conclusions are involved in assumptions. Yet the fundamental position is sound. The radium is there, and in such quantities that its energy must be a primary factor in the evolution of the earth. Its distribution within the globe is perhaps the most crucial point awaiting settlement. On the existence of the rich surface layer of very small depth, much of Prof. Joly's argument rests. The very unsatisfactory state of our knowledge of underground temperature-gradients seriously interferes with the estimate of this depth, while the average radium content of the surface rocks can scarcely be considered as settled. Should Eve's average be anywhere near the mark, the story would be considerably altered. When Prof. Joly adduces Alpine metamorphism as evidence of radio-active heating, we think he scarcely allows sufficiently for hydrothermal action. The assumed depths of 20 to 40 kilometres, below which the rocks are supposed to yield hydrostatically, are much greater than those indicated by earthquakes and the formation of thrust-planes for the attainment of that condition. The explanation of the great overfolds of the Alps as due to the pushing of the rigid crust over these hydrostatically yielding layers might apply in that case, assuming that such folds in fact exist, but the same phenomenon may be observed on very much smaller scales, and there the theory fails. It appears to us that the estimates of the "geological age" from sedimentation and sodium accumulation are rather overweighted. The former method probably fails because the thickness of sediments is usually governed by the rate of subsidence rather than by the supply of sediment, while the data for the latter are very uncertain.

Some of the speculations may be considered rash, but the treatment of the subject is intentionally light; and it is well so. The book is full of suggestion and new lines of thought. It will compel interest, and should do much to encourage and direct investigation into what cannot fail to be a richly fruitful field.

ARCHÆOLOGY AT AVEBURY.

A Guide to Avebury and Neighbourhood. By R. H. Cox. Pp. 68. (London: E. Stanford, 1909.) Price 2s. net.

"A GUIDE to Avebury" a fascinating title, giving hope of a learned speculation as to the uses of this, the most stupendous work of ancient times in this island. Was it within the circle of this great earthwork that the astronomer-priests conducted their observations, and was the great bank thrown up to form an artificial horizon to mark the lapse of time and change of season by the movements of the sun and stars, or was it simply to veil the mysteries and maintain the secrecy of the rites of a dominant priesthood, on whom the people, in those days before almanacs were thought of, were dependent for instructions when to sow and when to carry out any other of the operations of agriculture or of life that are subject to the seasons for their accomplishment? But no! there is little upon these questions to be found in this "Guide," which gives, indeed, a sort of general introduction to the study of the ancient remains in and around Avebury, and catalogues the camps, the tumuli and the trackways to be found in a long excursion from Barbury Castle round by Oldbury Castle, Oliver's Camp, St. Ann's Hill, Rybury, and Martinsell to Marlborough, but we look in vain for any real conception of the grandeur and mystery of the place.

The maps are a feature of the book, but they are difficult to understand; on p. 22, for instance, there is nothing to show what the red lines mean, and the red spots marking tumuli and camps cannot be distinguished, and do not by their size in any way indicate which are the more important; then there are only two indications of sarsen stones, the northern labelled "Grey wethers," and we wonder if the author has ever seen the vast sea of sarsen stones near "Glory Ann" and "Totterdown."

On p. 44 we are informed that near Urchfont is the watershed between the head-waters of the Wiltshire Avon and the "Stour," an extraordinary statement, as the Stour rises some thirty miles away to the south-west, and the waters from Urchfont (Hart's fount) flow into the Bristol Avon.

On p. 53 we have the statement that the West Kennet Long Barrow is now taken over by H.M.'s Board of Works, and on the same page the author writes of it as "the Government's long barrow," all of which is pure imagination, as the barrow is no more the property of the Government than is Silbury Hill or Avebury. These inaccuracies make us chary of accepting the author's statements, but they are insignificant compared with Lord Avebury's statement on p. 6 that the earth and chalk from the ditch have been thrown up on the *inner* side, whereas, of course, the curious fact at Avebury is that the bank is on the outside of the ditch.

As the author makes no mention of the late Rev. A. C. Smith's "British and Roman Antiquities of North Wiltshire," we presume he does not know the book or the elaborate maps contained in it, showing every road and trackway, every camp, tumulus, or sarsen stone that exists, or of which there is tradition, in the 100 square miles round Avebury, and we venture to think a careful study of it would have been useful to the author.

We hoped, when the delving archæologists were collected at Avebury this summer, that something might be done to protect the most interesting relic of all—the two remaining stones of the "cove" of the northern circle—but apparently the use of these stones as protection for a hayrick was deemed quite appropriate.

R. H. C.

VENOMS AND ANTI-VENOMS.

Venoms, Venomous Animals, and Anti-venomous Serum-therapeutics. By Dr A. Calmette. Translated by E. E. Austen. Pp. xvi+403. (London: John Bale, Sons, and Danielsson, Ltd., 1908.) Price 15s. net.

WHATEVER may be thought of their reputed powers in other directions, there is no question of the peculiar fascination exercised by snakes upon the popular imagination, so that a translation of a work by Prof. Calmette, whose name in all that relates to snake-venoms and antivenoms is familiar in men's mouths as household words, is certain to command attention.

The volume consists of five rather unequal parts, dealing respectively with the classification, habits, and geographical distribution of poisonous snakes; the chemistry and physiology of snake-venom; immunisation, and the preparation of antivenoms; the venoms of various classes of animals other than Ophidia; and records and results of numerous cases of snake-bite treated with the author's antivenin.

The book is addressed particularly to medical men, naturalists, travellers, and explorers, and the author believes that physiologists also may read it with profit. Its value to the physiologist is diminished by the fact that, as a summary of our knowledge, its design is hardly catholic enough; but that it will prove of very great service to the medical man, and particularly to the medical officer stationed in the tropics, there can be no two opinions. For just those things that the medical man wants to know, and the medical officer is expected to know, about snakes—what venomous species he is likely to encounter in his own province, how those species may be recognised, how their various venoms manifest their action and to what degree they are dangerous, and on what rational principles the treatment of snake-bite is based—are here to his hand in a single volume of convenient size and of moderate price.

The first part of the book, which deals with poisonous snakes from the systematic and geographical points of view, may be described as a condensed extract of the British Museum Catalogue, leavened with remarks on habits, and finely flavoured with well-chosen figures. The British Museum Catalogue, which itself is a marvel of conciseness, does not lend itself to condensation of this sort, but the figures in this instance make it good. What one misses, in a book meant for medical men and travellers, are good, plain descriptions and diagrams giving the names and explaining the relations of all those parts of the snake's skeleton and integument that are of applied value in classification. Here there are descriptions and figures, but they do not explain *all* the terms employed in the specific and generic diagnoses; moreover, some of the terms used are not those commonly current, and some do not correspond in text and figure. Thus the well-known quadrate bone is referred to as the tympanic; and the shields which in the text are called, in accordance with the authorised British version, internasal, prefrontal, frontal, and parietal, appear in the figure under other names. Seeing that the differentiation of species, and even of genera, largely depends upon scale-characters, this is hardly a matter of little moment.

The second part, which treats of snake-venoms, describes the methods of collecting venom and the chemical composition of the secretion, and gives an account of the way in which in the laboratory the various constituents of the venom act upon the blood and tissues. The gross effects of cobra-bite and viper-bite are also contrasted. The author naturally draws largely on his own experiments, but the work of other investigators is duly considered. It is rather surprising, however, not to find any mention whatever of D. D. Cunningham, who for many years was in India the observed of all observers in this field.

The third part brings us to the cream of the subject, namely, the acquisition of immunity against snake-venom and the use of the serum of immunised animals as a cure for snake-bite. This subject is so largely the author's own that criticism can only be offered with deference. But, considering merely the way in which the matter is represented in the book under review, the author appears to rely rather too much on his own large experience with cobra-venom, and also to be hardly consistent; for although he seems to adhere to the untenable opinion that neurotoxin is the essential toxic constituent of *all* venoms, whether colubrine or viperine, he allows that cobra-antivenin is of no avail against what, by a strain of language, he calls the "local" effects of viperine venom, and he concedes the practical point that an antivenin of general efficacy can only be obtained from an animal that has been immunised against *both* kinds of venom, colubrine and viperine.

The only other part of the book that requires notice is that concerned with the venoms of animals other than snakes. Here we find many interesting fragments of information about the venom of polyps, sea-urchins, arthropods, molluscs, fishes, and amphibia. The venomous Mexican lizard, Heloderma, and the spur and femoral gland of Ornithorhynchus are also remembered, but, strange to tell, the dreadful sting-rays, the notorious jelly-fishes, and the molluscan Toxiglossa are quite forgotten.

As to Mr. Austen's translation, it is as near as possible perfect, being wonderfully faithful to the original, and yet, so far as technical terms do not interfere, good English. In the case of some of the technical terms, however, Mr. Austen's unflinching fidelity sometimes goes near to make the reader wince. There are expressions, such as "gingival fold," "ergastoplasmic venogen," "sanguinolent serosity," "laccate," "chloridate," "asporogenous," to which even the hardest-mouthed jargonmonger will object.

THE SCOTTISH LAKE SURVEY.

Bathymetrical Survey of the Fresh-water Lochs of Scotland. Under the Direction of Sir John Murray, K.C.B., F.R.S., and Laurence Pullar. Pp. viii+288; maps and plates. (London: Royal Geographical Society, and Edward Stanford, 1908.)

IN some countries it appears so natural that the national surveys should present a complete delineation of the solid surface of the land that the accident of certain hollows being filled with water does not excuse the surveyor from continuing his contour lines across the submerged slopes. With us, however, until the Survey Department was supplied with the necessary data by private investigators, no sub-lacustrine contour lines appeared even on maps of the largest scale, and large surfaces of paper remained blank save for the artistically graduated lines which indicated the difference between a water and a land surface. Most of the English lakes were surveyed in 1893 and 1894, and the contour lines appear on the later editions of the six-inch maps, with due acknowledgment of the source whence they were derived.

The volume now before us completes the preliminary publication of the survey of the lakes of Scotland undertaken by Sir John Murray and Mr. Pullar in 1896, and now brought very near completion. It represents an immense amount of work of national importance carried out at the personal cost of the authors, and its very magnitude makes it impossible to give any serviceable summary here of the additions to limnology it contains. Eighteen papers appeared in the *Geographical Journal* between 1900 and 1908, illustrated by bathymetrical maps of 213 fresh-water lochs, and this volume, published separately by the Royal Geographical Society, gives particulars and bathymetrical maps of a further series of 349 lochs, making a total of 562 surveyed and described. The number is so great that we cannot help regretting that it has not been made complete, but the rule appears to have been that no steps were taken to survey those lochs on which a boat was not available. In this way some sheets of water of considerable size and great interest have been left unsounded, a fact the more regrettable because difficulties due to sporting rights in some of the nearly inaccessible valleys in the heart of the great deer forests may prove insuperable to less known investigators in the future, while the high distinction of Sir John Murray's name might possibly have smoothed a way in the course of his great survey.

Apart from this, the record of the Loch Survey is one that Sir John Murray, Mr. Pullar and their numerous assistants may well be proud of. How great a body of work it represents may in part be gathered from the complete index, which includes all lakes described here and in the articles which have appeared in the *Geographical Journal*; but a mass of additional material bearing on the physics and biology of the waters has still to be published.

The bathymetry of the lake-basins was determined by series of close soundings in lines transverse to the long axis, and the scale of the maps is sufficiently large (3 inches to 1 mile) to allow of all the soundings being represented in figures as well as by contour lines. We think that a longitudinal line of soundings along the axis of maximum depth would have been a useful addition in all cases, and a valuable check on the transverse series. Supplementary soundings would also have been useful in many places where the exceptional run of the contours suggests some unusual configuration. Such additional lines have been run on some of the lochs, and the maps of these inspire a more complete confidence as to detail than do the others. We should have liked to see some larger-scale surveys of such individual features as the sub-lacustrine slopes of delta fans, screes, steep rocky shores, and the transition belt between the steep sides and flat floors of many of the basins.

The sounding of the large area of fresh water which fell between the two stools of the Admiralty and the Ordnance surveys is a splendid example of public-spirited private enterprise undertaking and carrying through work which should have been included in the routine of a Government department. It is, happily, not the only case in which the collective shortcomings of the nation in matters affecting the advancement of scientific knowledge have been made good by individual effort and at private expense. When the right men are at the head of such an investigation, and their labours are not trammelled by the want of means, we are of opinion that better work can be done at a smaller outlay than if the operations were conducted by an official department or under the auspices of a committee of many specialists on different subjects; but when the right men are not to be found the lack of Government interest in the completion of our knowledge of our own land and its resources may lead to unhappy consequences. It is fortunate, indeed, that Sir John Murray and Mr. Pullar have had both the will and the power to carry out the work, which, when completed by the publication of the additional material already collected, will form a noble monument to the memory of the late Mr. Fred Pullar, to whose energetic assistance the early stages of the research were so much indebted.

H. R. M.

THE OLD AND THE NEW MECHANICS.

(1) *A First Dynamics.* By C. S. Jackson and W. M. Roberts. Edited by W. J. Greenstreet. Pp. viii+412. (London: J. M. Dent and Co., 1909.) Price 5s.

(2) *Elementary Mechanics.* By Prof. C. M. Jessop and Dr. T. H. Havelock. Pp. viii+277. (London: George Bell and Sons, 1909.) Price 4s. 6d.

(1) SO many new series of mathematical school-books have appeared during the last few years that the present series has remained almost unnoticed. This is the more remarkable in view of the wide reputation of the editor, Mr. Greenstreet, and also of the fact that the contributors are also mostly well-known authorities in the mathematical teaching world. Messrs. Jackson and Roberts have fully justified the existence of their book by the amount of freshness and originality they have put into it, and particularly by the extent they have treated the subject from a common-sense, practical point of view. As the authors point out in the preface, there have been in the past two classes of book in which the relations between force, matter, and motion are dealt with. There has been, first, the book on applied mechanics, in which the principal object has perhaps been to describe machines, and there has next been the "academic" book, in which dynamics might perhaps better be described as "dogmatics," the most prominent feature of which has been a collection of exercises in algebra.

It has been the object of the present authors to make the principles of dynamics the prominent feature of their book, and to illustrate them by applications to phenomena of everyday life rather than by algebraic drill. In this they have been very successful, so far as can be judged without an extended trial of the book in the class-room.

The main crux in writing a book on dynamics is the question of units. Shall the author use poundals and please one class of teachers, or shall he use slugs and be commended by another section? It seems to have been generally forgotten that there is a third alternative which still allows those who wish to do so to replace Newton's "proportional" by "equal" in the laws of motion. That alternative is to take the gee (g) as unit of acceleration, and write force in lbs. wt. = mass in pounds and acceleration in gees; and if any writer chose to champion the claims of the gee, he could point to the fact that the foot, if defined by the length of the seconds pendulum, is really a gravitation unit of length.

Messrs. Jackson and Roberts, while discussing the two generally recognised systems, adopt the more rational plan of basing their treatment on the proportion:—

$$\frac{\text{force}}{\text{weight}} = \frac{\text{acceleration}}{g}.$$

It has been popularly supposed that this plan is theoretically good, but how would the equations of motion of complicated systems be written? Now in Mr. Jackson's hands the equations all look delightfully simple; not only is there no more difficulty than occurs somewhere in every system, but *it is very easy to see if the results written down are correct in their dimensions.* The suppression of constant multipliers in physical equations does not always conduce to simplicity; it more often causes confusion, especially in connection with electrostatic and electromagnetic units, and also in hydrodynamics, where problems of discontinuous motion are solved for jets of one particular breadth (generally π) with one particular velocity, and the solution appears inapplicable to other jets differing in size and velocity. A little doubt may occur as to whether momentum should be defined as Wv/g, as Mr. Jackson does, or simply as Wv; but this is a matter in which experience will indicate the wisest choice.

The subject-matter treated includes such applications as the instantaneous centre of a connecting rod, two-speed gears, and the elements of dynamics of rotation. There are many reasons why the latter subject should be included in an elementary treatise; indeed, the authors claim that, "frankly, unless a student means to know, in broad outline, about as much of the principles of mechanics as we have given, he may with advantage allot more time to some other subject."

In certain details the book leaves something to be desired. It would surely be better, for example, to give the rule for composition of relative velocities after, instead of before, the construction for the relative displacement and velocity of two moving bodies. The present order is a survival of the old idea that because the parallelogram of forces is the fundamental proposition in statics, the parallelogram of velocities ought to be the fundamental proposition in kinematics. In the proof of the relations between angular and linear velocity, a 60 is introduced unnecessarily and then cancelled by considering the space described in a minute instead of in the unit of time (a second) assumed in the definitions. In several places where uncertainty exists as to how much should be included in the text and what should be omitted, the final result suggests that the authors were not given sufficient facilities for making alterations when the proofs were in type. The paragraphs are unnumbered, and this is a great drawback, but the worst feature is the illustrations, which are badly reproduced, with coarse, unsightly lettering. In one of them, on p. 177, a capital V looks like a Greek γ. If books of this class are to hold their own in the field of competition, not only should the figures be above reproach, but a large amount of time and thought must be devoted to minor alterations and emendations such as only suggest themselves when the text has been seen in print.

(2) If novelty and originality is one of Mr. Jackson's strong points, this cannot be said of Prof. Jessop and Dr. Havelock's book. It brings back to memory days of long ago, with its "forces of 1, $\sqrt{2}$, and $\sqrt{3}$ lbs.," its Roman and Danish steelyard, its three classes of lever, the oar being included in the second regardless of the man's thrust on the rowlock, its mechanical advantage instead of the more modern velocity ratio and efficiency, its systems of pulleys which only lift a weight a small fraction of the height of the supporting beam—and perhaps do not lift it at all if the ropes are extensible, and its Attwood's machine neglecting inertia of pulley, in the first instance, although this is now taken into account at the end of the book. But Jessop's "Elements of Applied Mathematics" was an excellent book when it was written, and it is not the book which has gone backward in its present revised edition, only other people have moved forward. Moreover, the present reviewer can ill afford to find fault with an author who is prevented by his professorial duties from completely rewriting his text-books when his opinions on certain points have changed. At the same time, in view of the fact that revision has been undertaken by Prof. Jessop's lecturer, we think something more might have been done. The separate formulæ for the resultant at angles of 30°, 45°, and 60° might surely be struck out *now*, although the present reviewer pleads guilty of having perpetrated the same barbarisms (under protest) when he was younger and was informed that certain classes of students required them. On the other hand, the addition of sections on harmonic motion, bending moment, and shearing force (under graphical statics), and the chapter on energy of rotating bodies are valuable additions. In the latter chapter the moments of inertia of simple figures are stated without proof. Perhaps this is the best way, in view of the fact that integral calculus is now usually taught at an early stage; had this not been the case, the use of the geometric progression formula for making the necessary summations would have been recommended.

A student might do worse than use Prof. Jessop's book for algebraical drill, supplementing it by a course of experimental mechanics, or by Mr. Jackson's book; and whatever else may be said, no exception can be taken to the general appearance of the book, or the diagrams, which fully maintain the high standard that characterises Messrs. Bell's text-books.

OUR BOOK SHELF.

The State and the Farmer. By Prof. L. H. Bailey. Pp. xii+177. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1908.) Price 5s.

Less than a generation ago farming and farmers made very small figures in the public eye; men of affairs, when they gave the subject a thought, regarded British agriculture as a dying craft, something that had ceased to pay and might be left to extinguish itself quietly, leaving the country for the recreation of the town-dweller, to provide sport for the rich industrial, health and the gratification of his æsthetic tastes for the employee. Business men paused sometimes to make pharisaical remarks about the wastefulness of the farmer; men of science scolded him for sticking to his old ways, not adventuring his substance on the crude generalisations which were put forward to represent the infinitely complex life of animals and plants; the politician had no use for the agriculturist, whose vote he knew was safe in the landlords' pockets; and the journalist saw little but comic copy to be got out of Hodge and its ways. As Sir Horace Plunkett said in his British Association address, modern civilisation has joined the rural exodus.

But latterly there have been signs of change; the triumphal march of industrial progress, with its concomitants of vaster factories and ever extending suburbs of mean streets, has proved less satisfying than its prophets had promised; the nation has begun to awake to the essential instability of such a system, and to the need of keeping up agriculture as the soundest basis of the State and the only means of creating wealth, whether of men or things.

To some men the necessity of drawing men back to country life seems little less than a holy cause into the service of which they are ready to put their whole strength, and among such men Prof. L. H. Bailey, of Cornell, is perhaps most prominent on the other side of the Atlantic. In the little book before us Prof. Bailey pleads for the better organisation of rural life with eloquence and conviction; rural life, not merely because it pays, but because it is the life best worth living, most calculated to raise a sober and strenuous race of men. The author's particular text is the function of the State in fostering agriculture; left to himself, the farmer is normally a strong individualist, who readily becomes isolated and hidebound. His sole chance of success in modern life is collective action, and Prof. Bailey discusses in successive chapters the extent to which the State can profitably intervene in the organisation of rural life by education and by starting various forms of cooperative work which will lead the farming community to act together. Different as the agricultural conditions are in this country and in America, the problems are the same in both places, and Prof. Bailey's discussion of the subject gains a special interest for us at this moment, when the Chancellor of the Exchequer has just set aside a "development grant" to be devoted to the promotion of all agencies for encouraging rural life.

The Problem of the Feeble-minded. An Abstract of the Report of the Royal Commission on the Care and Control of the Feeble-minded. With an introduction by Sir Edward Fry, G.C.B. Pp. x+113. (London: P. S. King and Son, 1909.) Price 1s. net.

THE appearance of this abstract is most opportune. The small committee of persons interested in social problems which is responsible for its publication is anxious to bring before as large a section of the public as possible the urgency of the matters in question, and points out in the preface of the book that the Poor Law Commissioners have given it as their opinion that if the recommendations of the Commission on the Care of the Feeble-minded were carried into effect, a system of control over the feeble-minded would be initiated which would free the Poor Law administration from one of its greatest difficulties and, we may add, the country from a cause of enormous expenditure. In his introduction Sir Edward Fry quotes Bagehot's sad reflections upon the undue haste and benevolent thoughtlessness with which so much philanthropic effort is attended, and the terrible question which he poses as to whether the benevolence of mankind does not do more harm than good. Sir Edward Fry can, however, recommend the work of the Commission on the Feeble-minded as one done with deliberation and not with "a wild passion for instant action." The various problems which came before the Commission, such as mental defect and drink, mental defect and crime, and mental defect and illegitimacy, are adequately epitomised, and the far-reaching recommendations of the Commission duly considered as to the essential points. The book also contains some special articles, of which that upon segregation, by Mr. Galton, we can especially recommend to our readers.

The Economy and Training of Memory. By Henry J. Watt. Pp. viii+128. (London: Edward Arnold, 1909.) Price 1s. 6d. net.

THE training of the memory is undoubtedly a part of any good education, and it has hitherto been too much the peculiar field of the faddist and of ingenious but ignorant *a priori* system-makers. This little book, which aims at making of practical value to student and teacher the results of scientific experiment into the subject, is therefore to be welcomed. It is true that some of its precepts appear obvious, but where there are so many conflicting truisms the selection of the right obvious is not unimportant; and much definite information is given on particular points where the merely empirical adviser is quite at a loss, *e.g.* the advantages and disadvantages of specific types of mental imagery, and the variations of method corresponding to differences in the material to be memorised. Moreover, if the book did no more than free the ordinary adult from that excessive distrust of his memory, which is so bad in effect, and is, perhaps, too optimistically believed by Mr. Watt to be quite ungrounded in fact, it would be abundantly justified.

Mr. Watt considers the mechanical memory of association to be, in a sense, more fundamental than the intelligent memory based on connection of thought, since the association between word and "meaning" is in itself mechanical. It seems doubtful if that ultimate "association" of meaning and imagery can be expressed so simply; but the point, though of great interest, is of minor importance in a confessedly practical book.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Rate of Helium Production from the Complete Series of Uranium Products.

A KNOWLEDGE of this constant is essential to the estimation of the ages of minerals from their helium content. In a paper published in Proc. Roy. Soc., July 28, 1908, I gave the ages of some minerals provisionally on the assumption that the rate was $9 \cdot 13 \times 10^{-8}$ c.c. per gram U_3O_8 per annum. This rate was calculated from Rutherford's indirect data. It has received much support from Sir J. Dewar's determination of the rate of production by radium with its immediate products. I am now in a position to confirm it further by an experiment on the rate of growth of helium in a solution of pitchblende; I speak of *a* solution, but it has been found impracticable to take up all the constituents by one solvent. Two solutions were necessary.

The pitchblende solutions contained 115 grams of U_3O_8, and yielded in sixty-one days a quantity of helium which was measured as 2×10^{-6} c.c. in the capillary of a McLeod gauge. This gives the rate as $10 \cdot 4 \times 10^{-8}$ c.c. per gram U_3O_8 per annum. No stress can be laid on the close agreement with Rutherford's estimate in view of the very small gas volume measured. The experiment proves, however, that that estimate is of the right order of magnitude. Larger scale experiments are in progress, and these, in conjunction with similar experiments on thorianite, will, it is hoped, enable data on the quantity of helium in minerals to be translated into estimates of time with full confidence. R. J. STRUTT.

Imperial College of Science, South Kensington,
July 27.

A Kinematic Illusion.

PEOPLE are sometimes amazed by noticing that in a motor-car seen through railings the wheels appear to revolve the wrong way. As the eye follows the moving objects it is convenient to imagine that the car, which may be actually running to the right, is stationary, while a vertical rail is moving past it to the left with an equal velocity. The apparent intersection of this rail with the upper edge of the wheel is a point running round in a contrary direction to that of the rotation of the wheel. This moving point suggests rotation of the wheel. When oblique lines swing in front of vertical lines the movement of the intersections is curious to watch. It is true that the lower half of the wheel goes against our theory, but at a given moment its effect may be less noticeable, either from being hidden in dust or because the eye has a very small range of close attention. I have seen the appearance, and have had reports of it from others, but cannot speak with precision as to the condition of seeing it effectively.

It is common to rotate vacuum tubes while a discontinuous spark illumines them. A spark may pass at the instant of starting one revolution, and the illumination may recur slightly before or after the beginning of a second round; in either case there is a false suggestion as to the rotation. The railings would make discontinuous vision of the spokes of the motor wheels, and a spoke might be seen upright in one gap but at slightly different angles at other gaps. I do not feel that the solution of the problem lies in this direction.

Winchester College. W. B. Croft.

Natural Selection and Plant Evolution.

Many readers of Nature must have been browsing with delight in the goodly volume on "Darwin and Modern Science" which Prof. Seward, of Cambridge, has taken such admirable pains to collect. Of all its many chapters few are more significant than that on the palæontological plant record by Dr. D. H. Scott, because there, perhaps for the first time, the evidence of the fossils with regard to the influence of natural selection has been fairly tackled by competent hands.

Dr. D. H. Scott does not attempt to maintain that the record to-day is nearly so imperfect as it was when Darwin wrote his famous chapter thereanent, fifty years ago. Dr. Scott's namesake and collaborator from Princeton speaks even of the record as, in some parts, "crowded with embarrassing wealth of material"; and yet what about evidence of natural selection? The present writer ventured to say (*Contemp. Rev.*, July, 1902, p. 83):—"Modern palæobotanists furnish us with next to no evidence at all of the work of Natural Selection in evolving new species." Prof. Seward vehemently challenged my statements next month; yet, seven years later, Dr. Scott feels constrained to tell us:—"As regards direct evidence for the derivation of one species from another there has probably been little advance since Darwin wrote."

To put it more plainly, Dr. Scott is forced to admit that he can adduce absolutely no satisfactory evidence at all. All he does is to affirm his own firm conviction (as it is Prof. Seward's too) that natural selection must have been the chief agent; and he instances two cases where he thinks the possible inference extremely plausible, viz. (1) the case of the pollen tube, quite absent in the Palæozoic seed-plants, found very short and imperfect in the living cycads and ginkgos, and fully developed in the angiosperms, but fossil proof of linking forms there seems none; (2) the embryo in the angiospermous seeds, whilst Palæozoic seeds contain none. It may, as he says, be "impossible" to some "to resist the conclusion" that the nursing of the embryo by the seed was a process of adaptation. But, at any rate, there is no fossil proof thereof; and yet, as Dr. Scott will scarcely deny, there surely ought to have been some hint and trace thereof, the record being so comparatively rich and full as it is. In the case of the Tertiary mammals the action of natural selection can be very clearly demonstrated in numberless cases. If natural selection was *the* factor in plant evolution too, why is the record so obstinately silent?

Dr. Scott, like Prof. Seward, takes refuge in the thought that our plant record, for many purposes, begins far too late. "An immense proportion of the evolutionary history lies behind the lowest fossiliferous rocks." My chief object in writing this letter is to ask, Is there any valid proof of this in regard to *land plants*, the matter specially in hand? Their record begins, actually, in the Upper Silurian, and though it is very, very meagre and imperfect, the traces are too widespread to be denied. To deny the existence of known Upper Silurian plants is rankest scepticism, though Dr. Scott avoids all reference to them whatsoever. Why, even so very cautious an investigator as Mr. Robert Kidston tells us of "a plant showing woody structure," a plant so high as that, in the Lanarkshire Ludlow beds (Summary of Progress of Geol. Survey for 1897, p. 74). The most important Upper Silurian plant-remains are probably those from the Tanne Greywacke of the Harz, a fairly numerous and well-developed series, of age a good deal lower than Wenlock. Drs. Scott and Seward ("Encyclop. Brit.," Supplement) wish to pronounce all these fern-like and other plants Devonian, because of their facies; but Sir Archibald Geikie ("Textbook of Geology," ii., p. 976) tells us that these Tanne plants are found a long way below shales with graptolites, which surely is proof enough of Silurian age.

We have, then, fair evidence of land plants in the Upper Silurian. Our very first air-breather or land animal, a cockroach, comes from the top of the Lower Silurian; and the fossil record of the whole Silurian is rich, varied, widespread, without gap. Yet it yields no hint of conditions favourable to land life below the top of the Lower Silurian. Is it, then, scientific to postulate dogmatically land plants earlier than the Silurian, simply because a theory requires it? Dr. Scott admits quite freely that the known facts go the other way.

He tells us not only of the opposition of the mighty like Nägeli, he also tells us that, as regards the succession of species, there are no greater living authorities than Grand'Eury and Zeiller, and that, in their opinion, "the evidence from continuous deposits favours a somewhat sudden change from one specific form to another." This is most certainly true of the palæontological record as a whole. The evidence is overwhelming here, if only our men of science would be brave enough to forget their theories for a little while. Why insist on exalting the *a priori* methods of the schoolmen on the fair field of modern science? Why insist on refusing all evidence that does not suit? Why? Surely it is not, and cannot be, to enjoy the pleasure of barring out all design from the world in which we dwell.

James B. Johnston.

Musical Sands.

I cannot call to mind the occasion upon which Dr. Irving suggested that grains of hyaline quartz might produce the notes from musical sands, but, as a matter of fact, the grains do not "ring," or vibrate individually as sonorous bodies, and there is no apparent resonance or sensible continuance of the note after the plunger is withdrawn. I do not think any particular variety of silica is essential, because coral-sand is often musical, and my artificial musical sands are made up almost entirely of silicate of iron.

I have already shown that the natural sorting action of winds and waves is a requisite condition for the formation of musical patches on sea-beaches.

Mr. M. S. Gray's letter in Nature of July 29 giving interesting particulars of his visit to the musical sandhill near Copiapo, in Chile, confirms the statements made by the inhabitants to Darwin in 1835. In his "Journal during the Voyage of H.M.S. *Beagle*" Darwin referred to this hill of sand as "El Bramador"—"the roarer or bellower," but he did not personally visit the spot.

The extraordinary sensations experienced by Mr. Gray were probably similar to those which have been described by the various writers who, from time to time, visited Rig-i-Rawán and Jebel Nakous, both of which were referred to at length in my paper on musical sands in 1888. Particulars of the artificial production of notes from certain sands were also given by me in Nature of August 6, 1891.

Cecil Carus-Wilson.

A Question of Percentages.

If a student obtains 37 out of 50 in one paper, 50 or full marks in a second, and 71 out of 100 in another, what is his percentage on the three taken together? If we add the marks as they stand we get 158 out of 200, or 79 per cent. If, on the other hand, we double the marks on the first two papers, we have 74 per cent., 100 per cent., and 71 per cent. If we add these we get 245 out of 300, or $81\frac{2}{3}$ per cent. Will any of your mathematical readers kindly tell me which of these two different results is the true percentage for the three papers taken together? The answer may be very obvious; I can see that the two results must be different, but I cannot see which is the more correct method to use.

J. T. Cunningham.

60 Milton Park, Highgate, N., July 24.

THE UPPER CRETACEOUS IGUANODONT DINOSAURS.

DISCOVERIES of the last few years in Wyoming and Montana have thrown a flood of light upon the great herbivorous dinosaurs of the Upper Cretaceous which Joseph Leidy named Trachodon, so that now they are by far the most completely understood group of the dinosaurs, not excepting the famous iguanodonts of the Wealden or Lower Cretaceous of Bernissart.

It has long been known that Trachodon is readily distinguished by the elaborate and compound nature of its multiple grinding teeth, which present as great an advance upon those of Iguanodon as the teeth of Equus do upon those of the Eocene Orohippus; but there prove to be other characters indicative of the fact that Trachodon followed a fundamentally different line of evolution from that initiated by Iguanodon, or by the nearly contemporary, closely related Camptosaurus of America. These true Lower Cretaceous iguanodons are probably typical terrestrial forms, as shown in the familiar restorations of the Bernissart specimens, possessing a short manus with the first digit set well apart, as if adapted to grasping the branches of trees or shrubs, or to supporting the animal while browsing.

Trachodon also has been represented as a terrestrial animal. One of the skeletons mounted under the direction of Mr. F. A. Lucas in the United States National Museum, and another mounted under the direction of the late Prof. Charles E. Beecher in the Yale Museum, represent the animal in a walking or running position, using the tail as a balancing organ. On the other hand, Mr. Barnum Brown, who has been the leader of the American Museum expeditions, under the writer's direction, to the Laramie or Upper Cretaceous of northern Montana since 1902, is convinced that these animals were principally aquatic or swimming forms, which used the tail chiefly for propulsion through the water, a view shared by Mr. Charles H. Sternberg, another field explorer. It may be added parenthetically that observation in the field often affords the most important indications as to mode of life.

It will be interesting to discuss the question of the appearance and habits of these animals from materials in the American Museum, which are being very thoroughly studied by Mr. Brown in preparation for a memoir. Of the two skeletons represented in the accompanying photograph (Fig. 1), this museum has acquired three skeletons. The one mounted in the quadrupedal pose (Fig. 1) was discovered in South Dakota, north-east of the Black Hills, by Dr. J. L. Wortman, in 1882, while collecting for Prof. Cope. It had been complete, and the skeleton was surrounded by impressions of the skin, most of which were destroyed during excavation. Some epidermal parts were preserved on the broad bill, showing an interlocking, tooth-like series of points on the horny sheath. As the skeleton lay in the rocks a stream had cut through it, carrying away both femora, most of the pelvis, and twelve presacral vertebræ. The erect specimen (Fig. 1) was found in central Montana by Mr. Oscar Hunter in 1904, and originally "swapped" for a "six-shooter" revolver. In 1906 it was purchased by the American Museum and excavated by Mr. Brown. An important feature of this skeleton was that the vertebral column was connected throughout, and all the bones which the Cope specimen lacked were preserved, together with both lower jaws and two bones of the skull; the rest of the skull is restored after the Cope specimen. In both specimens the tip of the tail is missing.

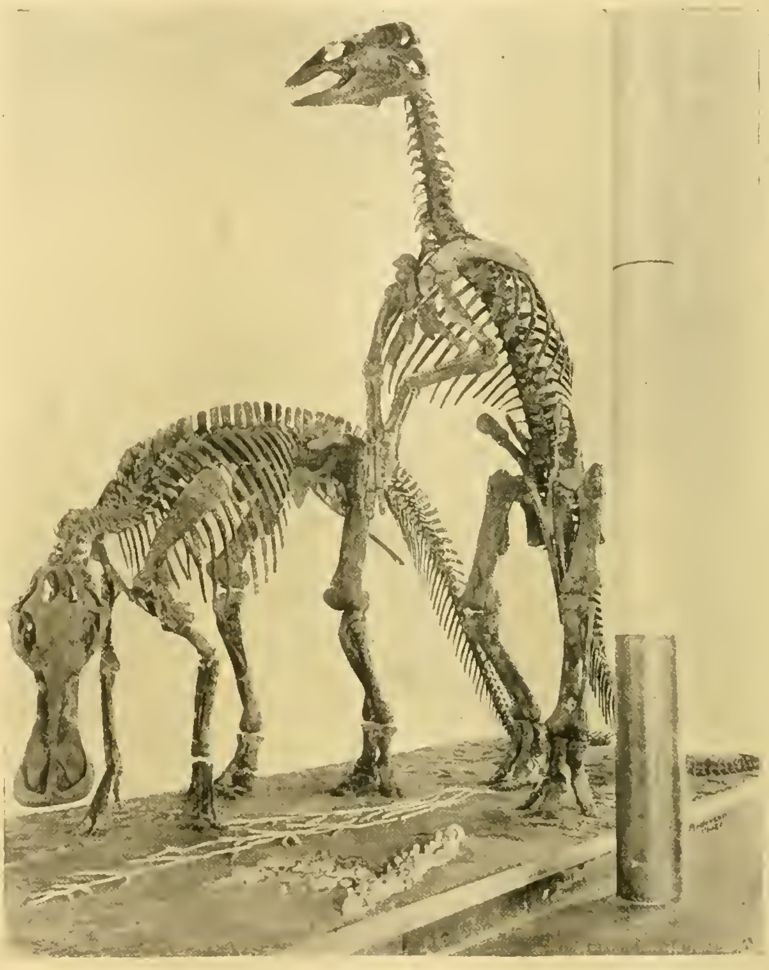

FIG. 1.—Oblique front view of two specimens of *Trachodon mirabilis* as mounted in the American Museum of Natural History.

The difference in the preservation of these two animals partly controlled the design which has been adopted for the mounting; the animal with the perfect head, well known through the descriptions and figures of Cope as *Diclonius mirabilis*, is represented in a feeding posture, which brings the head where it can readily be examined, while the imperfect skull of the second skeleton is "skied" where it cannot be seen. The conception of this group takes us back to the close of the Cretaceous period, when trachodons were among the most numerous of dinosaurs; as two of them are feeding along the marshes, one is startled by the approach of a carnivorous enemy, Tyrannosaurus, and stands on tip-toe better to overlook the foliage; the other, unaware of danger, continues browsing. On the base of the group are shown impressions of leaves, fruit, wood, and shells, replicas of fossils actually associated with the bones of Trachodon. The leaves of the ginkgos, natives of China, were mingled with the cones of Sequoia, or big tree of California. Horsetail (Equisetum) rushes were abundant and luxuriant in growth, an imperfect specimen here represented measuring sixteen feet in length. Fruit and leaves of the fig are also abundant, and with the leaves of a species of banana and numerous palms attest a warm climate in the northern United States during the period.

Hardly was this carefully studied group completed late in 1907 when the fortunate discovery was made in Converse County, Wyoming, in August, 1908, by Messrs. Charles and George Sternberg, father and son, of another specimen of Trachodon with the epidermal impressions very extensively preserved. This completes our knowledge of the animal. Among many other new features it especially brings out the very important difference between the fore feet of Trachodon and of Iguanodon. As noted above, the manus of Iguanodon is a short organ with grasping function. In Trachodon the manus is long and very slender; the thumb, or first digit, is not free, but closely appressed to the side, and still more remarkable is the fact that the entire hand was encased in an epidermal web, so that the digits are not freely movable, but closely united, and thus strongly indicative of a paddle function while moving in the water. This bears directly on the question whether these animals were aquatic, amphibious, or terrestrial. The terrestrial theory may apply to Iguanodon, but certainly not to these animals. The littoral or amphibious theory was that held by Prof. Cope. The familiar restoration by Charles R. Knight, which was made under his personal direction, represents one Trachodon on the shore in a sitting position, a second wading and feeding in shallow water. The enormously powerful hind limbs, provided with three large digits incased in hoofs, together with the long lines of osseous tendons connecting the vertebræ of the back with the vertebræ of the tail, both point to capacity for land progression on the hind limbs, with the use of the tail as a balancing organ. No habitually swimming animal would retain such limbs or acquire such inflexibility of a large region of the backbone as is suggested by the ossification of the tendons. On the other hand, river-frequenting or littoral habits are indicated first by the webbed nature of the epidermis on the fore feet, as well as by the observation of Mr. Brown that of all Upper Cretaceous dinosaurs these are the only ones the remains of which are found in off-shore marine deposits. This fact may be cited as a proof, either that they frequented shallow- and still-water bays of the sea, or that their remains were carried seaward in rivers.

Fig. 2.—A portion of the tail of *Trachodon mirabilis* preserving the pavement epidermal scales.

The position selected for the group accordingly represents these animals as on a ripple-marked shore; one, the Cope specimen, in the quadrupedal position, with the tips of the digits of the manus lightly resting on the ground rather as balancers than as supporters. This is the first time an iguanodont has ever been mounted or represented in this position, and the justification for it is found in the fact that the fore limbs do readily reach the ground and terminate in expanded phalanges, which indicates the retention and occasional use of hoofs. If the trachodons in this phylum had never assumed a quadrupedal position, or used the fore limbs in this way, it is safe to infer that the limbs would have been either still more reduced and degenerate, or else the digits would have spread or expanded into true swimming paddles.

This method of mounting two or more specimens together, but in different poses to illustrate the supposed habits of feeding and of locomotion, is one which is being generally adopted. In the present case it brings out in side and rear views every important feature in the osteology of these animals. By an accident the tail in both these specimens terminates at the same point, but in other specimens in the Yale and National Museums smaller terminal vertebræ have been found which would add about five feet to the tail beyond the parts preserved in these specimens.

The actual height of the head above the ground in the standing Trachodon is seventeen feet; the total length of the body is thirty feet. Remains of still larger individuals of this species have been found which indicate greater height and length.

It is first of all evident from these skeletons and models that these Trachodons, like all the iguanodons, were full-chested and slim-wasted, to use the terms of fashion; while the longitudinal diameter of the pelvic region is enormous, the vertical diameter is very slight. Thus the proportions of the abdominal girdle directly reverse those of the Sauropoda and carnivorous dinosaurs, in which the vertical diameter is the greatest. The shape of the chest is exactly preserved in the new Sternberg specimen, as well as in the indications of the muscular outlines of the limbs and of the presence of a dermal frill on the neck and anterior part of the back. The neck and chest regions are relatively short. The gape of the mouth is placed exactly at the front of the great rows of grinding teeth, as in the mammals. There is evidence that the skin was thrown into loose folds at the junction of the arms and legs with the body, as well as on the sides of the chest.

The Trachodon with the epidermal impressions was found in the region of Converse County, Wyoming, made famous by the explorations of Hatcher for remains of the great horned dinosaurs or Ceratopsia. The entire animal lay in a normal position on its back. The left fore limb was outstretched at right angles to the body, while the right fore limb lay stretched over the under surface of the head. The hind limbs were drawn up and doubled on themselves. The hinder portion of the pelvis and the entire tail had been removed by erosion. The epidermal impressions are best shown on the throat and anterior part of the neck, on the arms and fore limbs, the entire right side of the body, including the axillary region, and especially over the abdomen. The skin is inflected like a curtain over the entire abdominal region without a single break, with brilliant impressions of the scale pattern. This abdominal infolding, the close appression of the skin to the surface of the bones, and the sharp transverse folds all indicate that after death the body was exposed for a long time to the sun, and the muscles and viscera became completely dehydrated; in other words, the body became thoroughly dried and mummified, while the epidermis became hardened and leathery under the action of the sun. In this condition the dinosaur mummy was caught in a freshet, and rapidly buried in fine river sand, which took a perfect cast of the epidermal markings before the tissues disintegrated under the solvent action of the water.

There is no evidence in any part of the epidermis either of coarse tubercles or of overlapping scales;. on the contrary, the epidermis is extremely thin, and the markings are very fine for an animal of such large dimensions. In all parts of the body observed, the epidermis is covered with scales of two kinds—namely, smaller tubercular scales and larger pavement or non-imbricating scales. The latter are perfectly smooth, and, as grouped in clusters or rosettes, assume a rounded or irregularly polygonal form. Over the throat, neck, sides, and ventral surface these clusters are regularly disposed in different patterns, separated by rows of finer tubercular scales, but in the tail, as indicated in the specimen of *Trachodon mirabilis* (Fig. 2), it is probable that the cluster arrangement disappears, and that the entire tail is covered with the tesselated or pavement scales. The vigorous use of the tail among Iguanodontia as a balancing, and perhaps partly as a swimming, organ would lead us to expect this strong development of the scales in the tail region. This disposition of the scales into larger pavement groups and smaller tubercular rows is unlike that observed by the writer in any Lacertilia; it appears to be unique.

NATURE STUDIES IN NEW ZEALAND AND AT HOME.[1]

(1) MR. THOMSON is well known among zoologists by his discovery of Anaspides, a very interesting genus of Crustacea, on Mount Wellington, Tasmania. In this volume he has collected observations made in the neighbourhood of Dunedin during the last thirty years. The articles appeared originally in the New Zealand Press, and were obviously written without any intention of subsequent issue in volume form. They are necessarily somewhat slight, and touch upon a great variety of topics without systematic treatment. Yet they possess a value which often attaches to first-hand observation written down at the time, for the animals and plants of the island are undergoing a rapid change. Destruction of the bush and the importation of a European element has transformed the neighbourhood, not only of Dunedin, but of other parts of New Zealand. The indigenous plants, insects, and birds are, in many places, becoming scarce, or have disappeared, and only a few more tenacious or more resistent have survived the process of change which has accompanied the development of the South Island. Hence these notes of garden and field life will be of interest to all who are anxious to preserve records of older societies, whether of animals or plants. It would be of the greatest interest to discover how rapidly and completely the introduced flora and fauna acquire the new periodicity of the seasons in New Zealand, and Mr. Thomson's notes may give the requisite stimulus to observers for further investigation on the indigenous and alien organisms of that country.

(2) This work has already appeared in serial form, and will prove a welcome gift-book to many a budding naturalist. The illustrations are excellent, and bring

out the characteristic features of the subject with the utmost faithfulness; the topics range from thunderstorms to valley formations, and through a great variety of field and garden forms of life. Amongst such a feast of good things it is invidious to select, but we may mention the articles on British carnivores and rodents, on the grasses and sedges, on the "cryptozoic" fauna, and on certain British trees, as among the most attractive. The physiographical papers by Dr. Lockyer, Mr. M. Duncan, and the late Mr. Lomas are of great interest. No more fascinating work could be easily suggested that would appeal to the eye with such success as this volume does, and though the text is of unequal merit, it has throughout the advantage of being the work of trained observers in the field.

(3) By this new volume of Prof. Farmer's "Book of Nature Study" the student is introduced to plant life. The headings of the first four chapters seem to us remarkably chosen. They may be summarised thus:—Seeds and seedlings, the bud and its growth, vegetative methods of reproduction, the importance of hairs. Surely this is a very inadequate and unequal manner of treating the subject. Miss Laurie has, however, described the objects under discussion well, and the illustrations are good. May we point out that two of the experiments could not be got to work as described and figured? An incompletely described experiment is worse than useless in an elementary book. On p. 40 (Fig. 29) carbon dioxide would enter by the lower edge of the bell-jar, and thus vitiate the experiment. One inch of water is, of course, needed. Fig. 30 (p. 50) represents an experiment which even the author would find physically impossible to set up in the manner described. Sufficient stress, furthermore, is not laid on the fact that all parts of the plant breathe. On p. 56 the storing function of the stem is not referred to. We must, in fact, state that the four chapters give one an inadequate idea of plant life. Prof. Lang's chapters on some flowering plants require no comment. We have here a few flowers, or, rather, complete plants carefully described. The types chosen are readily obtained, and thus every student can have a living plant by his side when working through the descriptions in the book.

RESEARCHES AT THE NATIONAL PHYSICAL LABORATORY.

VOL V. of the Collected Researches of the National Physical Laboratory, which has recently appeared, consists of reprints of thirteen memoirs emanating from the laboratory, and extends to 266 pages. Engineering subjects are answerable for about eighty of these pages, while the rest are about equally divided between electricity, metallurgy, and cosmical physics.

Of the engineering memoirs that dealing with wind pressures is of great importance. By experiments on plates and on lattice-work structures, both in natural winds and in pipes within which a uniform flow of air was maintained, it is shown that the pressure is proportional to the square of the velocity, and further, that the actual pressure on a lattice-work structure when exposed to the wind may be found by observations taken on a small model placed in a pipe through which a uniform current of air is flowing.

A second memoir of interest to engineers is that on a new fatigue test for metals. The material tested is in the form of a ring, which is kept rotating about its own axis under pressure by means of three rollers which bear on its outer surface. Under a test of this kind the superiority of nickel steel rails for railway work is well brought out.

In the electrical section, one of the most important memoirs deals with the history of the standards of electrical resistance kept at the laboratory. The ultimate standards are of mercury in glass, and were first set up in 1902. They show no change in the interval, but many of the secondary standards have increased in resistance by a few parts in 10,000 since they were constructed, some ten, others twenty, years ago. Some of the secondary standards have, however, proved more satisfactory, those of platinum, some of those of platinum-silver, and some of the manganin ones, appearing to be unchanged.

As the result of a comparison of the new electric current balance of the laboratory with the standard ampere balance of the Board of Trade set up fourteen years ago, it appears that the two agree to within 1/100th part of 1 per cent.

In the metallurgical department the alloys of lead and tin have been investigated in considerable detail, both thermally and microscopically, and the eutectic found to be 37 per cent. lead, 63 per cent. tin. A new method of determining the phosphorus in phosphor tin has been also worked out, and promises to be both shorter and much more convenient than the older methods.

Only a portion of the work of the department which deals with cosmical physics is recorded in this volume. This portion consists of a discussion of the magnetic declination as recorded at Kew during the years 1890–1900 in the light of, or, rather, the obscurity provided by, the multitude of theories of terrestrial magnetism now in the field. It is shown that the records are incompatible with any theory which regards magnetic disturbances as directly dependent on the area of the sunspots visible at the time. From the report of this department we note that at Kew the mean declination during 1908 was 16° 16′ W., the mean dip 67° 1′ N., and the mean horizontal force 0·1852 c.g.s. units. By the end of the present year it is hoped that the new observatory at Eskdalemuir will be in full working order, many of the recording instruments being already installed.

From this short summary it will be seen that vol. v. is well worthy to rank with its predecessors, as a contribution to science of which the nation may feel proud.

C. H. L.

JOHN REID, 1809–1849.

UNDOUBTEDLY 1809 was an *annus mirabilis*. Nineteen hundred and nine is, therefore, the hundredth anniversary of the birth of certain great ones in letters, in politics, and in science. Several epoch-makers have their statues in the intellectual Valhalla of the nation, but it would not be well if we allowed the statues on their pedestals to make us overlook the busts in the smaller niches. One of the busts in the Hall of Shades is that of the Scotsman, John Reid, born April 9, 1809, the son of a cattle-dealer, dying July 30, 1849, Chandos professor of anatomy and medicine in the United College of St. Salvator and St. Leonard in the University of St. Andrews. Forty-nine years only intervened—they were filled with the activities of a strenuous Scottish character.

John Reid, the sixth child of Henry Reid and Jean Orr, his wife, was born in the little town of Bathgate in Linlithgowshire, the same in which two years later James Young Simpson, the epoch-maker, first saw the light.

From his native parish school, Reid passed, at the age of fourteen, to the University of Edinburgh. In 1824 he entered for the classes of humanity and Greek; in that year "Richard Owen, Lancaster," was a fellow-student. In 1825 Reid "signed on" for the class of chemistry, and thus entered the faculty of medicine; two years later, "James Simpson, Linlithgowshire," did the same thing. In 1825 the third Munro was in the chair of anatomy, which he was to occupy for forty-eight years, and William Pulteney Alison in that of the "Institutes of Medicine," a subject he taught from 1821–42. From the former, Reid got the least, from the latter the most, inspiration which as a student he received from his teachers.

Early in his studies, Reid showed a preference for anatomy and physiology, and as these formed part of the one and "final" examination for the degree of M.D. (there being no M.B.), Reid dissected from the beginning to the end of his student days. He graduated on August 7, 1830, his Latin thesis being "De aneurismate."

Reid was, therefore, dissecting during 1827 and 1828, the very years in which the Burke and Hare murders were committed. It is believed that "the rooms" both at the University and at Dr. Knox's (Surgeons' Hall) were supplied by the miscreants just named.

His parents had hoped that Reid would study for the Church of Scotland; after having graduated, he himself thought of a surgeonship in the Royal Navy; but neither the Church nor the Navy was to have him whom Science had marked for her own.

Early in 1833 Reid received an invitation from Dr. Knox to become his assistant at Surgeons' Hall, so large had the classes there become. Prof. Monro's dullness had driven the majority of the students over to Knox's rooms. For three years Reid demonstrated for Knox, and so laid for his subsequent physiological researches that surest of all foundations—a sound knowledge of human anatomy. For the session 1835–36, John Reid was one, and J. Y. Simpson was the other, of the presidents of the Royal Medical Society, which presidentship has always been regarded as the "blue ribbon" of the Edinburgh Medical Societies.

Towards the end of 1836, Reid received a most gratifying invitation to succeed Dr. Fletcher, lately deceased, as extra-academical lecturer in physiology. The requisition was signed by no fewer than eighty-six persons, one of them being later the well-known writer on physiology, Dr. W. B. Carpenter, of London University. They asked him to accept the lectureship, for, by so doing, they said, he would "increase the reputation of this city as a school of medicine." "The zeal and success with which you have hitherto prosecuted physiological investigations being already well known to the public." Reid replied to this flattering invitation in the most modest way, and immediately consulted Prof. Alison. Alison not only advised him to take the step suggested to him, which virtually transformed Reid into Alison's own rival, but he proposed him for the Fellowship of the Royal College of Physicians of Edinburgh, into which learned body he was admitted on October 4, 1836.

During 1835 and 1836 Dr. Reid published papers upon obliteration of the vena cava superior at its entrance into the heart; phlebolites; peculiarities of the fœtal circulation; monsters; mesenteric glands in the whale; transposition of abdominal viscera; venisection relieving the heart; and the anatomy and physiology of the heart.

During the next two years Reid carried out the most important of his experimental researches—namely, that into the functions of the ninth, tenth, and eleventh pairs of nerves. Hughes Bennett tells us in his "Memoir" that between 1836 and 1838 he performed upwards of one hundred experiments on animals in order to unravel the functions of the so-called "eighth pair of nerves." A copy of this paper lies before me; it extends to sixty-two octavo pages, and consists of a thorough investigation into the activities of the glossopharyngeal, the pneumogastric, and the spinal accessory nerves. After giving a full account of the French, German, and Italian literature accessible to him, he details the experimental procedures employed to arrive at an understanding of the functions of the many branches of these three great nerve-systems. When we consider the technical difficulties under which he worked, having no stimulus more satisfactory than the galvanic current or chemical or mechanical irritation, no anæsthetics other than prussic acid and morphia, and the knowledge of no procedures known as antiseptic, we are amazed that he discovered so much and of so elusive a character. This work on the nerves was his *magnum opus*, probably the last important piece of work in physiology anterior to the introduction of the stimulus of the "interrupted current" from the laboratories of Germany. It is curious to notice the absence of tracings in the paper; Reid was the last pre-graphic physiologist in Scotland. Amongst other things long since fully corroborated, Reid showed that the heart had the double innervation through the vagi and the sympathetic. He came within a very little of discovering the cardio-inhibitory functions of the vagus. The memoir was published in full in the *Edinburgh Medical and Surgical Journal* (No. 139), but an *epitomé* of it had been read at the Liverpool meeting of the B.A. in 1837.

One or two paragraphs from this admirable paper are worth quoting in the light of to-day:—"It may appear to some that I have repeated many of these experiments with unnecessary frequency and a wanton sacrifice of animals, but I naturally felt diffidence and distrust in the accuracy of the results I obtained when opposed to those of more experienced observers, and it was only after repeated and careful examination of the phenomena that I could feel myself justified in calling these in question. It is also sufficiently obvious that nothing is more injurious to the progress of science than hasty and partial observations, and I was anxious to avoid . . . adding to that mass of conflicting evidence which there is already so much reason to deplore."

"It is obvious that, without the aid of active and intelligent assistants, it would have been perfectly impossible to have proceeded with such an investigation."

It is interesting to us to be told that one of these assistants was Sharpey.

Had Reid lived only a little longer, so as to have used the DuBois' Inductorium, he would unquestionably have discovered much more; the pity was, he had to cease working "in the rich dawn," physiologically speaking, "of an ampler day."

In 1838 he was appointed pathologist to the Edinburgh Royal Infirmary, and a year later superintendent of the Pathological Department. As the result of his observations at this time, he compiled "Tables of the Weights of some of the most important Organs of the Body at different Periods of Life" (published 1843). In 1839 he brought out a paper, "On the Effect of Lesion of the Trunk of the Ganglionic System of Nerves in the Neck on the Eyeball."

