

The
TROPICAL
AGRICULTURE

ES. 2,016.

Supplement to this day's issue.

"Step after step the ladder is ascended."—George Herbert, *Jasuka Prudentum*.
Agriculture is the most healthful, most useful, and most noble employment of man."—WASHINGTON.

THE
TROPICAL AGRICULTURIST:

(ESTABLISHED 1881.)

A MONTHLY RECORD OF INFORMATION FOR PLANTERS

OF

TEA, CACAO, COFFEE, PALMS, RUBBER, CINCHONA, SUGAR,
FIBRES, COTTON, TOBACCO, SPICES, CAMPHOR, RICE,

AND OTHER PRODUCTS SUITED FOR CULTIVATION IN THE TROPICS:

Circulating in India, Ceylon, Burma, Straits, Java, Sumatra, Borneo, Northern Australia,
Queensland, Fiji, Mauritius, Natal, East and West Africa, West Indies, South and Central
America, California, Southern States, and throughout Great Britain.

EDITED BY

J. FERGUSON,

Of the "CEYLON OBSERVER," "CEYLON HANDBOOK AND DIRECTORY," "PIONEERS OF THE
PLANTING ENTERPRISE," PLANTING MANUALS, "CEYLON IN 1893" (ILLUSTRATED), &c.

"It is both the duty and interest of every owner and cultivator of the soil to study the best means
of rendering that soil subservient to his own and the general wants of the community; and he, who
introduces, beneficially, a new and useful *Seed, Plant or Shrub* into his district, is a blessing and an
honour to his country."—SIR J. SINCLAIR.

VOL. XXI:—Containing Numbers I. to XII. : July, 1901, to June, 1902.

CEYLON: A. M. & J. FERGUSON, COLOMBO.

LONDON:

JOHN HADDON & Co.; KEWAN PAUL, TRENCH, TRUBNER & Co., LTD.; LUZAC & Co., &c

TO OUR READERS.

In closing the Twenty-first Volume of the "**Tropical Agriculturist**," we would as usual direct attention to the large amount of useful information afforded and to the great variety of topics treated in the several numbers. From month to month, we have endeavoured to embody in these pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business-men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, besides being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the index pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of common sense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

Special attention has, for a few years back, been given to the introduction and extension in Ceylon, the Straits, Burmah, &c., of an industry in rubber-yielding trees (more especially in the planting of Para and Castilloa trees), and much literature on the subject will be found throughout our pages; also on cacao in Central America and the West Indies as well as in Ceylon; to "Spices" of various kinds (nutmegs, camphor, &c.); to palms, especially "coconuts" in different districts; to coffee and allied products in Brazil, Mexico, Costa Rica, East Java, Nyassaland, British Central Africa; Liberian coffee in Sumatra, Java, the Straits Settlements; and to other new developments in palms and tobacco planting, &c., in the Malayan Peninsula, Sumatra and North Borneo, as well as in this Island.

The Tea-planting Industry has sprung into so much importance in India (South as well as North) and Ceylon, as also in Java, that a considerable amount of space is naturally given to this great staple; and with reference to all Companies' Reports, to Sales and Prices, as well as to hints for economising, we think it will be admitted by impartial judges that the *Tropical Agriculturist* should be filed, for the convenience of planters, in every Tea Factory in this Island, in India and in Java.

A full and accurate Index affords the means of ready reference to every subject treated in this, the Twenty-first Volume, which we now place in our subscribers' hands, in the full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

To show how fully other Products besides Tea are treated in this volume, we may mention the number of entries under several headings as follows:—Coffee (including Liberian) 28; Cacao 20; Indiarubber 59; many to Gutta Percha; to Coconuts and other Palms, Rice and other Grain, Cinchona, Camphor, Cloves, Fibres, Tobacco, Fruits and Miscellaneous Products nearly 1,000. In the 21 volumes, the references to Rubber, Cacao and Coffee number many thousands, as also to Coconuts and other Palms.

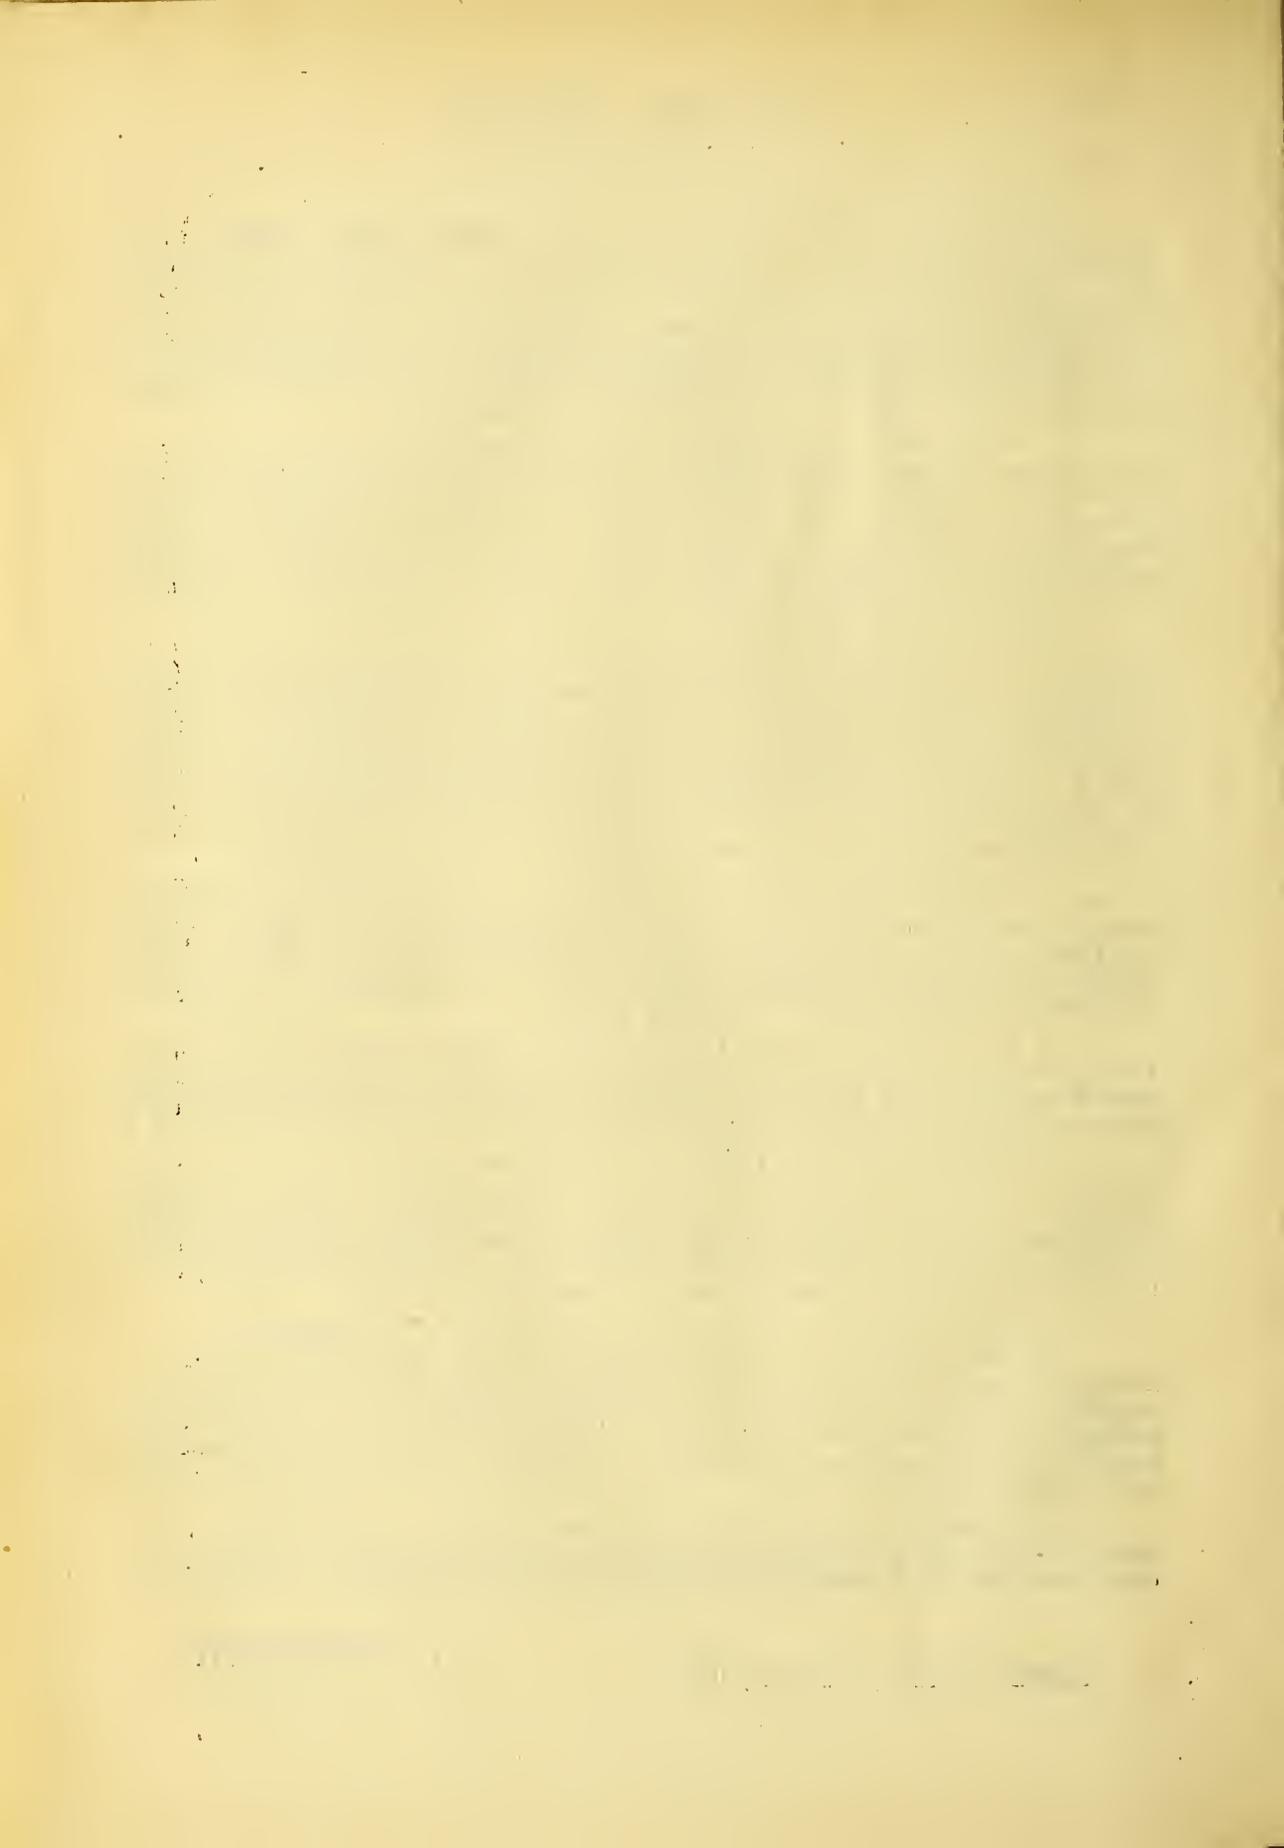

A "Topical Index" to the twenty-one volumes is in course of preparation.

We are convinced that no more suitable or useful addition can be made to a Planting Company's Library or gift to a tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the twenty-one volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industries.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "**Tropical Agriculturist**" continue to do well.

J. FERGUSON.

UNIVERSITY OF MICHIGAN LIBRARY

12

 All Planters of New Products or Pioneers in new lands should not fail to order this periodical as their best instructor.—Every Tea Factory, Coconuts or Cacao Store ought to have a file of the TROPICAL AGRICULTURIST, which contains a vast amount of information about these products, and a Record of the Tea and other Produce Sales.

The Portraits and Biographies of some more OLD COLONISTS AND PLANTING PIONEERS are likely to appear in the next Volume.

ORDER FOR THE
"TROPICAL AGRICULTURIST."

.....1902.
Sirs,

Please forward the above publication from the beginning of Vol. XXII, 1st July, 1902.

Please send also (lettered as for.....Estate)
Vols. I, II, III, IV, V, VI, VII, VIII, IX, X, XI, XII, XIII, XIV, XV, XVI, XVII, XVIII, XIX, XX, ^{AND}_{OR} XXI, for 1881-2, 1882-3, 1883-4, 1884-5, 1885-6, 1886-7, 1887-8, 1888-9, 1889-90, 1890-91, 1891-2, 1892-3, 1893-4, 1894-5, 1895-6, 1896-7, 1897-8, 1898-9, 1899-1900, 1900-1901, ^{AND}_{OR} 1901-1902.

I am, Sirs,

Yours faithfully,

.....
To Messrs. A. M. & J. FERGUSON,

"CEYLON OBSERVER" OFFICE,

COLOMBO, CEYLON.

SUBSCRIBERS TO THE

* "TROPICAL AGRICULTURIST" *

are reminded that with the June Number, already received by them, and the Index and Title-page now issued, the TWENTY-FIRST VOLUME (1901-1902) is closed.

SUBSCRIPTIONS are due payable in advance for 1902-1903, at the following rates:—

For Ceylon and India { <table style="display: inline-table; vertical-align: middle; border-left: 1px solid black; border-right: 1px solid black; padding: 0 10px;"> <tr> <td style="padding: 0 5px;">Yearly</td> <td style="padding: 0 5px;">Rs. 12</td> </tr> <tr> <td style="padding: 0 5px;">Half-yearly</td> <td style="padding: 0 5px;">Rs. 7</td> </tr> </table>	Yearly	Rs. 12	Half-yearly	Rs. 7	For Europe, &c. { <table style="display: inline-table; vertical-align: middle; border-left: 1px solid black; border-right: 1px solid black; padding: 0 10px;"> <tr> <td style="padding: 0 5px;">Yearly</td> <td style="padding: 0 5px;">£1 6.</td> </tr> <tr> <td style="padding: 0 5px;">Half-yearly</td> <td style="padding: 0 5px;">15s.</td> </tr> </table>	Yearly	£1 6.	Half-yearly	15s.
Yearly	Rs. 12								
Half-yearly	Rs. 7								
Yearly	£1 6.								
Half-yearly	15s.								

N.B.—Subscribers to the *Ceylon Observer* or *Overland Ceylon Observer* Rs. 4 (6s.) LESS per annum.

Single copies, Rs. 1; back copies, Rs. 1½.

Per Bound Volume, Rs. 16; or £1 6s.

Those who have not settled for past subscriptions are requested to do so by return of Post, and to send Cheque, Post Office Order, or Bank Draft in favour of A. M. & J. FERGUSON, Colombo.

Covers for binding the Twenty-first Volume, July 1901 to June 1902 (862 pages) can be obtained for Rs. 1-50. Cost of binding and cover Rs. 2-50.

WHAT IS THOUGHT OF THE "TROPICAL AGRICULTURIST."

A gentleman resident in the Central Province, who has a good opportunity of knowing what is of benefit to Planters as anyone we know, sent us the following explicit testimony to the value of the "T.A." :—

"Since its commencement, I have regularly seen and perused the *Tropical Agriculturist*. There can be but one opinion that its scope and object are highly important, and that it supplies a distinct desideratum, which it is to the interest of every estate proprietor, to have available in the bungalow for the use of his *locum tenens*, or superintendent. As a magazine it provides varied and instructive fresh literature at intervals; deprived, as most in Ceylon are, of easy access to libraries; and as years go by it will growingly become 'The Ceylon Encyclopædia' with reference to agricultural operations. Viewing estate property as practically a permanent investment to any proprietor, the trifling charge of Rs. 12 per annum—a rupee a month—is certainly of no account, provided the separate numbers are kept and bound together yearly as a book of reference for the benefit of the manager and his successors. In that light, as the property of an estate to be handed over just as much as its office furniture, few proprietors would probably refuse to authorise its being taken and filed regularly (if the periodical was brought under their notice), more especially as on looking over the most recent volume one cannot fail to see how much valuable information on 'Tea' has been collated. In the belief that 'Tea' has restored prosperity to Ceylon, and that plantation property is a good investment for capitalists, such should not omit the office and connected equipment so advisable on all 'pukka' estates, a part of which should be the *Tropical Agriculturist*. I find I have gone on writing, but, as I am getting the numbers for the past year ready to be bound, the volume is before me."

THE VALUE OF THE "T.A." TO CEYLON ESTATE OWNERS.—A planting correspondent wrote some time ago:—"I think proprietors should supply every tea estate with the T.A. The information in it with regard to everything in connection with tea, &c. is invaluable: it would pay its value over and over again. Owners of estates should not leave it to hard-up superintendents to take it in."

A CORRESPONDENT WRITES:—"I venture to say the volumes of the *Tropical Agriculturist* will be at a premium a few years hence; it is a book which is bound to rise in value as time rolls on, and subscribers will probably, if they so choose, be able to sell at a handsome profit, besides having had the benefit of using the information in the meantime."

FROM A PROPRIETOR:—"I wonder how many planters know what they lose in not subscribing to your wonderful publication? The cost is absolutely nothing, compared to the convenience of having in at hand book all that is interesting and necessary in the literature of their calling. Information culled from a thousand sources, price lists of all produce sold locally, and home advertisements not seen elsewhere, and a hundred other things necessary for them to see and to know. The T.A. is, in fact, a convenient file of useful information daily arising and permanently preserved."

SIR W. T. THISTLETON DYER, F.R.S., F.L.S., C.M.G., OF KEW GARDENS:—"Sir Joseph Hooker and myself always look out for the successive numbers of the T.A. with eagerness, and I keep a file in my office for reference. It is impossible to speak too highly of the utility of such a publication and of the way it is managed."

SIR GEORGE KING, LATE OF THE CALCUTTA GOVERNMENT MUSEUM:—"I know your *Tropical Agriculturist* well, having carefully secured every number since the beginning. You have succeeded in making it a wonderfully useful magazine of information for planters."

SURGEON-MAJOR BIRDIE, F.L.S., OF THE GOVERNMENT CENTRAL MUSEUM, MADRAS:—"I find the *Tropical Agriculturist* a most interesting and useful publication. It finds a place on the table of our Public Library and is much prized."

* The TROPICAL AGRICULTURIST *

COLOMBO, JULY 1st, 1901.

No. 1.

PLANTING PRODUCTS IN THE STRAITS.

(From Annual Report of United P. A. Malay States.)

CONSUMPTION.—In an interesting Report the Selangor Planters' Association shows that in the principal European countries and the United States of America, the consumption of coffee during approximately the last 10 years has increased

from 1,101,146,000 lb. to 1,495,296,000 lb. and that the rate of consumption per head of the total population of the same countries has risen from 2.83 lb. to 3.59 lb. These figures are obtained from a return supplied to the House of Commons dated 3rd August, 1900, and may therefore be regarded as absolutely reliable. It is explained that accurate returns of production were not obtainable, owing to the ignorance of "statistical science" on the part of producers, principally in the Central and South American States, so that it is to the London Brokers' Reports that we have to refer for statistics regarding the balance of production over consumption, in other words, for the world's stocks, and these we find by latest advices to amount to 1,449,000 bags (a bag being approximately a pikul) as against 659,000 bags a year ago.

The Director of the San Paulo Agricultural Institute has compiled a valuable report upon the existing condition of the estates in Brazil and their future prospects, and, without quoting from it at any length, it is sufficient to say that most estates are burdened with heavy mortgages, that they require much greater attention, especially as regards manuring, than they are receiving, whilst the rise in the value of the milrei from 8 13-32*d.* to 11 19-32*d.* in the last year (Rucker and Bencraft's Circular of 21st March)

cannot exercise other than an extremely deterrent effect upon that industry. The Brazils (Rio and Santos) produce such an enormous percentage of the world's supply, that an even partial collapse in that country would undoubtedly result in greatly improved values. The date of the San Paulo report is not known, but when it was written the milrei was 6½*d.*, and we find it stated that "with exchange a 6½*d.*, and coffee at \$15 in Singapore [*i.e.* Mexican dollar value] 3½ per cent interest could be paid on the capital"; again, if the Brazilian planter had to pay his labourers in gold he would have been ruined long ago, but he *sells his coffee in gold* which he reconverts into milreis, and the consequent effects of a rise of 3 3-16*d.* in one year and of 5 3-32*d.*, since that report was written, must be disastrous in the extreme. There is no denying, however, that the world's stock of coffee has increased over 100 per cent. in the last year, and the only conclusion to be drawn is that mortgages have foreclosed and resold to a large extent, and that estates, at consequently a much lower capital value in other hands, are still capable of being worked at a profit. Your Committee have endeavoured to obtain statistics of coffee exported from Selangor, Negri Sembilan, and Perak. The following figures have resulted from their efforts:—

	1898.		1899.		1900.
	Piculs	...	Piculs	...	Piculs
Selangor ...	22,948	...	26,407	...	34,295
Negri Sembilan	3,163	...	4,541	...	6,199
Tota..	26,111	...	30,948	...	40,494

We have not been successful in getting any returns from Perak, but from this State and other sources it is probable that the total production, in 1900, amounted to at least 50,000 pikuls, or say, roughly, 3,000 tons. That we have not been idle in endeavouring to get our coffee, straight from the plantations, brought

prominently before the public will be seen from reference to the subject elsewhere in this report, but it must be admitted that we are far from being satisfied with our curing, though year by year no doubt the quality improves. There is a growing feeling that possibly a more acceptable coffee may be produced by sun-drying the cherry, and your 1901-1902 report will undoubtedly supply you with the result of several systematic experiments which are now being undertaken.

RUBBER (*Hevea Braziliensis* or *Para*).—This variety of Rubber continues to come on exceedingly satisfactorily, the average growth of trees from nine months upwards amounting to about 1 foot per mensem, whilst at three years their average circumference at 3 feet from the ground is about 16 inches. This far exceeds anything reported from Ceylon and other countries where Para is being planted, and we consider that Mr. Curtis's description, in the 1900 annual Report on the Botanical Gardens of the Colony, of the tapping of the 15-year-old Para tree in the Gardens at Penang, is conclusive evidence of the contention of the writer "that in this cultivation lies a source of wealth of the greatest importance." In two years 12½ lb. of dry marketable rubber were procured "without any apparent injurious result to the health of this tree," and the conditions under which it is growing are reported as anything but favourable. It appears, in the opinion of the different Directors of the Botanical Gardens, that the size of a tree more than its age indicates its fitness for tapping, and probably a circumference of 30 inches 3 feet from the ground is the limit at which attempts to extract the rubber should be commenced. Reports from London show that prices for Para have of late declined, one reason alleged being the falling-off in the demand for bicycles, but in Para rubber we have undoubtedly the most valuable and highest quality rubber in the world, and your Committee feel that the large number of trees, amounting now to several millions, planted in the Federated Malay States, must, in the not very distant future, prove a source of revenue which will largely recoup the planters for the losses which they have sustained through the decline in value of Liberian coffee.

FIGUS ELASTICA (*Gutta Rambong*).—The only interesting fact that your Committee have to report over and above the continued luxuriant growth of this tree is the wonderful result obtained by Mr. R. Derry, of Perak, of 25 lb. per tree from two 19-year-old trees at Kuala Kangsar in one tapping. In your Annual Report for 1899-1900 it was recorded that some *Ficus Elastica* rubber which was sent home by Mr. Derry was valued at 3/6 per lb. as against 3/10 for the Para rubber sent to London for sale by the same gentlemen. Assuming, then, that the *F. Elastica* rubber resulting from the above-mentioned tapping in any way approximates in value the quotation for the former shipment, it is clear that, in this variety also, planters will have a valuable source of revenue. Mr. Derry's conclusions on the subject of tapping *Ficus Elastica* are that trees may probably be first worked when from four to five years old, and that the average yield should amount to ½ lb. for every year of the tree's age, the cost of collection, both with Para and *Ficus Elastica*, being from 30 cents to 35 cents—i.e., 7½d. to 9d. per pound.

COCONUTS.—During the past year many reports have come to hand of trees planted as seedlings, about 2 feet high, from two years and ten months, to three years and three months ago, throwing out bunches of spike and blossom which has set well, and now form sturdy bunches of young nuts. These coconuts are the common variety which have hitherto been supposed only to commence flowering in their fifth to sixth year, and there can be no doubt that, as with both kinds of rubber, the growth of our coconut trees also is quite abnormal. There are thousands of acres of alluvial land in the Malay Peninsula, capable of being converted into flourishing rubber and

coconut properties, and your Committee feel that, when the investing public know and realise this, agriculture in the Malay Peninsula will receive a stimulus which will lead to infinitely more extensive operations than we have had any experience of in the past.

SUGAR.—Your Committee hear that great success has attended the sugar industry in Perak during the past year, and that enormous extensions are being contemplated. Unfortunately, however, Perak takes little interest in our Association, and we are not in a position to supply you with any data.

INSECT PESTS.—The season under review has, on the whole in Selangor, been free of severe attacks of insect pests, the bee hawk moth caterpillar has broken out rather badly on a few estates, but no damage to speak of has been done, the eggs, caterpillars, chrysalids and moths having been promptly collected by hand and destroyed. In Negri Sembilan, however, a bad outbreak is reported, which led, in one instance, to the cutting out of all the coffee on a large Chinese estate, and caused some considerable damage to a neighbouring property. Various caterpillars and borers have been found on rubber trees of both kinds, white ants have continued to do a certain amount of damage and coconut beetles have had to be regularly collected, but remedies of all kinds have been tried, generally with some measure of success, and the discovery has been made that a decoction of "tuba" roots applied to the base of affected trees is apparently so efficacious that the white ant known as "*Termes gestroi*" is completely kept under by it. Such a simple remedy, involving as it does only the planting up of an acre or two of this quick-growing creeper, which is easily procurable and equally easily propagated by cuttings, is a most valuable discovery, and there seems no reason why, by continued and intelligent effort, this the worst and most destructive pest known to us at present should not be completely mastered and eventually cease to give us any trouble.

MANGOES.

If mangoes are not yet the most extensively grown and abundant fruit in Queensland, they soon will be. They thrive vigorously from Southport to Cape York. Almost everyone having a garden goes in for mangoes, but too frequently are regardless of the quality of the fruit, and hence really good mangoes are rare. Some growers realise this, and take all the care they can to plant nothing but the best kinds. Had this been done from the first, Queensland would now be celebrated for her mangoes, and prices would be more satisfactory. As an evidence of the increasing appreciation of choice fruit by growers, a seedsman has during the last three years realised 2s. 6d. each for some fine specimens. I learnt with regret, at the market, that hundreds of cases had been thrown away this season for want of purchasers. Another, however, told me he had always been able to sell good mangoes. It has been recorded that in some places up North mangoes have been allowed to rot on the ground, the grower being unable to sell or use them. This should not be so, for there are many purposes for which mangoes may be used besides as a table fruit. The following information, in no case original, may prove interesting and useful to some of your readers:—A very delicious preserve is made by simply peeling them when unripe but nearly full-grown; slice, place in a dish, pile on sugar, and bake in a slow oven. When properly prepared this preserve is unexcelled, and would meet with a large demand in Europe and America, as well as the Southern colonies. The making of mango jam is well-known to all housewives, its variation in excellence is doubtless owing to the quality of the fruit and sugar, also to the amount of care taken in cooking. The fruit should always be peeled. I am

informed that young mangoes, about the size of olives, make pickle superior to walnuts; if this is so, nothing can be better. In India full-grown but unripe fruit are partially cut through, the kernel removed, the cavity filled with chillies, ginger, and other condiments, then closed and put into vinegar. I do not know whether their yellow colour is imparted by mustard or turmeric. This pickle, which is excellent, is put up in jars of over 7 lb., and also in kegs. Mangoes make excellent sauce, equal to, and by many regarded as superior to, apple sauce. For making chutney mangoes are unrivalled. It is in this direction our pickle manufacturers should do a large trade; all the principal ingredients are produced in Queensland, and our market is secured to us by an import duty of 4s. per dozen quarts, 2s. per dozen pints, and smaller size in the same proportion. After our own wants are supplied there should be considerable demand for passenger ships. In vessels of the British India and P. and O. I have noticed chutney on the table three times a day; probably this is so in other lines of steamers. Chutneys are made in infinite variety, various grades of hot, sweet, and intermediate. Some of the following recipes may prove useful:—

1st.—Chillies, 1 to 1½ lb.; unripe mangoes, 1 lb.; red tamarinds, 2 lb.; sugar-candy, 1 lb.; fresh ginger root 1½ lb.; garlic, ; to ½ lb.; sultana raisins, 1½ lb.; fine salt, 1 lb.; distilled vinegar, 5 bottles.

2nd.—1 lb. salt, 1 lb. mustard seed, 1 lb. stoned raisins, 1 lb. brown sugar, ¾ lb. garlic, 6 oz. cayenne pepper, 4 lb. green mangoes, 2 quarts best vinegar—the mangoes (sliced) and boiled in a quart of the vinegar, the mustard seed gently dried and bruised, the sugar made into a syrup with a pint of the vinegar, the mangoes, sliced and boiled in a quart of the vinegar, the garlic to be well bruised in a mortar. When cold gradually mix the whole, and with the remaining vinegar thoroughly amalgamate them. To be tied down close. The longer it is kept the better it will become.

3rd.—2 lb. of unripe mangoes, peeled and boiled in a pint of vinegar (a strip or two of the skin may be included if flavour wished; 1 lb. onions, finely chopped. In another pint of vinegar boil two lb. sugar (not loaf sugar), 2 oz. ground ginger, and ¼ lb. salt: when cold mix thoroughly and add 2 oz. yellow mustard seed, ½ oz. red pepper, ½ lb. large raisins stoned, ½ lb. dates, and ½ lb. sultanas, all cut small; keep warm for a month.

4th.—3 lb. mangoes, 1 lb. onions, 1 lb. sugar 1 bottle vinegar, pepper and salt and any spices to taste; boil two hours.

5th.—Green mangoes, peeled and sliced 4 lb.; tamarinds, 1 lb.; sugar (preserving) 1 lb.; salt 1 lb., cayenne pepper, 3 oz.; or chillies (finely cut up) 1 lb. spices, 2 oz; vinegar 3 pints; mix the ingredients thoroughly, and boil slowly for hours.

6th.—50 mangoes, medium size, peeled and sliced ½ lb. preserved ginger, ½ lb. garlic, ¼ lb. chillies 1 lb raisins, 3 lb. sugar, 1 quart vinegar. Make a syrup with the sugar and vinegar, in which the mango must be boiled; when half done put in the other ingredients, mix well, and when thick remove from the fire. Time, one and a-half to two hours. Bottle when cold. I have not tasted any of those recipes, but some have been tried by friends who report favourably. Tastes differ considerably in chutneys; some persons prefer sweet to hot, others the reverse; it may, consequently, be found desirable to vary the proportions of some of the ingredients.

7th.—12 lb. peeled mangoes, 1½ lb. fine salt, ¼ lb. garlic, 3 lb. raisins, 2 lb. chillies, 3 lb. white sugar; 2 lb. green sugar, 7 bottle vinegar. The mangoes should be turning yellow, but not soft; remove the stone. These quantities are weighed when everything is peeled, and all put through a sausage machine. Boil till a nice brown for about four hours.

8th.—5 lb. green mangoes (weigh with stones in) 2 lb. raisins, ½ lb. mustard seed, ½ oz. red chillies, 1 oz. garlic or onion, 2 lb. dates, ½ lb. green ginger, 1½ lb. sugar, 2 oz. salt, 3 pints vinegar. Peel the mangoes slice half finely, put the rest through the mincer; chop half raisins and dates, put the rest through the mincer; ginger, garlic and chillies well pounded with a little vinegar. Boil all for an hour and bottle while hot.

9th.—Peel 4 lb. green mangoes, remove the stones and cut them into quarters lengthwise, boil them slightly in a bottle of vinegar, and put aside in a jar till cold. Take another bottle of vinegar, to which add 2 lb. sugar and boil till it becomes a thin syrup, put aside till cold. Take 1 oz. salt, 2 lb. picked and dried raisins, 1 oz. yellow mustard seed, 1 oz. garlic, 2 oz. dried chillies, 1 lb. green ginger sliced. Pound the garlic, chillies, and ginger finely in a mortar; mix all the ingredients together, bottle and expose to the sun for three or four days or place in a cool oven.—*Queensland Agricultural Journal.*

RUBBER IN PERAK.

We take the following extracts from the report just issued by Mr. R. Derry, Superintendent of Government Plantations, Perak:—

Para rubber (*Hevea brasiliensis*).—The result of a parcel of this rubber sent to London for sale was received early in the year, all the best quality rubber, 327 lb., sold at the rate of 3s. 10d. per lb., and the scrap, 33 lb., at 2s. 6d. The nett proceeds amounted to £61 1s. 6d., or \$617-18. I believe this to have been the largest parcel of para rubber sent home from the East. It realised 6d. per lb. more than that sent home in 1898, and was reported on as "para character."

The tapping commenced in March, 1899, and was carried on till July. It was intended to tap a few trees, those which ran most freely, with a view of obtaining the maximum amount of latex without injury, and to obtain about 4—5 lb. from other trees. This much could have been done, but owing to the exceptionally heavy rains which frequently interrupted the work, and in order that the seed crop should not be damaged, tapping was stopped and with several trees long before completed.

The average age of trees tapped is 14 years, taking the yield at 4 lb. per tree, and estimating the trees at 100 to the acre, this would give a gross return of £73 6s. 8d. at present prices, or at half the price, £36 13s. 4d., and what other tropical product gives the same return? If the trees were only half this age, say 6—7 years, there would not be much difference in the gross result, as then there would be double the number of trees to the acre.

HEVEA BRAZILIENSIS IN PERAK.

At Kuala Kangsar there are two well-marked varieties of Hevea—(1) the typical tree with large leaves attaining 13 inches long and 5 inches wide and generally branching low down; 2) smaller leaves, tall trunk and smaller rather pointed seeds, an inferior variety. The largest tree at Kuala Kangsar is 18 years old and has a girth of 8 feet 6 inches at 3 feet from the ground, this is larger than any observed by Cross in Brazil. Some trees planted by myself 3 years ago have now a girth of 1 foot 3½ inches at 3 feet from the ground. Hevea trees have a short resting season, shedding their leaves about the end of February, their new growth commencing with flowers followed by leaves. It is not uncommon, however, to see trees in September, half or many branches dormant, and without a leaf, while other parts are covered with verdant foliage. The seeds from March flowers commence ripening in August, those from September flowers in February, the heavier crop being in August. Here Hevea trees are planted on dry ground and also low swampy

ground. I have not observed any difference in yield of latex, but I would not recommend land which is liable to heavy floods.

Tapping.—I consider the latex flows most freely when the new leaves appear, which with most Hevea trees is about March, and the advantage of tapping about that time is not so much a question of actual yield as it is of the amount of bark removed in the operation, which would be less at the best season. There would also be another season commencing in September with those trees then flowering. As with all trees, the ratio of growth is variable at different periods, but taking the girth of Hevea trees here, a 3-year-old tree at 3 feet from the ground being 13-15 inches, and an 18 year old tree 100 inches, the annual increment would average nearly 6 inches in circumference, and I am sanguine that Hevea trees can be tapped in Malaya when 6 years old, if not earlier when I estimate the girth at 24-30 inches on good free soil. Tapping should be commenced at the base of the tree, working upwards to 6 or 8 feet if necessary, and if a tree be operated on in a workman-like manner three annual tapplings could be executed before going over old incisions.

COAGULATION.

Samples of rubber prepared at Kuala Kangsar have been reported on as equal to good para (Brazilian) and would fetch best para prices. I have always found the latex to coagulate readily with only the addition of a pinch of alum, and by placing immediately in smoke both putrefaction and mould are avoided. If the rubber is sound the market value depends on the state of dryness in which it is received. What has been prepared at Kuala Kangsar has been kept smoked until shipped. A parcel sent to London 3½ years ago was reported to have lost 26½ per cent. in washing and the manufacturers thought that if sent home in bulk the loss would reach 30 per cent. This, however, is a question for the planter himself. Smoke has a chemical action in the coagulation of latex from Hevea as well as saving decomposition, and assists in gradually drying. To be as dry as possible depends on the time the rubber has been kept smoked, and I am of opinion that dry marketable rubber could not be prepared under two months. Whether centrifugalisation will prove a practical method with Hevea is still in its infancy. I understand that the globules of *caoutchouc* in the latex of Hevea do not separate readily, as is the case with some other latices, and owing to its chemical combination the latex of Hevea will be probably best prepared by the natural method.

RAMBONG.

India rubber (*Ficus elastica*).—A sample of 5½ lbs. was sent to London, with the para parcel, for sale and opinion. It was reported on as "good clean Java character" and valued at 3s. 6d. per lb., but sold for 3s. 10d.

The largest tree at Kuala Kangsar is about 90 feet high, measures 88 feet and 3 feet from the ground, measuring round all the aerial roots, the branches extend to 36 paces, and the largest leaves are 13" × 7", its age 19 years. The growth of this tree has been remarkable during the last three years, from the time its aerial roots reached the ground.

Ficus elastica is an indigenous tree, found in Upper Perak. It is naturally an epiphyte, and its growth would be no doubt assisted if planted at the bases of felled trees. Its growth is slow at first but rapid when well established. Considering the enormous dimensions this tree attains, 10 to the acre would be close enough planting and as perhaps 8 years would have to elapse before the tree could be profitably tapped the intervening spaces could be utilized by some other crop, even Hevea, which would be beneficial to the growth of the *Ficus*.

YIELD.

I have not any information as to the age when *Ficus elastica* could be profitably tapped. At Kuala Kangsar there are two trees 12 years old, and two 19 years old; from the latter 25 lb. of rubber has been obtained from each tree, and the tapping was far short of being exhaustive. The result of the other trees has not yet been ascertained, but I expect good results.

Getah Singret (*Willoughbeia firma*). A small sample was sent to London with the Para parcel, and reported on as "good strong Borneo character," valued and sold at 2s. 6d. per lb. This is the best of the indigenous creepers, but I doubt very much if it ordinarily reaches the European market in a pure state, being usually used to adulterate getah percha.

Getah Taban Sutra (*Dichopsis gutta* var.). There is one example of this tree in the Kuala Kangsar garden which is said to be 17 years old, and fruited for the first time in November, 1900. A few herbarium specimens were obtained, all the other fruits being carried off by squirrels before being ripe. The height of this tree is 25 feet, and girth 2 feet at 3 feet from the ground; a jungle tree growing under heavy canopy would of course be much higher, with less branching habit and smaller girth.

Central America Rubber (*Castilloa elastica*).—About 150 seedlings of *Castilloa* from Ceylon seeds have been raised. It appears doubtful, however, whether the Ceylon trees are *Castilloa elastica* (true) or only an inferior variety, *Castilloa Markhamiana*, the results of the Ceylon trees being far below South American returns.

Getah Percha (*Dichopsis polyantha*).—A variety of getah percha which grows from near the foot of Larut hill to 3,000 feet. A mountain form may prove valuable for planting on high land. None, however, was observed in fruit, and it is presumed that with this tree, as with many indigenous trees, a fruiting season only occurs once every few years. Seedlings are abundant but the smallest seem two years old.

THE DATE PALM FOR QUEENSLAND.*

By T. MORRIS MACKNIGHT, F.L.S.

[Read at a meeting of the Natural History Society of Queensland, on 1st November, 1894]

WHY NOT FOR NORTHERN CEYLON?

The date palm is an example of extraordinary fruitfulness. Next to the coconut it is unquestionably the most interesting and useful of the palm tribe. Without it the desert would be uninhabitable. Do we not understand, then, the gratefulness of the Arab towards a tree which can derive its nourishment from the scorching sand, and scarcely less burning airs of heaven, and the brackish waters beneath the soil, which are fatal to all other kinds of vegetation; which retains its verdure fresh in the glare of a pitiless sun; which provides him with beams and coverings for his tent; cordage for the harness of his horses and mules; fruit to satisfy his hunger? What the vine is to the Italian, the coconut-tree to the Polynesian, the date palm is to the Arab. And more—far more. This single tree has peopled the desert. Without it the tribes of the Sahara would cease to be. The wealth of an oasis is computed by the number of its date trees.

* The author prefaced his paper with the statement that he made no pretence of having an expert knowledge of his subject. He had collected information from all the sources which were available to him, and had given the matter his consideration for some time past. The results of this compilation he submitted as a guide to those in search of summary information on the subject.

HABITAT.

The habitat of the date is North Africa, Arabia, Persia, Egypt, Nubia, Syria, and it does not go further east than the mouth of the Indus. It is indigenous in the Canary Isles; wanting in the south of Senegal, and it no longer appears in the Oasis of Darfur, between the 13th degree and 15th degree of latitude. The zone in which it grows well in general is that between 35 degrees and 19 degrees north. According to Link (*Die Urwelt*, I., p. 347), it flowers freely in the south of Europe, as in Sicily, the Morea, and the south of Spain; and also bears fruit there, though this is not sweet. In Sicily it still grows at 1,700 feet—namely, at Aderno and Trecastagne on Etna, but it probably does not bear fruit on this island (Philippi on *Vegetation of Etna*, 'Linnæa,' vol. 7, p. 731). It needs 5,100 degrees Fahr. of heat accumulated during eight months for the date to ripen its fruit perfectly. If the sum of the heat be less, the fruits set but do not grow to their full dimensions; they also remain bitter to the taste, and lack much of the sugar and albumen, to which they owe their nutritive properties. The requisite conditions are realised in the Sahara. The mean temperature of the year there averages from 68 degrees to 76 degrees, according to the locality. The heat commences in April, and does not cease till October. Keith Johnston's 'Physical Atlas' gives the temperature in summer and winter as—July, 81 degrees to 86 degrees; January, 52 degrees to 61 degrees; mean temperature (annual), 68 degrees to 76 degrees. Biskra, the celebrated date-growing district in North Africa, is in latitude 34 degrees 51 minutes, altitude 410 feet; it faces towards the hot tropical south, and is protected by mountains on the north side. It has an annual mean temperature of 68.5 degrees (January 50.2 degrees, July 89.8 degrees). The thermometer seldom sinks in the cold season more than 2 degrees below freezing point, and the date can endure 6 degrees of frost.

The neighbourhood of the sea is unfavourable to the production of good dates. The general altitude of the central districts of North Africa, where it thrives, is 600 feet to 2,000 feet; the date palm also grows in some Egyptian oases from sea-level to 600 feet. The lower portions of the Rivers Euphrates and Tigris in Turkey are from sea-level to 600 feet.

The amount of annual rainfall requisite for the best dates is from 5 inches to 10 inches; for those of inferior qualities, from 10 inches to 25 inches. Mr. A. S. White, secretary the Royal Geographical Society of Scotland, gives, in his work, the 'Development of Africa,' 1890, a map of the rainfalls in North Africa, Arabia, and Persia, which may be profitably referred to in this connection. Although the date requires a hot, dry climate, yet its roots must have access to moisture. And though it is essentially a tree belonging to desert regions, yet it is confined to the oases in these deserts where water is found. It flourishes in rainless countries, but only where there is moisture in the soil, either naturally or produced by irrigation.

IRRIGATION AND OASES.

The 'Oases of the Tableland,' writes Charles Martins, in his 'Du Spitzberg au Sahara,' 'are each watered by a stream or copious spring, and are but a short distance from the Mediterranean region. The oases of El Kantara is the first (Mangin) we met on leaving the Mediterranean region to penetrate to the Sahara through a ravine called the 'Mouth of the Desert.' It is 1,800 feet above sea-level, and its temperature just suffices to enable the dates to ripen. The oases of the Valleys of Erosion are watered by natural or artesian wells. An example is Ouargla, situated in a profound hollow. The palms are planted at the rate of 1,000 to 1,100 a hectare (2½ acres). Outside the gardens grow some wild date palms, which yield a smaller crop, but whose fruit is much more savoury. The

oases of the Sandy Desert need water. The trees are here planted in conical cavities hollowed by the hand of man, so that their roots may strike down to the subterranean reservoir which is to nourish them. These cavities are 15 feet, 25 feet, or 30 feet deep. The slopes around these hollow gardens are stayed indifferently well by a matting of palm-leaves. The wells are in the centre, and not deeper than 25 feet. These oases have a very precarious existence, as a gust of wind may bury them under an avalanche of sand. Every oasis is composed, in the main, of palms which seem to form a continuous forest; but in reality they are planted in rows and in gardens separated from one another by walls of earth, which are pierced with an aperture to admit of the entrance of the irrigating rill into the enclosed square. The soil employed in the construction of the walls is removed from the paths, which are consequently below the surface, and can be employed for a double purpose: they facilitate circulation in the oasis, and the waters, after having refreshed the gardens, discharge themselves into these hollow ways.

SOIL.

Meyen, in his 'Geography of Plants,' page 2, states that a sandy soil suits the date best; and Sonnini, in his 'Travels in Egypt,' saw it growing in the sands as well as in the more fertile parts. It will luxuriate even in saltish soil, and the water for its irrigation may be slightly brackish. The artesian water of the Oued Kur district in Algeria contains from 0.57 oz. to 1.07 oz. of dry salt in a gallon. Brigade-surgeon Bonavia says that on the whole it thrives best in sandy, granitic, schistic, and calcareous soils. The northern half of Arabia, which is an important centre for date culture, is granitic.

INFLORESCENCE.

The date is a dioecious tree, having the male flowers on one plant and the female or fruiting ones on another. The male flowers are considerably larger than the female, furnished with stamens only, and form a closed-up, folded, grape-like ball (previous to the ripening of the pollen) in an envelope called the spathe. 'It blossoms,' says Mr. Tristram, in his book 'The Great Sahara,' 'in the month of March. The male flower is borne on a very short calyx, a thin petalous corolla much larger, with six stamens, furnished with long linear anthers, the two cells of which open themselves from within by two longitudinal slits. The female flowers present a double floral envelope, each whorl of which is formed of three pieces, constituting three distinct pistils, each surmounted by a stigma in the form of a hook. Of these three pistils one only develops itself, ripens, and becomes an elongated ovoid berry, with a slight epidermis of a yellowish-red, a solid and slightly viscous pulp, and an endocarp represented by a slight pellicle enveloping the nucleus, which is the seed. The seed is grooved, and on the opposite side of it is a depression containing the germ.' Baron Mueller states that one male tree is considered sufficient for fifty females. Watts allows one or two males to from eighty to two hundred trees.

PROPAGATION.

The best trees are produced from suckers from three to four years old, having an average weight of about 6 lb. Those raised from seed are much slower in maturing, and are generally poor. The sucker is taken from the foot of the stem of an adult tree: when first planted it must be watered daily for six weeks, and on alternate days for another six weeks, after which the trees are watered once a week in summer, and every month in winter. The nut does not commence to germinate until from six to twelve months after planting have elapsed, and grows very slowly for the first two years. The trees yield fruit in from five to six years, and are in full bearing at from twenty to twenty-five years, after which they

continue fruitful for about 150 years. Several bunches of flowers are formed in a season, each producing often as many as 200 dates. Select trees are reported as having borne a crop worth £2, but the average may be put down at 4s. per tree annually, common kinds less than 1s. A good date tree is sometimes exchanged for a camel in North Africa.

FECONDATION.

"In Algeria and all over the East," says M. Cossona, a botanist who has studied the subject on the spot, "towards the month of April the tree begins to flower, and then artificial fecundation is practised extensively. The male spathe is opened at the time when a sort of crackling is produced under the finger, which indicates that the pollen of the flowers in the cluster is sufficiently developed, yet has not escaped from the anthers; the cluster is then divided into portions, each containing seven or eight blooms. Having placed these pieces in the hood of his burnous, the workman climbs to the summit of the female tree, supporting himself by a loop of cord passed round his loins, and at the same time round the trunk of the tree, and, having split open the spathe with a knife, he slips in one of the fragments, which he interlaces with the branches of the female cluster, the fecundation of which is made certain." Archer says that wild plants are fecundated by bees. The Arabs even keep the poll n from one year to another in case the male flower should fail the succeeding season. According to Watts the pollen is said to remain active for one or two months after its removal from the tree, so the flower is carefully kept and used as occasion demands. Hasselquist, who travelled in Egypt, describes the operations as follows:—"When the spadix has female flowers that come out of its spathe, they search on a tree that has male flowers, which they know by experience, for the spadix has not yet burst out of its spathe. This they open, take out the spadix, and cut it lengthwise in several pieces, but take care not to hurt the flowers. A piece of this spadix, with male flowers, they put lengthwise between the small branches of the spadix which has female flowers, and then lay the leaf of a palm over the branches. In this situation I yet saw the greatest part of the spadices which bore their young fruit; but the male flowers which were put between were withered. The Arab also stated that unless they in this manner wed and fecundate the date-tree it bears no fruit; secondly, they always take the precaution to preserve some unopened spathes, with male flowers, from one year to another, to be applied for this purpose in case the male flowers should miscarry or suffer damage; thirdly, if they permit the spadix of the male flowers to burst or come out it becomes useless for fecundation; therefore, the person who cultivates date trees must be careful to hit the right time of assisting the fecundation, which is almost the only nicety in their cultivation."

To climb trees which have no branches but at the top, and the straight and slender stem of which cannot support a ladder, the Egyptians employ a sort of girth fastened to a rope that they pass round the tree. On this girth they seat themselves and rest their weight; then, with the assistance of their feet, and holding the cord in both hands, they contrive to force the noose suddenly upwards so as to catch the rugged protuberances with which the stem is symmetrically studded, formed at the origin of the branch-like leaves that are annually cut. By means of these successive springs the top of the tree is reached where, still sitting, they work at their ease, either in lopping off the leaves or gathering fruit, and afterwards descend in the same manner.

Professor Burnett says the age of bearing is from six to ten years. Haldane says seven years. Baron Muller says that trees from suckers commence to bear in five years and are in full bearing in ten years.

The fig, pomegranate, and apricot, and sometimes the olive, are grown as auxiliary crops. I would suggest also the watermelon, pumpkin, vegetable marrow and lucerne.

VARIETIES.

Dr. James Richardson in a letter in "Hooker's Journal of Botany," Vol. II., writing of the dates of Fezzan, describes forty-six varieties. Nineteen-twentieths of the inhabitants of Fezzan during nine months of the year live on dates. In Northern Arabia there are more than a hundred kinds of dates, each of which is peculiar to a district, and has its own special virtues. Many varieties of date exist, differing in shape, size, and colour of the fruit. Those of Gomeria are large, and contain no seed. The Zadia variety produces the heaviest crop, averaging in full bearing trees 300 lb. to the tree. Professor Naudin states that the variety of "Daberes-sia" ripens its fruit early in the season. The "Deglet Nour" is considered the best for keeping.

TREATMENT OF FRUITS.

Four or five months after the operation of fecundation has been performed the dates begin to swell, and when they have attained nearly their full size (about the beginning of August) they are carefully tied to the base of the leaves to prevent them from being beaten and bruised by the wind. If meant to be preserved they are gathered a little before they are ripe, but when they are intended to be eaten fresh they are allowed to ripen perfectly, in which state they are very agreeable and refreshing. Ripe dates cannot be kept any length of time or conveyed to any great distance without fermenting and becoming acid, and therefore those which are intended for storing up, or for being carried to a distant market, are dried in the sun on mats. They are sent in this way to Europe from the Levant and Barbary. Each tree is capable of yielding only a certain number of good fruits, and on adult trees not more than twelve bunches are left to ripen. The whole cluster of fruit is cut before it is quite ripe, when it is put into a basket made for the purpose, having no other opening than a hole through which the branching extremity of the cluster projects. In this situation the dates ripen successively.

In the Hedjaz (which is the northern half of Arabia) the new fruit called *ruteh*, comes in at the end of June and last two months. The people cannot therefore depend on the new fruit alone, but during the ten months of the year, when no ripe dates can be procured, principally subsist on date paste, called *adjoue* which is prepared by pressing the fruit, when fully matured, into large baskets. "When the dates are allowed to remain on the tree till they are quite ripe, and have become soft and of a high red colour, they are formed into a hard solid paste or cake called *adjoue*. This is obtained by pressing the ripe dates forcibly into large baskets, each containing about 2 cwt. In this state," continues Burckhardt, "the Bedouins export the *adjoue*, and in the market it is cut out of the basket and sold by the lb. During the monsoon the ships from the Persian Gulf bring *adjoue* from Bussorah to Djidda for sale in small baskets weighing about 10 lb. each; this kind is preferred to every other."

The date seeds or kernels are soaked for two days in water, when they become softened, and are given to camels, cows, and sheep instead of barley. There are shops in Medina, in Arabia, where nothing else is sold except date kernels, and the beggars are continually employed in all the main streets in picking up those that are thrown away.

The best fruit is that which is gathered just before it is ripe and exposed to the sun for several days to mature. The crushed dates which arrive in England in bulk are inferior and damaged, having ripened on the trees and fallen. I have seen some beautiful dates in London on the stalks. These, in the same way as raisins, have the short

pedicels left on them. Then, again, I have seen, in Port Said dates, prepared somewhat as we often see them in shops in Brisbane, sold very cheaply, being, I suppose, the refuse of the date groves pressed into a paste or soft mass. This is sold by weight in chunks. In Egypt, the dates of Upper Egypt and the Oases are those which are the most delicate. The hotter and drier the climate the richer is the date, and near the coast the poor fruit is fit only for animals, as mentioned in "French Colonies," by Bonwick, 1886.

MISCELLANEOUS.

Tunis has 2,000,000 date trees; Egypt, 4,000,000; Bussorah, in Turkey, has enormous date groves stretching along both banks of the Euphrates for a distance of over 140 miles, yielding 40,000 tons in good seasons.

The price in England in March, 1894, was—Bussorah (boxes) 9s to 13s 3d per cwt.; Taflet, 44s to 50s per cwt.

Dates contain more than half their weight in sugar, but there is a fair amount of flesh-forming material present as well. Dates, without the stone, contain in 100 parts—

Water	20.8
Albumen	6.6
Sugar	54
Pectose and gum	12.3
Fat	0.2
Cellulose	5.5
Mineral matter	1.6

The pungent rigidity of the foliage protects the date from encroachment of pasture animals; hence it can be left without fencing or hedging.

QUEENSLAND AS A DATE COUNTRY.

I have now given all the general information I can find in regard to the cultivation, &c., of the date palm in North Africa, Turkey in Asia, and Arabia. It will be convenient now to see if in Queensland similar conditions of temperature, &c., can be found. The part of Queensland which, bearing in mind the requirements of the plant already set forth, seems to be the most suitable for the cultivation of the best dates is to the west of Hughenden, Longreach, and Charleville, and from latitude 23 degrees to the southern border of the State. The following remarks all refer to this area:—

TEMPERATURE.

Comparing the region of Queensland which includes these places, with Biskra, in North Africa, in latitude 34 degrees 51 minutes at an altitude of 410 feet, we have—

	Queensland.	Biskra.
Annual average temperature...	67.74	68.5
Mean temperature, coldest month ..	48.61	50.2
Mean temperature, hottest month ...	84.90	89.8

I do not know the extreme minimum temperature at Biskra, but the lowest in the part of Queensland above referred to is 26.4 degrees at Boulia in July, 1894. My information for Queensland is obtained from the Meteorological Reports, which are only available from 1st September, 1893, to 31st August, 1894. I believe this last winter was considered a very cold one throughout the colony, and as the date palm can stand as low a temperature as 26 degrees it should be safe even at Boulia from being killed by frost. The latitude, 20 degrees S. to 27 degrees S., also indicates generally the area in which the suitable temperature is to be met with.

RAINFALL.—In the above possible date-growing belt of Queensland the rainfall ranges from 5 inches to 24 inches, and in the more westerly portion this reaches the minor limit, therefore improving the quality of the date on account of the greater dryness of the air combined with the circumstance that there is greater heat also.

ALTITUDE.—Looking generally at West Queensland, the rivers and creeks all run to the south-

west, showing that the higher ground is the north and east. Then there are high downs between the Gulf of Carpentaria waters and the Diamantina and Thomson Rivers; so that all this higher ground must vary from 600 feet to 1,400 feet above sea-level. But to the south-west of Boulia and Windorah and to the south of T bargomindah and Charleville the altitude of the country is from sea-level to 600 feet. From the above figures it can easily be seen where there is the least likelihood of frost.

SOIL.—The geological formation in the region indicated is mesozoic, with desert sandstone on the higher ground between the various watersheds, and lower cretaceous on the plains and downs. As apparently the date palm prefers a sandy soil, the conditions in this case seem favourable also.

From the above data it will be seen that West Queensland is generally suited to the cultivation of the best dates. As to the local conditions, they must be ascertained by Queenslanders themselves. The object of this paper is to give to the State the information in regard to the date which is scattered throughout many books and is not easily obtained, and also to suggest the best place for initiating experiments in date cultivation in this country.

[We are indebted to Mr. Hy. Tryon, Government Entomologist, for the foregoing paper.]

ZANZIBAR PLANTING INDUSTRIES.

COCONUTS.

What return will a coconut tree bring in per annum? The average yield of nuts in Zanzibar island is probably from 25 to 30 per tree. Calculating the price at R20 per 1,000 on the spot and the yield at 30 we get a gross return of 9 3-5 annas per tree. Gathering may be set down at R4 per 1,000, which leaves a net return of about 7 1/2 annas, or half a rupee, per tree. Pemba trees yield less than Zanzibar; the average is probably less than 15 nuts per tree per annum. Labour is cheaper and the cost of gathering less than in Zanzibar: about R3 per 1,000. The net return per tree works out to about 4 1/2 annas per annum in Pemba. Mr. J. T. Last, F.R.G.S., writes as follows upon the benefits of cultivation as he has found them at Mangapwani:—

"There are at Mangapwani about 200 bearing palms from which the nuts are gathered every three months. About three years ago I had the ground well dug up for some 6 feet round the base of each tree, and then packed round the tree any manure, grass or decayed vegetable matter I could get, covering the same up with soil. This has been repeated every year. The result of these operations is that the number of nuts gathered is greatly increased.

Formerly the three-monthly gatherings would average about 3,000 nuts, now more than double that amount is obtained. The last gathering reached the number of 7033. Since I started mulching the trees there have always been one or more trees at each 3-monthly gathering from which I obtained 100 nuts.

At the above gathering from

1 tree	are gathered	110 nuts
2 trees	,,	100 ,, each
1 tree	,,	91 ,,
1	,,	89 ,,
1	,,	86 ,,
1	,,	80 ,,

Making from 7 trees 556 nuts.

I think, judging from the above results, we could fairly expect that, with proper attention, a healthy full-grown coconut tree would produce 100 nuts a year.

We find at Dunga that individual trees occasionally yield close on 100 nuts at a gathering, though we have

not found such good general results follow upon digging and mulching as Mr. East has at Mangapwani. Our trees have all been dug and mulched but the average yield of nuts remains about the same, though we are, looking for some improvement this year. Our trees are scattered about through enveloping native villages, and the nuts are consequently exposed very much to theft. Loss by theft is the greatest evil coconut planters have to contend with in this country.

PLANTING THE NUTS.

Natives plant nuts on their sides and sometimes in an upright position. They declare that in the latter case a stronger plant is obtained. Dr. Krapi in his Swahili dictionary has the following note:—

"The natives plant the coconut (which is to become a tree) on the fourteenth day of the moon, because the moon is then at her full power. This takes place before the rain. They put it into the ground without removing the husk, taking care that the *nite* or bud is placed downwards in the pit, which they dig to the depth of one *mukono* (cubit). The tree (like the mangrove) requires five years' growth before it bears fruit.

The Wanika consider the coco-tree to be their mother on account of its usefulness, therefore they will not allow it to be cut down. They believe that a *koma* watches over it. Therefore when the tree yields no *tembo* they endeavour to appease the *koma* by a sacrifice. On this account they place a coco-shell on the grave of the dead, and fill it with *tembo* from time to time, in order to induce the *koma* to give them much *tembo*. The Swahili cut down the coco-tree without scruple."

The generally accepted way of planting a nut is to lay it on its side in a trench about 7-8 inches deep (its own depth.) It has been rightly pointed out that if a nut be planted eyes downwards, the young shoot may rot before it reaches the surface; on the other hand if planted eyes upwards the milk inside, which is especially provided for the first nourishment of the germ, will settle at the bottom of the nut and the young shoot will then run a risk of being dried up. Nature seems to have especially pointed both ends of the nut so that, having fallen from the tree it shall remain upon its side to germinate. In the case of the mangrove the young seedling drops from the parent tree upon its pointed end and sticks in the mud and grows forthwith. But the bottom of the coconut could not have been pointed to enable it likewise to stick in the sand and germinate, because a nut always falls upon its side. This is well shown by dropping a few nuts from the roof of a high house. If the nut is suspended by the stalk, in the way it hangs upon a tree, and dropped, it will turn half over and fall sideways. The same thing happens if the nut be held upside down. If it be held horizontally, it will maintain this position till it reaches the ground. Nature is always a safe guide. Allow a space of nine inches or a foot between the nuts in the trench, and 18 inches between the trenches. This gives plenty room to lift the nuts when the time comes for them to be planted out, without doing much damage to the roots. April is the best time to plant out the seedlings, when they should be 5 or 6 months old. Hence the nuts should be planted in the nursery in November. But no hard and fast rule need be laid down, especially as our seasons are uncertain. 35 feet by 35 feet is a good distance for them to be placed in the plantation. This gives 35 trees to the acre.

ESTIMATE OF THE NUMBER OF TREES.

Coconut trees are scattered about so promiscuously that it would be almost impossible to arrive at the accurate number of trees on the islands. The average annual amount of copra exported from these islands during the last six years has been 6,519,216 lb. Counting that 2 nuts make 1 lb. of copra, this would be the product of 13,038,432 nuts. Probably as many nuts are consumed as food as are made into copra. If so the total average yield of nuts is 26,076,864. This is

the product of about 1,000,000 trees. If these trees were growing in regular plantations 35 feet apart they would cover an area of 28,571 acres.—"*The Shamba*," *Journal of Agriculture for Zanzibar*.

WALKING STICKS.

Messrs. Howell & Co., Old Street, London, have kindly supplied us with the following points to be observed in collecting walking sticks:—

Length.—The total length should not be less than 42 inches, end to end, but if possible they should be 48 inches.

Size.—The best sizes are of the diameter of $\frac{1}{4}$ in to 1-in., measured about *midway*; they should not be larger than $1\frac{1}{2}$ inches in diameter.

Form.—It is indispensable that the diameter should gradually diminish from the root or handle to the point, so that the stick is not "top heavy."

Handle.—It is always better, when possible, to send sticks with some kind of handle; if the plant be pulled up, the root should be left quite rough and untrimmed if a branch be cut off, a part of the parent branch should be left on to form a knob or crutch handle.

Sticks without Handles.—Sticks without handles can be used, especially if they are nicely grown, and have any peculiarity of structure or colour—but if there is any handle, however small, it should not be cut off. Young saplings of the different kinds of Palms, Bamboos, &c. should always have the root left on.

Short Handles.—Occasionally, the form of the root or handle part is attractive, while the stick itself is weak and defective, in such cases the handles only should be sent, and they should measure from 15 to 18 inches in length.

Send only Specimens in first Instance.—In sending specimens of new sticks, it is better to send only small quantities, say, 1 or 2 dozens at most of each kind, then if approved, further quantities can be asked for.

All kinds of wood.—Specimens of anything remarkable for form or colour, whether in the Roots or Stems, of Woody, Herbaceous, or Reedy structures should be sent, as sometimes the most unlikely things are found to possess value, for use either as Umbrella Handles or Walking Sticks.

Details.—Details as to quantity to be procured prices, &c., should be sent, if possible.—"*The Shamba*" *Journal of Agriculture for Zanzibar*.

RUBBER IN PERU.—The German Consul in Payta-Piara (Peru) reports the discovery of large rubber forests on the Niera River, a branch of the Amazon, which can be reached from the middle of the tobacco plantations by an eight-days journey. Several German firms organised a large expedition to start for the interior and to secure the rights to collect the rubber. As the natives are very poor, it is expected that cheap native labour will facilitate the collection.—*Engineering*.

SUGAR IN HAWAII.—Regarding the possibilities of the cultivation of sugar cane in the Hawaiian Islands, Prof. Stubbs said the soil was the best in the world for the cultivation of cane, being superior to that of Cuba. The yield on the arid and irrigated lands of the islands is from eight to fifteen tons of sugar per acre, while in Louisiana the yield is about $1\frac{1}{2}$ tons per acre. But about all the available lands having been taken up in the cultivation of cane already, the increase of production cannot far exceed the present output. The total value of the agricultural produce of the islands is about \$20,000,000, of which \$17,500,000 is to be credited to sugar. Thus it will be seen that the islands have already reached, or nearly reached, the limit of yield. The drawbacks to the cultivation of cane in these particularly favored islands are the high price of coal—which reaches as high as \$12 per ton—the cost of irrigation and the great cost of sugar house plants. Nevertheless, the profits are so large as to practically preclude the cultivation of any crop but cane.—*Louisiana Sugar Planters' Journal*.

PLANTING FRUIT TREES.

There are planters and planters. The first digs out a small hole in hard, unmoved ground, and thrusts in the roots about as deep again as they ought to be; the earth is filled in and the planter passes on under the impression that he has done a good thing—for himself perhaps—but certainly for posterity. Such comfortable feelings are all very well, and we would be the last to say a word that would deter anyone from indulging in tree planting, but the subject demands that sentiment has no place in this connection. We are bound to look at it in a practical light. Trees that are inappropriately planted never do well, therefore the inexperienced do not meet with the result their good intentions deserve. The moral, therefore, is that only those should engage in planting trees who are practically acquainted with the work. Before we go further let us dive a little deeper into the behaviour of trees which have been unskillfully planted. The first year they make no progress; they live, and that is all that can be said about them. The next year they do a little better, but the growth is not so strong as it ought to be. In succeeding years moss and lichen begin to accumulate on the stem and branches, the result of the beneficial influence of sun and air. Trees in this condition from such a cause do not die, but at best they are short-lived as compared to those that were planted in a proper manner. Nor is the crop of much value; invariably such trees bear irregular crops of small and badly-formed fruit. Let us now look at the behaviour of the trees which are planted by experienced hands. In the first place the cultivator makes his anxiety manifest to do the planting well by making himself acquainted with the character of the land. If it is of a retentive nature, with a heavy subsoil, he is careful to have the position efficiently drained. If the soil is poor, it will be enriched with manure: but, more than all, he will avoid planting a young tree in a spot from whence an old one has been removed. If he does so, the old exhausted soil is taken away and fresh soil put in its place; but to avoid the labour attending the latter plan a fresh position altogether is selected, which in the end will be more satisfactory than supplying fresh soil to an old position.

The Depth to Set the Roots.—In every case the careful planter will study to plant his trees in ground that has been well moved up 18in. or 2ft. deep. If the whole of the space is not trenched over, then most of it must be, so that the roots have, for the first year or two at least, some recently-moved earth to feed upon. This is not all that the experienced man does. He will not plant a tree more than a few inches below the surrounding level on land that is liable to get water-logged in winter. In some cases he will plant altogether on the surface, and place a mound of soil over the roots. This plan has much to recommend it where there is not sufficient depth of good soil, as it gives the roots all the room there is of good earth; but it is not advisable to plant on the surface on light gravelly land. Such, then, are some of the differences between men who have experience in this matter and those who have not. We have not drawn upon our imagination to prove a case. We, and many others, have long been familiar with such mistakes in planting, and have seen both time and money wasted; but in all probability more trees are crippled through deep planting than from any other cause. Some cultivators of fruit purposely plant the roots deeper than they otherwise would do under the impression that the trees are not so easily blown down when they get old. A very little reasoning ought to convince anyone that they are under a mistake. To bury the stem of a tree more than 6 in. under the surface is an error that will speedily show itself in its after behaviour. This is a fact that has been demonstrated in practice many times during our experience, where

people in making alterations have, when excavating out the soil for a road, buried up the stems of trees 2ft. or more in height rather than remove them altogether. The result has always been that the trees so dealt with died in a few years. We therefore maintain that, if old trees suffer by having their roots too deep, young ones would also suffer in a proportionate degree.—The "Fruit Grower," London.

PRUNING.

By H. CONSTANTINE THOMAS, JAMAICA.

Pruning, from an agricultural point of view, may be briefly defined as regulating growth, cutting away all superfluous growth for the benefit of a tree or its fruit. Pruning is one of the most delicate and yet important branches of agriculture; not even a leaf should be cut off a plant unless the operator has some definite object in view; ignorantly performed, its injurious effects do not hesitate to manifest themselves, such as taking a cutlass and chopping off a branch from a cocoa tree a foot from the stem, the piece left on starts decaying, and this process continues right into the main stem itself, and often results in the death of the tree. On the other hand, when carried out intelligently by individuals who base their practice on the laws governing vegetation, regular symmetrical growth, production of well developed leaves, branches and fruits are secured. The beneficial results of pruning, done at the proper time, and in a proper manner, are too numerous for enumeration here, but I mention a few. By pruning, all the fruit-bearing branches of a tree are fully exposed to a free access of air and light: two things that are absolutely indispensable for the successful culture of plants. Leaves are the digestive organs of a plant, and should not be destroyed wilfully. The best season for pruning is a question of great importance, since the conditions under which the plants to be pruned are placed act such a prominent part, but under ordinary environments I think the best season is nearly the end of the dry season, just prior to the heavy rains, which in most of our districts can be correctly guessed. The implements are a pruning knife, a pruning saw, a pair of shears, and, in case of large trees, pole-pruning shears or a tree-pruner. The wounds must be smooth, *i.e.*, after using the saw take the knife and smooth off the surface well; the benefit derived therefrom is that it renders their healing easier, quicker, and with less strain on the plant. After having smoothed the surface of a wound it is also beneficial to rub it over with a little tar. This is a very useful antiseptic and is retailed at a very reasonable price.

Pruning at the time of transplanting is very technical. If citrus plants for example have to be transplanted during the dry season all the leaves must be carefully removed, as in such a case they would help to kill the plant by letting off all the moisture they contained; if it happens to be rainy they are to be left. Citrus trees require very little pruning after they are established; once in two years, and that slightly, is enough; in such cases the operator should confine himself chiefly to the removal of dried twigs. Some plants need constant and regular pruning; the cocoa for example. It is quite an ordinary thing for people to plant out "at stake" and never look after the plants from the day they discover that the seeds have grown until they are bearing. This plant naturally sends out branches as soon as it has reached the height of three or four and a half feet under favourable conditions; when shaded excessively it grows a long, spindly stem, often branching when entirely out of easy reach, and since climbing is detrimental, it is best to grow the plants so that the fruits can be obtained more easily; in climbing the flower-buds are rubbed off, thus lessening the next crop. I cannot deal with the general culture of the plant here, so returning

to my subject—pruning. Let me say that when the trees have put out these branches all should be taken away when young, save three, which three must form the best triangle and left to develop into the three main branches. These branches also send out secondary ones; these secondary branches must not be left to grow on just as they came out, but care must be taken to remove every alternate one, leaving, on an average, eighteen inches between each. Gormandizers (or suckers as they are sometimes called), always block out air, use up a lot of valuable plant-food and give, comparatively, nothing in return. The tree should be kept clear of these. My definition of a gormandizer is a shoot springing from the stem of a plant, going straight up, and in the case of the cocoa, particularly, giving little or no return, thus wasting what would be profitably used by the true branches of the plant. I do not want to be called a critic, as I opine that, to-day, we have more agricultural critics than agriculturists; still the present system of plucking off the pods from the cocoa-tree is abominable. The flowers are produced chiefly on the stem of the fruit (the peduncle) and when the fruits are torn off, apart from the destruction of the bark of the parent-plant, the crop is greatly reduced the following year, so I would recommend people gathering the pods to use a knife and cut off the fruits; several little rings or marks will be seen on the peduncle, cut the fruit in the third one from the stem. With regular pruning this plant will yield two heavy crops annually; one about June and another in December. The time has come when all useful details must be brought out, "Experience teaches wisdom." Let each of us mention our experience, not thinking what the next man will say, and our fellow-men may benefit therefrom.—*The Journal of the Jamaica Agricultural Society.*

THE PAPAWE TREE.

"Forester" writes to the *Indian Planters' Gazette*:—This fruit tree, the Carica Papaya, Willd, is cultivated all over India for its fruit, which is eaten in its ripe state as well as cooked and used in curries when green. They can also be pickled and made into preserve. If the Linnæan sexual system wanted any additional proofs of its being established on the most solid foundation, Roxburgh's experiment with this plant would have furnished a very strong one. The writer recently had occasion to consult his mukhtear on some business and noticed some very fine papaya fruit commencing to ripen in his compound. Upon remarking that they would be much better if thinned, he was informed that previous to some more trees being brought from a neighbouring compound about half-a-mile away they never grew thickly and what did grow were small and of little use in comparison with the fruit he had been getting since. Of course the reason was obvious enough. He had only one tree to start with and that was a female, and the trees he got from a neighbour were a mixed lot containing both sexes. When this was explained the man of law was incredulous; he had never heard of such a thing as a sexual system belonging to the vegetable kingdom, and was very much inclined to think that he was being humbugged. It must be said for him that he had some reason for doubting the truth of what was being explained to him, as he had somewhere or other seen the male tree fruiting. A Chittagong friend of the writer's informed him that he had male trees which regularly fruited. Some specimens of the male tree with fruit on them were shown to Dr. Roxburgh in 1793 by Sir William Jones. Dr. Roxburgh had never seen the male tree bearing fruit, and it was the only instance that had come to his knowledge where female or hermaphrodite flowers were found on the male papaya tree. It is said that the fruiting of the male tree is common enough in some districts. There is nothing impossible about it, as, if the male flowers are carefully examined,

they will all be found to be possessed of female organs, although as a rule they are merely rudimentary. The papaw tree, although usually looked upon as dioecious, perhaps would be more correctly described as being dioecio-polygamous or a polygamo-dioecious plant. Last season the writer came across what had every appearance of being a male tree with a lot of pear-shaped fruit hanging upon its pendulous racemes. It was growing amongst a lot of other trees close to the cook-house. He mentally marked it down for observation, but on going to examine it a few days later somebody (who, as usual, was nobody) had cut it down and taken away the fruit. This was in the Dibrugarh neighbourhood, but he could not find out whether there were any more in the district. In 1790 and 1791 Dr. Roxburgh reared a number of young trees in a garden situated a mile and a half from any other papaw tree. As soon as he could distinguish the male trees he had them all destroyed. The females, of which there were nine, grew luxuriantly, being in a good soil and well watered. They blossomed as usual and the fruit grew till it was about half the usual size; then as before they uniformly fell off without appearing to have more than the rudiment of seeds. If Dr. Roxburgh had made an experiment the reverse way, by destroying the female and preserving the male trees, he possibly might have had the male in the absence of the female tree fertilized by its own pollen and producing fruit. As often happens with other kinds of trees, the pollen of the male may be entirely impotent in regard to its own pistil only when the more vigorous pistil is present on a separate tree. The question is of more than botanical interest, as when the so-called male tree fruits, it is said that the juice is more copious and produces more of the digestive ferment papain, which the unripe fruit of this tree contains.

The hope which was once entertained that papain would prove a curative agent for cancer has not been realised. But, according to a paper read by Dr. Hirschfeld at a meeting of the Royal Society held at Brisbane, it has been found to be a most valuable palliative on account of certain qualities possessed by it that had been overlooked, namely, its analgetic and its antiseptic properties. It is somewhat strange that the natives of India do not seem to be aware of the properties of its juice. One variety of the plant at least is a native of this country—the common Carica papaya of the busters, which was introduced into England in 1690. Besides this variety we have Carica cauliflora, a native of Caraceras; C. citrifolia, a native of Lima; C. microcarpa monica; C. pyriformis, Peru; C. spinosa, Guiana.

As the name indicates Microcarpa monica would appear to answer the description of the male tree which is said to bear fruit. If this were the case it would not be the male tree bearing fruit, as this variety is a hermaphrodite tree.—*The Indian Agriculturist.*

A NEW BANANA IN THE CONGO FREE STATE.

In the February number of the above journal, Mr. E. De Wildemans, Curator of the Botanical Gardens at Brussels, gives the following description of a new series of banana which was discovered by Mr. J. Dybowski, Director of the Colonial Garden at Nogent-sur-Marne, during his travels in the Congo country, of which he had neither seen the flowers nor fruit. Subsequently to his last voyage some fruits were received, of which the seeds were sown, and produced young plants at Nogent, and it is from these that Mr. Dybowski has given a summarised description of the "fetish banana" (*Musa religiosa*).

Although we have not been able to study the description of flowers, we immediately recognised that the plant from the French Congo had a great resemblance to those we propose to describe here. Mr. Dybowski has been good enough to forward, at our request,

specimens of the seeds and a fragment of the fruit of his *Musa religiosa*, but these are not sufficient to enable us definitely to solve the question whether *M. religiosa* and *M. Gilletii* are two specific types.