Dr. Reid had unsuccessfully contested first the chair of medicine, and later the chair of anatomy in the

University of Aberdeen, but in 1841 he was unanimously elected to the Chandos chair in St. Andrew's. In the same year he published his important paper, "On the Relation between Muscular Contraction and the Nervous System," whereby he made a contribution to a controversy then already quite a century old—as to whether the irritability of muscle was or was not "inherent." The great Haller had taught it *was* inherent (the "vis insita"). Robert Whytt, professor of medicine at Edinburgh just a hundred years before Reid's time, had been a strenuous opponent of the doctrine of inherent irritability. Follow-Boerhaave, the leader of the Batavian school, who had trained so many of the professors of Edinburgh, Whytt considered that his experiments confuted the opinions of Haller. When Reid took up the subject in 1834, it was still a controversy.

Reid, using frogs, demonstrated :—

(1) That the muscle of a nerve-muscle preparation, fatigued by stimulation through its nerve, could still contract when it was stimulated directly.

(2) That a muscle, the nerve of which had been cut, would not waste away, provided it was "daily exercised by galvanism."

He even then pointed out the now obvious therapeutic application of this latter fact. His position was: irritability is indeed inherent, but the muscle must be constantly in use in order not to suffer from "dis-use atrophy."

Amongst his collected papers we find one "On Sensational and Emotional Reflex Actions," from which we may conclude that Reid had grasped the essence of the conception of reflex action in such a way as to see that the presence of consciousness need not make the action any the less truly "reflex."

After going to St. Andrews, Prof. Reid published two long papers on the epidemic of fever in Edinburgh in 1836. He began to study the marine biology of the bay, and papers on polyps, molluscs, and medusæ were, between 1844 and 1847, communicated to the "Philosophical Society of St. Andrews," a society still existing.

In 1844 John Reid was married to Miss Ann Blyth, of Edinburgh. Their two sons died in infancy; their two daughters died before their twenty-fifth year; his widow, who was married to a Mr. Foster, survived him more than forty years.

Prof. Wilson, his biographer, describes Reid's appearance in these words :—"Tall, with a strong figure, diminished in height by a stoop acquired by so much bending over books, dissections, and microscopes, his complexion fresh and even ruddy, his forehead expansive, his eyes small, but of a bright black; his hair, which matched his eyes, was worn long."

By August, 1848, it had become evident that Reid was suffering from cancer of the tongue and throat. On August 31, at Prof. Simpson's, 52 Queen Street, Edinburgh, John Reid underwent an operation at the hands of his friend, Mr. (later Sir) William Fergusson; Goodsir, James Duncan, and Hughes Bennett (his old pupil) assisting. On November 29 a second operation was considered necessary; this was carried out at Prof. Goodsir's, 55 George Square, by Duncan, Spence, and Goodsir. For a third time (January 1, 1849) did poor Reid submit to the knife; he warned them about admitting air into the veins of the neck; they could not have forgotten that he had written on "Death by Admission of Air into the Venous System." Doomed at forty, Prof. Reid, after visiting Keswick and Innerleithen, returned for the last time to his house in North Bell Street, St. Andrews (now re-named Greyfriars Garden). On his death-bed he collected all his published papers in a large octavo of 659 pages. He had the courage to review a work by Hughes Bennett on "Cancer." His sufferings were extreme: morphia and the newly-discovered chloroform alone could assuage them. The end came none too soon on July 30, 1849.

In the "Life of John Reid" (Edinburgh, 1857) Prof. Wilson tells us that he attended the funeral on a "singularly bright and beautiful day."

We who know the old city have seen such days, rare indeed, but memorable in their rare beauty when they come. We can so well picture the sad, slow procession from the Town Kirk to its goal within the ruins of the noblest of Scottish cathedrals; there, amongst green graves, they laid John Reid to rest where the murmur of the everlasting sea makes moaning music through the roofless fanes.

Scotland has produced greater anatomists, pathologists, zoologists, and physicians than was John Reid, but I question whether, having regard to the limitations of his scientific environment and to the imperfections of the methods and of the technique with which he worked, anyone would undertake to deny his right to be considered one of the most original and prescient physiologists of purely Scottish birth and training.

I venture to believe that in this year of centenary commemorations no man of science will grudge John Reid his own. D. Fraser Harris.

NOTES.

The collection of fossil Brachiopoda formed by the late Mr. J. F. Walker, of York, has been presented to the British Museum (Natural History) by his executors, Mrs. Walker and Mr. Gelson Walker. It consists of several thousand specimens arranged in groups to illustrate the variations of species and the gradation of several so-called species into each other. It therefore supplements the Davidson collection, which was bequeathed to the museum in 1885. It is especially rich in material from the English Jurassic and Cretaceous formations, to which Mr. Walker devoted much attention; but it also contains important series of specimens from other English strata, besides several small collections for comparison from the European continent. The greater part of the collection will be kept for reference in the original cabinets, but more than a hundred important specimens, described and figured in Davidson's "Monograph of the British Fossil Brachiopoda," will be placed in the exhibition cases of the public gallery.

Mr. W. R. Boelter writes to urge the institution of a people's "Arbour Day" in October for the purpose of planting fruit trees along roadsides as they are in some parts of Germany. From a report issued by the Minister of Agriculture of Saxony it appears that the department in charge of these trees made a profit of 12,000*l.* during 1908 from a countryside corresponding to our Black Country. As, however, the system of road maintenance in Germany differs completely from that followed in England, similar success can scarcely be anticipated here, where the roads are controlled by numerous district and county authorities. Farmers object to trees on the roadside near arable land, and road surveyors in general dislike trees, because the highway does not dry up well under them after rain. Even when permission has been obtained to plant fruit trees along roadside waste in some districts, it will be necessary to appoint officers whose duty it is to protect the trees and promote their satisfactory growth. We are afraid that few local authorities are likely to add to their responsibilities by undertaking the care of young trees along the roadside, much as we are in sympathy with Mr. Boelter's suggestion.

The *British Medical Journal* announces the death of Prof. A. Fraser, occupant of the chair of anatomy in the Royal College of Surgeons, Dublin.

From an obituary notice by Herr von Konkoly, appearing in the *Astronomische Nachrichten*, we learn with regret of the death of Herr Eugen von Gothard, known throughout the astronomical world for his brilliant researches on the spectra of comets, nebulæ, novæ, and other celestial objects at his private observatory at Herény, Steinamanger, Hungary. In 1892 von Gothard photographed the spectrum of Swift's comet on the same plate as the spectrum of the base of a Bunsen flame, and thereby showed the two spectra to be identical so far as the fourth band. He also obtained illuminating spectra of Nova Persei in 1901, and did a great deal of experimental work on the construction of various astronomical instruments. At the time of his death, May 29, von Gothard was only fifty-two years of age, a fact which makes the loss of a devoted worker, possessing exceptional abilities, more keenly felt by all those interested in the progress of astrophysical science.

Prof. F. H. Seares has resigned the directorship of the Laws Observatory, of the University of Missouri, to become superintendent of the computing division at the Mount Wilson Solar Observatory. This post he assumed on August 1, and asks that all correspondence, pamphlets, &c., shall be addressed to him at the Solar Observatory, Pasadena, California.

The Baly medal, awarded by the Royal College of Physicians of London every alternate year to the person who shall be deemed to have most distinguished himself in the science of physiology, has been awarded to Dr. Emil Fischer, professor of chemistry in the University of Berlin; and the Moxon medal, awarded every third year to the person who shall be deemed to have most distinguished himself by observation and research in clinical medicine, has been awarded to Sir W. R. Gowers, F.R.S.

The recorder of the Engineering Section of the British Association has sent us a copy of the provisional programme of the proceedings at Winnipeg, in which the following papers appear in addition to those mentioned in the article on July 15:—the National Transcontinental Railway, Duncan MacPherson; improvements in the navigation of the St. Lawrence, Lieut.-Colonel William P. Anderson; great engineering works on the Canadian Pacific Railway, J. E. Schwitzer; losses from high-tension overhead lines due to brush discharge, E. A. Watson; on the calculation of the charging currents in three-core cables and overhead transmission lines supplied with three-phase currents, E. W. Marchant.

Reuter messages state that two severe earthquake shocks were experienced in Mexico City at 4.20 a.m. and 4.25 a.m. on July 30. Half the city is said to have been destroyed by the earthquake. Chilpanzingo and Chilapa are reported to have been destroyed. Earthquakes are also reported as having occurred at intervals for fourteen hours at Iguala and Guerrero. At Acapulco not a single building escaped some damage; in this locality the most disastrous shock occurred during the afternoon of July 31, when the water in the harbour is said to have receded 33 feet and then to have risen with great force, causing much damage. Seventy-three shocks were felt during the three days July 30 to August 1.

The second International Congress for the Repression of Adulteration in Food, Chemical Products, Drugs, Essential Oils, Aromatic Substances, Mineral Waters, &c., is to be held in Paris on October 17–24. There are likely to be representatives present from every civilised country, and official delegates have been appointed by many Governments. The particular object of the congress is to define what operations are permissible in the handling of food, and follow upon the definitions accepted at the congress held in Geneva last year. The Society of the White Cross of Geneva originated the idea of holding these international congresses, and four congresses have been arranged; the third will be held probably at The Hague in 1910, and the fourth in London in 1911. The work of this year's congress will be held in three sections:—the first, on alimentary technology, will be presided over by Prof. Muntz, director of the chemical laboratories of the National Agronomic Institute, Paris; the second section, dealing with hygiene, will be presided over by Prof. Landouzy, of the faculty of medicine in the Paris University; and M. Guignard, director of the School of Pharmacy, Paris, is the president of the third section, which will be concerned with crude drugs, essential oils, chemical products, and mineral waters. Prof. Bordas is the president of the executive board, and M. Maurice Rivière, 16 Place Vendôme, Paris, the treasurer. Mr. Loudon M. Douglas, 3 Lauder Road, Edinburgh, is the honorary secretary for the United Kingdom, and men of science and others in this country proposing to attend the congress are asked to send an intimation of their intention to him. Subscriptions, which vary in amount according to the character of the membership, should be sent direct to the treasurer.

No. 1 of vol. xvii. of the Proceedings of the Royal Physical Society, Edinburgh, is devoted to the presidential address of Mr. William Evans, in which our present knowledge of the fauna of the Forth area is discussed at considerable length.

We have been favoured with a copy of the report of the Colombo Museum for 1908, in which the director, Dr. H. Willey, emphasises the fact that the scope of that institution is restricted to the products, natural and artificial, of the island of Ceylon. Special attention is directed to a collection of bronzes and stone implements, several of which are figured, found by the Archæological Survey in 1907, and deposited in the museum last year.

We have received from the author, Dr. E. Balducci, a copy of a paper, issued in the *Pubblicazoni de R. Istituto di Studii Superiori Practici e di Perfezionamento in Firenze*, on a forest-hog from the Upper Congo, for which the new name *Hylochoerus gigliolii* is proposed. No mention is made of *H. ituriensis* from the same region, named in 1906 by Dr. P. Matschie in the Annals of the Congo Museum, but there can be no reasonable doubt that the supposed new species is identical with that form.

To vol. v., part vii., of the Annals of the South African Museum, Dr. R. Broom communicates further particulars with regard to the milk dentition of the aard-vark. The full dental formula he believes to be $i.\frac{3}{3}$, $c.\frac{1}{1}$, $p.+m.\frac{9}{9}$. Dr. Broom accepts, provisionally, the opinion that Orycteropus is not an edentate; but there is at present insufficient evidence to determine its true affinities. It is suggested that the above-mentioned dental formula is inherited from an early ancestor, and that the genus may consequently be allied to the Mesozoic mammals, a number of which, he states, may probably have had a similar formula.

At the conclusion of an article on the sense of direction in man, published in the July number of the *Revue des*

Idées, Mr. V. Carnetz, who bases his opinion on observations made on natives of the Tunisian Sahara between the years 1891 and 1894, denies that the power of orientation is due to the possession of a sixth "sense." We have to deal rather, it would seem, with an instinct, if it may be so called, acting as an intermediate innate agent between the external medium and the sense of vision, of which it forms a kind of offshoot. It cannot act without vision, but the latter alone is insufficient for the purpose of finding the direction.

IN the summer number (vol. iii., No. 6) of *Bird Notes and News*, attention is directed to the transference of the offices of the Royal Society for the Protection of Birds from No. 3, Hanover Square, to 23, Queen Anne's Gate, Westminster, this transference having become necessary owing to the impending removal of the Zoological Society's offices from the former address. The summer number is accompanied by a pamphlet giving a summary of the arguments in favour of bird-protection and of the efforts which the society has made in this direction, together with an appeal for further assistance in carrying out and developing the society's work.

THE July number of the *Zoologist* contains an article by Dr. E. Menegaux, of the Paris Museum, translated by the author from *La Nature*, on American egrets as victims of fashion. According to statements made by the well-known traveller and naturalist, Mr. Geay, large quantities of "ospreys" are collected as shed feathers by the natives of Venezuela and Colombia, and also that when the plume-hunters kill the birds themselves, they always spare the young birds, which yield no ornamental feathers; while it is further stated that when the parents of nestling egrets have been slain, the latter are fed by other birds, so that deaths from starvation do not take place. As an appendix the editor reprints a document published by the Royal Society for the Protection of Birds as a kind of counterblast to Mr. Geay's assertions.

THE degeneration of armour in animals forms the subject of an article by Dr. Felix Oswald in the July number of *Science Progress*. As instances of this disappearance the author refers, among many other examples, to labyrinthodonts as contrasted with modern amphibians, to the disappearance of the solidly armoured glyptodonts and the survival of the less immovably shielded armadillos, the disappearance of the Palæozoic ostracoderms and placoderms and the emancipation from armour of modern fishes, and very specially to the numerous independent instances where the shell has been more or less completely discarded by gastropod molluscs. He might also have referred to whales and dolphins as contrasted with the zeuglodonts, and to the evidence recently quoted in NATURE as to the presence of vestiges of a dermal armour in the fox.

To *Naturwissenschaftliche Wochenschrift* for July 18, Prof. H. Kolbe communicates an interesting article on the theory of a former extension of the Antarctic continent, with remarks on the distribution of animal life in the southern hemisphere. Commencing with a reference to the hypothesis that the Arctic region formerly enjoyed a mild climate and a large continental area which served to a great extent as a centre of dispersal and radiation for animals in the northern hemisphere, the author proceeds to adduce evidence in favour of the former existence of very similar conditions at the opposite pole. Reference is made to recent discoveries indicating the large area still occupied by the Antarctic continent, and to the occurrence of a fossil flora in high southern latitudes which must have required a comparatively warm climate for its development. Ortmann's work on the Lower Miocene marine deposits of Patagonia, New Zealand, and Australia, which are certainly of littoral origin, is next cited as evidence of an inter-continental connection in later Tertiary times in high southern latitudes. Further testimony to the same effect is adduced from the present faunas of the great southern continents, more especially from beetles and other insects. The idea that such resemblances as exist between the different southern faunas may be explained by "convergence" is shown to be untenable, as convergence consists in resemblances between different groups, not the likeness of allied forms. A South Polar union of the southern continents in later Tertiary times is considered by the author to be now demonstrated.

THE anatomical structure of the Holothurians is described and discussed in an elaborate manner by Dr. Siegfried Becker in the third part of vol. i. of Dr. Spengel's "Ergebnisse und Fortschritte der Zoologie" from the point of view of the phylogenetic relationships of the various members of the class. In the opinion of the author, considerable modification of the generally accepted phylogeny of the group, as given, for instance, in the "Cambridge Natural History," is necessary. The Synaptida, for example, are regarded as a very ancient group, which, with certain other forms, are widely distinct from the modern types. The Dendrochirota and the Molpadiida, again, in place of being, in common with the Synapta, derived from a hypothetical common stock, are regarded as of independent development. The remainder of the part last quoted is devoted to a memoir, by Dr. Max Rauther, on the morphology and mutual relationships of the nematode worms.

THE *Journal of Comparative Neurology and Psychology* for June (vol. xix., No. 3) contains an interesting paper by Mr. R. E. Sheldon on the sensitiveness of the general body surface of the smooth dogfish to those chemical stimuli which in man provoke sensations of taste and smell. Both normal and "spinal" dogfish were under observation; in other dogfish the spinal cord had been destroyed, in others, again, the olfactory crura or the four branches of the trigeminal nerve had been divided. The author finds that the dogfish reacts to chemical stimuli applied to any spot on the body surface or to the mouth or nostrils, that acids and alkalis, even when very dilute, are potent stimuli, that salt and bitter substances are less powerful, and that no reaction occurs towards sugars. The results of experimental interference indicate that the extreme sensitiveness of the nostrils of the fish is due to the trigeminal rather than to the olfactory nerve. The nerves of the lateral line appear not to be concerned in these "chemical" sensations, as no reactions occur after destruction of the spinal cord, the fish being viable for some weeks in this state. Cocaine is found to abolish tactile sensibility before response to chemical stimulation is affected. The author concludes that the sensitiveness to chemical stimuli is due almost exclusively to the nerves of general sensation, not at all to the olfactory and very little to the gustatory nerves, and that a special nervous mechanism, distinct from that for touch, constituting the apparatus of a distinct "chemical" sense, exists alike in the vertebrate and in the invertebrate world.

AN essay by Miss B. Freire-Marreco on the hair- and eye-colour of school children in Surrey appears in the July number of *Man*. The essay was prepared for the diploma examination at the Oxford School of Anthropology—a welcome indication of the progress being made in this department. The observations, which extended to 591 subjects, have been tabulated on the plan recommended by Dr. John Beddoe, and have been examined by the aid of the index of nigrescence adopted by the same authority, and also by the index of M. Collignon. According to the former, the people of these Surrey parishes turn out to be four times as fair as the fairest people of Scotland; according to the latter the result is inconclusive, the reason being that the outstanding feature of the record is the predominance of medium eyes and the comparatively high percentage of brown hair. On the whole, girls are slightly darker than boys, and as the difference lies mainly in eye-colour, this is possibly a sex characteristic; and there seems to be some connection between red hair and medium eyes. The author suggests a third method of examination in addition to those of Beddoe and Collignon. The paper, on the whole, shows a decided aptitude on the part of the author for statistical work of this kind, and it may be hoped that she will follow up the subject, largely increasing the area of her inquiry and the number of subjects.

One of the most interesting of the numerous writings to which the recent Darwin anniversaries have given occasion is the first article in the current number of the *Quarterly Review*. The article, which is by Prof. Poulton, discusses the various criticisms that have been directed against the Darwinian theory both in early and in recent times. The author passes in review the work of Weismann, of Mendel, and of de Vries, showing the relation of the results obtained by each of these investigators to the conclusions reached by Darwin. He demonstrates by an ample series of quotations that the idea of "mutations" was constantly present to Darwin's mind, and that he only rejected the supposition that they might be concerned in the production of new species after giving the fullest consideration to the whole question. Prof. Poulton concludes, on several lines of evidence, including that of palæontology, that the mutationist theory of evolution is untenable, and that the only explanation of the course of evolution which really accounts for the facts is the principle of the accumulation of small differences by natural selection, as maintained by Darwin and Wallace. He is inclined to attach weight to de Vries's distinction between "elementary species" and varieties, as exemplified by their different behaviour in relation to Mendel's law, but he considers that the only fundamental change in the original Darwinian doctrine which is actually valid is that brought about by Weismann's denial of the transmissibility of acquired characters.

A first volume of Transactions has been issued by the Liverpool Botanical Society, in which are published several papers read before the society, and a biographical list of deceased Lancashire botanists, prepared by the secretary, Mr. A. A. Dallman. A communication by Prof. R. J. Harvey-Gibson on the problem of photosynthesis concludes with a reference to experiments supporting the hypothesis that formaldehyde is produced in the leaf from carbon dioxide by electric currents generated by the chlorophyll. Messrs. J. A. Wheldon and W. G. Travis contribute a list of hepatics for South Lancashire.

In the course of an article in the *Sitzungsberichte der kaiserlichen Akademie der Wissenschaften*, Vienna (vol. cxvii., part viii.), describing certain fungi collected in Java, Prof. F. von Höhnel adduces convincing evidence to show that there has been indiscriminate naming of tropical fungi, due partly to great variation in the species, partly to the examination of insufficient or dried material. Thus, with regard to fungi growing in the nests of white ants, all the portions of agaric material collected were referable to a single species, which the author assigns to *Volvaria eurhiza*; two species of Xylaria were also found in the nests, and a species of the nature of a Hypocrea. Another variable species is determined as an Oudemansiella. Among the new species identified are a Sphærocreas and a Corditubera.

We have received a copy of the schedule and rules of the International Agricultural Exhibition to be held at Palermo (Buenos Aires) by the Sociedad Rural Argentina from June 3 to July 31, 1910, under the auspices of the Government of the Argentine Republic, in celebration of the emancipation of the Argentine, May 25, 1810. The conditions of entry of live-stock, implements, &c., are clearly set forth, and full information is given for intending exhibitors.

The education committee of the Durham County Council has issued a report on further experiments on the feeding of dairy cows at Offerton Hall, by Messrs. F. P. Walker and S. H. Collins. The effect of brewers' grains has been again tested, both on the quantity of milk produced and on the percentage of butter-fat present. Mr. Collins also shows, in another experiment, that boric acid can get into milk if the cows are fed on food which, like Indian cotton cake, contains much of that substance.

The reports on experiments with crops and stock carried out during the past year at the Midland Agricultural and Dairy College, Kingston-on-Soar, and in the contributing counties, have just been published, and they show a very commendable zeal and activity on the part of the staff. The experiments deal with varieties of mangolds, potatoes, swedes, and oats, and also with the manuring of swedes and oats, and are designed to assist the farmers in selecting varieties of crop and the combinations of manure likely to prove profitable.

An interesting series of papers by Dr. Juritz has been appearing in recent issues of the *Agricultural Journal of the Cape of Good Hope*, discussing the soils of Cape Colony. Large numbers of chemical analyses and a certain number of mechanical analyses are quoted, and references are made to the special agricultural characteristics of some of the soils. Whilst the work in question forms by no means a complete soil survey, it marks a beginning, and shows that the Cape agricultural authorities are fully alive to the necessity of making systematic examinations of their soils.

A number of bulletins have reached us from the United States Department of Agriculture Bureau of Entomology, including papers on the codling moth in the Ozarks (E. L. Jenne), the striped cucumber beetle, *Diabrotica vittata*, Fab. (F. H. Chittenden), the hop flea-beetle, *Psylliodes punctulata*, Melsh. (F. H. Chittenden), the spring grain-aphis, *Toxoptera graminum*, Rond. (F. M. Webster), and the wheat-straw worm, *Isosoma grande*, Riley (F. M. Webster and G. I. Reeves). A very useful pamphlet gives a list of all the publications issued from the Bureau since it was established in 1863.

The *Journal of Agriculture for South Australia* for June publishes the report of the experiments made at the Roseworthy College for the seasons 1907–9. The most important experiments are naturally those on wheat. Land values in many parts of South Australia are rising, and the old plan of growing wheat as the main crop with frequent fallows is no longer so profitable as before. The experiments show that the fallow is not necessary, but can be displaced by another crop; a rotation system has therefore to be evolved. The average rainfall is 17·4 inches.

FUMIGATION under tents with hydrocyanic acid gas has been the principal means of controlling scale-insects on citrus fruit trees in California for many years. Most of the commercial orchards in the State are fumigated at intervals of one or two years, at a cost ranging from 25 cents to 1·50 dollars a tree. The results of the work of different manipulators, and against different scale pests, show considerable discrepancy, and a good deal still remains to be done to put the whole method on a sound basis. Mr. Woglum has recently published the results of investigations made in California with the view of clearing up some of the discrepancies; the paper, which is well illustrated, forms Bulletin No. 79 of the United States Department of Agriculture Bureau of Entomology.

THE summary of the weather for the week ending July 31 shows that the period was again cold for the time of year over the whole country. The highest maximum shade temperature for the week over the United Kingdom was 73° in the east of England and in the Midland counties, whilst in the north and east of Scotland and in the north of Ireland the thermometer did not exceed 68°; the rainfall over England was everywhere largely in excess of the average. The summary for the eight weeks of summer, as yet expired, shows that the thermometer has not exceeded 77° in any part of the kingdom, and in the north-east of England the highest temperature is 73°. The excess of rainfall for the eight weeks amounts to 1·6 inches in the west of Scotland and in the north-west of England, and to 1·3 inches in the Midland counties. At Greenwich the excess of rain for June and July amounts to 2·4 inches, the aggregate measurement being 6·85 inches. The duration of bright sunshine for the summer, so far, is largely deficient of the average, the deficiency exceeding eighty hours in the north-east and south-east of England.

IN the *Archiv for Mathematik og Naturvidenskab* (vol. xxix., No. 12), Mr. A. S. Steen discusses the mean temperature of the sea surface on the Norwegian coast, "reduced" for the thirty-year period 1874–1903. With one exception the observations were made at light-stations between Torungen in the south-east and Gjesvær in the extreme north (lat. 71° 6'). The lowest mean values occur in February and March, and the highest in August. Selecting two stations on the Atlantic coast, we find at Utsire (lat. 59° 18') those values to be 39·2° F. and 58·5°, and at Andenes (lat. 69° 20') 33·3° and 51·1° respectively; up to lat. 63° the mean annual temperature of the 30-year period does not fall below 46·4° F. The tables also include departures of the monthly means from the normal value for each of the separate years 1874–1903.

AMONG several useful papers on the climatology of Italy recently received from Dr. Eredia, we may refer to two of special interest, relating to torrential rains in Sicily (1879–1907), and to the disastrous floods, especially in the provinces of Syracusa and Catania, caused by severe thunderstorms in November last. The heaviest rains occur on the eastern slope of the island between September and April; at Riposto a fall of 7·64 inches within twenty-four hours occurred in November, 1889, and one of 8·12 inches at Catania in September, 1902. In the thunderstorms of November 17 and 18, Riposto recorded daily falls of 18·29 inches and 8·11 inches; 5·91 inches fell in twenty-five minutes. At Sant' Alfio the falls were 8·68 inches on November 17, and 14·39 inches on November 18. This remarkable downpour was caused by a shallow barometric depression passing from the south of Spain to Algeria, with high barometric pressure existing at the time over the Balkans and Upper Italy.

AFTER the Kangra earthquake of April 4, 1905, Prof. Omori, who had been sent by the Japanese Government to India, lent to the Indian Meteorological Department a portable seismograph of his design. This instrument was set up in Simla, and in vol. xx., part iii., of the Memoirs of the Indian Meteorological Department a list is given of the seismographic records obtained with it between June, 1905, and November, 1908. The instrument is of the pattern which records by the movement of a tracing point on a travelling sheet of smoked paper, and has a heavy mass of about 10 kg. at the end of a boom 75 cm. in length. Experience has shown that instruments of this type seldom give satisfactory records of the preliminary tremors unless the heavy mass is at least 25 kg., and the seismograms, reproduced in the memoir, show that the Simla instrument is no exception to this rule.

IN a recent number of *Globus* (xcvi., 1), Mr. W. Reinhard gives a short description, with facsimile, of a MS. map of the British Isles preserved in the British Museum, which does not seem to have hitherto met with the attention it deserves. It is of interest as occupying an intermediate position between early productions such as those of Matthew Paris, and the more precise work of Christopher Saxton, or even of Mercator and Ortelius. It is without date or author's name, but may be assigned with some confidence to the middle of the sixteenth century, being thus about contemporary with (Mr. Reinhard says *earlier* than) the map of George Lily (1546), stated by Gough to be the first exact map of Great Britain. While not quite so correct as this as regards the outlines, especially of Scotland, it is perhaps superior as regards the amount of detail supplied, at least for England. Besides most of the principal towns and villages, it names a number of physical features. Among islands, we find Holy and Farne islands (Northumberland); Mersea and Foulness (Essex); Mt. St. Michael (Cornwall); Priestholm or Puffin island, near Anglesey. The name Portland appears on the mainland, while Corfe and Selsea are both shown as islands. Of towns and villages swept away by the sea, we find Dunwich, Orwell (misplaced), and others, but not Ravenspur, though this had been destroyed only about 1530. A large island seems indicated within the mouth of the Humber, though it would probably be risky to argue changes of coastline from such evidence. There is still much room for research as regards the data on which such maps were based.

THE June number of *Terrestrial Magnetism and Atmospheric Electricity* contains a frontispiece showing the magnetic survey yacht *Carnegie* under full sail, and an article describing her construction and the work she is intended to do. She has a displacement, when fully equipped, of 568 tons, and is built almost without iron, her bolts and metal fittings being of bronze, copper, or gun-metal. The observation rooms are amidships. The yacht is to make a magnetic survey of the oceans during the next fifteen years, with the object of correcting the magnetic charts and compass data at present available. Her first voyage will be to Hudson Bay and the North Atlantic Ocean.

THE *Electrician* for July 16 contains an article, by Mr. L. W. Wild, on the comparative merits of photometers of the Bunsen type, of the Lummer type, and of the flicker type, for testing the brightness of lights of different colours. Mr. Wild has used two or three photometers of each type in the comparison of a carbon with a tungsten filament lamp, and comes to the conclusion that for accurate work photometers of the Bunsen type are to be preferred to those of the flicker type. He considers the latter, although more sensitive than the former, give readings for the comparative brightness of the two lamps about 6 per cent. from the true value. He finds photometers of the Lummer type come short of the Bunsen in sensitiveness, and he thinks that in time the Bunsen will displace the other photometers at present in use.

BULLETIN No. 30 of the University of Illinois consists of an important paper, by Mr. J. K. Clement, on the rate of formation of carbon monoxide in gas producers. The numerous theoretical works on the processes taking place in the fuel bed of the producer have been built up on a rather slender experimental basis, and the present communication fills a decided gap in our knowledge. The experiments deal more especially with the rate of formation of CO in the reaction $CO_2 + C = 2CO$, previous researches having been rather directed to the study of the final equilibrium than to the rate at which the reaction takes place. Three authors contribute to this memoir, J. K. Clement, L. H. Adams, and C. N. Haskins, dealing with the subject from the physical, chemical, and mathematical point of view respectively. The result of this collaboration is a valuable monograph, which cannot be neglected by anyone interested in gas producers.

MR. W. B. CLIVE has published a second edition of Mr. William Hall's "Modern Navigation." The text-book deals also with nautical astronomy, and is intended to meet the needs of cadets of the Royal Navy and the syllabus of the Board of Education. The scope of the volume is limited to instruction in navigation so far as, and including, the problem of fixing position by one position line derived from sights of the sun and another derived from a bearing of land. The book has been entirely re-cast. Its price is 7*s*. 6*d*.

AN abstract of Dr. John Morrow's contribution to part iii. of the third volume of the Proceedings of the University of Durham Philosophical Society was published in NATURE of July 29 (vol. lxxxi., p. 128). The volume contains, in addition, other articles of interest, among which the following may be mentioned:—Prof. Thornton describes a new method of measuring π; Prof. G. H. Stanley contributes a note on an artificial formation of zincite; Dr. D. Woolacott writes on borings at Derwenthaugh and Dunston; Mr. A. S. Horne describes observations on protoplasmic structure and streaming in potato; Messrs. Harold Crofts, H. Tiplady, and A. Forster discuss certain chemical experiments; and Messrs. T. Herdman and E. Merrick record observations in local geology. The third report of the Boulders Committee is also included in the volume.

OUR ASTRONOMICAL COLUMN.

MOVEMENTS IN THE SUN'S UPPER ATMOSPHERE.—In continuation of his previous papers, giving the results of the solar researches carried on at Meudon, M. Deslandres has a paper in No. 3 of the *Comptes rendus* (p. 179, July 19) wherein he describes and discusses more recent results dealing with the question of motion in the upper layers of the solar atmosphere. First he mentions the connections previously shown to exist between spots, "filaments," and "alignements," and points out that owing to the greater size, frequency, and distribution of the latter, they afford much more trustworthy and continuous data on which to base any researches or theories dealing with solar changes than does the study of spots alone; but for any exhaustive study of these phenomena the velocities of the solar vapours in the line of sight must be determined, and it is to this determination that M. Deslandres has in the more recent work returned. As Meudon is the only observatory employing the *spectroenregistreur des vitesses radiales*, the results are of great interest.

To measure the radial velocities all over the disc would take much more time than the Meudon staff are able to devote to the work, so, for the present, only those in the neighbourhood of filaments near the centre of the disc have been measured. A diagram of a typical radial-velocity curve shows that in the filament, shown on the "K_3" image, the vapours are moving towards the observer, the displacement of the line being towards the violet. At first glance this appears to contradict M. Deslandres's previous conclusions, and the fact that whilst, in May and June, when spots were scarce, or small, the filaments were well developed, yet further suggests that the two phenomena are not physically connected; but M. Deslandres thinks it necessary only to modify and enlarge these conclusions, and shows how solar convection currents, analogous to Benard's cellular liquid *tourbillons*, would account for the apparent discrepancy of the results, and, at the same time, afford an explanation of Evershed's radial motions observed in the penumbræ of spots.

SEARCH-EPHEMERIDES FOR COMET 1896 VII. (PERRINE).—In No. 4342 of the *Astronomische Nachrichten* Herr F. W. Ristenpart publishes a set of elements, brought up to the equinox of 1910, for the comet discovered by Perrine in 1896; the time of the next perihelion passage is given as 1909 November 4·12 (M.T. Berlin). Three search-ephemerides, computed from the elements by Messrs. R. Castro and A. Repenning, are also given, T being taken as October 27·5, November 4·5, and November 12·5 respectively. According to the second ephemeris, the comet is at present in Pegasus (August 6, 12h. M.T. Berlin, α = 23h. 44·2m., $\delta = +31°$ 40·2′), and will apparently travel, in a north-easterly direction, through Andromeda towards Perseus; on August 24 its position should be α = oh. 11·4m., $\delta = +40°$ 12·4′, and the comet should appear about as bright as when discovered. The computed brightnesses at perihelion are 6, 13, and 20·5 respectively, according to the date of perihelion passage.

OBSERVATIONS OF JUPITER.—Some incidental measures of the positions of Jupiter's belts and of the polar diameter of the planet are given by Prof. Barnard in No. 4339 of the *Astronomische Nachrichten* (pp. 307–10). For each recognisable feature he gives the distances from the south and north limbs and the apparent latitude; the observation on February 19 8h. om. (central standard time), 1907, gave the apparent polar diameter as 40·78″, and, reducing this to $\Delta = 5·20$, the polar diameter therefore becomes 36·11″.

On this date a narrow south belt, 2″ wide, in apparent latitude −9·88″, showed several ill-defined white spots, and on May 26, 1908, the north equatorial belt was double for part of its length.

THE ORBIT OF X SAGITTARII, A CEPHEID VARIABLE.—The variability of the star X Sagittarii was discovered by Schmidt in 1886, and the radial velocity detected by Slipher in 1904. In No. 157 of the Lick Observatory Bulletins Mr. J. H. Moore discusses a series of one-prism and three-prism spectrograms taken at Mount Hamilton during the period 1904–8. Plotting the velocity- and the light-curves for the same epoch, it is shown that the times of light-maximum and of greatest velocity of approach agree very closely, this being a fundamental characteristic, as Mr. Albrecht has shown, of all variables of the δ Cephei type. No such close agreement is shown, however, between the epochs of light-minima and maximum recession.

THE LEEDS ASTRONOMICAL SOCIETY.—The energy and activity of the Leeds Astronomical Society in popularising the study of astronomy is well illustrated in the Journal and Transactions for 1908. This journal contains abstracts of the papers read before the society, and a large number of astronomical notes contributed to various periodicals by Messrs. Elgie and Whitmell, members of the committee. Among the former there appear papers on sundials (Mr. T. Wright), variable stars (Mr. Ivo Gregg), and "other inhabited worlds" (Mr. T. Benton), while an interesting popular paper dealing with the fancied figures in the moon is contributed by Mr. Elgie.

THE SOLAR ECLIPSE OF JUNE 17, 1909.—Observations of the contacts, during the solar eclipse of June 17, were made by Father Rigge, at the Creighton University Observatory, Omaha, and showed that the phenomena actually occurred a second or two earlier than the computed times. At first contact the difference was 2·02s., and is trustworthy, but at the last contact a difference of 18·4s. was observed, and may largely be due to the extremely bad conditions under which the observation was made, the sun being within fourteen minutes of setting (*Astronomische Nachrichten*, No. 4340).

RECENT IMPROVEMENTS IN THE INTERNAL-COMBUSTION ENGINE.

I.

A SURVEY of the progress made during the last twenty-five years in almost any field of engineering work would show an immense advance. Even during the past ten years very considerable progress has been made in certain branches of applied science, and in none of them to a greater extent than in the internal-combustion engine. We need not in this comparison claim the gun as a form of internal-combustion engine, though we are naturally entitled to do so. We may leave lethal weapons aside, and think only of the remarkable development of the reciprocating internal-combustion engine, and of the many changes it has brought about in our times. It has revolutionised cross-country transit. It has given us the long-deferred, but now actually achieved, victory called the "conquest of the air." It is extraordinary to think of the numbers of men who have spent ingenious years in seeking a solution of the problem of flight. The solution has come in the unexpected form of a pair of long, sail-like arms, driven forward by a small high-speed internal-combustion engine. This simple form of design, which, owing to the relation between centre of pressure and angle of tilt, seems to be naturally stable, bids fair to be adopted in a great output of flying machines shortly to be constructed. The hardly less novel, but less interesting, dirigible balloon owes the whole of its dirigibility, whatever that may amount to, to the internal-combustion engine.

Less startling, but of considerable material importance, is the utilisation of "waste heat" in our coal- and iron-producing areas. Our coal supply is admitted to be limited, and there seems to be at least an indication that at the present rate of consumption mankind would, in a few centuries, have to be prepared to turn its attention to the unlocking of some other form of stored-up energy, perhaps a radio-active one. It is not too much to say, however, that if the power available from the waste gases of blast-furnaces and coke-ovens in this country—and the amount can hardly be less in the aggregate than 1,000,000 h.p.—were put to use, the saving in the coal consumption might perhaps give us another half-century or two in which to look about for some substitute for coal.

In writing of what has been already achieved, we have to remember that we are only yet at an intermediate stage in the development of the internal-combustion engine. The internal-combustion engine gives us a bigger return for heat put in than any other known form of engine. We cannot imagine the development of the future "going back," so to speak, on such an advance as that. The internal-combustion engine must come, and existing steam engines be replaced. This means the supersession of the steam turbine, and may therefore seem to suggest a retrograde step, since the rotary engine is mechanically an improvement on the reciprocating one. We have to remember, however, that evolutionary processes sometimes take a step backwards to an earlier form in bringing forward the latest and most developed creation. No one would look on any reciprocating engine as a final improvement on a rotary one, even although, as is now the case, large gas engines are capable of so uniform a rotary motion that alternators are easily driven by them in parallel—the standard test of excellence in this respect. The day of the gas-engine turbine must come. Numbers of men are working at the problem which it presents; but little has as yet been published as to the result of their labours—an indication that the many difficulties are not yet mastered.

The present stage in the development of the internal-combustion engine is a convenient one at which to summarise briefly what has been done in regard to its improvement. We therefore propose in this and the succeeding articles of the series to state the problem and the lines on which, with such a striking measure of success, its solution has been attempted.

The problem can be stated in a very simple form. Given one pound of carbon of, say, 12,000,000 ft. lb. calorific value, which is a normal estimate, find how to obtain the largest possible amount of useful power. So far this energy has always been liberated in the form of heat. This heat has been given to some body which, by its subsequent cooling, can give out mechanical energy—such a body is a mass of gas or vapour. Let us assume that a mass of gas is chosen as the working medium. It is obviously desirable that the heat liberated should be absorbed as completely as possible by the gas, but in investigating whether this has been effected one at once meets with a check. To tell whether the whole of the 12,000,000 ft. lb. of heat energy has reached the gas, we may either look out for possible chances of heat leakage or may measure the amount of energy in the gas at the end of the operation. But to do the latter is practically impossible, for we do not know the specific heat at high temperature of any gas, and to do the former is extremely difficult, owing to the very short time the heat transference usually takes, and owing also to our lack of knowledge as to the temperature of metal or other surfaces in contact with, and enclosing, the gas. Many attempts have been made to ascertain what happens to the heat liberated, and much has been written on such topics as "dissociation," "after-burning," and "increasing specific heats." There would be no difficulty in filling the whole of the allotted space with a discussion of the various experiments that have been made and theories that have been built on this subject, but as many other matters have also to be dealt with, and as the author has already written on this topic elsewhere,[1] he does not now propose to go into the matter at length.

Briefly summarised, the result of gas-engine experiment is to establish that only about 50 to 55 per cent. of the heat energy known to be liberated is accounted for by multiplying the measured rise of temperature by the commonly accepted figure for the specific heat at constant volume. The same ratio of 50 to 55 per cent. was found for all sizes and shapes of containing vessel, and for all mixtures of gas. This constancy at once disposed of the theory that the "suppression of heat" was due to dissociation, as such an effect would naturally be dependent upon, and increase with, the increasing temperatures due to the richer mixtures. Equally it showed that the cooling of the gas by convection currents, radiation, and conduction to the walls of the containing vessel was an inadequate explanation. The suggestion of the French physicists, MM. Mallard and Le Chatelier, that the effect must be due to increase of specific heat with temperature was open to precisely the same objection as that of dissociation, and involved values of the instantaneous specific heat much in advance of what was then thought likely. It is now generally recognised that the real explanation of the apparent suppression of energy is due to a combined cooling effect and rise of specific heat. "After-burning" is now generally believed, as a result of many tests, not to occur in normal circumstances. With a weak mixture the time of explosion, and therefore of cooling, is a long one, so that the cooling loss has time to become considerable, and this compensates for the lesser degree to which the theory of increasing specific heats is effective for these weak mixtures and low temperatures.

The constancy of this apparent "loss" made it clear that no great improvement in the internal-combustion engine could be looked for in any increase of pressure and temperature in a gaseous mixture of given strength. We cannot alter the specific heat law of a substance. We might, perhaps, alter our working medium, which now for the most part is nitrogen, but no other gas is so cheap or so easily obtained; but we may vary the part of the temperature scale over which we work, and, within limits, we may affect the cooling loss by altering the shape of the containing vessel or cylinder. Experiments have shown

[1] "The Internal-combustion Engine" (Constable and Co.)

that the less the ratio of cooling surface to volume the less the proportionate cooling loss, and therefore the greater the amount of thermal energy converted into work.

Engines that have "pockets," that is, cavities in their walls, in which to contain ignition plugs or valves, are known to be less efficient than those that have not. On the other hand, it must not be forgotten that although this loss of efficiency exists, it is at any rate partly compensated for by the greater flexibility of the engine. It has been found, particularly in motor-car engines, that "pockets" have a very useful effect in enabling very variable mixtures to fire. The ignition plug is placed in a pocket so that, even when the mixture is a very poor one, there will be sufficient local "richness" in its neighbourhood to start an explosion which, once started, proceeds throughout the mass of the gas. Another fact which may have the result of increasing "pocketing" is the recently measured temperature limit for pre-ignition. Prof. Hopkinson has found that surfaces below 700° C. will not cause pre-ignition, whilst those above may do so—if above 750° C. they are pretty sure to do so. Now the surfaces most likely to rise to such temperatures are those remote from the cooling water in the jacket. The projecting end of an ignition plug is such a surface, and when exposed to the full heat of the explosion, as it is when the plug is not pocketed, pre-ignition may well occur. Prof. Hopkinson has shown also that when once a point of metal gets hot enough to cause pre-ignition, the very ignition of the flame in its neighbourhood will tend to cause the temperature to rise still higher, so that the phenomenon grows on itself and persists. It is not everyone who is moved, however, by such considerations, and we have lately seen in the design of the new Daimler engine a clearly expressed intention to avoid pocketing and its consequent loss of efficiency without any apparent fear of introducing other features much less desirable. It is only fair to say, however, that this engine is still on its trial. The ideal plan would appear to be to pocket the ignition plug but not the valves, and so combine the good features of both systems.

This frank abandonment of the highest possible efficiency by those who use pocketed engines brings us naturally to the consideration of thermal efficiency and the laws that regulate it. One may say at once that the theory of the internal-combustion engine has, until lately, been in a chaotic condition. The standard of efficiency for gas engines laid down by an influential committee had been found subsequently to be unsatisfactory as giving an impossibly ideal figure. That such remarkable progress in invention and mechanical perfection should have gone on side by side with this uncertainty as to the true standard of performance has often struck observers with astonishment. The considerable scale of the practical side of gas-engine development is illustrated by the fact that of one well-known make of double-acting gas engines alone, no fewer than 247 engines of an aggregate output of 308,000 b.h.p. have been built or ordered during the last six years. This corresponds to the large figure of more than 50,000 b.h.p. per year for only one of the many firms engaged on the work. At the moment the total capacity of gas engines in use must be well over 2,000,000 h.p., and of petrol engines much more than 1,000,000 h.p., making a total of more than 3,000,000 h.p. in internal-combustion engines. These are striking figures. Some of these engines and plants work with solid fuel and some with liquid. It would not be possible, even were it considered desirable, to use liquid fuel to the entire exclusion of any other. The present output of petroleum over the whole world is only 20,000,000 tons, a very small figure compared with the yearly consumption of 800,000,000 tons of coal. Unless, therefore, fresh supplies of oil are discovered, there can be no development of the internal-combustion engine which would lead to liquid fuel replacing solid fuel altogether.

In the articles that will follow, the author intends to deal with the problem of efficiency, taking into account the now established increase of specific heat with temperature, its effect on rating, and the recent practical improvements in the design and operation of gas engines and gas-producing plant.

H. E. WIMPERIS.

CONTINUATION SCHOOLS AND NATIONAL EFFICIENCY.[1]

AMONG the numerous problems now confronting English educational administrators, probably the most urgent is that discussed in the valuable and exhaustive report on attendance at continuation schools recently issued by the Consultative Committee of the Board of Education. To some extent the report covers similar ground to that traversed in the educational sections of the Majority and Minority Reports of the Poor Law Commissioners, arriving at almost identical conclusions.

The essential features of the problem are as follows:—Under the existing Education Acts, children must attend school from their fifth to their fourteenth birthdays, subject to certain exemptions (prescribed by local bye-laws) during the last three years of the school period. Local education authorities may grant (*a*) total exemption from school attendance at eleven years of age to children engaged in agriculture, (*b*) full-time or half-time exemption, or both, to children between twelve and fourteen. The "leaving age" is generally twelve or thirteen. Full-time attendance at a day school until fourteen is now compulsory over areas comprising about 22 per cent. of the population of England and Wales. The committee estimates that in the year 1907, the latest year for which full statistics were available, there were about 211,000 children under fourteen years of age who had obtained full-time exemption from day-school attendance. Of these, only 40,500 were attending evening schools in the year 1906–7, leaving 170,500 children between the ages mentioned not attending any form of week-day instruction. Further, the estimated population of England and Wales between the ages of fourteen and seventeen is 2,022,300. After deducting from this the number attending elementary, secondary, technical, or evening schools, it is estimated that nearly 1,498,000 (or approximately 74 per cent.) boys and girls between the ages of fourteen and seventeen are not receiving any form of scholastic instruction. We have therefore, about 1,668,500 boys and girls from twelve to seventeen years of age whose formal education has entirely ceased for the time being. Recent inquiries in London and Glasgow render it highly probable that a very large proportion, if not the majority, of these boys and girls, if in wage-earning occupations, are employed in purely mechanical work of a monotonous, uneducational character, of no industrial value when the child becomes an adult.

Under these conditions the education, such as it is, given in the elementary school is being rapidly forgotten. The boys and girls are almost entirely exempt from parental control; they are falling victims to the prevailing passion for cheap amusements and to the attractions of the streets. Any slight gleam of intellectual aspiration which may have been aroused in the elementary school is rapidly being extinguished. The enormous sums spent by the State upon the elementary education of these young people are almost entirely wasted. All that remains is a certain facility in reading, writing, and very elementary arithmetic. Even if the boys are definitely apprenticed to a trade, matters are not much better. Under the present industrial conditions, involving the minutest possible specialisation in the works, the employer cannot possibly afford, even if he wishes, to give the boy the all-round training which was given by apprenticeship under the older industrial *régime*. Industry now requires, in addition to manual dexterity, a general industrial knowledge and a trained intelligence which will enable the worker to adapt himself to ever-changing industrial conditions; but this knowledge and training are not now given by apprenticeship. Hence, an education outside, but concurrent with, the workshop is essential. A further important factor is that even if a boy be apprenticed to a skilled trade, he is generally not taken on until about sixteen years of age. The intermediate years, between leaving school at thirteen and commencing apprenticeship at sixteen, are usually spent in "blind alley," uneducational occupations such as that of errand boy, van boy, messenger, &c.

For many years to come the formal education given to

[1] Report of the Consultative Committee of the Board of Education on Attendance, compulsory or otherwise, at Continuation Schools. Board of Education, White Paper. Cd. 4757. (London: Wyman and Sons.) Price 1s. 6d.

the bulk of the population of this country will be that imparted in the elementary school, the continuation evening school, and the evening technical (including by this term commercial, or art or craft) school. The nation, at enormous expense, has instituted a system of national education which is almost entirely confined to children under fourteen years of age. In addition to this, an elaborate system of evening technical education has been established, mainly for those above the age of seventeen; but no adequate national system of evening continuation schools, for the boys or girls between the ages of fourteen and seventeen, linking on the elementary school to the evening technical institution, has yet been developed. The boy or girl leaves the elementary school at the age of thirteen. At seventeen or eighteen the youth may realise the necessity of attending evening classes for technical instruction relating to his special industry, assuming he is engaged in some skilled occupation or other. At the technical school he finds that he is unable to profit by the instruction given. During the years between thirteen and seventeen his powers of assimilation have declined through disuse, he has lost the habit of study, and most of his previous small stock of knowledge, *e.g.* mathematics and English, has vanished. He speedily becomes disheartened and ceases to attend. As a result, the greater portion of such chances as he possesses of rising in his trade, or of even keeping his position in a few years' time, vanishes. Not only is the worker thus damaged in an industrial sense, but the community loses, first by his diminished efficiency as an industrial unit, and secondly by the lessening in the sum total of sustained intellectual effort made by its citizens. Every workman, who by systematic instruction passes from the level of the ordinary artisan to that of the trained, intelligent worker, becomes an asset of increased value to the nation.

The problem now is, What can be done to (*a*) carry on the education of the wage-earning youth of this country during the years from thirteen to seventeen, (*b*) bridge over the present gap between the elementary school and the centres of higher evening instruction, such as the technical school? The solution lies in the development and the increased efficiency of the evening continuation school. The following statistics for 1906–7 from the report are not without interest as showing to some extent the measure of success which has been obtained:—

	Number of evening schools	Number of scholars on register in evening schools	Average attendance in public elementary schools (from five years upwards)	Percentage of evening scholars to day scholars
Lancashire ...	436	49,833	230,584	21.6
Yorkshire (West Riding)	308	29,447	211,281	13.9
Surrey	132	10 788	70,047	15.4
Birmingham ...	31	12,544	77,540	16.2
Bradford	34	8,361	35,372	23.6
Halifax	15	3,578	11,334	31.6
London	438	175,482	509,800	29.3
Manchester ...	92	26,838	88,887	30.2
Total for all counties in England and Wales	4,506	315,522	2,846,653	11.1
Total for all county boroughs in England and Wales	1,427	420,990	2,063,569	20.4

In recent years special attempts have been made in some districts to persuade boys and girls on leaving the elementary schools to join the continuation schools without delay. Some striking results have been obtained. In Widnes about 80 per cent. of the boys leaving the elementary schools commence attendance at evening schools without a break. Halifax has secured 66 per cent. The Lancashire County Education Committee reported in January that in the larger boroughs 37 per cent., and in the smaller boroughs 22 per cent., of the boys and girls leaving school during the year ending October 30, 1908, to secure employment, joined the evening schools immediately.

The principal recommendations of the Consultative Committee are the following:—

(1) The leaving age should be raised to thirteen years, and after a short period to fourteen years.

(2) Full-time exemption from the day school should only be given to boys and girls under sixteen when the parents or guardians can show that the children in question are suitably employed.

(3) It should be the statutory duty of each local education authority to make suitable provision of continuation classes for the further education of young persons up to the age of seventeen.

(4) Local education authorities should be empowered to make bye-laws compelling attendance at continuation classes for young persons up to the age of seventeen, and employers should be compelled to make provision enabling such young persons to attend the continuation classes.

(5) Employers should be forbidden under penalty to employ any young person under seventeen years of age who fails to attend the evening continuation classes regularly.

(6) The curricula of the continuation schools should be such as to continue the general education given in the primary school. It should have reference to the crafts and industries in the district, and prominence should be given to practical and manual instruction.

Most educationists will heartily support the above recommendations. Numbers (3) and (4) of the above are taken from the Scotch Education Act of 1908. The committee points out that in Germany attendance at continuation schools is compulsory in portions of twenty-two out of twenty-six of the constituent States of the Empire, and in Switzerland in portions of nineteen out of the twenty-five cantons of the Republic. The committee is of opinion that there is now a strong and rapidly increasing body of public opinion ready to support its recommendations. The committee estimates that the total cost (imperial and local) of "maintenance" which would follow from raising the leaving age to fourteen would be about 490,000*l.* per annum. The corresponding cost of compulsory continuation classes (exclusive of new buildings) would be about 2,600,000*l.* per annum.

The proposals of the committee, if adopted, would have important educational and sociological results. Thus for example, one of the main causes of unemployment would be eliminated. Educationally the proposals would have a far-reaching effect upon the develoomeut of a complete national system of education. As has been before indicated, the continuation schools would take the boys and girls from the elementary schools, continuing without a break their general education, while specialising to a limited extent in either commercial, agricultural, technical, or domestic work, depending upon the requirements of the pupils. At the age of seventeen the boys and girls, after this preliminary training, could then be drafted on to technical, or commercial or art schools. The continuation schools would thus link on directly, and coordinate with, the elementary schools on the one hand and the technical institutions on the other.

The direct and indirect gain to the community from (*a*) the improvement of the general education of the masses, (*b*) the increased technical efficiency of the workers, would be incalculable. In this connection the following extracts from the report may be given:—

"An increasing stock of practical ability in a nation enlarges the range of its economic abilities and rapidly adds, through all the gradations of directive responsibility, to the number of well-remunerated posts which could never have existed if men had not been forthcoming to fill them."

"A rising level of education among the mass of workers increases the real level of their wages, though this may not be accompanied by a rise in their nominal amount. It conduces to wise expenditure of income and to the avoidance of thoughtless or harmful waste."

"Improvements in educational opportunity make possible forms of government which give to the working class in the community an effective voice in policy and administration."

"The temper, the outlook, the recreations, and the ideals of a nation may be so refined and raised by the right kind of training as to secure for the mass of the people a more choiceworthy life." J. WILSON.

CHANGES IN COLOUR AMONG TROPICAL FISHES.

THE Zoological Society of New York recently issued a very interesting paper written by Mr. C. H. Townsend on the instantaneous changes of colour among tropical fishes (thirteenth annual report, 1909). The specimens came from the Bermudas, and are kept under favourable

Dark Phase.

Banded Phase.

Two Colour-phases of the Nassau Grouper (*Epinephelus striatus*).

conditions in the aquarium of the society. The changes of coloration "begin to be in evidence within an hour of the arrival of new specimens, or as soon as they recover from the alarm produced by handling, and are produced as long as the fishes live in the tanks, which, in some cases, may be several years."

The phases of coloration are illustrated by a striking series of photographs, two of which are reproduced. From these it will be seen that the fish can pass from a uniformly dark (plumbeous) colour to a banded phase with white markings. Four other phases can also be assumed, including a uniformly creamy-white one. This plasticity of coloration is characteristic of most of the fish dealt with, which include Serranidæ, Scaridæ, Teuthididæ, and Scorpænidæ. There is frequently a pale and a dark monochrome phase when the fish is at rest. Under any excitement, such as the presence of visitors, the fish assumes a parti-coloured aspect. This paper clearly shows how inadequate and misleading are many of the descriptions of colour hitherto accepted, and is a very suggestive and attractive piece of work. An error occurs on p. 3, where it is said that "their different colours result from muscular action upon one or more kinds of cells." The mechanism of colour-change is not muscular, but nervous.

MINERAL OUTPUT OF THE UNITED STATES.[1]

THE well-known publication referred to below now appears in a form slightly different from the one to which we have hitherto been accustomed, being issued in two volumes, the first devoted to the Metallic products and the second to the Non-metallic products; this is done in consequence of a recent legislative enactment (Act of May 27, 1908), and presents some advantages, though it might be well to submit, with all respect, to the Government of the United States, that these (and sundry other) publications of the United States Geological Survey stand in far greater need of condensation than they do of expansion. When a work becomes unwieldy, there are two obvious remedies, either to issue it in two volumes or to compress the information it conveys into smaller compass; the latter is no doubt the more difficult proceeding, though the one that best serves the interests of the readers, and it is a matter of regret that, in this case, the line of least resistance has been followed. In the present instance it leads also to a few anomalies, as, for instance, the inclusion of crushed steel (as an abrasive) and of certain other metalliferous materials, such as arsenic, manganese, chromite, &c., in the volume devoted to non-metallic products.