We might give as a distinctive characteristic the colour of the seeds, which are grey and dull in the former, whilst in the latter species they are of a beautiful brilliant black; as regards the measurement they are about equal. In consideration of this difference, and in the complete absence of information as to the flower, we have preferred to describe our plant under a new name, and to dedicate it to our collaborator, J. Gillet, S.J., who devotes a large portion of his time to the collecting of the plants of the Lower Congo. Besides, this plant will shortly make its appearance commercially, for the seeds sent by J. Gillet to the Messrs. Damann, of San Giovanni, at Teduccio (Italy), have germinated and produced young plants.

MUSA GILLETII, De Wild a new species. Plant 1 metre 50 to 2 metres high (4 feet 9 inches to 6 feet 4 inches), not stoloniferous, more or less swelled at the base, completing its cycle of evolution in three years; during the first year, the plant is low, and has few leaves; in the second year it makes height growth still, foliated from the base; in the third year there is formed at the extremity of the stem, which bends over, a floral panicle. The lower leaves are elliptical-lanceolate, with a very strong sheathbed petiole, and with a very large and pronounced midrib. They are 1 metre 50 (57 inches) long, and have a translucent border. The upper leaves are 40 to 50 centimetres long (16 to 20 inches) those nearest to the inflorescence only attain to about 8 inches, and pass insensibly to the bracts; these become gradually narrowed as they reach the inflorescence; the leaves and the bracts are terminated by a narrow twisted elongated apex. The floriferous spike, shortly pedunculated, recurved, measures about 40 centimetres (16 inches) in length, not including the peduncle, and is formed of numerous persistent bracts, of which the ten or twelve inferior ones alone enclose the fertile flowers. The flowers situated at the seat of the superior bracts are male. The bracts are oval-lanceolate, more or less elongated, and are from 4 to 5 and 9 centimetres (1.3-5, 2, and 3.3-5 inches) broad; and 71 to 35 centimetres (6.4-5 to 10 inches) long, more or less cuneate at the top. The flowers are arranged in two rows, to the number of ten or twelve: five or six of the inside row, five on the outside. The perianth has two lips, the smaller enclosed at the base by the larger, the first tridentate at the top, and longitudinally mucronated, about $\frac{3}{4}$ inches in length, not including the prolongation; the longer caliculated, trilobed at the top, from 2 to 3 centimetres (4.5 to 1.5 inches) long with lobes sometimes 4 millimetres (4.25 inch) long, sub-obtuse or sub-acute at the top. Stamens to the number of six as long as the exterior lobe of the perianth, one of them often more or less abortive with slender pedicel, with 2-celled anthers, about 12 millimetres (12.25 inch) long, obtuse at the top, fixed at the top of the pedicel, attached in their whole length to the connective; pollen grains globular or sub-globular with a thick external wall showing grains at intervals. Inferior ovary, trilobulate, with numerous ovules, of 2-series with elongated style as long as the stamens, exceeding them slightly, terminated in a claviform stigma, irregularly lobed. Fruit oblong, angular, sub-pyriform, attenuated to a sort of pedicel at the base, shiny, greyish exteriorly, irregularly tuberculate in consequence of the protuberance of the seed crowned by the base of the lobes of the persistent perianth, enclosing about twenty-three seeds, and measuring about $5\frac{1}{2}$ centimetres ($2\frac{1}{2}$ inches) long by $2\frac{1}{2}$ centimetres (1 inch) broad towards the end. Seed enclosed in a pulp which becomes pulverous and white in a dry state, ovoid-angular through mutual pressure 8 millimetres (about 4 lines) high by 9-10 millimetres (about $\frac{3}{4}$ line) broad, the attaching cicatrice 3 millimetres (3.25 inch) in diameter of a beautiful shiny,

black colour, limp, furnished at the top with a little punctiform depression surrounded with a slightly protruding border. Habitat: Borders of the ravines in the region from Kisautu to Luvituku, the two extreme points of the Lower Congo, where up to the present it has been observed. (J. Gillet, 1900).

From what we have said above, it would appear clear that Gillet's plant belongs to the group of *Musa Ensete* Gmel., and that, therefore it belongs to the sub-genus *Physocaulis*, Baker (1), which includes only six species in tropical Africa and eleven in the whole world. From the size of the seed it approaches *Musa Livingstonia* and *proboscidea*, but in the first of these, instead of being smooth, they are tuberculous, and as regards *M. proboscidea*, the height of the plant (four or five times as tall as a man) and the length of the inflorescence are sufficient to show that it is widely distinct from the former.—*Review Des Cultures Coloniales*

CLOVE PLANTING.

Sir Lloyd Mathews writes to us as follows:— I send you a memorandum which was written for me by Mr. Lyne, and which please publish in the *Gazette*. It gives an idea of what the outlay would mean for anyone who desired to plant cloves in Zanzibar. Probably 20 per cent should be added to Mr. Lyne's figures to meet the case of a private individual who might not have such facilities as he had, as for example, in the employment of prison labour. Otherwise the figures represent what the actual expenditure would amount to in laying out and planting such a plantation as he describes.

As regards coconuts the cost per tree would probably amount to about 50% more, or roughly, 1½ annas per tree to plant. In the interval between planting and bearing the ground can be occupied by bananas, mulogo, sweet potatoes, and other annuals which might be expected to pay for the cleaning and cultivation of the plantation during that interval. Planting cloves and coconuts in Zanzibar is not, it will be observed, a very serious undertaking here, and is well within the reach of small capitalists.

THE LAYING OUT AND PLANTING OF A CLOVE PLANTATION OF 6550 TREES.

This work was begun at Dunga on March 5th and completed on April 22nd. Omitting Sundays and holidays—the Sifukuu of El Hadj fell within that period—the total number of working days was 39. As previous to March 5th no preparation had been made for the laying out of this clearing, and as from that time the work was carried on without interruption to its completion, it constitutes a useful experience as to the time and men required for, and the cost of, planting Cloves in Zanzibar. On an average there were 42½ native people occupied daily, beside overseers; of these 16½ were prisoners, 6 boys and 20 ordinary paid labourers.

The prisoners were employed chiefly in collecting the seedlings into the nursery, and afterwards, when the time came, in carrying them out to be planted. Some who were in leg irons were set on to dig holes, at which work they proved almost as good as the paid labourers. The boys were employed in helping the liners, in filling in the holes, in helping the planters and a few at times in digging holes. The employment of prisoners and boys has reduced the cost of the plantation considerably. Clove-planting consists of five main operations, namely: lining, holing, filling in the holes, collection of, and planting

the seedlings, shading and mulching. *Lining.* The trees were placed 21 feet apart, which gives 98 trees to the acre.

Two men and a boy are required for each gang of liners. Each gang has a rope—or better still a surveyor's chain, which will not stretch nor shrink with the weather—with a piece of turkey red tied on at the required distances. The gang is also provided with three or four bamboo flags or ranging rods; attached to each gang are two extra men with grass-knives, who go ahead and clear a line through the long grass. These men work singly, not two together in one line, and have flags to keep them straight.

No large clearing operations were undertaken before laying out. There was no time for this in the first place; secondly the ground in every direction was occupied with native patches of muhogo etc; thirdly, in the case of trees placed so widely apart, it is not necessary to clear all the ground at first. Lines were set out parallel and at right angles at convenient places and marked off into 21 feet spaces for keeping the liners straight. When they came to know their work, a gang and two leaders could do 300 pegs a day, though at first they could not do half that number.

The lining cost R38, which is at the rate of nearly R6 per 1000.

Holing was performed with English spades and small crowbars. The spades proved by far the better implements of the two. The men averaged 19.2 holes per day per man; a full day's task for an ordinary man was 20 to 30 holes according to the nature of the soil; boys less. The holes were 1½ ft. broad at the top, 1 ft. at the bottom, and 1½ ft. deep. The last three days of planting we reduced the dimensions of the holes to 9 inches wide and increased the task to 60 per man per day, as we were pressed for time and wanted to make the most of the rain. Holing cost R72-10, a little over R11 per 1000.

Filling-in. This should be done at least a fortnight before planting is begun, but owing to lack of time we had for the most part to plant immediately. The soil had therefore not sufficient time to settle in the holes and form firm compact beds for the reception of the young plants. The soil will now settle *after* the trees have been planted, instead of before, and thus disturb the roots. Filling-in cost R34-7-9 or R5¼ per 1000 and the fillers-in averaged 45 holes per diem.

Collecting the Plants. We had at the time very few plants in the nursery, so we sent into the plantations for self-sown trees and in this way collected 10,513 seedlings; 7,072 came from Machui and 3,441 from Mbweni. The latter we purchased at the rate of R1 per 100. Most of the young trees we gathered into the nursery, watered and hardened them to the sun. A fortnight of this treatment enabled the young trees to develop new root growth before being left to themselves. It also weeded out those that drooped and died.

We found the advantage of this after the clearing was finished, as the percentage of deaths among those trees so treated is at present very small. 1,500 trees were however put straight into their holes without being nursed. The weather was at the time very wet and excellent for planting. The contrast between the trees nursed and those planted straight-away is very marked. The former for the most part look extremely healthy

and resumed their growth almost immediately they were put out, while the latter drooped at once and I believe that a considerable proportion of them will die. It is too early yet to count the number of deaths altogether, as many of those whose leaves have drooped will doubtless recover.

The fact of our having collected 10,500 young trees in so short a time speaks well of the resources of the plantations if they were put to account. Most of the trees we planted had two years' growth, some three. Arabs, I believe, prefer to plant trees 3 to 4 ft. high. The method of lifting the trees in the plantation explains how it comes to pass that in Arab plantations several trees, sometimes as many as 7, are planted together. Self-sown clove trees often grow very thickly together. In lifting the trees the men carve out a cylinder of soil about 5 inches in diameter to preserve the soil intact about the roots, and as many trees as happen to be within that area are lifted and planted together.

The actual *planting* of the trees extended over 10 days and occupied on an average 4½ men a day. Thus each man planted on an average 145 trees per day. On April 10th 1225 trees were planted by 5 men, and on April 12th 1100 by 7 men.

The total number of trees collected into the nursery was 9013; of these 5050 were planted out and 2812 are still living in the nursery. Thus 1151 have died, a proportion of 12.7 per cent.

The plants cost R1.9 per 100 to collect.

Shading and Mulching.—This work is still continuing. After the first two days we ceased shading the trees that had come from the nursery, as it was found the exposure did not hurt them, that, in fact, they seemed to be better without the ferns. But the trees that were lifted and planted at once soon began to droop under the sun, and these were immediately mulched and afterwards shaded. We shall mulch all the trees, clear a large ring around them to let the air in, keep the soil round the roots well cultivated, and this will be all that they will require till they begin to bear, when the whole ground will have to be cleared.

TOTAL COST OF THE PLANTATION.

Nursery	...	50	—	9
Lining	...	38	—	—
Holing	..	75	10	—
Filling in	...	27	13	3
Collecting	...	102	5	0
Planting	...	19	4	9
Shading and mulching		23	3	6
General transport	...	7	1	9
Boys extra	...	13	2	—
Outside labour extra		11	11	0
Purchase of plants	..	44	7	—

Total...R412 11 6

The average cost per tree is therefore 4.03 pice. The plantation is 66.8 acres in extent and contains 6550 trees, planted 21 feet apart.

We are still lining and holing in preparation for filling up the gaps among the big trees and the space that intervenes between them and the new clearing in order to bring the cloves together into one block. There are probably 1500 to 2000 more trees to plant, but it will depend upon the weather whether we do it now or later.

R. N. LYNE,

Dunga, April 25th, 1901,

Correspondence.

To the Editor.

CEYLON AND INDIAN TEA IN LONDON
London, 10th May.

SIR,—I send you an analysis of the proportions of the three lowest grades of Indian and Ceylon Tea, taken from Gov. Wilson & Stanton's Circular:—

INDIAN TEA, APRIL 4TH, 1901.			
36,790	packages;— of this		
7,559	were Pekoe Souchong'or	20	cent
2,371	were Broken and Souchong or	6½	do
3,445	were Dust, Fannings &c., or	9½	do

Total lowest grades 35¾ per cent

CEYLON TEA, APRIL 4TH, 1901.			
25,479	packages;— of this		
2,991	were Pekoe Souchong or	12	per cent
107	were Broken and Souchong or	½	do
1,167	were Dust, Fannings &c., or	4½	do

Total lowest grades 17 per cent

INDIAN TEA, APRIL 19TH, 1901.			
32,594	packages;— of this		
7,270	were Pekoe Souchong or	22	per cent
2,447	were Broken and Souchong or	7½	do
2,053	were Dust, Fannings &c., or	6¼	do

Total lowest grades 35¾ per cent

CEYLON TEA, APRIL 19TH, 1901.			
31,594	packages—of this		
3,487	were Pekoe Souchong or	11	per cent
289	were Broken and Souchong or	½	do
1,362	were Dust, Fannings, &c., or	4¼	do

Total lowest grades 16⅜ per cent

INDIAN TEA, APRIL 26TH, 1901.			
25,236	packages—of this		
5,088	were Pekoe Souchong or	18	per cent
1,742	were Broken and Souchong or	7	do
2,581	were Dust, Fannings, &c., or	10	do

Total lowest grades 37 per cent

CEYLON TEA; APRIL 26TH, 1901.			
33,329	packages—of this

Total lowest grades 16½ per cent

I have not checked the figures. Anyone can do so, who may think they are wrong. They are worth consideration. As you know whence the figures are derived, you will be able to take them out for yourself; it will I think be worth your while to do so.

Those who ever thought that High Country planters would put out of plucking any of the Tea yielding profitable results, for the benefit of their Low Country neighbours, must have an imperfect knowledge of human nature.

It is the impracticable part of the scheme of the Joint Committee that has failed. Ceylon planters were blamed for making too much in-

ferior tea; they are now blamed for going to make too much good tea!! See Messrs. Gov, Wilson & Stanton's circular of 3rd May, 1901.

C. S.

P.S.—Does not making better tea mean restricted production from finer plucking?—C. S.

GROWING PEPPER AT A HIGH ELEVATION.

North Cove, Bogawantalawa, May 14.

DEAR SIR,—I have been looking through some of your back numbers for information about "Pepper" but can find nothing to help me. Would you or any of your correspondents tell me whether pepper may be grown to pay at 5,000 feet elevation, and if so what is the best variety to cultivate.

I know where to find any quantity of wild pepper and it seems to bear well. If you can afford me any information on this subject, I shall be extremely obliged, as I am thinking of applying to Government for a grant of land on lease for the purpose of experimenting at a high elevation.—I am, yours, &c.,

T. FARR.

[To save a delay of three weeks in answering, we venture to give Mr. Farr's letter insertion in our daily, in order to say that we have never heard of pepper being grown in Ceylon successfully above 2,000 to 2,500 feet. If therefore Mr. Farr is prepared to spend money in pioneering experiments at 4,000 to 5,000 feet elevation, he certainly will deserve encouragement by a grant of land. But first let him have the wild pepper tested by sending a sample to his Colombo and London Agents. Our manual "All about Spices" is unfortunately out of print; but we can send Mr. Farr two back numbers of the T.A. of which the late Dr. Trimen wrote in his Annual Report (in 1889) as follows:—

"As regards *Pepper*, I am glad to see signs of its being taken up on a larger scale. We have disposed of considerable quantities of both cuttings and seeds of the good native variety grown at Henaratgoda, and it is satisfactory to learn that a consignment of this sort grown on an estate near Kandy, so high as 2,000 feet, has sold in London at an excellent price. This cultivation is also of course eminently suited to the native villager, by whom indeed it has long been practised on a small scale. Good accounts of the modes of cultivation followed in Johore and in Malabar, respectively, will be found in the 'Tropical Agriculturist' for September and November, 1888, (pp. 154 and 354); the latter being probably the most suited to the conditions prevailing here."

—ED. T.A.]

RUBBER PLANTING IN CEYLON.

Upcountry, May 23.

SIR,—Would you advise anyone going in for rubber cultivation in Ceylon? What is the best kind to plant, and how long would one have to wait for returns? Any information on the above will much oblige, yours,

AN INQUIRER.

[Certainly, we advise rubber planting in suitable soil and damp climate up to 1,500 feet. Study "All About Rubber," and the *Tropical Agriculturist*, with the Royal Botanic Gardens circulars of Mr. Willis and his coadjutors—and see our summary of all available information in the "Directory and Handbook" early next month,

Enquire of Major Gordon Reeves if seed off his *Castilloa* trees is available: we should be inclined to try this kind in Matale.—ED. T.A.]

CULTIVATION OF CHILLIES IN CEYLON.

Colombo, May 28.

SIR,—Could you put me in the way of obtaining reliable information about the planting of chillies on a large scale. Has this ever been tried in this country by a European? I understand that most of the chillies consumed here are imported from India, so that there should be a good profit if planted on suitable soil where they will crop well.

The estate where I would propose to plant them has very good soil and is situated at an elevation of about 1800-2000 feet. The climate is a dry one, excepting for the months of the N.-E. monsoon. Any information will be thankfully received.—Yours faithfully,
W. E. G.

[We refer our correspondent to the *Tropical Agriculturist* for August, 1900, page 75, and still better to November, 1900, page 369, where—after instructions as to planting—it is stated that very little labour or trouble is required to cultivate chillies in almost any kind of soil on the N.-E. coast of Queensland. Whether that is a guarantee for success at 2,000 feet in Ceylon can only be proved by trial. We think the experiment well worth a trial. (Has our correspondent ever heard of the hard-up planter, whose coffee had gone to the bad, making an honest penny out of a patent medicine for rheumatism and other ills of the flesh in the mother-country—a medicine which took the breath away of old people, but certainly warmed them up in an innocent way: on being pressed by an old friend, the patentee confessed he had nothing but a decoction of Ceylon chillies!)—However, as our correspondent says, there is a real need for the local cultivation of chillies and other vegetables: it is a disgrace that we should be so dependent on India for so many products. Look for instance at our imports of arrow-root, tapioca and sago, all of which should be produced not only for local consumption but export; and yet Ceylon pays nearly R100,000 a year for its supply!—ED. T.A.]

CACAO PODS.

Wattegama, May 30.

DEAR SIR,—Since writing my first report on Cacao Pods and Seeds, I have received a pod said to be a new variety called *Puerto Cabella* and sold by one planter at 30 cents per pod. I have been asked to say whether that pod was anything like the pods I gave an account of. This pod was $7\frac{1}{2}$ inches long, $10\frac{1}{2}$ inches circumference, weighed 1 lb in all; Seed 12 roundish and 28 flattish; weight of wet seed $4\frac{1}{2}$ oz. and colour of pod, shape and seed, when cut open, as near as possible to what I described as No. 2 Cudeamor. This latter was the name attached to the original plant received by me from Trinidad in 1878 and there is now many

trees of that variety in Ceylon, planted from seed of that original plant. The pod I described was larger, more in weight, number of seed, &c. Another pod has been sent to me; this is from a Ceylon cacao estate and is also a *Cudeamor*, but grown on poor soil, weight of pod $\frac{3}{4}$ lb, 41 seed $2\frac{3}{8}$ oz. only (wet). C. P.

CEYLON (AND OTHER) TEA IN GERMANY.

Kandy, May 31.

SIR,—I herein enclose interesting statistics, received from Mr. J H Renton, regarding Ceylon tea in Germany.—I am, Sir, Yours faithfully,

NATIVES AND TEA DRINKING.

Ambegamuwa, June 10th.

SIR,—I think it would be a capital idea if you would invite suggestions in your columns for educating the natives of Ceylon to drink tea; you will remember what Lord Curzon said about the 300,000,000 natives of India that were only waiting to learn to like tea before taking many million pounds of our output off the present markets, or words to that effect. At present my idea is that, though tea is dirt cheap, it is not so very easy for natives to buy it at anything like the price we sell it for in Colombo, even supposing they wish to buy it; and a great proportion do not wish to buy it at all because they have never learnt to like it.

I consider it is our duty to teach them to like it and to enable them to buy it from us at the price we are getting for it in Colombo, minus brokers' charges, rail freight, &c.,—and packing in certain cases. Now for my suggestions. They are put forward for what they are worth; better ideas should follow, but someone must make a start.

(1). Let every Superintendent have a notice up in Tamil and Sinhalese at some place where it will catch the eye of the passer-by, to this effect:—

"Good tea for sale for cash (say) 1st grade 20 cents per lb., 2nd grade 10 cents per lb.

BRING YOUR OWN SACKS."

The above would be for red leaf and souchong. This would be a nuisance for the Superintendent, of course; it would be difficult, but not impossible, to check, and it might lead to thieving, which by the way would not be an unmixed evil, if they consumed what they stole. So much off the present market.

(2) Get natives under some sort of contract to hawk tea round the towns for sale cheap.

Here the Cess would have to come in. A certain amount of tea of low grades could be purchased from estates at ordinary Colombo rates, and sent round in carts and laded out for cash at the doors of the inhabitants. It would not be advisable to sell at a profit at the start, I should say.

(3) "Given away with a pound of tea" is a saying that does not convey as much uow perhaps as it used to, but, when I was a podian, the village grocer used to tempt the rustics to buy tea by giving as presents cheap crockery and ornaments of sorts to those that bought. What succeeded in the old country, and it did succeed, might succeed here.

If I were an enterprising Burgher lad, keen on making money and with a soul above commercial honesty, I would beg, borrow, or steal a waggon, bull, and stock; I would traverse the outlying districts from end to end, and I would flood the villages on my way with the cheapest of teas and the grandest of Birmingham tea-pots and German neckties.

There would be money in it. In towns Caddy-keepers might try the same thing. If too that enterprising Burgher youth could only learn the "Cheap Jack" business, what a time he would have of it. He might end up in the Legislative Council; think how his training would help him there, and, mind you, every pound of tea he sold, so much the better for us. You ought to get plenty of other suggestions; the difficulty is, who is to take it up? It is everyone's business and no one's business. Why cannot the "Thirty Committee" appoint a man (there are plenty out of billets) to boss the show, approach the principal natives, get their ideas, and try and work with them to open up a trade between the tea planters and the thirsty millions?

Who can deny that the object to be obtained is worth a little trouble and thought?—Yours, etc.,

"CHEAP JACK."

NUTS FROM THE COCONUT PALM.

ANOTHER "RECORD" NUMBER.

Hanwella, June 15.

DEAR SIR,—*Re* the question about the largest number of nuts of all sizes on a coconut palm at one time, in your paper of the 10th inst., I have much pleasure to inform you that, on a visit to Madampe, the large coconut planting district, about three years ago, I came across a few heavily laden palms, and out of curiosity I counted up the bunches and endeavoured to find out the number of nuts on one of the trees.

There were 27 or 37 bunches in all, and counted over 400 nuts of all grades, but I failed to count up all. I think there were about 500 to 600 nuts in all on that tree. As regards the largest number of nuts at a picking I know of some trees in the same district which gave 300 nuts at a quarterly picking. Of course, I admit that this is not the common yield of the district. I have a few well bearing palms here, some of which have about 20 bunches, having about 400 nuts of all grades.

A NATIVE PLANTER.

[Can any one beat this record? Signed letters preferred. Ed. T.A.]

RUBBER CULTIVATION IN CEYLON:
THE PRESENT STATE OF THE INDUSTRY;
BACKWARDNESS OF TEA PLANTERS IN
THE LOWCOUNTRY IN DOING THEIR
DUTY BY RUBBER;
GREAT ENCOURAGEMENT TO INTERPERSE
TEA WITH PARA RUBBER TREES IN
MOIST LOW DISTRICTS.

We have just had the estate returns analysed and summed up, and we are distinctly disappointed with the result as regards the extent to which rubber plants—especially of the Para (*Hevea*) variety—have been put out among the tea, or along boundaries, or in separate clearings, in the lowcountry districts which are most suitable for their successful growth. These specially include the districts of Kalutara and Udagama, Ratnapura, Kuruwita, Lower Balangoda and Rakwana, Lower Morawak Korale, and in fact all the South-west division of Ceylon with a large slice of the Kelani Valley, Kegalla and the host of minor districts included between the Kelani and Nil gangas. This is apart from the opportunities for successful planting in some of the Kandy and Matale districts up to 1,500 feet altitude. But in saying we are disappointed at the result of our investigation, we have the satisfaction of finding that the total extent is much in advance of the estimate with which the Director of the Royal Botanic Gardens has favoured us. In March 1878, Mr. Willis estimated that the equivalent of 750 acres were covered with rubber. On the 13th instant he writes:—"I should double that now; but, of course, this is only a rough guess; we have sold locally enough seed for 1,200 acres; but there is more private, than Government, seed now available." This is true, and considering that a census on only two estates—Culloden and Heatherley, certainly the leading rubber growers—in the Kalutara district, shows a total of all ages of 40,000 growing rubber trees and that another estate in Matale West reports 22,000 Paras (some up to 6 and 9 years old) and that patches and interspersings of rubber are found on so many other places, the grand total must, in area, be a good deal in excess of the Director's estimate of 1,500 acres. Of course, a great deal depends on how many trees should be counted to an acre. One counsellor or specialist has actually gone so low as 50 trees. This, we think, many too few. Counting 15 by 15 feet as a fair allowance between Para trees, to do them full justice, we take 200 trees in round numbers as the equivalent of an acre and we find that, in May, 1891, we can count on 2,597 acres as the extent represented by rubber plantings against 1,071 acres in July, 1898. Of course, if 100 trees be taken as the equivalent of an acre, we should have 5,000 acres to deal with; but in any case we do not get beyond the half-million of growing trees of all ages and kinds—chiefly Para, but including a certain number of Ceara—many of them old trees put out in the "boom" of 15 to 20 years ago—with a few *Castilloas* and some of the *Lardolphia* vine. Now with trees up to 9, 10, and 12 years, it is time we were hearing of

appreciable harvestings and exports of rubber. But it is a fact, as Mr. Willis hints, that the fortunate owners of old trees have gone in for crops of seed rather than of rubber, and our export returns for the past three years will show how freely Para seed has been purchased from Ceylon for the Straits and other Far East regions, as well as Burma. Here are the figures for two years: 1898—exported Rubber seed to the (Customs) value of R10,363 and in 1899 to the value of R40,714; while, we feel sure, there has been no falling off in 1900. As regards the export of crude rubber, the returns are very poor so far; but there is no question that the time is rapidly approaching when there should begin to be an appreciable export of rubber from Ceylon, and we would urge all low-country proprietors, who have not done so, to begin to add rubber as a minor, but valuable, product to their tea. Cannot something be also done with the old Ceara trees and their crops of seed, in districts not suitable for Para? Even this kind is not to be despised as has been shown by experience gained in Dumbara; while we append a recent report from an Uva district which shows that it should not be difficult to establish a nursery and to form clearings of Ceara, and, in spite of the drawbacks pointed out, a gathering of $\frac{3}{4}$ lb. of rubber per cooly per day should surely leave a profit:—

“There are a few large trees here now. When taking the bark off for tapping about six feet up the trunk white ants are attracted by the juice. They attack the trees most vigorously and kill them very quickly.* The trees seed very freely and a lot of young plants come up, which grow rapidly; in fact they are rather a nuisance where they get amongst the cultivated tea. A cooly will collect about $\frac{3}{4}$ lb. wet rubber per diem.”

But it is in respect of Para in our moist low districts that most planting has to be done and here is what one planter, of experience in rubber, writes:—

“A vast number of young plants die off before they have time to develop, but once established they are very hardy. (I am speaking of the Para variety). There are besides a number of old Ceara trees scattered about the country representing a very uncertain area, and lately some *Castilloa Elastica* have been planted, but not many.

“It has always been a surprise to me that more Para Rubber has not been planted through the tea on low-country estates. The shade they throw does the tea good rather than harm, and when they have reached a certain age (depending on soil and other conditions) they become a most valuable source of revenue.

“I have heard that the old trees on Culloden which, I understand, have been crudely tapped at intervals for some time past, must have averaged from 15 to 20 lb. of rubber apiece; and they are still in excellent heart, though the bark has been dreadfully lacerated by imperfect tapping. A cooly, after a little practice, can collect from 1 lb. to $1\frac{1}{4}$ lb. per diem and at present prices (3s 6d

This is something entirely new—we never heard of it in Dumbara—and it is surely due to very rough handling of the tree in tapping?—*Ed. T.A.*

per lb.) this leaves a very fine margin of profit. Planters, however, are always impatient for returns and it is difficult to get them to see the advantage of introducing a cultivation unless there is a prospect of a speedy turn-over; hence the few rubbers that have been introduced amongst the tea, a source of regret now and it may become still more so before long!”

We think the above ought to stir up low-country tea planters to lose no time in adding this rubber string to their bow. We should fain see not half-a-million but many millions of rubber trees growing in the island to add to its agricultural wealth and increase the value of tea plantations.

PLANTING NOTES.

FUMIGATING CITRUS TREES FOR SCALE.—An orchardist, writing to the Fruit Expert as to results achieved by fumigating citrus trees for scale insects, says:—“I have fumigated about 900 trees with the most happy results. Trees badly infested with scale lost a large portion of foliage, but the after-growth was very luxuriant indeed; and from unhealthy, forlorn-looking things, they were transferred into bright, glossy, healthy trees.”—*Agricultural Gazette of New South Wales.*

A PRODUCT FOR OUR PATANAS.—Australian wattles (the *acacia dealbata* or *decurrens*) should grow readily on our patanas and the bark is valuable for tanning. We read that “the Wairangi wattle plantation in the South Island of New Zealand contains 1,900 acres. The output of bark annually reaches 150 tons, and this will shortly be increased to 200 tons. The variety grown is the *Acacia decurrens*.” Why not Uva patana plantations covering thousands of acres?”

A GERMAN BOTANIST is said to have discovered that, out of 4,300 species of flowers cultivated in Europe, only 420 possess an agreeable perfume. Flowers with white or cream-coloured petals are more frequently odoriferous than others. Next in order come the yellow flowers, then the red, after them the blue, and finally the violet, of which only thirteen varieties out of 308 give off a pleasing perfume. In the whole list 3,880 varieties are offensive in odour, and 2,300 have no perceptible smell, either good or bad.—*Indian Agriculturist*, June 1.

FISHING WITH A STEAM PUMP.—A pond on the farm of La Marquette, bordered by rocky shores, had never been drained, owing to the expense. Last year the proprietor conceived the idea of making use of a powerful steam pump. Each stroke of the piston drew up a hectolitre (25 gallons) of water, and the pond was therefore emptied in a few hours, and not only was the water drawn off, but also all the fish that it contained. This was a revelation. All the owners of the ponds in the neighbourhood have followed suit, and the owner of the pump is making a speciality of this kind of work. He lets out one of his pumps, modified for this purpose. Each stroke of the piston brings up a torrent, with which are mingled fish and crawfish, together with dirt and débris such as are contained in every pond—old sardine boxes and the like. A sort of metal basket receives the whole. The water and slime escape, while a boy collects the fish and sorts them according to species and weight.—*Home paper*, May 25.

THE TEA PLANTING INDUSTRY OF
CEYLON, MAY 1901:
387,000 ACRES OF TEA ON PLANTATIONS
AND 5,000 CULTIVATED IN NATIVE
GARDENS.

A good deal of curiosity has been manifested by Visiting Agents and others as to how the figures for tea area would work out on the present occasion, in view of the check to planting and the possible abandonment of unprofitable fields. In July 1898, the total extent on plantations was 364,000 acres; but we showed that, reckoning a certain acreage of coffee planted up with tea and about 7,000 acres in native gardens, we might take the Tea Industry of Ceylon as being well on to 375,000 acres by the end of 1898. Now the extent covered with tea on the regular plantations is 387,000 acres, in consequence of additional clearings in 1899 and last year, besides 5,000 acres, which we make out the *cultivated* native gardens to represent at the present time, and a certain extent still, we fear, to come over from coffee fields; but, perhaps, against this may go the gradual exclusion of poor corners of tea in different districts, so that the safest reckoning will be to put 392,000 acres as representing the Tea Industry of Ceylon in May 1901—an increase of 17,000 acres on the full reckoning for 2½ years ago. Out of this total of 392,000 acres, we put the extent of tea which is five years old and upwards at 300,000 acres (and this must have given an average of 411 lb. per acre in last year's crop)—so that there are fully 30,000 acres of young tea yet to come into full bearing in Ceylon. This should be a further warning to our Indian neighbours against further planting at this time.

The greatest addition of tea to any district in the past two years is in Haputale, where the increase equals 4,000 acres; Badulla district shews an addition of 1,500; Kalutara 2,000; Kelani Valley 1,400; while Dimbula has more tea by 1,800 acres and Kuruwitta district an increase of 1,200 acres. On the other hand Dikoya has altered very little and the return for Pussellawa and a few other districts positively aggregates a less total than in 1898.

Dimbula of course heads the list with the largest acreage of tea—over 46,000; while the Kelani Valley comes next with well-nigh 35,000 acres, and Dikoya only a little under 30,000. In all Uva there are now 60,000 acres of the staple; while between Great Western and Adam's Peak the three districts comprise 95,000 acres—surely one of the finest expanses of tea in the world.

MR. KELWAY BAMBER AND OUR
TEA INDUSTRY IN UVA AND DIKOYA.

Mr. Kelway Bamber has been away on a visit to an estate in the Lunugala district and also (yesterday afternoon) to another estate in Dikoya, and returns to Colombo early next week. His investigations are widening and, after the preliminary canter hitherto, the results should increase in interest to the planting community. One of

the most curious things that has struck Mr. Bamber is that young tea on new clearings nowadays, he is constantly being told, does not give anything like the same result in growth in the same time as when tea was first planted. The cause of this, Mr. Bamber thinks, must lie in the smaller quantity of carbonic acid, which goes to form organic matter, that is drawn from the air nowadays by the average tea-bush in any one district; and new clearings near old tea-fields are thus bound to show smaller results than the former young clearings in new country. As little as 3 to 5 per cent of inorganic matter in the tea bush is drawn from the soil, the material for organic matter mainly from the air. It is to return some of this organic material to the soil that should be object of the cultivator. In addition to the burying of prunings, Mr. Bamber advises cutting down and burying the jungle *willu*,—after leaving it awhile to rot, preferably, so as to give off carbonic acid gas.

Other aids to tea-planters would be forthcoming if a Geological Museum, with specimens of rock from every district, were attainable in Ceylon. Rocks, it must be remembered, are almost invariably indicators of the soil to which they belong; and if such a geological branch could be added to the Colombo Museum, Mr. Bamber would be able to extend his scientific work to the analysis of the constituents of the rock-formations of the various districts and the determination of the suitability or otherwise of the soil for tea, or indeed for other products. We trust that, as soon as the time comes for Mr. Bamber to take his share in such a work—which, we think, will be intimately connected with the Geological Survey when *that* comes, but can scarcely wait for it entirely,—Government will do their part with a ready hand. The planters, in providing typical rock specimens from their several districts, we may be quite sure, will readily do their part.

SAMBUR-HUNTING IN CEYLON.

BY THOMAS FARR.

(From the *Wide World Magazine*, May.)

[A detailed description of a very exciting sport practised in the Horton Plains district. The photographs will be found interesting; but we desire to draw special attention to the spirited frontispiece and other special drawings which have been prepared for this narrative by Mr John G Millais, F Z S., etc. For twenty years Mr Farr has been the leading elk-hunter in Ceylon, and has been master of three different packs. In his article he describes "the run of his life."—ED.]

Sambur, or elk as they have been called in Ceylon from time immemorial, vary in courage to a most striking degree. There is the stag that will bellow and squeal almost as soon as he catches your eye—even before a hound has touched him; and then there is the gallant, fearless brute that will fight to the last and die game without so much as a groan.

But I must describe elk-hunting as it is carried on in Ceylon before I give you an account of the grand "day" we had on the 11th of June. Sir

Samuel Baker has described the sport in two most readable books; but beyond this I have seldom come across an accurate account of it as it ought to be and generally is, I have once or twice read descriptions which were ludicrous from their inaccuracy, and the sport seemed to have degenerated into a scurry with a nondescript pack of tykes, attended by a crowd of people armed with guns and spears.

Then comes a very good portrait of
THE AUTHOR, MR. THOMAS FARR, FOR TWENTY-YEARS THE LEADING ELK-HUNTER OF
CEYLON.

(From a photo by F and R Speight, 178, Regent Street, W.)

"Elk" hunting, as it has always been carried on by some two or three recognised packs in Ceylon, is almost entirely on foot, and the only weapon used is the hunting-knife with a ten-inch blade. A horse is occasionally useful to take one from point to point in a hard run, where some game track, native path, or road lends its assistance; but in nine cases out of ten you would find your horse up to his girths in a swamp before you had followed a pack of "elk" hounds across country for a quarter of a mile.

The country is a very stiff one, lying at the summit, more or less, of the mountain zone of the island, and falling down from this undulating plateau of some 8,000 ft. to elevations of 4,000 ft. and 5,000 ft. Vast tracts of forest are here interspersed with open downs of short, coarse grass called patanas, and at the bottoms of the valleys are streams of some volume and size. These will be found widening out into grand pools, narrowing to shallow rapids over rocky beds and impassable in floods, or plunging down deep gorges and chasms and falling over bare precipices and crags. Waterfalls of 50 ft. and 100 ft. are necessarily common in such a country, and one I know of is some 2,000 ft. At the very lip of this "Banjy" I once killed a magnificent stag. It is a big country, too, where I have chiefly hunted during the past twenty odd years, and where the hunt I shall endeavour to describe took place. It is known as the Horton Plains Country, and may be described as the "Roof of the Island." Through its open grassy downs meanders the most perfect trout stream it is possible to imagine. For some ten years ova have been imported from England, and the stream has been well stocked, affording splendid sport to the members of our fishing club.

As for climate it would be hard to beat anywhere, and at this high elevation, over 7,000 ft., it is easy to imagine that hard exercise, even in the tropics though it be, is not only possible but enjoyable. Often during December, January, and February the patanas are white with hoar-frost up to 6-30 a.m., whilst the shade temperature during the day varies from 55 deg. to 65 deg. Fahr.

"HOUNDS ARE UNKENNELLED BY 5 A.M. ON A HUNTING MORNING."

[Picture From a Photo.]