It is greatly to be regretted that the mineral statistics of the United States are issued in a form that makes comparisons with the mineral output of other nations difficult; for example, the various values of the metals are reported, not in the form of ore, but in the metallic state, though obviously the value in this form includes the cost of reduction of the metal, and leads to very serious duplication, which the compilers appear to have overlooked, although the introduction lays stress on the statement that "all unnecessary duplication has been excluded." To take an example, the production of iron ore is not given, but instead of it that of the pig-iron smelted from it, namely, nearly 26 million tons, valued at about 530 million dollars. Now the production of coke for the same year was 40 million tons, produced from 62 million tons of coal, valued at nearly 73 million dollars. Practically the whole of the pig-iron produced was made with coke as fuel, and, in the absence of exact figures, it will probably be a near approximation to the truth if we assume that three-fourths of the coke production, or, say, 30 million tons, was consumed in the production of the above pig-iron, so that coal to the value of, say, 55 million dollars was utilised in this way, and this sum is accordingly included in the above valuation of the pig-iron production; it is, however, also included in the sum total of the value of the coal production, and thus enters twice

[1] Mineral Resources of the United States, Calendar Year 1907. Part I., Metallic Products. Pp. 712. Part II., Non-metallic Products. Pp. 897. (Washington: Government Printing Office, 1908.)

into the grand total of 1904 millions of dollars given as the value of the mineral productions of the United States. The same is true of every other metal on the list; in some cases, notably, perhaps, in that of aluminium, the value of the metallic product is many times greater than that of the mineral from which it is produced; thus the value of the aluminium produced is given as 5 million dollars, whilst that of the bauxite from which it is produced is about 450,000 dollars; surely it is the latter figure, and not the former, that should enter into a list of the values of the mineral productions of any country.

In the non-metallic products similar anomalies are also to be met with; cement, bricks, oilstones and millstones are articles that owe a very great, if not in every case the greater, part of their value to the labour, fuel, and power used in their preparation rather than to the crude material from which they are produced; if an American sculptor carves a statue out of native marble, should the value of the finished statue be included in the sum total of the value of the mineral resources? There can only be one answer to such a *reductio ad absurdum*, and yet the principle is exactly the same as that of including the value of the dressed grindstones instead of that of the sandstone or grit from which they are cut.

The above are matters of principle which present, no doubt, great difficulties in arriving at a satisfactory solution; the coordination of the methods of tabulating the mineral productions of different countries, so as to admit of just comparison, has often been tried, but has never been attained successfully yet, so that all that statisticians can do is to take care that they thoroughly understand the differences that obtain between the various systems in vogue. In other respects the present volumes are quite up to the high standard that we have been accustomed to in the United States Geological Survey publications. As already said, they suffer from want of compression, and there are many repetitions that might be avoided and much superfluous matter that might well be excised. In fact, they require more careful editing than they receive at present, and this is all the more necessary seeing that the different articles are written by different contributors, and are of very unequal value.

For example, no careful editor would pass such statements as we find under the item fluorspar, where we are told that the mineral is "only slightly harder than calcite, and consequently crushes easily," whereas the ease or difficulty of crushing has nothing to do with hardness; and again, "When fluorspar is associated with zinc-blende, complete separation of the two minerals has been difficult on account of their nearness in specific gravity"; the specific gravity of fluorspar is about 3·1, and that of blende about 4, a difference which should afford an ample margin for successful separation in a suitable appliance.

Finally, it may be pointed out that although these volumes in their final form may be considered somewhat belated, no serious inconvenience results therefrom, as the wise precaution is taken of issuing the various sections in pamphlet form as soon as possible after the end of the year to which they refer, an advance sheet of statistics being, moreover, issued usually with considerable rapidity. This is a procedure that might well be imitated with great advantage by a good many other nations, our own not excepted. HENRY LOUIS.

THE INSTITUTION OF MECHANICAL ENGINEERS.

THE summer meeting of the Institution of Mechanical Engineers opened at Liverpool on Tuesday, July 27. The president, Mr. John A. F. Aspinall, and the council and members of the institution, were welcomed in the lecture hall of the Municipal Central Technical School by the Lord Mayor of Liverpool, Councillor H. Chaloner Dowdall, and the members of the Liverpool reception committee. The importance of Liverpool as an engineering centre secured an attendance of nearly 500 members, who participated in the excellent arrangements made regarding visits to works and excursions. The institution dinner was held in the Exchange Station Hotel on Tuesday evening, and the Lord Mayor and Lady Mayoress of Liverpool received the visitors in the Town Hall on Wednesday evening. Meetings were held for the reading and discussion of papers on Tuesday and Wednesday mornings in the Municipal Central Technical School. Brief extracts from these are subjoined.

Locomotives designed and built at Horwich were described in a paper by Mr. George Hughes, who is the chief mechanical engineer of the Lancashire and Yorkshire Railway. This company possesses 1517 locomotives, of which there are about 1100 in daily use. When the works at Horwich were opened, Mr. Aspinall, president of the institution, and at that time chief mechanical engineer, resolved to introduce standardisation and, wherever possible, interchangeability. Joy's valve gear was adopted, as it was found that the mileage between repairs was greater, and also that there was a slight economy in coal per engine-mile.

Among other types of locomotives described it is of interest to note six engines which were fitted in 1902 with Druitt-Halpin thermal storage tanks. Where stopping places are frequent on rising gradients there is distinct economy. Certain tests carried out between Salford and Accrington resulted in a saving of one ton of water, and under similar conditions elsewhere the saving was 12 per cent. On other sections of the line, which are not so favourable, the all-round economy of these engines is brought down to 4 per cent.

A four-cylinder passenger and express goods engine, built to the author's designs in June, 1908, is also of interest. Absolutely perfect balancing could have been achieved without the aid of balance weights if the crank angles, the disposition of the cylinders, and the weights of the reciprocating parts had been arranged to neutralise amongst themselves the reciprocating disturbing forces; then, by balancing the revolving masses, the variations of rail load and the horizontal swaying couple would have disappeared. Excepting for a slight vertical component produced by the obliquity of the connecting-rod, the engine would then have been perfectly balanced. This arrangement, known as the Yarrow-Schlick-Tweedy system, would have involved an independent set of valve gear for each cylinder. Actually, the cranks were arranged in pairs at about 180° apart respectively, and the reciprocating masses, being made equal in weight, balance each other. The masses of the connecting-rods were divided between the rotating and reciprocating masses as suggested by Prof. Dalby, and the revolving masses were balanced by revolving balance weights. This engine is a very steady and smooth-running machine.

The discussion centred round the important questions of boiler deterioration, corrosion, and priming. Mr. Hurry Riches expressed the opinion that the best way of avoiding troubles due to the nature of the feed-water is to remove the impurities before feeding into the boiler; it is, however, inadvisable to reduce the hardness of feed-water below 6°.

A paper on reinforced concrete was contributed by Mr. Arthur C. Auden, of the firm of Messrs. William Cubitt and Co. Reinforced concrete is by no means a new thing; it has passed the experimental stage, as is evidenced by important structures erected in London in 1889, and still in use. On the Continent equally large structures exist which are now twenty-five years old, and have never been strengthened or patched. Failures have occurred through bad design or workmanship, but the proportion of these is small. The cost of the proposed structure is affected by the cost of its constituents, and these in turn by the cost of freight and carriage. Hence the author briefly classifies the materials, and gives useful hints on the properties of each.

For aggregates, the eastern counties' flint is often the only stone available locally. Good, tough concrete can be made with this, but is untrustworthy for fire-resisting purposes, owing to its tendency to crack and "fly" under heat. This tendency can be much reduced by first crushing all the stones. The same remarks apply to limestone, a material which is not more fire-resisting after being broken. As it is apt to disintegrate to powder under the action of heat, it is inadvisable to use this material where fire-resistance is an important consideration. Limestone always requires washing before use to get rid of the fine dust which covers it and prevents the cement properly bonding with it. Sandstone, as a rule, is too soft, porous, and absorbent for use in reinforced-concrete work. It may be safely used if it will stand about $1\frac{1}{2}$ tons per square inch under a crushing test, and also if the difference in weight when clean and dry, and after being two days under water, does not exceed 8 per cent. Quartzite stone is fairly good if not too soft and open in texture, in which case the same precautions apply as for sandstone. It should be noted that the test pieces for crushing tests should have an area of at least 10 inches or 12 inches.

With reference to artificially produced aggregates, broken earthenware and stoneware from the Potteries district make a good aggregate, but these must be unglazed, as the glaze prevents the proper adhesion of the cement. Burnt clay and gault may be used provided they are tough and hard, and do not soften or crumble after being left in water for two or three days. In general, broken bricks are not a good aggregate for reinforced concrete. They may be employed safely if hard and close in texture and free from mortar. Coke-breeze is cheap and readily obtained, but cannot be regarded as being really fire-proof. The effect of any sulphur present must also be considered. Ashes and clinkers may be used. In the case of ashes, only those which will float in water and are of uniform colour and texture, as well as being quite free from coal and dirt, should be used. Really hard and clean clinker alone is serviceable. In both of these sulphur must be considered. Slag from blast furnaces and cupolas makes a good aggregate if hard, tough, and free from dust; any sulphur present must be noted.

Sulphur is apt to attack the reinforcing steel with disastrous results. The maximum allowable percentage of sulphur in reinforced concrete aggregates is now being made the subject of experiments, and it is hoped an authoritative statement will soon be made. In the form of a sulphate sulphur is practically harmless, but is very deleterious if in the form of a sulphide.

It is of importance that no free lime be present in artificial aggregates; carbonate of lime is practically harmless. Washing and exposure to the air and sun will do much to convert sulphides into sulphates and free lime into carbonates. Good and accessible aggregates are often condemned because no discretion is exercised as to the form in which lime and sulphur occur.

A certain amount of sand is absolutely necessary in concrete, and no other material is at present known which can be substituted for it. Generally speaking, the better a sand is for moulding purposes the worse it is for reinforced concrete. Dirt in the form of slime, mud, or vegetable refuse is bad, but a little loam, enough to soil the fingers, but not enough to cause the sand to adhere to them, is no detriment. Small particles or nodules of clay do not appear to affect the strength of the concrete, but it is better to avoid them if possible. It is not good practice to use the stone aggregate, and its smalls and dust, together with some sand, upon the chance that they will be in proper proportion, and that the voids and spaces will be properly filled. Such a practice should not be allowed in reinforced work, where absolute homogeneity is so essential.

With reference to cement, any user is safe if he insists that his cement shall pass the British standard specification in every detail, and purchases from a trustworthy maker. It should not be one of the many mixtures imported into this country as cement, which do not deserve the name, and are costly at any price.

Methods of inserting the reinforcement in beams, slabs, columns, &c., together with hints on erecting various structures, take up the remainder of this valuable paper.

Prof. Unwin spoke of reinforced concrete construction as demanding excellent execution and supervision to be successful. In regard to formulæ of the empirical class, largely employed in this subject, the range of experimental work should rule the trustworthiness of the formulæ. Much of the present methods of design is based on guesswork. He took the opportunity of urging the necessity for more extended experiments.

In presenting his paper on the advance of marine engineering in the early twentieth century, Mr. Arthur J. Maginnis naturally devotes a great deal of his space to the marine steam turbine. While the use of turbines has produced practically no advance or improvement in fuel consumption since 1901, still, an advance has to be recorded in that a greater speed has been attained. During the past eight years experience has shown the trustworthiness of the Parsons turbine machinery. Notwithstanding that there are now more than seventy steamers continuously plying to and fro, no sailing schedules have been upset by a failure of machinery, nor has a turbine steamer ever had to be towed into port. The author has no hesitation in stating that rotary machinery must eventually replace the present system in cargo steamers as well as in liners.

Combined systems of reciprocating and turbine machinery were referred to, but the author does not think that an extensive adoption of this system will be made. In evidence of the saving in weight in the boilers where turbines are installed, owing to the lower steam pressure which may be used, the author states that in the case of the *Lusitania* and *Mauretania* the saving in weight on the boilers alone is about 120 tons over and above that which would have been required if triple or quadruple piston engines had been used.

The author gives a summary of the results attained by marine engineering to date as follows:—vessels of close upon 800 feet length and more than 38,000 tons displacement are being propelled across the Atlantic at an average speed of $25\frac{1}{2}$ knots by turbine machinery working up to about 70,000 horse-power, having a consumption of upwards of 1000 tons per day. Similar results have been obtained in the turbine-propelled warship *Indomitable*, of more than 40,000 horse-power, and maintained across the Atlantic with water-tube boilers.

The electrical operation of textile factories formed the subject of a paper by Mr. Herbert W. Wilson. The principal advantage claimed lies in the fact that a much greater steadiness of drive can be obtained, with consequent higher average speed and increased output. Slight variations in speed above that corresponding to the maximum safe tension breaks the threads, and unless absolutely constant speed can be obtained, it is necessary to allow a margin of safety and to run at a speed materially below the breaking point. In one case in Lancashire, with two mills under the same management and of about the same size, and working under the same general conditions, the results obtained from the electrically driven factory have been distinctly superior to those from the mechanically driven one. The improvement in the quality of yarn was so noticeable that the output from the electrically driven mill fetched a distinctly better price than that from the other factory, the increase being stated at about $2\frac{1}{2}$ per cent. As regards increase in production, mills in this country which have adopted electrical driving may be estimated as showing an improvement of 5 per cent.

A paper on the indicating of gas engines was contributed by Prof. F. W. Burstall, of Birmingham University. The Standards Committee of the Institution of Civil Engineers expressed the opinion in their 1906 report that the indicating of gas engines was open to very much greater errors than was the case with steam engines, and this matter has been considered by the Research Committee of the Institution of Mechanical Engineers. In the tests undertaken by the author, two indicators were used simultaneously, one of the ordinary string type and the other an optical indicator. A Premier gas engine was used having a cylinder 16 inches in diameter by 24 inches stroke, running at 165 revolutions per minute. The only variation in the four tests recorded was the amount of gas admitted, the mean pressure varying from $5\frac{1}{2}$ kg. per $cm.^2$ up to about $7\frac{1}{4}$ kg. per $cm.^2$

The string indicator employed was of the Crosby type, selected for these tests by the Crosby Company. Before and after each set of trials the indicator was tested for backlash and friction, and the spring also calibrated. The backlash was in all cases negligible, and the friction amounted to less than 1 lb. with a spring having a scale of 400 lb. per square inch. The optic indicator was lent by Prof. Hopkinson, and was calibrated at the University.

Both indicators were mounted on a branch piece connected to the engine cylinder, and the indicator diagrams were taken simultaneously. The indicator barrel of the Crosby indicator was rotated by a phosphor-bronze stranded wire wound round the barrel and led to a bell-crank lever. The bell-crank lever was driven by a steel wire attached to the usual lever driven by the engine piston. A very heavy spring, in which a compression of 400 lb. produced a contraction of 2 inches, controlled the bell-crank lever. The optic indicator was also driven by means of a phosphor-bronze stranded wire.

The mean diagrams were prepared from no fewer than twelve individual diagrams, each being divided by the method of ordinates, and the heights read by an accurate steel rule. With care it was possible to read the Crosby diagrams to an accuracy of half of 1 per cent. The optic indicator diagrams could readily be measured to the same order of accuracy. The diagrams were plotted on squared paper, and superposed one on the other, so as to exhibit whatever differences there were between the indicators.

Speaking generally, the compression curves are coincident. The maximum pressures practically agree in two of the tests; in a third, the Crosby indicator gave the higher initial pressure, and in the fourth the Hopkinson gave the higher. Down the expansion line the two indicators agree for the third of the stroke. After that the Hopkinson indicator gave a persistently higher expansion line, the difference between the two lines being higher than the probable experimental error of the measurements. The effect of this difference is to make the Hopkinson indicator give about 3 per cent. higher mean pressure than the Crosby.

In the Hopkinson indicator the spring was in the form of a flat bar rigidly fixed at the ends and loaded in the centre; the central deflection of this beam is a direct measure of the pressure on the piston. During calibration with dead weights, from which the scale of the spring is obtained, the ends of the bar may be assumed to be absolutely fixed, but when the indicator is in use it is possible that there is a slight slip in the bar through the screws which restrain it. The effect of this would be to prevent the pressure falling so rapidly in this indicator as in the Crosby indicator. The author believes that this explanation is more likely to be correct than that the effect is due to inertia or friction, and is inclined to prefer the results obtained from the Crosby indicator.

While the results of this comparison do not offer an absolute proof of the accuracy of either indicator, there is still strong evidence that both give results very close to the truth. The indicators are of entirely different types, one multiplying the indicator piston movement by six, the other by about 120, a very similar multiplication being the case with the rotation of the drum and the mirror. In the optic mirror inertia is certainly negligible. That the two give results to within 3 per cent. on the mean pressure, and very nearly the same figures for the initial pressure, is good presumptive evidence that, when either indicator is used with the precautions regarding driving described, the results so obtained are at least as accurate as any other measurement which can be made in engine testing. Unless these precautions are taken, the results can only be regarded as affording a clue to the valve setting, and give no trustworthy figures as to the power developed in the engine cylinder.

The council of the institution has issued the conditions under which the second award of the water arbitration prize will be made in 1910. The prize will have a value of about 30*l*., and will be awarded to the author of the best original paper dealing with any branch of the mechanics of the supply or distribution of water. The latest date for sending in papers will be September 1, 1910.

MR. HALDANE ON THE PROMISE OF AVIATION.

In Committee on the vote of 36,464*l*., including a supplementary sum of 6500*l*., to complete the sum necessary to defray the charge for sundry grants in aid, scientific investigation, and other grants, there was an interesting discussion in the House of Commons on August 2 on the subject of aviation for naval and military purposes. Mr. Haldane made a statement giving the views and intentions of the Government.

Mr. Haldane said he had made up his mind that there could be no real progress unless we proceed scientifically and in order—that is to say, unless we are perfectly clear about what we want, as to the structure of the machines which will be used for the purposes in view, and the production of them in a way which should be at least effective. The first thing done was to ask the Committee of Imperial Defence to investigate this question and to discuss it with the technical subcommittee. The report was to the effect that the class of machines must be divided into three heads:—rigid dirigibles, non-rigid dirigibles, and aëroplanes. For naval purposes the rigid dirigible is probably the only instrument of the kind which is of real value, at any rate in the present state of knowledge. For the army the rigid dirigible has certain disadvantages. It is more difficult to work, to bring back, and to bring to rest. It is more difficult for the army than for the navy. The non-rigid dirigible is the best for army purposes. The aëroplane may become available for army purposes, but at present it has certain defects. It will have to rise much higher before it can be a safe instrument for reconnoitring. But M. Blériot's splendid feat in crossing the Channel and the successes achieved in the United States point to a time when the aëroplane may be an instrument capable of achieving great results.

To the navy has been assigned the duty of investigating, with the view of constructing, the rigid dirigible, the ship of the Count Zeppelin type. To the army has been assigned the duty of experimenting with the non-rigid dirigible, the machine of varying type, and also with aëroplanes.

To make their study of aviation scientific, Mr. Haldane said the Prime Minister constituted the advisory committee, under Lord Rayleigh's presidency, on which there is some of the best scientific brains in the world. Continuous work has been going on at the National Physical Laboratory. Meetings have been held there and at Aldershot and the War Office. The committee is to advise, its purpose is to scrutinise inventions submitted in the course of the work of the departments concerned, and to conduct systematic experiments. In a few days the first report of this committee will be made public. The committee, said Mr. Haldane, has such men as Lord Rayleigh and Dr. Glazebrook on it, and such men on the practical side as Mr. Lanchester and Mr. Mallock, and others like Prof. Petavel and Dr. Shaw, and also such high authorities on the army and navy side as Major-General Hadden and Rear-Admiral Bacon, and is well furnished from the various points of view. This committee has been at work, and the first thing it has done is to determine the general question which should be studied. There have been various memoranda by the experts on stability, screw propellers, wind structures, petrol motors, and a very difficult thing which has arisen in connection with balloons, the accumulation of electrostatic charges. Everyone knows what a peril electricity is in the air. Then the committee has mapped out the general field of its work. There are certain general questions in aërodynamics, questions specially relating to aëroplanes, such as the mathematical investigations of stability, the effect of rudder action, gusts of wind, and half a dozen other things which I need not enumerate. There are propeller experiments; there are questions relating to these motors which have to be of special construction for air work, general questions relating to airships, and still more general questions relating to meteorology.

The committee has entered into communication with the Aëronautical Society, the Aërial Club, and the Aëro League. The design is to afford assistance to private inventors wherever this can properly be done, because progress in this matter will be, not merely a Government, but a national matter. The Admiralty is concentrating, under Admiral Bacon, Director of Naval Ordnance, on the building of a rigid dirigible of the very largest type, at least the size of the *Zeppelin*. That is being built at Barrow-in-Furness by Messrs. Vickers. The combination of experts and practical men may give us a practical result some time next spring. The War Office is reorganising its factory at Aldershot. The instruction, which is at present given to balloonists under the superintendence of Colonel Capper, is being separated from construction, and at present preparations are being made for the construction of a shed which will take in the largest size of dirigible. The Admiralty has in prospect one great rigid dirigible, the War Office has three, and besides those we have our balloons for war purposes. At the present time we have certain aeroplanes, and the prospect of two new aeroplanes which are to be presented for experimental purposes, and may hereafter be acquired. That is the actual position of things.

IMPROVEMENTS IN PRODUCTION AND APPLICATION OF GUNCOTTON AND NITROGLYCERINE.[1]

II.

In the year 1846 Schönbein discovered guncotton. In the year 1886, that is, forty years later, the French chemist Vieille invented his smokeless powder for military purposes. This explosive, which was primarily designed for use in the small calibre Lebel rifle, consisted essentially of guncotton, and the secret of its success lay in the fact that Vieille so altered its physical state that its rate of combustion, when confined, was under complete control. This condition was arrived at by treating the fibrous guncotton with suitable solvents which entirely destroyed the fibre and converted it into a colloidal, horny substance quite devoid of all porosity. The gelatinised guncotton resulting from this treatment burnt, when ignited, from the surface inwards, and by varying the surface area any required rate of combustion could be obtained. The use of smokeless powders manufactured in this way was very soon extended to all natures of ordnance.

The next step in the development of smokeless powders was the combination of nitroglycerine with nitrocellulose. The first powder of this type was the "ballistite" of Alfred Nobel, patented by him in the year 1888. The original ballistite was composed of equal parts of nitroglycerine and of soluble nitrocellulose, a variety of guncotton soluble in nitroglycerine, and no solvent was therefore required in its preparation, although a certain proportion of camphor was used to promote the solution of the nitrocellulose. Another form of nitroglycerine-nitrocellulose explosive is the British service powder, cordite, which originally consisted of nitroglycerine, 58 parts, guncotton, insoluble in nitroglycerine, 37 parts, and mineral jelly, a product of the distillation of crude petroleum, 5 parts. To effect the gelatinisation of the guncotton, the solvent acetone, obtained indirectly from the destructive distillation of wood, is employed. The result of subjecting nitrocellulose in suitable machines to the action of nitroglycerine or of solvents, of which there are several suitable ones besides acetone, is to destroy its fibre and convert it into a gelatinous mass, in which condition it can be formed into any desired shape. Where solvents are used to produce this result they remain in the mass during subsequent operations, and are finally driven off by means of heat. The resulting products, somewhat incorrectly termed "powders," which are manufactured in a variety of forms, such as grains and flakes of different shapes, ribbons or strips, solid cords, tubes, &c., vary in consistence with the quantity of nitroglycerine they contain. The more nitroglycerine present the softer the powder, pure nitrocellulose powders being hard to brittleness.

For practical purposes modern smokeless powders are of two types:—

(1) Those consisting entirely of nitrocellulose, and termed "nitrocellulose powders."

(2) Those consisting of a mixture of nitrocellulose and nitroglycerine, known as "nitroglycerine powders."

Opinions differ somewhat as to the relative merits of these two types; in this country the latter type is preferred. Their characteristic features are, briefly, as follows:—

A nitroglycerine powder is more powerful than a nitrocellulose powder, and the more nitroglycerine present the more powerful the explosive. Therefore, for equal ballistics, a smaller charge of the former than of the latter is required, and, consequently, the chamber capacity and the size and weight of the breech mechanism are reduced; on the other hand, the higher the proportion of nitroglycerine the higher is the temperature of combustion and the greater the erosive effects on the surface of the bore of the gun.

The presence of nitroglycerine in an explosive allows of the more easy and rapid elimination of the solvent used in manufacture and of moisture, a small quantity of which is always present in nitroglycerine and guncotton. The sooner this is attained the better, because the longer the time that the powder is being heated in order to dry it, the more likely is its chemical stability to be affected. Moreover, it is a well-established fact that with nitrocellulose powders it is impossible to remove the volatile matter with anything like the same completeness as can be done in the case of nitroglycerine powders. The consequence is that the slow evaporation from nitrocellulose powders of the residual volatile matter which takes place in store tends to produce changes in their physical character and renders them in course of time liable to alter in ballistic properties, and even to develop dangerous pressures in the gun.

Nitroglycerine powders are cheaper than nitrocellulose powders, weight for weight, and even more so for equal ballistic effects.

The original cordite, the manufacture of which commenced in 1890, contained a high proportion of nitroglycerine, 58 per cent., and the erosion produced, especially in large guns, was considerable. This led to experiments being carried out at Waltham Abbey with the view of the production of a less erosive explosive, and the final result was the introduction into the service, in 1901, of a modified cordite known as "cordite M.D.," in which the percentage of nitroglycerine is reduced to 30 per cent., so that the composition becomes:—nitroglycerine, 30 per cent.; guncotton, 65 per cent.; and mineral jelly, 5 per cent.

The constants of explosion of cordite and cordite M.D., determined at the Royal Gunpowder Factory some little time ago, are as follows:—

Explosive	Density of Loading	Heat of Explosion at Constant Volume, Water Gaseous	Total Gases, Water Gaseous at 0° C., 760 mm.	Temperature of Explosion
		Calories per gram	c.c. per gram.	C.
Cordite ...	0·2	1156	871	2663
Cordite M.D.	0·2	965	920	2374

An inspection of these figures shows that the alteration in proportions of the explosive ingredients results in a decrease in the heat of explosion of about 16½ per cent., and an increase in the volume of gases of about 5½ per cent., whilst there is a decrease of 289° C. in the temperature of explosion.

As would therefore be expected, the erosion produced by cordite M.D. is very much less than that produced by the original cordite for the same ballistics, and is certainly not greater, if as great, as that produced by the best forms of nitrocellulose explosives.

Although of minor importance to smokelessness, flamelessness is a desirable quality for propulsive explosives to possess. In this respect cordite M.D. is superior to cordite in the case of rifles and machine guns; unfortunately, a suitable ingredient has not yet been discovered which will render smokeless powders flameless in large guns.

A third ingredient in both natures of cordite, viz. mineral jelly, although present in a comparatively small proportion, is a very important constituent.

Cordite in the advanced experimental stage consisted of nitroglycerine and guncotton alone, and as their combustion produced no solid residue of any kind, the surface of the bore of the magazine rifle in which the early experiments took place was not fouled in any way. The result was that the cupro-nickel coated bullets, propelled in succession at high velocity through a clean barrel, deposited some of the cupro-nickel in the bore. In order to prevent this a number of substances were incorporated with the nitroglycerine and guncotton, with the object

[1] Discourse delivered at the Royal Institution on Friday, January 29, by Sir Frederic L. Nathan, R.A. Continued from p. 147.

of producing a deposit in the bore, which it was hoped would get rid of the difficulty of metallic fouling. Of all these various substances the one which appeared to answer the purpose most satisfactorily was refined vaseline, and this material became the third ingredient of cordite as eventually introduced into the British service. When the manufacture was commenced on a large scale, vaseline, which is the proprietary name of one of the refined products of the distillation of petroleum, was replaced by mineral jelly, the same material, but in a cruder form.

The original object with which mineral jelly was introduced was of no importance when cordite was substituted for the black and brown powders used in large guns, but in order to have but one nature of smokeless powder in the service mineral jelly was added to all cordite, whether for use in small arms or artillery. Subsequent experience has demonstrated how very fortunate was the selection of this material for rifle cordite and the extension of its use to all sizes of cordite.

Mineral jelly is one of the best ingredients it is possible to have in smokeless powders from the point of view of their chemical stability. This important fact, not recognised originally, was brought out in the following way. In order to facilitate the explosion of cordite in blank ammunition for the rifle it was cut into very thin flakes, and the non-explosive mineral jelly was omitted from its composition. After a comparatively short storage in a hot climate the stability of the smokeless blank, as it was called, was found to have suffered seriously, whereas the stability of normal cordite containing mineral jelly was not appreciably affected. These facts led to a thorough investigation at Waltham Abbey of the action of mineral jelly in preserving the stability of cordite, and it was discovered that mineral jelly contained constituents which had the valuable property of combining with the decomposition products (the result of prolonged storage of cordite at high temperatures) to form stable bodies, thus removing these decomposition products, which undoubtedly exert a deteriorating influence on the cordite from their sphere of action.

When Abel was engaged on his researches in connection with the production and properties of guncotton, it was obvious to him that some test of a chemical nature was required in order to ascertain whether or not the finished guncotton had been thoroughly purified in manufacture. It will be remembered that accidents occurred in the early days of its production because this purification had not been carried sufficiently far. The test which he devised was based on the principle that if guncotton be subjected to an elevated temperature, traces of oxides of nitrogen will be given off, and will reveal their presence by acting on a suitable reagent.

The test is carried out by heating guncotton in a test-tube placed in a water bath, and suspending over it a strip of moistened filter paper impregnated with potassium iodide and starch. If the purification of the guncotton has not been sufficient, the discoloration of the test paper takes place early; as the result of experience Abel fixed a time before which no reaction should take place. This test, known as the Abel heat test, is a test for the purity of guncotton and of nitroglycerine, and of freshly made explosives containing either one or both of these ingredients. For this purpose no test has yet been devised which equals it. But it was never intended to be, and is not, a quantitative test, and is therefore only a rough guide, though a very useful one, as to the stability of an explosive which has been in store for more or less prolonged periods, or under more or less adverse conditions.

Smokeless powders of the types dealt with are all subject to deterioration, and there is very little doubt that this deterioration is for any given explosive a function of the temperature of storage. The higher the temperature the more rapid the deterioration.

The necessity, therefore, of some quantitative test which would enable a judgment to be formed as to the extent of deterioration suffered by any given sample of cordite is obviously of great importance, because such a test would afford the means of determining how much longer it would be safe to store any given batch of cartridges or lot of cordite at any given temperature. Any such test must be a heating test, and it must be possible to correlate the temperature and duration of the test with any given temperature and duration of storage. The rate of deterioration as a function of the temperature was determined by Dr. Will for guncotton, and later by Dr. Robertson at Waltham Abbey for nitroglycerine. From these and other experiments carried out at Waltham Abbey, a factor of increase in rate of deterioration of cordite with increase of temperature was deduced. This factor having been determined, what is known as the "silvered vessel test" was worked out at the Royal Gunpowder Factory. In this test, of which the details will be described presently, cordite is heated in a specially designed vessel at 80° C., a temperature not too far removed from those to be met with when cordite is stored under the worst service conditions, and the number of hours' heating at this temperature any given sample will stand before it shows signs of active decomposition are ascertained. Then, by means of an equation, containing the factor connecting rate of increase of deterioration with rise in temperature, a calculation can be made converting the hours of heating at 80° C. the sample withstood to years and fractions of a year it would stand at any given temperature of storage, and therefore a knowledge is obtained of how much longer it would be safe to store this cordite at any given temperature.

This test was applied to a considerable number of samples of known age and thermal history. From these data, and knowing the number of hours at 80° C. that newly made cordite of good stability will stand before showing signs of decomposition, the number of hours that the different samples should stand the test were calculated. When the samples were actually tested, the number of hours' heating at 80° C. they withstood were in close agreement with the number of hours it was calculated they should stand.

The form of vessel in which the heating is carried out is the well-known vacuum vessel of Sir James Dewar. A glass bulb silvered externally is enclosed in an outer bulb silvered internally. The space between the two is highly evacuated for the purpose of limiting the dissipation of any heat evolved by exothermic changes on the one hand, and on the other for the purpose of minimising the effect of accidental slight changes in temperature of environment.

In the centre of the inner bulb is situated the bulb of a thermometer, the stem of which passes through a cork in the neck of the vessel. A side tube is attached for the purpose of making observations on the colour of the gases evolved. For heating the vessel a bath is provided with cylinders closed at the bottom, and wide enough to admit the vessel to such a depth as the side tube will permit. The bath is surrounded by insulating materials. The vessels are packed in the cylinders with wool yarn, and the tops of the cylinders are closed with felt discs to exclude draughts.

The bath is fitted with a gas regulator or other means for securing that the temperature of the explosive is kept constant.

The cordite is coarsely ground, and 50 grams are used.

Readings of the thermometer are taken at intervals, and the time is noted when a rise of 2° C. in the temperature of the explosive above the temperature of 80° C. occurs. At the same time, visual observations are made as to the colour of the column of gas in the side tube, since it is found that, previous to the rise in temperature occurring, orange-coloured fumes of nitric peroxide are evolved. When the temperature exceeds 82° C. the test is complete, and the flask is withdrawn. The number of hours which have elapsed since the start of the test is the measure of the stability of the cordite.

Until about sixty years ago, the only explosive known for all purposes was gunpowder. With the discovery of guncotton and nitroglycerine, gunpowder was gradually replaced by them for blasting purposes. In their early days the two explosives were used singly, guncotton as guncotton, nitroglycerine—first of all alone—and then as dynamite. Later on the two were combined as blasting gelatine and explosives of a similar nature, but it was quite forty years after their discovery before either became of practical use for propulsive purposes.

The invention of "Poudre B" by Vieille marked the commencement of a new era in connection with the science of artillery, and it was not long before smokeless powders made from the violent guncotton, or of guncotton combined with the still more violent nitroglycerine, entirely superseded the centuries-old gunpowder. Modern explosives are characterised by very greatly increased power, giving enormously greater range to projectiles fired from both rifles and artillery, thus altering entirely the conditions of both land and naval warfare.

It is at present not easy to forecast in what direction further improvements in propellants will take place. It is also difficult to conceive what the explosive of the future will be which will produce a change as revolutionary as that which took place when smokeless powders superseded the old-fashioned black powders. For some time to come, probably, the manufacturer of explosives will have to content himself with endeavours to improve them as far as he can, both from a ballistic and from a stability point of view, with the ingredients now at his disposal.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. A. ROBINSON, professor of anatomy in the University of Birmingham, has been appointed to the chair of anatomy in Edinburgh University in succession to the late Prof. D. J. Cunningham, F.R.S.

IT is stated by the *Frankfurt Gazette* that the National Assembly of Iceland has decided to establish a university at Reikjavik, the capital of the island. The new university is to have four faculties, with sixteen professors and lecturers.

MR. EDWIN TATE has presented new library buildings to Battersea Polytechnic. The total book accommodation is 20,000 volumes. The cost of the buildings, including fittings, is estimated at about 6000*l*., and the whole is being defrayed by Mr. Tate.

A CORRESPONDENT informs us that the appointments to the chairs of chemistry in the Technical High School at Munich have just been officially announced. The names of the various professors are:—organic chemistry, Prof. Semmler; inorganic chemistry, Prof. A. Stock; physical chemistry, Prof. R. Abegg. Each professor has an institute of his own, and Prof. Abegg retains, at the same time, his position as extraordinary professor in the University of Breslau. The Technical High School, which is being built at a cost of something like five million marks, is making good progress, and is to be opened officially in October, 1910.

THE commencement address last June at the South Dakota School of Mines, Rapid City, South Dakota, was delivered by the president of the Colorado School of Mines, Mr. Victor C. Alderson, who took for his subject "Artist or Artisan—Which?" "The artisan," he said, "understands machinery; the artist-engineer is a master of the kinematics of machines. The artisan works with his hands and lets his mind rest; the artist-engineer uses his brains to relieve his hands. The artisan becomes a skilled workman and no more; the artist-engineer sees beyond the mere machinery to the economic management of his plant, to the percentage saving possible, to the market for his product, to the efficient service of his employees, to the general success of the entire plant. To do all this he must have an ideal." Every young engineer, he proceeded to say later, should decide early in life whether he will become merely an artisan-engineer or an artist-engineer. Mr. Alderson then gave some inspiring advice to young engineers as to the physical, personal, intellectual, and moral characteristics they should strive to develop. Incidentally, he said the chance for the untrained or uneducated man to make a success in this age is practically *nil*. Taking "Who's Who" as a standard of national prominence in America, it is found, said Mr. Alderson, that it takes approximately 10,000 grammar-school pupils to produce one man worthy to be enrolled in "Who's Who." Of high-school students 250 suffice, while of fifty college graduates one will, on the average, rise to sufficient prominence to be enrolled in this book.

THE proceedings in connection with the celebration of the 500th anniversary of the founding of the University of Leipzig began on July 28, when a reception was given by the University to the representatives of German and foreign universities and learned societies invited to participate in the proceedings. On the following day a festival service in the University Church was attended by the King of Saxony. A commemorative meeting in the new theatre followed the service, and the King delivered an address and presented two medallions to the University to be worn in future by the rector of the University on his chain of office. The medallions bear images of the King of Saxony and of the founder of the University. The Saxon Minister of Education in an address afterwards outlined the history of the University. On July 30 further commemoration speeches were delivered. Prof. Wundt was the principal speaker, and during the course of his speech remarked, although the German people seem to be in the current of an intellectual movement in which the demand for higher education is hardly less strong than was the revival of learning in the Middle Ages, he said, in the words of Leibnitz, "It is the past which contains the future." Prof. Mahaffy spoke on behalf of the British delegates. The following honorary degrees were conferred among others:—Doctor of Medicine, Prof. E. B. Wilson, of Columbia University; Doctors of Philosophy, Sir Archibald Geikie, K.C.B., P.R.S., Prof. J. Loeb, of California University, Prof. J. Ward, of Cambridge University, and Mr. F. L. Griffith, reader in Egyptology, Oxford University.

ASIATIC PALMS.

Annals of the Royal Botanic Garden, Calcutta, Vol. xi. Asiatic Palms—Lepidocaryeæ. Part i., The Species of Calamus. By Odoardo Beccari. Pp. iii+518; 2 4to plates; 238 plates large fol. (Calcutta: Bengal Secretariat Press, 1908.) Price 7*l*.

THE palms of Asia have received considerable attention in the Royal Botanic Garden at Calcutta, where there is an extensive Palmetum, with a noble collection of living species. Roxburgh, superintendent of the garden from 1793 to 1813, studied the palms of the Indian Peninsula, and left, in addition to descriptions posthumously published in his "Flora Indica," a series of drawings of the species he knew alive. Anderson, superintendent from 1861 to 1870, described the palms of Sikkim in the Journal of the Linnean Society, vol. xi., in 1869. Kurz, curator of the Calcutta herbarium from 1864 to 1878, dealt with the palms of Burma in the Journal of the Asiatic Society of Bengal, vol. xliii., part ii., in 1874. But the work of Roxburgh was only preliminary, the work of Anderson and Kurz only supplementary to that of Griffith, who acted as superintendent of the Calcutta garden during 1842–4. This able observer died at Malacca in 1845, and his treatise, "The Palms of British East India," was not printed until 1850. Less complete than he could have made it had he lived to see it through the press, this work by Griffith yet remained the standard authority on the subject until the appearance, in 1892, of the account of the Indian Palmeæ by Beccari and Hooker in the "Flora of British India," vol. vi. The long-standing association of the great Calcutta garden with the elucidation and illustration of Asiatic palms is now happily continued by the publication in its Annals of the first portion of a comprehensive account of the family by Signor Beccari, who dedicates his work to the memory of the gifted Griffith.

This volume commences the discussion of the tribe Lepidocaryeæ, palms the fruits of which are clad in a mail of reflexed, adpressed, closely imbricating scales, and deals with the genus Calamus, the largest and most important in that tribe. Workers who know these "Rotangs" as they grow are familiar with the difficulties that attend their study; those unacquainted with these fascinating but formidable "canes" in a wild state will learn something of these difficulties from the essay with which the volume opens. All will welcome a work on the subject by one whose knowledge of the species in the field is comparable with that of Griffith himself, and who has had the advantage, which was denied to Griffith, of access to practically all the herbarium material of the genus that exists.

The greater part of the letterpress is devoted to detailed accounts of the various species which the accompanying plates illustrate. Those who study these descriptions will be grateful to the author for the conscientious absence of uniformity in their presentation. Where his material is adequate, the author has provided full and carefully weighed statements of the specific characters; where his material is limited he has restricted himself to faithful accounts of the actual specimens on which his species are based. His work is thus free from that unconscious tendency to generalise more widely than the material at a writer's command will justify, which sometimes detracts from the value of treatises wherein the descriptions of species that depend on the study of perhaps a solitary example are cast in the same mould as those based on extensive suites of specimens. At the same time, he has shown himself fully alive to the advantages of methodical treatment, and, in a careful synopsis which immediately precedes his detailed descriptions, the author has characterised all the species he is able to recognise with sufficient fulness to admit of their determination, and in a manner that leaves nothing to be desired so far as uniformity of presentation is concerned.

In a systematic conspectus of the species, which follows the definition of the genus, the author has skilfully applied to the practical task of establishing order among what would otherwise be an undisciplined horde of forms that knowledge, at once comprehensive and minute, of the morphology of Calamus to which the introductory essay testifies. He is thereby able to throw his species into sixteen readily recognisable groups, some of which admit of further subdivision, while the whole of them are capable of aggregation into four series. One of these series, it is true, contains but a single group, the characters of which are admittedly anomalous, while the imperfect nature of the material as yet available renders it impossible, in the case of about 5 per cent. of the species, to state with certainty to what group they should be referred. But this conspectus will enable the worker in the field, whose needs should be the first consideration of conscientious systematists, to recognise with comparative ease at least the affinities of any "Rotang" he may encounter. The applied botanist, too, will feel indebted to the author for the many economic notes that accompany the detailed accounts of such species as are practically useful.

The plates which accompany the work are mainly phototype reproductions of the author's natural-size photographs of herbarium specimens; in a few cases, where the material available did not readily lend itself to this method, lithographed drawings take the place of phototypes. Photographic methods, though usually satisfactory so far as fidelity is concerned, when applied to the illustration of herbarium specimens often leave something to be desired from the æsthetic standpoint. Here, however, there is little ground for criticism on this score, and if it be true that specimens of Calamus lend themselves more readily to the requirements of photography than herbarium material usually does, this is not the whole explanation of the success that has here been achieved. That success is in large measure due to the care and skill of the author, who has, moreover, been fortunate in the matter of reproduction from his negatives, which reflects much credit on those to whom it has been entrusted. The size of plate adopted, it may be observed, is that of the double plates issued in former volumes of the Calcutta Annals, so that librarians who desire to bind the illustrations in conformity with the text are left free to do so. But there will probably be others who may prefer to leave the plates unfolded, and the editor of the series has earned the gratitude of those into whose hands this volume may come for his decision to issue the illustrations in a larger portfolio than that which contains the letterpress, thereby leaving them free to decide the course to be adopted. The work before us is a valuable addition to the series of volumes for the initiation of which the scientific world is indebted to the late Sir George King, and botanists generally will not only feel grateful to Signor Beccari for its preparation, but will desire to associate themselves with him in his appreciation of that "enlightened munificence" on the part of the Government of Bengal which has rendered its appearance possible.

GYROSCOPIC MOTION.

An Elementary Treatment of the Theory of Spinning Tops and Gyroscopic Motion. By Harold Crabtree. Pp. xii+140 and 3 plates; with illustrations. (London, New York, Bombay, and Calcutta: Longmans, Green and Co., 1909.) Price 5*s*. 6*d*. net.

THIS enchanting and bewildering subject has in recent years been admirably expounded in two well-known books, one somewhat more severe in its treatment than the other. The author has now provided a third, which will be valued by those who already possess and take pleasure in the other two even more than by those who approach the subject for the first time. The mathematical treatment is far more severe, so much so that the average student who scoffs at the term elementary on the back of some of his text-books will certainly in this case consider it inconsistent with the subject-matter of the last few chapters. However, if he will afterwards read the subject in, say, the "Encyclopædia Britannica," he will realise that the term is not so misleading after all.

The method by which the theory is introduced is admirable. In an introductory chapter, illustrated by twenty-six figures, all sorts of tops and spinning things, familiar and otherwise, are described, and their curious behaviour in each case simply stated. An interest is thus awakened, and the reader, if unfamiliar with the subject, realises at once what sort of thing he is going to have presented to him. In the writer's opinion this method would be advantageous generally where a difficult subject is being opened. If, for instance, before the first chapter of the typical book on the integral calculus or before Euclid's definitions there were a lightly written chapter giving more or less familiar experiences which are puzzling, but which will in due time be made clear, the reader would be more encouraged than he is by the existing openings.

The author clears the ground by giving very exact ideas on the subject of rotation about a fixed axis, laying stress at every point on the dimensional identity of the two sides of every equation. In dealing with the subject of precession, he is by no means content to handle the ultimate condition of steady precession, but he goes fully into that more difficult subject which may be summarised under the term gyrostatic elasticity, and which includes the immediate displacements and vibrations or wobblings of axes when disturbing couples are applied or removed.

The latter part of the book is in large part devoted to the difficulties connected with the motions of the axis of rotation of an ellipsoidal body within itself and in space. Among matters of interest discussed will be found the behaviour of celts, the self-turning of a falling cat, with kinematograph views, the diabolo, the Brennan mono-rail, and Schlick's gyroscopic device for steadying ships.

While criticism is misplaced, the writer would suggest that those diagrams, such as Fig. 20, in which bent arrows are intended to show a direction of rotation round an axis indicated by a line, are, as drawn, ambiguous, for it is impossible to tell whether the arrow is intended to be in front of or behind the line. If one or other were broken through the meaning would be evident, as it is, for instance, in Fig. 18, where the arrow is clearly in front of a material axle.

C. V. BOYS.

MAGIC SQUARES.

Easy Methods of Constructing the Various Types of Magic Squares and Magic Cubes, with Symmetric Designs founded Thereon. By Dr. John Willis. Pp. 256. (Bradford and London: Percy Lund, Humphries and Co., Ltd., 1909.)

A MAGIC square is an example of a problem which is a particular case of another which from its enunciation may be subjected to mathematical analysis. The n^2 cells of a square of order n may be supposed occupied, each of them, by one or more numbers in such wise that the sums of the numbers in the n rows and in the n columns have given values varying from row to row and from column to column. The enumeration of such squares, or more generally of such rectangles, has been made the subject of mathematical investigation employing algebraic symmetric functions and the allied differential operators, and complete success has resulted. The absolute magnitude of the numbers appearing in the cells may be restricted, and any number of the cells may be empty; no additional difficulties present themselves. Other problems of enumeration of the magic square kind, of which the simplest is known as the Latin square, first examined by Euler, and by others up to the time of Cayley, have also in recent years completely yielded to the same calculus of symmetric functions. In all these cases row and column properties are dealt with, but directly we introduce what may be termed diagonal properties the analysis fails to overcome the great difficulties which are thereby imported into the problems. The problem of the magic square involves restrictions and limitations of the general problem above mentioned which render it impossible of complete treatment by any known method of analysis. The condition that the first n^2 natural numbers must appear one, and only one, in each cell, is, to begin with, of a most difficult character, and is made more so by the importation of the diagonal conditions. Many kinds of magic squares, moreover, involve additional properties connected with broken diagonals, nuclear squares, symmetrically placed cells, &c., which mathematically are of a most arduous nature. It thence arises that though many mathematicians of repute from the earliest times have studied the subject, they have devoted their labours mainly to observational and tentative methods of actually constructing different classes of these squares, and have seldom seriously attempted the enumeration.

Dr. Willis has put together in this work all the best-known methods of constructing the various types, and he gives a good idea of the magnitude of the numbers that may be reached when attempt at enumeration is made. There is one magic square of order 3, and 880 of order 4; beyond this huge numbers may be expected. As an illustration he takes the case of the "square of eight in magic quarters" (chapter viii.), and in forming an estimate he takes as unit the number of different squares which could be printed in a year; if this could be done at the rate of a million per second, by keeping the press at work day and night without ceasing during $365\frac{1}{4}$ days; his conclusion, "at a very moderate estimate," is that 150,000 years would be required. A particular kind of pernuclear square of order 20 is similarly shown to have a number of forms approximately given by 2953 followed by 135 zeros.

Chapter x., on magic cubes and geometric designs, takes the reader somewhat out of the beaten track, and will be found particularly interesting. In introducing the subject of magic designs, he says:—

"By making use of magic cubes in which the horizontal squares are magic . . . we may form a mosaic design which is magic in the sense that the n horizontal squares, from which the design is formed, may be found by inspection of the number of tesseræ of n different colours contained in each of the n^2 squares of which the complete design consists."

The author gives five examples of these beautiful patterns printed in colours. Anyone who will take the pains to master the method explained will find himself able to add to these to an unlimited extent, and probably possessed of the power of evolving new principles of mosaic design.

The late Prof. Sylvester was enthusiastic about mosaic designs based on mathematical principles, and one of his "anallagmatic squares," carried out in marble, was for many years in the hall of the United Service Club.

This book will be useful to the numerous persons who find the subject an amusement and recreation. The mathematical equipment required for its comprehension is limited to the multiplication table. The book is well and appropriately printed, and the different types used for both letters and numbers are of much assistance to the reader.

P. A. M.

PHYSICAL CHEMISTRY.

Grundriss der allgemeinen Chemie. By Wilhelm Ostwald. Vierte, völlig umgearbeitete Auflage. Pp. ix+661. (Leipzig: W. Engelmann, 1909.) Price 20 marks.

TWENTY years have passed since the appearance of the original edition of "Ostwald's "Grundriss," in which the principles of modern physical chemistry were first competently placed before the general scientific public. From time to time new editions have appeared, but comparatively little change was made in the original form, the lines of development of physical chemistry having been determined by the work of van 't Hoff, Arrhenius, Nernst, and the author at a period immediately preceding the composition of the book.

The fourth edition, which is now before us, has in many respects been profoundly modified. The discovery of radio-activity and the investigation of gaseous ions give a new point of departure for chemical research and theorisation, and this the author has fully recognised in the present volume. It says much for his open-mindedness that he now relinquishes definitely and explicitly his former position that the existence of atoms and molecules received no cogent experimental proof from chemical or physical science. In his preface he writes:—

"Even the most cautious experimental man of science is now justified in speaking of the atomistic nature of extended matter—on the one hand by the isolation and enumeration of the gaseous ions, the crowning-point of the excellent and persevering work of J. J. Thomson; and on the other by the correspondence of the Brownian movements with the demands of the kinetic theory which has been shown to exist by a number of investigators, finally and most completely by J. Perrin."

With the further remark of the author that this, for him, new point of view should be first properly introduced in the chapters devoted to the results of these researches, one may be disposed to agree, in view of the real pedagogic danger of allowing the student to believe that the stoichiometric laws can only be valid owing to the existence of atoms, instead of being, as they are, generalisations from experiment, and independent of any hypothesis as to the constitution of matter. The author has, therefore, made only a subsidiary use of the atomic hypothesis in the earlier part of the work.

The volume is now subdivided into the following books:—i., substances; ii., stoichiometry; iii., chemical thermodynamics; iv., electrochemistry; v., microchemistry; vi., photochemistry; vii., chemical affinity. Chemical kinetics and equilibrium receive treatment in book iii., colloidal solutions in book v., and radioactivity in book vi.

The author has made a deliberate attempt to meet the criticism that former editions of the book were too difficult for the ordinary scientific reader. The extreme compression and logical treatment aimed at certainly required an amount of concentration beyond that at the disposal of the student when he began the study of physical chemistry. It may be said at once that the author has been very largely successful in his endeavour to adapt the subject to the comprehension of those to whom the book would be most useful. It is not even yet easy reading—it is doubtful if any thorough text-book of physical chemistry *can* be easy reading—but no intelligent advanced student of chemistry can neglect to peruse and ponder it if he wishes to be abreast of the latest developments of the theoretical side of his science in their actual and in their potential aspects. We learn with pleasure that an English translation of this important work is in course of preparation.

THE CHEMISTRY OF DRUGS.

(1) *Grundriss der Pharmakochemie.* By Dr. O. A. Oesterle. Pp. xii+562. (Berlin: Gebr. Borntraeger, 1909.) Price 17.50 marks.

(2) *Southall's Organic Materia Medica. A Handbook treating of the more important of the Animal and Vegetable Drugs made use of in Medicine, including the whole of those contained in the British Pharmacopoeia.* By J. Barclay. Seventh edition. Revised and enlarged by E. W. Mann. Pp. xx+376. (London: J. and A. Churchill, 1909.) Price 7s. 6d. net.

(1) DURING the past quarter of a century a steadily increasing amount of attention has been devoted to the study of crude drugs. The investigations of these have proceeded largely upon botanical lines, many researches having been published on the morphology and anatomy of vegetable drugs and the microscopical characters of their powders. The authors of modern text-books of pharmacognosy have, in most instances, confined themselves almost entirely to dealing with their subject from this point of view, and have been very niggardly in the treatment of the history, commerce, and chemistry of drugs. Great strides have, however, been made in the chemical investigation of the constituents of vegetable as well as animal drugs. The constitution of many has been satisfactorily elucidated, and not a few have been synthetically prepared. The literature of these investigations is, unfortunately, scattered in various journals and special publications, and every teacher of pharmacognosy will have experienced the difficulty of, as well as the necessity for, collecting such information, notwithstanding the useful works of Brühl, Pictet, van Rijn, Schmidt, Dekker, and others.

Prof. Oesterle's work appears, therefore, most opportunely. He deals with those crude organised vegetable drugs the constitution of the constituents of which has been more or less completely ascertained, but has excluded the resins and oleo-resins, as these have recently been exhaustively treated by his colleague, Prof. Tschirch. The individual drugs are grouped according to their characteristic constituents, a rational arrangement, since allied constituents commonly have similar therapeutic action, and it is for this that drugs are employed. The important constituents alone are considered, but they are considered very fully. The manner in which their constitution may be demonstrated, the successive stages in their decomposition, and the synthesis of the substance itself or of a characteristic decomposition-product are fully explained, though perhaps here and there speculation is somewhat in evidence. To the section of alkaloidal drugs 159 pages are devoted, to aromatic drugs 247, to glucosidal 46, to colouring matters 64, and to tannoids 12. Hence the second section has the lion's share, which, perhaps, is scarcely in accordance with its importance from the therapeutical point of view. To the constituents of opium 33 pages are devoted, to those of cinchona bark 19, while the consideration of menthone alone occupies 7.

Hydrastine may be selected as an example of the manner in which the constituents are treated. First the steps are shown by which hydrastine, by exhaustive methylation, is converted into hydrastonic and hemipinic acids, the constitutional formulæ, occupying three pages, being given; next the production of hydrastinine and opianic acid from hydrastine, and the conversion of hydrastinine into oxyhydrastinine and hydrastininic acid are shown together with the production from the latter of hydrastic acid and methylamine; then the action of caustic alkali upon hydrastinine resulting in the formation of hydrohydrastinine and oxyhydrastinine is explained, and finally the synthesis of hydrohydrastinine from piperonal and acetalamine.

A slight feeling of regret may be expressed that the author has confined himself to vegetable drugs, as those of animal origin contain several important constituents which have been isolated and examined.

Prof. Oesterle's work will be heartily welcomed by all who are interested in the constituents of drugs. It forms a unique contribution to scientific pharmacognosy, and will undoubtedly stimulate others to labour in a similar field.

(2) The fact that this work has now reached its seventh edition is sufficient testimony of the estimation in which it has been held, and the new issue, revised by Mr. Mann, who is well known for his contributions to the chemistry of drugs, will doubtless enjoy a similar popularity.

The general arrangement of the subject-matter remains the same, but increased attention has rightly been given to the chemical constituents of drugs, which have been dealt with, on the whole, in a very satisfactory manner, although here and there, as, for instance, the cyanogenetic glucosides of cherry-laurel leaves, wild cherry bark, &c., they have not been brought quite up to date. So far as the utility of the work from the point of view of the student is concerned, there are certainly two or three weak points. In the first place, the restriction of the description of official drugs to the characters given in the British Pharmacopœia has involved the omission of much that is important as well as interesting. Official descriptions of drugs are necessarily brief, and mucn that the student should observe and know concerning them is omitted. Details of the production, collection, preparation for the market, commerce, history, &c., are but meagre. Considerable help might have been afforded by a few judiciously selected illustrations, but these the author considers undesirable.

The large number of drugs dealt with renders the book extremely valuable for reference, but the defects alluded to militate against its efficiency as an educational work for students. HENRY G. GREENISH.

MAGNETO- AND ELECTRIC-OPTICS.

(1) *Magneto- und Elektro-optik.* By Dr. Woldemar Voigt. Pp. xiv+396. (Leipzig: B. G. Teubner, 1908.) Price 14 marks.

(2) *Cours de Physique.* Cinquième Partie. Électroptique. Ondes Hertziennes. By Prof. H. Bouasse. Pp. 426. (Paris: Delagrave, n.d.) Price 14 francs.

(1) THIS is a work on one of the most fascinating branches of modern science by one of those who have done most towards its development. To all students of physics the volume is to be specially recommended as giving an admirable account of a subject which has the most intimate bearing on present theories of the constitution of matter; to those who are themselves working in the same field the name of the author will be sufficient to indicate that the book is indispensable.

The subject dealt with is not the electromagnetic theory of light in general, but, in Prof. Voigt's own words, "that special branch of optics which deals with the action of a magnetic or an electric field on the optical properties of bodies." The study of this special branch of optics may be said to have begun in 1845 with Faraday's experimental demonstration that the plane of polarisation of a beam of polarised light is rotated by the action of a magnetic field having its lines of force parallel to the direction in which the light is travelling. Since that date an enormous amount of attention has been given to the phenomena due to the action on light of a magnetic or an electric field. In 1876 Kerr succeeded in detecting the rotation of the plane of polarisation when light is reflected normally from the surface of a ferromagnetic metal in a strong magnetic field. In 1896 Zeemann showed that the periods of free vibration of the light emitted by a flowing gas are changed by the direct action of a magnetic field, and that there is a corresponding action on an absorbing medium. In 1898 Voigt himself showed that a body in a magnetic field becomes doubly refractive in the direction perpendicular to the lines of force, in the same manner as a uniaxial crystal perpendicular to its axis. In the section of electro-optics, the advances made are less marked. Kerr's demonstration that an isotropic insulating substance becomes doubly refractive in the direction perpendicular to the lines of electric force may be taken as fundamental. An army of workers has followed along the main lines thus indicated, and to-day the mere marshalling of the known facts of observation is a task of no small difficulty, while there are many points of which theory yet fails to give any convincing explanation.

Prof. Voigt's book is founded on lectures given by him at Göttingen University The material thus available, however, has clearly been greatly extended and amplified, with results which may be regarded as exceptionally satisfactory. Thus the elementary and fundamental facts of observation, as well as all the more important experimental appliances and apparatus, are very fully and clearly described, while, on the other hand, a large amount of detail as to the latest developments, both in experiment and theory, is included. In a branch of knowledge so necessarily subject to modification under the influence of new ideas, it is usually to be expected that a volume will be already almost antiquated by the date of its publication, but one of the chief claims of the present work to attention is the extent of the information given as to the most recent work.

The first two chapters are devoted to setting forth the fundamental observations and the principal experimental methods and developments in connection with the Faraday effect and the Zeeman effect. The two chapters following, covering some 120 pages, are concerned with the explanation of these observations on the electron theory. The chief feature of Voigt's own work is the establishment of a simple connection between the emission and absorption phenomena and the rotatory effect of the magnetic field, and the development of the theory here given is founded on the series of papers published by the author between 1898 and 1902 in the *Annalen der Physik.* The theory is, however, here further extended, and includes, in chapter v., a discussion of Becquerel's more recent experiments on crystals of compounds of the rare earths.

The remaining chapters are devoted to the discussion of the "magnetic" Kerr effect, and the consideration of the fundamental phenomena of electro-optics. In the field of electro-optics the experimental difficulties have rendered progress slow. Insulation breaks down under very high voltages, and conduction is never entirely absent, and more refined methods of observation are necessary before the indications of theory can be verified. The subject is, however, of great theoretical interest and importance, and the publication of the present work will no doubt do much in stimulating further research.

(2) The general plan of the "Cours de Physique," of which the present volume is the fifth part, is somewhat unusual. The volumes previously issued bear the titles:—(1) "Mécanique Physique"; (2) "Thermodynamique—Théorie des Ions"; (3) "Électricité et Magnétisme"; (4) "Optique. Étude des Instruments," the part here considered being devoted to the general discussion of electromagnetic radiations, including Hertzian waves. Part vi. is to be entitled "Étude des Symétries"; from the references in the present volume we gather that this might best be translated "Crystallography." We are by no means clear that the arrangement thus outlined is satisfactory. In the volume before us especially, the inclusion of the discussion of Hertzian waves, though entirely logical and perfectly defensible on theoretical grounds, seems to us unfortunate. The questions involved are essentially practical and of special interest to the electrician, and the early chapters devoted to

their treatment form a section quite distinct from the remainder of the volume.

At the same time, it must be remembered that the whole work is one written for the student, and from this point of view it may be maintained that the logical arrangement is to be preferred. The usefulness of such an extended general treatise on physics is, however, far from being limited to the purposes of a university course, and the convenience of the older student who needs his theory for its application to practice might well have received more consideration.

It is to be remarked also that Prof. Bouasse's "Cours de Physique" is essentially a treatise on mathematical physics. The author takes a keen interest in the most recent developments in physical science from the theoretical point of view, but it is not to him that we should turn for information as to experimental work.

This premised, it may be said that the work is one which should command attention. Prof. Bouasse has the faculty of presenting his mathematics in a clear and attractive form, and his theoretical discussion of practical points often presents novelties of value to the practical experimenter.

The first chapter is devoted to the discussion of Maxwell's equations of the electromagnetic field. It is unfortunate that so much reference to vol. iii. of the work should be necessary, but, nevertheless, the matter is presented with admirable clearness, and the student has no cause to complain of the author's dictum:—

"The reader cannot spend too much time on this first chapter; if he understands it well, all the rest of the volume will appear clear to him. If he fails to understand it—*nous ne saurions trop lui conseiller d'abandonner la théorie électromagnetique de la lumière.*"

Then follows the section of some seventy pages on Hertzian waves and their application in wireless telegraphy. The treatment is of interest; it includes an account of the general theory and a mathematical discussion of various practical questions, especially the propagation of a disturbance along a wire; but it is necessarily incomplete, and would be of more value in a volume not so specially devoted to optical theory.

The main part of the work is that devoted to the discussion of double refraction and of polarised light. The theory is directly based on that of the propagation of electromagnetic waves in an anisotropic medium; from this is deduced the equation of the wave surface and the construction of Fresnel. This leads up to a sufficiently full treatment of the phenomena connected with double refraction as dealt with in any modern treatise on physical optics; as elsewhere, the mathematical presentment has many original and attractive features.

In the succeeding chapters reflection and refraction, dispersion and absorption are fully discussed from the standpoint of the electromagnetic theory. A somewhat brief treatment of the electron theory leads to the consideration of the Zeemann effect, and the phenomena of emission, phosphorescence and fluorescence, &c., while the concluding chapter deals with the thermodynamics of space, including such topics as Poynting's experiments on radiation pressure and the discussion of Stefan's law.

As has been sufficiently indicated, the whole of the section of physical optics here dealt with is treated as a deduction from the equations of the electromagnetic field. This may be a simplification from the point of view of theory, but we are inclined to think that to the student it may give an air of unreality to a subject which, above all others, is based on the most complete and exact experimental data.

OUR BOOK SHELF.

On the Poison of Venomous Snakes and the Methods of preventing Death from their Bite. Reprinted papers by the late Sir Joseph Fayrer, Sir Lauder Brunton, and Major Leonard Rogers. Pp. iii+174. (London: Macmillan and Co., Ltd., 1909.) Price 2*s*. 6*d*. net.

THIS publication consists of a re-issue in book form of six papers reprinted from the Proceedings of the Royal Society. The first four papers deal with the physiological action of snake venoms. They were first published more than thirty years ago, and then represented important advances in knowledge. They cannot, however, be expected to reflect the present-day knowledge of the action of snake venoms. The fifth paper, belonging to the same period, deals with chemical methods of destroying the activity of cobra poison, such as by chloride of gold or of mercury. The last paper, which was published in 1904, and is the only one of the series in which the last-named author cooperated, deals with the experimental results of the treatment of snake-bite by free exposure of the wound and local application of potassium permanganate.

To be of practical service in the treatment of snake-bite, any remedial measure must be rapidly available and easily applicable. To meet these conditions, one of the authors devised a special instrument consisting of a small lancet-shaped blade to expose the wound made by the serpent's bite, this blade being set in a short wooden handle, which is hollowed so as to form a receptacle for sufficient permanganate of potash. Experiments were made on rabbits and cats to test the value of the method and instrument. The results, especially in the latter animals, were encouraging, in so much as it was found that death could be prevented from a dose of venom considerably larger than that which was sufficient to kill a control animal. At the same time, it may be pointed out that the conditions of these experiments do not represent adequately the conditions obtaining in an ordinary case of snake-bite. The efficacy of the antidotal action of potassium permanganate depends solely upon how far the venom can before absorption be destroyed by intimate contact with the permanganate. In the authors' experiments the venom was injected into the subcutaneous tissues, in which case it was relatively easy to ensure contact of the venom with the antidote, whereas in a case of snake-bite the venom is injected usually into deeper tissues, when it is much more difficult to bring the permanganate into contact with the venom. It is thus probable that these experimental results ascribe to this method of treatment a value higher than would be found to attend it in practice.

While from its simplicity and cheapness this method of treating snake-bite ought not to be lost sight of, it probably does not represent the ideal attainment, which is by local application and general administration of an antivenomous serum, and further efforts ought to be made in the direction of obtaining such serums of high antidotal properties. If dried, an antivenomous serum retains its neutralising power for a long period, and it possesses this great advantage over a mere chemical antidote, that it can also antagonise venom which has been absorbed, and may thus be of service for a longer time after injection of the venom.

Bathy-orographical Map of Africa. 1–8,400,000. *Bathy-orographical Map of Asia.* 1–9,300,000. (Edinburgh: W. and A. K. Johnston, Ltd.) Price 12*s.* each.

We must congratulate Messrs. W. and A. K. Johnston on these excellent additions to their series of orographical maps. The elevations in Africa show 10,000, 5000, 2000, and 1000 feet and below sea-level. The general effect is satisfactory, though the very deep green is, we think, somewhat unpleasing. The 10,000-feet contour shows the higher elevations of the Atlas, Abyssinia, the Lakes Plateau and the Drakensbergen, but the tint is indistinguishable by a class. It would, however, have probably made the map more useful if the 8000-feet line had been selected, as the highest points are not of great importance for an educational map except in the region of the great lakes. As it is, the mountainous areas do not indicate their special character.

The other contours selected show the formation of Africa well. The sea depths shown are 100, 1000, 2000, and 3000 fathoms. It is to be regretted that the same contours have not been chosen to represent both the land and sea, as the plateau character of Africa would have been brought out with much greater effect.

Both in Africa and Asia, physical names have been very fully shown. As they cannot be read by a class, it is a pity that they have not been printed faintly in blue, like the initial letters of towns. The mass of black lettering largely spoils the graphic character of the maps.

Actual mistakes are few, though one may be noted—in the north-east of Abyssinia the area below sea-level has been coloured as more than 1000 feet.

The map of Asia is more effective than that of Africa, possibly owing to the selection of the contours. The 10,000-feet affords a means of comparison with Africa, but it should, if possible, have been printed the same depth; then the 15,000- and 20,000-feet lines would, with suitable graduation, have illustrated the character of the Tibet Plateau. At present minute and close examination is necessary to distinguish the features of the North-West Frontier. The lower elevations are much better shown. The 100, 3000, and 6000 feet bring out well the great river valleys and depressions of Asia.

In spite of these defects, the maps are likely to prove more useful for schools than any that have previously been published of these continents.

Publications of the Research Defence Society. March, 1908, to March, 1909. Selected by the Committee. Pp. xv+216. (London: Macmillan and Co., Ltd., 1909.) Price 2*s.* 6*d.* net.

The Research Defence Society was founded on January 27, 1908, "to make known the facts as to experiments on animals in this country; the immense importance to the welfare of mankind of such experiments; and the great saving of human life and health directly attributable to them." The president is the Earl of Cromer, himself a champion in the cause of kindness to animals; the committee is a strong one, its members representing all branches of science, and also including many theologians and laymen, and in March of this year the membership of the Society numbered more than 2250.

This first volume of publications contains the president's address at the inaugural meeting, a review of the Home Office Report for 1907 on, and some facts as to the administration of the Act regulating, experiments on animals, and several essays (also published separately in pamphlet form) by well-known experts dealing with the knowledge that has been derived from experiments on animals, and the saving of human life therefrom. Prof. Cushny shows that the nature of the action and therapeutic use of all drugs of recent introduction, and the potency of the preparations of many of the older drugs (*e.g.* digitalis and ergot), have been elucidated solely by experiments on animals, the value of diphtheria antitoxin and of serum treatment in epidemic cerebro-spinal meningitis (spotted fever) is discussed by Dr. Courtauld and Dr. Robb respectively, Sir David Bruce writes on the extinction of Malta fever, and Dr. Bashford's article in Nature on recent advances in knowledge of cancer is reprinted. The evidence of Lord Justice Fletcher Moulton before the Royal Commission on Vivisection is given *in extenso*, and is a powerful vindication from the ethical side of the right to employ experiments on animals for the benefit of mankind.

If the standard of its publications be maintained at the level of those contained in this volume, the Society will be doing excellent work in the cause of experimental research.

R. T. H.

Milk Testing. A Simple Practical Handbook for Dairy Farmers, Estate Agents, Creamery Managers, Milk Distributors, and Consumers. By C. W. Walker-Tisdale. (Northallerton: W. R. Smithson.) Price 1*s.* net.

The author of this little book is already favourably known by his early publications, jointly with Mr. T. R. Robinson, on butter-making and soft cheese-making. He holds an important position in the dairy world, and, as general manager of the Wensleydale Pure Milk Society, knows at first hand all the difficulties that beset the dairyman. The result is an admirable little volume, sound in regard to analytical methods, and direct in its appeal to the man for whom it is intended. It is more than a mere collection of methods, and includes discussions of such cognate subjects as the use of preservatives. Occasionally a request is heard in certain quarters that a preservative should be allowed in milk, but our author will have none of it, and advises the dairyman to keep clear of them all, even of a certain preservative offered for sale, "guaranteed to contain no boron or boric acid, and claimed to be undetectable by chemical analysis"! Quite apart from considerations of the general health of the community, the author shows that the dairyman himself would suffer, since foreign milk would invariably be imported if preservatives were allowed.

E. J. R.

The Journal of the Cooper Research Laboratory. Edited by Walter E. Collinge, Director. (Berkhamsted: The Cooper Research Laboratory, 1909.)

The fact that the principal of a large and well-known firm like Messrs. Cooper should start a research laboratory and publish a journal is a satisfactory proof of the widespread interest now being taken in science by all who have to do with agricultural and horticultural matters. The special province of the firm—treatment of insect and fungoid pests—certainly borders more closely than usual on pure science, and no doubt a trained staff would have been wanted in any case. But here we have something more. The laboratory, we are told, "is in no sense a financial venture or business concern." Its functions are to answer inquiries from farmers, fruit-growers, and gardeners as to preventive and remedial treatment for diseases of plants and parasitic diseases of animals, to investigate life-histories of various insects, parasites, &c., and generally to advise on subjects relating to economic biology, agricultural chemistry, and bacteriology.

The articles in the journal are mainly summaries of work done elsewhere rather than accounts of original work; perhaps this was only to be expected from an almost new laboratory. Mr. Collinge deals with the use of lime, with special reference to its influence on plant diseases like potato-scab and finger-and-toe fungus; he has also collected a good deal of scattered work on the woolly aphis. Mr. Barlow deals on similar lines with the effect on plants of copper salts used as fungicides. The summaries themselves call for no special comment, but the journal as a whole is well got up. We shall be interested to see how Sir Richard Cooper's experiment works—whether the laboratory can maintain the detached position essential for the publication of scientific work, or whether, as has happened elsewhere, it becomes merged in the purely commercial side.

Cambridge County Geographies: Somerset. By Francis A. Knight, assisted by Louie M. (Knight) Dutton. Pp. xi+192. (Cambridge: University Press, 1909.) Price 1s. 6*d*.

THE characteristics of the series to which this volume belongs were enumerated in our issue for May 13 (vol. lxxx., p. 305), and much of what was written on that occasion applies to the present book. The authors' interpretation of the scope of geography is wide enough to include a history of the county, its antiquities—ecclesiastical, military, and domestic—its administration and roll of honour. Like previous volumes in the series it is well illustrated, brightly written, and generally attractive.

LETTERS TO THE EDITOR.

Difference between Longitudinal and Transversal Zeeman Effects in Helium Lines.

IT is easily shown on the theory of electrons that the amount of separation of the outer components of a transversal Zeeman triplet must be slightly different from that in a longitudinal doublet. Some time ago I showed that the transversal separation in weak magnetic fields does not strictly follow the linear relation with the magnetising force, but, owing to an indirect method of measurement, the exact amount of the separation could not be measured with accuracy. By measuring the longitudinal effect of helium lines with an echelon spectroscope of thirty-five plates, each of 1 cm. thickness, made by Hilger, I found that doublets can be distinctly separated in a field of 180 gauss, when the right- and left-handed circularly polarised light is linearly polarised in mutually perpendicular directions, by interposing Fresnel's rhomb in the course of the beam. Taking a number of points at intervals of about 300 gauss from $H=0$ to $H=2000$, and ten to thirteen points from $H=2000$ to $H=14,000$, I found that for the three lines $\lambda\lambda=6678$, 5876, 5016, the relation between the amount of separation $\delta\lambda$ and the strength of the field H is exactly linear, so that $\delta\lambda/H=$constant also in weak fields. In these experiments it was necessary to gauge the strength of the field accurately for each point before and after each micrometric measurement by means of a small coil. The values of e/m were found to be for

$\lambda=6678$	$e/m=1\cdot86\times10^7$
$=5876$ (D_3)	$=1\cdot68\times10^7$
$=5016$	$=1\cdot80\times10^7$

The separation of the satellite of D_3 is complex, but there is one component which gives the same value of e/m as D_3.

With the transversal effect the ratio $\delta\lambda/H$ is not constant in weak fields. With D_3, the curve representing the relation between H and $\delta\lambda$ is such that it increases very slowly to $H=800$, then rapidly to an inflexion point in $H=1700$, makes a bend, and from $H=2000$ follows an accurately straight course up to $H=14,000$, which is the strongest field used in the present experiment. In the latter part of the curve $d(\delta\lambda)/dH=$constant, which is smaller for the transversal than for the longitudinal effect, so that the curves representing these effects cross each other in $H=1200$ and $H=10,900$. The initial part of the curve for the transversal effect shows a striking resemblance to that of magnetisation in ferromagnetic substances. The satellite accompanying D_3 shows remarkably complex separation, as shown by Lohmann, but there are two components which take a similar course to the principal line D_3. The lines are already separated before reaching the inflexion point above mentioned, so that the method which I used in my former experiments, is confined only to weak fields. With the line 6678, the initial course of the curve for transversal effect is similar to that of D_3, but the inflexion point is reached in a higher field $H=2700$, and the curve becomes a straight line from $H=3600$ upwards. The curve for longitudinal effect lies entirely above that for the transversal, and $d(\delta\lambda)/dH$ in strong fields is greater for the former than for the latter.

The usual calculation of e/m is made on the supposition that $\delta\lambda/H=$constant, which is strictly obeyed in the longitudinal, but not in the transversal, effect; the discrepancy in the value of e/m calculated from longitudinal and transversal effects is at once explained. The initial course of the curve can be accounted for by Voigt's theory, but the appearance of the inflexion point before attaining the straight course presents some difficulty. The resemblance of the curve of transversal effect to that of magnetisation seems to have an important bearing on the exposition of the theory, which would explain these characteristic features. The extension of these experiments to stronger fields and with different elements is being undertaken.

Physical Institute, University of Tokyo, July 16.

Natural Selection and Plant Evolution.

THE letter from Mr. James B. Johnston in NATURE of August 5 touches on many important points, which cannot be fully dealt with in a letter of reasonable length.

In his opening sentence the writer, speaking of chapter xii. in "Darwin and Modern Science," says that "there, perhaps for the first time, the evidence of the fossils with regard to the influence of natural selection has been fairly tackled"; I may point out that the chapter cited really relates mainly to evolution, and especially phylogeny; only the last section refers to natural selection, a subject on which, from the nature of the case, the fossil record can throw comparatively little light.

I cannot think that, on the main question, there can be any very fundamental difference between the writer's views and my own, for he says:—"In the case of the Tertiary mammals the action of natural selection can be very clearly demonstrated in numberless cases." Mr. Johnston cannot seriously mean that he accepts natural selection for animals and rejects it for plants. The question is simply one of evidence. As I have myself pointed out, the direct evidence for the derivation of one species from another is at present less satisfactory in the plant than in the animal record ("Darwin and Modern Science," p. 204); on this point we may hope for new light from further research, though, as regards the efficacy of natural selection (an essentially different question), I doubt if palæontological evidence will ever be really decisive.

My point in speaking of the evolution of the pollen-tube and seed was to show that such characters are *adaptive*, a view to which Mr. Johnston is not likely to object. In the present position of biological science evidence of adaptation is commonly accepted as presumptive evidence of the action of natural selection.

The question whether a belief in the efficacy of natural selection can be regarded as "barring out all design from the world in which we live" is not one that can be discussed here. Mr. Johnston will find this subject admirably treated, from a theologian's point of view, in Mr. Waggett's contribution (chapter xxiv.) to "Darwin and Modern Science."

The question of the antiquity of land-plants is of great interest. Assuming, for the sake of argument, that the highly organised lycopods and fern-like plants described by Prof. Potonié as Upper Silurian (" Die Silur und die Culm-flora des Harzes Geb.," *Abhandl. d. k. Preuss. Geolog. Landesanstalt*, Heft 36, 1901) were really of that age, it would appear certain that land-plants must then have already passed through a very long course of evolution. No one is likely, in these days, to suppose that Bothrodendron and Sphenopteridium were specially created. The doctrine of mutation (of which Mr. Johnston appears to be an adherent) does not materially help in hurrying up the process of evolution, for, as Prof. de Vries himself says, "Mutations do not necessarily produce greater changes than fluctuations" ("Darwin and Modern Science," p. 73).

The problem confronts us, and its solution must simply await further evidence. D. H. Scott.

Oakley, Hants.

The Perseids of 1909.

The weather, fortunately, took a very favourable turn on August 3, and observations have been obtained nearly every night since, though moonlight has rather seriously interfered with the work and obliterated many small meteors. Up to August 9, and including that date, the display of Perseids was decidedly poor, and quite disappointed expectation. On August 7 and 9, particularly, there appeared to be very few meteors, but the moon was shining rather strongly in the east.

On August 8 there were several brilliant Perseids observed. At 10 p.m. a fine, long-pathed meteor shot from Camelopardalus across ι Draconis towards ζ Ursæ Majoris. At 10.8 p.m. another Perseid, equal in brightness to Jupiter, passed from χ to between β and η Draconis. At 10.34 p.m. a third shot exactly from α Cygni to close to β Cygni. These meteors left streaks, and, in combination with a few other paths recorded on the same night, indicated a radiant at $41^\circ + 57^\circ$.

The shower will probably arrive at its most abundant phase on August 11 or 12 this year, so that the meteors already reported are merely the vanguard of the approaching main group. W. F. Denning.

Bristol, August 10.

The Ringing of House-bells without Apparent Cause.

Kindly allow me space for a few remarks upon Sir Oliver Lodge's theory, put forth in Nature of July 22 (p. 98), to the effect that "the bells get charged with electricity (atmospheric), and are attracted to a neighbouring wall or pipe, and then released suddenly by a spark." Now, while it is conceivable that a bell might be rung under certain conditions in this manner, during the progress of a thunderstorm or display of sheet-lightning, and granting that ordinary non-electric bells have been rung and wires fused when a house has been struck by the electric current during such storms, still, this theory is inadequate to explain those cases of mysterious bell-ringing on record, and for one reason, among others, that these ringings, often violent and prolonged, have been extended over a term of several weeks or months, and have constantly taken place when no storms or strong electrical conditions were apparent, and when every effort was being made to ascertain the cause.

I speak from personal experience of a case which occurred in my house when resident in the south. For a period of two months there were constant ringings—often violent, the bell lashing to and fro—of the indoor bells, without apparent cause. In the case of one bell the wires were cut, but still it rang. The utmost endeavours were made to solve the mystery, but it defied all our efforts. There were no rats, the house having been made rat-proof, nor did we see one rodent during our stay. The wires were carefully traced and examined. Pendulums were affixed to all the bells to detect slight motion, and they were strongly illuminated by a powerful light and a watch kept, sometimes all through the night. The chief offender among the bells was one communicating with a private room. The wire from this ran, high up near the ceiling, upon the varnished paper, except where it passed through a wall, which it did through a half-inch pipe. It was impossible for a rat or mouse to touch it all along its course. This bell rang repeatedly from early morn to late at night. The room was thoroughly searched and secured—the shutters put up and barred and the door locked. Still the bell rang, and defied all our efforts to elucidate the mystery. On one occasion, when the whole household was together in another room, some little distance away, one of them said, "I wonder if it will ring to-night?" The words were scarcely spoken before the bell rang out, first faintly, then so violently that the bell lashed from side to side. All ran out and saw it swaying. I can state that during the whole period we had no thunderstorm, it being winter, and the ringings were so frequent that it would have needed scores of storms and abnormal electrical conditions to produce them, even if these had been the cause. This theory is ingenious, but one doubts whether Sir Oliver advances it seriously. Whatever is the cause of these mysterious ringings, it is patent to anyone having had experience of them, or knowing the cases on record, that it is not electricity, atmospheric or other. C. L. Tweedale.

Weston Vicarage, Otley, Yorks, August 6.

Variation in Relative Intensity of Helium Lines

It has long been an open question whether the spectra of gases were subject to any general law of intensity variation such as the Wien-Paschen displacement law for incandescent solids. Reasoning from Kirchhoff's law, it is frequently assumed that the Wien-Paschen function must be an envelope to the radiation spectrum of any gas, at least for certain selected lines. Pflüger's work with the mercury lamp (*Ann. Ph.*, July, 1908) indicated some such variation in relative intensity, but the energy (temperature) effect was obscured by the effect of varying vapour density. The latter is known to be large, so that the existence of the former was not proven.

We have recently taken up this question, using a pair of helium lamps containing very pure gas at 5 mm. pressure, and found *no variation* whatever when the intensity was varied by a factor of eighteen. The method was to hold one of this pair of lamps constant at a moderate current (5 milliamperes per mm.^{2}), while the intensity of the other was varied from 0·15 to 2·70 times this value. Spectrophotometric settings were made on the brightest red line (λ 668) and the bright blue line λ 447. The uncertainty in the ratios of high/low intensities was less than 2 per cent. in both red and blue; the observed difference in these ratios between red and blue was less than 1 per cent. The red and blue lines then increase in the same proportion over a wide range of intensity.

According to the Wien-Paschen function, an incandescent body should, for an increase in total radiation of 18 fold, increase in temperature 2·06 fold. If this increase is from 1500° to 3090°, then λ 668 would increase in that range 1721 fold, and λ 447 would increase 66,850 fold in intensity, so that the blue increases 38·8 times as much as the red, whereas for helium we found no difference so great as 1 per cent. P. G. Nutting.

Kohlrausch's "Physical Measurements."

I should like, through the medium of Nature, to direct attention to an erratum in Kohlrausch's "Physical Measurements" (third English edition, Churchill, 1894), p. 434, table 8. The value for $k(s=2{\cdot}0)$ is given as 0·458, its true value being 0·457(1). Other editions, English or German, not being at hand, I do not know whether the mistake is repeated or not. As this occurs in a very useful table in a universally used reference work, it should be of interest to a number of your readers.

E. W. Nelson.

The Laboratory, Citadel Hill, Plymouth, August 2.

THE BRITISH EXPLOSIVES INDUSTRY.[1]

A VALUABLE addition to the literature on explosives has been published under the auspices of the seventh International Congress of Applied Chemistry by its explosives section, with Mr. Brayler Hodgetts as editor. It owes its inception to Mr. Oscar Guttmann, to whom the publishers pay a well-deserved tribute for his able assistance and the facilities he has afforded them by placing his unique and valuable library at their disposal.

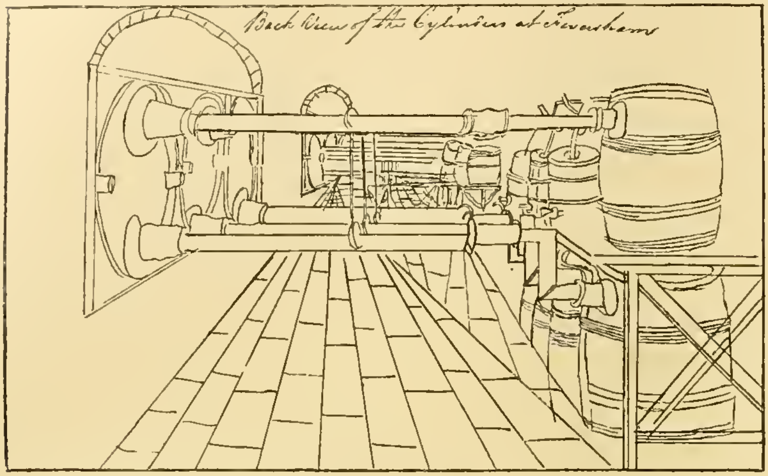

FIG. 1.—Charcoal Chambers in 1798. Back View. Reduced from "The Rise and Progress of the British Explosives Industry."

All who have been associated with the compilation of the work are to be highly congratulated on having produced a volume which will certainly fulfil the hope expressed by Captain Tulloch in his preface, that it will "in years to come be looked upon as a work of reference connecting the past with the future," for all will agree with him, after perusing it, that "it is the only work of the kind containing so complete a history of the manufacture of explosives in this country."

The book is divided into two main sections, historical and descriptive. In the former are articles devoted to each of the principal explosives, and such related subjects as percussion caps, safety fuses, and fireworks, contributed by writers specially competent to deal with each. It is impossible to single out any one article for comment, but the contributions of Mr. G. W. Macdonald on the literature relating to researches on gunpowder, nitroglycerine, and nitrocellulose, with the full references to the original papers, will prove of considerable value.

Outside of what may be regarded as the purely scientific or technical articles, that on legislation, contributed by the editor, is of great interest. Although prior to 1860 there had been many Acts placing restrictions on manufacture and storage, the supervision was very lax, leading to great carelessness in the manufacture and handling of such dangerous substances. Colonel Moody's report on the disastrous explosion of powder magazines on the river-bank at Erith in 1864 (from which report some startling extracts are given) fully emphasised the necessity for more stringent regulations, and led in October of that year to the appointment of Colonel Boxer to "inspect and examine any mill, magazine or place" in which any kind of explosive was manufactured or kept. Later, a further disaster at Birmingham, by which fifty-three lives were lost, resulted in the appointment of permanent inspectors on the recommendation of the late Colonel Sir V. D. Majendie, K.C.B., who, as chief inspector, became so well known to the public at the time of the Fenian outrages. The Explosives Act of 1875 was the final outcome of these disasters, an Act which has proved of the greatest value through the tactful administration of the inspectors and the conscientious manner in which its provisions have been observed by the industry.

Special mention must be made of the bibliography and of the chronology. It is claimed for the former that it gives a complete list of the books on explosives published in England, whilst the chronology covers the period 1242–1700, and is a remarkably complete work reflecting the greatest credit on those responsible for its compilation. The licences granted and the restrictions imposed for the sale of the ingredients of powder and for its manufacture are often extremely quaint and of great interest. This chronology should appeal to the antiquarian equally with the student of applied science.

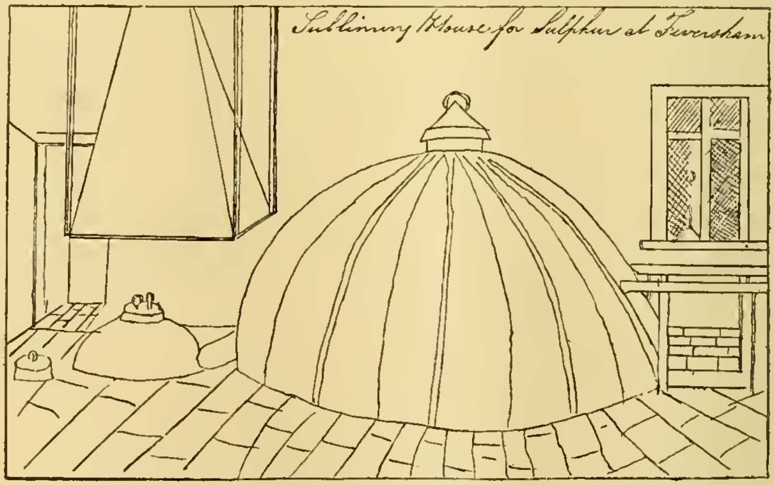

FIG 2.—Sulphur Subliming Chamber in 1798. Side View. Reduced from "The Rise and Progress of the British Explosives Industry."

In the second section of the book, devoted to description of existing factories, the information as to development, specialities of manufacture, organisation, &c., is very complete. Space only permits of reference to the articles dealing with Government

[1] "The Rise and Progress of the British Explosives Industry," Published under the Auspices of the Seventh International Congress of Applied Chemistry by its Explosives Section. Pp. xiv+418. (London: Whittaker and Co., 1909.) Price 15s. net.

establishments, in each case written by the superintendent—the Royal Laboratory, Woolwich, by Colonel Sir Hilaro Barlow; the Royal Gunpowder Factory, Waltham Abbey, by Colonel Sir Frederic Nathan; and the recently re-constituted Research Department at Woolwich, by Major H. Mansell. The history and development of these important Government establishments will prove of general interest. The Royal Laboratory alone must be prepared to manufacture at short notice some 3000 articles of approved design for war purposes. An interesting comparison of the cost of shells may be quoted. In 1849 the finished shell for 8-inch smooth-bore guns alarmed the authorities. It was *11s. 3½d.* The modern 12-inch shell costs about *29l.* when completed!

One extract may be permitted from Colonel Jocelyn's article on military fireworks. "In the Mathematical Society of London a rule existed which imposed a fine of sixpence on any member who should let off fireworks in the place of meeting." This but reflects the playfulness of the times when Pepys and his friends enjoyed pelting each other and "the people over the way" with fireworks.

The book is illustrated with some fine portraits of those who have been prominently associated with the industry, and a number of old illustrations of powder-making processes, which greatly add to the value of the work. Those selected for reproduction are of more general interest than others relating to powder manufacture itself. The recovery of by-products from the carbonisation of wood, as shown in the first illustration (Fig. 1), cannot fail to be of interest to chemists, as will also the sulphur-refining plant (Fig. 2) with its retort, fume-hood, and condensing chamber.

J. S. S. B.

DANISH RESEARCHES ON THE EEL AND THE PLAICE.[1]

THE "Kommission for Havundersøgelser," the official body entrusted with the execution of Denmark's share in the international exploration of the sea, devotes a considerable portion of its resources in endeavouring to solve certain important problems connected with the natural history of the eel and the plaice. These investigations are producing very definite results.

Two papers recently contributed by Dr. Johs. Schmidt to the "Meddelelser" of this commission considerably advance our knowledge of the metamorphosis and distribution of the larvæ of the eel and other murænoids. Since the publication of Dr. Schmidt's notable treatise of 1906, in which the distribution of the larvæ of the eel in the Atlantic, west of Europe, was described in detail for the first time, a large quantity of new material has been collected by means of the Danish research steamer *Thor*.

The new captures included more than 500 larvæ of the common eel, 300 of which were in different stages of metamorphosis. The material previously dealt with (in the treatise of 1906) consisted of 265 specimens, only eight of which showed an advance on the leptocephalus stage. Taking the captures of 1905 and 1906 together, the following is a list of the leptocephali of murænoids so far taken by the *Thor*:—Leptocephalus of eel, 790; of Synaphobranchus (deep-sea eel), 126; of the conger, 32; other leptocephali belonging to four unknown species, 12.

Confining our attention to the common eel, it may be said that these new researches throw light on obscure points, amend former statements, and fill up several gaps. The more important new facts may be briefly summarised as follows:—

(1) In May all the leptocephali were in stage 1; in September they were mostly in various stages of metamorphosis. This implies that the propagation of the eel is limited in the main to a certain portion of the year, as is the case with most other fishes.

(2) In September the later stages were found further towards the shore than the earlier stages. This indicates shoreward migration during metamorphosis.

(3) It was found that both leptocephali and glass eels were larger in the southern than in the northern part of the area of distribution.

(4) Whereas in the treatise of 1906 calculations of the shrinkage of the larvæ during metamorphosis were based on fragmentary material, belonging to different regions and different years' groups, it is now possible to say definitely that the diminution in length involved in the retrogressive metamorphosis amounts to 1 cm. This average is based on a large number of measurements of leptocephali and glass eels *from the same region, and belonging to the same year's group.* Further, weighings of leptocephali and glass eels prove for the first time that the metamorphosis involves an actual loss of substance, the dry-weight of glass eels being only one-third of that of leptocephali.

(5) There is good evidence that the larvæ execute diurnal vertical movements in the sea, coming nearer the surface at night than during the day.

(6) There are places where the larvæ of the eel are the commonest fish, just as we find in the case of the different species of gadoids, each of which (as we know from Dr. Schmidt's own investigations) chooses its own conditions of depth, salinity, and temperature for spawning purposes. Thus the specific trait shows itself in the selection of spawning habitat, as well as in anatomical and physiological peculiarities.

The first and final chapters of this weird and fascinating history have yet to be written. Neither the eggs nor the spawning adults have been found, though there is good reason to believe that the former are bathypelagic, *i.e.* floating at considerable depths, as is the case with other murænoids, Argentines, and other deep-sea fishes. The discovery of these things can only be a matter of time and resources. Ships and men are not lacking, apparently.

In regard to other murænoids, the recent investigations show that the conger is a more southern form than the eel. Its larvæ do not range further north than Rockall, whereas the leptocephali of the eel extend to the latitude of the Færöes. The larvæ of the conger do not occur over such great depths as those of the eel. They show the same inshore movement during metamorphosis, there being a close connection between depth and pre-anal length.

The larvæ of the deep-sea eel (*Synaphobranchus pinnatus*) were never taken so near the surface as the leptocephali of the common eel, never higher in the water than 100 metres. In the case of this species there is nothing to suggest shorewards migration. During metamorphosis the larvæ sink to the bottom in deep water, where fully-developed eels of this species were caught in large numbers over a wide area of the north-east Atlantic.

Of the other leptocephali (four kinds) it is impossible to say at present to what species they belong,

No. 3. Johs. Schmidt: Remarks on the Metamorphosis and Distribution of the Larvæ of the Eel (*Anguilla vulgaris*, Turt.). With one plate and one chart.
No. 5. A. C. Johansen: Contributions to the Biology of the Plaice, with special regard to the Danish Plaice Fishery. iv. Is the Plaice Indigenous to the True Baltic? With Two text-figures.
No. 6. Johs. Schmidt: On the Occurrence of Leptocephali (Larval Murænoids) in the Atlantic W. of Europe. With two plates and one chart.

and it may be some time before this can be stated, owing to the difficulty of capturing the slippery and swift-moving adults. It will be necessary to have these for comparison with the leptocephali (*e.g.* to count the vertebræ). From the small numbers of these leptocephali captured, it is practically certain that their breeding-places or "nurseries" are considerably to the south of the Bay of Biscay.

Leptocephalus hyoproroïdes is particularly interesting, because it is the only species which it has been possible to trace back to the not fully-grown pre-leptocephalus stage, which, it is significant to observe, is also pelagic, like the later stages.

Much praise is due to those concerned in the production of the three beautiful plates of photographs which illustrate these two papers. One plate (in No. 3) shows seven stages (typical size) in the metamorphosis of the common eel. These figures are a great improvement on the photographs of the same series of stages published in Dr. Schmidt's original treatise; they are larger, and were taken from specimens in a much better state of preservation, so that they display the characters of the larvæ, especially the glassy transparency, more faithfully. The same remark applies to the plates illustrating No. 6. One of these shows seven stages in the *growth* of the pre-leptocephalus into the leptocephalus of "hyoproroïdes."

Leptocephalus latus. Slightly less than three times natural size.

Dr. A. C. Johansen, in No. 5, makes a very important original contribution to the much vexed question, "Is the plaice indigenous to the true Baltic?" For a long time, neither eggs, pelagic larvæ, nor early bottom stages of the plaice could be found in the true Baltic, and Dr. Petersen, the chief Danish scientific expert on sea fisheries, considered that the large stock of this fish in these waters must be entirely derived by immigration from the Belts and southern Kattegat. He thought that they must begin to immigrate when about one year old. As time went on, however, the capture of large numbers of eggs in the cold saline bottom water of the Baltic, and of *occasional* pelagic larvæ and bottom fry, seemed to indicate that this extreme view might require modification. It seemed unlikely, however, that the eggs could develop in the cold water at that depth, and the fact that the number of pelagic fry obtained were extremely few in comparison with the numbers of eggs and adults lent support to this view. But is was not impossible that the stock of plaice was partly, if not mainly, indigenous, being an "accumulated stock" grown up slowly by means of small additions from year to year. This problem had been the subject of continual investigation and discussion by German and Danish investigators under the international scheme, with, so far, inconclusive results. It seemed even probable that a third alternative might be the right explanation, viz. that the fry had not been looked for in the right places with the proper appliances. This seems to have been the case. Dr. Johansen, in the present paper, records the capture in the true Baltic of large quantities of yearling plaice "for the first time in such numbers as to compete with each of the older annual series." He also found that pelagic fry of this species were plentiful everywhere in the water between Falster and Bornholm. Other convincing evidence of the plaice being indigenous to the true Baltic is also brought forward, it being shown that the average size of plaice of a given age and the average size at first maturity are much smaller in the Baltic than in the Belts and southern Kattegat. This could hardly be the case if any considerable immigration from the latter regions took place. More light on this question may reasonably be expected from marking experiments in the future. The few experiments of this kind which have so far been made in this region have not yielded conclusive results.

In No. 1, Dr. C. G. Joh. Petersen gives the results of an exhaustive study of the diagnostic characters of Arnoglossus, Zeugopterus, and Solea in the larval and post-larval stages. These results (which need not be detailed here) are quite new. The author also discusses in a critical manner all previous observations in regard to these species and stages. Dr. Petersen is the greatest living authority on the later development of the Pleuronectidæ, and this paper and his other papers dealing with the subject are of standard importance, and indispensable to the investigator.

THE POSITION OF SCIENCE TEACHING IN PUBLIC SCHOOLS.

THE Board of Education has issued as an "Educational Pamphlet" a report on science teaching in public schools. The material for this report, made at the instance of the Association of Public School Science Masters, has been collected and edited by Mr. O. H. Latter, of Charterhouse, and the pamphlet is both instructive and amusing. The ground covered by the report is to some extent the same as in another report recently made by a committee of the British Association on the sequence of science studies in secondary schools; but a comparison of the two lists of questions sent out will show that Mr. Latter's investigation deals more particularly with equipment and finance. On the other hand, the field of inquiry was restricted to the class of school represented on the Association.

Of the seventy-one schools to which the circular was sent, twenty-four made no response, and one sent a definite refusal. It is doubtless annoying to be asked twice in the course of a year to fill up forms which require minute particulars, perhaps not ready to hand, and it is possible—in fact a study of one of the appendices makes it probable—that some of the information has been supplied without meticulous verification of the details.

If we put schools into three science classes, (*a*) those born scientific, (*b*) those that achieve science, (*c*) those that have science thrust upon them, it will be found that only (*b*) and (*c*) are represented in Mr. Latter's report. Class (*b*) supplies all the most valuable information, and it is to be hoped that it will be found useful by the governors of the third class, now a very small one.

The opening pages of the pamphlet are retrospective and historical. Darwin's experiences at Shrewsbury are given, including the public rebuke administered by the headmaster for time wasted on chemistry. This uncompromising attitude gave place later to faint encouragement. There are still to be found those whose memory of Prof. Pepper's popular lectures supplies their ideal of a school science course. The first public school to achieve science was Rugby, and Canon Wilson's reminiscences are perhaps the most interesting pages of the whole pamphlet. He was appointed science master by Temple in 1859, and taught at first in the cloakroom of the Town Hall. A small chemical laboratory with six benches was built in 1860, and here he received a visit from Babbage, brought by Temple to look at one of the first spectroscopes. In due time the Rugby science master became headmaster of Clifton, and it was here that the next real advance was made. Prof. Worthington's "Physical Laboratory Practice, First Course," has been "the model on which nearly all the existing schemes of elementary physical work have been based."

In addition to Rugby and Clifton, the scientific histories of Cheltenham and Charterhouse are briefly related, the experiences of these schools being taken as typical of what has happened at other places. Again, to quote the words of the report, "The mere historical statement conveys very little idea of the conditions under which much of the earlier teaching was conducted. In most schools the idea underlying the new work was to impart a modicum of gentlemanly information concerning natural phenomena and such special branches of science as were attracting public attention and receiving some notice in the daily press."

Among the external influences which have helped to establish the position of science, the increasing importance attached to it in university examinations is regarded as the chief factor. The recent changes in the army examinations have led to an increase in the accommodation and the teaching staff. A well-deserved tribute is paid to the influence of Profs. Armstrong and Miall in the direction of reformed methods of teaching.

To turn from past history to present conditions, it may be said briefly that the result of the inquiry is in the main satisfactory. Governing bodies appear to recognise the claims and importance of science in the most practical manner, and in nearly every instance where laboratories are inadequate new ones are being built. No hint of insufficient funds appears to have been given in any of the replies. The financial question is fully dealt with. It is inevitable that science should cost more than any other subject. Apparatus and materials must be supplied and continually renewed. Gas, water, and electricity must be consumed. In addition to masters' salaries, assistants, trained or untrained, must be paid for. In the latter respect there appears to be a deficiency. "A large number of those responsible for school service have not yet realised the value and importance of employing at least one expert attendant."

In a few cases it has been possible to estimate the cost of the science teaching per boy per hour, including everything except masters' salaries, and the average is just under 3*d*. This may be regarded as a reasonable standard in schools where the science buildings form one block in which apparatus and attendance can be shared by different class-rooms. The schools which have put off the building of specially designed laboratories until the eleventh hour are fortunate in being able to make use of experience gained by those who have borne the burden and heat of the day. We are still feeling our way, but we understand much better than we did ten years ago what is indispensable and what is superfluous in a school science building. The methods of meeting the expenses of the science teaching are very various. Some schools charge an extra fee. In others the entire cost is met by the general funds of the school without any extra charge except in cases of culpable negligence. This, no doubt, is the ideal system, and ought to obtain wherever science is compulsory. On the other hand, when there has been no raising of the general fees to meet special expenditure incurred on behalf of a few, it is not unreasonable that those few should be asked to contribute. The important points in this connection appear to be, first, that no boy should be debarred from taking up science on grounds of expense, and, secondly, that no cheapening of the science course should be effected by lowering the salaries of the staff. Economies of this kind have been known, and have been accompanied by a lowering of the standard.

To turn now to the arrangement of classes and the sequence of studies, it seems that dissatisfaction with present circumstances appears to be infrequent. It may be taken, therefore, that the average conditions are not very far wrong. Mr. Latter finds that the average ratio of masters (in all subjects) to boys is 1 to 14·5, that one out of every nine masters is engaged solely in teaching science, and, allowing for help given by mathematical masters and others, the ratio of science masters to boys is about 1 to 70. These are important facts, and should be carefully considered by school authorities who are in doubt as to their curriculum.

One of the questions asked was, "Are science classes arranged in sets according to attainment in science or according to aggregate in all subjects?" Here is a practical problem of great difficulty. It is complicated by the lack of uniformity among preparatory schools and in public school scholarship examinations in their recognition of science. Thus a clever boy coming to a public school with a scholarship but without any training in science may find himself placed with boys who have already been at the school for one or two years and have passed through its elementary scientific course. The plan of rearranging an entire school of 500 according to attainment in science alone is, of course, impracticable, and in schools where the forms are grouped in blocks, subdivision of a block for science purposes can only be possible when the proportion of masters to boys does not fall below the average already stated. In some cases the classification for science is the same as that for mathematics, and this plan is commended to the consideration of preparatory schoolmasters as well as to those who teach elementary physics at public schools.

The sequence of subjects has already been dealt with in another report. Mr. Latter urges the claims of botany and zoology with some force, and publishes in an appendix six different schedules of science work, which will doubtless be valuable and suggestive to teachers. In fact, the report should be read by all public-school governors and teachers, pastors and masters.

THE EGYPTIAN LAND SURVEY.[1]

THIS interesting volume forms a worthy termination to a piece of work of considerable interest and of immediate practical importance, the construction of the great land map of Egypt.

The fertile valley of the Nile has been a densely populated and closely cultivated tract from the earliest dawn of civilisation; so far back as 2000 B.C. methods of boundary delimitation and area computation are recorded as being in use, methods which, with modifications and improvements only at rare intervals, have lasted down to quite recent times. Seeing the intimate connection of the system of land tenure with the daily life of the people, we might be surprised to find that, up to ten years ago, there was in existence no general land map. It is, however, quite possible for a complex and orderly scheme of land-holding to coexist with an entire absence of maps—our own islands could be adduced as an example of this; in fact, it is not in general until required for fiscal purposes, *i.e.* for some form of land taxation, that a complete cadastre, or accurate large-scale map, is demanded.

In Egypt, when the present Survey Department was constituted in 1898, following upon a survey of State lands begun in 1892, it was found that though vast sums had been expended upon spasmodic efforts at map-making, no work of a permanent nature had been done and for all practical purposes most of the money so spent might as profitably have been thrown into the Nile. Thus, for example, during the ten years from 1878 to 1888 an elaborate cadastre of part of five provinces was made, but being based upon no system of triangulation or other accurate fixation of points, and being carried through so that no part of the work was really self-contained and complete, the whole was well-nigh valueless. In this way about 400,000*l.* was spent. If we cared to calculate the sums similarly wasted on previous abortive attempts we could doubtless exhibit a very handsome total, driving home the lesson that in map-making inaccurate and inefficient work spells, not only trouble and delay, but a large, direct waste of public money.

In 1898, however, this waste, so far as Egypt is concerned, came to an end; a standing survey department was established; the idea that the mapping of a region is a temporary business, which can be completed in a definite period and then set aside as finished—a delusion still found lingering in certain quarters—was discarded, and the whole work was started upon sound and permanent lines. The result of this wise procedure is that the administration now possesses a map of the cultivated area, upon a uniform scale of 1/2500, a possession of enormous value to the agricultural development of the country, without which it would be almost impossible equitably to collect the revenue due under the great water-supply schemes now in existence and likely to be undertaken in the future.

In general, we may fairly say that the account of a cadastral survey would not be of any appreciable interest except to the professional surveyor. In the case of Egypt, however, this limitation by no means holds, and many portions of the present volume, especially the descriptions of the old land measures and the methods of arriving at the areas of holdings, will be found attractive to the general reader. To the surveyor this graphic summary of modern map-making in the land generally accounted the birth-place of his science cannot fail to prove enthralling. There is possibly no country where exactly the same conditions are to be found as those obtaining in the Nile valley, but there is much in this volume applicable to the survey of any closely populated, flat district. Anyone who has the planning of such work, or who is in any way concerned with its execution, owes a debt of gratitude to Capt. Lyons and his staff for the trouble they have taken to place on record the fruits of their accumulated experience.

E. H. H.

NOTES.

DR. A. BREINL, who has worked in connection with the Liverpool School of Tropical Medicine for the past five years, has been appointed director of the newly founded School of Tropical Medicine in Western Australia.

PROF. WILHELM VALENTINER has resigned the directorship of the Astronomical Institute of the grand ducal Observatory of Heidelberg. This institution is now merged with the Astrophysical Institute, under the general direction of Prof. Max Wolf.

LIEUT.-COLONEL ALLAN CUNNINGHAM, R.E., announces the verification of a Mersenne's number (the lowest as yet unverified) to be *composite*, viz.

$$2^{71}-1=228479.10334355636337793.$$

The nature of the large factor has not been determined.

THE death is announced in *Science* of Prof. S. W. Johnson, emeritus professor of agricultural chemistry in Yale University, where he held a professorship for fifty-three years. He had been a member of the National Academy of Sciences since 1866, had served as a past-president of the American Chemical Society, and was eminent for his contributions to agricultural chemistry.

THE Tuberculosis Exhibition which was held at the Art Gallery, Whitechapel, with great success (see NATURE, July 8, p. 48)—more than 70,000 people visiting it—has been moved to the Imperial International Exhibition (White City), Shepherd's Bush, and was opened there on Friday, August 6, by Lord Balfour of Burleigh. We understand that the organisers have already enough invitations to take the exhibition to the various districts of London and the provincial cities to keep it occupied for quite a year.

THE Cracow Academy of Sciences has awarded the Nicolas Copernic prize, amounting to 1000 crowns, to M. Jean Krassowski, of Cracow, for his treatment of the question, "A l'aide de la méthode de M. A. Schuster, examiner la question si les périodes des variations des latitudes, indiquées par MM. Chandler, Kimura, &c., sont réelles ou non." The Constantin Simon prize, of 900 crowns, for a work in the Polish language on mathematics or physics, has been adjudicated to M. Stanislas Zaremba, for his book "Exposé des premiers Principes de la Théorie des Nombres entiers."

THE British Museum (Natural History) has obtained from Mr. C. H. Sternberg a series of remains of the large dinosaurian Trachodon, from the Laramie Cretaceous formation of Wyoming, of which an account was published in our last number. They have just been placed on exhibition in the gallery of fossil reptiles in a case near the remains of Iguanodon, with which it is interesting to compare them. Besides portions of skulls, jaws, teeth, and limb-bones, there are also fragments of the remarkable skin-impressions which have been described by Prof. Osborn.

It may be remembered that the late Mr. Harry Barnato left by will the sum of 250,000*l.* for the purpose of founding some charity in the nature of a hospital, or kindred institution, in commemoration of his brother, Mr. Barney Barnato, and his nephew, Mr. Woolf Joel, both of whom died before him. After full and careful consideration of the merits of the many schemes put before them for the disposal of the money, the trustees have now decided upon applying it to the building and endowment of an institution for the reception of cancer patients. With the view of increasing the potentialities of the bequest, the new institution will be administered, except as regards its finance, in connection with the Middlesex Hospital, and the trustees have procured a suitable site in Nassau Street, adjoining this hospital's special cancer wards. The trustees, with Prince Francis of Teck, Lord Cheylesmore, Sir John Purcell, K.C.B., and Mr. Felix Davis, will form the committee which has been entrusted with the task of putting in train and carrying out this project.

The Rev. F. St. John Thackeray, vicar of Mapledurham, gives in the *Spectator* of April 7 a few interesting stanzas from Tennyson's works to show the poet's appreciation of scientific truth. Tennyson and Darwin were born in the same year, and they did not meet until 1868, but many years previously the poet wrote the words, "So careful of the type she seems, So careless of the single life." Here, it is held, there is a suggestion of the principle of natural selection; and in other poems written before Darwin's work appeared there are anticipatory expressions upon the development of living organisms from simple to more complex forms "Till at last arose the man." Mr. Thackeray points out that Lord Tennyson says in his notes in the Eversley edition, "My father brought 'Evolution' into poetry. Ever since his Cambridge days he believed in it." It must not be forgotten, however, that the idea of evolution, as opposed to the doctrine of special creation, has been under discussion for quite twenty-four centuries. Greek philosophers, with their natural curiosity, considered the problem in detail; and six hundred years before the commencement of our era the idea of the marine origin of life was put forward by Thales. But recognition of the process of evolution is quite a different matter from the discovery of the cause. So far as we read Tennyson's lines we find in them no clear anticipation of Darwin's views as to variation and natural selection being the prime factors of organic evolution. Mr. Thackeray's letter shows that Tennyson was familiar with the general principle of development, but it provides little evidence that he anticipated the principle formulated by Darwin.

An interesting piece of antiquarian work has just been completed by the Essex Field Club by means of a grant from the Essex County Council. It appears that in the time of Charles I. so much of this country had become "afforested" that the inhabitants of those districts subject to forest law found the conditions so burdensome that relief was applied for and sanctioned by the King, who authorised the restoration of the boundaries of all the forests to what they had been in the twentieth year of the reign of James I. This Act was passed in 1640, and in compliance therewith a court of inquiry was held at Stratford in 1641 in order to fix the boundaries of the Waltham Forest, an area comprising the forests known subsequently as Hainault and Epping. The Perambulation resulting from this "inquisition" set forth very explicitly the limits accepted by the commissioners. In defining these boundaries, natural features and the main (Roman) Colchester road were adopted for the western, northern, and southern limits respectively, but on the eastern side, where no well-defined natural or artificial features existed, certain stones, named and dated, were put up. In 1894 these long-forgotten boundary stones were re-discovered and identified by Prof. Meldola, who published a paper about them in the *Essex Naturalist* in 1895. The stones had been badly treated in later times, as several had been uprooted, and were found in ditches near their original sites. Last year the matter was formally brought under the notice of the Essex County Council, which body authorised the re-erection of the stones by the club at a cost not exceeding 100*l.* The work has now been completed, and a meeting of the club and of representatives of the County Council went over the district on July 31. Out of eight stones seven have been identified with certainty, and the site of the eighth has also been marked. The stones have been set in solid concrete beds, and an appropriately inscribed tablet let into the foundation of each. The Essex Field Club is to be congratulated in having rescued from complete oblivion this chapter in the history of a district the greater part of which is rapidly becoming covered with the bricks and mortar of the modern builder. The forest in 1641 began "at the Bridge of Stratford called the Bow."

We learn from the *Revue scientifique* that an International Congress on Radiology is to be held in Brussels in 1910.

It is stated that the Museum of Natural and Physical Science at Barcelona was destroyed during the riots in that city on July 28.

We have received the first number of a journal published at Skagen under the title of *Fiskerhøiskolens Beretning*, and devoted to the schools which have recently been established in various parts of the country for instruction during the winter in all matters connected with fisheries.

Imitation in monkeys forms the subject of an article by Mr. M. E. Haggerty in the August number of the *Century Magazine*. The monkeys experimented upon exhibited five phases of imitative behaviour, summarised as (1) simple arrest of attention; (2) following; (3) reaction to locality; (4) reaction to an object; and (5) exact repetition in detail of an observed action. By No. 1 is meant the watching by one monkey of the action of others, or, in other words, "looking," while No. 2, or "following," indicates a higher grade of mental action, and so on through the series.

According to the report for 1907–8, the collections in the Transvaal Museum are increasing so rapidly that the accommodation afforded by the present building is altogether inadequate, this being notably the case with the mounted specimens of large mammals, of which a considerable number was added during the year under review. In the study collections the congestion is even worse, and as these include a great number of rare, and in certain instances unique, specimens, the urgent need of extension is evident.