Hounds are unkenelled by 5 a.m. on a hunting morning, and with luck are back on their benches by twelve noon. The pack consists of foxhounds, deerhounds, and kangaroo hounds. The following would be a very "killing" lot: eight to nine couple of 23 in. English foxhounds, three to four couple of deer and kangaroo hounds, and three or four good, hardy Norfolk lurchers to run with the finders. Foxhounds are too apt to confine themselves to baying the hunted stag, which

will often stand and defy them in the jungle, while he gets his wind, whereas a lurcher will give him a nip somewhere as a hint to move on.

As a rule the quarry carries a fine scent, and you may often see your lurchers ahead of the foxhounds, driving him for all he is worth. At this pace, especially if it is a matter of a mile up-hill or a quarter of a mile up a steep patana bluff, the stag gets blown, and comes down to the pool below to make his stand. There the deer and kangaroo hounds play their part. These are known as "long dogs" or "seizers," and they are distributed by one knowing the country and the run of the deer. Dog-boys are told off for this work, generally assisted by one or two of the field.

On more than one occasion I have seen the hunted stag or hind lie down in a pool close in front of hounds, all but the nostrils hidden beneath the surface of the water, and I have actually seen half a pack pass within a few feet of a stag's head just above the water without winding or seeing it. When, sooner or later, he stands to fight it is generally in shallow water to begin with. On some narrow ridge of rock in mid-stream, with deeper water around him, he awaits the leading hounds—one or two couple probably, which have to approach him swimming. He shows no sign of fear, but an impatient stamping of the water with his fore-feet betrays his rage. As more and more come on, and the more formidable-looking "seizers" arrive on the scene, the situation changes.

Instead of attacking his pursuers in fierce rushes, he breaks his "bay" and seeks deeper water where even the big kangaroo hounds must swim to reach him. Here he will stand up to his chest in water, rearing up occasionally to pound huntsmen and hounds as they approach him. The knife being the only weapon used, a near approach is necessary to give the fatal thrust behind the shoulder.

The stag, too, takes good care to keep his head towards you, so that the vulnerable point in his side seems unattainable. Then, when still harder pressed, he takes to deeper water, and swims at such a pace that, unless hampered with hounds at his ears, no human being in his clothes can hope to keep near him. As he crosses the shallows at the head of the pool or passes some convenient rock the sportsman takes his opportunity and a skilful thrust is often as effectual as a well-directed bullet would be.

If the stag takes to deep water, unless a man be a good swimmer it were wiser for him to remain on the bank and watch the fight until he can see his way to a dash at his quarry on the shallows. The stag uses his fore-feet with terrific force, and I have seen strong seizers ["WHEN, SOONER OR LATER, HE STANDS TO FIGHT

IT IS GENERALLY IN SHALLOW WATER

TO BEGIN WITH.—Picture.]

almost cut in two by them; while with his hind-feet he is as quick and handy as a pony. Now for the story of the fighting stag.

It was on the 11th of June that four of us met on the Horton Plains: Maitland (the Master), Ross, Wilson, and myself. The morning was fine, and we left the kennels at 5:45 a.m., but it was too windy to be called a good hunting morning, as it was almost impossible to locate sound accurately.

Seizers having been placed, Maitland with a short pack of about eight couple drew in along a low ridge of thick forest running parallel with the

river. A stag had been harboured there the day before, so we were certain of a find. Just above Figure of Eight Pool the first whimper was heard, and Beauty proclaimed a good find, for immediately afterwards the hounds went away with a fine burst of music.

[A TYPICAL "PATANA" OR OPEN DOWN OF SHORT, COARSE GRASS.—Picture.]

Crossing the river and still keeping along the valley, Ross, Wilson and I ran down the open, keeping in touch with the pack now tonguing merrily on our left and making for a narrow belt of patana into and almost through the jungle above us. Here two seizers, Dainty and Vengeance, had been placed, as the stag was pretty sure to cross it on his way to Baker's Falls, where he would probably make his first stand, or, at any rate, cross the river there.

We reached the belt of patana just in time to see the tail hound flash out on to the grass, and just below us in the hollow we could hear a "bay." Before we could get to it the stag broke bay and dashed into the forest, heading for the falls. We could just catch a glimpse of a nasty red gash on the off-shoulder of Dainty, the fast kangaroo hound, as he passed us, and following we heard the whole pack racing down a precipitous slope to the top of the falls.

Getting over the top of a knoll, in front of us we could hear a grand "bay" going on in the river some 200 feet below us. We were tumbling down the patana side to this when the "bay" ceased, and a big, heavy stag passed in full view on a bit of swampy ground on the other bank of the river. Hounds were close at his heels and, after a momentary check in a stream down whose rocky bed the stag had trotted knee-deep in water, they dashed into the jungle on his line. A second later, amid a chorus of music, a fine stag trotted back into the open, apparently from the very middle of the pack. At the time it appeared that he must be the hunted stag, but subsequent events proved that this was not the case. Not a single hound came out on his line, and he was soon out of sight again in the jungle.

In the meantime we could hear hounds getting away up the opposite slope now in thick forest; but the noise of the wind and rushing water made it impossible to locate the sound. The "field" now divided, Maitland and I following the direction the pack had started in, whilst Ross and Wilson, thinking hounds had turned right-handed, made the best of their way in that direction. After a sharp run of about three-quarters of a mile to Onion Patana, with nothing but instinct to guide me, I heard far away in a thickly-wooded gorge a distinct baying of hounds. So, getting into a game path by the edge of the stream, I ran along as fast as dense undergrowth and trailing creepers would let me, and after going about half a mile all sound ceased.

THE FIGHT IN MID-STREAM COMMENCES.

The stag had again broken "bay" before I could come up with him and, swinging round left-handed up a narrow gorge, he soon took the pack out of hearing. Coming back to Onion Patana and disturbing on my way a large troop of Wanderoo monkeys, whose bark or grunt is sometimes uncommonly like that of a wild boar, I met Maitland. He had heard no tongue, but had picked up two couple of hounds that had been thrown out in the run. Around us the forest trees swayed in the wind,

and occasionally the note of a distant bird or the wail of chafing branches would make us start with hope that we heard hounds running. The jungle was sodden with last night's rain, and by this time I was wet to the skin, so that standing still in the cold wind was not at all to my mind.

"THE STAG WOULD REAR HIMSELF UP ON HIS

HIND LEGS."—ENGRAVING.]

We decided to return to the open plains by the way we had come and so got to the river as quickly as possible. The hounds we had recovered had evidently come from a high, forest-clad ridge rising some 600 ft. between us and the river. To get round a spur of this was now our object, and we had hardly entered the forest for this purpose when to our joy we heard the welcome sound of a "bay" far away below us, and again in the direction of Baker's Falls. Making the best pace we could, we were soon out on the open patana again.

Now the baying of hounds became more and more distinct, and forcing our way through the fringe of long grass and brambles, always to be found where jungle and patana meet, we gained a view of the river. Here a lovely and striking picture met our view—a long, broad reach of water extending to the very lip of the falls, and broken here and there by ridges of rock and rapids and intervening pools.

In one of these, out in the mid-stream, stood a magnificent stag at bay. His head was lowered to below the level of his withers, and his mane bristled with rage. Taking advantage of every favourable feature in the surroundings, the hounds approached him, baying furiously from ridges of rock, from the bank, and more venture-some ones from the water itself, all in a grand chorus. The stag was in fighting trim and fighting mood, and at frequent intervals with a bound or two forward he would rear himself up on his hind-legs and with lightning stroke his hoofs would break the water with a splash above or within a few inches of an approaching hound. To avoid his terrific and sudden attacks the old and experienced hound would allow himself to sink beneath the surface, whilst the water would break the force of the blow. So far only the leading hounds were up, and no seizers. We knew it was useless to expect to keep him at bay for long, or kill him with only half-a-dozen foxhounds, so the situation was becoming critical.

The master then blew his horn, giving his signal to the dog-boy to bring the seizers, and after many anxious minutes, during which the stag was fast getting his wind, first one and then another appeared in the distance galloping to the 'bay.' A few more hounds had come up on the line, and the bay became louder and louder as they joined in.

Then down the steep slopes to the river came Venns and Strathspey, Rover and Dainty, with Vestal, Vengeance, and Victor, Slavin and Rufus—a truly formidable band, all racing to join the baying pack. In a moment the situation was changed.

The hounds took heart of grace from the plucky seizers and leaped from rock to rock, whilst the latter splashed through shallow pools and, bursting through scrub and grass on the bank, soon showed the stag he had more formidable opponents to deal with than a few baying foxhounds. In a moment the stag broke his 'bay' at once, and with a few bounds was across the river and once more in the sheltering jungle.

The pack, now almost all up, pressed him fiercely, and raised such a chorus on his line that even the roar of the falls and the noise of the wind could not drown it. They hustled him along through the dense forest, and now he tried a desperate move to baffle his pursuers. We were on the very top and brink of the falls, and Maitland waded across the pool just above where the stag had made a short stand, whilst I waited, expecting he would run a short ring and return to the same pool to continue the fight. Leaving the falls for a moment, I could hear hounds getting lower and lower, baying as they went.

It was a frightful bit of country. The falls are broken into three steps or ledges, with a deep pool worn into the solid rock, into which the water plunges with a roar. The first fall is some 25ft., on to a narrow ledge, thence, after a swift swirl in its water-worn basin, it spouts out again over another 15ft. of rock on to a broader ledge below. Above, the river has divided so that, while half of it descends to the narrow ledge I have just described, the other half falls sheer over some 30ft. into a deep, dark pool at its base. On either side of these falls and within the influence of the water are perpendicular cliffs, from crevices in which magnificent tree-ferns lean their graceful fronds towards the spray.

It had now become evident to me that there was no chance of the stag ever reaching the top of the falls again, and the sound of hounds could now only faintly be heard through the roar of water. Crossing with the greatest care over the very brink of the precipice, where a false step or a slip would have meant certain death, I reached the other bank, and forcing my way through dense undergrowth away from the falls I could again hear the furious baying of the pack now far below me.

Looking over the edge of the precipice, which extended into the jungle from the river, I could see Maitland lowering himself by saplings, roots of trees, and trailing creepers into a perfect chasm. But the baying of a pack of hounds and a fighting stag will lead a man anywhere, and down I went hand under hand, hanging sometimes directly over Maitland's head.

Just as I reached the bottom, drenched and almost blinded by the spray of the left-hand fall, I witnessed an extraordinary sight. On the brink of the fall in one living, struggling mass were the stag and two-thirds of the pack—the stag with his feet in the air and Rover fast on his ear. The good old hound had made his seize with such effect that the shock and the slippery foothold had turned him over. It was only a momentary glimpse, for at that instant the whole lot of them went over the fall together. The force of the stream and the narrowness of the ledge gave no chance for a single hound to avoid it.

Following Maitland, who was the clambering down the side of the fall, through pools and over boulders and down another wall of rock, we reached the second pool. Here the stag had reached his last stronghold wherein to make his final effort, and a gallant effort it was. The depth of the pool into which he had fallen had saved his life for the moment, for he had somehow crushed poor Rover in his fall. He lost no time in making good his advantage. The ledge of rock here was much broader than the one they had just left and the rocky basin was some 40ft. long and 20ft. wide. From this there was only one way out except over the falls, for on the far side rose a spur of some

50ft. whilst on the right was the fall and left the lower fall.

The rest of the field here joined us, coming down the face of the precipice where a few shrubs and saplings grew. Now the fight began in earnest. It was a grand and awesome sight that we looked upon. From above us the upper fall plunged down into the deep, dark pool at our feet with a thundering roar, and clouds of spray rose into the air around us. At the tail of the pool, and on the lip of the lower fall, in the fierce rush of the descending torrent stood the stag, facing the pack, as the bolder ones dashed or swam towards him. Below and behind him no living creature could have gained one second's foothold.

[THE MASTER SOUNDS HIS HORN AFTER THE KILL TO CALL UP STRAGGLERS.—ENGRAVING.]

[HERE IS A UNIQUE PHOTOGRAPH SHOWING TWO HOUNDS ABOUT TO ATTACK A STAG AT BAY IN THE STREAM.—ENGRAVING.]

The water from the pool confined in its narrow, worn channel rushed with swirl and eddy past him, breaking over his hocks, but barely reaching his knees. To reach him here with the knife was quite impossible. Over a sheer wall of rock the fall plunged with a reverberating thud into the pool some 30ft. below—a solid rock cauldron of black, seething water.

The gallant stag here held his own and gained his wind once more. Hound after hound, feeling the danger of the stream and fearing to face the stag in such a place, came away to adjacent rocks and ledges to bay their feelings to the full. But Venus, a grand white deerhound, was not to be denied. With the courage and recklessness of the best of her race she made her spring to seize, trying for the ear as Rover had successfully done in the pool above; but she missed her point. In a second she was drawn into the vortex of the deadly rush of water, and in another she disappeared like a flash into the pool some 30ft. below.

It was a sickening sight for her owner—indeed for us all—to see this grand hound whirled down, out of sight even before she was well over the cruel fall. Her attack, however, dislodged the stag, and forward he bounded once more into the safer environment of the pool. But other hounds encouraged by the good seizer's effort, had ventured too far out in the stream, and in a moment, one after the other, Beauty and Rosebud—a splendid couple of foxhounds—and Rufus and Pillager were swept past us over the fall. Another good hound followed and then another, and two were saved on the very brink.

Now hound after hound dashed in to seize, only to be pounded by the stag as he stood on some submerged rock as a point of vantage to meet his foes. Wilson sprang in at him knife in hand, but missed his point behind the shoulder, merely grazing the skin.

With all one's clothes it was no light matter to swim in the swirling eddies near these great falls and it was with some difficulty that he regained the ledge of rock from which he had jumped. The stag in the meantime, startled by the sudden plunge and the prick of the hunting-knife, swam immediately under the fall, and as he passed under the torrent of water he threw his head back and seemed to lift himself away from the suction of the under current, which must have been very strong where the fall met the pool.

Coming round to my side, where I guarded the only path out of the pool to possible freedom, he faced me quite undaunted and walked calmly right up to the point of my knife as I stood on a ledge of rock level with the water. I knew I could not reach his heart with my knife in this situation, even if I had plunged straight in, and he did not consider it advisable to approach any nearer. A few hounds dashed in again and some of those still swimming tried to seize, so once more he swam across the pool.

Wilson then made a second attempt, and this time the under current seemed to draw him down; it was only by the greatest effort that he succeeded in clambering up to the ledge once more.

Dainty, in spite of the wound on her shoulder she had received at the first short "bay" on the patana, here seized magnificently, and over and over again had the stag by the ear, but the water was too rough for her. The stag would sink or even dive to choke her off, and invariably succeeded in doing so. Vestal, one of Venus's fine litter and almost a puppy, was barely a moment on the bank; and Blithesome and Reckless, two fox-hounds, went in over and over again most pluckily, but against them all the stag held his own most gallantly. We, too, were not idle, making a dash here and there as he seemed to expose himself to attack; but as often he eluded us. At last after an hour's fight Ross, taking an advantage of a fine bit of eezing by Vestal and Dainty in the shallow channel between the pool and the lower fall, got his knife into the heart. Our quarry was a fine stag, and must have weighed fully 30st. clean; a better fighter I have never seen. Having dragged the carcass ashore and performed the usual offices, the hounds were duly rewarded as they so well deserved.

We now turned our attention to the wounded and missing. Of the six hounds that had gone over the lower fall Venus, Beauty, and Rosebud had joined us. How any living creature could survive such a fall it was impossible to imagine; but all three took part in the "bay" again, although it must be confessed with ardour somewhat damped by their descent into the pool below.

Three hounds or more were still away and we feared the worst, but poor old Rover claimed our first attention. He seemed in a very bad way, indeed. While the "bay" was going on we had noticed him for some time perched on a boulder shivering and taking no interest in the proceedings; as we moved away to reach the open we realised how bad he was. He staggered and fell on his side, and seemed quite unable to move. A little whisky was poured down his throat, and he was at once carried to camp; but when we reached home an hour afterwards he was dead. Welkin, one of the fox-hounds, was badly pounded at the beginning of the "bay." The stag had caught him fair on the back and temporarily injured his spine. It was hours before he came round, and weeks before he could leave the kennel again. One or two others had bruises and slight wounds, but none of any consequence. Venus was injured going over the big fall, and for sometime showed signs of injury. We found the rest of the missing ones shivering on the sides of the pool—two of them so placed that another plunge into it was necessary before they could reach us.

CAOUTCHOUC FROM THE CONGO.

WHENCE OBTAINED—PROTECTION AND FOREST CONSERVANCY—VARIETIES OF CAOUTCHOUC—PREPARATION OF THE JUICE—PROPAGATION—MULTIPLICATION—PLANTING.
(RUBBER.)

Almost the whole of the caoutchouc exported from the Congo is obtained from climbing plants of the genus *Landolphia*, and some other Apocynaceous plants. Caoutchouc from some species of *Ficus* appears sometimes on the market.

The authorities of the Congo State have wisely decided that so valuable a product as caoutchouc should be protected from the inroads of traders and of natives, and that the trees should be carefully cultivated. King Leopold signed, in January, 1900, the necessary documents for the institution of a "Service de Controle Forestier."

This institution is of great importance from an economic point of view, and I may mention that the first results obtained by it have been highly satisfactory.

According to the regulations it is ensured, under the superintendence of this forest-service, that every individual who collects caoutchouc be by law obliged to propagate either the Lianas or the trees yielding the rubber, according to the discretion of the superintendent of the district. Therefore societies of growers (and they are numerous in the Congo States) have so well recognised the profit obtainable by working on a large scale, as the new State regulation requires, that they expect a bright future, and have despatched many specialists simply to re-stock exhausted forests, and to increase the riches of the others. It is certainly remarkable in colonial annals that a regulation, made in January, 1900, and confirmed in March, should not merely be in action within that year, but that important Liana plantations should within that short time be under the control of the appointed agents.

Already the plantations in the equatorial district (among others) include 3,000,000 of these Lianas. When in September, 1897, I left the Royal Gardens, Kew, for my duties in the Congo State, there was but little said concerning any extensive crops in equatorial Africa, except Coffee and Cocoa. Cultivations of Rubber-plants has come up wholly in the last two or three years.

VARIETIES OF CAOUTCHOUC.

In Congo there are four very distinct caoutchoucs of the *Landolphia* genus, besides the "des herbes" species (*Carpodinus lanceolatus* and *Clitandra Henriquesiana*, an allied genus), and three other species imperfectly determined. The "des herbes" Caoutchouc is well-known. The difficulty of collecting the rubber, and the impurity of it, renders it of little use. The other species are quite distinct; the one is white, the second is black, the third is rosy.

The white caoutchouc (called by the natives Matofemongo, and by other names, according to the village in whose vicinity it is procured), is a vigorous Liana, whose stem rarely measures as much as a foot in diameter. The fruit is round, and from about the size of a green Walnut to that of a large Orange. The skin is thin, slightly wrinkled, violet when young, yellow-red or bright-red at maturity. The fruit contains from ten to thirty-two seeds, each surrounded by hairs, and

filled with sugary-acid juice. The whole resembles yellowish-white mucilage. This is probably *Landolphia ovariensis*.

The rosy caoutchouc is probably a variety of *L. ovariensis*; it also is a sturdy Liana, the stem of which is sometimes 6 inches in diameter. It bears small, pyriform, yellowish-green or reddish-green fruits, with, at maturity, a "nubly" wrinkled skin, and containing from four to twenty seeds, surrounded with yellowish-white hairs filled with acid juices. This yields the most valuable rubber; specimens quoted 4s. 5d. per lb. Native names for the plant are Bongow, Mongew, &c.

Black caoutchouc (Mondongo, Boole, &c.), or *Landolphia florida* var., is a sturdy Liana, the stems from 4 to 6 inches across, bearing round fruits, easily recognisable, as the seeds are surrounded with a blood-red viscous pulp. They number from four to ten.

The Congo caoutchoucs are remarkable for their purity. The natives coagulate the milk either by precipitation in boiling water, or by the addition of a very acid juice, which at once incites the collecting together of the molecules held in suspension in the milk. Thus are both the white and the red caoutchouc coagulated immediately by the addition of juice from a plant known in all the equatorial regions as *Bosasanga*, the *Costus afer*. A fine specimen, brought from the Congo in 1896 by Professor Laurent, of Gembloux, is in the Victoria Regia house at Kew.

The rubber of the black caoutchouc, however, is not influenced by this material, and is only coagulated by precipitating it in boiling water. It is ignorance of these facts that cause the production of inferior rubber. For instance, if the native gathers in his calabash the white and the black rubber, and submits them to the influence of the *Costus* juice, the white rubber coagulates, and includes the molecules of the black rubber with it, but remains always more or less viscous. Similarly, if the mixture is precipitated in boiling water, the black rubber coagulates immediately, but as it encloses the white, the mass is depreciated in value. Thus merchants recommend that the different kinds be collected separately. Other natives, instead of precipitating the mondongo in boiling water, simply boil the milk, thus forming a porous and elastic mass. Coagulation with *Costus* juice is practised thus: the milk flowing from the incisions is first collected in leaves left under the cuts, then gathered into calabashes and taken to the village. While one man cuts the *Costus* canes and strips off the leaves (it is a somewhat shrubby plant, sending up suckers from 3 to 6 feet high, and from $\frac{1}{2}$ to 1 inch in diameter), another man passes a piece of Banana leaf over the fire, rendering it wonderfully supple. A small hole is made in the ground in which the Banana leaf is laid and the milk poured into it. Three or four canes of *Costus* taken together are twisted above the milk, which coagulates immediately under the action of the acid juice. With the hands it is made up into a ball and firmly pressed until the rubber is all extracted.

It is noticeable that all caoutchouc coagulates naturally by simple evaporation if left in shallow vessels in airy and shady places. The product thus obtained is absolutely pure.

The caoutchouc Liana is found in all equatorial forests, whether these are inundated or not, and be the soil clay or sand. In the Congo (according to the botanist E de Wildeman) are found *Landolphia*

Hendelotii, *ovariensis*, *Kirkii* var., *Klainii*, *lucida*, *florida*, and *florida* var. *leiantha*; *Carpodinus ancolatus*, *turbinatus lignistrifolius*, *leptanthus*; *Oltandra gracilis*, *myriantha*, *Mannii*, *Schweinfurthii*, *visciflua*, and *cirrrosa*.

Several ways of propagating have been tried, as by cuttings, layering, collecting seedlings, and seed-sowing. Cuttings are not successful except when managed by practised hands, under glass, and where there is bottom heat. I have seen thousands, and not one has rooted. Layering on a large scale is not practicable, as it is too slow a method.

As regards the collection of seedlings it should be said that the ripe caoutchouc-fruits fall from a great height and generally break in so doing. The seeds retain germinating power but a short time, and owing to the very moist atmosphere of the undergrowth they germinate all together in the fruit, so that the fruits must be collected and the young plants separated. This task must be perforce trusted to natives who would gather the whole of the seedlings beneath the trees, and so they would exterminate the young plants found in the forest.

The chief propagators of the caoutchouc Lianas are the apes who swallow the ripe fruits whole, and the undigested seeds germinate perfectly afterwards. This I discovered through a native, when I asked him if certain species did not grow in dry as well as in inundated forests. He replied, "Do not the apes climb all the trees." Another unconscious planter is the native who is also fond of the Liana fruit, so that frequently near a village small plantations arise full of caoutchouc Lianas accidentally established there.

MULTIPLICATION.

To turn from these casual acknowledged methods of cultivation, it may be said that the rubbers grow best from seed. The nursery must be made in the forest in a space between fine trees that is large enough for the formation of several borders. No tree must be cut down, and there need be no large plantation in any one place. The borders must be fenced but not roofed as the trees around afford sufficient shade. Each border should be about 3 ft. 6 in. wide, and of any preferred length, and several borders may be divided by narrow paths. If the ground is sloping, the length of the border should be parallel with the slope and the plantation should be surrounded with a ditch, to keep the seeds from being washed away. The nursery can only be established when the fruits are ripe unless the soil is not in a fit condition for the seed to be sown.

Fruits brought in by the natives are at once opened and seeds are sown singly, thrusting them with the finger half an inch into the soil and each seed half an inch to an inch away from its neighbour. I insist on the immediate sowing of ripe seed, as dry seed is useless. Unripe fruits become ripe if stored. Germination generally ensues in a fortnight and when the seedlings have eight leaves they are easily transplanted. Seed in the nursery grow equally well as that *en place*; the fruits remain ripe for two or three months only. It is, therefore, advisable to gather as many as possible to be sown in an allotted space in the forest prepared for them.

PLANTING.

The nursery-ground made and the seeds planted, the space to be allotted to the Lianas is marked out in plots of (say) 24 acres. A central avenue is

to be made as straight as possible, and about 16 feet wide by half a mile in length. Of course, not a single tree should be sacrificed, only small branches being removed. Further straight walks are made every 650 feet, measuring 16 feet wide and 1600 feet long. Thus are obtained plots of about 24 square acres each. If the forest is a very fine one, this area may be doubled.

When seedling plants with eight leaves are ready for moving the men prepare a place in the forest with their hatchets, cutting down the undergrowth but leaving all trees, old and young. They remove just enough brushwood to enable them to reach the foot of the trees. Experience has shown that 100 men can in a day prepare twenty-four acres of standard forest (*haute futafe*) suitably for the reception of Lianas. The forest is well adapted to a nursery ground and is worked with a short-handled shovel, with which the Lianas can be transplanted without injury to the roots. The planters take with them vessels of water into which they trust the roots of the young plants. These pots, full of a certain number of specimens, are taken to one of the prepared squares and there, with a dibber or shovel, little holes are made round each tree for a specified number of the plants, which are set in up to their first leaves. The number of each group varies from two to twenty according to the size and shape of the supporting trees. These trees are not so much to prop as to arrange the Lianas, which might otherwise choose a resting place more than 300 feet away. The plants are set some 12 to 20 inches from the foot of the trees, not in the fibrous earth generally found there to a certain extent but in the actual and firm natural subsoil. Thus there is a minimum of about 2500 Lianas for every 2 acres. After planting the ground is supervised for two months, and when the grower has replaced any dead plants and is certain that all are doing well, the forest is left to itself; in this consists one secret of caoutchouc growing. The plants require stagnant air saturated with damp and should be disturbed as little as possible. They should be allowed to ascend to the tops of the trees and after some years form a thicket impenetrable to the sunshine, thus destroying all the underwood. It is absolutely necessary to institute organised surveillance to guard against the depredations of natives and of animals who might destroy the trees and form new paths. No other precaution is necessary.

There is much difference of opinion as to when the caoutchouc may fitly be collected. I am disposed to say that the plants should not be disturbed before their tenth year.

The question of the number of Lianas to be planted to every 2 acres has little importance; from 2,500 to 5,000 is a fair estimate. Perhaps in the course of a few years some improved method of extracting the caoutchouc will be discovered, for, if all the rubber could be drawn from the tissues of the bark and leaves, the yield would be trebled.

It is in the above-mentioned manner that we have, in equatorial Africa, established trial-grounds on the scale of 10,000 plants per 2 acres on 74 acres of the forest. Wherever this industry may be started, it will be found indispensable to keep strictly to a detailed plan on a scale of 1 to 5,000, for instance, made of the ground under cultivation. Guide posts are also to be recommended for use in forests thus utilised. *Louis*

Gentil, Inspecteur Forestier de l'Etat Indépendant du Congo.—Gardeners' Chronicle,—April 27.

SPORT IN DAYS OF OLD.

AFTER ELEPHANT IN BALANGODA JUNGLES

By H. B.

Dunraven Estate, Mlanje, British Central Africa. It was in the year 18—when living at Ratnapura, Ceylon (in the most relaxing, hot, wet, and steamy climate in the world) that I was pining for a change but did not know where to go. So a happy thought struck me, viz., "write to old J M—get up to an elevation of about 3,000 ft. above sea level, recruit my lost energy, and have some sport at the same time"; for I heard there was a

ROGUE ELEPHANT

near J M's estate, which should afford good sport; for the beast had the reputation of having hunted many a Tamil cooly, and being accountable for the death of a few, on a lonely path which had to be traversed by the labourers on their way to Balangoda bazaars for their weekly supply of rice.

This huge monster was said to be both deaf and blind, but his sense of smell was keen and he had hunted down his victims like a bloodhound: his age was guessed to be great by his enormous size and the fact of his having large white blotches all over his body,—particularly about the head, ears, and neck. A reward of R50 was offered by the Government for the destruction of this reputed rogue, said to be then in the neighbourhood of Bambarabotuwa, not very far from Adan's Peak.

Although I was bent upon shooting a rogue elephant (for which no license was required); in case of meeting others during my forest rambles I decided to obtain a license for one elephant, and also a license for shooting other game. So I proceeded to the Government Agent's Office, and obtained the documents necessary to save me from being run in by any officious village headmen, who are always ready to report any and every European shooting in their neighbourhood, whether licensed or not, although those officials always overlook and share in game shot without a license by natives in their district.

Well, my horse-keeper had orders to get ready for the road at 5 a.m. next morning, and my appu to have everything else prepared for a fortnight. By the appointed hour I was up and soon trotted along the road as far as Pelmadulla, where there is a Government Resthouse, 12 miles from Ratnapura. Here I intended to stop for only a few minutes to see an old acquaintance and get the news. I was told by my friend that I must stay breakfast, as he had an elephant yarn to tell me; of course, anything about such noble sport, especially as I was bent on shooting the notorious Bambarabotuwa rogue, was sufficient inducement for me to stop, although I fully intended to get along another nine miles or more.

Meantime my friend called for whisky and soda for two, by way of an appetiser to the yarn he had so often repeated to others before me, and which by the way I had, second-hand, heard myself. He began, "You know, B.—, the

INTELLIGENCE OF ELEPHANTS

is past my understanding. Y— and myself were after a herd in that belt of forest in R—district just above S— estate (there were four in the herd) last month. I managed to get up to within 20 yards and Y— was close behind me, when one of the beasts turned round and deliberately walked towards me. Although dead with fear, I fired and down went the elephant; no sooner was he flat on the ground than I was behind him and out with my hunting knife, this very knife you see in my belt, and off with his tail before you could say Jack Robertson. Meantime Y—had fired, and I went off to see what luck he had. Upon my reaching the spot, he shouted, "Come along, old chap, and let us drink to the bag." So up we scrambled on to the top of the carcase of Y.'s fine bull elephant, killed by one bullet in the temple. Z—had got his tail too and we stood together and emptied the flask between us, oh! so proud of our tails. I soon set to work to cut off the elephant's feet with the assistance of my gun-coolies; meantime Z—went off to do the same but had not gone many minutes when he returned to say the other dead elephant was "non est," would I come and see for myself. I went and sure enough there were only the marks of the beast having fallen; nothing else but blood from the bleeding stump of the tail to be seen.

We got the feet of one beast carried down to the resthouse, and I have with others been so chaffed by Z—about the tail that I cast it away and hardly ever mention elephant-shooting now. The coolies were sent next morning to bring the ears of the dead elephant but they returned with a yarn that the herd had returned during the night, carried away their comrade's body and thrown it over a precipice where they could not go!"

By the way when

COCONUT PLANTING

was first started in Jaffna the elephants were so destructive, nipping off the tops of the young trees, that a reward was offered by Government for their destruction.

For some time great numbers of tails (which was all that was required of the beast's body to lay claim to the reward) were brought in to the kachcheri; the reward, of R5 I think, was always paid up, till it became known that large numbers of elephants were to be seen tail-less. The order was issued immediately to bring elephants' heads before any reward would be paid, but very few heads ever came in from Sinhalese guns although they were expert enough at cutting off tails.

Upon resuming my journey after a good meal, I began to ascend the zigzag approaching Balangoda; the air became so bracing and cool that it made me feel a new man after the sweltering heat of Ratnapura. I soon reached my friend's estate where I found a welcome and the hospitality, which planters have the reputation for, was liberally extended to me. After a few days rest, I felt as fit as ever and, with the permission of my host, I got ready for a start in pursuit of the rogue elephant. Coolies were mustered for carrying our belongings and we were soon on the footpath leading straight up to the forest where the rogue was said to reside. M—pushed through abandoned coffee estates as if walking for dear life, which was more than my feelings could stand, for I had not the

iron limbs, broad shoulders, and expanded chest of a coffee planter; so I called a halt, and sat down shouting to M—to join me in a bit of luncheon, or I would not and could not go any further that day. We sat down, had a sandwich and a drop of the 'crathur' and made another start soon after. M—began to yarn when he saw it was no use trying to pump me and said, "Do you remember B—?" "Yes" said I. "Well, he shot a cooly for a wild-boar on the face of that hill when out

ELK HUNTING

with me some 10 years ago, and it was never found out what became of Kyapen of H—estate. Of course I knew but I never told anybody but yourself before. B—is now in Australia." From early morning till nearly sunset we walked over hill and dale, M—keeping me up to the mark by yarning about old H—and M—estates, gem mining, &c. in days of old, till we reached a woody piece of open patana grass-land in the middle of virgin forest. "Here," he said, "we must camp for the night." My reply was, "But how much further have we to go for the rogue?" "Oh, no distance from here," said he, "we are sure to hear him trumpeting during the night."

For several years past I had been used to a sedentary life, and right glad I was to cry halt for the day. After a tub and some lunch, whether due to the keen mountain air or the food I cannot say, but I never felt better and suggested fishing, and off we went followed by our coolies to a large pool in the stream which was full of fish. A couple of dynamite cartridges, with a stone to sink them attached, was thrown into the pond, resulting in a grand haul of fish, about half a bag full. After all were collected, we returned to camp. Some good sport was got following and catching wounded fish in the pool which were only stunned, and dived whenever we tried to catch them, added to the difficulty in holding the slippery things when we did close on them. We found the best way to catch them was with both hands or by the gills with one hand; but one must be an expert swimmer with the feet to be able to use the hands freely at all.

Sportsmen, when out for a short time will find it a good plan to put up a few dynamite cartridges, with fuses and detonators, for fishing in time of need, but one must be careful not to get in the way of the smoke from a cartridge in case of a severe headache, caused by the nitro-glycerine burning; further, wait for no hints from your friends as to the best place to throw the explosive, (as I heard of a man doing once till his hand was blown to pieces) but decide beforehand, and throw the charge as soon as the fuse is lighted.

We turned in early and I heard M—giving orders to the boy to have tea ready by 4 a.m. and to wake him sharp at that hour, first cock-crow. It was quite dark and abominably early and cold, when I heard "Boy! Boy!" and a rattling of a bucket or basin in lieu of a tomtom. "Yes, Sar," shouted the boy. "I said I wanted tea at 4, and there is daylight. What the d— I do you mean?" and whizz went a boot. "Sar," roared the boy, "toast and tea nearly ready. Now coming, Sar." When I found it impossible to sleep after repeated attempts I got up, and I found M— ready dressed for the road and still blackguarding the servants. Early tea over,

WE STARTED

along a narrow foot-path through dense forest with a beastly matted undergrowth of bamboos which had fallen on the path in places, making it most difficult to get along at anything like a couple of miles an hour. The heat had now become terrible. Owing to the labour of getting along in a stooping attitude, the perspiration was pouring out of us both. I vowed I could not go on another 20 yards but M— kept on at the heels of Muttusamy for fully half an hour after this without paying the least heed to my protestations. His locomotion at last seemed to slow down, and finally stopped dead. Crawling up, I whispered "what is it?" "Look here," said he, "the finest tusker in Ceylon." "How do you know?" was my reply. "Just look at the shape of his foot, it's not round but long; tuskers have feet always shaped different to common elephants." "What is to be your move now? Shall we sit down and have some refreshment or go on?" "Go on, of course," said he, and off he went and I after him as fast as my legs could carry me till I got hold of his coat tails to stop his fearful rate of locomotion. I said, "Better wait for the coolies with spare guns as we may stumble upon the rogue at any moment" as the spoor looked quite fresh and, besides, we were running great risk which M— did not seem to see at all. The guns arrived and I whispered to Ramasamy to keep close to my heels with my 577 double express. Although I knew the least danger would send him flying up the nearest tree, my gun would be handy if pitched on the ground or stuck up against the nearest tree. I was carrying a Martini sporting carbine, and M— had a double 12 rifle, and a cooly carried his No. 8 bore. His son, a lad of about 18 years, was armed with a 12 bore rifle.

We had not gone very far when a large open space with steaming elephant's dung was found. My heart throbbed against my side when I saw M— making a move and pointing in front of him, I could see nothing but jungle. Up went his hand pointing in another direction. Suddenly some

HUGE FORMS

caught my eye, great black objects like so many rocks. I moved nearer to the living monsters, to within 10 yards. I saw M— moving along the path in front of me, clutching his rifle evidently intent upon shooting something. My beasts began to shake their legs and ears about, and suddenly one wheeled about as if by magic on his own axis. My rifle was up and Bang! Bang! and slowly one sank to the ground never to rise again. Screaming, trumpeting, and swaying of trees in every direction went on for a minute, and all was still again, till the silence was broken by the ring of M's rifle. I heard a shout "Look out, he's charging." I turned round to look for my 577. Of course Ramasamy was safely perched upon the top of the biggest tree in the neighbourhood. I ran along the path and picked up my rifle lying right in the middle of the road where the rogue was bound to pick it up and smash it to pieces. I just got hold of the weapon when "Shoot, Sandy, shoot! Somebody shoot!" rang in my ears. Upon turning round I saw Sandy (who was between me and his father) fire at the rogue (who was in full charge after his father) right over the old man's head, and on they came, father and son, pursued by the elephant. How I kept steady and waited till M— and his son ran past me, without

running myself, I hardly know. However, there I stood, a few feet off the path till, M— was within ten yards of being seized by the beast's trunk, when I fired and down went the rogue crushing the scrub like straw under him, killed by a small bullet instantaneously. M— looked back when he heard my shot, followed by the crash of the falling body, many tons in weight, which struck the earth all around. M— gasped, "Is he dead? look, he'll be up, his sides are moving, give him another shot!" which I did, but not a move was in him except that described above.

My remark to M—, when all the commotion was over, was, "I saved your life, then, old chap; for he nearly had you by the tail of your coat." "Oh no," said he, "I had my running legs on." I smiled, and he looked very angry, so I said nothing more but "come and let's drink to our good luck," and we did with good relish after cutting off the tail to make sure of this ever-coveted trophy.

To stand still

WHEN AN ELEPHANT CHARGES

till he gets within 20 or 30 feet, and then clear out of his way is much safer than running, being pursued by the infuriated animal, as he is sure to catch any man either in the open or in jungle, forest or scrub, but when in full charge and the object of vengeance has disappeared from the line of vision the beast goes on some distance, evidently unable to stop, and rarely returns: at least, that is my experience of a charging elephant. We returned to see my first bag and found a medium-sized bull with no ivory. When engaged examining the head as to the direction of the bullet, crashing through the scrub came a youngster right on top of us, taking us all so much unawares that we fled in every direction, nobody thinking of anything but his own safety, although the calf was only about 4 feet high. We wanted to shoot the little brute when we returned, but I proposed getting jungle ropes and tying him up, and taking him home a prisoner; this we failed to do, however, as nobody could hold him secure enough to get him noosed; the tail, trunk, and legs were all tried in vain, giving us fully three hours' grand sport; till at last the little beast made off, deprived of his tail which Sandy cut clean off near the root.

The cause of the trouble with the elephant which M— had fired at, and afterwards charged him, and I laid low, was in defence of her calf. We never saw the rogue elephant on this occasion, and were satisfied with the two we had bagged.

M— declared that the shot he fired was at my

FIRST ELEPHANT,

and not at the cow which charged him and became positively furious on the subject, setting to work with his coat off and shirt-sleeves turned-up to cut the head off, to find his bullet in proof of his assertion; the bullet was found buried about two feet in the head nearly escaping at the neck, and proved to be my 577 solid express. M—'s mouth dropped and his features changed and we retired to camp at the stream for the night.

Next morning large slabs of skin were cut from a carcase and the feet removed, the former to make a table, and the latter to be dressed as work-boxes, footstools, &c.

M— was a well-known Shikari, a splendid shot at all kinds of game, and as fearless and determined an elephant hunter as ever lived. It

was he who was selected to go into the kraal, held at Labugama, Ceylon, for the young Princes in 1886, and shoot the mother of a young calf, which almost spoiled the whole affair by killing natives, &c.

A cow elephant with a young calf, a cow and bull elephant together, and a single bull, usually a rogue, are always dangerous to sportsmen; at least, I have always found it so.

CACAO CULTIVATION IN CEYLON. (MAY 1901.)

In July 1898 the estate returns showed a total of 21,260 acres under Cacao; and in May 1901 the aggregate, worked out, amounts to 23,696 acres, or an increase of 2,436 acres. But this is apart from native gardens of 50 acres each and less, of which a special separate list has been compiled, showing a total in cultivation of very nearly 9,000 acres. We have therefore a grand total under Cacao Cultivation in Ceylon, of all ages and conditions, equal to 32,600 acres. Seeing that our heaviest export hitherto has been 42,745 cwt, it is quite clear that a large proportion of the acreage must be very young or in very poor bearing; for we should hope that when all the trees are mature, and the fields and gardens properly cultivated, our export should reach to 100,000 cwt. This would not average much more than 3 cwt an acre, which we suppose can be readily harvested from every properly planted and cultivated plantation. There are, however, enemies to reckon with, and successfully overcome: as these may be under the Cryptogamist's directions, we do not suppose that the bumper crop we refer to can be anticipated for five or six years to come.

One thing seems very clear, that Ceylon can never be a leading Cacao-growing country,—can never attain, for instance, the position of Trinidad, which is officially credited with a yearly crop exceeding 200,000 cwt.; and still less that of Ecuador, which annually exports 500,000 cwt., or nearly one-third of the world's requirements. Ceylon Cacao planters have, at least, the consolation that their product is not likely to be overdone in this Island, in the sense in which Tea is supposed to be already overproduced. What they have to do now is to maintain and improve the high reputation of their product; to perfect their methods of curing; to apply (in Mr. Carruthers' words) "more sanitary methods of cultivation" and gradually to improve their varieties of Cacao by selection and other means so as to increase the profit from their fruit trees.—What the Cacao tree is capable of may be judged from the solitary specimen of the Caracas variety growing on Keenakelle estate, Badulla, to which we have so often referred in our Handbook. Mr. Carruthers has found that the tree is about 17 years old, over 22 feet high, with a spread of 30 feet; and for the last five years it has given an average of 434 ripe pods per annum; this is at 3,800 feet above sea-level. Of course, it would be absurd to assume what a plantation could be made to do from this solitary, well-cared-for tree;

but still this experience affords some idea, we trust, of what many of our Cacao planters may anticipate as their trees, planted in good soil, grow older and fully matured.—Dumbara, the Matales, Panwila, Kurunegala and Galagedara, and Monaragala are the leading Ceylon Cacao-growing districts, and we do not suppose the Government, if their officers were so instructed and tried their best, could sell another 5,000 acres of Crown land, really well adapted to the cultivation of *Theobroma cacao*—which requires not only rich, deep soil but shelter from wind and good drainage.

ADVENTURE WITH A LION IN CENTRAL AFRICA.

(To the *Editor C. A. Times.*)

Lualaba River, 21-1-1901.

Dear Sir,—I have read with deep interest, and I need hardly say with deep sorrow, the account of Mr. W R Johnston's death in your issue of the 1st December, 1900. He was undoubtedly one of the best sportsmen and shots in B C A.

I narrowly escaped the same fate, this time last year, in the Upper Choma Valley, being

KNOCKED DOWN BY A HUGE MAN-EATING
LIONESSE

I had severely wounded the previous evening, and which I was following up in terrific grass and "wait-a-bit" thorn trees. She charged and sprang at me almost before I had time to fire, which, owing to the grass, I was unable to do till she showed up about six yards from me. It was a bit—more than a bit—tantalising to hear her roaring (short, sharp, coughing roars) and crashing through the high thick grass, which had been badly burned, and therefore would not burn again, towards us without being able to fire a shot. As she emerged she swerved, and, firing in no end of a hurry at the same moment; my bullet, I fancy, went over her. The next instant my rifle was knocked yards away, and I was sprawling on my back with the lioness on top of me. Luckily, weighing a mere nothing, I had gone down like a ninepin with the lioness's weight and she therefore partly overshot me, only her stomach being on my face and chest. Her foreclaws were busily engaged on the exposed hindquarters of one of my boys who had taken shelter behind me, and who, ostrich-like, had hidden his head in the grass, fondly imagining the rest of his person invisible. My two gun-bearers, each with a spare loaded double-barrelled express rifle, bolted and surveyed the scene from a safe distance, leaving me to see it out as best I could. Neither attempted to come to my rescue or fire a shot. I escaped without a scratch, though a bit bruised and sore about the stomach and chest, but my clothes were torn. The details of this little adventure will appear in my book (if it ever gets as far as being published) so I will not encroach on your space here. One's

GUN-BEARERS

are in 99 cases out of 100 the rankest cowards out in an emergency of this sort, and it is as well for sportsmen to realize that they have only themselves to depend on in a tight corner; that not the slightest reliance is to be placed upon their gun-bearers.

I do not wish for a moment to say a word in favour of Mr. Johnston's followers, police, etc., but how many white men, let alone natives, are there who would undertake to leave a post of safety to hand a spare rifle to a man in a tree at the foot of which, or at least within a very few yards of which, were two infuriated lions, one unwounded, the other wounded? Not many, I think.

I fully concur in your strictures on

THE SALE OF WORTHLESS AMMUNITION

such as Mr. Johnston was too evidently using, and those who offer it for sale are deserving of the deepest censure. It would be interesting to ascertain from whom this ammunition was procured, so that those who have laid in a supply from the same source could hand it back with the request to be refunded the amount. A couple of years ago I had occasion to buy in Blantyre, not without great misgivings, however, some soft-nosed bullets for my '303. My misgivings were justified, for at least four out of six cartridges were misfires. One day I had five in succession and therefore laid my '303 aside until the arrival of reliable ammunition from my gunmakers.

With regard to the fatal accident to Mr. Johnston, a native told me that the deceased gentleman had come across six lions. One came at him which Mr. Johnston wounded, but was killed by it. The police, he said, then accounted for the remaining five! In conclusion it is always advisable to carry a small revolver—if one has such an article—fastened to the belt at the back. Had either Mr. Johnston, or Dr. McKaye of the *Herald*, or possibly many others who have been fatally mauled by lions or leopards, adopted this simple precaution, the majority would doubtless be living now. Personally, however, I never, by any chance, think of burdening myself with either a revolver or a knife, but it is always "on the cards" that I may one day (but I trust, not before my book is completed) regret not having done so. As regards this bit of advice, it is a case of "Do as I say, but don't do as I do."—Yours, etc, **POULETT WEATHERLEY.**
—*Central African Times*, April 13.

PROGRESS IN BRITISH CENTRAL AFRICA.

From Mr. H. Brown, a former Ceylon planter, we have to acknowledge receipt of a copy of the Postal Guide of British Central Africa, which, from its up-to-date rules, bears evidence of the progress made in British Central Africa. It contains all necessary information and should be carefully studied by all who have any correspondence with the Colony.

TOBACCO CULTURE.

We have to acknowledge receipt, through Messrs. Freudenberg and Co., of a very useful little pamphlet (profusely and well illustrated) on this subject, published by the German Kali Works, 93, Nassau Street, New York City, by whom we are promised other publications, including "Potash in Agriculture," "Cotton Culture," "Principles of Profitable Farming," and "Farmers' Guide" which we shall be very glad to notice. With regard to the present brochure we fully endorse what the Compiler says:—

It is believed that this will give the Tobacco grower many "suggestions" which may be of value in a practical way. Thus, there are described the various Plants, Soils and Manures, and how the suc-

cessful Tobacco planter uses them in order to produce the very best, as well as largest crops, for quality in Tobacco culture is a more important item than quantity.

We notice that:—

At present, more than 7,000,000 acres of land are planted each year in this country (U.S.) with Tobacco. According to the Census report of 1890, the crop amounted to 488,255,896 pounds that year, valued at \$34,444,499.

TROPICAL FRUIT IN NATAL.

AN INTERVIEW WITH A GROWER.

[By "Ergates" in Durban "Agricultural Journal."]

From Pinetown to Durban the railway passenger sees on either side farm after farm of sub-tropical fruit. These farms are small, and possibly gardens might be a more appropriate word. The land is valuable, most of it within a mile of the railway stations being worth from £20 to £40 per acre. To get some information about this important district, I made inquiries as to a good authority and, by several who should be competent to judge, I was recommended to see Mr. Vincent Seymour, of Malvern. Mr. Seymour wrote, saying he would be pleased to give me all the information I might ask for. Mr. Seymour comes from a family of gardeners, one of his forbears having devised the plan in the middle of the eighteenth century of training fruit trees on walls, and still known under the name of "Seymour's System of Wall Training"; see "Louden's Encyclopaedia of Gardening." The land now occupied by Mr. Vincent Seymour was purchased by his father, the late Mr. George Seymour, in 1881.

"What are the fruits chiefly grown here?" I asked.

"Pines and bananas. The growing of these fruits is the most attractive to the Indian, and the Indian is a large cultivator in these parts. For the most part he is only a tenant; he pays £1 or so per acre per year, and tries to get the quickest return possible. It is only the white man who goes in for orchards, for the rearing of trees means capital lying dormant."

"One pound per acre rent is apparently tempting to landowners?"

"It is; but whether the policy is good I don't know. The Indian takes all he can out of the ground, growing all together at the same time bananas, beans, groundnuts, tobacco, round potatoes, mealies, and so on. Rest is never given to the soil, and nothing in the shape of manure is ever returned to the land. Having worn out one plot of ground, he moves on to pastures new, and continues his former programme. As a reviver for exhausted soils dhall is one of the most effective things that can be grown on the Coast lands. Some Indians are beginning to buy outright. 'Bombay' merchants advance them the money. A great many of the cottages dotted about belong to mechanics, and their owners often do a little bit of fruit cultivation."

BANANAS.

"Bananas," said Mr. Seymour, "require good soil; bush land, if gettable. In such soil they will last seven or eight years with help but in grass land they will be of no use in three years. In Durban County alone enough bananas are grown to supply all South Africa, but I doubt, if you wanted 50 cases delivered today, whether you could get them owing to the last three years of drought. As with others of our fruits, it is glut or nothing. What is wanted is cool storage at the moderate charges of other Colonies. We look to getting about 12s per case, for the fruit only; a packing case costs 3s, and a case signifies 800 of the fruit. When the Johannesburg market was closed by the 3d per lb prohibitive duty I was glad to get 4s, though the price was utterly unremunerative. On

good soil, such as I have, the banana, requires manuring after the second or third year—stable manure or rough weeds. The manuring may be called mulching. Mulching, of course, means spreading the manure over the roots and surface of the stool of plants, but here, with the hot absorbing sun, the overspreading of soil on whatever is applied is necessary. Shelter from wind is most necessary for bananas, and for practically all Coast fruit. There cannot be too much of it, for the wind is our worst enemy. Every fruit-grower here should have high trees, say gums, growing as break-winds to the south and west of his farm. Orange trees are also good for shelter, and mealties help at a critical time. It is distressing for a grower to see all the beautiful leaves of his bananas torn into ribbons, as for the most part they are."

MANGOES AND PINEAPPLES.

"The most marketable mango is the 'Bombay.' It is very large and not at all stringy. For my own eating I prefer the common kind. This country, however, is barely tropical enough for the mango. A cold, wet spring is fatal to the blossom, and such springs are not infrequent. In favourable seasons, however, crops are very heavy."

"The 'Jamaica Queen' is the best pine. It does not top-sucker so much as the ordinary Natal kind. Pines, like potatoes, mealties, nnts, &c., require periodical changing. Pines should be top-dressed before fruiting. They require good land, and are benefited by artificial manures—potash, preferably. Between the middle of October and the middle of December pines often fetch from 3s to 8s per dozen, for large, well-grown fruits, and afterwards they become a drug, and fetch barely as many pence. Jam-makers rarely offer more than a halfpenny per lb. for them, and, as they need only half a pound of sugar for the pound of fruit, the returns should be good at the price jam is sold. Messrs. Barker Bros., living near here, are generally recognised as the growers of the finest pines."

CITRUS FRUIT.

"For the white man, the owner of land, citrus cultivation, in my opinion, is the most desirable. When once an orchard of these trees has been established—about seven years is necessary—he is in a good position. The profits are good, and the annual outlay in labour becomes comparatively small. Which of the varieties is best to plant? I unhesitatingly reply the naartje—a Dutch name. It is really the mandarin orange, or perhaps more correctly the China orange, although originally it came from Assam, India. We are much in want on the Coast of a Fruit Growers' Society, to attend, among other things, to the nomenclature of our fruit. For instance, the Cayenne pineapple is popularly called the Queen, and Isabel grapes are called Catawbas, and so on. The common orange does not pay well, only 1s 6d to 2s per hundred, on the average. The naartje, on the other hand, fetches 2s to 5s per 100; it is less bulky, and travels well. Naartjes require plenty of attention. Half-a-dozen different blights.—mussel, green and round scales, American blight, &c. attack the trees from the earliest stage upwards, and the paraffin emulsion sprayer is in almost constant employment. Grasshopper 'soldiers,' who strip off the young bark, are also at times a great nuisance. I always plant from seed, and in tins, choosing only seed from the largest and finest quality fruits. Some prefer grafting on to lemon stocks. I think the fruit is not so good, although I know many will disagree with me on that point, and the gain in time, if the growing of the stocks is taken into consideration, is practically nothing. Naartjes should be transplanted in the second and third year. They require good soil. Where my soil is too light, I put on ant-heap. All along the Coast we have ant-heaps ten feet high, and more in diameter. The soil of which they are composed is of the most tenacious character, and is just the thing wanted for sandy lands. Our soil is in

great need of lime, and I hope, when the Port Shepstone railway is opened, that we shall be able to get it at a moderate price. I give my trees bone dust. In setting out naartjes, I always plant just a trifle above the general surface. No earth should be thrown up against the stems, or canker will follow. In manuring it should always be borne in mind that the side roots extend for a long way from the stems, and that they are never deeper than twelve inches from the surface. Proper pruning is most essential. At 18 or 20 in. from the ground let the tree branch out. I can show you an object lesson in this matter. One tree, which I pruned up to 2ft 6in, is as miserable a specimen as can well be conceived, and the next, with a short stem, where the soil and other conditions are identical, is about as fine a specimen as a grower can wish to see. The wood is hard, and the outer bark is closely attached to the wood, and will not stand the direct rays of the sun, especially when the thermometer registers—as it does sometimes—90 to 95 in the shade. The fruit should be all off by the middle of September. The 'Spanish Lemon' is also a good citrus for planting. The demand locally is small, but in England they would sell well. Some years ago I sent a small lot to Messrs. Wm. Draper & Sons, of Convent Garden, one of the leading fruit-breaking firms in London, and the lemons were valued at 12s per 100 there in October or November.—*Natal Mercury*, April 15.

AN ISLAND ROMANCE.

THE STORY OF CHRISTMAS ISLAND.

During the century which has just passed, the stream of population has practically completed the circle of the globe, yet it was only in its closing years that a tiny little colony was founded on an islet in the Indian Ocean, whose history to future generations promises to read as thrillingly as a tale from the Arabian Nights.

Far away in the Southern Seas, some 200 miles from the coast of the ancient "land of gold," and almost 1,000 miles from the sunny country of the Golden Fleece, there may be described this little speck of land jutting heavenwards like an emerald cone. Scientists regard it as an upraised coral atoll, and take a peculiar interest in it from the fact that until the past few years it was the only known tropical island of any large extent which has never been inhabited by a savage or a civilised race. It is called Christmas Island. Why, no man living can tell. As to the date of its first discovery, the past is equally oblivious; yet it has been an object of spasmodic attention on the part of voyagers on the high seas for at least two and a-half centuries.

In 1666 the wandering Dampier of Holland sighted this small woody island, and since that date it has appeared in Dutch maps, but it was not until 1886 that a British surveying vessel succeeded in finding an anchorage and in landing and partially exploring the island. The following year H M S "Egeria" made further explorations, and the conclusion of the commander, in the light of what has since happened, is interesting:—"Man has never lived on Christmas Island, nor would it be a pleasant residence, as, apart from the fact that there is no water—the rains sinking into the limestone rock—the extreme discomfort of locomotion, and the absence of any harbour, whence the product could be conveniently shipped, will deter any settler from seeking a home there until other more favourable spots are occupied." Within ten years or so after this prophecy, the island has a population living and thriving on it of some 600 souls, and from the phosphate deposits found

on it a Pactolean stream of gold is flowing into the pockets of British shippers, commission agents, agriculturists, insurance agents, and stockholders of the company working it.

EARLY DEVELOPMENT.

The story of the island—which is situated in S. lat. 10 deg. 35 min. E long. 105 deg. 42 min.—is romantic and of more than passing interest. Its discovery in the commercial sense dates from the days of the 'Challenger' expedition. That expedition cost this country £300,000, and there have been many who have carpied at the expenditure of so large a sum for results which apparently were of little value in an ordinary utilitarian sense.

The expedition has, however, been the indirect means of adding Christmas Island to the British Crown, and in years to come Singapore, and the mother country also, are likely to receive from it alone much more than the cost of the Expedition, the leading scientific member of which was convinced, in face of the eminent geographer's report quoted above, that there was value scientifically and also commercially in the island. His researches among the deep-sea deposits in the vicinity of the island led him to this conclusion, and, in order to secure protection in developing it, he pressed the Government in 1887 to take over the island, obtaining the assistance of the late Duke of Argyll, and Christmas Island was formally annexed by the British Government in the following year, a lease extending over a hundred years being granted to this scientist and Mr Clunies Ross of the Cocos-Keeling Island, jointly, at a yearly rental of £150.

The prospecting of the island covered fully a decade, and finally a small private Company, composed of a few men eminent in the worlds of science, chemistry and engineering, was formed. This Company, as if by a magician's touch, has transformed what was previously only a haunt of bats and rats and a resting-place for sea-birds into a basis for the output of one of the most valuable fertilisers known to modern agriculturists. Within a single year after the commencement of operations, the hidden wealth of the island has begun to teem from it, and quarters of the world as distant as England and Germany and Australia and Japan are absorbing its manurial treasure and calling out for increased supplies.

FULL OF PHOSPHATES.

To return to the island. This up-raised top of a submarine mountain, round which seas run down almost perpendicularly from its shores to a depth of three English miles, is but ten miles long and seven broad with an area of 46 to 50 square miles. As already indicated, it rises out of waters deeper than those which surround any other tropical island.

Moreover, from a scientific point of view, it is the most interesting island on the face of the earth. When the pioneer inhabitant pitched his tent on the virgin shoreland of the isle, he could only discover two species of bats, two species of rats, and a shrewmouse. These were the only mammals. Down to the very water's edge the surface of the islands is covered with vegetation. Slopes, clad with trees, 'tall as Norwegian pines,' through which nothing is visible but glints of the sky, lead to a great central plateau, some 800 to 900 feet above the sea level, and the highest peak in the island, called Murray Point, is 1,100 feet above the level of the Indian Ocean. The plateau is covered with excellent soil, so rich that all tropical fruits and plants grow luxuriantly, and a special form of

sago may yet find its way to the markets of the world from Christmas Island.

The plateau is one long succession of blocks of phosphate varying in depth down to 40 feet. At present these blocks are picked up from the roots of the trees and exported. They are white almost as snow, and full of pure phosphate of lime to the extent of 85 per cent. Great difficulties were for a time encountered in obtaining an anchorage, and as many as ten barges have been lost, but these difficulties have now been overcome in Flying Fish Bay, and on shore a line of railway, two miles in length, carries the phosphate to the point of embarkation. During last year 30,000 tons of phosphate were exported, giving a profit of 75 per cent on the capital; within a year, it is confidently hoped, the output will rise to at least 100,000 tons. Even then the wealth of phosphate will only be tapped, and the supply at a much greater rate of output will easily outlast the term of the lease.—*Singapore Free Press*, May 7.

GERMAN PUBLICATION ON TEA PLANTING.*

—We have to thank Mr. J H Renton, our tea commissioner, for a copy of a supplement to the "Tropenpflanzer" the organ of the Colonial Husbandry Committee, forming the May number of this periodical. It is a pamphlet of some 80 pages and gives the results of very recent research and work, whether of Mr. Kelway Bamber's or the writer's own analytical and chemical work. But it also explains very fully the processes of planting and tea-making, goes into the soils and climate required for profitable planting, the questions of labour and profits per acre. In fact we can imagine no more complete statement of the whole case in a nutshell than this *brochure*, and one well brought up to date. The pages upon fermentation and the relative values of first, second, third fourth and old leaves in the analysis are especially interesting; the writer also goes into the effects of light or heavy rolling and of various methods of withering which will all well repay a careful study by those who can manage the German.

RUBBER IN PERAK.—Mr. Derry, Superintendent of Government Plantations, has just published a very encouraging report which we shall reproduce in full in the *Tropical Agriculturist*. Moderately tapping 82 trees Para rubber, averaging 14 years in age, between March 1899 and July 1900, a harvesting of 327 lb. best quality and 33 lb. scrap rubber was got, and sold in London at 3s 10d for the former (pronounced equal to best Para), and 2s 6d for the latter. The net proceeds were £61 1s 6d which must be pronounced very handsome. Mr. Derry thinks that 200 trees to the acre at 6 or 7 years old might be able to give as good a return, —say, 2 lb. per tree, in place of the 4 lb. gathered from each 14-year old tree. But that has yet to be proved. Still the result is very encouraging to the planters of Para rubber in suitable soil and climate, and the margin of profit seems wide enough to cover all contingencies.—In the Kalutara district, we believe, 4 lb. per tree have been got from trees 10 years old.

* Beihefte, Zum Tropenpflanzer. No. 2. Mai. 1901, Berlin, N.W. Unter den Linden 40i.

TEA PLANTING IN INDIA AND CEYLON:

A TOTAL OF 927,000 ACRES (OF WHICH
132,000 YOUNG) TEA;
CHINA STILL THE LARGEST EXPORTER
OF TEA;

LONDON OPINIONS OF TEA "PROS- PECTS" AND "MANURING."

Against the 392,000 acres now under tea cultivation in Ceylon—with 30,000 acres not yet in bearing,—we may put the area of tea in all India at not less than 525,000 acres, of which as many as 100,000 acres have been planted from 1897 onwards and cannot therefore be considered to represent mature trees or fields in bearing. There is therefore altogether, 130,000 acres of young tea which must be taken into account, in order to emphasize the absolute necessity for both countries fighting for new markets in Russia and the Continent of Europe generally, as well as in America. The case stands thus for the British Tea-growing industry:—

Total.	Acres in bearing.	Young tea, acres.	Tea crop 1890—lb.	Estimate crop when all in fine plucking.
INDIA ..	435,000	100,000	187,500,000	220,000,000
CEYLON ..	360,000	32,000	148,400,000	160,000,000
Totals..	795,000	132,000	335,900,000	380,000,000

[India has had planted over 250,000 acres with tea since 1885, and the greatest areas by far in single years were in 1896—37,000 acres; and in 1897, over 36,000.]

Now, we do not think there is anything to frighten us in a total output—say three years hence—of 380,000,000 lb. of British-grown tea; and we are prepared to give good reasons for our hopefulness. In the first place, let it be remembered that China is still by far the largest exporter of tea. During 1899 she sent away altogether no less than 217,467,000 lb. of tea and for 1900 we do not think the figures can be less. This includes overland supplies to Russia in Asia (in fact Central Asia altogether) as well as to Russia in Europe. By sea China sent away 8 millions lb. more in 1900-01 than in 1899-1900. This should make up for any shortage overland. In fact, China and Japan together still supply the world with no less than 270 to 280 million lb. of tea distributed to North America, Europe, Australasia, Central Asia, &c. Now we see no good reason why British-grown tea should not by 1904, supersede the teas of China and Japan to the extent of 45 million lb. of tea, apart from the natural growth of the world's consumption of our staple. This presupposes of course, that the campaign on the Continent of Europe on behalf of both Ceylon and India will be carried on energetically for the next three years, and that the "sinews of war" will be supplied by an Indian, as well as by a Ceylon, Tea Cess.

It may be of interest to learn that Travancore (and Cochin) in all its divisions has now about 27,000 acres under tea of which 11,000 (together with 1,700 acres of coffee, 660 cinchona and 300 cardamoms) are reported for Sir John Muir's Kanan Devan and

Anglo-America Companies in North Travancore—all being of course, comparatively recent plantings.

WHY RUBBER PERISHES.

The latex of plants may be compared with the milk of animals; it consists of a number of oil globules held in suspension in the form of an emulsion. In the case of rubber this oil is chemically a terpene C₁₀ H₁₆, which by oxidation becomes an oxidised terpene or resin. Hence they could understand why it was rubber eventually was said to "perish." The juice became oxidised to such an extent that resin was formed, and the mass becomes brittle.

Mr. T DAVIS, Chemist.
—British and Colonial Druggist.

RUBBER IN MEXICO.

There are wild and cultivated rubber trees, now growing on the Isthmus, sufficient to make the country rich, without regard to any other product. Mexican rubber is now worth 80 cts. per lb. gold. A good, healthy, rubber tree will produce from two to four lb. of rubber annually at from eight to twelve years old. A rubber forest of 1000 acres, containing 250 trees per acre, would yield at least \$1 per tree profit, or \$250,000 annually. The Isthmus is the only natural rubber producing country within the limits of civilization. The demand for rubber is increasing at a rapid rate, and those who are now growing rubber forests confidently expect to see Mexican rubber sell for \$1 per lb. before their trees are in bearing. Those who have invested in rubber on the Isthmus will be well rewarded for their patient waiting.—Home paper.

BEE-KEEPING IN CEYLON.—Although greater interest is being shown in this pleasant and useful calling than, say, ten years ago, we are afraid as much attention is not paid to the domestication of the honey-bee by residents up-country and in the plains as might be done with profit. We fancy it is the sting of the bee, more than aught else, that deters people from experimenting as apiarists; but with experience there is really little to fear. Anyway, it is of interest to read that "Mr. W K Morrison, the bee expert attached to the Imperial Department of the West Indies, has recently discovered several colonies of stingless bees in the island of Montserrat. He is now trying what can be done by the use of modern hives to improve their honey-producing capabilities. Modern apiarists are of opinion that they can make the honey-bee conform to almost any conditions, so that Mr. Morrison's experiments will be watched with some interest. The honey of the stingless bee is clearer and thinner than that of ordinary commerce." In certain years there has been a considerable export of both honey and bees-wax from Ceylon to India; but usually, there is a steady import of the former for local use and this ought certainly to be saved by local production.

THE RUBBER PLANTING COMPANIES.

[Plantation: 'Buena Vista,' canton of Acayucan, state of Vera Cruz, Mexico.] "While we now have upwards of 500,000 rubber trees, ranging from young trees to $4\frac{1}{2}$ years of age, the best showing on the isthmus [of Tehuantepec] is undoubtedly made by one of our neighbors, B Griffin, who has fully 30,000 rubber trees with his coffee, of $3\frac{1}{2}$ and $4\frac{1}{2}$ years of age, closely followed by J C Harvey, another neighbouring planter, who has occasionally written you articles on the subject." Rubber is planted 800 to the acre, with the idea of thinning out, by excessive tapping of some trees, when old enough to become overcrowded. Harvesting of sugar, tobacco, coffee, ginger, and corn has begun, and the first shipment of coffee was expected soon at Chicago. The Company favor rubber shade for coffee. Cultivated trees are reported to be shorter but of larger diameter than wild trees of the same age, and to yield more rubber. [Plantation "San Luis," near Palenque, department of Palenque, state of Chiapas, Mexico.] The Company own a tract of 24,700 acres, watered by the river Michol which empties into the Tujila, and that in turn into the Usumacinte, which enters the gulf near Frontera. The estate is divided into three "fincas"—named "San Luis," "San Francisco," and "Los Angeles"—the development of each of which has been begun. Up to January between 900 and 1000 acres had been cleared, except that trees of eight or 10 inches diameter are allowed to stand. Planting was begun last year, resulting in about 60,000 trees now standing. In January there were 50,000 or more nursery trees, to be transplanted this spring, when they would be a year old. Preparations are under way for creating more nursery stock, in order to provide for planting each season as additional land is cleared. Trees are planted sixteen feet apart, each way, the ground being cleaned for a space 5 feet square for each tree. It is estimated that one clearing of these spaces per year will be sufficient until the rubber trees have become large enough to dominate all other growths. —*The India Rubber World*, April 1.

"BASIC SUPERPHOSPHATE":

MR. JOHN HUGHES' PATENT;
AND THE MANURING OF TEA.

A planter, who has paid a good deal of attention to the subject of the proper manure for tea, thus deals with Mr. Hughes' pamphlet:—

"I have looked into Hughes' pamphlet on Basic Superphosphate. Unless it is relatively cheaper than Basic Slag, I doubt if there will be much sale for it in Ceylon. Phosphoric acid in my experience is an essential ingredient that tea draws upon only to a small extent. Many Ceylon soils have ample for all requirements, for apparently an indefinite period. Basic Slag, however, is largely used along with buried prunings and generally speaking is most effective applied in this way, more so than burnt and slaked coral lime applied in the same way. The acids formed during decomposition appear

to supply the necessary solvent, which in certain soils, if applied in the ordinary way, might be a-wanting. The cost per ton is not stated, which is rather an important omission, as there is no means of comparing the value. For instance concentrated superphosphate, and finely slaked coral lime, where lime was deficient, might be found a cheaper form of restoring the balance. Quick acting manures for annuals are economical and sound, but for tea the problem is more complicated. It is one rather, of adjustment of the essential ingredients in available forms and in due proportions, over much longer periods. We have rough and ready ways of arriving at this, but are yet a long way, I fear, from having accurate and scientifically recorded facts that can aid us much. The complexity of the conditions which even vary from time to time, are great."

CINCHONA AND CARDAMOMS.

A planter on the Annamalai Hills, Coimbatore district, India, says that a large amount of *Ledgeriana cinchona* will be planted this year, the very free, deep soil, with its splendid drainage, appearing to suit to perfection. Some neighbours of his are giving *Succirubra* and Hybrid a trial, thinking that cinchonidine will pay. The planter in question, however, believes in good-class *Ledgeriana*, and, if it grows as well as it promises, he thinks there will be no difficulty on the part of the Indian planter holding his own against the Java average of $5\frac{1}{4}$ per cent. quinine sulphate, or even the Java Government average of 7.16 per cent. As regards cardamoms, about 1,000 acres have been opened up to date in the Coimbatore district, Mysore seed has been tried, but not always with success.

EAST INDIAN DRUGS.

At a recent drug-auction five bales of jambul-seeds from India were offered, but no bid was made for them. This drug is apparently produced by *Eugenia Jambolana*, a myrtaceous tree, usually of considerable size, found in India and Ceylon, and distributed throughout the Malay Archipelago to Australia. The cotyledons are thick and more or less united or distinct. The fruit is subacid and edible, and is improved under cultivation. Of late years the seeds have been recommended as a remedy in diabetes, and the dried seeds, in combination with those of *Mangifera indica*, are administered with good effect as a powder in cases of diarrhoea and dysentery; they are also stated to be employed as an antidote to nux-vomica poisoning, the dose being 160 gr. in the form of a powder. Dymock, in "Pharmacographia Indica," gives the information that a vinegar is prepared from the juice of the ripe fruit, which forms an agreeable stomachic and carminative, and is also used as a diuretic. The bark is astringent, and is employed either alone or in combination with other drugs in gargles and washes.

Another East Indian drug offered at the same auction was three bales of hydrocotyle herb (*Hydrocotyle asiatica*), which we briefly noted at the time. The plant is a prostrate herb found in tropical and sub-tropical regions, occurring in India to an altitude of 2,000 feet in the Himalayas, and distributed throughout the Peninsula to Ceylon. It was known to Sanskrit writers of very remote times, being regarded as alterative, tonic, and useful in diseases of the skin. Boileau made its uses known in 1852 in the treatment of leprosy, and later, in 1885, Hunter experimented with it in Madras for the same disease, with sufficiently satisfactory results to bring about its admission to the Indian Pharmacopoeia. In preparing the plant for use the leaves are stripped from the petioles, and are air-dried in the shade and ground to a powder, as it appears that if dried in the sun or by artificial methods they lose

a great part of their medicinal properties, owing to volatilisation of the oil which is their active principle. Another representative of this genus—viz. *H. Centella*, a native South of Africa—has astringent properties, the roots and stems being employed by colonists in decoction against violent diarrhoea. It is also said to be of great service in the treatment of chronic dysentery.

WILD VANILLA.

In an interesting article in last March number of *Chambers's Journal*, Mr Rowland W Cater relates his experiences and adventures while gathering vanilla in Central America. The author, while staying at San Jose, casually fell in with a native trader, and together they undertook an expedition into the interior of Costa Rica with the object of collecting wild vanilla and other forest products. Port Limon was the starting place, whence train was taken to Jimenez, a small settlement on the branch-line to Carillo. Here the travellers alighted and struck into the bush, the passage through which was comparatively easy. On the second day out a wild vanilla vine was discovered, hanging from a huge *zapotillo* tree, from which twenty-two pods were obtained and by sunset that day the travellers had found nearly 250 pods, or about twelve pounds, and that within a distance of little more than sixty miles.

Mr Cater gives a description of the wild vanilla vine (*Vanilla sylecstris*), which he says often reaches over 30 ft. in height, and is usually about the thickness of one's little finger. The vine is round, knotted at intervals, and covered with dark-green spear-shaped leaves. It throws out a number of thin arbus or aerial roots as it rises, which, attaching themselves to neighbouring trees, appear to derive therefrom such nutriment that the vines are little dependent on the soil. Occasionally the wild vines completely cover the branches of the tree, and, running from it into adjacent ones, they will hang in huge festoons and arches so thick that they seriously impede one's progress in the bush. The vines blossom profusely—usually in the spring—the strange and delicate flowers, with their long, straggling, and pale-yellow petals, springing from the angles where the leaves branch off. After a few days' existence the flowers wither and fall; and as their chance of fertilisation through any of the outside agencies on which they depend is a brief one, and precarious at best, very few of them are succeeded by fruit. This takes the form of a large pod, and, although the pods attain their full growth within fifty days from the fall of the petals, they take fully seven months to ripen.

The pods vary from 5 to 12 inches in length, and are about an inch across. In shape they resemble a knife-sheath; hence the word vanilla, which is a corruption of the Spanish word *vanilla*—a small scabbard. Each pod contains a quantity of small black granules, surrounded by a balsamic pulp whose peculiar combination of oil and acid is supposed to impart to the pods the delicious flavour and powerful aroma they possess. Altogether the travellers were in the bush eight days, and as provisions were giving out they hastened with their plunder to Tortugero, where Mr Cater sold his portion to his companion at the current price in the settlement, and, having paid his share of the expenses of the trip, he came out financially so far to the good that he was prepared there and then to set out on a similar expedition, had the opportunity offered. Mr Cater winds up with a detailed description of the systematic cultivation and curing of vanilla in Central America (*Vanilla planifolia*), about which so much has been written in recent years by consuls and others. It is a fact not generally known, however, that Mexico produces the finest vanilla in the world, and that practically the whole of it is consumed in the United States.—*Chemist and Druggist*, April 20.

TURKEY'S PEARL FISHERIES.

A strong German syndicate is negotiating with the Porte for a monopoly of the pearl fisheries along the Ottoman shores of the

Red Sea and Persian Gulf, which are to be thoroughly developed by the most scientific methods. One-third of all pearls won will belong to the Porte.—Constantinople, May 8th.—*Daily Express*.

BANANAS RIPENED BY GAS.

The West Indian banana, possessing a tougher skin and "keeping" fully a week longer than its rivals, has speedily popularised itself among the London costers. Every fortnight ten railway trucks full are consigned by Messrs. Elder, Dempster at Bristol to one of their agents, who has been appointed a member of the Costers' Federation. The fruit is stored, quite green, in the head offices of the federation in London, and ripened by many gas jets. Here the costers select their own bunches, and are charged nothing for storage.—*Express*, May 9.

NORTH BORNEO.

The new Governor of North Borneo, Mr E W Birch, C M G, leaves London on 8th inst. for Singapore *en route* for his new post. He has had much experience in the Malay States of opening new territories in the tropics and is possessed of many qualities that admirably fit him for the duties he will shortly undertake in North Borneo.