The Borough of Maidstone has issued an excellent and well-illustrated guide to the local museum and art-gallery, with a history of Chillington Manor House, in which the natural-history collections are preserved. Special attention is devoted in the museum to the local fauna, both recent and extinct, notices of various groups of which are given by local naturalists and geologists. The illustrations include photographs of the type-specimen of *Chelone benstedi*, a local Chalk chelonian now in the British Museum, and of part of the cranium of *Odontopteryx toliapica* from the London Clay of Sheppey, preserved in the Maidstone collection, the only known specimen of that remarkable bird except the type.

The all-importance of selection to breeders and, in perhaps a somewhat smaller degree, to plant-growers (where hybridisation comes more largely into play), is universally admitted, but difficulties arise in practice when, as is generally the case, it is desired to improve more than a single characteristic of the animal or plant under experiment. As an aid in overcoming these difficulties, Messrs. Pearl and Surface, in the July number of the *American Naturalist*, suggest the adoption of a system of "selection index numbers," the idea of which is to combine in a single numerical expression the values of a series of important characteristics, all of which a breeder may be desirous of improving simultaneously. The analytical expression of this idea is discussed in the article, with illustrations drawn from maize and poultry raising, and it is thus shown that the index numbers form a valuable adjunct to the score-card in judging stock.

Two notes on the feathers of kalij pheasants (Gennæus) are communicated by Prof. A. Ghigi to vol. xii. of the *Rendiconto* of the Royal Academy of Sciences of the Institute of Bologna, the first of these relating to a case of mutation in *Gennaeus swinhoei*, while the second is devoted to the development of the secondary sexual characters in *G. argentatus* and certain other birds. In the case of Swinhoe's kalij, certain marked variations from the normal type made their appearance in the feathers of a bird born in captivity, and as these cannot be attributed to hybridism, they are regarded as an instance of true mutation. In the second note the variations from the normal type of colouring and pattern produced in the feathers of the silver-pheasant and its hybrids by accelerated and retarded development are described and figured, and their bearing on the production of secondary sexual characters discussed.

From among a number of articles on natural history and geological subjects forming the second part of the fourth volume of *Aus der Natur*, we select for notice one by Prof. O. Jaekel on a new "find" of Devonian vertebrates between Cassel and Marburg, which has already yielded some very interesting remains, and is likely to produce many more in the near future. From this deposit, which is especially rich in armoured "placoderms," remains of no fewer than sixty different species of fish and fish-like vertebrates have been obtained, mostly in a wonderfully fine state of preservation, five or six of these belonging to forms previously known only by small portions of the armour. The author gives a restoration of the external form of Coccosteus, based on the new material, and differing very widely from the one in Dr. Smith Woodward's "Catalogue of Fossil Fishes." As now restored, the creature has four paired fins, a low but long dorsal fin, with a gap above the interval between the paired fins, and a somewhat similar ventral fin, continued along part of the long, whip-like tail, this long, slender tail being hypothetically added from evidence supplied by Dr. Traquair. In conclusion, Dr. Jaekel remarks that the most noteworthy feature in the new deposit is the occurrence of the remains of a number of forms of placoderms in one spot, whereas in other places only a few such are found in association. It indicates, in the author's opinion, a kind of "explosive development."

We have often been surprised at the curiously unscientific, but unfortunately very common, use of the term "ovum" by medical writers to designate a human embryo which has developed very far beyond the unicellular condition to which alone the term ought to be applied. We believe that a certain section of the medical profession is apt to question the importance of preliminary scientific education, but the short time spent by the medical student over his elementary biology would not be wasted even if it did no more than give him some idea of accurate terminology. The immediate occasion for these remarks is afforded by a paper by Maximilian Herzog in a recent number of the *American Journal of Anatomy* (vol. ix., No. 3), in which the author describes a very young human embryo, closely resembling that known as "Peters' ovum." Our information as to the early stages in the development of man is, from the nature of the case, so extremely meagre that any fresh light on the subject will be welcomed by embryologists. The embryo in question is regarded as representing the earliest stage of normal human development hitherto known, perhaps from one to two weeks after fertilisation.

The Bulletin of the Liverpool School of Tropical Medicine, of which the first number has just been issued, contains correspondence relating to malaria and mosquito reduction at Ismailia and Helouan. At Ismailia the expense of the anti-malaria measures has averaged 18,000 francs per annum. In 1903 malaria cost the Suez Canal Company 38,200 francs; in 1908 this item dropped to 16,800 francs.

We have received the second number of the *Eugenics Review* (i., No. 2, July), published quarterly by the Eugenics Education Society. The contents include editorial notes and reviews of books, and articles by Sir Francis Galton, Mr. John Russell, Miss A. H. P. Kirby, and others. The review cannot fail to be both interesting and instructive to all those who have the welfare of the race at heart.

Nicolle and Adil-Bey in 1902 reported that the infective particles of cattle-plague virus would pass through the Chamberland porcelain filter "F," and their results were confirmed by Yersin. E. H. Ruediger states (*Philippine Journal of Science*, iv., 1909, No. 1, p. 37) that he was not able to verify these results, and in a second series of experiments, using four different filter candles, confirms his previous work, no filter candle having been found to allow the cattle-plague virus to pass through.

It is a usual custom in pharmacological work to state the dosage of drugs as so much per kilogram of body-weight of animal or man, the subject of experiment or treatment. Prof. Benjamin Moore points out in the *Bio-chemical Journal* (iv., Nos. 5, 6, and 7, July) that this method of stating dosage is inaccurate, the dose of a drug for two individuals of different size, apart from peculiar idiosyncrasies, being proportional, not to their weights, but to their *body surfaces*, in other words, to the two-thirds powers of their weights. Thus an adult of 150 lb. weight cannot be given fifteen times the dose for an infant of 10 lb., but much more nearly a dose only six times as much. It may be that it is this principle which limits the value of some drugs. Thus atoxyl will cure trypanosome infections in mice and rats, but in cattle, horses, and man it is much less effectual. A rat of 140 grams weight can be safely given 0·02 gram of atoxyl. If the dose were proportionate to the body-weight, a man ought to be able to tolerate 10 grams, but, as a matter of fact, about 1 gram is the maximum safe dose, which is in close correspondence to the two-thirds powers of the ratio of weights (1/500).

The progress of forestry in the University of Cambridge is briefly summarised in the second annual report of the forestry committee issued recently. It is announced that Mr. H. J. Elwes has made an offer to provide 1000*l.* towards the erection of a building to serve as a museum and a laboratory, where special attention would be devoted to the study of home-grown timbers. The reader in forestry, Dr. A. Henry, has taken steps to test the suitability of the western larch, *Larix occidentalis*, a native of North-west America, for planting as a forest tree in the British Isles and Europe; the canker disease of the common larch is being made the subject of systematic experimental investigation by Mr. E. R. Burdon.

Horticultural and general botanical articles form one of the leading features of the *Country Home*. The August number contains a contribution by Mr. G. C. Nuttall on plant aspects and plant names, in which, by means of a few examples and clever illustrations, the author shows the reasonableness of popular floral names; it is suggested that the subject is a suitable one for investigating during a holiday. A practical article on tomato culture is provided by Mr. F. W. G. Blyth, where again the excellent reproductions from photographs are conspicuous, and Mr. W. L. Térasse gives advice on the intensive cultivation of strawberries. The monthly calendar and special instructions for the month's work in garden and greenhouse add to the value of the publication.

Owing to loss of the paper for printing, the early numbers of the *Philippine Journal of Science* for the current year have been delayed. The first botanical number opens with a contribution, by Dr. E. B. Copeland, on the ferns of the Malay-Asiatic region. Largely in connection with the identification of specimens from the Philippines, Dr. Copeland has acquired a knowledge of the ferns of the Malay Archipelago, which has induced him to present a fern flora of this region. This first part refers to ten families, from the Ophioglossaceæ and Marattiaceæ to the Cyatheaceæ. Keys and short diagnoses are given for each family, genus, and species. The most striking innovation is the reduction of the genera Alsophila and Hemitelia to Cyathea. Cyathea thus becomes a genus of about 400 species, of which one-fourth occur in the region under consideration; Dicksonia and Balantium are retained. Under Marattiaceæ a fifth genus is provided by the author's monotypic genus Macroglossum, and Kaulfussia is lost under the synonym Christensenia.

Mr. W. J. Bean contributes to the current number of the *Kew Bulletin* (No. 6) a note regarding the effect of the past winter on trees and shrubs in Kew Gardens, with special reference to plants of recent introduction. It is pointed out that alternations between cold and unseasonable warmth were more potent than the actual intensity or duration of cold, and, incidentally, it is noted that plants growing in low, damp situations were killed, while specimens situated on drier ground survived. A considerable number of recently introduced Chinese plants, including *Davidia involucrata* and *Ailanthus Vilmorinii*, came successfully through the ordeal, and the author gives a list of rhododendrons from north India that may be considered hardy. Bamboos suffered greatly, with the exception of *Arundinaria nitida* and *A. fastuosa*. Other shrubs that proved hardy are *Erica stricta, Cistus laurifolius, Genista virgata,* and *Vaccinium padifolium.*

The Bulletin of the College of Agriculture, Tokyo Imperial University, Japan, vol. viii., 1909, No. 2, contains a paper by S. Kusano on the cytology of *Synchytrium puerariae* and *S. decipiens*, parasitic fungi belonging to the phycomycetes, with bibliography, and illustrated with several excellent plates; a description of a new species of moth belonging to the genus Latirostrum, by T. Miyake; and a revision of Japanese Arctianæ, insects injurious to farm crops and fruit and forest trees, by the same author, with descriptions of some new species.

A series of Bulletins, Nos. 141–4, issued from the Colorado Agricultural College, deal with various phases of market-garden work. No. 142 discusses general problems such as tillage, manuring, &c., in the light of local experience, and lays stress on the conditions which must be fulfilled in Colorado if success is to be attained. Among them is the necessity for "shade" crops, *i.e.* for crops grown with the view of shading the ground from the sun's heat, or, in winter, of reducing the loss of heat by radiation, and thus of keeping the soil temperature more uniform. Another effect of a "shade" crop in summer is to diminish loss of water by evaporation. The other bulletins deal with special crops—grapes, cabbages, and celery.

Some of the most important agricultural problems of Cape Colony are associated with water supply, and that this fact is recognised is abundantly proved by the number of articles devoted to it in the Agricultural Journal of the Colony. The Karoo is a dry region, and at the same time possesses a very rich soil; this combination is not unusual, and can be paralleled in the dry belt of British Columbia, of parts of the United States, and elsewhere. Its productiveness is limited by the water supply, and recourse is had to various methods for conserving and increasing the amount of moisture in the soil. Special methods of cultivation are found to diminish loss of water by evaporation, and dams are built to store rain-water, which can then be used for irrigation. Attention is also being directed to the effect of forests on water supply.

The *Bulletin de la Société d'Encouragement pour l'Industrie nationale* (vol. iii., No. 3) recently published a long and interesting article by M. Hitier on agriculture in Russia. The various regions are described, and a good account is given of the black soils, the steppes, and other well-marked types of soil. Analyses are quoted showing the presence in black soils of 0·5 per cent. of nitrogen, 7 per cent. of organic matter, and distinct quantities of carbonates, along with sufficient potash and phosphates; the area covered by these wonderfully fertile soils is considerably larger than that of France. The natural conditions are eminently favourable for agricultural development, but the economic conditions, especially the collective ownership of land and the power of the Mir, are regarded as great obstacles, and the author does not consider any advance possible until these artificial hindrances are removed.

The movements of the deeper waters of the Skagerack form the subject of an interesting paper by Dr. O. Pettersson which is published as No. 47 of the *Publications* *de Circonstance* of the Conseil Permanent International pour l'Exploration de la Mer. Dr. Pettersson finds that in the underlying deep waters there is a tidal oscillation which can have daily, monthly and annual periods. These oscillations produce variations in the temperature and salinity of the sea at certain depths, and their investigation becomes of great commercial importance owing to their action in determining the coming and the migration of the herring shoals. The great annual oscillation of the coastal water in the Norwegian sea shows amplitudes of more than 100 m., and the corresponding expansion of the coastal waters of the surface to the westward, in the summer months, was found by Hjort and Nansen to cover an area more than 100 miles broad.

THE fourth report on earthquakes in Jamaica, by Mr. Maxwell Hall, contains a catalogue of shocks recorded since the commencement of the weather service in 1880, and some interesting particulars regarding the fracture of cables by the earthquake of January 14, 1907. The cable to Colon was broken four miles south of Bull Bay, and to the south of the break the cable was so deeply buried in mud that it parted in the attempt to raise it. A more extensive break took place at twenty miles further south, where the cable had been dragged from west to east, and the fractured ends were fully a mile apart, and further south the cable was again buried in mud and had to be abandoned. Captain Morrell, of the repairing ship *Henry Holmes*, reports that the two ends of the cable fitted together perfectly, the cable was in perfect condition, there were no signs of erosion, and the wires were broken clean as by a tremendous strain, which he considers to have been produced by a landslide from the direction of the shallow water to the deeper. Mr. Hall points out that the soundings indicate a gradient of 740 fathoms in five miles, or about 1 in 6, on the average, from the California bank, but where the great break occurred the sea-bed is apparently level or nearly so; consequently, he considers, the dragging of the cable for a mile or so to the east, and the parting of the ends to the same extent, could only have been produced by a great chasm opening in the bed of the sea to the east of the great break.

THE first part of the "Bergens Museums Aarbog" for the current year records an important discovery at Jaederen of a house of the Middle Iron age. It consisted of a single oblong room, the roof resting on beams set upright, distinct marks of which were found in the clay floor, and the interior being filled with remains of the birch-bark roofing. The fireplace was a paved depression in the centre, but fires had been made also in other parts of the apartment. The antiquities discovered were, on the whole, disappointing, consisting mainly of earthenware pots and grindstones, of which illustrations are given in the report. This discovery is notable, because this is the first house of this type which has been found in Norway; but in Sweden they are well known in Gotland, Oland, and Uppland, and they seem to have been noticed in Finland.

PROF. JUNE DOWNEY contributes an article on muscle reading to the July number of the *Psychological Review*. By muscle reading is meant that well-known communication between one person, the guide, and another, the subject, by means of involuntary movements of the guide, when his attention is riveted in a given direction. The writer contends that concentration of the guide's attention not only induces free involuntary movements, but also leads to more complex forms of "automatic" activity. For instance, although the guide's attention may be momentarily distracted, his involuntary movements persist unaltered. Or, again, despite his concentrated attention in a given direction, his movements may have reference to a preceding test instead of to the present one. Unfortunately, the scant experimental data given in the present paper and her defects of experimental method make it difficult to accept with confidence any of the writer's interesting conclusions.

DURING a stay at the Sonnblick Observatory (3106 metres) in July, 1908, Dr. A. Wagner, of the Austrian Meteorological Office, made some interesting observations on cloud elements, the results of which are published in the *Sitzungsberichte* of the Vienna Academy for December last. The author deals with the water contents, both in the gaseous form, as shown by the hair hygrometer, and in its fluid form in drops or ice-crystals, also with the size of the drops. During thick fog the humidity was generally more than 100 per cent., and only sank below that amount when the sun became visible through the fog. The mean of the measurements of the fluid contents of the clouds was about 2 grams per cubic metre; the greatest value was 4·84 grams, and the smallest 0·12 gram. The total of the fluid and gaseous contents varied between 9·98 grams and 4·17 grams per cubic metre; the fluid contents were always less than the gaseous. Visibility was found to be inversely proportional to the fluid contents; its dependence on the size of the drops could not be determined, owing to the few measurements made of the latter. The mean diameter of the drops, determined by the optical method, was 33 μ, but only eighteen such observations were made, on three days.

THE July number of the Journal of the Röntgen Society contains a paper by Dr. G. H. Rodman on the historical collection of sixty-three Röntgen-ray tubes which has been got together by the society, and is now in the possession of the authorities of the Victoria and Albert Museum at South Kensington, and will in a short time be installed in two show-cases in the museum. The paper is well illustrated by photographs of the tubes, and will be of great use to those who are unable to pay a visit to the museum to inspect the tubes themselves.

A VALUABLE report by Dr. H. Happel on the present position of our knowledge of the properties of the monatomic gases is to be found in the *Physikalische Zeitschrift* for July 15. The author, after giving an account of the theoretical advances made by Sutherland and by Reinganum on the assumption of hard spherical molecules, refers to the older work of Maxwell and Boltzmann, based on the molecules repelling each other according to the inverse fifth power of their distance apart. He shows that the experimental work done during recent years on the viscosity, heat conduction, and diffusion of the simpler gases does not provide more than general support for any of these theories, and that there is great need of further investigation of these properties over very wide limits of temperature. The theory of the gas-liquid state and the theory of binary mixtures as stated by van der Waals have, in Dr. Happel's opinion, proved valuable weapons in the hands of those who, like Ramsay, Travers, Dewar, and Kamerlingh-Onnes, have been engaged in investigating the thermal properties of the monatomic gases and of mixtures of them.

A PAPER on refrigerating installations, with special reference to the arrangements necessary when narrow limits of temperature are required, was read by Mr. Robert Balfour at a meeting of the Institute of Marine

Engineers held at the White City on July 24. The author's references to the difficulties of dealing with beef are particularly interesting. Beef is much more difficult to keep in condition during a voyage than mutton. The temperature must never be low enough to produce solidification; such would cause the substance of the meat to burst, and on thawing the meat would have a flabby appearance, which would depreciate its value, although perfectly wholesome as food. The temperature should be maintained as nearly as possible at 29·5° F. The animals must not be excited immediately preceding slaughter, or have any sprained joints which would produce decomposition of the joint oil. The atmospheric conditions must not be thundery or sultry at the time of slaughter, or the air heavily charged with moisture, and scrupulous cleanliness must be observed throughout. Indeed, the ideal conditions for the slaughter-house should be those of the operating theatre of a modern hospital. An article in *Engineering* for July 30 states that there has not hitherto been much success in the bringing of chilled beef from Australia, but an experiment is now being made with a large consignment, and will be watched with interest.

In the recently issued report of the proceedings of the International Committee of Weights and Measures at its meeting held in March last, the following points are of interest. Investigations made at the bureau of the committee at Sèvres have shown that when water at temperatures between 6° C. and 8° C. is saturated with air, the density of the water is diminished by about three parts in a million. Vols. xiv. and xv. of the *Travaux et Mémoires* of the committee, which are expected to be published shortly, will include the researches of M. Chappuis on the above subject, and also an account of the experiments conducted by MM. Benoît, Fabry and Perot with respect to the length of the metre in terms of wave-lengths of light. The former volume will also contain three important memoirs on the mass of a cubic decimetre of water. The committee announces the adhesion of Chili and Uruguay to the metric convention, and expresses much satisfaction with the proposal of our Colonial Office to distribute copies of the convention to all the British colonies and dependencies. The report includes two appendices by M. Guillaume. The first is a supplement to his paper entitled "Récents Progrès du Système métrique," which was presented to the general conference of weights and measures in 1907, and the second gives an account of the present state of the question of standard end-measures of length. It would appear from the latter paper that Airy's method for determining the lengths of end-bars, which had almost fallen into desuetude, has recently been employed at the International Bureau with considerable success.

The issue of the *Chemist and Druggist* for July 31 celebrates fittingly the attainment of our contemporary's jubilee. The occasion of the annual summer issue of the magazine has been taken to publish a history of the growth of the periodical from its modest beginning in 1859 to the important technical journal it has since become. The contents of this jubilee issue remind us that the *Chemist and Druggist* has for many years given prominence to the scientific aspects of pharmacology, and has insisted consistently upon the value of a knowledge of pure science if scientific principles are to be followed successfully in technical processes. The present issue contains, in addition, an exhaustive account of the proceedings at the annual meeting of the British Pharmaceutical Conference, held at Newcastle-on-Tyne towards the end of last month.

A list of the lectures arranged for the session 1909–10 in connection with the extension section of the Manchester Microscopical Society has reached us. The purpose of this section is to bring scientific knowledge, in a popular form, before societies unable to pay large fees to professional lecturers. The lectures are given gratuitously by members of the society, and all fees paid for lectures are devoted to the working expenses of the section. In addition to lectures, the honorary secretary is willing to arrange practical demonstrations in microscopy, microscopical exhibitions, and the mounting of microscopic objects, in connection with the work of natural history societies in the neighbourhood of Manchester. It is noteworthy that there are about sixty lectures from which to choose. The honorary secretary is Mr. R. Howarth, 90 George Street, Cheetham Hill, Manchester.

OUR ASTRONOMICAL COLUMN.

Observations of Saturn's Rings.—It will be remembered that on the occasion of the disappearance of Saturn's rings in 1907, Prof. Barnard, and other observers, found that even when the rings were at minimum visibility there still remained bright condensations on either side of the planet. These, Prof. Barnard suggested, were possibly due to the sunlight sifting through and being reflected from the particles comprising the crape ring.

Observations made during 1908 tend to confirm this hypothesis, for, when seen very obliquely, the crape ring appeared much brighter than when seen at such times that the rings are more open, thus showing that the particles are probably but sparsely disposed, and would permit of such transmission and reflection of sunlight as was suggested. The relative apparent brightnesses of the inner and outer bright rings as seen at different epochs also change, for during 1908, when the foreshortening of the rings was great, the outer ring appeared to be the brighter. Prof. Barnard suggests that if we could look normally at the surface of the rings the outer one would be relatively dark, and the crape ring, perhaps, invisible. Although careful search was made for it, Prof. Barnard was unable to detect any trace of the outer dark ring discovered at Mount Revard, and subsequently observed at Geneva and Greenwich (Monthly Notices [R.A.S.], vol. lxix., No. 8, p. 621).

The Relative Atmospheric Efficiency of Telescopes.—In a letter to No. 411 of the *Observatory* Mr. R. T. A. Innes directs attention to the subject of the relative efficiency of telescopes of different apertures as compared with the theoretical efficiencies. By tabulating the results obtained by Burnham, with various apertures, he shows that if the efficiency of the 36-inch Lick refractor be taken as 1·0, that of the 6-inch refractor used by Burnham is, relatively, 2·5, the efficiency per inch of aperture apparently decreasing regularly as the aperture increases.

This phenomenon is attributed by Mr. Innes to atmospheric interference; with a large instrument it is more difficult to find a night with perfect definition, and it is only on such nights that close doubles, at the limit of the observer's vision and the telescope's power, can be observed.

The Motion of the Pole.—No. 4344 of the *Astronomische Nachrichten* contains a paper by Mr. H. Kimura discussing the polar motion and the z component during the period 1890·0–1908·5. The investigation of the fourteen-months' period shows that it changed rather quickly, being 436 days in 1893, 442 days (maximum) in 1897, and 427 days in 1907. No such abrupt change of amplitude accompanied this change of period.

The new discussion is opposed to the previous theory that the annual period varies quickly while the fourteen-months' period remains nearly constant, the opposite appearing to be the case; but, as Mr. Kimura points out, the problem is a complicated one, in which many variables are inherent, and will have to wait for further observations and study before any definite conclusions are arrived at. Special attention must be given to the effect of latitude, and it may be found that the slow variation of the z component, especially in phase, is not unconnected with the sixty, or seventy-five, year period of the annual term which was announced by Dr. Chandler.

REPORTS OF OBSERVATORIES.—Mr. Hough's report of the work done at the Cape Observatory during the year 1908 cannot be summarised effectively in a brief note, but one or two points may be especially recorded. The Victoria telescope was in use on 165 nights to secure 601 stellar spectra for line-of-sight determinations; the solar parallax programme having been completed in May, the spectrograph was dismounted, repaired, and adjusted, and is now employed in the determination of the radial velocities of 365 stars between declination 30° N. and the south pole. The value obtained for the parallax was $8{\cdot}800'' \pm 0{\cdot}006''$. The astrographic telescope was employed in taking proper-motion and parallax plates of some of Prof. Kapteyn's "selected areas."

In the report of the Paris Observatory for 1908 M. Baillaud outlines the re-organised programme of the observatory work. Among other things, we note that the small equatorial *coudé* is to be employed, by M. Hamy, for the study of sun-spot spectra.

SOLAR RESEARCH.—In the August number of the *Observatory* Mr. A. A. Buss discusses, at some length, the possible purport of the results obtained in recent solar research, dealing principally with appearance of the D_3 line of helium. In concluding, he states that he has, on a number of occasions in recent years, seen immense "dark" hydrogen clouds projected on the dark background of the sun's surroundings; this phenomenon he attributes to the projection of the clouds against the slight luminosity of the sun's hydrogen corona.

A BRILLIANT METEOR.—Observing at Marseilles on June 26, M. Borrelly saw a splendid meteor, which appeared at 14h. 0m. 56s. (Marseilles M.T.), and illuminated the whole of the sky for some three seconds. The light was extraordinary, and the meteor travelled from Pegasus to the Dolphin, above ϵ Pegasi, in a N.E. direction (*Astronomische Nachrichten*, No. 4339).

PHYSIOLOGY AT THE BRITISH MEDICAL ASSOCIATION.

THE chief points of general scientific interest in the proceedings of the British Medical Association at Belfast are to be found in the communications read in the sections of anatomy and physiology, bacteriology and pathology, on July 28–30. The following account is practically limited to a brief summary of Prof. Sherrington's presidential address to the section of anatomy and physiology, entitled "The Deep Afferents—their Distribution and Function."

In contrast with our considerable knowledge of the surface afferents, our knowledge of the deep afferents is relatively slight. The deep afferent system may be subdivided into a visceral and a muscular portion, using the latter term in a somewhat wide sense.

From one point of view the visceral portion may be regarded as superficial with reference to the lining membrane of the alimentary canal and respiratory passages, but practically this fact may be neglected. The consciousness of the body is normally almost entirely confined to the external surface. When we take food, it normally disappears from our ken after its passage through the fauces, and consequently if we were guided only by our own consciousness we might doubt the likelihood of the existence of visceral afferents associated with sensation. Yet numerous examples of dim visceral sensations, especially gastric ones, might be adduced. For example, after drinking hot fluids a characteristic gastric sensation is produced. Under pathological conditions numerous visceral sensations may be obtained. The explanation and localisation of the latter form a fruitful field, in the investigation of which physiologists, anatomists, and clinicians might usefully combine. Further, it has long been recognised that afferent nerves are not necessarily associated with sensation. Numerous examples of this fact will be given in the course of this account.

The mouth and nasal cavities form an intermediate field between the external surface of the body supplied by the superficial afferents, and the remainder of the alimentary canal and the respiratory passages supplied by the deep visceral afferents. In this region the nature of the effective stimuli alters. Whereas mechanical and physical stimuli are specially effective when applied to the external surface, chemical stimuli, both gustatory and olfactory, become specially effective in the intermediate zone both in the direction of yielding sensations and of inducing reflexes.

Prof. Sherrington next passed from the consideration of this intermediate field to that of the deep visceral afferents proper. Formerly, gastric and intestinal movements and digestion were believed to be controlled by mechanical and chemical stimuli affecting afferent visceral nerves. More recently a deeper insight into the mechanism controlling gastric and intestinal movements and digestion has revealed a number of difficulties which militate against the acceptance of the older views. For example, the intestinal movements, both the simple pendular and the more powerful and less frequent peristaltic movements, take place in an isolated loop of intestine after section of all the nerves passing to the loop. In this case there cannot only be no conscious reaction, but even no true reflex act. Further, the removal of the abdominal sympathetic in the dog does not cause any obvious alteration in digestion or intestinal movements. Under such conditions the regulation of movements and digestion is controlled by the intrinsic nerve mechanism of the alimentary canal, namely, Auerbach's and Meissner's plexuses.

A very interesting phase of recent physiology is the suggestion by Bayliss and Starling of a mode of chemical regulation other than that through the nervous system. They have extracted from certain organs substances called hormones, which are capable of exciting the activity of correlated organs. One of the best known of these is secretin. Bayliss and Starling showed that secretin is effective after severance of nervous connections, and have thus rendered doubtful Pawlow's view that the co-adjustment of organs is mainly nervous in origin. Other examples of hormones are a substance extracted from the cardiac end of the stomach, which acts on the pyloric end, and carbon dioxide, which may be regarded as the hormone affecting the bulbar respiratory centre.

Prof. Sherrington next passed to a subject of great theoretical and practical interest, namely, visceral pain. This subject has long formed a field of controversy, largely on account of the obvious difficulties in the way of its investigation. The observations which have been made on visceral pain are best dealt with in historical sequence.

Haller, one of the earliest investigators of this subject, distinguished parts which feel from those which do not feel. He included the viscera, tendons, and blood-vessels amongst the non-feeling parts. His results were largely obtained by investigation of the human subject, using interrogation of the patient as the test. He also experimented on animals. The methods of stimulation used in the latter cases were extreme in character, and consequently throw no light on the results which might be obtained by the use of more normal and adequate stimuli. Johannes Müller held views diametrically opposed to those of Haller. He maintained that the viscera are sensitive.

Amongst later observers, Head almost takes visceral pain for granted, and, following Ross, develops the idea of "referred pain." Lennander's papers are the most recent on this subject. As the result of experiments on man, he comes to the conclusion that the abdominal and thoracic viscera do not feel. The parietal peritoneum is also insensitive, but the subserous layer of the peritoneum is highly sensitive even under normal conditions. When slightly inflamed the subserous layer becomes hypersensitive.

Meltzer's results are opposed to those of Lennander. From a large series of experiments, chiefly on the dog, but also on man, he comes to the conclusion that stimulation of the liver and intestines elicits reactions that indicate pain. After a short period of exposure to the air, the viscera appear to become hypersensitive, slight stimuli producing well-marked reactions.

On considering the results obtained by these observers, it is difficult to imagine that the powerful vaso-motor reactions obtainable by stimulation of the abdominal sympathetic are not associated with sensation. The distinct reflex contraction of the abdominal muscles resulting from stimulation of the abdominal sympathetic is another reaction which it is difficult to believe is not associated with sensation. The latter phenomenon has a two-fold interest. In the first place, it is the basis of a well-known clinical symptom, the rigid belly wall, and, secondly, it represents a form of tonic contraction not directly inducible by artificial stimuli.

On examining critically Haller's, and to a less extent Lennander's paper, we are struck by the fact that the stimuli used are unnatural in character. It is not likely that the viscera are equally responsive to all forms of mechanical stimuli. Twisting, stretching, or squeezing the wall of the intestine from the outside may be ineffective, because the nerve endings in these organs are adjusted for stimuli of another kind. In the case of the bile duct and of the ureters a twist produces no vaso-motor effect, but distension by injection produces a well-marked rise of blood pressure.

The "referred visceral pain" was discussed next. Dr. J. Mackenzie denies that a viscus is ever directly painful, the pain felt being essentially a "referred one." For example, in pleurisy the lungs and parietal pleura are insensitive. While agreeing with Lennander in the view that the subserous layer of the pleura is sensitive, Mackenzie holds that the pain of pleurisy is mainly a referred pain due to cramp of the muscles of the thoracic wall. Mackenzie gives the following theory as to the mechanism of the different forms of "referred pain." He holds that stimulation of afferent visceral nerves by some influence increases the excitability of afferent centres in the cord connected with corresponding areas of skin. The pain is consequently referred to these cutaneous areas, and is only indirectly the result of stimulation of deep visceral afferents.

Head gives a somewhat different explanation. Impressed by the fact that inflammation of spinal ganglia produces herpes zoster, he was led to believe that afferent visceral fibres in their passage through the same ganglia as certain afferent cutaneous nerves can affect the adjoining cells connected with the latter and thus produce "referred cutaneous pain." This view is opposed to Müller's law, and was finally given up by Head. He ultimately transferred the seat of the nervous mechanism from the ganglia to deeper centres in the cord. The segments of the cord connected with "referred pain" do not correspond with the segments of the spinal axis as indicated by the ganglia. Head suggests that the "referred pain" areas correspond with the primitive phylogenetic segments of the cord. He leaves the mechanism of overflow unexplained. A remarkable fact is that the area of skin affected by referred pain is a mere patch or couple of patches, not a segment, but nevertheless more or less segmentally arranged.

The deep visceral afferents from the heart are not only those which have been most fully investigated experimentally, but also form an intermediate group between the pure visceral deep afferents and those of somatic or muscular origin. The chief afferent nerve of the heart is the depressor, and the receptive field for its stimulation is its nerve terminations in the wall of the aorta. The most adequate stimulus is distension of the walls of that vessel. The result of stimulation is a lowering of blood pressure due to a diminution of vascular tone. The nature of this tone, like that of voluntary muscles, is still obscure. It is doubtful whether stimulation of the depressor gives rise to pain directly. The areas of "referred pain" given by Mackenzie are not cranial, as we should expect, since the vagus is a cranial nerve, but mainly lie in the chest wall. Tender spots, however, are also found on the head.

Prof. Sherrington then gave a brief survey of deep non-visceral or muscular afferents. Since the work on this subject is largely due to himself, and since he has elsewhere stated his views more fully, it would not serve any good purpose to try to epitomise this part of his paper.

The paper was followed by an interesting discussion, in which Prof. J. S. Macdonald, Dr. Graham Brown, and others took part. The discussion chiefly referred to the nature and functions of the terminations of the deep afferent muscular nerves. A number of other papers of anatomical and physiological interest were also read by the following:—Prof. Dixon (Dublin), the development of the achondroplasic skeleton; Prof. Anderson (Galway); Dr. Dickey (Belfast), the cervical pleura; Dr. Johnston (Dublin), the intercostal nerves; Drs. Goodall and Earle (London), the structure of the pancreas in relation to its functions; Dr. Maclean (Liverpool), phosphatides in the light of modern research; Prof. B. Moore (Liverpool), the chemistry of hæmolysis; Dr. S. Spicer, some points in the mechanics of respiration; Prof. Thompson, the development of the fœtal heart; Dr. Leonard Hill, F.R.S., the influence of inhalations of oxygen on the onset of muscular exhaustion; Dr. Rutherford, some points in connection with the anatomy of the cranium of the fish; Dr. Waterston, some instruments used in anthropometry.

RECENT IMPROVEMENTS IN THE INTERNAL-COMBUSTION ENGINE.[1]

II.

WE have already explained how important in the economical development of the internal-combustion engine is an accurate and precise knowledge of the physical properties of the working medium. The two chief features of which a knowledge is required are the calorific value of the explosive mixture and the relation between the specific heat and temperature of the ignited gases. The calorific value has been carefully ascertained for most of the gases commonly used, but the specific-heat relation is still a matter of unfortunate uncertainty. At the Leicester meeting of the British Association in 1907, under the sectional presidency of Prof. Silvanus P. Thompson, the desirability of clearing up the doubts that surrounded this subject was so keenly felt that an important committee was appointed for "the investigation of gaseous explosions, with special reference to temperature." An account of the findings of this committee was published in NATURE of June 24 last. From our present point of view the important result of the committee's work is expressed in the following extract from its report:—"Recent researches on the properties of the gases at high temperatures have definitely shown that the assumption of constant specific heat is erroneous, and have given sufficient information about the magnitude of the error to show that it is of material importance. . . . The closer approximation to the real cycle which is made by taking account of the actual properties of the working fluid, though it leads to some complication of formulæ, gives compensating advantages of real practical value." This bears out, also, a remark made by the late Prof. Zeuner[2] to the effect that "at any rate there must be dropped from the theory of the internal-combustion motors the former assumption of the constancy of the specific heats of the products of combustion." A curve connecting the specific heat at constant volume (C_v) of the mixture of gases, formed by the explosion of one part of coal gas in nine parts of air, with temperature centigrade (θ), which was considered to be accurate within 5 per cent., was included in the committee's report. A formula which fits this curve closely is

$$C_v = 0{\cdot}172 + 0{\cdot}075 \frac{\theta}{1000},$$

and although the constant in the second term on the right-hand side of this equation can only be looked upon as a first estimate, however carefully chosen, the equation does, probably, represent the high-water mark in our present-day knowledge, and from it can be deduced the limiting theoretical efficiency of engine cycles in which such a working medium is employed.

It is well known that on the basis of a constant specific heat the ideal efficiency (η) can be found from the following equation,

$$\eta = 1 - \left(\frac{1}{r}\right)^{\gamma-1},$$

where r is the ratio of compression and γ is the ratio of the specific heats. This relation applies with equal truth

[1] Continued from p 172.

[2] "Technical Thermodynamics," by Prof. Zeuner.

whether the cycle followed is (1) the constant-volume cycle, (2) the constant-pressure cycle, or (3) the constant-temperature cycle, an important discovery attributed to Profs. Unwin and Callendar. The problem now arises to re-calculate the thermal efficiency (η) for a working medium of which the specific heat is *not* constant. Most of the important internal-combustion engines operate on the constant-volume cycle, and if we re-calculate the equation to suit this case, making the necessary approximations to secure a workable result of sufficient accuracy, and using the above linear law based on the British Association Committee's figures for specific heats, we find that the new efficiency equals

$$\eta\left\{1-\frac{1}{4000}\left(\overline{1-\eta}\,.\,T_2+T_0\right)\right\},$$

where T_2 is the maximum absolute temperature (centigrade) in the cycle, T_0 the suction temperature, whilst η is the value obtained from the equation

$$\eta=1-\left(\frac{1}{r}\right)^{\gamma-1},$$

using here the value of γ corresponding to the *absolute zero of temperature*. The value of T_0 is practically independent of the compression, and in round figures suitable to this calculation may be written down as 400. The value of T_2 for a given richness of mixture will depend upon the degree of compression before ignition, and can be calculated therefrom. In this way a new expression for the real thermal efficiency can be obtained in terms, not of T_2, but of r, and the following table shows a few comparative figures worked out in this way. The figures for the "air-standard" efficiency are also given by way of comparison.

Thermal Efficiency.

Ratio of compression	"Air standard"	Real thermal efficiency (approximate figures)
4	0·43	0·30
10	0·60	0·45

Ratio, air/gas = 9/1.

It will be seen that in each case the real efficiency is about a quarter less than the "air-standard" efficiency.

This discrepancy sufficiently explains why those associated with the design and building of gas engines have expressed their dissatisfaction with the "air standard" of efficiency. The adoption of the "air standard" has led to the setting up as an ideal, to be aimed at and striven after, of a series of figures which it now appears are about one-third above the thermal efficiencies theoretically possible, and it is not surprising that engine builders, who from their practical work realised that there must be something wrong with the theory as then put forward, should have objected. It is not too much to say that had the engine builders to depend in the past solely on scientific guidance as the mainspring of their investigations, there would have been far less progress made than has been effected by the system of trial and error. Even now the state of knowledge as to gaseous specific heats is so uncertain that no accurate quantitative theory of the thermodynamics of the internal-combustion engine can be laid down. The writer has, however, endeavoured to show here and elsewhere how the problem may be investigated symbolically, and so prepared for expression in numerical form as soon as the thermal properties of the gases are actually known.

Mr. Dugald Clerk, in his 1907 paper[1] before the Institution of Civil Engineers, made some estimates of real efficiencies based on theoretical maximum temperatures of 1600° C. and 1000° C., and his results are given below.

	Ideal efficiencies		
r	If maximum temperature of cycle 1600° C.	If maximum temperature of cycle 1000° C.	On air standard
2	0·195	0·200	0·242
3	0·286	0·293	0·356
4	0·354	0·356	0·426
5	0·384	0·394	0·475
7	0·439	0·443	0·541

It was apparently contemplated that these figures might be used in comparison with engine performances in which the *real* maximum temperatures were also 1600° C. and 1000° C. This, however, would be open to several objections. As an instance, take the case of an engine which by improved design was made capable of giving for the same mixture and the same compression ratio a higher maximum temperature and pressure. Such an effect might be produced, let us say, by decreasing the ratio of cooling surface to volume through an alteration in the amount of pocketing. This new engine, on the basis of comparison with an ideal cycle having an identical maximum temperature, would probably show little, if any, improvement in relative efficiency over the old engine. Such a result would tend to defeat the purpose for which comparisons with ideal cycles are made. It would seem to the author that the better way would be to compare both old and new engines with an ideal cycle having a maximum temperature corresponding to the known richness of the mixture, its calorific value, and the ratio of compression.

A factor that has affected most advantageously the recent progress of the internal-combustion engine is the great improvement that has taken place in engine indicators. The old moving lever design, although thoroughly serviceable for most steam engines and for many slow-moving internal-combustion engines, has been found entirely untrustworthy with modern high-speed internal-combustion engines. A new form of instrument has been devised in which the recording lever is a beam of light, which, having no inertia, has no time-lag. This vitally important improvement in the indicators was due, in the first instance, to the prescience of Prof. Perry,[1] and in its later stages to the experimental skill of Profs. Callendar and Hopkinson. The writer has recently calculated out the case of an indicator of which the free periodic time of oscillation was 1/300 sec., and has shown that explosions occurring even in so short a time as 1/200 sec. could be adequately followed and recorded. We believe that this oscillation period represents about the sensitiveness of one of the reflecting indicators used by Prof. Hopkinson at Cambridge, and the calculation serves to show how accurately the new instruments can be made to follow extremely rapid explosions.

It would be useless to base any deductions on the records given by one of the old type of instruments in such a sharp explosion as this. Errors of as much as 5 per cent. are now known to have occurred in the measurements of horse-power made by the old instruments. On the other hand, it cannot be denied that the older type was a great deal easier to handle, and that it could be used by comparatively untrained persons. The new reflecting kind, despite its accuracy of measurement to within 1 per cent. of the power, is rarely seen in workshops, and the measure of "indicated horse-power" has been very commonly abandoned in favour of the measurement of "brake horse-power" both in the case of large and small engines. In the case of the numerous small high-speed petrol engines, the practice of actually measuring brake horse-power is often replaced by the use of a rating formula giving a "nominal" horse-power. It seems at first sight extraordinary that there should be a reversion to the old unscientific "N.H.P.," but, despite their apparent similarity, the "N.H.P." of the old days of the steam engine and boiler, and the "rating H.P." of the modern petrol engine, are really based on very different considerations, and, as there appears to be every likelihood that the latter will be constantly revised with the aid of the best scientific advice possible, there is little real foundation for any scientific objection to it. The pioneer work done by Prof. Callendar in promoting this advance cannot be too gratefully acknowledged. Others have also worked at the problem since, and a considerable "output" of rating formulæ has resulted. That in most common use is $\text{H.P.}=\frac{D^2.N}{2\cdot5}$, where D is cylinder diameter in inches and N is the number of cylinders. This formula was put forward with the authority of the Royal Automobile Club, and experience has shown that in the great majority of cases it gives wonderfully good results. It may even be doubted whether any of the far more complicated

[1] Proc. I.C.E., vol. clxix., p. 145.

[1] "The Steam Engine," by Prof. Perry, p. 117.

formulæ since brought forward give a more accurate measurement. It is, of course, not fitted for use with racing motors, in which everything in design is sacrificed to piston speed, high mean pressure, and a sufficient endurance to last through a few races. For an engine having 4-inch cylinders the Royal Automobile Club formula gives a rating of 25·6 horse-power, which is about the brake horse-power that a normal engine of this size would yield when driven at a normal speed. Racing motors of this size have, however, given almost, if not quite, 100 horse-power, and even if it were possible to do so it is a question whether it is worth while to search out a formula which would embrace such divergent practice and conditions of operation. The Royal Automobile Club formula corresponds to combining a piston speed of 1000 feet per sec. with a mean pressure of 67·2 lb. per square inch. Before it can be revised a complete series of careful experiments on engines of sizes ranging from 2 inches to 10 inches should be carried out.

In the succeeding article the writer proposes to discuss details of the recent mechanical improvement of the internal-combustion engine in relation to the theoretical investigations already discussed.

H. E. WIMPERIS.

CONFERENCE OF ENGINEERS AND SHIPBUILDERS AT GLASGOW.

A JOINT summer meeting of the members of the Institution of Engineers and Shipbuilders in Scotland and of the North-east Coast Institution of Engineers and Shipbuilders was held in Glasgow on August 4, 5, and 6. It is of interest to note that, although a large number of works and shipbuilding yards was thrown open to visitors, no works in which Admiralty work is under construction were included. This arises from the firms concerned paying respect to the wishes of the Admiralty that as much secrecy as possible should be observed regarding the details and progress of Government work. Wednesday and Thursday mornings were reserved for the reading and discussion of papers, of which we give brief extracts.

Sir Andrew Noble contributed some notes on the history of propellants. Perhaps the easiest way of showing the striking difference between the old gunpowders and some of the modern propellants is to quote two tables given by the author. As both the units of heat and the quantity of gas vary considerably, depending on the pressure under which the propellant is exploded, the author has taken the transformation approximately at the pressures at which the propellants are generally used in guns.

Older Propellants.

	Pebble	R.L.G.	F.G.	Mining powder	Spanish powder
Volumes of gas	278	274	263	360	234
Units of heat	721	726	738	517	767
Comparative energy	200,438	198,924	194 094	186,120	179,478

Modern Propellants.

	Cordite, Mark I.	Italian ballistite	M.D. cordite	Norwegian 167	Nitro-cellulose	Norwegian 165
Volumes of gas ...	875·5	810·5	913·5	899 9	934·0	909·9
Units of heat ...	1246·0	1305·0	1030·0	1005 5	924·0	935·5
Comparative energy	1,090,873	1,057,703	940,905	904,850	863,016	851,212

It will be seen from the tables that the comparative energies of the modern explosives are more than four times as great as those of the older propellants.

As regards the serious question of erosion, in the case of very large guns it is important to remember that, while the surface of the bore subject to the more violent erosion increases approximately as the calibre or a little more, the charge of the propellant required to give to similar projectiles the same maximum velocity increases as the cube of the calibre. Consequently, unless special arrangements as to the projectile are made, or other means adopted, the life of the largest guns before re-lining must be short when compared with that of smaller guns. Attention should be given to the best method of reducing erosion when very large charges are used, either by lowering the temperature of explosion or possibly by introducing some cooling agent with the charge.

The author has tested the capacity for erosion of several explosives, and has found these to vary considerably, but all give similar results with varied charges. Thus the erosion due to one three-quarter charge was less than that of a full charge, but two three-quarter charges gave more erosion than one full charge. Two half charges gave less, but three half charges gave more, erosion than one full charge. These experiments controvert the statement which has been made frequently that the erosion due to four three-quarter charges, as also that due to sixteen half charges, are equivalent to the erosion due to one full charge.

A paper on the trials and performances of the S.S. *Otaki*, by Engineer-Commander W. McK. Wisnom, R.N., is of interest in view of this vessel being the first merchant vessel fitted with a combination of reciprocating and turbine machinery. The *Otaki* was built by Messrs. Denny, of Dumbarton, and delivered in November, 1908. She has since completed a voyage to New Zealand and back, and is virtually a sister ship to the twin-screw vessels *Orari* and *Opawa*, fitted with reciprocating engines and constructed by the same builders. All three vessels belong to the New Zealand Shipping Company.

The only important differences in the vessels consist in an increase in length of the *Otaki* of 4 feet 6 inches to make up for the loss in cargo capacity due to three shaft tunnels instead of two, and also the modified design of the stern and stern post in the same ship. The boiler installations in the three vessels are identical. The engines of the *Otaki* consist of two sets of ordinary triple-expansion reciprocating engines driving wing propellers, and a low-pressure turbine driving a central propeller. In ordinary ahead working the reciprocating engines exhaust into the turbine, and change valves are fitted so that the reciprocating engines can also exhaust direct to the condensers.

At the trials on the measured mile at Skelmorlie the *Orari* attained a mean speed of 14·6 knots; the *Otaki*, under the same conditions, attained a mean speed of more than 15 knots for a total water consumption per hour of 6 per cent. less than that of the *Orari*. The total water consumption per hour in the *Otaki* at 14·6 knots was 17 per cent. less than in the *Orari* at the same speed.

On the run from the Clyde to Liverpool, with the vessel partly loaded, on November 21 and 22, 1908, at about half power, the coal consumption was about 1·387 lb. per horse-power per hour for all purposes. Scotch coal was used, having a heating value of about 7500 centigrade units.

As regards the performance of the *Otaki* on service, the coal consumption on the voyage from Liverpool to Teneriffe was 11 per cent. less than the mean for the sister vessels *Orari* and *Opawa* under similar conditions and at practically the same speed. For the round voyage, at the same speed, the coal consumption of the *Otaki* is about 8 per cent. less than that of her sister ships. The engines of the *Otaki* made a non-stop run from Teneriffe to New Zealand, a distance of 11,669 miles as logged, which is probably the longest continuous run yet made by a marine turbine. The turbine worked perfectly satisfactorily throughout the whole round voyage.

The New Zealand Shipping Company is to be congratulated in allowing this experiment to be made, and also for its courtesy in rendering available the very full information contained in the paper regarding the performances of their vessels.

PAPERS ON REPTILES AND FISHES.

A NEW species of leathery, or leather-back, turtle from the Miocene of Maryland is described by Mr. W. Palmer in No. 1669 of the Proceedings of the U.S. National Museum under the name of *Psephophorus calvertensis*, this being the first representative of the genus, which was previously known from the Tertiaries of Europe and Egypt, hitherto recorded from American deposits. It is, however, pointed out that certain dermal armour from the Zeuglodont Limestone of North America, figured by Müller in his work on Zeuglodon, probably belongs to the same genus.

In No. 1681 of the same publication Dr. L. Stejneger gives the name *Mesopeltis longifrenis* to a snake from

Panama, which appears to have been previously undescribed.

The first part of the second volume of the Memoirs of the Indian Museum is devoted to the initial portion of a report, by Dr. N. Annandale, on the fishes taken by the Bengal fisheries steamer *Golden Crown*; this section, which is illustrated with five plates, dealing with the skates, rays, and sawfishes. In the group of sting-rays and butterfly-rays, new species of the genera Trygon and Urogymnus are described and named, while in the torpedo-rays, in addition to a new species of Narcine, Dr. Annandale proposes the unclassical term "Bengalichthys" for a ray distinguished from Astrape by its thickened and fleshy disc, rudimentary pectoral fins, and degenerate eyes.

A second new genus of rays, Dactylobatus, has recently been proposed by Messrs. B. A. Bean and A. C. Weed in No. 1682 of the Proceedings of the U.S. National Museum for a species of which two examples were taken off South Carolina nearly a quarter of a century ago. The generic name refers to the presence of a finger-like process jutting from the middle of each pectoral fin, which, together with the subcircular form of the disc, distinguishes this handsomely spotted species from the typical rays of the genus Raia.

In No. 1677 of the publication last quoted Messrs. D. S. Jordan and J. O. Snyder describe, under the name of *Coregonus oregonius*, a new "white-fish" from the McKenzie River, Oregon, where it is locally known as the "chisel-mouth Jack." It is an active, predaceous fish about 18 inches in length, which takes the fly readily.

To the June number of the *Zoologist* Mr. R. Elmhirst, superintendent of the Marine Biological Station at Millport, communicates a note on whelks as cod-food. Cod, it is well known, feed chiefly on crustaceans, but two cases are on record where large numbers of whelks were taken from the stomachs of these fishes. Now, although these molluscs, generally with the operculums cut off, are frequently used as bait in cod-fishing, the number of whelks with their operculums in the two instances mentioned indicates that these had not been taken on lines, but devoured in the course of natural feeding. The author is of opinion that cod seize whelks when the foot is protruded, and swallow this part alone, rejecting the shell and its contents by means of a vigorous shake.

In the same issue Mr. L. E. Adams gives some additional notes on the flying-fish problem, in the course of which it is suggested that the discrepancy between the accounts of different observers with regard to the occurrence of wing-vibration may be due to the "personal equation" in the matter of vision-power.

PRIMITIVE DIPROTODONTS.

AT last, it seems, the true position of Plagiaulax, of the Dorsetshire Purbeck, described by Hugh Falconer in 1857, has been more or less definitely determined, and this by means of its early Tertiary American relative Ptilodus, of which remains, in a much more satisfactory condition than any hitherto known, have recently been discovered in Montana. These are described by Mr. J. W. Gidley in No. 1689 (vol. xxxvi., pp. 611–26) of the U.S. National Museum Proceedings under the name of *P. gracilis*. Of late years Plagiaulax and Ptilodus, together with a number of more or less nearly allied types, collectively forming the Multituberculata or Allotheria, have been tentatively associated with the Metatheria on account of a presumed resemblance of their cheek-teeth to those of the platypus. A study of the skull, pelvis, and limb-bones of the American genus has, however, convinced Mr. Gidley that this is wrong, and that the Plagiaulacidæ (together with the other Multituberculata) are really marsupials. The unequal development of the fore and hind limbs, the characters of the incisors, the form of the palate, and the position of the cheek-teeth indicate, in his opinion, a close, although not ancestral, relationship with the diprotodont marsupials.

This is practically a confirmation of the original view of Falconer, who regarded Plagiaulax as related to Hypsiprymnodon (Potorus). Cope (who was followed by Mr. Lydekker on p. 195 of the fifth volume of the "Catalogue of Fossil Mammalia in the British Museum") endorsed, in a somewhat modified manner, this opinion, regarding the Multituberculata as primitive diprotodonts presenting some very specialised features. In the course of his investigation Mr. Gidley has been led to conclude that Bolodon of the English Purbeck is inseparable from Plagiaulax, while the American Chirox is identical with Ptilodus.

The dental formula of Ptilodus is $i.\frac{1}{1}$, $c.\frac{1}{0}$, $p.\frac{4}{2}$, $m.\frac{2}{2}$ The lower jaw is attached obliquely to the skull in such a manner that its condyle is raised above the line of the cheek-teeth (thereby doing away with an objection raised by Owen against the herbivorous nature of Plagiaulax), and the greater portion of the large cutting lower premolar does not, in consequence, bite against the upper cheek-teeth, which extend considerably in advance of the same. Mr. Gidley's views, especially if the Triassic Microlestes (a name which it has recently been proposed to replace by Thomasia) belong to the same group as Plagiaulax, will considerably modify opinion with regard to the origin and radiation of the diprotodonts.

PROBLEMS OF AVIATION.

THE interim report of the Advisory Committee for Aëronautics, which, in his recent speech in the House of Commons, Mr. Haldane promised shortly, has now been published (Cd. 4711). It will be remembered that the duty of the committee is to advise on questions submitted to it by the Government departments to which the work of constructing and experimenting with aëroplanes and dirigibles has been entrusted. This work necessitates, in some cases, experimental research at the National Physical Laboratory. The committee is intended generally to advance the applications of the science of aëronautics by such means as may seem best. It has arranged already for a series of reports as to the present state of knowledge on the questions which will have to be considered. These reports are to include papers on the following subjects:—Mr. A. Mallock, on general questions to be studied; Dr. T. E. Stanton, on recent researches on the forces on plane surfaces in a uniform current of air; Sir G. Greenhill, on stability and on the screw propeller; Dr. W. N. Shaw, on wind structure, dealing especially with the phenomena of gusts, and on the variation of wind velocity with height; Mr. F. W. Lanchester, on petrol motors for aëronautical purposes; Dr. W. Rosenhain, on light alloys; and the secretary (Mr. F. J. Selby), on existing knowledge on the subject of the accumulation of electrostatic charges on balloons, and the precautions to be adopted to avoid the dangers arising therefrom.

To make it possible to decide what work should be undertaken first at the National Physical Laboratory, the committee drew up a list of desirable experiments as follows:—

I.—*General Questions in Aërodynamics.*

(1) Determination of the vertical and horizontal components of the force on inclined planes in a horizontal current of air, especially for small angles of inclination to the current.

(2) Determination of surface friction on plates exposed to a current of air.

(3) Centre of pressure for inclined planes.

(4) Distribution of pressure on inclined planes.

(5) Pressure components, distribution of pressure and centre of pressure for curved surfaces of various forms.

(6) Resistance to motion of bodies of different shapes; long and short cylinders, &c.

(7) Combinations of planes; effect on pressure components of various arrangements of two or more planes.

II.—*Questions Especially Relating to Aëroplanes.*

(8) Resistance components for aëroplane models.

(9) Resistance of struts and connections.

(10) Resistance of different stabilising planes, both horizontal and vertical.

(11) Problems connected with stability:—(i.) mathematical investigation of stability; (ii.) the stability of aëro curves of different section and of different plan (Turnbull's experiments); (iii.) effect of stabilising planes and investiga-

tion of questions as to their size and position; (iv.) effect of rudder action; (v.) effect of gusts of wind; (vi.) investigations as to stability of models for different dispositions of weight, &c.

(12) Materials for aëroplane construction.

(13) Consideration of different forms of aëroplane, monoplane, biplane, &c.

(14) Other forms of heavier-than-air machines, helicopters, &c.

III.—*Propeller Experiments.*

(15) Efficiency and the effect on the efficiency of variations in blade area, pitch, and slip.

(16) Positions relative to the machine.

IV.—*Motors.*

(17) Efficiency.

(18) Trustworthiness and steadiness.

(19) Materials of construction.

(20) Design.

V.—*Questions Especially Relating to Airships.*

(21) Materials of construction, strength, &c.:—(i.) alloys, wood, bamboo, &c.; (ii.) balloon fabrics; (iii.) wires, cords.

(22) Production of hydrogen.

(23) Gas-tightness of fabrics.

(24) Detection of leakage.

(25) Air resistance to ships of different form; experiments on models:—(i.) effect of shape of ends; (ii.) effect of length; (iii.) variation with speed; (iv.) distribution of pressure as affecting stability, strength in construction, position of propellers, fins, &c.; (v.) total resistance of models rigged to represent different balloons.

(26) Questions as to stability of airships in different positions.