Probably one of his first endeavours will be to devise means for increasing the population of the territory. North Borneo, like other districts of the vast island, is very sparsely populated. The all-important question in relation to enterprises almost invariably relates to labour, which is one of the crying wants of the country. Fears have also been expressed that the railway contractors for the Beanfort-Jesselton line may, to get their contracts through in time, raise the price of labour. It is not difficult to get up such rates by an abnormal and temporary demand but it is nearly impossible to get them back again to ordinary rates, unless an adequate supply is available. We believe that the new Governor is authorised to give assistance to the extent of \$20 to \$25 per man, which, though probably not sufficient to land a man in the country, goes a considerable way towards it. Free grants of land along the railway from Jesselton to Tenom, or in the vicinity of the line, will also be made. When the line is working through to Tenom one of the first matters, as a corollary to its construction, will be to provide that back country, of which such glowing accounts have been given, with a population. The numbers in that district and up the Tambunan Valley only total a very few thousands and will need largely supplementing. Chinese is the class to strike for, as they are enterprising, hardworking, thrifty, and immediately assist the revenue in various ways. If the development of North Borneo has not hitherto been as rapid as that achieved in the Malay States we must remember that it has not had such a fortune ready at hand as the tin deposits have supplied. But it possesses a soil and climate singularly blessed in many ways. Its land will produce most tropical products, whilst, like the Malay Peninsula, it is remarkably free from devastating storms and great natural disturbances. Capital would come easier if the great difficulties attaching to labour supply were not superadded to the other ordinary commercial or planting risks.—*London and China Express*, April 5.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop, August-September delivery 1901; booking necessary before the end of April; quantities of 100,000 and over at special low rates. Plants available all the year round. 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year."

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery, 1901, booking necessary before the end of March; large quantities on special terms; Plants in Wardian cases.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter, in sending an order for this seed, wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Kickxia Elastica.—(*Frentunia Elastica*).—Seeds and Plants, orders booked. (Lagos rubber.)

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Urceola Esculenta and U. Elastica.—Same as above. (Burma rubber.)

Parameria Glandulifera.—Orders booked for seeds for January-February delivery; also plants; immediate booking necessary. (A good rubber creeper of Malacca.)

Landolphia Kirkii.—Seeds in July-August, early booking necessary. Plants can be supplied all the year round. (A highly-recommended species.)

Chonemorpha Macrophylla.—Seeds and Plants; orders booked. (A very valuable rubber-yielding creeper.)

Memus ops Globosa and Payena Leerii.—Seeds and plants in July-August, booking necessary before April.

Achras Sapota, Willughbeia Firma, W. Edulis and other Rubber and Gutta Percha yielding Trees and Creepers, Seeds and Plants.

Cinnamomum Zeylanicum (Cinnamon superior variety). New crop of seed in April to June, booking necessary before the end of February; also plants.

Coffea Arabica, Liberian Hybrid and Maragogipe Hybrid.—New crop March-April; immediate booking necessary.

Cinchona Ledgeriana.—Seeds now ready, also other varieties.

Seeds and Plants of Nutmeg, Clove, Sandalwood (white and red), Pepper, Cardamom, Vanilla, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products of Foreign countries for 1901-1902, now being prepared, and will be ready in a few months.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Price List of Seeds and Plants for CEYLON use, post free, on application.

Our new Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms &c., Timber Trees, Trees for Avenues, Hedges, Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Orchids, Bulbs, Dracaenas, now being prepared, and will be ready shortly.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Telegraphic Address:

J. P. WILLIAM & BROTHERS,

WILLIAM, VEYANGODA, CEYLON.
Lieber's, A.I. and A.B.C. Codes used,

Tropical Seed Merchants,
HENARATGODA, CEYLON.

CASTILLOA RUBBER IN MATALE.

Major Gordon Reeves is good enough to answer our enquiry about this rubber as follows:—

"About Castilloa Rubber, this tree grows luxuriantly on suitable land, not only two miles from Matale, but on clearings opened ten miles to the North.

"Year-old plants are having a growth of 3 to 4 feet. Our experiment in tapping at Wiharegama gave us a yield of about 2 lb. per tree good rubber; valuation of which has already appeared, viz., 3s 6d per lb.

"This was tapping from October to June. Latex does not flow in dry weather. These trees are about 10 to 12 years old and girth about 36 to 42 inches at 4 feet from ground."

Well done! This beats the Straits—7s per tree in 9 months is exceedingly good. What now about seed?—which from 10-12 years old trees ought to be very valuable.

THE BAMBOO IN FLOWER.

Has anything, we wonder, corresponding to this been observed in Ceylon?—

"Mr. A. Smythies of the Forest Service writes to the *Indian Forester* on the extraordinary flowering of the bamboo in the Central Provinces of India: A somewhat remarkable event is taking place in the Chanda district of the Central Provinces, and that is the flowering, on a large scale of the ordinary bamboo. The area over which the flowering extends is estimated at 1,200 square miles, and in this area, although a few clumps here and there have escaped, the phenomenon is universal. But the extraordinary point about it is that clumps of all ages are flowering—not only mature clumps but quite slender seedlings of six or seven years' growth or even less. Last year the droughts affected the bamboos in the Dhaba Range of this district, and the bamboo flowered over a small area, and produced a kind of manna. Many thousands of people were kept alive for some weeks on the seed. This year the area is infinitely larger, and the whole population will, in course of time, flock to the forests to gather the seed. The consequences to the people in the vicinity of this flowering and subsequent death of the bamboo will be rather serious. It is probable that, in this district at least the bamboo does flower gregariously over fairly large areas, as three of the oldest inhabitants informed me that they had seen the bamboo flower twice."

PRODUCE, PLANTING AND COMMERCIAL NOTES.

Discussing the new season for China teas, "The Grocer" points out that "statistics, if they mean anything, are unfavourable. Taking the official figures for the first four months of the year only, we note that, while the importations of China tea into the United Kingdom were but 3,201,066 lb., against 4,376,970 lb. in 1900, the clearances for home use had shrunk to 3,970,377 lb., in contrast with 6,277,523 lb. in the same period last year; and the quantity exported diminished to 3,988,648 lb. instead of reaching 8,780,505 lb. as in the four months of 1900. In all these totals the comparison for the year 1901 is on the wrong side, and to this fact must be added another of equal significance, viz., that a stock of over 30,000

half-chests of old season's teas are lying unsold or unshipped at Foochow Foo, at a time when the port there ought to be clear of such goods and waiting to receive arrivals of the new crop directly they are sent up from the interior. One cause for the flat condition of the market for China tea is that the chief blenders mix them much less freely than they did a year or two ago. Then there was an appreciable difference in the prices between China tea on the one hand and both Indian and Ceylon growths on the other—which difference was entirely in favour of China. Now, however, market rates for Indian and Ceylon are as low as, if not lower than, those for China teas; and consequently the former kinds claim more attention from the putters-up of packet teas than the latter. As is well known, the big blenders, who once took the commoner class of China tea to increase the bulk of Indians and Ceylons, and so bring down the averages of value where quotations for a quick sale were thought to be too high, are now careful to keep strictly to British-grown sorts which are extremely cheap and much more suited to their purpose."—*H & C Mail*, May 17.

SISAL HEMP.

(From a letter of Dr. Morris, C. M. G., Jan 1901.)

As no doubt you are aware considerable sums have been lost in attempting to start a Sisal industry in the Bahamas, chiefly through want of knowledge of the requirements of the plant and the sudden rush of persons who took up perfectly useless land at ruinous prices, I have estimated that under favourable conditions the cost of cultivating and extracting the fibre should not exceed about £10 or £12 per ton. The market price, however, is very variable. It has been as low as about £13 per ton; on the other hand, it has, for one or two years continuously, been as high as £30 to £40 per ton, or even higher. The plant will undoubtedly grow in Trinidad and Tobago. There are already a large number of plants running wild in the latter Island. It is to be remembered that it is not a cultivation for small proprietors. It is carried on on very much the same lines as a cane cultivation. I estimate that it requires a capital of about £7,000 to £10,000 to start and maintain a plantation of, say, 1,000 acres in regular working. Anything less than the area above given would not keep the scutching machines in full working, and thus add to the cost of management and the up-keep of the plantations. As only about three per cent. of the weight of leaves is returned in fibre, there is a heavy cartage of leaves to the factory. On an estate turning out say 500 tons of fibre not less than about 15,000 tons of leaves have to be brought to the mill. This necessarily involves considerable expenditure in carts and stock, or in estate tramways. It is stated that in very rich soils the fibre is not so strong and abundant as in comparatively poor soils in dry climates. Again, in the Bahamas, it was found that absolutely barren land was quite useless and led to disappointment and loss. I would only add a word of caution that no one be advised to embark on the industry unless he has ample means and can afford to wait some years before the plantation begins to yield the first returns.—*Trinidad Bulletin*.

CEYLON HILLS TEA ESTATES COMPANY.—We regret to see that it should be deemed necessary to wind up this Tea Plantations Company, but apparently there is no alternative. The Company owns four plantations: Rowley in Balangoda, Agra-oya and Hardenhuish in Lower Dikoya, and Laxapanagala in Maskeliya—altogether about 1,314 acres of tea.

ECONOMIC GARDENS FOR INDIAN TEA DISTRICTS.

Although we have no wish to underestimate the value of the several botanical gardens scattered throughout India, they must be considered more in the light of public pleasure grounds and museums, of little use to the commercial world. One of the mistakes usually made is that of locating these places in the vicinity of the sudder station, in provinces where variations of soil and climate are as diversified as they are in Assam, the Dooars and Darjeeling districts, as results obtained in one case are apt to be regarded as infallible tests for the whole; thus many plants that would receive fair play in congenial situations receive condemnation, being considered of no account. We have an instance of this in

VANILLA,

which many planters, including a Kew gardener, have endeavoured to raise in the hot steamy plains. Had the habitat of the plant been taken into consideration and operations conducted in accordance with it adhered to, many places in Assam would now have been exporting the pods, or their essence, in considerable quantities; but those who have hitherto essayed this cultivation have, for convenience sake, attempted to do so at least 3,000 feet below the elevation, in similar latitudes, where it attains the requisite marketable qualifications. To ascertain the real value of the products of a province it will, we believe, be conceded that the sites for these must be

SELECTED IN ACCORDANCE WITH THE HABITS OF THE PLANT,

instead of forcing, or attempting to, the latter to conform to unaccustomed conditions. Many plants have been sent down to Sibpur that no amount of skilful treatment has been able to induce to yield the product they do in the localities whence they are obtained; Chalmugr is one. *Ficus elastica* grows luxuriantly enough in Government House compound, the Eden Gardens, and many private grounds, but no one in his senses would endeavour to argue from this that a rubber plantation would prove remunerative in Lower Bengal. It is therefore incumbent that each of the plantations many people are suggesting should be stocked with such plants as are indigenous to the elevation, aspect, and climate.

TO RENDER THE PROPOSED ECONOMIC GARDENS COMMERCIALY VALUABLE

there must be a series of them, and as Assam, more especially, possesses the prototypes of most plants known in the commercial world, besides, as has been recently pointed out, enjoying a perfect epitome of climates, there should be no difficulty in choosing eligible sites for each; but, if it is sought to clump all together in one spot for the convenience of forest or district officers' inspection, we have no hesitation in prophesying that two-thirds of the experiment will turn out abortive.

What is more essentially required to make the proposed plantations of real benefit, productive of revenue alike to Government and profit to the cultivator, is a close study of all the bountiful vegetable wealth of the provinces, for though both the Dooars and Darjeeling districts have been in the past most ruthlessly ransacked and exploited, there still remains sufficient relies to show what they once produced and so indicate suitable localities for propagation. Assam has

not been so much denuded, so there is no difficulty there. It is not enough to argue that, because oranges, pineapples and other fruits are found growing from the plains up as high as 2,000 feet and more, a plantation of them will thrive equally well anywhere between these elevations; but we must ascertain at what height the best are produced, selecting the proper zones accordingly. No great expense need be incurred, as there are tea plantations already at various elevations on which a few acres could be set apart for experiments. Just

AT PRESENT THERE IS A RUSH FOR FIBRES, the quotations for the most valuable have been lately given, and there is an enquiry for Manilla hemp, great doubts having been expressed as to the genuineness of the plants sent up to South Sylhet some years since, yet this plantain or something very closely allied to it, is, if we mistake not, to be found in the damp terai ravines under the northern hills from Mymensingh to the Jerri. Thus no great exercise of judgment is required in selecting fields for its cultivation. The best pines, either for fruit, or leaves from which latter the hill people's carrying bands are made, come from between 1,500 and 2,000 feet, which would also correspond to the height at which the Socotra aloe grows; sarsaparilla, ginger, turmeric, though generally considered the product of the plains, attain much greater perfection in the jhums at the same elevation, while salep, though inferior to the Afghan tuber, as also a course truffle, may be found among the roots of the stunted oak in the scattered woods from 4,000 feet upwards. To gather these in the hot plains or high up in cloud-land, and expect each and all to attain perfection under such conditions, is manifestly absurd.—*Indian Planters' Gazette*, May 25.

CONCERNING ELEPHANTS.

In the January Number of the *Indian Forester*, Long Tom sums up his curious article on "Cowardly Elephants" with the sweeping assertion that the elephant has always appeared to him to be "the slowest in thought of all animals that are trained by man, and to be absolutely lacking in reasoning power * * *." No doubt, a number of Forest Officers, who are friends of the patient beasts that do so much work for us, (and that I think with sufficient cleverness,) will come forward to prove, at length, that elephants are quite as sagacious and as capable of reasoning as, and even more so than, many domestic quadrupeds—like the horse—of whose intelligence we generally hold a high opinion.

Leaving such authorities on the subject to discuss the question to its right conclusion, I would like to just throw in a few observations of my own, in order to add weight to such arguments as may be forthcoming in favour of elephants and their decided ability to think. Perhaps Long Tom does not mean his article to be taken seriously, and, probably, wrote it to relieve his feelings after that old "female elephant" had smelt another dead green pigeon. But now that I have begun to write, I may as well go on for the sake of argument.

Firstly, it is beyond dispute that wild elephants show much cleverness, which is more of the nature of *thoughtfulness* than of common *instinct*. The way they collectively aid or defend their young; the practical manner in which they choose their feeding grounds and travel by well-selected permanent paths from one ground to another, just, as it seems, at the right time; the cunning manoeuvres of the rogue.—all go to prove this. So do the incidents befalling at any Khedda.

Then, in the tame state, can any other animals be found that are able to remember and understand so many different words of command as our working elephants? Those who have seen elephants at work in timber yards, at any rate in Burma, will call to mind how cleverly they stack timber, although the methods of stacking may not be uniform. In rafting sunken timber, an elephant will readily, at command, hold a sinking log at the surface of the water until it is secured to some that are buoyant. In such cases, all that an elephant does cannot surely be put down to blind force of habit!

In the Andamans a few years ago, one of the forest tramways ended at a steep "shoot," leading down to a tidal creek that was used for floating out Padouk. The logs were large and far too heavy to be handled by men. So an old elephant, Bisheswar Prasad by name, was employed daily, when the timber was brought in from the fellings, in turning each log round on its truck until it was in line with the shoot, and then sending it off with a butt from behind. Often he did this without guidance from his mahout, and he would do it *accurately* every time. Another elephant sometimes helped to put up rough bridges, and would lift a beam to the required height, and *hold it there* until it was secured to the uprights. I do not say that this elephant knew that a bridge was being built so many feet above flood-level; but he appeared to understand that his mahout wanted the beam lifted up and held in place for a certain time, and he patiently listened to and carried out orders without a mistake. There is no need to quote more instances of this kind, although there is no end to the variety of them. These two alone, with what I have written above, seem to me sufficient grounds for concluding that elephants, either wild or tame, are by no means "*absolutely* lacking in reasoning power."

—*Indian Forester.*

GYOK-BIN.

COCONUT PLANTING IN THE TEA DISTRICTS AND INTERIOR GENERALLY.

An enquiry, as to the number of seed coconuts supplied from a well-known Veyangoda plantation to tea planters, has brought us the following interesting bit of information which we venture to quote:—

"I have sold about 80,000 seed nuts and plants during the last six years, of which about 32,000 went to the Kelani Valley. That ought to do, at 70 to the acre, for over 450 acres; but I believe, in order not to interfere with the Tea too soon, and not to shade the bushes out of flush, the plants have been put out 30 to 40 feet apart—say 50 to the acre; that would work out about 650 acres. I am surprised to hear that this estate had almost the sole honour of stocking the K.V. I thought resort was had to me after disappointment with purchases elsewhere. Any way, the progeny from here must cover a good part of the Island. Some nuts have, I think, gone as far as Anuradhapura; while the founder of the settlement got a contribution of seed nuts from me for Lemesuriagama! Then, next to the K.V., my largest customer was Pallegama which took over 20,000 seed nuts; but, from what I hear, very few plants have survived the drought, neglect, porcupines and thieves in that ill-fated venture. The other districts I have served are Kaduganawa, Peradeniya, Kandy, Matale, Gampola, Wattagama, Nawalapitiya, and even Ragama and Kalutara in the low country; while several thousand nuts sent to Mr. J.—in the Kurunegala district means the faith of that veteran in change of seed, as he might have got any quantity of nuts in his own district."

Probably quite 1,000 acres of tea in the Kelani Valley have been covered by the 32,000 nuts interspersed.

1889 TO 1901: CHANGES IN CEYLON.

IN THE MOUTH OF THE KELANI VALLEY:

FIRST VISIT TO A PLUMBAGO MINE: KEGALLA AND WESTERN DOLOSBAJE.

(By an Old Planting Correspondent.)

We had made up our minds to visit the TUMBAGE plumbago mine, and our party should have been six at least, but at the last moment dwindled down to two. Leaving early in the afternoon, we reached the Kegalle and Yatiyantote road at the 56th mile-post, crossing the fording place in safety beside the old suspension bridge. There is a bazaar and many people both Sinhalese and Tamil hanging about here.

The cart road is a new one and the three bridges between the 56th and 54th mile-posts are well constructed, with well-built stone abutments. The scenery is wild and in places picturesque. At the first bridge there is a waterfall above and below the road; then we came to many zigzags which might have been avoided by taking longer sights and a little extra blasting. At present the zigzag at the foot of one of the tea estates is rather unsightly; however, the Government made it and it must therefore be right.

We had the pleasure of meeting Messrs. Daniell and Lewis, both recently returned from South Africa. The former gentleman succeeded Mr. Fraser of WAHARAKA, about 450 acres of tea. After resting for half-an-hour at the bungalow, we proceeded to GLENALLA estate, one of the GANG WARILY Group, making up about one thousand acres of tea of the Company with Havilland and Gang Warily itself.

GLENALLA estate is a compact little place of 200 acres, awfully shut in by the hills around and sometimes very warm, about 92° in the shade. However, the tea looks well and so do the fruit trees and shrubs about the bungalow. Mr. Reeves is the present Superintendent. I doubt whether there is a thousand acres of tea requiring harder work than this group, in Ceylon. DEDUGALLA and ST. BLANE are very steep places; but not so large an area.

After early tea we started for the Tumbage Plumbago Mine and rode through the Glenalla Factory through the Bazaar and past some villages, arriving at the settlement of the Tumbage Plumbago Mine about 9.30 a.m. The ascent to the pits was something awful, a gradient of one in five or one in three or four, in places.

THE TUMBAGE PLUMBAGO MINES IN KEGALLA OR KELANI VALLEY.

It was difficult to walk up these short cuts on account of the plumbago spilt on the paths making it very slippery and, by the time we reached the pit's mouth, we were very much out of breath.

My companion, Mr. W., did not take long to decide about descending the first shaft

and your correspondent followed, holding on to the lining of the perpendicular wall with a coir rope stopped at intervals between the steps. It was quite an undertaking to climb down, but what about getting up again! I am glad the correspondent of the local "Times" was wrong in his statement that the shaft was two hundred feet deep. It was really only about fifty, but on reaching the bottom we had to creep along a serpentine tunnel for about one hundred feet, passing small galleries to the right and left, until we arrived at another shaft of fifty feet with two feet of water at the bottom of this pit. W. jumped into the bucket and the men lowered him down to the water up to his knees. One Sinhalese was working in the side gallery, using a jumper, and the vein or seam of plumbago, about four inches wide, was embedded in granite rock, requiring to be blasted out, when the plumbago would be reduced to chips and dust and require washing and picking over before being ready for despatch. My friend was well pleased with his adventure into the bottom of a plumbago mine and obtained a sample from the vein or seam. My sample of plumbago came from the heap; however, my sample is still firm and in one block, whereas my companion's lump went to bits in his coat pocket.

Now for the

TUG OF WAR:

climbing up the shaft into the open air again, we found youth won the prize and your correspondent made a bad third in the race; but being an old sailor, he would not be beaten and, though much out of breath, climbed the side of the shaft to the pit's mouth, puffing and blowing like a grampus. We were glad it was over and much pleased with the civility of the miners and the young Sinhalese guide sent with us by the clerk of Mr. Peris, the proprietor of the mine.

The clerk informed me that the mine had paid the three proprietors very well; that they employed 200 Sinhalese, and that the output was from 40 to 50 tons, monthly, valued, at one time, at several hundred rupees per ton. We understood him to tell us that the Tumbage plumbago mine had made as much as £100,000 (one hundred thousand pounds) and, when we remarked that it was better than tea growing, he, the clerk, laughed long and loud and thought it a splendid joke. Since our conversation, some planters tell me that plumbago reached as high a figure as fifteen hundred rupees* a ton. The working expenses would be heavy as the work is very hard and disagreeable; skilled men are paid 1½ and 2 rupees a day and the foremen four and five rupees daily. We found men washing the plumbago and spreading it out to dry. Then it is removed to a shed where a number of boys and girls are employed picking it over and sorting it into three qualities. We were agreeably surprised to find the Sinhalese plumbago miners willing and obliging and not the scum of the population as often mentioned.

Our visit will, however, last us a long time for it requires "an effort" on the part

of the visitor to understand the *modus operandi*, and he requires to be in "good form;" Many pits have been closed down through the fall in prices last year, yet as much as 7,981 tons were said to have been quarried in 1900 in the Kegalle district. There is another plumbago mine at the top of GLENALLA Estate, which is at present closed. It is called Knavesmire mine on KNAVESMIRE Tea Estate, also in the Kegalle district.

Our horses were very restive, waiting on the cart-road, and we had difficulty in holding them in returning to Glenalla bungalow to a late breakfast; however, it was part and parcel of the morning's adventures and a good shake up, though unpleasant at the time, may be beneficial afterwards. Anyhow, we had a good appetite for breakfast and did justice to a good curry.

The monsoon really seemed to have arrived on the afternoon of the 27th, and the wind and rain rushed through two gaps at once, making a great noise—yet this morning was as fine as the day before, and we enjoyed the ride back to HAVILLAND, the pony ridden being the third animal on this trip kindly lent to me by the planters on this side in Kegalle, Kelani Valley, and West Dolosbage. We must explore DOOLGALLA next journey.

H. COTTAM.

PEARLS AND PEARL SHELLS FROM WESTERN AUSTRALIA.

The following is a list of the principal Westralian exports for the last three years:—

Articles.	1898.	1899.	1900.
	£	£	£
* Pearls ...	20000	20000	20000
Pearlshell ...	78784	90647	86513
Sandalwood ...	31812	29719	39038

* Estimated.

Pearl Shell (decrease, £4,134).—This industry, as far as quantity of shell raised is concerned, has practically kept up to the excellent record of the previous year; but the value seems to have suffered a slight reduction. From returns published every year by this department, I have tabulated some figures which cover a period of eight years, and shed considerable light upon the state of the industry. These I now submit for your information, as follows:—1893, 523 tons; 1894, 441 tons; 1895, 350 tons; 1896, 361 tons; 1897, 366 tons; 1898, 619 tons; 1899, 783 tons; 1900, 737 tons.—*Perth Herald*, May 15.

RUBBER IN PERAK.—The following paragraph appears in Mr. Derry's Report:—

Central America Rubber "Castilloa elastica."—About 150 seedlings of "castilloa" from Ceylon seeds have been raised. It appears doubtful, however, whether the Ceylon trees are "Castilloa elastica" (true) or only an inferior variety, "Castilloa Markhamiana," the results of Ceylon trees being far below South Africa.

Mr. Derry must be referring to trees in our Botanic Gardens; for nothing can be better surely than the Wiharagama tapping of 10-12 year old trees, 9 months tapping giving 2 lb. of rubber worth 3s 6d per lb.

UNITED PLANTERS' ASSOCIATION, F.
MALAY STATES.

(Extracts from Report for 1900.)

EXPERIMENTAL GARDENS.—Mr Stanley Arden has been sent out from Kew Gardens and, after a period spent in Ceylon, acquainting himself with the methods in vogue over there, visiting the various Malay States with their Botanical Gardens, and becoming known to the planters, has now been entrusted with the opening of an Experimental Garden. At the time of writing this report the locality is still under discussion, though probably one of the blocks situated near Sungai Rengau will be the situation selected. The headquarters of the Manager, locality of the garden, products to be treated, &c, have all formed the subjects of correspondence between the Government and the Association.

PROPOSED LEGISLATION FOR DEALING WITH ABANDONED OR NEGLECTED COFFEE ESTATES.—The Chairman informed the meeting that, after very careful consideration, the Committee had come to the conclusion that they were not in a position to recommend legislation, inasmuch as it was the experience of members that "shuck" estates were never attacked, but only fine coffee, the owners of which would take prompt measures to keep the pest within bounds, and that they therefore proposed with the sanction of the meeting to forward the following resolution to the Government:—"That the Committee of the United Planters' Association do not feel disposed to take on themselves to recommend legislation on their own responsibility, but desire to express their great sense of the interest and assistance which the Government have shown in the matter, more particularly in connection with the remedial measures proposed by the Acting British Resident, Negri Sembilan." This resolution was eventually carried by 14 to 4.

EXPORT OF COFFEE TO EUROPE.—For some considerable time the question of finding a better market than Singapore has been before the Planting Community; various solutions were suggested. A bonded warehouse where coffee could be stored to enable it to mature has been and is still under discussion. An assessment of all estates to enable the Association to advertise has also been proposed. During the past year, and very largely on the recommendation of Mr. T Haslop Hill, who has taken infinite pains in London to discuss the question, samples were sent home to Messrs. Sanderson & Co., of Mincing Lane. These samples were on the whole favourably reported upon, and the prices quoted were distinctly higher than those then obtainable in Singapore. The Association, on receiving guarantees of over 100 cwt. a month from various members, decided to try the experiment of monthly shipments. A special Committee of Selangor and Negri Sembilan Planters was elected, but owing to various initial difficulties, the first shipment has only recently been forwarded, the result of the sale being still unknown. It may be of interest to the Association to learn that the small retail business initiated by one of the Selangor Estates, under the name of the Kajang Coffee Co., is progressing favourably and, though at one time it was thought possible that the venture would have to stop, recent reports go to show that the monthly output, though small, is an increasing, and to a small extent a paying, venture. We understand that a similar concern is working successfully in Edinburgh. The fact that at various Temperance Exhibitions the Kajang Company's stall has earned bronze and gold medals proves that, if properly treated, our Malay coffee finds favour.

An interesting experiment is also being tried. Some 12 pikuls of coffee have been bought from the Port Dickson Coffee Curing Mill by the Association, five pikuls of which have been sent to Aden and the remainder kept at Port Dickson, with the object of testing the system of storing coffee in a dry place

before putting it on the market. Six months was the period decided upon and this has not yet elapsed.

[The Notes on "Planting Products" will be copied in full into our *Tropical Agriculturist*.—Ed. T.A.]

SOME CONDITIONS OF COCOA :
ATTENDANT ON THE GROWING OF
SUCKERS.

The following is the paper on the above subject, read before the Uva Cocoa Committee on the 11th May, by Mr. L. Haweis:—

Mr. Chairman and Gentlemen.—There can be little doubt that, if canker had never made its appearance, the question of growing suckers on cocoa had never cropped up; therefore, at the outset, sucker-growing should be regarded as a method of defence against canker, and in no other light. Incident on the growing of suckers, however, it has been noticed how, generally speaking, the spread of a tree may be increased and its height curtailed, and, as this introduces quite another element into the question, the original motive for their cultivation is apt to be lost sight of, and even sacrificed to what at existing distances must be the very uncertain advantage of growing a broader tree. This advantage, or possibly disadvantage, I will not dwell on here; suffice it to say that sucker-growing for purposes of yield is contrary to all tenets of fruit-culture, and we have yet to learn that these do not apply to cocoa. I allude to the fact that fruit-trees bear best when kept to the primary branches; and if "spread" is the objective the means must be sought not in sucker-growing but in pruning.

There is an idea that the less the knife is used upon cocoa the better. It is obvious that any excess of its use must be deleterious but, to avoid excess, it is not necessary to go to the opposite extreme; that is no logical or sensible conclusion.

In the

WEST INDIES,

I believe, the cocoa tree, like fruit-trees all the world over, is subject to a certain amount of pruning; and pruning, as pruning, is not confined to what in relation to cocoa we call "suckers" and "gormandisers." The reason why the opinion is prevalent in Ceylon is owing probably to the fact that cocoa—Caraccas, at any rate—if carefully tended from its youth up, requires very little pruning of the larger branches and we have consequently been misled into the idea that the pruning of these larger branches is wholly unnecessary. Further it is said that every cut in a cocoa-tree is a door for a parasite to enter, but this applies chiefly, I take it, to the older wood and, considering the small amount of pruning needed, it is not absolutely unpractical to suggest that all larger cuts be treated with tar or some other preservative less injurious to green wood. On the other hand the objection strikes me as being of academic interest in comparison with the immense good obtained by a judicious use of the knife; theoretically the door is open, practically it is comparatively rarely utilised, except possibly by white ants—and white ants do not like tar, or a kerosine emulsion—while borers of all sorts show no particular preference for a cut surface, but prefer rather their own insidious method of the combined gimlet-and-corkscrew variety in greener and softer wood. But it is also a fact that very old wood is often actually softer than younger wood, and this may help to explain why such old wood does in many cases actually fall a prey to all sorts of insects—scavengers and others. This brings me round to my original point, for when the old wood arrives at the stage when on account of its softness it attracts pests, it seems fairly reasonable to cut it out. And this wood it is which most planters will believe with me to be most subject to canker.

Canker having left its card in yellow leaves and impressed its seal of the familiar claret-hue, nature's first impulse is of reproduction. This effort may take the form of fruit or "suckers," or both. When the process of dying is rapid, the tree has time for no exhibition of this kind; but when it is long-drawn-out, fruit or suckers, or both, may appear, according to the virility and general condition of the tree. In the case of suckers, as in the case of fruit, they mature according to the extent they are unaffected. If affected badly the pods turn black, and the tips of the suckers droop and follow suit; but the suckers rarely die back in this way unless the process of dying is going on fast.

The process of dying, however, may be delayed and, under certain conditions, arrested by proper treatment, when the life of the suckers is saved, and we get new wood from the old root. It often happens, too, that the old tree recovers and, if not too many suckers are allowed from the base, continues to bear as formerly. But if the tree is aged, the old wood gets weaker and softer, the whole of its strength being absorbed by the suckers. When this is the case the old tree should be cut out to give the suckers every chance, and then?—then we have lost all crop from that tree for a year or eighteen months, until the suckers have matured.

This, I think, is a fair statement of facts, and this it is which has turned planters' attention to growing suckers, not merely on diseased trees, but on healthy trees also, in order to be prepared for a possible attack of canker.

Now, what is

THE EFFECT OF CANKER

in the old tree upon the suckers? It is clear that, if the suckers are to justify their existence, they must be kept from canker. A certain sacrifice of crop may have been, and is generally is, the immediate result of growing these suckers, therefore their well-being is of paramount importance; for should they become diseased we shall have lost both crop and suckers, and from every point of view this is disastrous. Then comes the fatal question, Can we cure the canker in the old tree? If we can, we must do so; if we cannot, the old tree must come away; for to keep tinkering at the tree while the canker is possibly spreading to the suckers is not to be recommended. The risk is too great, for once the suckers are gone our labour has been in vain. As scarcely the boldest, and youngest, planter would guarantee, I imagine, to "cure the canker," let us suppose the old tree is cut out. The immediate effect is probably diminution of crop, the ultimate effect the rotting away of the old stump. If the old stump rots away quickly, the suckers are again in jeopardy. Suckers, however, if close to the ground, or if the earth be heaped up around them, will throw down fresh roots, which very usually are not strong enough at first to bear their own weight. Sometimes, perhaps, in the majority of cases, nothing will induce them, short of props, to retain the perpendicular, and the weight of any pods they may bear generally brings them down in spite of the props which are seldom free from white ants. So, what are we to do? We cannot honestly trust 75 per cent. of these suckers, so that the need of putting in a supply becomes obvious. What is even more obvious is that the supply should have been there six years before.

The effect of canker on a medium-aged tree is not dissimilar but eminently more hopeful. There is little doubt that the best "bush-cocoa," that is to say, the bush the suckers may be trained into after the old tree is cut out, is grown from medium-aged trees. Their luxuriance of growth nearly always infects the old stump which is not so liable to decay, but they are by no means so apt to throw down roots of their own. The case appears to be one more of adaptation to circumstances than of independent action, and it is possible that, on this very account, perhaps, they are far more to be relied on than

suckers from aged trees. A medium-aged tree, the provided that the main stem is cut in time, has a fair chance against canker, but the suckers rarely bear under the year.

It is a curious thing, and I wonder if others have noticed it, that suckers in bearing while the old tree is still alive, when it is cut out, do either one of two things, but rarely both; either they continue to bear putting on leaf very slowly, or they expend the increased energy they obtain from the large root, deprived of its main stem, in growing out into a fine spreading bush, the branches of which cease bearing altogether, save for a pod or two, until they are fully matured. This applies to suckers on old and medium-aged cocoa alike, and points to the fact that "bush-cocoa" can be grown only at a sacrifice of crop, illustrating the old and unexploded dictum that suckers on fruit trees are deleterious.

But a tree in bush form has the advantage, not of being any less subject to canker indeed, but of having several more stems than nature usually supplies; so that it is often possible to cut away half or three-quarters of the bush, and still have something to show in its place. That such bushes bear as well as the original tree may be doubted, but that they do bear at least fairly well is undisputed; and, possibly, under a modified system of culture, they may be almost as remunerative. At any rate, experiments are encouraging.

So that, as it is obvious that a young plant, in bearing, if possible, should be ready to take the place of an old cankered tree, it now occurs to me to ask whether it would not be desirable to be ready with a tree in bush form.

Now,

THE GROWING OF BUSH-COCOA

introduces variations on methods and results, with which we are not entirely familiar.

Anyone who has cocoa at 12 ft. by 12 ft.—and we all have—knows that well-grown Caraccas trees in terrace at that distance; therefore, greater spread on our old fields we do not want. On the other hand, most of us are now replanting with Forastero, of altogether larger growth, and I am aware of an instance of a proprietor having planted Forastero at 18 ft., who complains of being laughed at. Some of you, gentlemen, at least will know of Forastero at 12 ft. and also that 15-year-old trees have an average perimeter of at least 20 feet; but I am not aware, except in one or two instances, of any practical conclusions having been drawn from that significant fact. On the contrary the "piling of Pelion on Ossa" is common, for on a certain such field I have in my mind the V. A. ordered suckers to be grown.

If, therefore, it proved advisable to start the cultivation of 'bush-cocoa' in good earnest, the usual distance of planting is manifestly inadequate for even Caraccas; how much more so, then, for Forastero.

And now I am going to be heterodox. Nothing is more noticeable in the story of Ceylon cocoa than the 'rule of thumb.' Cocoa in Ceylon was originally planted—I speak generally—without shade. Something occurred—probably helopeltis—to show that shade was beneficial. Everyone planted shade—even planters the condition of whose estates left nothing to be desired. I will not dwell on what distances that shade was planted at; everyone knows that; it was overdone. Then canker came; light was pronounced inimical to canker; the shade was cut out. Neither will I dwell on how that shade was cut out; everyone knows that that, too, in many cases was overdone. But canker has taught us something else: it has indicated that Forastero is the hardier (if less valuable) variety of the two; and, as Caraccas dies out, Forastero is now being almost universally substituted. And what I want to ask is whether this also does not threaten to be overdone. Unless Forastero is as remunerative as Caraccas, and as at present cultivated

it certainly is not, it is quite possible planters will regret the universal adoption of it. Incidentally, it occurs to me to ask what would a large majority of estates have done if, instead of Caraccas, there had originally been planted Forastero? There can be little doubt that the wonderful bearing qualities of Caraccas have done for cocoa in this canker crisis what Forastero, as known at present, can never do. There is, however, good reason to suppose that many varieties of Forastero hybrids, besides being hardier (a fact which has not been indisputably established) are quite as remunerative as Caraccas, but they have yet to be sorted out and this has not been done. Moreover their great irregularity of form largely augments the difficulty of their cultivation, and it is well-known that Forastero suckers act in a very different and far more irresponsible manner from Caraccas suckers. To grow a fine bush from a felled Forastero tree is infinitely more difficult than from a Caraccas tree, so that it almost seems that suckers, if grown at all, were better started during the new clearing stage, and it has yet to be proved that suckers on new clearings, however carefully tended, do not increase the non-bearing period a full year, or even two.

The question of growing suckers, then, is a much deeper one than on the surface appears. In the latest stage they are untrustworthy, and as canker generally attacks the oldest trees first and worst, it would be well if, at the age of, say, ten or twelve years, all fields were planted up again, especially as cocoa planting is not an expensive item, and this system would be an excellent preventive against at any rate the spreading of canker, for we could well afford to cut out the old trees for the sake of the new ones. But a tree at ten or twelve years of age is at its prime—just the time when the most successful bush may be grown; the growing of it into a bush at this age in the event of canker making its appearance does not, however, obviate the necessity of supplying up.

Remains, then, the question whether planters are willing to start suckers on new clearings. I confess to a great reluctance on this point, and, in view of what may be done in the way of planting up afresh and cutting out later, the matter scarcely seems worth as much consideration, except as a counter to canker, as whether Caraccas should not again be planted up rather than Forastero.

Gentlemen, it has been said, and said truly, that the wisest minds are open to doubt; and I would point out that there is even more doubt in the cultivation of Forastero than in that of Caraccas, about which latter we certainly ought to know more. Whatever advantage Forastero can legitimately claim at this present over Caraccas, it is almost entirely speculative; for not even greater immunity to canker has been proved. Yet I am willing to cede this point, considering all things, and in ceding it I will quote against it height, twice and three times the yield, plus as near total immunity from canker as may be obtained by cutting out at a suitable age in favour of a younger and more vigorous tree.