(27) Stabilising and steering appliances, fins, rudders, &c.; form and position.

(28) General design.

(29) Navigation of airships. Mooring, &c.

(30) Efficiency and position of propellers for airships.

(31) Motors for airship work.

VI.—*Meteorology.*

(32) General information relating to variations of wind velocity and phenomena connected with gusts of wind.

(33) Relative variation in speed and direction of the wind at different heights above the earth's surface.

(34) Vertical movements in the air.

(35) Rotary movements in the air.

(36) Electrical phenomena.

(37) Formation of clouds, snow, hail, &c.

Eventually the committee decided that the following researches should be undertaken at once:—

(*a*) Experiments on air resistance and on air friction as outlined in (1) to (7) above, and including experiments on models of airships and aëroplanes, resistances of wires and connecting stays, &c.

(*b*) Motor tests.

(*c*) Propeller experiments.

(*d*) Tests for gas-tightness of materials suitable for dirigibles.

(*e*) Experiments on the behaviour of different materials with reference to the accumulation of electrostatic charge, and generally as to means of protecting airships from the effect of electrical discharges.

The interim report points out that additions to the existing buildings at the National Physical Laboratory have been found necessary to provide space for part of the experimental work, while a special building is also being provided for the whirling table referred to below. The equipment which is now being installed comprises the following:—

(i.) A wind channel 4 feet square and about 20 feet long, with a fan giving a draught of 40 feet per second, special arrangements being made to obtain a uniform flow. This will be employed for the determination of the air-pressure components on plane and curved surfaces, for the resistance of models of airships and aëroplanes, and for observations on the centre of pressure, frictional resistance, stability, &c.

(ii.) A whirling table of about 70 feet diameter. For this a special building is being erected; the table itself is under construction in the laboratory. It will be employed for a repetition of Dines's and Langley's experiments, as well as for propeller tests, which are urgently called for.

(iii.) Two wind towers for experiments in the open. These will enable some of the air-channel experiments to be repeated on a larger scale in the natural wind, and will, it is hoped, afford valuable information as to the varying conditions which obtain in practice.

(iv.) Apparatus for efficiency tests on high-speed motors up to 50 horse-power.

In addition, certain machine tools, &c., are being provided for workshop use.

The evidences provided by the interim report of the activity of the committee are gratifying in view of the activity being displayed in other countries in practical aviation. We notice that, on August 7, M. Sommer added another triumph to France in this province of aëronautics. M. Sommer beat the world's record for length of time in the air by flying at Châlons for 2h. 27m. 15s. The record was previously that of Mr. Wilbur Wright, who, on December 31 last, remained in the air at Le Mans for 2h. 20m. 23s.

THE MAGNETIC OBSERVATORIES OF THE U.S. COAST AND GEODETIC SURVEY.[1]

A LIBERAL addition made in 1899 to the funds available for magnetic work by the U.S. Coast and Geodetic Survey enabled a great extension to be made in the direction of magnetic observatories. Previously to that date the only magnetographs run by the Survey were an old Brooke instrument, first set up in 1860 at Key West, and an Adie instrument installed in 1882 at Los Angeles, and subsequently in use elsewhere. These two instruments are still in use, the Brooke in modified form at Vieques, the Adie at Cheltenham (fourteen miles south-east of Washington, D.C.), the central station of the Survey. Cheltenham also possesses a new set of Eschenhagen instruments, and similar instruments were also obtained for Baldwin, Sitka, and Honolulu. The curves from the five observatories are tabulated at a central office, and the volumes containing the earliest years' results have recently appeared. The material is dealt with after a uniform plan. Each volume discusses the buildings and instruments, and enumerates the base-line and scale-value changes. It is interesting to learn that the experience at Cheltenham "is decidedly favourable to the old Adie type, on account of its greater stability and the less frequent adjustments required." Another instrumental point of interest relates to the temperature coefficients of the horizontal force instruments. That of the Adie instrument appears exceptionally large for an instrument of its type, but it is less than half the average value for the four Eschenhagen instruments, and only one of the latter is worse than the Brooke in this respect. When a rise of 1° C. in temperature produces the same effect in the trace as a fall of 17 γ in the force—as seems to be the case at Honolulu—satisfactory elimination of temperature effects must be troublesome. If the cause lies in the quartz-fibre suspension, a substitute should be sought for.

The greater part of each volume is devoted to the hourly readings from the curves. Declination and horizontal intensity results are given for all the stations, but vertical intensity results only for Cheltenham. Mean hourly values are deduced for each month, first from all the days, and, secondly, from the ten least disturbed days. The latter form the basis of the regular diurnal inequalities given for each month. Inequalities are calculated for the northerly and easterly components as well as for declination and horizontal intensity, and at Cheltenham for dip as well as for vertical intensity. Under the heading "Daily Range of Declination" we have tables of values

[1] Results of Observations made at the Coast and Geodetic Survey Magnetic Observatories, Cheltenham, Maryland, 1901–4 pp. 206; Baldwin, Kansas, 1901–4, pp. 138; Sitka, Alaska, 1902–4, pp. 129; near Honolulu, Hawaii, 1902–4, pp. 130; and Vieques, Porto Rico, 1903–4, pp. 70. By Daniel L. Hazard, Computer, Division of Terrestrial Magnetism. (Washington: Government Printing Office, 1909.)

of the maximum and minimum for each day, and their times of occurrence, to the nearest minute; but the actual *range* is not given explicitly. The space allowed to the date is unnecessarily large, and it would probably be found possible to add the daily range without unduly crowding the figures. This would be a welcome addition.

An interesting feature is a list of the disturbed days, classified 1 to 4 according to the intensity. The highest figure, 4, is reserved for one or two exceptional disturbances, being applied at one or two stations only to October 30–31, 1903. Copies are also given, except in the case of Baldwin, of the curves from a considerable number of the disturbed days, the same selection being made for all the stations. This is likely to prove a valuable feature. Its value, however, is somewhat lessened by the fact that the curves are shown on a considerably reduced scale. Comparisons requiring high accuracy in the time must suffer. The fact that local time is employed is also somewhat of an obstacle to inter-comparisons. The disturbed curves are all from Eschenhagen instruments, which record all the elements on one sheet. This brings before the eye all that was happening simultaneously in the several elements. This is a distinct advantage in the study of disturbances, provided the different curves can be kept distinct. Sitka, owing to its higher latitude, is exposed to larger magnetic storms than the other stations, and the clearness of a good many of the curves reproduced suffers from crossing and confusion of the declination and horizontal force traces. October 30–31, 1903, was naturally an outstanding case of this; but on that occasion there was, besides, great loss of trace, the movements being so rapid that no clear record appeared on the photographic paper. The sensitiveness of the horizontal force instrument at Sitka was reduced towards the end of 1904 to about 1 mm. $=3\gamma$, as compared to an average of about 1 mm. $=1\cdot8\gamma$ in 1902 and 1903. The sensitiveness that used to be aimed at in temperate Europe is 1 mm. $=5\gamma$, and we cannot but think that the reduction of sensitiveness in Sitka might with advantage go a good deal further than it has yet gone. Though not quite so easily effected, a reduction in the sensitiveness of the declination instrument at Sitka might also be advantageous, at least for a study of the larger features of magnetic storms. The device of two mirrors adopted in the magnetographs to avoid loss of trace is an alleviation if the movements are slow, but if, as is frequently the case, the movements are not merely large but rapid, this device may only aggravate the confusion of trace.

The volumes contain a great mass of facts, clearly printed, presented in a readily intelligible form. Having put their hand to the plough, it is to be hoped that those responsible for the work of the Coast and Geodetic Survey will not turn back until simultaneous records have been obtained for at least one sun-spot cycle at all the stations.

C. CHREE.

RECENT ADVANCES IN OUR KNOWLEDGE OF SILICON AND OF ITS RELATIONS TO ORGANISED STRUCTURES.[1]

NOT only is silicon widely diffused in nature in the many forms of its oxide, but it also constitutes between one-third and one-fourth of the original and non-sedimentary rocks—of which the solid crust of the earth largely consists—in these cases being chemically combined with oxygen and various metals, forming natural *silicates*. The subjoined table gives a necessarily very rough estimate of the relative proportions in which the chief constituents are present.

THE EARTH'S CRUST.

Approximate average Composition of non-sedimentary Rocks.

Oxygen	about	47	per cent.
Silicon	,,	28	,,
Aluminium	,,	8	,,
Iron	,,	7	,,
Calcium and magnesium ...	,,	6	,,
Alkali metals	,,	4	,,

[1] From a discourse delivered at the Royal Institution on Friday, May 28, by Prof. J. Emerson Reynolds, F.R.S.

The crust of the earth is, in fact, a vast assemblage of silicon compounds, and the products of their disintegration under the influence of water and other agents are the various forms of clay, sand, and chalk which constitute so large a portion of the earth's surface.

The solid crust of the earth is actually known to us for but a very few miles down—thirty at most—our deepest mines being mere scratchings on its surface; but, so far as known, practically all its constituents are fully oxidised, and this is probably true at much greater depths. During æons past oxygen has been absorbed as the earth cooled down, and the product is the crust on which we live.[1] It is probable that the proportion of oxygen diminishes away from the surface until it disappears almost wholly. What of the deeper depths? Are the comparatively light elements arranged more or less in the order of density? Are we to suppose that silicon and some carbon, aluminium, calcium, the elements chiefly comprising the crust, are those nearer the surface, and iron, copper, and the heavier metals nearer the centre?

Until recently we knew little more than that the earth is some 8000 miles in diameter, that its mean density is 5·6–5·7, and that its relatively thin outer skin, or crust, has approximately the composition already described. By a very skilful use of earthquake observations Mr. R. D. Oldham has, however, lately[2] given us something like a glimpse within the ball, and concludes from his observations that about five-sixths of the earth's radius includes fairly *homogeneous* material, and that the remaining sixth at the centre consists of substances of much higher density. Assuming this to be even roughly true, we conclude that silicon forms probably as great a proportion of this large mass of the earth—whether in the free state or in the forms of silicides—as it does of the crust.

Having thus magnified the office of the important element of which I wish to speak to you, I shall pass to my next point, which is how the element can be separated from quartz or other forms of the oxide, for it is never met with unless combined with oxygen in any of the rocks known to us.

I have already mentioned that quartz is a dioxide of the element—in fact it is the only known oxide—hence if we remove this oxygen we should obtain free silicon. This is not a very difficult matter, as it is only necessary to heat a mixture of finely powdered quartz with just the right proportion of metallic magnesium. The metal combines with the oxygen of the quartz, and forms therewith an oxide of magnesium, while silicon remains. If the material be heated in a glass vessel the moment of actual reduction is marked by a bright glow, which proceeds throughout the mass. When the product is thrown into diluted acid the magnesium oxide is dissolved, and nearly pure silicon is obtained as a soft, dark-brown powder, which is not soluble in the acid. This is not crystalline, but if it be heated in an electric furnace it fuses, and on cooling forms the dark crystalline substance on the table, which, as you see, resembles pretty closely the graphitic form of carbon, though its density is rather greater (2·6, graphite being 2·3).

Silicon Analogues of Carbon Compounds.

The points of physical resemblance between silicon and carbon are of small importance compared with the much deeper-rooted resemblance in chemical habits which exists between the two elements. This is expressed in the periodic table of the elements as in the following diagram:—

$$\begin{array}{ccccccc} Na=23, & Mg=24, & Al=27, & \mathbf{Si}=28, & P=31, & S=32, & Cl=35\cdot5 \\ Li=7, & Be=9, & B=11, & \mathbf{C}=12, & N=14, & O=16, & F=19 \end{array}$$

where silicon is represented as the middle term of a period of seven elements of increasing atomic weights, just as carbon is the middle term of the previous period. The fact is, these two electro-negative or non-metallic elements play leading parts in the great drama of nature, silicon

[1] An interesting calculation has been made by Mr. Gerald Stoney, from which it appears that a stratum only 9 feet in depth of the surface of the earth contains as much oxygen as the whole of our present atmosphere. (See *Phil. Mag.*, 1800, p. 566.)

[2] R. D. Oldham, "Constitution of the Interior of the Earth." (Quarterly Journal of the Geological Society, vol. lxii., 1906, pp. 456–75.)

dominating that which has to do with dead matter, while carbon is the great organ-building and maintaining element of all living things. While each carries on the work to which it is best suited under existing terrestrial conditions, they both go about it in somewhat similar ways, and each one shows a tendency to overstep the border line and perform the other's part. This tendency is for various reasons much more marked in the case of carbon, but I hope to show you presently that silicon is by no means out of touch with living things, and, further, that it exhibits capacities which render it a potential element of life under other conditions of our planet, but more especially at a much higher level of temperature.

I do not propose to dwell in much detail on the remarkable parallelism of some silicon and carbon compounds, but must refer shortly to a few of them, and the oxides naturally come first.

The lecturer then described silicon oxide, chloride, bromide, chloroform, &c., with the analogous carbon compounds, and continued:—Both silicon and carbon form gaseous compounds with hydrogen of similar composition:—

$$CH_4 \text{ and } SiH_4.$$

Neither of these hydrides can be obtained by direct union of the respective elements, though they are easily obtained by indirect means, with the details of which I need not trouble you. Both are colourless gases, as you see. The carbon hydride, or marsh gas, is combustible, but requires to have its temperature raised considerably before it takes fire in air, and its flame is only slightly luminous. It produces on complete oxidation water vapour and carbon dioxide gas. The analogous silicon hydride takes fire much more easily in air, and when not quite pure is even spontaneously combustible under ordinary conditions, and it burns, producing water vapour and solid silicon dioxide.

"*Silico-organic Chemistry.*"

Now, just as marsh gas may be regarded as the starting point of that great branch of science which is usually spoken of as organic chemistry, so the analogous hydride of silicon is the primary compound from which many substances, which are often termed silico-organic compounds, can be derived by various means, and these were discovered in the course of the classical researches of Friedel, Crafts, Ladenburg, and others.

I wish to avoid using many chemical formulæ, which probably would convey but little meaning to some of those whom I address; it will suffice merely to indicate the *lines* on which investigations have proceeded in this direction.

In the older work of Friedel, Crafts, and Ladenburg, they produced complex substances by the substitution of various radicles (always carbon groups), for one atom of hydrogen in SiH_4, and ultimately replaced another atom of hydrogen by the OH or hydroxyl group. The substances so formed were silicon *alcohols*, which may be represented in the following manner, A, B, and C being used to indicate the different complex replacing radicles:—

$$\mathrm{Si}\begin{cases}\mathrm{H}\\ \mathrm{H}\\ \mathrm{H}\\ \mathrm{H}\end{cases} \qquad \mathrm{Si}\begin{cases}\mathrm{A}\\ \mathrm{H}\\ \mathrm{H}\\ \mathrm{OH}\end{cases} \qquad \mathrm{Si}\begin{cases}\mathrm{B}\\ \mathrm{H}\\ \mathrm{H}\\ \mathrm{OH}\end{cases} \qquad \mathrm{Si}\begin{cases}\mathrm{C}\\ \mathrm{H}\\ \mathrm{H}\\ \mathrm{OH}\end{cases}$$

In this way silicon alcohols were built up which proved to be analogous to well-known carbon alcohols, and afforded analogous acids, &c., on oxidation. These discoveries laid the foundations of a silico-organic chemistry, and have been further extended in later years. For example, it has been found possible to pursue the analogy with known carbon compounds in the direction of replacing all the hydrogen in silicon hydride by different radicles, and these changes, which can be effected in successive stages, may be represented in harmony with those just given:—

$$\mathrm{Si}\begin{cases}\mathrm{A}\\ \mathrm{H}\\ \mathrm{H}\\ \mathrm{OH}\end{cases} \qquad \mathrm{Si}\begin{cases}\mathrm{A}\\ \mathrm{B}\\ \mathrm{H}\\ \mathrm{OH}\end{cases} \qquad \mathrm{Si}\begin{cases}\mathrm{A}\\ \mathrm{B}\\ \mathrm{C}\\ \mathrm{OH}\end{cases}$$

The two last of these are *asymmetric*, since all four radicles are different. Consequently, they should exist in two isomeric modifications if really analogous to known carbon compounds of the same order, and each form should be capable of acting differently on polarised light.[1] Dr. F. Stanley Kipping, who has specially investigated this kind of substitution with much success, finds that the analogy between these asymmetric silicon and carbon compounds is complete in regard to optical activity as to other general characters.

Silicon Compounds including Nitrogen.

This was all good so far as it went, but some highly important information was still wanting. As you know well, the various compounds including carbon and *nitrogen* play by far the most important parts in building up organised structures under the influence of vital energy, but in the silicon series we were almost wholly ignorant of the existence of such compounds until within recent years, when I undertook definitely to investigate this branch of the subject.

All that was known at the period of which I speak was that silicon forms a white nitride of uncertain composition when strongly heated in an atmosphere of nitrogen gas, and that when silicon chloride is brought in contact with ammonia and similar substances violent action occurs, but the nature of the products formed was not known owing to special practical difficulties in separating them.

The first step taken was to examine the action of silicon halides (*i.e.* chloride, bromide, &c.) on substances free from oxygen, but rich in nitrogen. The earliest of these worked with were thiocarbamides, but in all these cases the silicon halide merely united with the nitrogen compound as a whole, in some instances producing very curious substances, of which the one with allyl-thiocarbamide,

$$(C_3H_5.H_3N_2CS)_8SiBr_4,$$

is a good example. This is a liquid which flows so slowly at ordinary temperature that it requires nearly a month in order to fall from the top of its containing tube and find its level at the bottom. Several similar substances have been obtained and examined, and their products of decomposition studied, but they do not belong to the class of which I was really in search.

It would weary you to give the details of scientific prospecting which one has to go through in order to attain definite results in a new line of work like this; suffice it to say that success attended the efforts at last, and a finely crystallised and perfectly defined compound was obtained in which silicon is wholly in direct chemical combination with nitrogen, and a specimen of that substance I now show you. Its composition is represented by the expression

$$Si(NHPh)_4,$$

where Ph stands for the phenyl group, and its name is silicophenylamide.

This substance when heated undergoes some important changes, which resemble rather closely similar changes that can be effected in analogous compounds of carbon with nitrogen. Thus it first affords a *guanidine*,

$$\mathrm{Si}\begin{cases}\mathrm{NHPh}\\ \mathrm{=NPh}\\ \mathrm{NHPh}\end{cases},$$

analogous to the well-known carbon guanidine, and further a di-imide, $Si(NPh)_2$, which only needs the addition of a molecule of water to convert it into a silicon *urea*, $SiO(NHPh)_2$. Many other substances have been produced similar to silicophenylamide, and they afford analogous products to these just mentioned; but these have been fully described elsewhere, and need not be dealt with here.

Silicon in Relation to Organised Structures.

The general results of these researches are that we now know a considerable number of silicon compounds including nitrogen, which resemble those of carbon with nitrogen, both in composition and in the general nature

[1] These changes are represented above as having been effected through the silicon alcohols in order to avoid complicating the general statement; other compounds have, in fact, been found more convenient for the purpose.

of the changes in which they can take part. Some of these carbon analogues are closely related to those which are concerned in building up organised structures of plants and animals.

All theories of life assume that its phenomena are inseparably associated with certain complex combinations of the elements carbon, nitrogen, hydrogen, and oxygen, with the occasional aid of sulphur and phosphorus. These are the elements of that protoplasm which is the physical basis of life, and by their interplay they form the unstable and complicated groupings of which that remarkable material is composed. All the phenomena we call vital are associated with the change of some protoplasm, and the oxidation of carbon and hydrogen; but it is quite open to question whether the connection of life with the elements first specified is inevitable. We can conceive the existence of similar groupings of other analogous elements forming other protoplasms capable of existing within much greater ranges of temperature than any plants or animals now known to us have to withstand. For example, we can imagine a high-temperature protoplasm in which silicon takes the place of carbon, sulphur of oxygen, and phosphorus of nitrogen, either wholly or in part. In fact, protoplasm, so far as we know it in purest form,

FIG. 1.

always contains some sulphur, and often a little phosphorus, representing a very partial substitution of the kind in question.

In view of our newer knowledge there is, therefore, nothing very far-fetched in supposing that under suitable conditions a plant or an animal organism may be able to construct from silicon compounds, ultimately derived from the soil, something akin to silicon protoplasm for use in its structures.

You will now ask me whether there is any evidence that anything of this kind actually occurs in nature. I think there is, although I admit that the evidence is not very varied so far as we yet know.

First, as to the *vegetable* kingdom. It is well known that many plants take up silicon in some form from the soil, and use it in ways which my botanical friends tell me they do not at present understand. Silicon is present in the straw of cereals, such as wheat, oats, &c., and in most of the Gramineæ. It was supposed that the stiffness of the straw was secured by a siliceous varnish, but this view is not now in favour, as it has been found possible to remove silica from the straw by careful treatment without diminishing its rigidity. It is also present in the leaves of some palms, for my friend, Dr. Hugo Müller, in the course of his extensive researches on the sugars present in certain palm leaves, has been much troubled by the presence in the extract from the leaves of siliceous compounds of unknown nature. Again, a well-known substance called "tabasheer," consisting largely of hydrated silica, including some organic matter, is obtained at the nodes of some bamboos. What purpose silicon serves in these plants, which seem to have special need for it, we do not know, but the subject appears to be well worth closer examination than it has yet received at the hands of plant physiologists.

I have on the table some good specimens of tabasheer, and can show some portions on the screen which have been rendered nearly transparent by soaking in benzene, and under these conditions exhibit traces of structure.

Next, as to the *animal* kingdom. The most satisfactory evidence that we can at present offer as to the organ-building capacity of silicon comes, curiously enough, from some of the simpler organisms of the animal kingdom, but the only group the short remaining time at my disposal permits me to notice is that of the *sponges*.

You know that these curious forms of undoubted animal life live in sea-water, and are usually anchored to rocks. The sea contains a very minute proportion of silica in solution, and the sponge has the power of appropriating very considerable quantities in the course of its life and as a part of its normal food supply. What does it do with this silica? It appears to use it in cell production, and from the cell evolves the beautiful and minute siliceous spicules which are so abundant throughout the structure of many of the sponges.

FIG. 2.

I have here some photographs of these spicules which I have had taken, and shall throw them on the screen. Two of the best of them have been made from microscopic specimens kindly lent to me by Prof. Dendy, who has made a special study of these spicules and of their modes of growth. One of these slides is reproduced in the engraving (Fig. 1).

These structures do not represent mere incrustations, but rather definite growths from the cell protoplasm, and are themselves in the nature of cells of characteristic forms. Prof. Dendy informs me that these spicules in certain cases become surrounded by a horny substance and seem to die, as if by cutting off the supply of energy as well as growing material.

In some of the larger sponges, as in the beautiful *Euplectella aspergillum*, or "Venus' flower basket," represented in Fig. 2, the siliceous material constitutes the greater part of the sponge, as the soft portion resembles a somewhat gelatinous coating from which the exquisite siliceous structure is developed.

To sum up, then, I have shown that silicon can easily take the place of carbon in many nitrogen compounds, as well as in others not including nitrogen. It therefore seems to me that we hazard no very violent hypothesis in supposing that the silicon which enters the sponge in its food, probably as an alkaline silicate, is in the marvellous animal laboratory made to take the place of a portion of the carbon of the protoplasm from which the spicules are ultimately developed.

The hypothesis is at any rate suggestive, and I hope enough has been said to commend it to your consideration, for there seems to be no doubt that silicon is capable of playing a larger part as an "organic element" than we hitherto had reason to suppose.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

The appointments to chairs of chemistry in the Technical High School at Breslau were announced by mistake in last week's Nature (p. 180) as referring to the Technical High School at Munich.

The governors of the South-Western Polytechnic Institute, Chelsea, have appointed Mr. W. Campbell Houston to be head of the department of mechanical engineering in succession to Mr. W. W. F. Pullen, appointed to the inspectorate of the Board of Education. For the past six years Mr. Houston has been the assistant professor of engineering in the Heriot Watt College, previous to which he was chief assistant to Prof. Watkinson at the Glasgow and West of Scotland Technical College.

The Board of Education has issued a memorandum directing attention to changes in certain syllabuses of examination for 1910 affecting students engaged in engineering and building trades. The changes affect the syllabuses in practical plane and solid geometry, practical mathematics, and applied mechanics, and aim at bringing the distribution of the subject-matter of instruction and of examination more fully into line with the prevailing requirements in these subjects in relation to the building and engineering trades.

Attention has been directed recently in these columns to the serious efforts being made in several directions to secure the efficient education of children in elementary schools during the years of ordinary school life, and to provide for their further instruction in continuation schools after they have begun to work for their living. In our issue for July 8 (vol. lxxxi., p. 50) the question of child employment and evening continuation schools was considered, and in Nature of August 5 (vol. lxxxi., p. 172) the recently published report of the Consultative Committee of the Board of Education on attendance, compulsory or otherwise, at continuation schools was reviewed. The most recent evidence of this desire to improve our system of elementary education is the Parliamentary paper (Cd. 4791) containing the report of the Inter-Departmental Committee on Partial Exemption from School Attendance. The committee was appointed (i.) To inquire into and report upon the extent to which existing enactments relating to partial exemption from compulsory school attendance are taken advantage of in urban and rural areas in England and Wales; the occupations in which children so exempted are employed, and the effect of such occupation upon the general education and industrial training of the children. (ii.) To consider the practical effects of legislation providing for the abolition or restriction of half-time employment upon industries and wage-earning, and upon educational organisation and expenditure. (iii.) To report whether, and to what extent, in view of these considerations, it is desirable to amend the law by raising the age at which partial exemption from attendance at public elementary schools is to be permitted, or by raising the *minimum* age for total exemption concurrently with affording facilities for partial exemption. The committee examined fifty-two witnesses, including representatives of chambers of commerce and agriculture, of associations of employers and of trades unions, officials of the Home Office, of the Board of Education, and of local authorities, members of the Consultative Committee of the Board of Education, certifying factory surgeons, teachers, farmers, and others whose opinions seemed likely to be of value. After an exhaustive inquiry the committee recommends:—(*a*) that all partial exemption be abolished from a date not earlier than January 1, 1911; (*b*) that, at the same time, total exemption under the age of thirteen be abolished; (*c*) that the attendance certificate for total exemption be abolished; (*d*) that total exemption at the age of thirteen be granted only for the purposes of beneficial or necessary employment; (*e*) that the ordinary condition for total exemption be due attendance at a continuation class, but (*f*) that, subject to the approval of the Board of Education, an authority may adopt as an alternative condition the passing of a standard not lower than Standard VI.; (*g*) that nothing in any legislation shall affect any children who, at the date on which it comes into operation, are partially or totally exempt from attendance at school under the by-laws previously in force; (*h*) that in the application of the Factory Act to England and Wales the provisions of sections 68–72 shall cease to be operative.

SOCIETIES AND ACADEMIES.

Paris.

Academy of Sciences, July 26.—M. Émile Picard in the chair.—Methods for collecting and preserving the gases from fumaroles, springs, or volcanic soil: Armand **Gautier**. The methods suggested are described in detail, and diagrams are given. The gases are transferred, after drying, to a vacuous tube, the latter being sealed by fusion on the spot. The amount of steam accompanying the gas is also determined.—The law of fixed dissociation pressures: Henry **Le Chatelier**. A discussion of the effect of porosity on the application of the phase rule to dissociation phenomena.—The transcendental singularities of inverse functions of integral functions: Pierre **Boutroux**.—Uniform analytical functions with discontinuous singularities: Arnaud **Denjoy**.—Study of the thrust of the air on a surface: A. **Rateau**. The apparatus used allows of the simultaneous measurement of the vertical and horizontal components of the thrust separately. Curves are given showing the experimental results for certain plane and curved surfaces.—The ultra-violet band spectrum of phosphorus: A. **de Gramont** and C. **de Watteville**. The results are given in tabular form, showing a comparison of the flame and spark spectra.—The ratio between uranium and radium in radio-active minerals: Mlle. **Gleditsch**. The results published by the author in an earlier paper not being in accord with those of other workers on the same subject, the analytical method employed has been subjected to a critical examination, but without causing any appreciable change in the figures obtained. There does not seem to be any constant ratio between uranium and radium in different radio-active minerals. This conclusion necessitates a modification in the views held as to the mechanism of the transformation of uranium into radium.—The action of gravity on the induced activity of radium: Louis **Wertenstein**.—A method of registering the length of the path of the α rays, and on a peculiarity of this path: B. **Szilard**. A layer of the radio-active material was placed horizontally, and a glass plate carrying a layer of zinc sulphide, and backed with a sensitised plate, is fixed at an angle with this layer. The range of the α rays found in this way was always about 2 mm. less than that given by the ionisation method.—The decomposition of water by the ultra-violet rays: Miroslaw **Kernbaum**. The ultra-violet rays decompose water in a similar manner to the β rays of radium, hydrogen and hydrogen peroxide being produced.—The disengagement of the radium emanation: H. **Herchfinkel**. The hydrates of iron and uranium carry down nearly the whole of a radium salt in solution, and the precipitates, when dry, give off a large proportion of the emanation.—Ionisation by chemical methods: Léon **Bloch**. A criticism of notes recently published by Reboul and by Broglie and Brizard.—The ionisation of paraffin at different temperatures: Tcheslas **Bidlobjeski**.—The conditions of stability of the Poulsen arc: C. **Tissot**.—A new method of analysis by curves of miscibility; its application to oils used for food: E. **Louïse**. Various proportions of the oil under examination are mixed with pure acetone, and the temperature of complete miscibility noted. The percentage of oil plotted against the temperature of miscibility gives a curve characteristic for the oil.—The allotropic states of phosphorus: Pierre **Jolibois**. Ordinary red phosphorus is an unstable condition. By heating alone to 360° C., or in presence of a catalyst above 250° C., a new stable modification of phosphorus is obtained, termed by the author pyromorphic phosphorus, characterised by its density, 2·37. Red phosphorus melts at 724° C.—The hydrates of thorium chloride and bromide: Ed. **Chauvenet**.—Some double sulphates: M. **Barre**.—Some derivatives of 1:2:4-butanetriol: M. **Pariselle**. The derivatives described include oxyhydrofurfurane, bromobutylene oxide, and 1:4-dibromo-2-butanol.—The formation of gold deposits: L. **de Launay**.

—Biological observations of the Tonkin india-rubber tree: M. **Eberhardt** and M. **Dubard**.—A new parasitic entophyte of one of the Coleoptera: L. **Léger** and E. **Hesse**. —The genital stolon of the compound Ascidians; its evolution in the course of partial regression: Antoine **Pizon**. —Study of the toxic powers of the strophantines according to the method of administration: J. **Pédebidou**.—The paralysing influence exercised by certain acids on alcoholic fermentation: Mlle. M. **Rozenband**. The results, given in tabular form, show the concentration up to which no prejudicial effect is produced, and the concentration at which fermentation is completely stopped. —The action of the ultra-violet rays upon the acetic fermentation of wine: Victor **Henri** and Joseph **Schnitzler**. The ultra-violet rays from a quartz mercury vapour lamp completely arrested the acetic fermentation after thirty minutes' exposure, a smaller exposure causing the action to slow down.—The hydrolysis by diastase of the α- and β-methyl-*d*-glucosides: H. **Bierry**.—Researches on the electric charge of textile substances plunged into water or into electrolytic solutions: J. Larguier **des Bancels**.—The variation of some diastases during the metamorphosis in *Limnophilus flavicornis*: Xavier **Roques**.—The tectonic relations of the internal pre-Alps with the Helvetic strata of the Morcles and the Diablerets: Maurice **Lugeon**.—The neogenic continental formations in the Hautes-Plaines, Algeria: A. **Joly**.—An oscillation of the sea noted on June 15, 1909, in the port of Marseilles: Louis **Fabry**. This oscillation had an amplitude of 40 cm. to 80 cm., and appears to be connected with a sudden rise of 2 mm. in the height of the barometer.—Some earthquake shocks felt at Yunnan: Ch. **Dupont**.

August 2.—M. Bouquet de la Grye in the chair.—Is the virulence of the trypanosomes of mammals modified after passage through cold-blooded vertebrates? A. **Laveran** and A. **Pettit**. When blood rich in *T. lewisi* or *T. evansi* is injected into the peritoneal cavity of a snake (*Tropidonotus natrix*) the trypanosomes pass rapidly into the snake's blood, and live there several days, although their number rapidly diminishes. Some days after the disappearance of the organisms from the blood the latter remains infectious. No definite proof of the modification of the virulence of the trypanosome by passage through the snake has been obtained.—The figure and mass of the planet Uranus, deduced from the motions of the two interior satellites: Œsten **Bergstrand**. The calculations are based exclusively on observations made at the Lick Observatory. The flattening of Uranus is probably of the order of one-twentieth, corresponding to a period of rotation of thirteen hours. The mean density of Uranus is 0·16 that of the earth.—The elasticity of the terrestrial globe: Ch. **Lallemand**. A discussion of the measurements made at Potsdam by Dr. Hecker.—The variation of the magnetic double refraction of aromatic compounds. Surfused bodies and substances in the vitreous state: A. **Cotton** and H. **Mouton**. The variation of the magnetic double refraction of nitrobenzene and salol with temperature was found to be linear.—The magnetic properties of carbon and organic compounds: P. **Pascal**.—The latent heat of fusion and the specific heat of propionic acid: G. **Massol** and M. A. **Faucon**. Direct measurements of the latent heat of fusion gave 23·35 cal. per gram by one method and 19·07 cal. by another. Indirect methods based on the formulæ of van 't Hoff and de Forcrand gave 26·7 and 30·5 cal. respectively. The causes of this discrepancy are discussed.—Some ethylene amido-derivatives: G. **Busignies**. A description of a series of ethylene derivatives obtained by the action of the Grignard reagent upon alkyldiamidobenzophenones.—Remarks on the nuclear evolution in the Ascomycetes: A. **Guilliermond**.—The growth of Fucus: P. **Hariot**. Observations of the rate of growth.—Contribution to the study of sterilisation by the ultra-violet rays. Application to the butter industry: MM. **Dornic** and **Daire**. The water used in washing butter made from Pasteurised cream is treated with ultra-violet rays from a quartz mercury vapour lamp, and partially sterilised. A comparison of two samples of butter made from the same Pasteurised cream showed that the one washed with ordinary water was rancid after eight days, whilst the sample washed with the treated water was fresh after the lapse of a month.—The existence of carbonophosphates in milk. Their precipitation by Pasteurisation: A. **Barillé**.—The action of the pancreatic juice on glycogen, starch, and its components: Mme. Z. **Gruzewska** and M. **Bierry**.—The examination of plants for raffinose, and on its presence in two leguminous seeds, *Erythrina fusca* and *Entada scandens*: Em. **Bourquelot** and M. **Bridel**.—The slight penetration of the ultra-violet rays through liquids containing colloidal substances: J. **Courmont** and Th. **Nogier**. Owing to the opacity of solutions containing colloidal substances to the ultra-violet rays, the practical difficulties in the way of sterilising such liquids as beer or cultures of organisms are very great.—The action of ultra-violet light on the toxin of tetanus: Mlle. P. **Cernovodeanu** and M. Victor **Henri**. —The relation between phenol eliminated in the urine and epilepsy: J. T. **Florence** and P. **Clément**.—The geological history and the tectonic of the Atlas of eastern Numidia (Algeria): J. Dareste **de la Chavanne**.

THURSDAY, AUGUST 19, 1909.

OILS, FATS, AND WAXES.

Chemical Technology and Analysis of Oils, Fats, and Waxes. By Dr. J. Lewkowitsch. Fourth edition, entirely re-written and enlarged. 3 vols. Vol. i., pp. xx+542; vol. ii., pp. xi+816; vol. iii., pp. viii+406. (London: Macmillan and Co., Ltd., 1909.) Price 2*l.* 10*s.*

THE third edition of this work was reviewed in these columns about five years ago (vol. lxx., p. 502). It is therefore unnecessary again to describe the plan of the book in any detail. In the broad outlines it remains unaltered, though there are changes in the arrangement, and considerable additions.

Much has been done, and much written, in this branch of technology since 1904; wherefore the author has found it necessary to expand the work into three volumes. Broadly speaking, the first volume describes the general chemical constitution of oils, fats, and waxes, and the usual physical and chemical methods adopted in examining them; vol. ii. treats of the individual natural products; and the third volume is devoted to the various groups of manufactured articles, such as edible oils, oxidised oils, candles, soaps, and glycerin. Some new sections, dealing with emulsified oils, the fatty-acid industry, and wax technology, have been added to this part of the work; and more space than formerly has been allotted to the description of manufacturing operations.

Apparently no pains have been spared in making the book as complete and as modern as possible. So far as the reviewer can judge by testing the information here and there, no recent work of importance on the theoretical and scientific side has been overlooked. Thus Bömer's process for the identification of pure glycerides is summarised, and a description is given of the "direct" method for isolating and determining glycerol recently proposed by Shukoff and Schestakoff. Valenta's suggested method of quantitatively separating aromatic hydrocarbon oils from those of the aliphatic series by extraction with dimethylsulphate is dealt with at some length; and an account is also given of the criticisms of the process by subsequent workers.

On the technological side an interesting development is mentioned which may prove of some importance in the candle industry. A large quantity of liquid oleic acid occurs as a by-product, and one of the standing problems of the industry has been to find some mode of converting this liquid acid into its solid homologue, stearic acid, thereby rendering it available as a material for candle-making. Many suggestions have been made, and many patents obtained, with this object in view; but no great success has hitherto attended these efforts—at least, on a manufacturing scale. It seems, however, that an application of Sabatier and Senderens' classical researches upon the "reduction" of organic compounds by means of finely-divided nickel may mark a new stage in the matter. Several investigators have proposed such an application, and Dr. Lewkowitsch states that, by a systematic study of the Sabatier and Senderens reaction, he has recently succeeded in converting oleic acid into practically the full quantity of stearic acid theoretically obtainable from it. What, however, is not quite clear is whether the translation from laboratory experiments to factory practice has been successfully accomplished. Details are withheld.

The author gives a tabulation of oils, fats, and waxes based upon the magnitude of the iodine values. He looks upon this as the most convenient classification for practical purposes. Probably it is; but there are, as would be expected, some inconsistencies and overlapping of groups in this arrangement. Thus certain of the non-drying oils have a greater iodine value than some of the drying and semi-drying oils. But as every chemist dealing with diverse varieties of oils and fats probably constructs some such table for himself, it will be useful to have a fairly complete tabulation of critically-selected values for general reference, even though it is not an ideal basis of classification.

Turning for a moment to commercial matters, most people know that we import large quantities of butter into this country, but many may be surprised to learn that lard is imported to the value, roughly, of five millions annually, and another million pounds' worth, our author calculates, is made at home. The section of the book devoted to this important fat has been increased considerably. Some of the statements made in the earlier editions have had to be modified—notably as regards the range of iodine values—but this was only to be expected, in view of altered circumstances of production. The author discusses at some length the difficult problem of detecting small admixtures of beef-fat with lard. Tables are quoted showing the melting-points of the crystals which deposit from solutions in ether of lard and beef-fat, respectively. The beef-fat crystals have much the lower melting-point. It seems, however, to have escaped the author's notice that the crystals obtained from a mixture of beef-fat and lard have also a lower melting-point than those from lard alone. Used with discretion, such as the author wisely inculcates in other matters, the importance of this fact in solving the problem is obvious.

In dealing with the adulteration of butter the author stigmatises as futile the attempt to prove "that an admixture of beef-fat or lard has taken place if only low titration-numbers for the insoluble volatile acids are found." Undoubtedly such an attempt is futile. It is so obviously futile as to raise a shrewd suspicion that there has been a misunderstanding somewhere.

In some minor matters we do not always see eye to eye with the author. For example, he unduly minimises the value of the specific gravity indications in the examination of butter-fat. His objection is that the test "would hardly lead to the detection of smaller quantities of an adulterant than 30 per cent." In a sense, that is true; but it is also true, in a sense, of every other single criterion which could be applied.

These, however, are small points. Summing up one's impressions of the book as a whole, they are that it well maintains its place in the front rank of works devoted to the study of oils, fats, and waxes. To the chemical technologist it is practically indispensable.

C. SIMMONDS.

A CYTOLOGICAL TREATISE.

Plasma und Zelle. Erster Abtheilung. By Prof. Martin Heidenhain. Erste Lieferung, Die Grundlagen des mikroscopischen Anatomie, die Kerne, die Centren, und die Granulalehre. Pp. viii+500. (Jena: Gustav Fischer, 1907.) Price 20 marks.

THIS somewhat bulky volume is the first instalment of Prof. Martin Heidenhain's treatise on "Plasma und Zelle" which is to form a part of Bardeleben's great work on human anatomy.

The method which the author has adopted is perhaps not the ideal one, but it must be remembered that the science of cytology is young, and its vigorous development has manifested itself in the growth of an enormous amount of details which some day will become connected up so as to make a coherent organism, despite the fact that at the present time the different sections seem to be somewhat isolated. The features which in one group appear to be of fundamental importance may elude recognition in, and perhaps be really absent from, others; and thus that logical connection so dear to the minds of many is difficult, and at present often impossible, to trace. Probably for some time to come the trees will be more apparent than the wood. Prof. Heidenhain has chiefly worked on the cells of a few vertebrate animals, and it must be confessed that throughout the somewhat lengthy treatment of his subject this point of view is rather strongly reflected. There is hypothesis in plenty, together with much really acute analysis, but one cannot repress the feeling that the chastening influence of the protozoan nucleus is rather conspicuous by its absence.

The treatment is frankly morphological, and upon a somewhat narrow range of very detailed observation of comparatively few forms a theoretical superstructure of doubtful stability has been erected. Some cytologists, at any rate, will criticise one of the earlier pronouncements (p. 3) in the book, to the effect that discussion (Erörterung) of biochemical structure forms no part of the province of scientific morphology, and that the latter must take the former as granted. Surely the trend of modern morphology is in the direction of discontent with such a position. Some of us, at any rate, believe that form and structure are merely the expression of biochemical constitution, and it is just this latter problem that we want to attack.

Prof. Heidenhain postulates "units of living substance" as the essential elements of an organism. The cells are regarded as a special case of the aggregation of these living units. In this he is practically following those who regard the cell as by no means the real unit of the organism, and unquestionably this is a tenable position; but, nevertheless, the cell, despite its complex organisation, represents actually the lowest rank in the polity of the multicellular organism out of which the organism itself is built up; nor is the case really different in syncytial bodies. The quarrel with the cell from this point of view is perhaps partly due to the fact that we have not been clear as to what we mean by an organism. A human society is made up of the individuals which compose it; we are justified in regarding them as the ultimate constituents of such a social organism and we cannot usefully push our analysis further back, for they form the lowest units which propagate themselves and differentiate into the complex structure of which the society is composed. Of course, we are aware that each one can be resolved still further into tissues and cells, but these things do not come into the scheme of the social organism as such. The same holds good when we get still lower in the scale. The cells plainly continue to be the units of which the *corpus* is built up—until we get to the unicellular organisms. In the latter we find a more elaborate differentiation than is characteristic of the metazoan or metaphytan cell, but in essentials it seems to be the same. The protoplasm and the nucleus still are requisite to maintain it as a going concern, and reproduction by fission or otherwise is always connected with the distribution of a combination of both to each of the offspring. This is strikingly shown in some forms in which a nucleus as such is perhaps absent, and only the stuff of which the nucleus is made is present in a more or less distributed condition in the cell.

But although we may not agree with the author in his belittlement of the cell, many will assent to his conclusion that it has been made too prominent as the "be all and end all" of the living body. The organism is higher than its parts, and itself determines what form it shall take—or, to put it more plainly, the reactions that are due to the relations subsisting between one part of the organism and another, or between it and its environment, are of such a kind as to influence the fashion of development of the new cells and new tissues.

Prof. Heidenhain's position with regard to the cell is clearly stated on p. 81, where he says that

"it is not the cell which is the bearer of life, but life is inherent in every living particle, down to the smallest molecular group which can be called alive. The cell is rather only a special apparatus which itself is made up of living material."

The crux of the matter obviously lies in the meaning we attach to the word "living."

Many pages are devoted to cell organs, such as centrosomes, and to a very lengthy discussion of Altmann's so-called "granular theory." We confess that much of the space thus allocated seems to us to be hardly well utilised; and although it is not fair finally to criticise a work of which only the first part has appeared, it appears to us that a more real service to cytology would have been rendered if Prof. Heidenhain had focussed the information which is so rapidly accumulating as the result of the study of the lower forms of life upon the problems presented by the higher types.

But he has, at all events, laid those who are interested in cytological development under a debt of gratitude by the exhaustive treatment he has accorded to those topics which he decided to discuss.

MARINE PROPELLERS.

The Screw Propeller: and other Competing Instruments for Marine Propulsion. By A. E. Seaton. Pp. xii+255. (London: Charles Griffin and Co., Ltd., 1909.) Price 12*s.* 6*d.* net.

THE author of this book is well known, both as a practising marine engineer and as an author. His "Manual of Marine Engineering" has long served as a text-book, and has passed through many editions. It was natural, therefore, that the announcement of a work by Mr. Seaton dealing with marine propellers should awaken interest over a wide circle of readers, more especially as the problem of propeller design has not yet received a complete solution. As Mr. Seaton says, "even in modern times . . . . our best men do sometimes fail to achieve success," although there are now available the results of much experimental and theoretical investigation on the subject. After seventy years' continuous work it still remains true that when novel types of ships or unprecedented speeds have to be attempted, although use may have been made of all available data, and the best advice taken, full success is not always or at once achieved. On the contrary, considerable gains in efficiency are frequently attained by a process of "trial and error," out of which comes a final selection of the propeller forms and dimensions best suited to novel conditions.

Such a confession may be thought discreditable; indeed, it is sometimes so treated by critics who have not themselves had occasion to undertake responsibility for ship and propeller designs; but it represents the facts of the case, and the explanation is not far to seek. When a problem has been unsuccessfully attacked by men like Rankine and William Froude, amongst those who have finished their work, and by men like R. E. Froude, Cotterill, Greenhill, and D. W. Taylor, who are still alive and interested in finding solutions, it may be presumed that the problem involves considerable difficulties. When one considers the almost endless variety of the conditions involved in ship propulsion, the failure to reach a complete solution of the problem need not cause astonishment, and it is reasonable to anticipate that we shall have to be content for some time to come, if not permanently, with partial solutions chiefly based on experimental investigations, and on careful scientific analyses of the results.

Mr. Seaton definitely states in his preface that the

"object of the present work is to amplify and extend what [had been given] in skeleton or in rudimentary form" (in his "Manual of Marine Engineering") in the shape of rules for guidance in the practical work of designing propellers. These rules are said to have been "generally based on scientific reasons and always capable of giving results agreeable with the best and most successful practice": and it is claimed that by means of successive improvements "they have become generally applicable to the design of a screw for an Atlantic liner or a torpedo boat." It is added that "the more abstruse and highly mathematical investigations connected with the theory of the resistance of ships and propellers have been left to be studied in the text-books and . . . . valuable papers" of various authors.

More or less empirical rules such as Mr. Seaton proposes no doubt have a certain value as representing his own practice and deductions from his study of published results of steamship trials, but it cannot be admitted that such rules can be depended upon absolutely when new conditions have to be faced. If it were true that the best results could be ensured by the use of any known rules in the designs of screws over the wide range from "an Atlantic liner to a torpedo boat," difficulties such as have been mentioned would disappear, and the work of the naval architect would become easy of performance. The occurrence of these difficulties demonstrates the imperfection of existing rules.

Turning to the general scheme of the book, it may be said that the section dealing with the history of marine propellers is both interesting and valuable. Bourne's book, giving the early history of the screw propeller, is not now generally accessible, and Mr. Seaton's summary will be found useful for reference. Paddle wheels, screws, and hydraulic (or jet) propellers are treated separately, their principles of action are explained, rules being given for their practical design. One chapter is devoted to an explanation, in popular language, of the modern theory of the resistance of water to the motion of ships, but readers desiring full information on the subject will necessarily have to turn to other sources, as Mr. Seaton only attempts a brief sketch. Naturally, screw propellers claim most attention, their various forms, numbers and positions are described; and the effects of changes in numbers, shape, and proportions of blades are also discussed at some length. Much information has been collected and collated respecting experimental trials made with screw propellers, but it seems doubtful whether the large amount of space devoted to trials made by the Admiralty and other experimentalists in the early period of screw propulsion might not have been better utilised, seeing that these trials were made on ships the forms, proportions, and speeds of which in no way represent present practice, while many important conditions affecting results are not definitely known. An antiquarian interest attaches to them, and from their consideration certain useful deductions may be, and, indeed, have been, made; but radical differences exist between conditions prevailing thirty or forty years ago and those of the present day, and the devotion of much time to this subject, when better and later information is available, is not desirable. The chapters dealing with the geometry of the screw and materials used in the construction of the screw propeller are excellent.

The book is well produced and illustrated. It has an excellent index, and as a work of reference will be found of service to all interested in the propulsion of ships.

STUDIES ON IMMUNITY.

Studies on Immunity. By Prof. Robert Muir, in collaboration with Drs. Carl H. Browning, Alexander R. Ferguson, and William B. M. Martin. Pp. xi+216. (London: Henry Frowde, and Hodder and Stoughton, 1909.) Price 7s. 6d. net.

THIS book contains a record of original work on the theory of immunity carried out during the past six years by Prof. Muir, of Glasgow University, in collaboration with his colleagues, Dr. Browning, Dr. Ferguson, and Dr. Martin. Eleven original papers, all of which have already appeared in various scientific journals, are incorporated in the present volume, but, by judicious alterations and additions, the author has endeavoured to knit the subject-matter of these papers into one continuous whole, so that the volume serves as a connected account of the particular immunity processes (hæmolysis and opsonic action) with which the author deals.

A work which treats in strictly scientific fashion of questions so difficult and complicated as those of hæmolysis and opsonic action must of necessity appeal only to the expert, and it is unfortunate that Prof. Muir has not seen fit to bring the subject up to date by the inclusion of references to papers which have appeared since the publication of the authors' original researches. Had he done so, the book would have appealed far more forcibly to the present-day worker, who, one may presume, has been for some time familiar with these highly important researches of Prof. Muir and his collaborators.

The volume opens with an interesting chapter on the properties of hæmolytic sera generally, and the technique usually employed in the investigation of hæmolytic phenomena. There follow chapters on the mode of union of the immune body with the red corpuscle, and the relation of this union to complement action. With regard to this latter question, Prof. Muir finds himself in agreement with Bordet, whose view is that there is no direct union of immune body with complement, as Ehrlich supposed, but that the complement unites with the cell receptor, which has, so to speak, been sensitised by the immune body. "A complementophile group in the amboceptor is not proved, and the use of the term 'amboceptor' does not appear to be justified." Certain interesting filtration experiments performed by Prof. Muir and his colleagues showed very convincingly that at 37° C. a direct union of immune body with complement was highly improbable. The question of complementoids is discussed in great detail, and the author believes that Ehrlich's views with regard to these bodies have been completely confirmed.

Some interesting researches are described showing that complement may act as an agglutinin. Thus, if a certain amount of immune body (obtained by immunising an animal with the red cells of the ox) be added to ox corpuscles in the presence of ox complement, scarcely any lysis occurs, but marked agglutination of the red cells takes place. If guinea-pig's complement is employed, lysis, of course, occurs, and if the ox serum be now added, the stromata flocculate as before. Like complement, this agglutinating body in ox serum is thermolabile, and acts only in cooperation with immune body. Whether this agglutinating complement and the ordinary lytic complement are one and the same, further research must determine.

Anti-immune bodies and anti-complements are treated at great length, and a considerable amount of space is devoted to the question of the deviation of complement, a process which forms the basis of numerous diagnostic methods of great practical importance. The delicacy of this reaction is compared with that of the precipitin method as a test for the presence of protein of human origin.

The concluding chapters of the book deal with the authors' experiments on the opsonic action of normal and immune sera. In view of their finding that the opsonic action of a normal serum could be almost entirely removed by saturating it with sensitised red cells or other combinations which absorb complement, they came to the conclusion that the opsonins of normal serum belong to the group of complements. This view, which attributes to complement an entirely novel property of acting alone, and takes no account of the presence of normal amboceptors, has not met with general acceptance, and a considerable amount of evidence has accumulated in the last two years, showing that in normal serum, as well as in immune serum, amboceptors cooperate with complement to produce an opsonic effect. One cannot yet say, however, that the question whether the opsonic action of normal sera is strictly analogous to that of immune sera is definitely settled, and in the last chapter of the book Prof. Muir brings forward evidence that in some cases normal bactericidal action may differ from that which takes place through the medium of an artificial immune body. Normal bactericidal action may, in fact, follow from the direct union of complement with the bacterium, and not necessarily from an indirect union through the medium of a natural amboceptor. All workers interested in these questions will find Prof. Muir's book worthy of careful perusal.

THE SCIENCE OF EDUCATION.

Psychologie de l'Enfant et Pédagogie expérimentale. By Dr. Ed. Claparède. Second edition. Pp. viii+283. (Geneva: Librairie Kundig, 1909.) Price 3·50 francs.

THE second appearance of Dr. Claparède's book in a greatly enlarged form is an excellent indication of the interest which has been aroused by the effort of recent years to give a scientific basis to the practice of education. If further evidence were wanted, it will be found in the opening chapter, which gives a brief account of the development of the movement and of the literature of the subject. Child-study societies and child-study journals have an almost world-wide currency—from Japan in the Far East to California in the Far West. No doubt there is more zeal than science in much of the published work, but the critic is already at work, and we may hope that science will follow in his wake.

Dr. Claparède is a psychologist, and the interest of the book is mainly psychological. As a justification for the subtitle he makes certain pedagogic deductions, not, however, as tentative hypotheses upon which experimental inquiry may be founded, but rather as so many statements of fact. This seems unfortunate, and students of education who take up the book in the hope of deriving guidance and inspiration in their own class-room investigations will surely feel some disappointment. The dogmatic spirit in which the author treats certain fundamental issues is not reassuring. He finds, for example, that the prime motive power in the mental development of the young, is their inborn tendency to play and to imitate. Groos's interpretation of play is, in the main, accepted, and we are led into a strongly-worded plea for "attractiveness" as the sole principle in educational practice. The plea is backed up with the "best opinion," and ends thus:—

"It is true that certain scholastic successes may be obtained by the opposite method. But see later what the effect upon the victims is! Worked out at school, they are left without initiative, and the power of energetic action. They never become men because they have never been children."

This sweeping generalisation applies avowedly to the whole school system. Not a word of evidence is put forward in its support, though probably few of the readers of the book would regard it as a self-evident proposition. It is not a satisfactory method of laying the foundations of a science of education.

The author is more successful as an exponent of child-psychology pure and simple. He gives a brief summary of the various sources of our knowledge, and his chapter on mental development is a useful introduction to current views on the subject of play, imitation, and interest from the standpoint of biology. The student who is anxious to learn something of actual methods of research will find references to special monographs in the bibliographies appended to each chapter. It is only when he treats the subject of fatigue that the author himself gives detailed accounts of experimental methods the value of which readers can test for themselves. The curves which are given in the text of earlier chapters, showing the variations in suggestibility &c., at different ages, embody results of investigations the character and significance of which are not in any way discussed. Perhaps in a later edition the author may find it possible to strike out what is mere dogmatism, and enlarge upon those parts of his book which deal with scientific inquiry. The value of the book might in this way be greatly increased.

J. A. GREEN.

BOOKS OF REFERENCE IN ORGANIC CHEMISTRY.

(1) *Analyse und Konstitutionsermittelung organischer Verbindungen.* By Dr. Hans Meyer. Second enlarged edition. Pp. xxxii+1003. (Berlin: J. Springer, 1909.) Price 28 marks.

(2) *V. v. Richter's Chemie der Kohlenstoffverbindungen oder organische Chemie.* By Dr. R. Anschütz and Dr. G. Schroeter. Erster Band, Die Chemie der Fettkörper. Pp. xx+793. (Bonn: F. Cohen, 1909.) Price 18 marks.

(1) THE study of structure may be looked upon as the basis of all investigation in organic chemistry. It is the fundamental distinction between this and other branches of the science.

Whilst physical chemistry is chiefly concerned with the mechanism of reactions, inorganic chemistry with the conditions determining the formation of compounds, organic chemistry is mainly directed to synthetic processes, for which a knowledge of structure is essential. It is as an aid to this knowledge that Dr. Meyer's book has been written. That it has found favour with chemists and is regarded as a valuable addition to chemical literature is shown by the fact that within a few years of its first appearance the publication of a new and enlarged edition has been called for.

The volume before us has reached the respectable bulk of one thousand pages. The chief addendum is the second part, on the determination of the parent substance, containing chapters on oxidation, reduction, and alkaline fusion; many new methods have also been introduced, and older and less trustworthy ones discarded.

The book is too well known to need anything in the way of general description. It contains methods of elementary analysis, methods for determining molecular weights, for ascertaining qualitatively and quantitatively the presence of certain groups, and for breaking up the molecule into simpler fragments. One may look in vain for any serious omissions. On the other hand, the great variety of methods and the long lists of references are rather bewildering, and constitute, perhaps, the chief defect of the book. There has been, apparently, no attempt at critical examination. Every method and every modification of it seems to have found a place. The reader is left to make his own choice and to draw on his own experience.

We would take as an illustration the well-known method of Zeisel. The original and obsolete form of apparatus is described and pictured in detail, together with modifications by Benedikt and by the author (the latter being described as the simplest and most convenient), whilst the method of Perkin, generally adopted in this country, is only indicated by a reference along with five others.