With regard, then, to what is going on around us, I mean the almost universal adoption of Forastero, I would ask you to decide, if possible, upon something definite. I would ask you to weigh carefully all the pros and cons, and to judge whether Caraccas has indeed merited the disgrace heaped upon it. It has done us more good than ill. Whether canker has come to stay or not, it will not do, however, to be unprepared for it; but neither is it advisable to deceive ourselves into thinking that sucker-growing on old trees is effectual counter-policy. I have tried to point out that as a makeshift it passes muster, but that it cannot obviate the necessity of eventual supplying up. And I know of too many instances to the contrary to be convinced that sucker-growing on new-clearings is satisfactory. There can be little doubt that they delay crop, and there can be no doubt at all that, should the tree be attacked by *helopeltis*, it suffers more through being killed back

from six extremities than one. To carry the idea a little further is to introduce a possible absurdity, but it is worth noting that the abundance of extra flush may even be regarded as the finest attraction for *helopeltis* that human ingenuity could invent.

So that, except as a makeshift against canker, I have no good thing to say for sucker-cultivation—least of all for Forastero-suckers which, after abusing every confidence and baffling every hope, not seldom remain to delude the trustful superintendent into apologising for them in the name of experiment.

On the other hand, and in conclusion, I have heard it mooted (I believe in connection with Samoa) that suckers on new clearings actually induce the tree to bear earlier! I do not know what truth there is in this, but we do know it is contrary to all cocoa planters' experience in Ceylon, and I am inclined rather to be content with those ills we have, and to make the best of them, than fly to others we may end by regretting even more.

THE FUTURE OF "COFFEE"—was thus sketched by Messrs. I. A. Rucker and Bencraft (on May 16th). On July 9th, 1900, we wrote about as follows:—"The 1899-1900 Brazil crop at first was said to be probably the largest ever grown (1897-98 crop was 10,461,000 bags), and half way through it was still estimated at 9,750,000 to 10,000,000 bags. It turned out 8,971,000 bags, or at least 1,500,000 bags short of the original idea. On the same day we wrote that the general belief was that the 1900-1901 Brazil crop would be smaller than the 1899-1900 crop. Estimates varied from 7,250,000 to 9,000,000 bags, about the mean appearing a reasonable figure. The 1900-1901 crop is turning out at least 10,500,000 bags, or over 2,000,000 bags larger than the mean figure. If under ordinary circumstances estimates are fallacious, are they likely to be less so under the conditions now current? Bears argue:—(a) That the visible supply will be the largest ever known on August 1st, next, for that period of the year, and at least 1,000,000 bags heavier than that on August 1st, 1900. (b) That we shall then be facing a Brazil crop of 11,000,000 to 12,000,000 bags. (c) That the sterling value, say 30s for g.a. Santos, is 5s 6d above the lowest point some two years ago. (d) That the currency value in Santos is of no importance to the consumer, and that, even if it were, in the early eighties 3,000 reis were current against 4,000 reis now. As regards (a) let us assume that the visible supply on August 1st next is 1,500,000 bags instead of 1,000,000 bags larger than a year ago. The figures will then read:—

	1901	1900	1899
August 1st ...	430,000	340,000	399,000 tons

or an increase at the rate of 15,000 tons per annum since 1899, which is not very appalling, and hardly justifies all we hear about the enormous over-production. (b) Here Bears argue as if the crop were already harvested and secured; above, we have shown how erroneous estimates are. (c) The value of this statement of fact can only be gauged in conjunction with (d). We have seen it stated by a statistician that the equivalent, now, of 3,000 reis in the early eighties is near 5,000 reis, but, however that may be, 30s combined with 4,100 reis is a different tale to 24s 6d combined with 5,800 reis. The important point is, does 4,000 reis pay the planting community as a whole, or does it not? Time will determine these problems, and the position is undoubtedly one which may lead up to surprises."

THE CEYLON COMMISSIONER ON THE AMERICAN TEA MARKET.

The following letter has been addressed to Mr. E Tye, the secretary of the Indian Tea Association (London):—DEAR SIR,—As requested by you, I send a short report on our tea business in America, as I found it during my recent visit there. Although the progress made in the introduction of Ceylon and Indian teas has been, I think, very considerable during the last seven years, it might have been very much more so, were it not for the many unforeseen obstacles we have encountered. Four years ago "standards" with a sieve-test were sprung upon us, in order that leading American houses might, by keeping out low grade teas, sell an immense quantity they had in hand. The success of this political move will be understood when I say that the value of their stocks rose from 4 cents per lb to 10 cents, as soon as the law was passed. Then followed the 10 cents duty, which has lowered the consumption of tea in the U.S. by 3rd lb per head, or nearly 25,000,000 per annum. Our teas are the only kinds which have not fallen away, but on the contrary have increased year by year. Last year the war in China threw an immense surplus supply of China Congous into the States. This tea cost an average of 10 to 11 cents in New York, but owing to quantity the price fell at once to 8 to 9 cents, and cheap as our blacks have been they could not compete. Houses already loaded with Congous could not purchase other black teas, however cheap. The imports to the States and Canada during eight years of Ceylon and India tea have been as follows:—1894, 4,723,000; 1895, 7,792,000; 1896, 9,474,000; 1897, 11,361,000; 1898, 13,608,000; 1899, 16,700,100; 1900, 16,130,000. This last year shows a slight falling off, but very slight indeed, considering the statistical position of China Congous. The fall has been entirely in Indians, Ceylon showing a good increase. Can this be due to India's withdrawal of funds? Ceylon: 1899, 8,298,000, 1900, 9,173,000. India: 1899, 8,487,000; 1900, 6,958,000. In the teeth of all those obstacles, and especially considering the enormous decline in the U. S. consumption of tea generally, I think the expenditure incurred by Ceylon and India in introducing their teas into America has been amply justified by results.

The imports of Congous last year were over 19,000,000 lb. against 11,300,000 lb. the previous year. These figures are the shipments from Shanghai and Foochow, and with, say, 16,000,000 lb from India and Ceylon, represent the consumption of black teas in the States and Canada.

Of green teas, and partly fermented Oolongs and Formosas, the imports are about as in this table:—

Green Japans ..	36,000,000 lb.
Green China ..	15,000,000 lb.
	<hr/>
	51,000,000 lb.
Oolongs & Formosas	17,000,000 lb.

We have already got the market for 16,000,000 lb, out of an average consumption of about 28,000,000 lb of black teas. Not the taste of the consumer, but his indifference to quality of tea and the vested interests in the East of the old established importers prevent us from rapidly acquiring the greater part of the remaining 12,000,000 lb.

Now as to green teas and partly fermented teas, where the field is 68,000,000 lb. as against

28,000,000 lb. of blacks—here again I must warn planters against the assertions of disappointed editors.

To London alone more than this amount has come. There is one firm in Colombo that executes a contract with a Toronto house for 20,000 lb. of green tea per month. This same firm landed 1,000 chests in America last week, in execution of an order entirely independent of the above Toronto firm. If only 16,000 lb. have been shipped, what has become of the 4 to 500,000 lb. on which duty was paid during December and January, February and March? I think there are four firms doing extensive business with Canada who can account for most of it.

I notice those editorial attacks only to show how difficult it is in the face of them to induce those interested in it to continue patiently the manufacture of green tea, until it becomes a factor on the American market. The enemy is in our own household. But, notwithstanding, I am more confident today of the ultimate success of Ceylon and Indian greens than I have ever been. I have had numberless opinions of its quality and merits from dealers able to judge and, except the coarseness and ugliness of the pekoe souchong, made when coarse plucking was in vogue, I have had only one complaint viz., that—for Quebec Province—the liquor was too fine.

Of course there are very strong obstacles—the strongest being the vested interests in the East (China and Japan) of those who control the grocers, as brewers do "tied houses." These few firms are more united in opposing our greens than they were with the blacks, because their trade in greens is so much larger. A second obstacle is indifference. A Montreal gentleman, who has been pushing our greens, writing a fortnight ago, says: "It is not so much public indifference as it is trade indifference, because Japans have an established sale and for Ceylon greens missionary work is necessary. Then the wholesale trade are showing a much more interested front in keeping out the greens; their travellers poison the grocers' minds against giving our teas a chance. In dealing with the grocers we are not dealing with business men, but with mildewy fossils, who will not draw one tea against another. If they did they would be speedily convinced." Another writing me some months ago said he had bought a few hundred chests: "The liquor of Ceylon greens, in our opinion, is excellent, but the leaf of the Ceylons being so different will make them hard to introduce. Can you not imitate the dry leaf more closely? Try to please the eye as well as the palate. This is the time to push them; one dollar spent now is worth double or treble six months hence, when Japans may be cheaper, and the sentiment for British goods not so strong." True, but I can spend nothing while I get nothing; I can only include "green" with "black" in advertising.

A few small subsidies just now would greatly help to remove prejudice. I believe the difference in appearance of dry leaf is merely a matter of machinery. A roller need not necessarily twist. Another obstacle is the way business is done in America. When our teas are bought in Calcutta or Colombo they are consigned to an agent or broker, say, in Toronto. This agent must sell to a wholesale house, not to the grocer direct. Now, wholesalers in the States and in Canada (French and English) have told me repeatedly they

never handle a new article until the grower or manufacturer has made a market first. They will not do missionary work, their travellers object to it as, while they engaged in education, another firm's travellers sell the grocer what his customers have been accustomed to take. Travellers have to earn their wages, which depend on sales.

Now we had been making green teas in some quantity in Ceylon for six months before I reached Toronto in March. Nearly all these teas had been consigned to about six brokers in Toronto and Hamilton. I had been warning the Ceylon Committee almost every mail that their bounty and the very low prices for black teas would, combined, cause an accumulation in Toronto, as we had no money to help to make sales and overcome the obstacle of the wholesaler and his travellers. I found it so. True, some string packet tea firms were pushing the green teas, but they drew most of their supplies direct from Colombo. A few houses had bought some, which were chiefly used in packets. But the brokers were all loaded up, and had wired to stop shipments from Colombo. Things looked very blue, and the only encouraging features were that the packet people were hopeful, energetic, and full of praise of the quality, and that Japans were scarce and dear.

One importer suggested to me to get a number of ornamental canisters made, large enough to hold 50 or 60 lb of tea, and offer one to each wholesaler for each 100 lb of green he bought. This canister was to be given to any grocer who bought 100 lb of green, and photos of the canisters to be given to the travellers to show the grocers. I had 1,000 canisters made, marked "Ceylon Green Teas" in large letters, and the accumulation of teas was swept off in a fortnight. I returned to New York, and when there I had letters from various Toronto brokers to the effect that they had sold their stocks and all afloat. One of them wrote: "I wired on March 10th to double my order, and on the 20th inst. to treble it." These canisters are standing advertisements for Ceylon greens in perhaps 1,000 shops. In Montreal no wholesaler would listen to me, as they are much more conservative there. But I hope to break through the ring there before the end of this month. I have been waiting for greens to arrive from Colombo, as there were none left in Canada. In New York I will only say that I was surprised by the favourable reception our greens were receiving about end of March, and I have had most encouraging news since I returned.

I could give many pages of quotations from letters from many sources, all of which are encouraging. But I must confine myself to a few. From New York, a fortnight ago: "The only thing we have to fear now is cheap inferior teas being sent from Colombo to cut prices, destroy profits, and disgust our friends." This is from a strong New York tea firm. From Buffalo: "Our trade in this city in blacks is 1,000 lb a week. With the same trouble we should do 5,000 in greens. In Utica and Syracuse 'green' is the great factor. See enclosed orders." He strongly recommends our doing something to attract attention during the Exhibition at Buffalo, but, unfortunately, there is no money. From Toronto: "One of our travellers sent us nine orders this morning, six of which were for greens." Another Toronto man writes: "I am getting on well with the greens; had orders for 400 lb this morning." Another grocery firm in the country beyond Toronto writes: "We had 100 lb green Ceylon

first week in January, 500 lb at end of January, 500 lb early in March. It is the finest tea we ever tasted, and we have yet to hear the first complaint about it.' These rare samples of scores, all sent unsolicited. They may be deceiving me, but I think not. Many grocers have ordered them a second, third, fourth, and even fifth time, while, of course, others return theirs. It seems to me there are two ways of getting the teas introduced.

1. Make a large quantity and send it over to be sold for what it would fetch. If 2,000,000 lb were made in India and dumped in America at 1d per lb loss it would cost India £8,000, which the industry could well afford. It would relieve the English market, and be an introduction to the American one.

2. That Companies should agree as to who should make the tea, that the makers should blend the standards in large lots and that instead of making a loss of 1d per lb as in the first method, the teas should be held for paying prices, the 1d per lb being used to grease the wheels of distribution, as I did with the canisters in Toronto.

There are many other important matters of which I do not care to write, but over which I would like a talk with you.—Yours truly,

W MACKENZIE.

P.S.—What is wanted is a regular supply of green teas for America. Spot teas can be sold, but orders for teas to be delivered four to six months hence cannot be obtained. At present it is the supply, not the demand, that fails us. Since I wrote the above letter I have had two instances of valuable progress with those green Ceylons. A New York firm bought 25 chests six weeks ago, the first they had handled. Within a month they had opened up 90 accounts with grocers who had not handled any Ceylon green before, and they had increased their purchases from 25 to 300 chests. Another firm in New York bought 25 chests three weeks ago—their first order. I have just learnt by wire they have bought another 150 chests.—*H C Mail*, May 17.

RUBBER CULTIVATION IN BURMA.

(House of Commons, May 18.)

In reply to Mr. Sharpe (Kensington, N.),

Lord G. Hamilton (Middlesex, Ealing) said:—The Government of India have recently authorised an extensive experimental plantation of the Para rubber tree in the Tenasserim Division of Burma, where the climate and other conditions are believed to be favourable. I am aware that attempts are being made to develop the production of rubber in Ceylon and elsewhere by private enterprise, but I do not think that this is a reason why the Government of India should not do their best to develop their resources in that country and encourage private enterprise by showing that this tree can be profitably cultivated in parts of India.—*London Times*.

PRUNE COFFEE and prune rum furnish a couple of channels for the relief of the terribly burdened prune market. The prune coffee contains 70 per cent. of the fruit, the remainder being cereals, and will soon be placed on the market in neat cartons. The distillers, however, are likely to get the larger part of the surplus of prunes.—*Merchants' Review*.

CEYLON VS. INDIA IN THE TEA CONTEST.

We are favoured with the following remarks by an observant planting correspondent:—

"In the race for the survival we have this pull over India: owing to their short season and longer transport, I assume that most of their estates have to be financed in advance for the cost of production, whereas we can to a greater extent live from hand to mouth; but I am afraid the weaker in both cases will go to the wall. Gow, Wilson in their circular of the 10th show an annual increase in consumption, varying from nine to 26 millions Ceylon is not likely to exceed last year's exports; what is India going to do? Some of the Indian growers must have made serious losses in 1900. You published some months ago the profits per acre for the leading Indian Companies for 1899: these, with one or two exceptions, were shown at less than 30s per acre, say equal to 1d a lb. on a yield of 360 lb., less if the average yield was larger. Since then Indian teas for season 1900 dropped a 1d—where is the profit?"

There is much truth in what our correspondent says about "financing" and the advantage Ceylon has by its nine or ten months' plucking season. As for profits, we hear very little of such this year in connection with many Indian Companies. We notice that a Calcutta contemporary ("Indian Gardening and Planting") has been taking up the ridiculous view that, if India had gone in for extensive planting operations fifteen or twenty years ago, it could have closed Ceylon. The writer shows himself ignorant of the conditions prevailing in Ceylon, where 250,000 acres of land lying fallow (after the coffee collapse) did not require to be cleared, but were simply ready for planting at our planters' hands and the planting had to be done or the property thrown away. Moreover we do not see that Indian Tea planters have restrained themselves very much in their annual planting at any rate in recent years, when we find that since 1897, they have put in 100,000 acres of tea on new land, and in two years no less than 73,000, although in 1899 it came down to 19,000 and we suppose to less in 1900 with the shock which non-paying prices must have administered.

THE ST. PETERSBURG EXHIBITION.

INTERESTING INTERVIEW WITH THE IMPERIAL CONSULAR AGENT AT COLOMBO.

"We are officially authorised to state that the English exhibition which was to be held in St. Petersburg in November next, and about which full particulars have been published in the *Daily Mail*, has been postponed until March next. It has been found impossible to prepare the Tauride Palace, which the Czarina had promised to lend for the exhibition, by the date originally fixed. The decision is on many grounds to be regretted, although some of the Russian supporters of the scheme declare that March will be a better time for the exhibition to be held. Be this

as it may, the novelty of an exhibition held at the height of the mid-winter season in St. Petersburg will be lost."

The above appears in the latest issue of the *Daily Mail* to hand by the last (French) mail and is dated May 18th.

We called this morning on Mr. Tchokoff, of the local Russian firm of Messrs. Stcherbatchoff, Tchokoff & Co., and Imperial Consular Agent for Russia, to learn if he was able to give us any further particulars of the Exhibition,—to be represented at which we understand Ceylon is already making a move. At least, the official papers dealing with the subject have already been received by the local Chamber of Commerce and we understand that the Chairman of the Planters' Association has been asked to give the subject his early consideration.

"Mr. Bois was anxious to hear all we could tell them about the Exhibition," Mr. Tchokoff said, "but as nothing has appeared in the Russian newspapers or reached us officially from home as yet, we were unable to assist. But, as I have told Mr. Waldock, Ceylon should be well represented at St. Petersburg, for it must do it a great deal of good as regards the sale of tea in Russia. I was eleven years at St. Petersburg," said our informant, in response to a query, "and I know the Tauride Palace well. It is the largest palace in St. Petersburg"—and here followed a significant pause, for St. Petersburg as every one knows is a city of great buildings—"and could cover half Colombo!"—Mr. Tchokoff remarked, laughing, but adding: "No, not quite that, but most of the Fort, certainly."

"On what scale will the Exhibition be?"

"Well, of course, it will not be anything like as big as the Paris Exhibition. It is purely a British Exhibition, for which the Czarina lends her palace. But for Ceylon it is quite as important as the Paris Exhibition and perhaps even more important. There will, of course, be a number of visitors from all parts of Europe, but it is chiefly for the information of the Russian people that the Exhibition will be of use. There are quite enough people in Russia of the classes to be reached by Ceylon tea to make it worth while for Ceylon to be well represented at St. Petersburg."

SALE OF TEA AT THE EXHIBITION.

"Will the sale of Ceylon tea be permitted at the Exhibition?"

"Well, of that I am not sure. I have had no first-hand information on the subject. The papers which are in the hands of the Chamber of Commerce say that the sale of refreshments is not to be allowed; but this refers probably to intoxicating liquors and with due application from the Ceylon representative I have little doubt that not only will the sale of tea in packets be permitted, but a considerable business may be done in making known Ceylon tea to Russian visitors.

CEYLONS PREFERRED TO CHINAS IN RUSSIA.

Mr. Tchokoff, we should mention, has great belief in the future of Ceylon tea in Russia. It is not he, he thinks, a mere passing

boom of 2, 3 or 4 years; but the increase in the quantity taken from Ceylon is a true indication of a growing taste in Russia for our teas. Compared with China, too, Ceylon is well off—for recent telegraphic advices mention that out of the last offerings of China tea, usually sold in a day, not more than 3 breaks could be disposed of and that this took 3 days to effect! The fact is, Mr. Tchokoff thinks, that China has been attempting to compete with Ceylon in the matter of cheap teas and that in these it is unable to hold its own against our local product.

"Have you any information as to the expense of representation at St. Petersburg?" we asked.

"No, but if you apply at the Chamber of Commerce you should be able to see the papers with regard to the Exhibition, which have only just been received. I am to see Mr Bois on the subject very shortly. I have heard nothing about the date of the exhibition; which I do not think has been fixed, so that news of its postponement is a little premature." (Mr Tchokoff here referred to the *Daily Mail* announcement which we had already showed him.)

Thanking Mr Tchokoff for all he had told us, we next proceeded to the Chamber of Commerce; but first had a word with Mr Tokmakoff, of another Russian firm—Tokmakoff, Molotkoff & Co—whose early departure from Ceylon has just been announced. We asked if Mr Tokmakoff would be doing anything at St. Petersburg. "No; you see we can do all we want in the ordinary course of our present business, by sending samples through our Russian offices to our customers in Russia." Mr Tokmakoff was uncertain when he would be returning to Ceylon. He felt in need of a holiday, but did not know how much he might require.

AT THE CHAMBER OF COMMERCE

we learnt that Mr Renton had forwarded the papers dealing with the Exhibition and had offered to look after the installation of a Ceylon section at St. Petersburg, as he proposed in any case going to the Russian Capital in October to open a

CEYLON TEA ROOM AT ST. PETERSBURG.

The space in the Exhibition would be charged at 8s per square foot. Mr Renton's offer will doubtless receive early consideration, whether the Exhibition be postponed till next spring, or be opened in November, which is now reported to be impossible.

THE COMMITTEE AND PATRONESS

From the official papers, which are headed simply "British Exhibition in St. Petersburg, 1901-2" we found that the Exhibition (*confined solely to British producers and manufacturers*) is to be "held in the Tauride Palace and Grounds, St. Petersburg." Though these are "graciously lent for that purpose" by Her Imperial Majesty the Empress Alexandra Feodorovna, the Exhibition will be under the patronage of H.I.H. the Princess Eugenie of Oldenburg and administered by a distinguished Russian Committee of 18 persons; amongst them, the most important are:—H.E. Count Lamsdorf, Foreign Minister; M de Staal, Russian Ambassador in London; the Rev. Alex. Francis, Pastor of the British-American Church at St. Petersburg, and M.A. Bilbasoff Secretary to the Russian Section at Glasgow

The

COMMISSIONER FOR THE UNITED KINGDOM

is Mr George Collins Levey, C.M.G.; the Secretary, Mr. Edward Gorery, and there is a British Advisory Committee of 21 persons, chief of whom is Lord Avebury, President of the British Chambers of Commerce, and among whom we notice: Sir Jas. Fergusson, Sir Chas. Dilke, Mr. Geo. Wyndham, M. P., Sir Edward Sassoon, Sir H Seymour King, Sir Albert Rollitt, Sir Christopher Furness and Sir Jas. Linton.

The intention is to open the Exhibition on November 14th, 1901, and to continue it till February 14th, 1902. It is at this season of the year that Russian aristocracy, officials, army and navy, professional and mercantile classes, are resident in the capital, and Ceylon will thus have

A SPLENDID OPPORTUNITY

of bringing its products before the wealthy and intelligent classes of Russia. Part of the *raison d'être* of the Exhibition is the decline between 1888 and 1899 of British trade with Russia: in exports from Russia 15 per cent (36.5 of the total, to 21.5), and in imports 4.1 per cent (25.9 to 21.8). In 1899

TEA

is the first of a list of articles showing increase as compared with 1898. Meanwhile Germany's trade had increased during the decade to 38.8 per cent of the total imports of Russia or 17.3 more than those from Great Britain. The national prosperity is at stake and it is pointed out that Russia's magnificent display at Glasgow betokens Russia's desire to extend her trade with the United Kingdom. There are no less than 31

RULES AND REGULATIONS FOR EXHIBITORS

which will doubtless be made fully known in due time. The most important are: (3) The Exhibition will be proclaimed a Bonded Store Warehouse; (4) space will be charged at 8s per square foot, arrangements for over 100 feet, or for special positions, being procurable. Minimum charge, £10; (15.) No articles of alimentation, refreshment, food, drink or tobacco shall be either sold or given away by any Exhibitor except by special arrangement with the Administration; (14) all goods to be in St. Petersburg not later than October 15th—penalty, forfeiture of both space and any money paid; (31) 25 per cent of the space money to be payable on application, the balance on allotment.

OTHER ARRANGEMENTS.

Injuries of Russian and British subjects will award diplomas on the same principle as at Paris. The profits of the Exhibition will be devoted to the erection of improved dwelling-houses for the poorer classes of St. Petersburg on a site which has been granted by the Municipality. The Countess Elizabeth Schouvaloff, (who is on the Exhibition Committee) is president of the society devoted to the work. The Russian Committee will heat, light, and guard the buildings and grounds of the Tauride Palace and will make the necessary arrangements for music, publicity &c. It is intended that the Exhibition should be

OPEN AT NIGHT.

In conclusion, the following facts, indirectly affecting Ceylon (as a dependency of Britain and a colony trading with Russia) may be added. "The Russian Empire" covers one-half of Europe and one-third of Asia; contains every soil and climate, from arctic to sub-

tropical; possesses vast forests and tracts of arable and pastoral land, mines of every known metal, extensive vineyards and productive oil wells. The present population is 129, 211, 213, the foreign trade in 1899 was £1,399,000. But Russia, with resources developed, could easily support three times her present population and indefinitely extend her trade. In that trade Ceylon wishes to take a substantial share and towards attaining that object one step will be getting the best possible representation at the forthcoming British Exhibition in St. Petersburg.

CEYLON TEA COMPANIES' RESULTS.

The disastrous effects of over-production are very evident in the reports of the Ceylon Tea Companies, most of which, dealing with last year's results, are now to hand. Indeed, 1900 may be said to have marked the floodtide of over-production to date, and as the year advanced the effect on prices grew more and more serious, until in the autumn, and especially at the turn of the twelve months, the depreciation in values became very severe. The fall in prices more particularly affected the cheaper classes of tea, the highest grades, indeed, holding their own fairly well. In addition to the over-production evil, the trade was hampered by the increased duty of 2d per lb and by the heavy anticipatory clearances which were made both in respect of the 1900 and 1901 Budgets, so that the market during a twelvemonth or longer was kept more or less in a state of disorganisation, which interfered with a correct appreciation of the relations of supply and demand. As regards the Ceylon companies, the main point, however, which is brought out by an inspection of their reports is that the high-class producers and those which have taken care to fortify their position and maintain their finances on a sound basis have not suffered severely so far as their dividend distributions are concerned. A glance at the following list will substantiate this statement, the chief sufferers in these, as in other cases, being, as will be seen, the producers of lower-grade teas :-

Company.	Net Profit.		Appropriations for Reserve and Depreciation.		Dividend.	
	1899 £	1900 £	1899 £	1900 £	1899 pc	1900 pc
Ceylon Tea Plantations	43,664	41,010	10,000	10,000	18*	15
Eastern Produce and Estates	23,615	15,790	nil	nil	7	3½
Standard Tea	10,780	12,148	1,700	2,800	15	15
Nuwara Eliya	17,290	18,263	2,300	2,963	7	7
Scottish Ceylon Alliance	6,960	5,318	1,400	638	12	10
Yatyan-tota	7,900	4,660	1,000	1,000	8	7
The first company in our table, the	12,120	6,753	1,000	1,000	7	4

CEYLON TEA PLANTATIONS, shows only a slight diminution in net profits as against the preceding year, and it has been able to maintain its dividend at the usual rate of 15 per cent, although this time the 3 per cent bonus which was distributed on account of 1899 is not forthcoming. The Company, however, appro-

* Including bonus of three per cent.

priates £10,000 for depreciation, and as it possesses a reserve fund of £100,000, which is partly invested in coco-nut plantations, thus giving it a second string to its bow, it occupies a very strong position, and may be fairly expected to maintain its ground.

The EASTERN PRODUCE AND ESTATES Company, which comes next on our table, makes, unfortunately, a very different showing. The Company grows only medium, and in some parts indifferent teas, and it is handicapped by being obliged to redeem every year £7,500 of Debentures until the latter have been reduced to £50,000, an event which should take place in 1905. The fall in the price of cheap teas has, naturally, affected this Company severely, compelling a reduction in the dividend from 7 to 3½ per cent. It may be mentioned that an interim distribution of 2½ per cent. was made in the autumn, so that the Company appears to have been exceptionally hard hit by the break in prices which took place at the end of the season. It is probable that, so long as the undertaking is saddled with the heavy annual charge for debenture redemption, it will have rather difficult times to contend against. A strong contrast to the Eastern Produce Estates, and one well calculated to illustrate the differences which exist in this class of company, is presented by the STANDARD Tea Company, which, in a confessedly bad year, actually exhibits an increase of profits. The explanation is that the Company is a producer of high-class teas, and that it possesses a new acreage now coming into the yielding stage—a rather rare circumstance of Ceylon. It is consequently able not only to maintain its dividend at 15 per cent, but to increase its appropriation to reserves and depreciation. A point in favour of this Company is its small capital, but the fact that the shares most freely dealt in are only partly paid, having a liability of £4, will operate as a deterrent to some people. The NUWARA ELIYA has also enjoyed a very successful year, its prosperity being due to practically the same causes as those which we have just examined in the case of the Standard. Its estates, which are situated in the Highlands of Ceylon, produce first-class teas, and it also possesses some acreage of young plants which have just reached the bearing stage. Its profits, as will be observed, show a fair advance over those of 1899, and it has not only succeeded in maintaining its dividend, but also in strengthening its financial position. The quality of this Company's teas and the excellence of its grounds will probably enable it to stand out from the ruck both in good times and bad. A more indifferent though by no means a bad showing is made by the SCOTTISH CEYLON. This Company possesses a good middle-class garden, somewhat on the same lines as that of the well-known Ceylon Tea Plantations, and it has achieved very similar results during the past year. Its profits have fallen below those of 1899 and it has in consequence to reduce its dividend by 2 per cent., but it still maintains its distribution at the previously usual rate of 10 per cent. It may be remarked here that the shares of this Company are well held and are rarely negotiated. A heavy fall in profits has marked the operations of the ALLIANCE, and although it still distributes 7 per cent. dividend, against 8 per cent for the previous year, it has been obliged to reduce its carry-forward by nearly £1,000. This Company is not particularly strong in the matter of reserves, and under the circumstances it might well have been a more

prudent policy to cut down the distribution for a time. Another Company whose profits have been heavily reduced is the YATIYANTOTA. This property produces large quantities of cheap tea at a very low cost, and it succeeded in doing so last year. The extremely low prices ruling, however, hit the Company hard and are responsible for the diminution of the dividend from 7 to 4 per cent. Nor at the present range of tea values can the shares of the Yatiyantota be considered very attractive. Still it is possible that the swing of the pendulum will bring about some slight improvement in the value of low-grade teas before the close of the year. As an illustration of the severity of the drop in prices, it may be mentioned that, while 18 months ago the average figure obtained for tea from these gardens was 6d and upwards per pound, the product only realised an average of 3½d to 4d per pound at the end of the year. We have not included the DIMBULA VALLEY in our list of Companies because the last report issued only covers nine months, the financial year being made up to the end of December instead of March as heretofore, in order to bring it into line with the other Companies. A dividend of 7½ per cent is distributed for the nine months, or at the rate of 10 per cent per annum, while £1,000 is placed to the reserve and £1,970 carried forward; the rate is the same as that for the previous financial year, so that in the conditions prevailing the Company must be considered as having done fairly well. In connection with the Companies dealt with above, the report and table of prices, compiled by the Indian Tea Share Exchange and published in our today's issue, should be studied.

Writing on the Ceylon Tea Companies at this time last year, we referred to the cloud of over-production which still overhung the horizon. That cloud, as he have seen, has since burst with a vengeance and caused a great shrinkage in prices. We also remarked that large extensions of gardens were practically at a standstill, and that remark applies with even greater force today. It is doubtful, however, whether we have even yet quite got over the effects of the extensions of previous years, so that, unfortunately, the over-production bogey is not definitely laid. Efforts are certainly being made to bring about a reduction in output, either by finer plucking or by resting the less productive portions of gardens for a time, but we do not think that sufficient attention has yet been drawn to the necessity of checking the expansion of gardens, and we would urge everyone interested in the welfare of the industry, either as a shareholder or otherwise, to press home this point. In Ceylon the danger of over-expansion is mitigated by the comparatively poor character of the low-lying lands, some of which under cultivation are already rimoured to show signs of exhaustion. But in India there is room for unlimited expansion, and if everything else fails to check it we can but hope that the increasing difficulty of financing such propositions will have that effect. As regards the Ceylon Companies not included in our list, it must be confessed that the majority show poor results for 1900—in some cases exceedingly poor results—the extenuating circumstance being that the conditions were exceptionally unfavourable. With these concerns it is a question of the survival of the fittest, and the weeding out process will not be altogether disadvantageous to the stronger undertakings. With reference to present

conditions, the Ceylon crop, now in full swing, shows a slight curtailment, while the latest news with regard to the coming Indian crop is to the effect that the drought has delayed the early pickings, so that it will probably be somewhat late on the market. That, however, is rather a favourable feature than otherwise, since it will allow of time to clear off accumulations but, as the Indian season is only just commencing, it is too early to speak with any certainty on the subject.—*Financial Times*, May 14.

FISH CULTURE IN INDIA.

The following information contained in the *Asian* will be read with interest by local fishermen :—

During a Municipal discussion upon the condition of the water in the Ootacamund lake, it incidentally transpired that the imported carp and tench had multiplied up to myriads, as one piscatorial enthusiast put it. Whether due to climatic or other causes it is certain that the success of fish acclimatisation on the summit of the blue mountains is assured, and it is to be hoped, therefore, that efforts at emulation will be made in all our hill stations and other places where lakes already exist or can be improvised by bunding or stream diversion. A good deal of attention has recently been directed to Assam. It may not be generally known that in the mountain range, dividing that province, there are numerous lakes and tanks where pisciculture or rather acclimatisation could be carried out. Now that District Officers, like Mr. Earle of Darjeeling, have been permitted to take these matters in hand, we would direct special attention to the very considerable expanse of water at Nurtiang, eleven miles north of Jawai, in the Jyntia hills, the large artificial tank four miles west of that sub-division; the Batao tank (should the bund have been repaired), and the reservoir erected by Mr. Inglis in the centre of the abandoned station of Cherrapunji for, though the latter place has been given up as a European haunt, it is becoming a large native town. The localities mentioned are within easy distance now of steamer or rail communication.

INDIAN PATENTS.

Applications for the under-specified inventions have been made.

No. 162.—Andrew Gilmour McMeekin, tea planter of the Alynugger Tea Estate, Shamsnugger, South Sylhet, British India. Improvements in tea firing machines.

No. 164.—The Right Honourable Douglas Mackinnon Baillie Hamilton Cochrane, Earl of Dundonald, of 34, Portman Square, in the county of London, England. An improvement in tea and coffee pots.

No. 179.—Frank Edmund Winsland, engineer, and George Ernest Moore, engineer, both of Joyhing Tea Estate, North Lakhimpur, Upper Assam. Improvements in apparatus suitable for packing tea.

No. 180.—M Judah, mica merchant, residing at No. 40, Radhabazar Street, Calcutta. Improvements in sun-proof mica hats.

No. 182.—James Begg, tea planter, of Hoolumgorie Tea Estate, Assam. A new or improved machine for artificially withering tea leaf.—*Indian and Eastern Engineer*, May.

DOLOSBAGE IN 1889 AND 1901.

(By an old Planting Correspondent.)

DOLOSBAGE.—One of my old districts, with its Bible Rock and Sentry Box, are in sight and, with elevation, the mornings and evenings are much cooler and enjoyable.

DIFFERENT ESTATES—NOW AND THEN.

COOROONDOOWATTA was reached at midday and my old friend, A. J. S., gave me a hearty welcome, making me feel as much at home as he did down in the Fiji Islands.

We visited quite a new estate, called "Jak-Tree-Hill," next morning; in going there from Cooroondoowatta I had to retrace my steps towards Vellekande and descend a considerable distance into a deep valley, passing a few native tea gardens and Sinhalese villages—then the new bungalow appeared in sight and we made straight for it only to get a view of the country around, Mr. Blackett being absent in England. Jak-Tree-Hill is not only a valuable tea estate of over 200 acres, but is quite a Botanical Garden with shade trees and palms in profusion. Near the tea factory we came on some mango-steen trees in blossom; they bore a few dozen last year; cacao was doing remarkably well under the shade of fruit trees.

The factory is new with all improved machinery and Mr. Stephens has adopted his method of continuous hessian tats for withering. The battens at the ends are about eight inches and the whole jute hessian must be stretched tight; this system is a good one, preventing much waste of jute hessian and extra carpenter's work at the stanchions. There is an oil-engine driving power here and everything goes on satisfactorily under the able supervision of Mr. A. J. Stephens.

COOROONDOOWATTA is well suited for a tea estate, being a gentle undulation and easy to dig and manure; the old terracing of the coffee thirty years ago, black with age, supports the tea round the edges of roads and on hill sides. Timber trees are plentiful, including mango, jak, breadfruit, wild artocarpus, sapu, grevilleas, acacias, papaw, plantains, and palm trees.

In the factory we find some 17 or 18 chulahs as well as a sirocco. The chulah-fired teas are of good flavour and preferred to machine-made teas. At the beginning of tea manufacture in India and Ceylon, many planters were of opinion that chulah firing was preferable to the sirocco and that the fumes of charcoal were directly beneficial to tea-making; what is the opinion you have formed on this subject? (I remember when in Assam, acting as your Special Correspondent, that very many, if not all, the planters of Assam used chulahs and charcoal fires. This was in 1876.)* The cultivated area of Cooroondoowatta is three hundred and seventy acres, all under tea. With other charges, Mr. Stephens is managing about seven hundred acres of tea. Forking has been done here to advantage and there is a good flush on the bushes at the

present moment. Hapugahawatta is a good piece of tea, but not undulating like Cooroondoowatta; there is a drop down to the paddy fields below and an awful stiff climb up. However, A. J. S. looks in good condition, considering the amount of exercise he gets in a very steamy climate. It was a nice little walk up to Medegoda from Cooroondoowatta by short cuts, crossing a deep stream and climbing over slab rocks—my box cooly was a good fellow and helped me through all right. We had a coconut at a village and he got quite communicative; during the course of conversation in Tamil, Ramasamy expressed his views on the situation and the decline in the price of teas; he, Ramesamy, got a little mixed up about the war in South Africa and told me that so many gentlemen had been killed in the war that there was nobody left to drink tea and hence the sudden fall in prices; happy-go-lucky Ramasamy—his ideas of the outside world are very limited.

MEDEGODA is over 200 acres of tea. Coolies were clearing the drains and the estate looked well with some nutmeg trees in bearing and cacao thriving. We passed the bungalow and got into Wewekelle over the ridge. Wewekelle, the old place of Dr. Shipton, is now absorbed in the Tamaravelly group. We crossed the wide stream or river running below it and ascended Epplewatta on the other side. Old Stanmore Hill is forgotten in the Tamil name of Tamaravelly. By-the-by we noticed disease in the Lantana or wild Verbena; it is black with disease, a kind of blight. The planters must keep it clear of their boundaries or it will get into the tea. "Everybody" told me it did not hurt the tea, but unfortunately I found it very bad on some tea and hope it will not spread into tea as H. V. did into coffee. It would be good to cut it out and burn it in time. Lantana seeds very freely and spreads fast in chena lands and patana. There is not much in Dolosbage and it would not cost much to get rid of it at once.