We would not press this criticism too far. It is better to have too much information than too little, and if the reader has not the luck to discover at once the most suitable process, he will hit upon it in the end if he only perseveres.

It is needless to point out that the compilation of so much detail must have entailed immense labour, and has been carried out with painstaking German thoroughness. The book is well printed and illustrated, and should serve as a standard work of reference in the library of an organic laboratory.

(2) Twenty-five years ago Richter's "Organic Chemistry" appeared as a small companion volume to the one on inorganic chemistry. Since then each succeeding edition has steadily increased in bulk. A few years ago it was issued in two parts, and now it has been found necessary to enlarge the *format*. Nothing could illustrate more forcibly the growth of this branch of chemistry.

Whatever may have been the original purpose of the book, it has long ceased to be a text-book for students. One shudders at the thought of a student attempting to commit to memory such a mass of detailed information as is compressed into this volume It has developed into a portable book of reference, and as such is eminently useful and trustworthy for filling up gaps in one's knowledge as occasion requires.

Whilst deprecating the use of books of this type as class text-books, we do not share the feeling expressed by some that the bulk of new facts accumulated year by year in organic chemistry have little or no value, or that the motives which lead to their production are unworthy. The worst that can be said of multiplying compounds is that, without adding anything to the complexity of the subject, they fill in, as it were, the missing blocks in the picture puzzle, and merely complete what was anticipated; and as to the motives of those who produce them it may be pointed out that much of the research work of the compound-making type is done by young chemists as an exercise in that kind of skilful manipulation which counts for so much in every branch of chemical investigation, and for which organic chemistry seems so exceptionally well fitted.

J. B. C.

THREE FISH-FAUNAS.

(1) *Catalogue of the Fresh-water Fishes of Africa in the British Museum (Natural History).* Vol. i. By G. A. Boulenger. Pp. xi+373; illustrated. (London: Printed by Order of the Trustees; sold by Longmans, Green and Co., and others, 1909.) Price 32*s.* 6*d.*

(2) *The Fishes of Illinois.* By S. A. Forbes and R. E. Richardson, Nat. Hist. Survey of Illinois. Vol. iii., Ichthyology. Pp. cxxxi+387; plates, maps to accompany above, pp. 103. (Illinois, n.d.)

(3) *Andrew Garrett's Fische der Südsee.* Part viii. By A. C. L. Günther, Hamburg, Journ. Museum Godeffroy, vol. xvi. Pp. iv+261–388; plates, 141–160. (Hamburg: L. Friederichsen and Co., 1909.) Price 60 marks.

(1) THE zoological survey of the Nile, undertaken by the Egyptian Government during the administration of Lord Cromer, and the explorations of the great Central African lakes, initiated in that country, together with those of the Congo, carried out by the Belgian authorities, have resulted in an enormous expansion of the collection of African freshwater fishes preserved in the Natural History branch of the British Museum. That collection, moreover, as we are informed in the introduction to the first of the three works forming the subject of the present notice, contains a very large proportion of the type-specimens of the many new species which have been described as the result of the aforesaid explorations. It was, therefore, from all points of view highly desirable that a descriptive catalogue of this vast collection should be published, as such a work will serve as a basis for the discussion of the many points relating to the distribution and origin of the African fish-fauna, and likewise as a book of reference for workers in Africa itself, from which it can readily be ascertained whether specimens belong to already described species.

Mr. Boulenger, to instance only his volume on those of the Congo, published by the Government of the Congo Free State, has already devoted much study to African fresh-water fishes, and for this reason, coupled with his official position at the Museum, he was obviously the man to undertake the laborious task of writing this catalogue, which, it is considered probable, will run to three volumes.

The present volume, at all events to others than ichthyological specialists, will probably prove the most interesting of the three, as it includes some of the most distinctive and aberrant types of the African fish-fauna. To many naturalists it will be of special interest to learn that a shark (*Carcharias zambesiensis*) inhabits the Zambesi at a distance of 120 miles from its mouth, and also that a saw-fish ascends this and probably other African rivers to a considerable distance. Of the characteristic and peculiar Ethiopian types, two of the most remarkable are the bichirs (Polypterus) and Calamoichthys, the sole survivors of the fringe-finned ganoids, and the mud-fish (Protopterus). No fewer than ten species of bichir are now recognised, although the allied genus is still represented by a single known member; and there are two kinds of mud-fish.

Next in point of interest to these ancient types are the remarkable fishes forming the exclusively Ethiopian family Mormyridæ, many of the members of which display such extraordinary vagaries in the matter of beak-development—a development which has suggested for the group the not inappropriate name of elephant-fishes. Of these strange fishes eleven generic types are now admitted, some of which, such as Mormyrops (with thirteen), include a large number of species. It may be hoped that before long the author will take an opportunity of giving us his views as to the origin of this family, which, if determinable, will add considerably to our knowledge of th origin and relationships of the African fauna generally.

The other important family treated in this volume is the Characinidæ, which has a distribution similar to that of the Lepidosirenidæ, being common to Africa and Central and South America. The number of African genera admitted in the volume before us is twenty. The characinids, like the lepidosirenids, have been frequently quoted as affording evidence in favour of a land connection between Africa and America, but before it can be decided whether they are of any value in lending support to that theory, it is essential that their past history should be known.

Although we have not much to say in the way of criticism, it may be mentioned that *Elops saurus* (p. 25) has recently been shown by Mr. C. T. Regan to occur only on the American side of the Atlantic, and that there are now three African species of the genus, viz. *senegalensis*, *machnata*, and *lacerta*, the last of which is alone admitted in Mr. Boulenger's volume as a valid species. Then, again, family rank might well be granted to the genus Chanos. On the other hand, it is satisfactory to find that the author has recognised the correctness of Dr. Gill's removal of the Kneriidæ from among the Haplomi, and their transference to the neighbourhood of the Cromeriidæ. Finally, it may be pointed out that in the definition of the Cladistia the item "nostrils on upper surface of snout" is true of all the fringe-finned group, while in the definition of the Teleostei the statement that the supports of paired fins are dermal bones, and not endoskeletal elements, surely seems to stand in need of revision.

The volume is illustrated with a number of text-figures, for the most part of excellent execution, although some of these—apparently on account of the figures having been photographed from lithographs—are not printed so clearly as is desirable.

Mr. Boulenger and the trustees are to be congratulated on the issue of this valuable volume.

(2) Turning to the fishes of Illinois, it has first to be mentioned that the account of these by Messrs. Forbes and Richardson occupies a volume of cxxxi+387 pages of text, this being accompanied by an atlas showing the distribution of each species in the State. We learn from the introduction that the collections and field observations upon which this elaborate monograph are based were commenced so long ago as 1876, and continued, at somewhat irregular intervals, down to 1903. The establishment of a biological station in 1894 on the Illinois River at Havana first rendered it practicable to introduce exact methods of study and observation, such as had previously been impossible, and at the same time enabled the field-work to be conducted with greater regularity and continuity. The quantitative method of investigation, which yielded such good results in the case of the plankton, proved equally successful when applied to ichthyology.

In addition to numerous uncoloured illustrations in the form of both plates and text-figures, the volume contains a large number of coloured plates of Illinois fishes, which are admirable examples of modern colour-printing, and present life-like portraits of the species they portray. The monograph may, indeed, be regarded as a first-rate specimen of the thoroughness and completeness with which biological work is nowadays carried on in the United States, and of the excellent style in which the results are presented to the public.

The volume commences with an elaborate account of the topography and hydrography of Illinois, which is divided into a north-western unglaciated area, the areas of the Iowan and Illinoisian drift, the area of the Wisconsin drift, and the unglaciated southern area. This is followed by an equally full account of the river-systems of the State, after which we are furnished with notes on the fisheries of Illinois. All this occupies what may be termed the introductory portion of the volume, paged in Roman numerals, while the remainder is devoted to systematic work.

A total of 150 different species of fishes are recognised in Illinois. In the absence of geographical barriers to their dispersal, the causes influencing their distribution appear to be climatic, geological, and ecological. Geological limitations are indicated in the southern portion of the State by the fact that the area covered by the Illinoisian lower glaciation is inhabited by a certain number of species to the exclusion of others. An interesting fact in distribution is afforded by the existence "of a marked difference in preference of situation between nearly related species inhabiting the same area, the effect of which is to break the force of a competition between these species such as would prevail if they were similarly distributed ecologically as well as geographically. Closely related species are, as a consequence, often found much less frequently associated in their common territory than either is with widely unlike species of the same geographical range."

The Illinois fishes include the remarkable spoon-beaked sturgeon (Polyodon), locally known as paddle-fish, and now valued both for its flesh and as a source of caviare; and likewise true sturgeons, referable to the typical genus, and to the two exclusively American genera Scaphirhynchus and Parascaphirhynchus. The most interesting of these is the white sturgeon (*P. albus*), which appears to be a very rare species, represented only by about one specimen out of every three hundred examples of the common shovel-nosed *S. platyrhynchus*. Gar-pike and bow-fins form other exclusively American types among the Illinois fauna, and a large number of the genera of "white fish" are likewise solely American. The European perch is, however, represented by a nearly related species, and the same is the case with the bream; but one of the pikes of Illinois is inseparable from the well-known British fish. The authors of this monograph are to be congratulated on having made such an important contribution to the geographical study of fishes.

(3) Congratulations are likewise due to Dr. Günther on the completion of his famous work on the fishes of the South Seas collected for the founders of the Godeffroy Museum at Hamburg. This museum, we may remind our readers, was established by the Messrs. Godeffroy, the well-known Hamburg merchants, for the reception of the natural specimens collected by the officers of their vessels, and Dr. Günther accepted the task of describing the fishes, on the condition, we believe, that a selection of specimens, including all types, should be given to the British Museum. The portions of the work previously published were issued between 1873 and 1881, but for financial reasons the publication came to an end in the latter year. Now, through the generosity of Dr. W. Martin von Godeffroy, the means of completing the work have been provided, and Dr. Günther has, fortunately, been enabled to bring his long-delayed task to a successful conclusion. It should be added that a number of coloured illustrations of the Godeffroy fish collection were prepared by Andrew Garrett, and from these some of the beautifully coloured plates accompanying the present volume have been reproduced.

Since the issue of the preceding part of the work great advances have been made in our knowledge of the fishes of the South Seas, more especially as regards those of the Sandwich and certain other islands; and to correlate this new work with the material in hand required a large amount of investigation. Fortunately, this work could be most effectively done at the British Museum, where a large series of the Godeffroy fishes are preserved, and where also large collections of fishes from the Indian Ocean are available for comparison with those from the South Seas. The result of these investigations and comparisons has been to produce order and certainty where uncertainty and chaos—as regards the identification of species and the determination of their synonymy—previously prevailed to no inconsiderable extent.

Littoral forms of fish-life occupy a considerable portion of the part now before us, although a section is devoted to flying-fish and other pelagic types; but the deep-sea fishes do not come within the purview of the work. Coral-fishes, or coral-wrasses, of the family Labridæ, are treated in the commencement of the present part, and the brilliant hues and remarkable colour-patterns of these gorgeous fishes are most admirably rendered in the accompanying plates. Our sole regret is that the author appears to have made no attempt to explain the mutual relationships and special purpose of these varied markings. Ichthyologists will greatly appreciate the author's careful revision of the large number of species of flying fishes inhabiting the South Seas; but students of the habits of animals will perhaps regret that Dr. Günther has maintained a cautious reserve with regard to the manner in which these fishes perform their aërial flight. Both the "aëroplane" and the "vibration" theories are mentioned, with references, but the author does not give even a suggestion as to which he considers to be the more probable explanation.

With the bare mention that no new species are described, we repeat our congratulations to Dr. Günther on the completion of his long-deferred task.

R. L.

OUR BOOK SHELF.

Further Advances in Physiology. Edited by Leonard Hill, F.R.S. Pp. vii+440. (London: E. Arnold, 1909.) Price 15*s.* net.

THIS is the second volume of original articles issued under the editorship of Mr. Leonard Hill. The first appeared about three years ago, and was reviewed in NATURE, May 3, 1906. That the publishers have seen fit to issue a second volume is an indication that the first was a success. The present volume treats of a number of interesting and important questions which have recently been subjects of research among physiologists, and the senior student is thus provided with a summary of the latest views which otherwise it would have been impossible for him to have obtained without much labour and exploration in many journals. The idea of the book is thus excellent; one's only fear is that in the presentation of a good deal of controversial matter even the best of students may sometimes lose himself and wish there was more agreement among physiological workers. In some of the articles more attention is paid to points of difference than to points of agreement, and general conclusions to help the reader in the maze are not always forthcoming. On the other hand, from the point of view of the researcher, the descriptions given of recent work are too fragmentary in some cases to be of any real help, though perhaps this may be wise, for anything which tempts the original worker to neglect reading the actual writings of his predecessors on the same road is to be deprecated.

The articles contained in the book are the following:—Prof. B. Moore opens with a consideraton of the equilibrium of colloid and crystalloid in living cells; Mr. M. Flack comes next with an article on the heart, in which, *inter alia*, he discusses the *pros* and *cons.* of the myogenic and neurogenic theories; Dr. T. Lewis deals with pulse records in relation to the events of the human cardiac cycle; the editor advances his heterodox views on the part played by blood-pressure on such phenomena as lymph production and secretion; Dr. A. Keith contributes an anatomico-physiological article on the mechanism of respiration; and Dr. M. S. Pembrey an extremely useful essay on the physiology of muscular work; the problems of growth and regeneration of nerve, and the nature of the nerve impulse, are then considered by Dr. N. Alcock; Dr. J. S. Bolton treats of cortical localisation, and Marie's views on Broca's aphasia are described; and the volume concludes with an article by Mr. M. Greenwood on visual adaptation and colour vision.

The mere enumeration of the subjects treated indicates the wide-reaching interest of the book, and the names of the authors are a sufficient guarantee that the work is well done.

Weltsprache und Wissenschaft. Gedanken über die Einführung der internationalen Hilfsprache in die Wissenschaft. By L. Couturat, O. Jespersen, R. Lorenz, W. Ostwald, L. Pfaundler. Pp. iv+83. (Jena: Gustav Fischer, 1909.) Price 1 mark.

THAT an international language for scientific communication is desirable no one will question; that an artificial language will ever be generally adopted for such a purpose is more than doubtful. If success in this direction is to be attained, it will probably be on the lines indicated in the present pamphlet, which is a kind of unofficial manifesto of the "Délégation pour l'adoption d'une langue auxiliaire internationale" appointed in 1900. A commission including scientific and linguistic experts of different nationalities is more likely to devise an acceptable language than any individual, who of necessity suffers from the prejudice of his mother-tongue and a comparatively limited knowledge of the requirements of the new medium. After seven years' deliberation, the international delegation has adopted most of the principles of Esperanto, but with great modifications in detail.

For Europeans and Americans the fundamental requisites of a common artificial language are:—(1) a simple phonology and alphabet, only such sounds being admitted as are in actual use amongst all the principal European peoples (exclusion of English *w* and *th*, German modified vowels, French nasals); (2) a vocabulary composed, as far as may be, of words comprehensible at sight to cultivated Europeans; (3) as little grammar as possible. These principles are generally followed in the new lauguage "Ilo," the Slavonic peculiarities of Esperanto (*e.g.* the circumflexed consonants and absurd terminal j's) being carefully avoided. The vocabulary has a distinctly Romanic appearance, and grammar is reduced to small proportions, which might with advantage be smaller still. Word-formation from stems by means of prefixes and suffixes is systematic, but needlessly complicated. Why should we, for example, have the prefix *bo-* to indicate relationship by marriage? "Father-in-law"=*bopatro* is not a necessary word; "wife's father" or "husband's father" is equally simple and more definite. Again, to use *-isto* for "professional" and *-ero* for "amateur" is making a rather superfluous distinction. It may be convenient occasionally to distinguish between *fotografisto* and *fotografero*, but in the case of, say, *dentisto* and *dentero* the necessity is not so obvious.

Notwithstanding its shortcomings, "Ilo" is a great advance on its predecessors, and men of science who are interested in the general scheme may be cordially invited to join the "Uniono di l'amiki di la linguo internaciona." But for the general adoption of the language much enthusiasm will be needed, and it is rather disquieting to read in a specimen sentence:—"Omna entuziasmo posedas per su la tendenco, ne klarigar, sed trublar l'okulo di l'intelekto."

Einführung in die Lehre vom Bau und den Verrichtungen des Nervensystems. By Prof. Ludwig Edinger. Pp. iii+190. (Leipzig: F. C. W. Vogel, 1909.) Price 6 marks.

This is an excellent work consisting of fifteen lectures on the various parts of the central nervous system. Dr. Edinger has a very pleasant way of introducing information concerning the functions of the nervous structures as he describes them, a feature which makes his works much more readable than those which give merely geographical descriptions of the parts under consideration. Another feature of the present work is that it keeps the reader constantly informed respecting the comparative anatomy and evolutionary antiquity of the particular structure he is studying.

The book consists of 190 pages, but there are probably less than 100 pages of letterpress owing to the generous way in which it is illustrated. There are no fewer than 161 diagrams, in addition to a plate showing the development of the Neencephalon over the Palæencephalon. The diagrams are so clear and helpful to the student that a mere smattering of knowledge of the German language is probably all that is necessary for the book to be a useful addition to his library.

The first chapter, on methods of investigation of the nervous system, is largely historical; the second is devoted to the study of the histological elements; while the third is a charming combination and correlation of the histology, physiology, embryology and comparative anatomy of the nervous system as a whole. The author then presents a general survey of the brain and spinal cord, and subsequently discusses the various tracts of the spinal cord and traces them from their origin to their termination. Then follow chapters on the pons, cerebellum, mesencephalon, basal ganglia and connections of the optic nerve. The last four chapters are devoted to the various portions of the cerebrum, the corpus striatum, connections of the olfactory nerve, the internal capsule, &c.

On p. 61 there are two diagrams of the root distribution of cutaneous sensation (front and back views) which, so far as our memory serves us, are not in accordance with the findings of Head, Starr or Thorburn, and we are inclined to think that Edinger's diagrams are incorrect.

The addition of an index to the book would greatly enhance its value.

Annuaire astronomique de l'Observatoire royal de Belgique, 1909. Published under the direction of G. Lecointe. Pp. vii+347+258. (Brussels: Hayez.)

Of the numerous publications of the Brussels Observatory, none is, perhaps, more generally useful than this "Annuaire," and we know of no other annual which excels it in general usefulness. All the usual tables, ephemerides, &c., relating to the sun, moon, planets, comets, and stars are contained in the first part, which is followed by explanations as to how to use the tables, and a long list of the names and positions of the principal observatories of the world. A very useful and explicit statement of the legal time used in various countries is clearly illustrated by a folding map, particoloured to show the countries which have so far adopted "universal" time and those which have not; the date line is shown in detail too.

Other parts of the "Annuaire" deal with surveying problems—there are some useful formulæ and forms for amateur surveyors—the form of the earth and the more recent work in astronomy. W. E. R.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Mining Administration in India.

In view of the recent attacks made in the London *Mining Journal* on Mining Administration in India, and also, both directly and indirectly, on the director of the Geological Survey, we have deemed it advisable to send you the following extracts, one of which is taken from the *Mining Journal* of June 26, p. 801, and the other from the published evidence given by Sir Thomas Holland before the Royal Commission upon Decentralisation, and published in Blue-book Cd. 4369 (vol. x. of Minutes of Evidence, p. 47):—

From the *Mining Journal* of June 26, p. 801, leading article, headed "Mining Administration in British India."	Evidence of Sir Thomas Holland, director, Geological Survey of India, published in Blue-book Cd. 4369, being vol. x. of the Minutes of Evidence taken before the Royal Commission upon Decentralisation in India, p. 47:—
"We cannot close our observations on the evidence tendered to the Commission without noting the light thrown by the report on the sincerity of Sir Thomas Holland's attempt to suggest that we had imputed corruption to Government officials in India. As an argument against the establishment of a separate Provincial Survey, the director of the Geological Survey said:—	Question No. 43455: "Is not an officer who has to deal with mining concessions in any part of the world subject to great temptation?"
"'If I transferred an officer, say, to Burma, or any province beyond my control, and he was the officer who governed the granting of mining concessions, I have not the slightest doubt that within a year, if he had only ordinary intelligence, he would discover that his salary *would*[1] be only a fraction of his income.' We do not remember even to have seen the chief of what is professedly a scientific body so frankly confess his distrust of his colleagues' honesty and professional pride."	"Yes; if I transferred an officer, say to Burma, or to any province beyond my control, and he was the officer who governed the granting of mining concessions, I have not the slightest doubt that within a year, if he had ordinary intelligence, he would discover that his salary *need*[1] be only a fraction of his income."

By changing one word in quoting the Blue-book, the *Mining Journal* has altered the whole meaning of the remarks made by the director. In view of the comments made, it is for the *Mining Journal* to prove that this misquotation is accidental. Having regard to the claim of the *Mining Journal* that it "circulates all over the world," the writer of the article must know that it will be read by many to whom the Blue-books are not accessible, for no assistance has been given by a reference to the particular volume in which the director's evidence is recorded. As the inaccurate quotation has already received a start of some weeks before reaching us in India, we shall be glad if, by publishing this letter, you will assist in preventing any further dissemination of a grossly unjust insinuation.

With this sample before them, we can safely leave your readers to estimate the value of the attacks on the Indian administration recently made in the *Mining Journal.*

Needless to add, the relation between us and Sir Thomas Holland is one of perfect and mutual confidence.

We have been unable to communicate with three of our

[1] The italics are ours.

colleagues, who are at present absent in the field, but we are convinced that if they had the opportunity they would join with us in appending their signatures to this letter.

An Optical Phenomenon.

In reference to the query of "V. P." in Nature of June 3 (p. 398), under the above title, I describe a simple experiment which will, in all probability, lead to an easy explanation.

Allow sunlight to fall upon a vessel filled with water to a depth of a few inches. If the bottom be white, so much the better. A bath-tub is excellent. Now draw a finger through the water so as to produce a wake, in which are to be seen the familiar "dimples" characteristic of vortex motion. Then, on the bottom will be observed, corresponding to each dimple, a black shadow with a brilliant edge, just the same sort of appearance, in fact, as that described by your correspondent. The same, by the way, may be observed in shallow brooks.

The explanation in this case is not difficult. A very small central portion forms a concave lens, the enfeebled illumination of which on the bottom is negligible. The portion surrounding this and extending as far as the plane water-surface acts somewhat after the manner of a convex lens, concentrating the light passing through it into a more or less sharply defined ring, a "focal ring," so to speak, as contrasted with a "focal point." The diameter of this ring would approximate that of the whole dimple. By far the greater part of the light falling upon the area of the dimple is collected here, and, consequently, the field within appears black aided by contrast. It is easy to see that an essential is the relative smallness of the concave part of the dimple, as is borne out by failure to obtain the phenomenon on a large scale by stirring water in a beaker.

Now, following up this experiment and considering window-panes, one would expect to find there flaws of a dimpled nature, or else of a corresponding heterogeneity of refractive index. The former I have found to be the case, especially surrounding air-bubbles, as is easily to be detected by the touch in many cases. The formation of these flaws could be accounted for by the contraction of the air during cooling in process of manufacture. Moreover, in this instance, the bubble itself, forming the concave lens, need not always be small, since it is usually of a focal length far shorter than that of the surrounding portions of the pane.

Flaws of this type are rarer than those of an opposite or protruding type, which, of course, produce patterns with a white centre. L. G. Hoxton.

University of Virginia, July 26.

A Question of Percentages

In reply to the letter on the "Calculation of Percentages" in Nature of August 5, may I venture the opinion that the only common-sense method of finding the percentage of marks gained by a student in a series of examinations is to add together all the marks obtained by the student, and find what percentage this total is of the maximum possible?

By this method the more difficult papers, which have a greater number of marks allotted to them, retain an important proportion in the result, whereas the elementary papers, which are worth only a few marks, have only a small influence on the final percentage.

If one were to calculate the percentage for each paper, and then average these percentages, this would manifestly be the same as giving the same number (*i.e.* 100) of marks for each paper. This would necessitate equal difficulty in each paper set. Lewis Whalley.

39 Clarendon Street, Keighley, Yorks, August 13.

In Nature of August 5 Mr. Cunningham appeals to mathematical readers for information on the question of averaging three results, viz.:—

$$37/50+50/50+71/100,$$

either giving

$$(37+50+71)/200=79/100$$

or

$$(2\times37+2\times50+71)/300=81\tfrac{2}{3}/100.$$

Though I am not a mathematician, but a chemist, I trust I can give the required answer.

The way of averaging depends on the weight of the single results. By the latter way of calculating, the third result affects the average with twice the weight of the former way. Equal weights for each result require equal denominators. Taking for a very simple instance the problem of averaging between 20/100 and 40/100, which is obviously 30/100, the first way of averaging, as proposed by Mr. Cunningham, would permit a calculation like this (20/100 being $=2/10=1/5$, &c.):—

$$2/10+40/100=42/110 \text{ or } 1/5+40/100=41/105,$$

or (40/100 being $=400/1000=4000/10,000$)

$$1/5+400/1000=401/1005 \text{ or } 1/5+4000/10,000=4001/10,005.$$

These results, I believe, will explain better than many words the essential point of this question.

Breslau, Parkstr. 13. R. Abegg.

Kohlrausch's "Physical Measurements."

Replying to the letter of Mr. Nelson in Nature of August 12, the value given for the k in question in the ninth German edition of "Kohlrausch's Lehrbuch der praktischen Physik" (1901) is 0·457. But it must be borne in mind that this value is deduced on the assumption that the specific gravity of the brass weights is 8·4, and seeing that the specific gravity of various samples of "brass" varies not inconsiderably, it is immaterial whether one uses 0·457 or 0·458 for the correction factor. The rounded value, 0·46, is near enough for most purposes, and that is the one given in the tables of Landolt-Birnstein. For accurate work the specific gravity of the weights must be determined in any case, and the value of k calculated for these particular weights.

G. Rudorf.

"Ivor," Cranley Gardens, Muswell Hill, London, N., August 12.

A Kinematical Illusion.

The following experiment is easily tried, and throws, I think, some light on a certain type of illusions.

A small cogwheel from an old American clock is the only apparatus required. Holding the axle in the finger and thumb of the right hand, give it a twirling motion, say counter-clockwise. Let the teeth of the wheel click gently against a small card, or the finger-nail of the left hand. On looking at the wheel the spokes appear to revolve counter-clockwise (as they do) and the teeth to revolve in the reverse direction. C. S. Jackson.

25 Nightingale Place, Woolwich.

RÖNTGEN RAYS IN THE DIAGNOSIS OF DISEASE.

Great development has taken place in the last few years in the application of Röntgen rays to the diagnosis of disease. At first it was only possible to show the shadows cast by bones and by dense foreign bodies, usually metallic bodies. With improvement in apparatus and in method, the art of radiography has advanced in such a way that it is now possible to show, not only the outlines of the bones, but minute details of their structure, and, more than this, a considerable amount of detail can now be shown in the soft parts of the limbs. While at first surgeons alone found X-ray diagnosis useful, as in the diagnosis of fractures, dislocations, and foreign bodies, the physicians have gradually been able to take advantage of the useful properties of the Röntgen rays, and, indeed, the physicians commenced the use of this method of diagnosis very early, since it was found that the heart and aorta cast a fairly distinct shadow. Before long it was shown that certain diseases of the lungs were also recognisable, and still later some of the other organs, notably the kidneys and the liver, were added to the list of organs which were accessible to Röntgen-ray diagnosis. At the present time, not only these various organs, but the entire length of the alimentary canal can be revealed and explored. Opacity to Röntgen rays is almost entirely a function of density. Of the substances which enter into the construction of the human frame, the least dense is air. The healthy lungs have their spongy tissue filled with air, and they are, therefore, the most transradiant organs of the body. The lungs are contained in the thin-walled chest, so that there is very little substance to interfere with their transradiancy. In examining the chest upon the fluorescent screen, it is seen that the act of deep inspiration increases the transradiancy of the lungs, the shadows cast by the ribs being shown up in greater contrast than during expiration. This is exactly what would be expected, since the spongy tissue of the lungs becomes blown up and filled with air during the act of inspiration. The heart and aorta are far denser organs, and they are shown up in strong relief against the background of the air-containing lungs. It is, therefore, quite easy to estimate the size, shape, and position of the heart and aorta.

It must be remembered that the shadow cast upon the fluorescent screen (or obtained by photography upon a photographic plate) is greater than the actual size of the organ. For some purposes it is important to obtain an accurate measure of the true size of the heart. In this case the X-ray tube—which nowadays is always enclosed in an opaque box or shield—is so arranged that there is only a small opening through which the X-rays can emerge and penetrate the patient's body. The apparatus is arranged so that the X-ray tube can be moved to any position in its own plane. If the tube be moved around the margins of the heart, and these margins be marked out upon the glass which covers the front of the fluorescent screen, an outline of the heart is obtained upon the glass, and represents the true projection of the heart in the plane of the fluorescent screen, and for practical purposes this may usually be regarded as representing the true size of the heart. The pulsations of the heart and of the aorta can be studied minutely upon the fluorescent screen.

Coming now to the lungs, it will be clear that any tumour or condensed area in the lungs will be shown up in relief against the air-containing healthy lung tissue. In this way the consolidation due to phthisis is shown even in the earliest stages of the disease. For instance, there may be slight diminution of transradiancy near the apex of one lung. On deep inspiration the whole of the lung becomes more transradiant, showing up the impaired apex in stronger contrast. There are other signs observable on the fluorescent screen in phthisis; thus the range of movement of the diaphragm is much restricted. In more advanced phthisis the congested areas are shown as dark shadows, and in very advanced disease where there are cavities in the lung these cavities are frequently visible as lighter areas with irregular outlines surrounded by a darker area of congested lung. Other diseases of the chest, tumours in the glands, cysts, &c., are shown against the light background of the healthy lungs.

When there is fluid accumulated in the pleural cavity, *i.e.* between the chest wall and the lungs, it is necessary to examine the patient in the upright position in order to obtain the effect of gravity in causing the fluid to take up a position at the base of the chest. Fluid in the chest is very opaque when compared with the transradiancy of the lungs. When fluid begins to collect in the chest it is found at the most dependent part of the chest, where the diaphragm is attached to the chest wall. As the fluid accumulates, the opaque area increases upwards, its upper limit forming a curved line concave upward, the direction of which is from the middle line of the body upward and outward. The greater the quantity of fluid, the higher and the steeper does the position of this line become, but with increasing accumulation of fluid the lung itself, which is floated up upon the fluid, becomes more and more compressed, and, therefore, less and less transradiant, so that the line which separates the liquid from the lung becomes more and more ill-defined, and finally disappears altogether, the whole of this half of the chest becoming uniformly opaque, since the lung itself has become so greatly compressed that it no longer contains any appreciable quantity of air. As the fluid accumulates, it is observed that the heart becomes displaced further and further to the opposite side of the chest.

The foregoing description refers to cases in which there is an accumulation of liquid only, but in other cases (known as hydropneumothorax) not only is there a collection of liquid in the pleural cavity, but there is also free air in this cavity. In this case the appearances are fundamentally altered, for there is now a sharply-defined horizontal line of demarcation between the liquid and the air. The lung itself is collapsed, and usually occupies a small space close against the middle line of the body. The heart is displaced to the opposite side of the chest. We have here the physical conditions of a liquid contained in a vessel and placed in air. On tilting the patient, the liquid is at once seen to flow in a direction which enables its upper surface again to become horizontal. If the movements of the patient are fairly rapid, waves are produced in the liquid, and this is still better seen if the patient shake himself or be shaken. It frequently happens that the heart beats against the liquid and sends a regular series of waves along the surface of the liquid. Hitherto, in forming their opinion as to the nature of diseases of the chest, physicians have been dependent upon the information derived from the application of percussion and auscultation, and although very accurate information can in many cases be obtained by these methods, a Röntgen-ray examination is still of great importance in confirming the conclusions obtained from the other clinical methods of examination, and in supplementing information thus obtained. Thus in phthisis the degree and extent of the affected lung is shown with far greater accuracy by the Röntgen-ray method than by the methods of percussion and auscultation, and in many cases pulmonary lesions which are quite unrecognisable by percussion and auscultation may be clearly shown upon the fluorescent screen. In other cases the Röntgen-ray examination leads to a diagnosis entirely different from that obtained by percussion and auscultation.

In the examination of the abdomen, the conditions are very different from those which prevail in the case of the chest. There is usually no air in the abdominal cavity except such as may be contained in the stomach or in the large intestine. Consequently, the only structures which stand out in strong relief are the bones, viz. those of the vertebral column, the hip bones, and the lower ribs. There is a way, however, in which the conditions in the abdomen may be made more to resemble those found in the chest. Air may be forced into the large intestine, and its passage along the course of the intestine followed on the fluorescent screen. The air forms a very definite band of relatively high transradiancy. The size, shape, and position of all parts of the large intestine can usually be traced out by this means. The presence of air has a further advantage in that the solid organs of the abdomen stand out in sharp relief against the light background formed by the air-containing large intestine. Thus the lower edge of the liver is shown up as a well-defined margin; the upper margin of the liver is always obvious, as its domed surface lies in contact with the diaphragm on the right side, and has the base of the right lung immediately above it. On viewing the patient's back (especially if he lie prone on a couch with a loosely filled air-pillow under the abdomen, the X-ray tube being contained in a box under the couch), the shadows of the kidneys are shown one on each side of the vertebral column, and their movements up and down with respiration are easily observed. Should either kidney contain a calculus (stone), this is shown on the fluorescent screen, and it is seen to move with the kidney on respiration.

In a large proportion of cases in which there are symptoms suggesting the presence of a calculus, the Röntgen-ray examination shows that no calculus is, in fact, present. On the other hand, cases are by no means uncommon in which one or more calculi are found by the Röntgen-ray examination, when the clinical examination had led to an entirely different diagnosis. In these cases the calculi may be removed by the surgeon, and the patient cured.

There is another, an indirect, method of studying the digestive canal. For this method we are indebted to Prof. Rieder, of Munich, who discovered that large doses of bismuth salts may be given to patients without fear of ill effects. The salt used by Rieder in the first instance was the sub-nitrate. Unfortunately, several cases occurred in America in which the administration of large doses of sub-nitrate of bismuth was followed by fatal results, and we now know that this result was due to the formation of nitrous acid in the stomach, probably through the action of bacteria The carbonate of bismuth is now commonly used, and it is a perfectly inert and harmless substance. Two ounces is the dose usually employed, though three or four ounces may be given at a time. It is important to use a pure preparation, for the presence of arsenic or selenium as an impurity becomes an important source of danger where large doses are used.

By placing the patient upright in front of the X-ray tube, and trans-illuminating him in an oblique direction, the course of the food-pipe is revealed, occupying a clear space in front of the vertebral column. If the patient be now given an emulsion containing about two ounces of carbonate of bismuth to drink, the course of this drink from the mouth to the stomach can be observed upon the fluorescent screen, as the bismuth-containing fluid throws a very opaque shadow. Any obstruction in the food-pipe, or any deviation in its course, at once becomes apparent. The bismuth having passed through the food-pipe, it is now seen in the stomach occupying the most dependent part of that organ. The opening in front of the X-ray tube-box is now closed down to a small size, and this part of the stomach is examined in detail. The regular contractions by means of which the contents of the stomach are expelled into the small intestine may now be observed, and any irregularity in the shape of the stomach or obstruction at its orifice is clearly shown.

Some hours later the course of the bismuth meal may be clearly traced in its path through the large intestine, and here again the exact size, shape, and position of all parts of the large intestine is shown in strong relief through the opaque mass of bismuth with which the fæcal masses are mixed. These bismuth meals thus constitute a most valuable diagnostic method, and pathological conditions, the recognition of which is of extreme importance, are frequently shown in a manner more certain than is to be obtained by any other means of diagnosis.

One of the newest books dealing with the Röntgen-ray method of diagnosis as applied to diseases of the chest is that of Dr. Hans Arnsperger.[1] Improved apparatus and improved methods have led to so rapid an advance in this branch of study that few physicians have been able to keep pace with it. The literature is already large, and is rapidly extending. Dr. Arnsperger has given a full review of the literature, and has made a full and laborious exposition of the subject. He has lost no opportunity of discussing the application of the Röntgen-ray method to the elucidation of contentious problems in physiology and pathology. It is true some of the physiological views expressed by those who have studied the Röntgen-ray appearances do not tally with the results of physiological experiment; still, many important practical questions are discussed in a useful manner.

Dr. Arnsperger is careful to lay emphasis on the importance of using the Röntgen-ray method in conjunction with other clinical methods of diagnosis, for it is rarely safe to rely on a Röntgen-ray examination unassisted by a knowledge of the clinical history of the case. It is true that in a case of phthisis (for instance) the extent and distribution of the disease may be shown with great accuracy on the fluorescent screen or on a photographic plate, but in other cases the Röntgen-ray picture is capable of various interpretations, and the most useful information will be derived from the Röntgen-ray examination if the clinical aspects of the case are fully known. Dr. Arnsperger points out the advantages of the fluorescent-screen examination as compared with the examination of skiagrams. Screen examinations enable observations to be made of the living processes in the body, the movements of respiration, the beating of the heart, the pulsation in the aorta, the peristaltic contractions of the stomach, and so on. Skiagrams are chiefly useful in enabling permanent records to be obtained of the appearances described. In some cases, however, the skiagram shows more detail than is to be seen on the more coarse-grained fluorescent screen, and this applies particularly to the quiescent parts of the body, notably the bones and joints. Dr. Arnsperger's book contains twenty-seven plates, upon which fifty-two photographs are reproduced by the half-tone process. It is unfortunate that no known process of reproducing photographs in print represents successfully all the detail which the original negatives show.

A. C. J.

THE CYANAMIDE INDUSTRY OF FRANCE.[2]

In 1895 Frank and Caro laid the foundations of an important industry by discovering that barium or calcium carbide absorbs nitrogen at a temperature of 800°, and is converted into a cyanamide. They expressed the change by the following equation:—

$$CaC_2 + 2N_2 = CaCN_2 + C.$$

The cyanamide thus produced is a useful nitrogenous manure of the same class as ammonium sulphate, but has the further advantage of adding a calcium compound to the soil.

[1] "Die Röntgenuntersuchung der Brustorgane und ihre Ergebnisse für Physiologie und Pathologie." By Dr. Hans Arnsperger. Pp. 263+27 plates. (Leipzig: F. C. W. Vogel, 1909.) Price 12 marks

[2] A paper by M. Pluvinage in the Bulletin de la Société d'Encouragement pour l'Industrie Nationale, No. 3, vol. iii.

Cyanamide is made in France at the village of Notre Dame de Briançon, near to Montiers (Savoie). Abundant water-power is available, and is, of course, an essential condition for the success of the industry. At the power station there are now three turbines of 2200 h.p., but provision is made for more when necessary; these produce a three-phase current of 15,000 volts, which is conducted a distance of 11 km. to the factory. There it is transformed; part is used for making calcium carbide, and part for making cyanamide. The calcium carbide obtained has a purity of 80·5 per cent., estimated with sufficient accuracy by measuring the volume of gas evolved on treatment with water. Nitrogen is prepared by Linde's method. Liquid air is fractionated, and the vapours made to pass through a column, where they meet with liquid air, and then, higher up, with liquid nitrogen; in these circumstances, the percentage of oxygen in the issuing vapours is reduced to 7, and then finally to zero.

The calcium carbide is broken up and placed in an electric furnace, about 300 kilos. forming the charge. It is raised to a high temperature in presence of a stream of nitrogen; the operation may last from eighteen to fifty-six hours. The resulting hard mass is then reduced to a fine powder. The daily production is at present 10 tons, but this output could readily be doubled. It is estimated that 2 tons of carbide can be produced per kilowatt per year, and that 2 tons of carbide combine with 500 kilos. of nitrogen. Two grades of cyanamide are sold—one containing 15 per cent. of nitrogen, *i.e.* the quantity present in nitrate of soda, the other containing 20 per cent., the quantity present in sulphate of ammonia. The latter grade also contains 20 per cent. of lime, 7 to 8 per cent. of silica, oxides of iron and aluminium, and 14 per cent. of free carbon, to which the dark colour is due.

When added to the soil, it is rapidly decomposed by bacteria to form calcium carbonate and ammonia thus:—

$$CaCN_2+3H_2O=CaCO_3+2NH_3.$$

The ammonia is then nitrified and taken up by plants.

Direct field trials to ascertain its manurial value were first made in 1901 by Gerlach and Wagner, and have since been repeated in other countries. All experiments prove its value, and show that it is comparable in its effects with sulphate of ammonia. It should be applied before sowing, and may be mixed with basic slag or potassic manures, but not with superphosphates. The dressing recommended is 150 kilos. to 250 kilos. per hectare, or $2\frac{3}{4}$ cwts. to $4\frac{1}{2}$ cwts. per acre, the smaller dressing for cereals, the higher for potatoes and beets. In England it would not be customary to use for these crops more than half the above quantities of "artificial" nitrogenous manures.

THE "PREHISTORIC HORSE" OF BISHOP'S STORTFORD.

A COMPLETE skeleton of a horse was recently found during excavations at Bishop's Stortford. As this skeleton lay in an extended position some six feet below the surface in a deposit which had apparently never previously been disturbed by man, it is conceivable that it belongs to a wild variety which inhabited England in prehistoric times. The Rev. Dr. Irving first thought the skeleton might belong to Hipparion (*Standard*, May 24), but he eventually came to the conclusion that it is the remains of a horse of the Neolithic or Bronze age.

Unfortunately, it seems to be impossible to determine the age of the deposit in which the skeleton was found. The examination of the skull, teeth and limbs indicates that the Bishop's Stortford horse differs from all the known wild horses of the Pleistocene period—from, *e.g.*, the small, stout horse of the "elephant" bed at Brighton; the small, slender-limbed horse of the Oreston Cavern, believed by Owen to be an ass or a zebra; the Prejvalsky-like diluvial horse of Remagen; and the coarse-limbed horse of Westeregeln. On the other hand, the horse described by Dr. Irving and figured in the *Illustrated London News* (June 5) closely resembles a variety from Walthamstow believed to be of Neolithic or Bronze age. This Walthamstow horse was probably a blend of a "forest" and a "steppe" variety in which the broad-browed forest ancestors were dominant. The limb bones indicate that the Bishop's Stortford horse measured from 14 to 14·2 hands (56 to 58 inches) at the withers—several inches more than the Walthamstow horses represented in the British Museum.

It is generally assumed that the horse did not live under domestication in Britain until the end of the Bronze or the beginning of the Iron age, and that the native British horses up to the coming of Cæsar were too small to carry men. The Bishop's Stortford horse was, however, as large and powerful as the Galloways used in border raids. Should the Bishop's Stortford horse be proved to be of Neolithic or Bronze age, we may have to modify our views as to the size of the horses in the possession of the ancient Britons. For an opportunity of examining the skull and limb bones of the Bishop's Stortford horse, I am indebted to the Rev. Dr. Irving.

J. C. EWART.

METEOROLOGICAL STUDIES AT THE BLUE HILL OBSERVATORY.[1]

(1) THIS is an account of the methods employed and the results obtained at St. Louis. Seventy-seven ascensions were made, and in most cases good traces were obtained. The funds were supplied partly by grants from the Exposition Company and from the Hodgkins fund of the Smithsonian Institution, and the remainder by Prof. Rotch.

A very large proportion of the balloons were found, a proportion looked upon with envy by those engaged in similar work in England, and this occurred notwithstanding the fact that they were mostly sent up in the evening to escape the chance of solar radiation.

A full description of the method of working and of calibrating the instruments is given, and every care seems to have been taken to secure accuracy in the results; but it is incorrect to say that the only method of making the registration yet devised is that of writing on a smoked metal surface. The plan of scratching on an electro-plated but unpolished silver surface has answered excellently in England, and Mr. Field's plan of using glass silvered lightly by the ordinary solution seems to be quite satisfactory.

The results from each ascent are published in full, and it appears that about half the ascents afforded records up to 10 kilometres in height. The general conclusion is in striking agreement with that obtained

[1] (1) "Exploration of the Air with Ballons-sondes at St. Louis and with Kites at Blue Hill." By H. Helm Clayton and S. P. Fergusson. Pp. 92; 11 plates. (Cambridge, Mass.: The Observatory, 1909.)
"Annals of the Astronomical Observatory of Harvard College." Vol. lxviii., part i., Observations and Investigations made at the Blue Hill Meteorological Observatory, Massachusetts, U.S.A., under the direction of A. Lawrence Rotch.
(2) "Annals of the Astronomical Observatory of Harvard College." Vol. lviii., part iii., Observations and Investigations made at Blue Hill Meteorological Observatory, Massachusetts, U.S.A., in the year 1905, under the direction of A. Lawrence Rotch. Pp. 147–228; 2 plates. (Cambridge, Mass.: The Observatory, 1908.)

on the Continent and in England, excepting that the minimum temperatures are somewhat lower there than on this side of the Atlantic. This is probably on account of the lower latitude. The gradients for the various seasons are given, but the distribution of the ascents is not wide enough to make these figures of much value. Thus the value of the upper part of the gradient for the spring is obtained from ascents on sixteen consecutive days in the spring of 1906, and we have no ground for assuming that these sixteen days represent the average spring conditions.

There is also a discussion of the results obtained from the kite ascents at Blue Hill. The values of the pressure, of the departures from the normal of the temperature, of the humidity, and of the direction and strength of the wind at different heights are plotted for the various segments of cyclones and anticyclones, and the curves and tables are well worth careful study.

(2) In addition to the ordinary observations and to those made by means of kites during the year, there is a general summary for the period 1901–5, and a table of mean temperature for the twenty years 1886–1905. Although the great difference of climate on the eastern and western sides of the Atlantic is well known, one cannot help feeling surprise on being reminded by a publication of this sort how great the difference is. Thus at Blue Hill, in latitude 42° 12′ 44″ N., a latitude further south than any part of France, and, be it remarked, closer to the Gulf Stream than many parts of England are to the Atlantic, we find that, on the average, the ponds are covered with ice from the end of November to the end of March, while in England, 10° further north, few people under twenty-five years are able to skate, owing to the almost total absence of opportunity during recent years. The difference is, of course, due to the prevailing westerly winds, which bring the temperature of the Atlantic to western Europe and the continental temperature of North America to the Atlantic coast of Canada and the United States.

There is also a very interesting account of the meteorology of total solar eclipses by Mr. H. Helm Clayton. In the brief space of a review it is not possible to refer to this in detail, but the tables give a collection of the changes that have been observed on various occasions. The temperature effect is perfectly plain, and is shown to vary with the intensity of the natural solar radiation at the time and place. It is pointed out how difficult it is with the other elements to separate the changes due to the eclipse from the casual and diurnal changes that are going on at the same time, but it appears to be proved that the barometer and hygrometer are influenced.

The shadow bands of the eclipse are discussed by Prof. Rotch, who comes to the conclusion that they are produced by rays from the narrow crescent of light passing through strata of different refractive index, the motion being due to the wind.

AUGUST METEORIC SHOWER.

ON August 10 the sky was watched for $1\frac{3}{4}$ hours, but only 19 meteors were noticed, of which 12 were Perseids. The shower seemed disappointingly feeble.

On August 11 it became evident that the display had greatly intensified. In $2\frac{3}{4}$ hours before midnight 73 meteors were counted, and they were nearly all Perseids from 46° + 58°. Very few large ones were seen; in fact, the meteors were generally small, and the display could not be regarded as a very conspicuous one. The sky became rather foggy towards midnight, and many small meteors must have been hidden. The vapour increased, and next morning after sunrise there was a thick autumn-like fog, which was not dispersed until the sun had risen high.

On August 12 the atmosphere was beautifully clear when night came in, but meteors appeared to be scarcely so numerous as on preceding night. They were, however, of astonishing brilliancy, and made the shower a very attractive and notable one. In all 65 meteors were counted between 9h. and 12h. 52m., but clouds partially veiled the sky after 11h. and obscured many which would otherwise have been seen. Relatively to the total number counted, I have never, within a long experience, remarked such an abundance of fine, flashing meteors. Their long, graceful flights and highly luminous trails added to the interesting and striking nature of the spectacle. A fireball at 9.42 gave a lightning-like flash, and must have presented its best effect to observers at London and in the eastern counties. The following were the recorded paths of a few of the most brilliant objects :—

Aug. 12 h. m.		Mag.		Apparent path ° ° ° °
9 42	...	3 × ♀	...	5 + 27 to 357 + 15
9 42	...	♃	...	330 + 19 ,, $320\frac{1}{2}$ + 4
9 51	...	> 1	...	7 + 53 ,, 343 + $40\frac{1}{2}$
10 4	..	♃	...	$302\frac{1}{2}$ + 37 ,, 291 + 22
10 4	...	1	...	302 + 8 ,, 292 − 8
10 4	...	♃	...	265 + 1 ,, 259 − 15
10 18	...	♃	...	$352\frac{1}{2}$ + 24 ,, 340 + $3\frac{1}{2}$
10 14	...	1	...	17 + 37 ,, $12\frac{1}{2}$ + 30
10 19	...	♃	...	349 + 51 ,, $318\frac{1}{2}$ + 34
10 37	...	> 1	...	$342\frac{1}{2}$ + 25 ,, $326\frac{1}{2}$ + 6
10 43	...	> 1	...	358 + 62 ,, 332 + 51
10 46	...	♃	...	349 + 31 ,, 331 + 9
10 49	...	> 1	...	18 + 20 ,, 12 + 1

These were all Perseids, and duplicate observations would be valuable as furnishing data for the computation of the real paths. The very clear summer weather has recently offered an almost unique opportunity for studying the progress of the shower during its approach to the maximum.

The finest meteor which appeared during the display was recorded on August 12 at 9h. 42m. It lit up the sky like a flash of lightning, and left a streak which remained visible for several minutes. The fireball was observed at Bristol by the writer, and also by the following :—Observers at Greenwich; Dr. W. J. S. Lockyer, London; Howard E. Goodson, S. Kensington; H. Wilkie, Bognor; R. Langton Cole, Havant; J. S. Sowerby, Tatsfield, Surrey; T. K. Jenkins, Blaina; George Powell, Aberdare. The meteor was a magnificent specimen of the Perseids, and was quite noteworthy, even during a shower which consisted of unusually brilliant members. Its radiant point was at about 47° + 58°, and it passed over the earth from above a point ten miles W. of Ipswich to a point about 15 miles E. of Croydon. Its height was from 87 to 53 miles, length of path 68 miles, and velocity about 35 miles per second. The observations from Hayling Island, Bristol, and S. Kensington are in excellent agreement. The streak was generated in the latter portion of the flight. As viewed from Bristol, the nucleus brightened several times, and just where the outbursts had occurred the streak exhibited sections which were intensely luminous. From Hayling Island this streak lay 4 degrees under α and δ Cassiopeia, and during the short interval it remained in sight it assumed a serpentine form and drifted two or three degrees to the westwards.

The following are particulars of four brilliant meteors recently seen and estimated = ♃ :—

Date	Aug. 8	Aug. 10	Aug. 11	Aug. 12
G.M.T.	10.8	11.15	9.57	10.19
Height at first	94 m.	87 m.	103 m.	78 m.
,, end	65 ,,	52 ,,	48 ,,	52 ,,
Length of path	58 ,,	62 ,,	110 ,,	52 ,,
Velocity per sec.	48 ,,	40 ,,	—	30 ,,
Radiant	41+57	43+56	43+58	47+58

On August 13 the watch was continued, but the Perseid shower had greatly declined. About 25 meteors were recorded in about 2 hours before 11h. 45m. (when clouds came over), and of these 11 only were Perseids.

On August 14, observing for a similar interval, 19 meteors were counted, including 7 Perseids. The principal minor shower seen at Bristol recently was at 302°+22° in Vulpecula, and the same radiant was well marked in 1908, both in July and August.

W. F. DENNING.

NOTES.

ON Monday, August 16, an exhibition of manuscripts, portraits, medals, books, and natural history specimens illustrative of Darwin's life and work was opened to the public in the central hall of the Natural History branch of the British Museum. Although most of the special portion of the exhibits is displayed in one of the bays on the right side of the hall, a table-case, containing illustrations of the fertilisation of plants by insects and other animals, and a second devoted to insectivorous plants, have been placed in the middle of the hall. In addition to these, several of the permanent cases in the hall, such as those illustrating melanism, albinism, adaptation to natural surroundings, and the breeds of domesticated pigeons, are included in the exhibition. In order that the public may properly appreciate and understand the exhibition, an excellent little guide-book has been published, at the price of sixpence, in which, in addition to a brief but comprehensive biography of Darwin, and a photograph of the Darwin statue in the museum, will be found clear explanations of the leading features of the more important exhibits. These exhibits, apart from the two botanical cases, form a total of no fewer than 251, and certainly make a most instructive and interesting display. In the compilation of the guide-book it would have been better had the author avoided the use of words of the type of "exoskeleton," which are certainly not understood by the general public. As regards the specimens displayed, we must refer our readers to the guide, or, better still, to the exhibition itself.

THE fourth International Congress of Aëronautics will be held at Nancy on September 18–24.

MR. H. E. HARRISON, principal of Faraday House, and a fellow of several scientific societies, died on August 12 at fifty years of age.

CAPTAIN H. E. PUREY CUST, R.N., assistant hydrographer of the Navy, has been appointed hydrographer in succession to Rear-Admiral A. M. Field, F.R.S., whose term of office in that appointment has expired.

REUTER messages from Tokio report that a severe earthquake was felt at 3.30 p.m. on August 15 throughout Central Japan. Much damage was done to the important commercial city of Nagoya, which was practically destroyed by the earthquake that visited the district in 1891. Considerable damage is stated to have been done in part of the Shiga Prefecture.

WE learn from the *Times* that on August 12 the Italian balloon *Albatross*, manned by Lieut. Mina and Signor Piacenza, and starting from Turin, reached the height of 38,715 feet, at which point one of the two aëronauts opened the valve. The highest altitude previously attained in a manned balloon was 35,500 feet, reached by Berson and Süring on July 31, 1901. The new record is equivalent to an altitude of 7·3 miles, and shows the great heights which can be attained when improved means of respiration are employed.

WE record with regret the death, on August 14, of Mr. William F. Stanley at eighty-one years of age. Mr. Stanley was well known as a maker of scientific instruments; in 1856 he invented the first simple open stereoscope, and later he designed and manufactured scientific instruments for the use of various Government departments. He was the author of several text-books, and in 1895 he published "Notes on the Nebular Theory in Relation to Stellar, Solar, Planetary, Cometary, and Geological Phenomena," the book being reviewed in the issue of NATURE for November 14, 1895 (vol. liii., p. 25). In addition to other beneficent acts, Mr. Stanley erected and equipped at Norwood the Stanley Technical Trade Schools, where boys are educated on thoroughly practical lines. The schools have been endowed adequately, and are for the future to be administered by the Charity Commissioners.

As has been already announced, the ninety-second annual meeting of the Société helvétique des Sciences naturelles will be held this year at Lausanne on September 5–8. The business of the meeting will be conducted in six sections, as follows:—section of physics and mathematics, president, Prof. H. Dufour; chemical section, president, Prof. H. Brunner; section of geology and geography, president, Prof. Lugeon; agronomic section, president, Prof. E. Chuard; botanical section, president, Prof. E. Wilczek; and the section of zoology and physiology, president, Prof. E. Bugnion. On September 6 two lectures will be delivered, one by Prof. S. Finsterwalder on aërodynamics in aviation, and the other by M. Auguste Forel on comparative psychology, determinism, and the theory of memory. Three lectures will be delivered on September 8 at Vevey, as follows:—M. Fritz Sarasin, on the history of the animal life of Ceylon; M. Raoul Gautier, on some recent important results furnished by astronomical photography; and M. Martin Rikli, on the natural history of Greenland. Full particulars of the meeting may be obtained from the general secretary, Prof. Paul L. Mercanton, the University, Lausanne.

To *Annotationes Zoologicae Japanenses*, vol. vii., part ii., Dr. N. Annandale, of the Indian Museum, communicates a paper on Japanese freshwater sponges, in which an apparently new species is described. Of the five known Japanese species, three are widely distributed and the other two peculiar to Japan.

THE combined July and August issue of *Naturen* contains an important paper, by Messrs. Bjon Helland-Hansen and Fridtjof Nansen, on annual fluctuations in the mean temperature of the sea on the Scandinavian coast and their influence on the climate, agriculture, and fisheries of Norway. The paper is illustrated with a large number of temperature-charts.

IN the August number of the *Irish Naturalist* Mr. C. B. Moffat suggests that one reason why certain species of birds construct covered nests is to enable them to rear a larger number of nestlings than would otherwise be possible. The author supports this theory by mentioning that out of the eight species of Irish birds which make domed nests, six lay larger clutches of eggs than birds which are content with open nests.

The August number of *British Birds* contains reproductions from eight very remarkable photographs of a water-rail taken by Miss E. L. Turner. Some of these exhibit the bird in the act of removing its young from the nest; but whether this action represents a normal or an abnormal trait remains to be decided. To have obtained these beautiful photographs of such a shy and wary bird as the water-rail is a great triumph for the artist. We may also refer to a note by Mr. F. J. Stubbs, in which attention is directed to the fact that on certain Yorkshire grouse-moors there is no heather or heath, the place of which is taken by crowberry, and that on such grounds the birds, so far as can be ascertained, are free from disease.

We have to welcome a new biological serial, the Transactions of the Royal Society of South Africa, of which we have received the first part of vol. i., comprising 319 pages of text and twenty-four plates. Among the more important articles, reference may be made to Mr. R. B. Newton's report on Cretaceous shells from Zululand. Many of these are identical with or nearly allied to South Indian Cretaceous forms, especially those from the Trichinopoli group; and it is specially interesting to note that some of these indicate a connection between the Cretaceous fauna of Trichinopoli and Angola. This suggests that the great tropical land-barrier shown in Neumayr's map of the Jurassic epoch had become partially broken up by Cretaceous times. Another important communication is the first part of Dr. L. Péringuey's descriptive catalogue of South African Coleoptera, dealing with the family Meloidæ.

Owing to a severe outbreak of a fungal disease in the mulberry nurseries near Srinagar, connected with the silk industry in Kashmir, Dr. E. J. Butler was deputed by the Indian Government to investigate the matter. The results of his investigation are published in the Memoirs of the Department of Agriculture in India (vol. ii., No. 8). The disease was traced to *Coryneum mori*, a fungus of the Melanconiales, previously recorded only from Japan. The fungus is a wound parasite which found its opportunity after a severe frost; it was also discovered on mulberry trees outside the nursery, and on a jungle tree, *Celtis caucasicum*. Reference is also made to three other fungi: *Septogloeum mori*, producing leaf-spot; *Phyllactinia corylea*, a mildew; and the bracket-fungus *Polyporus hispidus*—none of which, however, were doing much damage.

The curious instances of polymorphism in the flower which occur in the orchid Cycnoches are described by Mr. R. A. Rolfe in the *Kew Bulletin* (No. 6), where he provides a revision of the genus. The production of flowers so different in appearance puzzled Lindley and other botanists until the solution was found in the dissimilarity between staminate and pistillate types. Nine species are recorded for which both types are known, and in six cases only the staminate flowers have been definitely identified. Two sections of the genus are recognised; in the Eucycnoches the difference lies chiefly in the column and attached sexual organs; in the Heteranthæ the distinction is more marked, as the staminate flowers are smaller, sometimes different in colour, and the lip is reduced to a small disc margined with clavate teeth.

Investigations on abstruse points in plant morphology have within recent years engaged the attention of several Austrian botanists. Two papers appear in the *Bulletin International* (1907), the official publication of the Académie des Sciences de l'Empereur François Joseph I., Prague. Miss M. Doubek contributes a discussion of the much-debated nature of the tendrils in the Cucurbitaceæ. An explanation is constructed on the hypothesis of adnation by different axes. The least complex examples—they cannot be described as simple—are furnished by Luffa and Cucurbita, but the author also offers solutions of the more difficult cases provided by Bryonia, Cyclanthera, and other genera. The second paper, communicated by Dr. B. Nemec, deals with regeneration in the unifoliate plant *Streptocarpus Wendlandii*. Some of his experiments were made with irregularly regular specimens bearing two well-developed cotyledons.

The arrangement of the botanical garden of the Johns Hopkins University, which is described in the University Circular (No. 217), shows some novel features. The garden, which is being established primarily as an aid to botanical research and instruction, is divided into four sections. Two are planned for the cultivation of typical forms illustrating vegetative and reproductive organs. The third is devoted to plant relationship, as exemplified by species, genus, &c., extending to systems of classification for which Engler's system is selected for complete exposition. The fourth section contains two divisions, one for economic, the other for cultivated plants. The latter should be quite the most interesting feature in the garden. The three genera Dianthus, Rosa, and Chrysanthemum are chosen as types to indicate the origin and natural relationship of horticultural races. Cultivated roses are arranged under fifteen sections, and in addition eight groups of hybrids are illustrated.

A pamphlet published by the Hawaiian Sugar-planters' Association as Bulletin No. 9 of the division of pathology and physiology is devoted to an investigation by Messrs. L. Lewton-Brain and Noël Deerr of the bacterial flora of Hawaiian sugars. Sugar agar was the most satisfactory medium, as, for some reason undetermined, it was impossible to get a good gelatin preparation. Another difficulty was presented by what the authors term a "weed-bacillus" that produced its spores within twenty-four hours, and so escaped sterilisation. The practical object was to isolate and identify types of bacteria with the view of studying their action on moist sugars. Five different types were distinguished by the shape of the individuals or of the colonies formed in different media; their general action is to reduce the sucrose and form invert sugar, gum, or other products in sugars containing 1 per cent. or more of moisture.

The Purdue University Agricultural Experiment Station has issued a pamphlet (Circular No. 15) on the growth of onions, an important crop in northern Indiana to which many hundreds of acres are annually devoted. The methods adopted on the large scale are described at length, and suggestions are offered for improvement; curing and marketing are also dealt with. Another pamphlet deals on similar lines with the Indiana cantaloup industry. In Bulletin No. 134 Messrs. Hunziker and Spitzer discuss methods for the estimation of fat in unsweetened evaporated milk. Since the introduction by the Act of Congress, 1906, of the new pure food standards requiring a definite minimum per cent. of fat and solids in evaporated milk, the product from numerous milk-condensing factories has been found below standard, rendering them liable to prosecution by Government and State authorities. It was known that no fat was removed by the firms in question, and the authors show that the fault lies in the method of analysis, the ordinary Babcock method failing to show all the fat in evaporated milk. A suitable method, giving correct results, is described.

THE introduction of labour-saving machinery on the farm has been one of the principal features of the modern revolution in agriculture, and has been rendered necessary by the difficulty of getting sufficient help. Few contrivances are more interesting than the milking machine. Rubber funnels are fitted on to the teats and connected by stout tubing to a milk-can; the pressure is diminished by a pump to about half an atmosphere when the milk begins to flow. A lengthy test has been made at the Wisconsin Agricultural Experiment Station, and is recorded in Bulletin No. 173. The machine worked more quickly and more cheaply than a man; it yielded a cleaner milk, which therefore kept better, and, finally, was shown to have no injurious effect on the udders or the general health of the animals. The machine, of course, requires proper attention and careful driving to get the best results, but proved decidedly economical in herds of thirty cows or more. There are already signs that the agricultural labourer of the next generation will be, in the main, an engineer.

WE have received from Mr. Stewart J. McCall, Director of Agriculture, Nyasaland, an interesting pamphlet on the growth of cotton in America. The four types dealt with are (1) Sea Island cotton, a small high-quality crop, forming less than 1 per cent. of the total American crop, but very important by reason of its quality; (2) upland cotton, short staple, the principal variety in commerce; (3) upland cotton, long staple, which has only been introduced within the last few years, and is almost exclusively confined to the rich bottom lands of the Mississippi; (4) Egyptian cotton, introduced to supply the manufacturers' demand for a lustrous cotton, well adapted for mercerisation. The pamphlet is written for the African cotton grower, and great stress is laid on the necessity for keeping out of Africa the cotton weevil, which has done incalculable harm in America, and made cotton cultivation impossible in some places. Mr. McCall suggests that all seed imported from America should pass through a Government Department for examination and treatment. The question of distributing insect and fungoid pests by artificial means has to be considered seriously. Unfortunately, our administrators are often insufficiently in touch with scientific problems to realise that a small pest which could at little expense be kept out of a country may do great damage once it is introduced.

THE mixed population of Manila, which includes almost all races of mankind in varying degrees of purity, has afforded to Mr. R. B. Bean an unrivalled opportunity of studying the different types of human ears, and formulating, for the first time, a morphological classification of the same. His results, which are published in the first number of vol. iv. of the *Philippine Journal of Science*, cannot fail to be of great interest to anthropologists. Names, such as Malay, Negroid, Cro-Magnon, Alpine, &c., are given to these various types of ears, which are characteristic of definite physical types of men, although it does not necessarily follow that they are also distinctive of all members of the races whose names they bear. The Alpine ear is, for example, the ear of the fat man. In the Philippines the author finds that ears not of European origin are morphologically older than those of European type, and from these data he draws certain conclusions as to the evolution of the modern Filipinos.

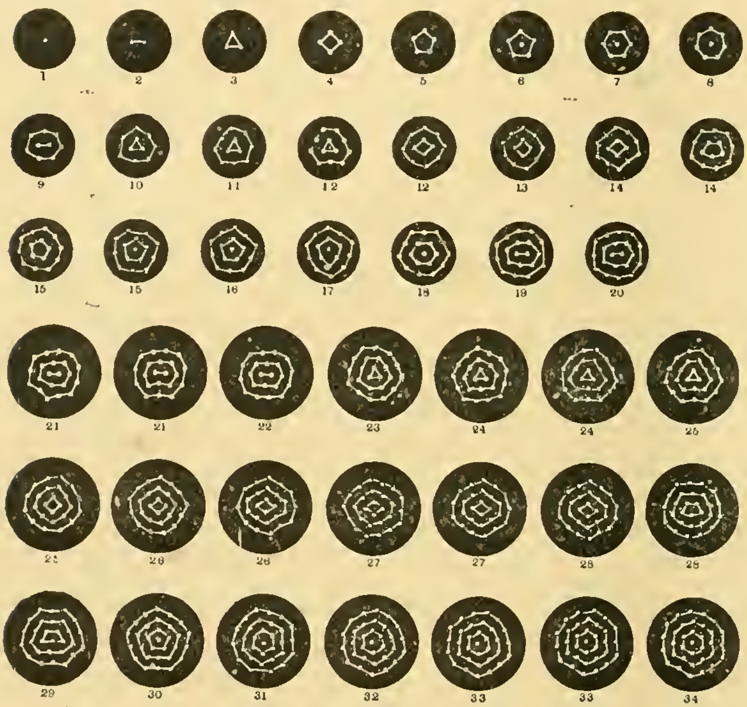
DR. F. ERK, director of the Bavarian Meteorological Service, has contributed to part i., vol. iii., of "Beiträge zur Physik der freien Atmosphäre" an interesting paper on the relations of the upper inversion of temperature to the areas of high and low atmospheric pressure. The author, who has the experience of a critical examination of daily weather conditions during the last twenty-five years, assumes, from the labours of recent investigators, that the relatively high temperatures of the region of the upper inversion (the "stratosphere") arise from the absorption of radiation, not from the surface of the earth, but from strata of some 4000 metres in height. He discusses at considerable length the effects of the descending air in the high-pressure areas of the upper regions and of the advance of the low-pressure systems towards the stratosphere, and shows how a registering balloon on entering the stratosphere must first meet with a rapid increase, and afterwards with a gradual decrease, of temperature. Photograms of the curves obtained during ascents at Hamburg and Munich on the same day and with similar instruments exhibit these phenomena very clearly, and show the desirability of the more frequent publication of results in this way instead of tabular statements only.

A NEW recording rain gauge made by Messrs. Negretti and Zambra, which the makers have named the hyetograph, is now procurable, and supplies a much-needed want. Meteorologists have looked forward to the time when a simple register should be obtainable of the duration and amount of rainfall day by day. The instrument has the advantage of great simplicity, and it is scarcely possible for it to get out of order. The only movable parts are the clock drum, the float, and the pen lever. The hyetograph practically gives equal results with the necessarily more expensive Halliwell's patent rain gauge, of which Messrs. Negretti and Zambra are also the makers. The funnel is 8 inches in diameter. The float has the capacity for measuring 4½ inches of rain, which is the maximum amount likely to occur in one day in almost any locality in Great Britain. The spindle attached to the float has a number of pins or projections, and these engage successively with a lever arranged so that when the pen reaches the top of the chart, wound round the clock drum, the lever disengages with the pin or projection and falls by its own weight on to the next lower pin, which is so placed as to allow the pen to fall to zero on the chart. The whole of the working parts are protected by a stout galvanised iron cover, and the water collected is removed by a hand-started syphon. The hyetograph complete, with 100 special charts, costs 6*l*. 15*s*.

THE "Report of a Magnetic Survey of South Africa," upon which Prof. J. C. Beattie, of Cape Town, and coadjutors have been engaged, with the aid of Royal Society and colonial grants, for a series of years, has now been published by the Royal Society at the price of 20*s*. net. It forms a quarto volume with numerous maps and plates, uniform with Rücker and Thorpe's Survey of the British Islands. Copies may be obtained from the Cambridge University Press Warehouse.

WE learn from the *Amateur Photographer* that Messrs. Aldis Bros., of Birmingham, have perfected a periscope lens which enables the observer to see completely round the horizon without movement of either himself or the lens. It consists of a ring of glass with an outer curved surface, while the inner surface, which is inclined and plane in one direction, serves to reflect the light that enters the system down the axis of the vertical tube that carries the lens at its upper part. A reflecting prism enables a horizontal eye-piece to be used. The lens has already been approved by the Admiralty for use in the conning towers of submarines. A photograph taken by it gives a well-defined annular picture of the view as seen in every direction around it.

WE have received a copy of a paper, by Mr. Louis Derr, on a photographic study of Mayer's floating magnets (Proceedings of the American Academy of Arts and Sciences, vol. xliv., No. 19, May). Although it is now recognised that inferences made in regard to the structure of matter from the exact behaviour of such floating systems must be received with caution, yet the groupings obtained are so suggestive that any fresh study of them is of interest. Mr. Derr has endeavoured to obtain a



Photographs of systems of floating magnets.

much more complete series, which he has photographed in order to show the progression from one form to another more clearly than can be done by tables. The magnets were clear $\frac{1}{4}$-inch steel balls, floated on freshly filtered mercury, as described by Prof. R. W. Wood, but initially magnetised by placing them one by one between the poles of an electromagnet. In the plate (part of which we reproduce) the balls as photographed have been connected together afterwards by lines, in order to bring out more obviously to the eye the formation in concentric groups. Many of the forms differ from those calculated by Sir J. J. Thomson; since the stability depends upon the exact law of force between the magnets—and in the experiments this is different from the law assumed in the calculations—the divergence is not to be wondered at.

THE May number of the Bulletin of the Bureau of Standards contains a description of a new method of determining the focal length of a converging lens system, by Mr. Irwin G. Priest. The method depends on the measurement of the diameter of one of the circular rings of the Fabry-Perot interferometer when seen through the lens by reflected homogeneous light. If viewed without the intervention of the lens, the ring system is localised at infinity, and with the lens a real image will be formed in the focal plane of the lens. The outer edges of the rings are sharp, and admit of accurate measurement of diameters by means of a micrometer. From two measurements of the diameters of the same ring with different distances between the interference plates, the focal length of the lens can be found with an accuracy of about half per cent., and if with the interference plates a fixed distance apart the constant of the apparatus be determined once for all, a single measurement of the diameter of a ring is all that is necessary.

THE four numbers of the Journal of the Royal Society of Arts issued in July contain the Cantor lectures on the public supply of electric power delivered by Mr. G. L. Addenbrooke before the society in January and February last. After describing with great clearness the present position of affairs, the lecturer points out in what directions we may reasonably look for improvements in the future. Whatever the improvements in prime movers, he believes that electrical power will still be the most suitable for factories. This power will, when gas engines and producers have been rendered more suitable and trustworthy, be produced by internal-combustion engines of the four- or six-cylinder type. He considers that the time now required to obtain a provisional order in the case of a power scheme should be greatly reduced, and wishes to direct the attention of legislators to the importance of facilitating the supply of cheap electric power.

NONE of the formulæ in common use connecting the pressure and temperature of saturated steam can be regarded as satisfactory. Any empirical formula should cover the whole range, give a fair representation of those experimental results which probably approximate most closely to the true relation, and should be easy of calculation. Mr. S. Godbeer, in an article in *Engineering* for August 6, presents a new formula which should be useful. For various reasons, a table given by Holborn in 1908, ranging from 0° to 205° C., together with experiments by Cailletet covering a range up to the critical temperature, have been used as data. A few irregularities have been corrected, and the formula is as follows:—

$$\log p = \frac{1319\,(t+226)\,(t+2299)^2}{192028\,(t+808)\,(t+329)} - 30\cdot203,$$

where p is the pressure in millimetres of mercury and t is the temperature centigrade. If pressure and temperature curves be drawn for the experiments of Cailletet, Battelli, and Knipp, it becomes evident that there is a sudden disturbance in the general trend of the curve between 240° and 270° C., and the author suggests that further experiments in this region of temperature would be interesting.

METAL-CUTTING by means of oxygen is now finding a place among engineering operations, and several interesting applications are given in *Engineering* for August 6. The instrument used consists of an oxy-hydrogen, oxy-coal-gas, or oxy-acetylene mixed blowpipe, through which an additional stream of oxygen can be supplied at will by the operator. The object is to heat to incandescence the part on which the jet of oxygen is afterwards to play, and to keep it at that high temperature all the time the oxygen jet is operating. This method has been found to overcome entirely the older difficulties with regard to unsteady manipulation of the oxygen jet, as well as the trouble due to the presence of iron oxide. Plates and slabs of steel up to 12 inches in thickness can be cut by this method. The cut is very clean, and, in one example illustrated, where a slab of steel 8 inches thick was cut into pieces $\frac{3}{4}$ inch in width, the width of the cut was only about $\frac{1}{4}$ inch, showing the intensely local nature of the operation. Another illustration shows an armour plate being cut circular by means of a special appliance carrying a blowpipe, the thickness of the plate in this example being 9 inches. The cut surfaces are left comparatively smooth, and the cut is square down from the face of the plate, although it is possible also to make bevel cuts. All grades of steel can be operated on.

MR. H. K. LEWIS, of Gower Street, London, has sent us a copy of a catalogue of the new books and new editions added to his medical and scientific circulating library during the second quarter of this year. The list will be sent post free to any address on application.

A SECOND edition of Prof. Marcel Moye's translation of Prof. Lowell's "Mars and its Canals" has been published at the office of the *Mercure de France*, Paris. The original volume has already been reviewed in these columns, and we are glad of this opportunity of congratulating Prof. Moye on the demand for a second edition of his translation of Prof. Lowell's interesting book. The price of the translation is five francs.

SIR WILLIAM RAMSAY'S volume of "Essays, Biographical and Chemical," which was reviewed in NATURE of July 29, has been translated into German by Prof. W. Ostwald, and published by the Leipzig Akademische Verlagsgesellschaft, under the title, "Vergangenes und Künftiges aus der Chemie." The German volume includes, in addition to the essays of the original work, an autobiographical sketch by Sir William Ramsay, occupying thirty-five pages.

OUR ASTRONOMICAL COLUMN.

OBSERVATIONS OF MARS.—Circular 110 from the Kiel Centralstelle announces that, at 2 p.m. on August 12, M. R. Jonckheere observed a brilliant spot detach itself from the polar snows of Mars and cover the Novissima Thyle, in longitude 320°.

In No. 4340 of the *Astronomische Nachrichten* M. Jarry Desloges records some observations of Mars made at the Massegros Observatory (Lozère) during June and July.

On June 20 and 23 a dark cutting was seen in the south polar snows, in longitude about 190°, and appeared to terminate in a rounded spot, which was of a darker shade. The crevasse observed by Prof. Lowell in longitude 350° was easily seen on July 4 with a 37 cm. refractor installed on the Revard plateau, and appeared to traverse the whole length of the visible part of the snow-cap. On the same day, at 4h. 15m. a.m., a broad, bright spot was seen on the dark edge of the snow in about longitude 30°.

RE-DISCOVERY OF PERRINE'S COMET.—A telegram from the Kiel Centralstelle announces that comet Perrine was discovered by Herr Kopff at 10h. 54m. (M.T. Königstuhl) on August 12. The position of the comet at that hour was R.A.=0h. 17·1m., dec.=35° 32′ N., and the magnitude was 15·0.

Of the three ephemerides given by Herr Ristenpart, the first (T=October 27·5) gives the nearest position to the above for August 12, the ephemeris place being

R.A.=0h. 40·2m., dec. 36° 45·9′ (1910·0).

THE NUMBER OF THE STARS.—In the August number of the *Observatory* (No. 412, p. 323) Mr. Gavin Burns directs attention to the discrepancy between the Groningen and the Harvard estimates of the total number of stars, and suggests that Prof. Kapteyn's estimate is probably excessive. Tabulating the figures given by each of the two observatories, he shows that from the tenth magnitude downwards the Groningen numbers are greatly in excess of those given by Prof. Pickering; for example, the respective totals, including all stars down to the 10·5 magnitude, are 697,551 and 604,000, but if the 13·5 magnitude be included they are 14,582,551 and 6,761,000. Then there is a note in the Harvard publication which suggests that if stars to the fifteenth magnitude were included the total would be raised to about 18 million, whereas Prof. Kapteyn's estimate for magnitude 14·5 is 38 million, and for magnitude 15·5 98 million. A published investigation of the Greenwich astrographic plates shows agreement with Harvard for the fainter magnitudes, and strengthens the suggestion that the Groningen estimates are too high.

THE FAINT COMPANIONS OF PROCYON AND SIRIUS.—During last winter Prof. Barnard employed the Yerkes 40-inch refractor on many occasions in an endeavour to detect and measure Schaeberle's faint companion to Procyon, but only on a few occasions was he successful. The results, which are published in No. 4345 of the *Astronomische Nachrichten* (p. 13, August 7), show that during the last five or six years the angular motion of the companion has been about 5·2° per annum, but the distance has changed but little. The weighted means, for 1909·162, were 22·51° and 5·26″ respectively. Prof. Barnard states that the least atmospheric diffusion of the light of the large star hides the close companion, and then explains a device which he uses to obviate the adverse effect of the stray light. This is to place a hexagonal diaphragm over the 40-inch object-glass so that the angles of the hexagon lie on the periphery of the glass. This collects the stray light into six thin bright rays, and the small star can be more easily seen in the dark space between a pair of the rays.

A similar device was employed in observing the faint companion to Sirius, and the measures made during the period 1903–9 are given in the same journal. These show that the angle is decreasing, from 115·38°, for 1903·808, to 92·53°, for 1909·135, whilst the distance is increasing, the values for the corresponding epochs being 6·32″ and 8·75″ respectively.

PROF. LOWELL'S NEW 40-INCH REFLECTOR.—A brief description of the new 40-inch reflector which Messrs. Alvan Clark and Sons are just completing for Prof. Lowell appears in No. 412 of the *Observatory*. The focal length is 18 feet 4 inches, and the mirror, cast at St. Gobain, is 7 inches thick and weighs more than 900 lb. The cell is an iron ring with zinc blocks so arranged that the combined expansion is the same as that of the glass, thus obviating distortion. For planetary photography the reflector can be used as a Cassegrain of 154 feet, or 75 feet, focal length, whilst for stars and nebulæ it will be used as a Newtonian with the plate at the principal focus. In order to protect the instrument from the wind, and partially from large temperature changes, it will be mounted in a pit sunk 6 feet into the ground, over which is erected a hemispherical dome of wood and canvas. The requisite diurnal motion is to be imparted to the instrument by two electric motors, one for driving, the other for slow motion.

WATER VAPOUR IN SUN-SPOTS.—In the July number of the *Astrophysical Journal* (vol. xxx., No. 1, p. 44) Mr. W. M. Mitchell discusses the various researches which have led to the suggestion that water vapour exists in sunspots. He points out that the spectroscopic evidence is not unanimous, either for or against, and is certainly not conclusive.

The affected spot lines may be due to other substances not yet identified, and giving lines of nearly similar wavelength. Then the apparent intensification may be a subjective effect, to which the varying intensities of the water-vapour lines in the normal Fraunhofer spectrum is a contributory cause. Mr. Mitchell suggests that very fine measures of the displacement of spot lines, caused by the sun's rotation, might settle the question as to the solar origin of the apparent intensification, and concludes that, as yet, the evidence adduced by various observers in favour of the presence of water vapour is by no means satisfactory.

THE PALISA AND WOLF CELESTIAL CHARTS.—Dr. Palisa announces that the second series of Celestial Charts, prepared by Dr. Wolf and himself, is now ready, the price, if ordered from him, being 30s.; the bookseller's price is 35s. After the end of November this series will cost the purchaser 40s., wherever purchased. Dr. Palisa's address is "The Observatory, Vienna, Austria."

THE PIMA AND TLINGIT INDIANS.[1]

THE introduction to the twenty-sixth annual report of the Bureau of American Ethnology (1904–5), 1908, by the chief of the Bureau, Prof. W. H. Holmes, indicates that the staff are zealously carrying on the work of the department. The report itself contains two excellent

FIG. 1.—Pima woman making pottery: supporting vessel on loose sand.

memoirs, one on "The Pima Indians," by Frank Russell, and the other on "Social Condition, Beliefs, and Linguistic Relationship of the Tlingit Indians," by John R. Swanton.

As Mr. Russell's memoir is a monograph of the Pima, he naturally pays a good deal of attention to the arts and crafts and food supply of the people, his account being fully illustrated. The Pima keep an annual mnemonic record of events by means of notched sticks. "The year notches are exactly alike. . . . Dots or shallow circular pits and short notches are the most common symbols on the sticks. These have no distinctive meaning, and are used for recording a great variety of events," but they never make a mistake. One man who lost his stick continued his history with pencil and paper, and this "introduced a tendency to use pictorial symbols rather than merely mnemonic characters, such as are most easily incised on the surface of a stick."

With all their surplus energies expended in warfare, the young Pima men formerly lived exemplary lives as compared with the youths of the last generation. Before the Pimas came in contact with "civilisation" chastity was the rule among the young women. On reaching puberty there were several taboos, and there was "danger" in the girl that must be breathed out by songs ere she, the members of her family, and the community as a whole were exempt from the hazard of the lightning stroke and other perils. The youths marry "early and often." In the majority of cases the choice is made by the girl, who seeks to avoid an alliance with a lazy man. Polygyny was practised to some extent, but the division of labour was such that no great economic advantage resulted. There were no groups within the tribe between which marriage was prohibited. Divorce was easily effected. They often had large families, and twins were received with general rejoicing. Male children were preferred, because "they would grow up to fight the Apaches." So strong was the feeling of the Pimas against the abnormal that they tried in recent years to kill a grown man who had six toes. Under the head of "Baptism" we find the following information:—at child-naming the child was held aloft to receive the first rays of the rising sun. Beads were formerly held up to receive the first rays of sunlight, and were then placed about the child's neck.

Descent is traced in the male line, and there are five groups that may be called gentes, though they exert no influence upon marriage laws, nor do they manifest any evidences of organisation so far as ascertained. The

FIG. 2.—A Piman holding a Calendar Stick.

Pimas are governed by a head chief and by a chief for each village. These men are assisted by village councils, which do not, Mr. Russell believes, appoint any representatives to the tribal councils. The head chief is elected by the village chiefs. The tribe acted as a unit against the dreaded Apaches. The slaves taken by the Pimas were chiefly from the ranks of the Apaches or their allies; they were well treated. The Pimas held possession of the best agricultural land in their section of the south-west, and were compelled to fight for the privilege. There was no law among them observed with greater strictness than that which required purification and expiation for the deed that was at the same time the most lauded—the killing of an enemy. Numbers of myths and songs are cited. The Pimas are far less given than their pueblo neighbours to the outward show of religion. The sun was appealed to. At the present time two deities are recognised, Earth Magician and Elder Brother. They live in the east, dividing the control of the universe between them. The stars are living beings. Some declared that at death the soul passed into the body of an owl, others that after death it went to the land of the dead in the east. Again, souls are supposed to hang about and perform unpleasant pranks with the living.

There are fourteen geographical groups or tribes of the Tlingit or Koluschan, each of which had at least one winter village and a section of coast where they camped

[1] Twenty-sixth Annual Report of the Bureau of American Ethnology, to the Secretary of the Smithsonian Institution. Pp. xxxi+512; 58 plates. (Washington: Government Printing Office, 1908.)

in summer and behind which they hunted in winter. As a whole, they are divided into two exogamous phraties with matrilineal descent, one called Raven, the other usually Wolf, and in the north Eagle as well. One small group outside both phraties could marry into either. Each was subdivided into clans or consanguineal bands, which originally appear to have occupied a particular camp. The larger geographical groups contained members of both phraties, and usually numerous clans. Finally, the clans are subdivided into house groups. Each clan claimed a few distinctive carvings and names; occasionally they might be borrowed. The house names and clan names were generally distinct, and confined to their respective phratry, but a man sometimes claimed the right to the house name owned by his paternal grandfather's clan, so that names sometimes go out of the clan. Those of a man's own phratry are called "friends," those of the opposite phratry "opposites" or "my outside shell." A list is given of the relationship terms. The importance of the phratry system is indicated by the rules of etiquette and the hospitality shown towards members of the same phratry, and the performance by the opposite phratry of certain functions at birth and death.

A mourning feast is given to members of the opposite phratry, food being put into the fire for the spirit of the deceased. All property given away or destroyed at a feast was dedicated to some dead person, who then actually received its spiritual counterpart. A Tlingit employed his opposites to do everything—put up his house and pole, pierce the lips and ears of his children, and initiate them into the secret societies. The secret society dances were imported from the south, but their observance by no means reached the importance attained among the Kwakiutl and Tsimshian. Whistles were essential concomitants of these dances. The putting up of a house or pole, and the accompanying secret society performance, feasts, and distributions of property were all undertaken for the sake of dead members of a man's clan. Rivalries between opposing parties of dancers at a potlatch often resulted in serious conflict, but the host's people often prevented them by rushing between them bearing their emblem or making the call of the phratry animal. A. C. H.

RECENT PUBLICATIONS ON AGRICULTURE FROM INDIA AND CEYLON.

THE recent issues of Circulars and Agricultural Journal of the Royal Botanic Gardens, Ceylon, contain interesting papers on cotton, *Hevea brasiliensis*, and other native crops. Mr. Lock issues a concise guide to the plots on the Experiment Station, Peradeniya, which will prove useful to visitors, and will, we hope, be the forerunner of a work setting out the general results obtained in the Ceylon experiments and the conclusions to be drawn from them. Mr. Petch deals with certain abnormalities in *Hevea brasiliensis*. Nursery plants with twisted stems are frequently sent in for examination and report. The stem generally makes a complete turn at the base, either in a regular curve or a combination of curves and abruptly angular bends; in other cases there are two complete turns, and in a single instance three have been observed. It was found possible to reproduce some of these abnormalities by varying the position of the seed in the soil. The insect pests—which mainly attack the root, since the rest of the plant is to a large extent self-protected by the viscid caoutchouc-producing latex—are dealt with by Mr. E. Ernest Green. Mr. Bamber deals in one pamphlet with tapioca, describing its method of cultivation in Malacca, and in another with the cultivation of strong-growing plants to overrun and "choke" weeds in rubber plantations. The plants suggested are *Passiflora foetida* and *Mikania scandens*; *crotolaria* is also used. When growth has attained its maximum, and before the plants die down, the whole mass of material, usually 12 inches to 18 inches deep, can be rolled up like a huge carpet, leaving the surface soil quite free from weeds. Mr. Jowitt describes several of the oil-yielding grasses, and Mr. Stewart McCall puts in a plea for the more extensive cultivation of cotton. Altogether the papers are fully up to the high standard we have learnt to associate with Peradeniya.

It has already been remarked in these columns that the *Agricultural Journal of India* ranks for general excellence among the best agricultural publications in the world, and the recent numbers in no way alter the impression. The list of articles includes several dealing with improved methods of cultivating cotton and paddy, besides a well-illustrated paper on improved implements of home-make adapted to the special conditions of the native cultivator. Mr. Maxwell-Lefroy deals with Eri or castor silk, and Mr. Marsh discusses certain indirect benefits of irrigation not generally recognised. Among these are the possibility of substituting new sowings in case of accidents to advanced crops, the certainty of fodder for the cattle, which are among the worst sufferers in time of drought, and the general improvement of the people and country which inevitably results when the conditions of life become stable. The journal is issued quarterly from Pusa, and the articles are well written from a general point of view; it may be confidently recommended to all interested in Indian affairs.

Probably no publication could give a better idea of the enormous size of India, and the great diversity of conditions, than the two volumes of agricultural statistics brought out by the Government of India. The first volume deals with British India, and contains 429 folio pages of closely printed figures; the second contains the records of native States, and is smaller. Comparing the year 1906–7 with 1897–8, the earliest given in the volume, we find the following areas, in acres :—

	British India		Native States	
	1897–98	1906–07	1897–98	1906–07
Net area cropped ...	196,497,232 ...	214,026,319 ...	10,120,324 ...	14,923,731
Irrigated...	30,418,454 ...	36,653,903 ...	1,425,895 ...	1,982,668
Total food grains ... (Rice, wheat, maize, pulse, &c)	182,725,689 ...	195,117,838 ...	9,126,337 ...	13,123,691
Other food crops ... (Gardens, orchards, spice, &c.)	5,773,267 ...	7,274,340 ...	369,392 ...	561,431
Total oil seeds ...	12,566,648 ...	13,965,315 ...	603,076 ...	836,335
Cotton	8,914,996 ...	13,771,214 ...	279,758 ...	625,694
Indigo	1,366,513 ...	448,594 ...	1,731 ...	18,182

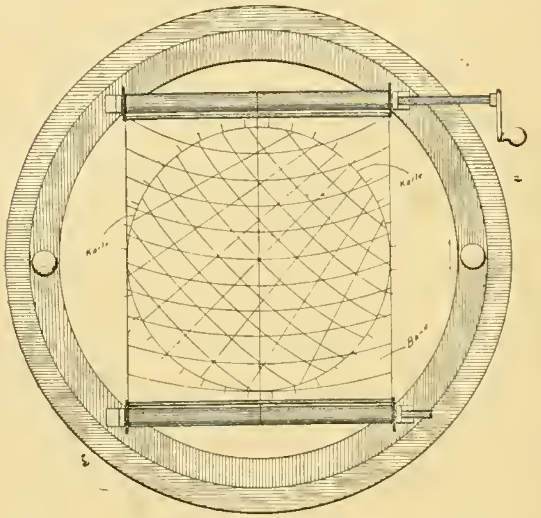
This steady, all-round increase in the area under the various crops furnishes abundant proof of the increasing prosperity of India, and must be a source of great gratification to the British administrators and advisers through whose labour it has been made possible. The one exception in the general prosperity is indigo. During the ten years the area has shrunk from more than one and a third million to less than half a million acres. The indigo planters are a highly enlightened body, and look to science to help them save the industry; their fortunes are very much involved in the contest now going on between the agricultural chemist and the synthetical organic chemist.

POSITION FINDING WITHOUT AN HORIZON.

THE Journal *Ila* of July 17—an aëronautical journal published at Frankfort—contains an article which in some respects is supplementary to that on the subject of position finding without an horizon which appeared in NATURE of July 22, or, as this article was the later in time, perhaps it would be more correct to say that it was supplementary to the one in *Ila*. The latter, which is written by Dr. Alfred Brill, relates to the reduction of observed altitudes for the purpose of finding position by means which can be quickly and readily effected in a balloon. After showing the inconvenience of the usual trigonometrical methods used on board ship, and how tiresome the use of tables must be which correlate time, latitude, declination, and altitude, he proceeds to describe his method, which is one eminently suitable and convenient, that is, where a graphic method is sufficiently accurate.

Dr. Brill employs a circular map of, say, Central Europe on transparent celluloid, the projection being one of least distortion. Before and behind this are two more sheets of celluloid, with the Sumner equal altitude circles drawn on the same projection. These sheets each have a central longitudinal azimuth line, while the map is provided with a circle of degrees round its periphery. The two Sumner sheets can be moved longitudinally on rollers like blinds, and these two and the included map may be turned in-their own planes relatively to one another, so that the azimuth line of either Sumner sheet always passing the centre point of the map may be brought to any bearing in relation to the map. Now the observation of altitude of a star at a given sidereal time having been made, a table calculated for stars of that declination and for the centre point of the map is consulted so as to ascertain what is the altitude and azimuth for the particular star at the moment of observation at the mid-point of the map. One Sumner sheet is then rolled until the line representing this altitude is over the mid-point of the map, and one is turned relatively to the other until the mid-line on the Sumner sheet is over the tabulated azimuth on the scale of degrees outside the map. Then the observer at the time of observation was somewhere on the Sumner line representing the observed altitude truly projected over the map. The corresponding observation of a second star is similarly transferred and the corresponding Sumner line on the other sheet brought into position. The observer is then at the point of intersection of the two Sumner lines of observed altitudes.

It will be seen that the device and tables are of a simple character, and that by their aid the principle of the Sumner method is applied graphically, so that the position may be



seen by inspection. The figure shows the map and one of the Sumner sheets only, the one behind not being shown to avoid confusion.

ARCHÆOLOGICAL AND ETHNOGRAPHICAL EXPLORATIONS.

FULL details have now reached this country of the remarkable discovery made by Dr. D. B. Spooner, of the Indian Archæological Survey, in the neighbourhood of Peshawar. Hitherto the site of the great Stupa erected at the ancient city of Purushapura by the Kushan Emperor Kanishka, who ascended the throne about 123 A.D., to enshrine the relics of Gautama Buddha, was unknown. It was described by Hieuen Tsang and other Buddhist pilgrims from China as far the most famous and magnificent of the pagodas in India. A few years ago M. Foucher, the eminent French archæologist, suggested that it lay beneath certain tumuli in the neighbourhood of Peshawar. Excavations conducted by Dr. Spooner corroborate this identification.

The ruins are of great extent, and within the pagoda the relic chamber was reached. In it was discovered a metal casket enclosing a rock crystal reliquary. The outer casket, cylindrical in form, has a lid in the form of a lotus supporting three figures in the round, a seated Buddha in the centre, with a standing Bodhisattva on either side. Round it is an elaborate frieze in low relief of flying geese bearing wreaths in their beaks and figures of the Buddha, with a large, standing figure of the Emperor himself in the well-known attitude in which he appears on his coinage. The casket bears the signature of a Greek artist, Agesilaus, who describes himself as "superintendent engineer" of the monastery. Incidentally the casket throws much light upon the Græco-Indian art of the age, and supports the view that the Gandhara school was in a state of decadence.

The actual relics consist of three small fragments of the bones of the Buddha. The question of the ultimate disposal of these remains will excite much interest in the Buddhist world, and the Indian Government will doubtless consider the claims of the Burmese, Siamese, and Sinhalese religious foundations to share in the custody of relics which, like the alleged tooth of the Buddha at Kandy, are sure to receive the homage of millions of pilgrims drawn from the Buddhists of Eastern Asia.

The return is expected shortly of an expedition undertaken in 1907, under the auspices of the trustees of the British Museum and the council of the Royal Anthropological Institute, and conducted by Messrs. E. Torday, W. M. Hilton-Simpson, and N. H. Hardy, to examine the customs and culture of certain tribes in the Upper Congo region. The chief tribes which came under examination were the Batalela, Basonge, and, in particular, the Bakuba, the true name of which is now found to be Bashongo. The latest news showed that the explorers had reached the Loange river, and after exploring the hitherto unknown Tukongo people, they hoped to penetrate the Kasai region, and to return thence to Europe in September next. Large materials in the shape of photographs, maps, phonographic records, and ethnographical collections have already reached England, and a selection from them has recently been placed for exhibition in the Ethnographical Gallery of the British Museum.

Much information has been collected regarding the almost unknown Bashongos, one of the most remarkable tribes in Africa. They have preserved much of their tribal history and legends, and are particularly famous for their skill in weaving and wood-carving. Some portrait statues of their kings are remarkable works of art, exhibiting a degree of artistic skill hitherto unknown in Africa outside ancient Egypt. Their embroidered cloths, made of palm-leaf fibre, in the oldest and best examples, suggest a distinct resemblance to Celtic art. They possess a decayed form of totemism, and records of their remarkable rites of initiation, recently discontinued, have fortunately been recovered.

Mr. C. H. Read, of the British Museum, who is largely responsible for the organisation of this important expedition, may be congratulated on the successful collection of a mass of novel ethnographical material about these hitherto unknown races, which must throw much-needed light on the ethnology of Western and Central Africa.

THE MICROSCOPE AND ITS PRACTICAL APPLICATIONS.

AMONG scientific instruments, the microscope is at the present time one of the most extensively employed, either for commercial or scientific purposes. In nearly all branches of science it has now become a necessity, both as an essential factor in preliminary training and for advanced investigations or pure research work, while in commerce its uses are so wide and varied that it is difficult to see to what practical purposes it may not sooner or later be applied.

That this is the case may be due to many causes, and a by no means negligible factor is the simplification in construction and design that has in recent years been effected in the mechanical portions of the instrument and in its essential optical parts. In this respect, perhaps, a microscope differs from the majority of scientific instruments, as in most of the latter elaboration of construction—often, it must be admitted, quite unavoidable—is the usual rule; but for general purposes microscopes were never more simple in design than at the present time. This simplicity has not been obtained at the expense of loss of efficiency, but rather the contrary. The cost, too, has been greatly reduced, so that unless objectives and other optical parts of the highest class are required, a complete microscopic outfit may now be obtained of good quality and of high efficiency for a few pounds. The same, however, can scarcely be said if objectives of the finest quality are required, but this is rarely necessary for commercial purposes or for laboratory use unless work of a highly critical nature is to be carried out.

In our present state of knowledge it may almost be said that the science and practice of microscopic optics has reached such a stage of perfection that it is difficult to foretell in which direction the next improvement is to be looked for, much less the means by which such may be effected. Attempts have been made to increase optical efficiency, particularly by various dark-ground illumination methods, but it must be confessed with somewhat disappointing results. While such methods assist in demonstrating the presence of particles or isolated objects not easily seen, or even invisible by other means, the resolving power of the optical system is not improved. The most promising development has been in the apparatus introduced by Messrs. Carl Zeiss for use with ultra-violet light. This certainly held out a prospect of definite increase in resolving power being obtained, and in some directions has probably justified its existence. For the ordinary worker, however, the great cost of the necessary appliances, the more than usual skill required in its manipulation, the necessity of using special mounting materials, as well as the impossibility of observing any object mounted in the ordinary way on glass, has prevented its use for any but very special purposes.

For a long time a form of microscope stand, known as the Continental model, in which the instrument was supported on a foot of a horseshoe shape, practically held the field; but English makers, fortunately, to a large extent maintained their more stable method of support by means of a tripod foot. The latter not only admits of the microscope body being more conveniently swung, but also ensures that at any inclination of the body-tube the centre of gravity of the instrument is well within the triangle formed by the three points of support. With the horseshoe foot this is not the case, as the point of support is usually in such a position that at any considerable inclination the instrument is unstable, while in a horizontal position for photomicrography or projection, some Continental types are so unevenly balanced that they will not even stand alone, much less allow of the proper use of their various adjustments. This may be in part overcome by clamping the instrument down to some stable base for such special purposes, but no microscope with any pretension to be regarded as well designed should require that precaution.

The influence of this condition is now being felt very largely, and most Continental makers are either adopting a more stable method of support approximating to the English model, or are embodying the English type in their later makes of stands. In some cases a fusion of the two types appears to have been attempted, with certainly beneficial effects, but unfortunately the objections to the Continental model are still to be met with in some that have only in part realised the advantage of the English design. Continental microscopes have also long been open to the objection that their substage arrangements are altogether too cramped, and as it is only for very special purposes that a microscope is of necessity a portable instrument, the reason for this is not easily seen; certainly some more space underneath the stage, a greater range of action of the substage condenser, and considerably more freedom of movement of the mirror, would result in the production of a more convenient style of instrument.

It is extraordinary how widespread the applications of the microscope are at the present time. A recent article on its use in metallurgy and engineering, by Mr. W. Rosenhain, which appeared in these columns (vol. lxxx., p. 250), has sufficiently and clearly indicated its value in this direction. It is well enough known that in trades like brewing the microscope has played a very important part, and, in fact, it may be said that all trades which are concerned in the production or use of fluids for human consumption—at least where the work is carried out on anything approaching a large scale—are now compelled to have the service of a trained microscopist. Dairy workers, mineral-water makers, and all authorities concerned with the supply of pure water for drinking purposes, are equally interested in the question.

As indicative of how great is the interest in this direction, it may be mentioned that the Cunard Steamship Company and the White Star Line have inquired of well-known makers for instruments and complete outfits suitable for their use. The presumption is that they intend to initiate some method of microscopically examining the water supply on their vessels, constituting, in fact, a miniature Water Board to ensure that their water supply is as free from any bacterial or similar contamination as even that to be obtained in great centres of population.

As indications of some other directions in which microscopes are being utilised, it may be mentioned that chemists and druggists, paper manufacturers, makers of Portland and other cement, such as the Associated Portland Cement Company, foundrymen, printers and half-tone block makers for photographic reproduction purposes, quarrymen, linen, cotton, and silk manufacturers, and various other allied trades, are using microscopes at the present time. Petrological microscopes, in the development of the design of which great improvements have been made of late, are being applied now for testing stone and for supplying architects with exact information as to the structure and quality of the stone supplied by quarrymen, and as to the suitability of such material for building purposes.

As the result of a series of lectures given to laundrymen by Prof. Herbert Jackson, of King's College, an interesting further use of the microscope has recently arisen. Some large laundries and dyeing and cleaning establishments are now installing a microscopical outfit. The result of this may be fairly widespread, as it will now be possible, when a customer brings an article to be cleaned or otherwise dealt with, to determine its exact constitution before any effort is made to carry out the process. The result may be that an article which has been, for example, described originally to the purchaser as pure silk may at once be recognised by the laundryman as something totally different, and he may thus be saved from many unpleasant recriminations and possible legal claims by obtaining definite knowledge of the article before doing any work to it. One single thread detached from the article will usually supply all the information required, and will, in addition, often decide the best method or process that can most suitably be employed to effect the desired renovation.

There is still need, however, for much educational work in the use of the microscope, and it is much to be regretted that there appears to be no institution where systematic instruction in its various uses and possible applications can be obtained. Even an elementary course in the use of the instrument, suited to the requirements of the student, would be more than useful. Medical students and others, who may sooner or later engage in research work, are too often given the barest instruction in microscopic technique, and it is easy to see that, could they but have even a short course of instruction—which should be regarded, not merely as incidental to, but as an absolutely necessary preliminary portion of their class work—then much of the rough-and-ready usage seen in the course of laboratory work might be avoided. It seems almost absurd that a student who is taking a course in bacteriology or pathology, which at its best requires the very highest knowledge of the use of the microscope, should usually receive little or only the barest and most superficial instruction in the methods of use of the instrument. With the great increase in the number of applications of the microscope, it may become essential that means should be provided for teaching systematically the elements of the theory of microscopic optics and the methods of using the instrument and its optical parts, and it is to be hoped that at no distant time this necessity will be recognised in some institutions of higher education.

J. E. Barnard.

RECENT IMPROVEMENTS IN THE INTERNAL-COMBUSTION ENGINE.[1]

III.

We have now to consider the way in which the recent great practical improvements in the design and operation of gas engines and gas-producing plant have come about, and how they are connected with the theoretical considerations referred to in the previous articles.

Despite the multitudinous ways in which the internal-combustion engine is employed, there is a general assortment into three main groups, which may be described thus:—

(*a*) Large gas engines for gas blowing, for the generation of electric power or other power purposes, the size being usually more than 1000 horse-power.

(*b*) Smaller gas or oil engines used for workshop driving, in sizes up to about 500 horse-power.

(*c*) Petrol engines for road transport, for marine work, and for aëroplanes, the sizes being usually less than 100 horse-power.

With class (*a*) are associated pressure gas producers, frequently worked with by-product recovery plant, and schemes for the utilisation of the waste gases of coke ovens and blast furnaces. The gas engines in class (*b*) usually derive their gas from suction gas producers, which are practically always of smaller size than the 500-horse-power unit, though attempts are now being made to work with the larger units suitable to marine work. H.M.S. *Rattler* is one of the very first instances of the application of the suction gas producer to marine purposes, and it has been remarkably successful. Looming in the distance is the prospect of using suction gas producers and gas engines in smaller units for road transport, but the difficulty of finding space on the present type of motor-car for the whole of the plant is a great one. On the other hand, the considerable economy in fuel to which this development would lead is an inducement to proceed with the endeavour to overcome these difficulties.

By far the most numerous class of internal-combustion engine is that of class (*c*), which includes the thousands of motor-cars and cycles now in use in all civilised countries. The fuel used is not invariably petrol, as successful attempts have been made to run on alcohol, benzol, and the heavier elements in the paraffin series. Ordinary commercial paraffin has recently been used with extraordinary success, particularly in tropical countries, and it is even reported from Uganda that the combination there of altitude with high temperature enables paraffin to be used as a fuel in small engines without any change in the usual petrol carburettor as used in this country.

Improvements in Class (a).

The chief direct practical improvements in this class are the better proportioning of parts, so as to avoid cracking by unequal heating, and the better general design of the fly-wheel effect in conjunction with such an arrangement of cylinders as to produce a more even turning moment, and therefore less cyclic irregularity. The former is evidenced by the greater trustworthiness to-day of the big engine, and the latter is abundantly illustrated by the following extract from Messrs. Andrews and Porter's recent paper[2] before the Institution of Electrical Engineers:—

"The large gas engines at the Bruckhauser, Homecomb and Heinitz installations visited by English engineers in August last are all provided with fly-wheels to maintain a cyclic irregularity within 1/250. The two former are single tandem engines, and the latter twin tandem, but no appreciable difference in the parallel running was noticeable."

The information derived from recent experimental work on piston and wall-temperatures will probably lead to still further improvements in the mechanical design of details, as once the conditions of the heat flow are known a proper proportioning and subdivision of parts is rendered possible. The recent improved trustworthiness of operation is shared equally by the two-cycle engines (such as the Oechelhauser, Koerting, and others) and the four-cycle engines, and it is very difficult to say that either type is gaining ground at the expense of the other. By-product recovery work is becoming better understood, although there is always the difficulty that the by-products, when produced, have to be sold, and one has therefore to take into account the effect upon the market price should a largely increased output result from the extended use of such plant. The utilisation in gas engines of the waste gases of coke ovens and blast furnaces is now very usual. This is especially so in Germany and Belgium, where a great deal of work has been done in this direction; in the United States there has been a rapid increase in the adoption of this process, whilst in this country matters have moved appreciably, although, owing to the low cost of fuel in England, there is not the same economic pressure to make the change. On Tyneside an excellent plan is in operation, whereby engines running on waste gases are made to generate electric power, which is then supplied to, and paid for by, the central electric generating station. By this method of pooling the current, which, of course, cannot be economically stored, but has to be used as fast as it is produced, the complicated questions as to its utilisation are avoided.

A notable recent improvement in the ignition of gas engines of all sizes is the adoption of the electric system with either low-tension or high-tension currents. On the whole it seems likely that, as with motor-cars, the latter will in the end become the most used, though at present the low-tension system with moving contacts inside the cylinder seems to be the most popular.

Improvements in Class (b).

In both this class and class (*a*) it is noticeable that the engines designed on the Continent are more complicated in appearance than those designed here. The British desire for simplicity doubtless is, at the root, a good one. One of its most noticeable illustrations in modern life is the steam railway locomotive. As applied to the gas engine, this desire takes effect in the much simpler method of governing. The usual English plan is to govern on the "hit-and-miss" principle, that is to say, when the engine runs up to too fast a speed the cylinder for one or more cycles will get no charge of gas at all, or else (which comes to the same thing) the ignition will be cut off and no explosion take place (this, though a very simple means of governing, is wasteful in fuel). The average Continental design provides for the throttling (as in a steam engine or by varying the lift of the inlet valves) of the entering charge, so as to cause a less intense explosion. This tends towards a steadier speed, but on the other hand leads to a constant lowering of the compression ratio, and therefore to a diminished thermal efficiency and an increased rate of fuel consumption.[1] In England the difficulty of speed fluctuation, to which the adoption of the hit-and-miss principle leads, is met by increased fly-wheel effect or by dividing the power between a number of cylinders, but several well-known English makers are now governing by throttling the mixture.

The standard of achieved thermal efficiency is continually rising, although the amount of the improvement is the less easy to state on account of the very optimistic way in which certain experimental readings seem to have been taken. Much depends upon the ratio of compression, and many attempts have been made to permit of a high compression pressure without pre-ignition. This has been successfully attempted in several ways, viz. by the method of water injection, so lowering the compression temperature corresponding to a given pressure, or else by the method of supercompression, which consists of causing the in-coming charge to be at a pressure of from 5 lb. to 10 lb. above the atmosphere, so that here also a higher pressure corresponds to a lower temperature, and sometimes by the method of decreasing the proportion of hydrogen present, and so raising the temperature at which the mixture would be liable to pre-ignition. In the usual form of suction producer, the proportion of hydrogen pre-

[1] Continued from p. 203.

[2] "The Use of Large Gas Engines for Generating Electric Power." Read before the Institution of Electrical Engineers, 1909.

[1] In a specific case the reduction of the compression pressure from 170 lb. to 120 lb. led to an increase in the thermal units used per horse-power from 9500 to 11,500.

sent is usually about 20 per cent., and a method of lowering the amount which has been employed recently is to admit exhaust gases into the producer in place of the usual water supply. The CO_2 then takes the place of H_2O as an energy absorber, and the chemical composition of the resulting gas is so greatly affected that the hydrogen sinks to less than 1 per cent. Another recent improvement in the suction gas producer is the regulation of the water admitted, so that the composition of the gas may be the same, no matter whether the "draw" of the engine is vigorous or slight. Without some such device the gas tends to become "wet" at the lower loads, and the producer to "go dead." To avoid this, the water supply to the producer has to be cut off, or greatly reduced, in proportion as the governor is cutting out working strokes in the engine.

Improvements in Class (c).

These are exceedingly numerous. The most recent decided change has been the adoption of the sleeve type of valve in the Daimler engine. Despite apparent drawbacks from the theoretical point of view, it has lately undergone an extremely severe test under the officials of the Royal Automobile Club, and has emerged victorious. It is understood that a number of other manufacturers are now considering the adoption of the slide type of valve.

Another innovation is the use of air pressure to force the fuel up from low-lying tanks to the carburettor. This is claimed to be an improvement on the exhaust pressure feed, as being less likely to choke. As regards heavy oil engines, the chief improvement to be noticed is the widespread use of water injection, which is even more useful here than in a gas engine on account of the very low pre-ignition point of mixtures of oil vapour and air.

Attempts have continually been made to produce an engine working on the two-cycle principle, and there would seem to be no reason why engines of this kind should not be as practically successful as any built to operate on the four-cycle principle. One would expect that in this way a lighter engine could be built, and lightness is a great asset, particularly in the most recent use to which the internal-combustion engine has been put, viz. aëroplane work. Wonderfully light engines have already been made for this purpose. The 50 horse-power engine on the aëroplane *Silver Dart* weighs only 220 lb. without oil and water, or 4·4 lb. per horse-power. The 50 horse-power "Wolseley" V-type eight-cylinder engine, built for aëroplane work, is reported to weigh only 340 lb., or 6·8 lb. per horse-power, although the engine is fitted with a water-cooling system. The somewhat similar 80 horse-power engine fitted to Mr. Moore Brabazon's aëroplane is reported to weigh only 366 lb., or 4·6 lb. per horse-power; this is also a water-cooled engine. The possibilities of the different types of engine have lately been summarised in the technical Press[1] as follows:—

Type of engine	Weight per brake horse-power lb.	Weight of 50-brake horse-power engine lb.
Four-cylinder vertical	8	400
Eight- ,, diagonal	6	300
Diagonal, with several cylinders grouped on one crank pin ...	4	200
Rotary	3	150

From this it appears that engines amply light enough for aëroplane work have already been built, and there is not much scope left for any improvement in this direction for which the two-cycle engine would be useful, although there is still room for general improvement by the avoidance of the use in the engine parts of all heavy materials of low mechanical strength. On the other hand, the lighter the engine the better, as it means the possibility of adding additional accessories that make for constancy of operation, such as duplicate ignition, ample water-cooling arrangements, &c. The aëroplane appears to offer little chance of an "altitude stop" to permit of the engine being adjusted, and constancy of operation is therefore the one essential thing so far as the motor is concerned.

Carburettors are continually being improved, but the ideal one, which will give a constant mixture at all speeds and all loads in all weather conditions, has yet to be invented. The high-water mark as regards fuel economy that has so far been reached is the performance of the White and Poppe carburettor in the 1907 Royal Automobile Club trials of commercial vehicles. This carburettor was fitted to a Maudslay car, and showed the very high "figure of merit" of 62 gross ton miles per gallon of petrol, which is nearly twice as good as was obtained from the average car of that time. In the last two years the average has, however, risen appreciably. This, with an assumed road resistance of 50 lb. per ton, would correspond to an efficiency of power transmission between the carburettor and the road wheels of no less than 15 per cent. What the road resistance really was is not known, but now, without doubt, such road resistances ought to be accurately measured and the results applied.

Conclusion.

With such a rapidly moving industry as that of the internal-combustion engine, prophesy is even more unsafe than it usually is. Writers have been bold enough to look forward to solid explosives being employed, but there one is faced with the difficulty of selecting any form of solid explosive that would have an entirely gaseous exhaust. When the gas turbine has taken practical shape, this consideration may be of less importance. Indeed, the combination of a solid explosive with a gas turbine promises this advantage, that the difficulty of the initial compression would thereby be removed. On the other hand, if we may judge by analogy with the steam turbine, provided that it were possible to keep the exhaust pressure sufficiently low, a high initial pressure would not be essential to economy. Whatever may be the outcome of the present experiments with gas turbines, or of gas producers, suitable for marine purposes on the one hand or to road transport on the other, one may be certain that the days of the external-combustion engine, the steam engine, are numbered, and that the engineers of the near future will not be satisfied with any less degree of efficiency than that which the internal-combustion engine will afford. One seems to see in the world of engineering the working of a continuous process leading to the supersession of those ideas, which, though old and tried friends, are found to produce less efficient results than those obtainable by more scientific methods. There is no reason that the writer can see to doubt the continued operation of this process during the present rivalry between the steam engine and the internal-combustion engine.