PEN-Y-LAN or Balatakanda with over 500 acres of tea is still to the fore and possesses some old tea planted in the forties by Mr. Lewellyn; some of that tea still exists and measures two feet circumference of stem, and there is a bush measuring about thirty-six feet in circumference. Mr. W. R. Tringham has borne the heat and burden of the day in Ceylon, numbering his 35 years' experience in coffee, tea, and cinchona, and looks well and hearty. There is a good distance between the factory and the bungalow and the writer did not go down to the factory, but proceeded on to Kellie over the next gap, passing through some seed-bearing trees to the new bungalow. The Kellie group factory is a very large one with both water and steam power; the water-wheel is thirty feet in diameter or ninety in circumference; the steam engine works the balance of the machinery and the three rollers and sifting machines may be seen all working at the same time. There was difficulty in getting up the boiler and elephants had to be employed. The Superintendent has good reason to be proud of his factory, as also of a flat field of tea, giving thirteen hundred pounds of leaf per annum per acre.

* Some of the London Brokers to this day regret the gradual disappearance of chulah-fired teas.—Ed. T.A.

The cardamoms at Hormusjee are a great success and looking remarkably well, some seventy acres, thirty of which are in bearing, extending to the source of the Doteloya river; and cardamom cultivation continues on the Doteloya estate in the shade of forest in the deep gorge or valley of the Doteloya river. Hormusjee tea looks very well and we had pleasure in meeting one of the sons of an old Dolosbage planter. Thirty two years ago the son of Archdeacon Glenie was Superintendent of Barnagalla. Mrs. Glenie is now in Travancore with her son on a tea plantation.

DOTELOYA ESTATE or **Nona Totum** is now incorporated in the Tea Corporation, Limited. There are some 700 acres cultivated and 645 acres of tea. I believe there are 30 acres of cacao and 30 acres of cardamoms besides nutmegs, cinnamon, annatto and other products noticed near the bungalow. The writer obtained permission from the late Mr. Blackett to visit some cotton planted on the site of Jak-tree Hill. Mr. B., senior, was quite a pioneer in new products and was a very successful planter. Doteloya tea looks well as does all tea in Dolosbage; the district compares favourably with other districts according to the opinion of experts. We met the Superintendent on the road and continued through the jungle with the intention of hunting up another old landmark of Dolosbage, one of the pioneers of tea and cacao planting in the district, Mr. John Drummond. The weather has been severe in this quarter and we got a very good ducking on this journey through the bush and down the hill, coming to some slippery places in transit. The box cooly said "Appa Sami" and helped me over some queer places during the storm, but we reached Oonankande and met Mr. Gidlow who soon made us feel comfortable. Mr. John Drummond turned up in the evening and we had a talk of old times.

OONANKANDE is quite a new estate, the tea looks well and there is a good view of the low-country from the bungalow, looking out on the Kelani Valley. There is a fine estate under tea called **YATADERIYA**, Kegalla; it stands out in bold relief in the forests of the low-country. We got a bird's-eye view of this property from the vantage ground of Oonankande. Poor Mr. Gidlow has just lost his sister who was killed by lightning at Gangwarily estate just below Oonankande; the lightning split up two verandah posts and entered the bungalow under the ground, killing and injuring all the occupants of the room, then escaping and splitting a rock on the other side.

Taking advantage of a fine morning we came down through **GANGWARILY**, visiting the scene of the lightning accident and passing the bungalow of Mr. Kellow, the present Superintendent of Gangwarily, who had gone down to his factory by the river side; we crossed a bridge leading to the factory of Dedugalla and St. Blane, from where we could see the Gangwarily factory with its water-wheel working. Cacao is plentiful on Gangwarily and looking well and the tea is flourishing; there are twenty acres, giving fourteen hundred pounds to the acre. The new Company, called the Gangwarily Estates Company of Ceylon, Limited, includes Havilland, 340 acres of tea, on the opposite side of the river. There are

370 acres of land in cultivation on Gangwarily estate. The climb from the bridge to the **DEDUGALLA** bungalow was good manual exercise before breakfast and the Superintendent received us kindly, on our mentioning that we had once been in charge of Dedugalla and St. Blane; the teas made here were of very good flavour and the turbine drives the machinery. There is also a turbine on Havilland, doing excellent work. Around the Dedugalla bungalow we found some loquat trees and other plants of our own planting in 1876, twenty-five years ago. We opened up St. Blane in 1874 and found it a steep and hard working place; the ageratum and other fancy weeds, such as the Spanish Needle, were very plentiful, but now the properties look clean and in good order, and the tea made of very good flavour. We had not visited **HAVILLAND** since we took a very prominent part in a tragedy in 1874, but we will let bygones be bygones and pass that over. Havilland uses wire-shoots for transporting leaf and wood; a gradient of one in ten is considered safe for both wood and leaf, the runners travel very well and the coolies enjoy seeing the bags flying through the air. Liberian coffee looks healthy, and in bearing there are about twenty acres of Liberian coffee and about five of cacao. The old seed-bearers on both sides of the bridle path are fine bushes and their stems quite ten inches in diameter. Mr. Kellow came up to dinner and gave us much information about South Africa and his personal adventures as one of the Ceylon Contingent, but somehow the authorities have forgotten to send him his service medal and balance of pay.

We walked down to the factory of Havilland yesterday and saw the machinery working, driven by the turbine. The tea packer is an interesting machine and does good work; when it's in motion one can insert one's hand into the tea, but as soon as the machine is stopped it is impossible to put your hand into the centre of the chest. The fermenting drawers or trays, set up like a huge chest of drawers, attracted my attention. In visiting different tea factories there are many different ways of manufacture, and one learns a good deal. Returning from the factory your correspondent was treated to a ride instead of walking and managed to reach the bungalow of Havilland before the tea leaf was shot down the wire-shoot. Before dinner (7:30) we were sitting in the front verandah and suddenly caught sight of the comet to the West and to the left of the constellation Orion. We hope to see it again tonight as the weather is fine.—Yours faithfully,
HENRY COTTAM.

[Can Mr. Cottam tell us about "Doolgala" block of land entered in the Directory for many years as belonging to the heirs of the late John Gordon.—**ED. T. A.**]

THE MIDLAND TEA PLANTATIONS COMPANY.—The report which we publish on page 52 contains a repetition of the tale, to which we have now become accustomed, of serious loss on the past season's working. We trust, however, that the finer system of plucking which has been adopted will have a beneficial result.

OUVAH COFFEE COMPANY, LIMITED.
REPORT

To be presented to the Sixth Ordinary General Meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Tuesday, the 14th day of May, 1901, at 12 o'clock noon.

The following annual accounts are now presented to Shareholders, viz.:-

Balance sheet made up to 31st December, 1900.
Profit and loss account for the year ended 31st December, 1900.

The receipts from the sale of produce were as under—

Tea from the Company's own Estate	1,114,513 lb.			
Tea made from bought leaf	...	161,035 do		
	Total	1,275,548 do	£	s d
Coffee 478 cwts. 3 qrs. 5 lb.	..		34,023	13 8
Cocoa 56 cwts. 2 qrs. 17 lb., estimated value	..		1,861	7 3
Cinchona 22,609 lb., estimated value	..		150	0 0
Plumbago 554 cwts. 3 qrs. 8 lb.	..		100	0 0
Sundry sales in Ceylon	..		394	18 8
			99	19 7

Total receipts ... £36,629 19 2

The total expenditure in Ceylon and London amounted to £23,908 3s 4d, and deducting this from the value of the produce a profit is shown of £7,721 15s 10d, to which has to be added the balance of £224 11s 9d, brought forward from the previous year, making a total of £7,946 7s 7d at the credit of Profit and Loss. From the above sum the Directors have transferred to the credit of Badulla Factory Account £1,000. The interim dividend of 2½ per cent., paid on 15th November, 1900, absorbed £2,500, and Income Tax £241 2s 3d, leaving a balance of £4,205 5s 4d, out of which it is proposed to pay a further dividend of 3½ per cent, making 6 per cent. for the year, and to carry forward to next account the sum of £705 5s 4d.

Favourable weather was experienced during the past year, and the yield of tea per acre was 602 lb. as against 404 lb. and 438 lb. obtained during the two preceding years. The tea market, on the other hand, has been over-supplied, and our average selling price dropped to 6'40d against 7'56d at which the previous 17 months' crop sold. The lower cost of production, brought about by the increased yield, has however to some extent compensated us for the fall in the value of our produce. The returns from coffee, cocoa and cinchona diminish as these products are replaced by tea. A heavy fall has taken place in the value of plumbago, and for this reason mining has not been actively pushed during the past year. Operations have been chiefly directed towards proving the extent and value of the deposits. If a sufficient body of mineral is proved to exist, it could be mined profitably at present prices with the aid of modern appliances. All the Company's properties are reported to be in excellent condition and promising well for the future.

The acreage of the Company's property is now as follows:—

	acres.
Tea, over 5 years old	1,775
do Planted Nov.-Dec.	1896 151
do do	1897 133
do do	1898 23
do do	1899 18
do do	1900 40
Area under Tea	2,140
Area under Coffee and Cocoa	386
Area under Fuel	336
Forest, Patana and Waste	713
Total Areas	3,575 acres

Mr. L FAMIN, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. DELOITTE, DEVER, GRIFFITHS & Co., the Auditors, also offer themselves for re-election.

By order, J. ALEC ROBERTS, Secretary.
London, 3rd May, 1901.

THE DIMBULA VALLEY (CEYLON) TEA COMPANY, LIMITED.

REPORT

To be submitted to the Shareholders at the Fifth Annual Ordinary General Meeting, to be held at the Cannon Street Hotel, on Wednesday, 8th May, 1901, at 12 o'clock noon.

The Directors, in accordance with the intimation given at the general meeting on the 25th June last, that the accounts would henceforth be made up as at 31st December, instead of 31st March, beg to submit the General Balance Sheet and Profit and Loss Account for the nine months ending 31st December last.

After bringing forward £1,987 13s 7d from last account, and providing for general expenses, London Office expenses, Superintendents' commissions and £380 8d for depreciation, the net amount at credit of profit and loss account for the nine months ending 31st December last is £13,293 9s.

A dividend of 3 per cent., less income tax, has been paid for six months on the preference shares, amounting to £1,720 1 0

An interim dividend of 3 per cent., less income tax, has been paid on the ordinary shares, and amounts to 3,439 19 0

It is proposed to pay a final dividend of 4½ per cent. on the ordinary shares, making 7½ per cent. for the nine months, or at the rate of 10 per cent. per annum, absorbing a further sum of 5,159 18 6

It is proposed to carry to reserve fund a sum of 1,000 0 0

Leaving to be carried forward 1,973 10 6

£13,293 9 0

The crop amounted to 803,672 lb. to 31st December.

To enable Shareholders to judge how the 12 months would have worked out, had the year closed on the 31st March as heretofore, it may be stated that the yield for January, February, and March has been 315,000 lb., thus giving a total of 1,118,672 lb., against 1,079,829 lb., for the previous 12 months, or an increase of 38,843 lb.

The cost of cultivation and placing the crop on board ship was 26'97 cents, against 25'77 cents the previous year. It must, however, be explained that the reason for the somewhat higher cost is that all expenses connected with the culture of the tea fields fell upon a nine instead of a twelve-months' season. January, February, and March teas, having to bear only the cost of management, plucking, weeding, and manufacture, would have brought down the cost well under last year's.

The total crop, including 50 cwt. coffee, realised £27,405 18s 8d, or an average, for the tea, of 8'98d, against 9'40d last year and 10'09d for the previous season.

The Directors regret losing the services of Mr. Melville White as Manager in Ceylon, owing to his retirement from the Colony. He has been succeeded by Mr Herbert Sinclair, a gentleman holding a large interest in the Company, and who has been in its employ since its inception.

The Managing Director recently visited Ceylon, and reports favourably on the condition and general appearance of the Company's Estates.

It is with extreme regret the Directors have to record the loss the Company sustained during the year by the death of their colleague, Mr. E. R. Macdonell.

Mr. D Erroll Sinclair has been appointed to the Board of Directors.

Mr. Theodore C Owen retires by rotation, but, being eligible, offers himself for re-election.

Messrs. Singleton, Fabian & Co., the Auditors to the Company, retire, and, being eligible, offer themselves for re-election.

JAMES SINCLAIR, Managing Director; ROWE, WHITE & Co., Secretaries.

29th April, 1901.

THE SOUTH WANARAJAH TEA ESTATES, LIMITED.

REPORT OF THE DIRECTORS.

The profit for the season, after writing off £250 for depreciation, is £1,490 19s 2d; out of which a dividend at the rate of six per cent on £7,000 preference shares has been paid, £420, leaving a balance of £1,070 19s 2d; from this the Directors recommend the payment of a dividend at the rate of five per cent on £20,000 ordinary shares, free of income tax, £1,000; and propose to carry to the next account the balance, £76 19s 2d.

The tea crop for the season, including that made from bought leaf, amounted to 592,641 lb. and the net average price was 4'93d per lb. The past year was generally unfavourable for tea producers, but the Directors are glad to be able to recommend a dividend of five per cent on the ordinary shares, after making a provision for depreciation to the extent of £250. The rate of exchange was 1s 4½d per rupee. To meet the unsatisfactory state of the tea market, owing chiefly to excessive supplies of inferior kinds, which forced prices down, the Directors have decided to adopt a finer style of plucking, and it is hoped that this system, coupled with close attention to manufacture, will enable the Company to secure better prices for the coming season's crop. The estates and buildings are reported by the Managing Director to be in good order. The acreages of the Company's estates are as follows:—South Wanarajah, 230 tea, three year's old and over; 25 grass, &c.; total 255—Dartry, 612 tea, three years old and over, 24 young tea, 44 grass, &c., total 680.

Under article 95 Mr. T. J. Lawrance resigned his office of Director, and the Board appointed Mr. William Figg to the vacancy. Under article 97 Mr. Figg retires, and, being eligible, offers himself for re-election. The appointment of auditors rest with the shareholders and Messrs. Fuller, Wise and Fisher offer themselves for re-election.

HUNASGERIA TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS

to be presented to the sixteenth ordinary general meeting of the Company on 14th May 1901, at 1 o'clock p m, for the year ended 31st December 1900:—The tea crop amounted to 479,170 lb, which sold in London for £10,432 13s 8d, giving an average selling price of 5'22d per lb. The ordinary expenditure in Ceylon and London amounted to £11,112 15s 11d, showing a loss of £680 2s 3d on the year's working. A credit balance of £152 16s 0d was brought forward from last year and, after deducting this, there is a sum of £527 6s 3d at the debit of profit and loss account. The area under tea remains at 763 acres of which 31 acres are only in

partial bearing. A severe drought, extending over 2½ months, was experienced during the early part of the year, but it is satisfactory that in spite of this a good yield has been obtained, the return from the 763 acres in bearing being 628 lb of made tea per acre against 613 lb and 414 lb secured during the two previous years. Cultivation has been well maintained and extended to the whole tea area and from an agricultural point of view expectations have been fully realised. The loss on this year's working is entirely due to the adverse market position. Last year's shipments of medium quality tea from Ceylon and India proved to be largely in excess of requirements and a heavy fall in value resulted. Our average selling price fell from 6'67d to 5'22d per lb. To meet the situation finer plucking has been almost universally resorted to in Ceylon, which while improving the quality will reduce the quantity coming forward, and it is to be hoped that this will tide over the present glutted condition of the market. Mr P C Oswald, a member of the Board, retires from office on this occasion and, being eligible, offers himself for re-election; and Messrs J & J Sawyer & Co, the Company's Auditors, also offer themselves for re-election.

THE ANKANDE ESTATE COMPANY OF CEYLON LIMITED.

Report of the Directors to 31st March, 1901.

	ACREAGE	acres
Tea	..	156
Cocoa and Liberian Coffee	..	104
Cardamoms	..	95
Jungle	..	197
Total	..	552 acres

The Directors have now to present to the Shareholders the Report, Balance Sheet, and Profit and Loss Account for the 15 months ending 31st March, 1901. Owing to the decline in value of tea during the period covered by this Report, and also to the short crop of cocoa, the result is far from being satisfactory.

Interest to the vendors was paid up to 30 June, but it has since been in arrears.

The total crops harvested during the period have been from

ANKANDE—Tea	..	71,024 lb
Cocoa	..	52-3-13 cwt
GLENURY Tea, Green Leaf	..	12,679 lb
Cocoa	..	45-0-9 cwt
ALTWOOD Cardamoms	..	5,335 lb

Depreciation amounting to R278-81 has been written off from Profit and Loss Account.

The Directors regret that, under the circumstances disclosed by the Profit and Loss Account, they are unable to recommend any dividend distribution on this occasion.

Mr. John Aymer retires by rotation and is eligible for re-election.

The appointment of an Auditor for 1901 will rest with the Meeting.—By order of the Directors,

BAKER & HALL, Agents and Secys.
Colombo, May 22nd, 1901.

PUNDALOYA TEA COMPANY OF CEYLON, LIMITED.

REPORT

To be presented at the Fourth Ordinary Annual General Meeting of the Company to be held at the Office of the Company, on Tuesday, the 7th May, 1901, at twelve o'clock noon.

1. The Directors now submit their Report for the year ending the 31st December, 1900, together with the Balance Sheet and Accounts of the Company, made up to that date, and duly audited, and they regret th

the Accounts have been unavoidably delayed, owing to the serious illness of the Manager of one of the Estates in Ceylon.

2. The Tea Crop amounted to 697,359 lb. of which 697,155 lb. shipped to London realised a gross average of 8'68d per lb. The crop exceeded that of 1899 by as much as 52,794 lb., chiefly owing to unusually favorable weather, but the average price of tea has been tending steadily downwards during the year, while, in consequence of excessive stocks and supplies, the state of the market is far from satisfactory, and there is at present little prospect of any permanent improvement.

3. During the year 42 acres have been cleared and planted with tea, which practically completes all the extensions contemplated. The young tea planted during the past four years is reported to be coming on well, and the earlier clearings will contribute something towards the crop of 1901.

4. The following statement gives details which may be of interest:—

Season.	Acres Plucked.	Total Tea Crop.	Yield per Acre.	Cost of Crop per lb. f.o.b. Colombo.	Gross Average price obtained per lb Tea.	Average rate of Exchange per Rupee.	Dividend on Ordinary Shares free of Income Tax.
	acres.	lb.	lb.	d.	d.	s. d.	per cent.
1900	1,640	697,359	425	4'86	8'68	1 4 17-64	6
1899	1,640	644,565	393	4'81	9'23	1 4 9-32	6
1898	1,640	627,886	383	5'29	9'27	1 4 3-16	6
1897	1,640	623,699	380	5'22	9'52	1 8 3-8	6

5. The net profit for the year amounted to ..	£7,857	10	7
To which has to be added			
Interest ..	170	18	11
And the Balance from last year of ..	£626	9	0
Less Factory Extensions ..	288	0	0
	338	9	0

Making a Total of **£8,366 18 6**

The Directors have already paid, out of this, Interest for the year upon the Mortgage, less Income Tax .. £436 3 1

Dividend for the year upon the 6 per cent. Preference Shares, less Income Tax .. 1,889 5 0
Income Tax .. 216 14 8

And they propose to deal with the Balance as follows:—

To pay a Dividend of 6 per cent., free of Income Tax, on the Ordinary Shares, requiring .. 3,960 0 0

To Transfer to Reserve for Depreciation and General Purposes (increasing this Account to £6,000) ... 1,500 0 0

To write off cost of Investments ... 100 0 0

And to carry forward the balance of .. 264 15 9

£8,366 18 6

6. The Director retiring on this occasion is Mr. Edward Christian who, being eligible, offers himself or re-election.

7. Mr. John Smith the Auditor also retires, and offers himself for re-election.—By order of the Board,

ROBERTSON BOIS & Co.,

Agents and Secretaries.

CEYLON PROPRIETARY TEA ESTATES
COMPANY LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the fourth annual ordinary general meeting of shareholders, to be held at the Office of the Company, on Monday, 20th May, 1901.

The Directors herewith submit the general balance sheet and profit and loss account for the year ending 31st December, 1900, duly audited.

The net amount at Credit of Profit and Loss Account after providing for General expenses, Income Tax, &c., is .. £ 4,695 16 0

Debenture Interest paid to 30th Sept., 1900 (less Income Tax) amounts to £718 15 0

Less from last account .. 181 5 0

Three months' Debenture Interest to 31st December, 1900 (less Income Tax) amounts to .. 178 2 6

Preference Dividends paid for 1900 (less Income Tax) amount to .. 1,246 9 6

Interim Dividend of 1½ per cent. on the Ordinary Shares paid 31st October, 1900, amounts to .. 1,175 14 0

It is proposed to pay a final Dividend of 1½ per cent. on the Ordinary Shares (making 3 per cent. in all, free of Income Tax) which will absorb .. 1,175 14 0

And to carry forward to next year a balance of .. 382 6 0

£4,695 16

During the past year the Company's estates have given an increased crop of tea of 89,047 lb., the yield per acre being 490 lb. against 439 lb. in 1899 and 407 lb. in 1898.

The gross price realised for the teas sold in London and Ceylon averaged 6.10d as against 7.11d last year, and the average rate of exchange is the same as last year, viz: is 4 13-32nds.

The profits of the Company have been seriously diminished owing to the general fall in the market for teas grown at medium and low elevations.

Year.	1897	1898	1899	1900

Profits.	6,277	4,834	6,790	3,680
	6	3	2	19
	9	11	5	3

The following statement shows the results of the working of the Company for the last four years:—

this Company having suffered in common with others from the severe depression in the tea market, resulting from supplies both from Ceylon and India during the greater part of the year being in excess of the requirements of the trade. The account being so unfavourable, the Directors have again waived their fees, and the London Agents have reduced their charge for office rent and secretarial work. Owing in a measure to the very wet weather from June to October the crop was a little short of estimate, and the amount obtained was 376,499 lb., which realised a net average price of 4.54d. per lb. The rupee exchange for the Company's business averaged 1/4-15 per rupee. The acreages under cultivation are:—Over four years old 966, under two years old 75, total 1,041; and the crop for the season is estimated at 385,000 lb, of which there have been sold to date 32,675 lb, at a net average price of 5d per lb. Every effort is being made by the staff in the East towards maintaining the efficient and economical working of the estates, and a somewhat finer system of plucking is now adopted, it being expected that this change will be beneficial to the Company. Under the Articles of Association, Mr W Dunn retires from the Board and, being eligible, offers himself for re-election. The auditors, Messrs Brown, Fleming and Murray, also retire and their re-appointment remains with the shareholders.

THE GREAT WESTERN TEA CO. OF CEYLON, LTD.

Report of the Directors for presentation to the general meeting of the shareholders, to be held on Saturday, the 8th June, 1901, at noon.

Directors:—J. C. Dunbar, Giles F. Walker, James Ryan, A. Cantlay.

The Directors submit their Annual Report and Accounts for the Season ending March 31st, 1901.

The yield of Tea has been 428,510 lb., being an increase of 12,535 lb. on last season's crop: the price realized on 365,850 lb. for which account sales have been received is 48.91 cents per lb. against 48.96 cents last season, and 48.74 cents in 1898-99, a very satisfactory price in view of the lower range of the market.

The Cost F.O.B. Colombo is 31.71 cents per lb. (including 4.77 cents for manuring) against 31.27 cts. (including 4.23 cents for manuring) last season.

Estimating the unsold portion of the crop at a safe figure, the amount available for distribution, after setting aside R6,079.19 for depreciation, is R64,728.85 out of which the Directors recommend the payment of a dividend of 10 per cent absorbing ... R58,400 00
 To place to Reserve Account a sum of 5,000 00
 And to carry forward the balance of ... 1,328 85

R64,728 85

The result of the year's working is fully equal to that of the previous season in spite of a lower market, as last year the balance carried forward from 1898-99 was R7,416.88 or R5,640.78 more than the balance carried forward to this season, while the general condition of the estate is at the present time greatly improved, owing to the good and careful work done by the Superintendent.

The estimated crop for the current season is 420,000 lb., to cost R133,975.00, being at the rate of 31.89 cents per lb. tea inclusive of 4.49 cents for manuring, but from the present condition of the estate and the yield to date the Directors are now of opinion that the estimated crop will be exceeded

A re-survey has been made of a portion of the Company's lands, and according to this there are 2,269 acres planted with tea, and the total area of the estates is 2,995 acres.

Under Clause 69 of the Articles of Association Mr. H K Rutherford retires from the Board on this occasion, but, being eligible, offers himself for re-election.

The Auditors, Messrs. Harper Brothers, Chartered Accountants, retire from office and offer themselves for re-election.—By order of the Board,

WM. JOHNSTON, Secretary.
 London, 11th May, 1901.

THE MIDLAND (CEYLON) TEA PLANTATIONS CO. LTD.

REPORT OF THE DIRECTORS

to be submitted to the shareholders at the ordinary general meeting, to be held on Tuesday, 21st May, with the accounts, duly audited, for the year ending 31st December, 1900.

The receipts for the season are £7,198 13s 2d., less working expenses in Ceylon £6,858 18s 3d., leaving gross profit £339 14s 11d. And the following being also chargeable:—Debenture interest—6 per cent. per annum on £15,000 £900; interest—of loans £175 6s 1d.: fees to trustees and auditors, office expenses in London, &c., £107 5s 3d., = £1,182 11s 4d.; the loss on the season's working is £842 16s 5d. Deducting the balance of profit for 1899, £300 6s 8d, the deficiency is, as shown in the balance-sheet, £542 9s 9d.

It is with much regret that the Directors report such a serious loss on the season's working,

The Acreage of the Estate is

A.	R.	P.	
921	2	12	Tea in bearing.
39	0	0	Fuel clearing.
38	2	4	Ravines.

30	0	14	Cart Road and Roads.
23	2	25	Railway.
1,082	0	0	

In terms of the Articles of Association Mr. James Ryan retires by rotation, and being eligible offers himself for re-election.

It will be necessary to appoint an Auditor for season 1901-02.

By order of the Board of Directors,
J. M. ROBERTSON & Co., Agents & Secretaries.
 Colombo, 25th May, 1901.

**SPRING VALLEY COFFEE COMPANY,
 LIMITED.**

REPORT

To be presented to the thirty-seventh ordinary general meeting of the Company to be held at No. 5, Dowgate Hill, London, on Tuesday, the 14th day of May, 1901, at 12.30 o'clock p.m.

The following annual accounts are now presented to shareholders:—Balance sheet made up to 31st December, 1900. Profit and loss account for the year ended 31st December 1900.

The crop of tea for the past season amounted to 656,220lb, and this, together with 15,845lb bought from neighboring estates and manufactured at Spring Valley, sold for £19,062 19s 5d; the average selling price being 6.81 pence against 7.73 pence obtained for the 1898-99 crop.

The crop from the few remaining coffee trees amounted to 173 cwts 3 qrs 2 lb, and realised £592 5s 11d, being at the rate of 68s 2d per cwt against 62s 10d obtained for the 1898-1899 crop. Coffee sold in Ceylon to the value of £29 15s 6d.

The total proceeds from the sales of produce amounted to £19,685 0s 10d and expenditure in Ceylon and London to £16,007 0s 1d, leaving a profit on the year's working of £3,678 0s 9d. To this profit has to be added a sum of £240 10s 4d brought forward from last Account, and after debiting £15 12s 11d for Income Tax and £1,275 for Dividend on the Preference Share Capital for the seventeen months ended 31st December, 1900, there remains a balance of £2,627 18s 2d to be now dealt with.

The Directors recommend the payment of a Dividend of 2½ per cent. on the Ordinary Capital, which will absorb £2,000 of the above sum, and that the balance of £627 18s 2d be carried forward to next year.

Good flushing conditions prevailed during the year under review, and a crop of 482 lb. of made tea per acre was gathered, which compares with 326 lb. secured during the year 1898-99.

Cultivation and manufacturing accommodation and appliances are being well maintained, and the tea planted in recent years promises well.

The only unfavourable feature is the tea market. Prices have been steadily falling for a long succession of years, and the heavy supplies, more especially of common sorts, that came forward from Ceylon and India last Autumn, caused a further severe shrinkage in values.

This is being met by finer plucking on most Ceylon gardens, and the improved quality and anticipated smaller supplies have already had a beneficial effect on quotations.

Present conditions must arrest further extensions, whilst the consumption of tea should be stimulated, and it is hoped that these causes will operate to raise values to a figure that will leave a

fair margin of profit to the grower. The area of the estate as on 31st December, 1900, was as follows:—

Tea 5 years old and over	1,362 acres
Planted November-December 1896 ..	159
" .. 1897 ..	194
" .. 1898 ..	196
<hr/>	
Total under tea ..	1,911
Total under fuel ..	163
Forest, &c ..	257
Oolanakande estate ..	365

Total area .. 2,696 acres

Oolanakande Estate, comprising 100 acres of tea, has been let on lease for a term of years at a nominal rental. The lease has now expired, and the cultivation of the Estate by the Company is for the present suspended, as it is found to be unremunerative.

Mr. P. C. OSWALD, a member of the Board, retires on this occasion and, being eligible, offers himself for re-election.

Messrs. DELOTTE, DEVER, GRIFFITH & Co., the Auditors, also offer for re-election.—By Order,
 London, May 3, 1901. J. ALEC ROBERTS, Secy.

**THE MALAY STATES COFFEE
 COMPANY, LIMITED.**

The Directors beg to submit to the Shareholders their report and accounts for the year ended February 28th, 1901.

During the year 79.97 piculs of coffee were secured, netting R2,385.59, this being slightly in excess of the amount estimated. The balance of the Capital has now been called up and it is calculated that the funds in hand will be sufficient for the working of the Estate until March, 1902, when it should be self-supporting. The cultivated acreage is now as follows:—

144 acres of coffee (from which 300 piculs is estimated as the crop for season 1901-1902.) 50 acres of Rubber planted 12' x 12'

34 acres of the Coffee has also been planted with Rubber 20' x 10' and with Coconut 54 trees to the acre, the remaining 110 acres of Coffee has likewise been planted with Rubber 20' x 20' and with Coconuts. The Rubber is all coming on well and we are advised by the Superintendent that the older trees are branching out, 8 to 10 feet up the stem.

The Directors have to record with much regret the death of their colleague, Mr. W Sandys Thomas, Messrs F W Bois and W Kingsbury have, owing to their departure from the island, resigned their seats on the board, and the three vacancies have been filled up by Messrs. J Ryan, H G Bois and E M Shattock.

In terms of the articles of association Mr. V A Julius also retires from the Directorate but being eligible offers himself for re-election.

It will also be necessary to appoint an auditor for season, 1901-1902.

“SOME NOTES ON COCOA PLANTING IN THE WEST INDIES”—is a neat little pamphlet of 70 pages, by our London “Cocoa Correspondent,” Mr. H Hamel-Smith, and contains a good deal of useful information, more particularly in reference to the industry in Trinidad and other West Indian islands, with estimates of cost of opening a plantation of this product (also of bananas,) and of the best means of improving the product. The author holds the opinion strongly that the world wants more cocoa than is as yet available and yet Trinidad exported over 260,000 cwt. in 1899.—Copies of the little work (published at 1s nett) will be made available locally very soon.

THE TEA TRADE:

According to an old newspaper, the tea habit is much more universal than is commonly supposed, as the following schedule will prove:

People of all classes take tea. Dead people take *terniT*; gay people, *festiviT*; nice girls, *puriT*; free people, *LiberT*; fashionable folks, *societT*; good people, *pieT*; successful candidates, *majoriT*; editors, *honestT*; solemn citizens, *graviT*; funny roosters, *leviT*; orthodox citizens, *deiT*; polite people *suaviT*; bashful fellows, *modestT*; kind ones, *chariT*; bachelors, *singulariT*; short people, *breviT*; cunning folk, *rascaliT*; romantic simpletons, *novelT*; respectable people, *ChristianiT*; artistic people, *beauT*; strong people, *responsibiliT*; criminals, *penaltT*; vicious cusses, *enmiT*; grocers, *varietT*—but the T-pot cracked at this juncture.

Among the fragments were found: Wedded couples, *feliciT*; Mormons, *multipliciT*; Quakers, *tranquilliT*; the asylums, *insaniT*, *mediciT*, *poverT*, &c.; pretty girls, *incomprehensibiliT*; lovers, *uniT*; everybody, *longeviT*; the one who does not pay his subscription, *T-total depraviT*.—*American Grocer* May 1.

CACAO DISEASE IN TRINIDAD.

MR. MASSEE'S REPORT.

Some time during the end of the year 1900, I received an enquiry from Surinam as to whether I had noticed in Trinidad a disease attacking the branches of cacao trees and causing growth in bunches like the European "Witches Brooms" or "Hecksenbesen." I was glad to answer that I had not yet seen such an appearance among our Trinidad trees. It was reported from several independent sources that the disease was very prevalent and did a large amount of damage to the trees, seriously affecting the crop. Specimens were kindly procured for me, and these on examination proved to be infected with one of the Fungi known to cause abnormal growth of the branches, running into knots or "brooms." The specimens were sent on to the Director, Royal Gardens, Kew, and attached is the Report of Mr. Massee the Mycologist who examined them:—

"*Eoasacus Theobroma*, Ritzema Bos, is the provisional name given to the Fungus parasitic on the Cacao branches, causing witches' broom thereon. The Author of the species could not find the fungus in a fruiting condition, neither did the material forwarded to Kew furnish fruit. Material should be sent at the time when the tips of the twigs are only slightly swollen, and covered with a white delicate bloom. In such swollen branches the fruit of the fungus has entirely disappeared and the persistent or perennial mycelium of the fungus can only be found. Owing to the perennial mycelium a crop of spores is produced each season on the diseased branches; such spores being spread to neighbouring trees by wind, &c., extends the disease. If it were possible to remove all diseased branches, the disease would soon disappear, but as this is hardly possible, in addition to removing as many diseased shoots as possible, it is advisable to spray with dilute Bordeaux mixture from time to time, so as to prevent the inoculation of young twigs and leaves."

It would be nothing short of a serious calamity were the infection introduced into this Colony, and steps have been taken with the view of securing effective regulations to prevent such an occurrence. Similar growths are to be observed in many trees growing in this Colony, Arabian coffee being con-

siderably troubled, but not so as to seriously affect its growth or productiveness. This, however, is not the same as attacks cacao, but is related thereto. It is probable that in the course of Nature many diseases exist among our indigenous trees which, on the occurrence of suitable conditions might attack and destroy many cultivated plants as did the *Hemeleia* with Ceylon coffee, and a careful watch is necessary for the first indication of disease, so that measures can be devised for its suppression before the damage becomes too extensive to be effectively dealt with. The disease of which we write is an easily recognised one and cultivators may see a preserved specimen showing its character, in the Herbarium of this department. In any case, where trees appear to be suffering, the department would be glad to receive and secure the determination of specimens which may be thought to be diseased.—*Trinidad Bulletin*.

CHEAP NITROGEN.

After four years of research and application, Sir William Crooke, the eminent agricultural chemist, has solved the problem of furnishing nitrogen to the plant world at a cost which brings this all-powerful stimulant and renovator within the means of the poorest cultivator. Hitherto nitrates have had to be imported from far-away scattered deposits and, though of recent years the price has been brought down to between £7 and £10 per ton, this has proved far beyond the means of the average horticulturist and farmer. Sir William now separates the gas direct from the atmosphere by electricity, and, although the experiment of fitting the nitrates so obtained for commercial purposes was costly, the product was sold at a remunerative profit of £5 per ton.—*Indian Planter's Gazette*, June 1.

TEA PLANTING IN ASSAM: THE OFFICIAL REPORT.

Cacutta, 7th June.—The official report of tea planting in Assam during the past year gives the total number of gardens as 8041, against 815 in the previous year, the total area being returned at 1,059,624 acres against 1028,431 in 1899. The number of persons employed permanently increased from 457,343 in 1899 to 468,326 during the year under report. Over 97 per cent. of the area under tea is in European hands, while less than 3 per cent. is owned by natives. The total output was 141,118,644 lbs. against 128,371,857 lbs. in 1899, showing an increase of 12,746,787 lbs.—*Madras Mail*.

GEM MINING IN CEYLON.

With the exception of the diamond, emerald, turquoise, and opal (says a writer in *Kuhlow's German Trade Review*) almost every precious and semi-precious stone is found in Ceylon, and frequently a great variety of them are dug out of the same pit. Rakwana is especially famed for its sapphires. Spinel of all colours and garnets are almost invariably found in conjunction with the other stones; also the different varieties of zircon, commonly termed jargoon. Cat's-eyes are usually found together with aquamarines and the different kinds of beryl, of which the alexandrite is the most sought after. A good proportion of the stones found are cut locally in the village of Ranapura and in Kalutara, a small place on the coast some 40 miles south of Colombo.—*Globe*.

THE CEYLON TEA CESS FUND.

We have been compiling some figures for our Handbook in reference to the above Fund and the outlay by the "Thirty Committee" which may be of interest to planting readers. The Cess Collection was provided for by Ordinance No. 4 of 1894—an Ordinance to provide for the continuance of the Export Duty on Tea levied under Ordinance No. 15 of 1892. The collection commenced the next year and, so far as we can make out, the total collection up to the end of 1900 was R3,140,333; but of this R155,799 up to the end of October, 1894, was taken for the Chicago Exhibition, leaving R2,984,534 to be dealt with by the "Thirty Committee." Up to the end of 1897, their outlay was R575,141; during 1898 it was R531,344; in 1899 it equalled R726,799, while it rose to R1,069,209 last year, and yet apparently, so far as we can judge, there should be a balance of R82,000 over on 1st January last? We make the total receipts to be R2,984,534
 Against disbursements R2,902,493

Balance R82,041

Of special interest is it to know that the total of votes for America would seem to be R1,421,255 or not far short of £100,000, or between 400,000 and 500,000 dollars. For Europe altogether, including Mr. Rogivue's votes, the total would seem to be about R1,033,950.

The total votes for Russia, so far as we can judge, amount to R275,957 and for the rest of Europe, including the Paris Exhibition, R757,975. Very likely some corrections may be necessary on our figures; but we think they should be found to be at least close approximations.

Now, the point is what have we got in return for nearly £100,000 spent in America. It is true, as some one has said, that Canada should not be taken so much into account, because the people there were bound to become more and more customers for Indian and Ceylon teas. It was the United States that had to be fought for, and all we need say now is that if there had been no "subsidising"—partial and more or less mysterious—but open frank advertising of a good article, with "demonstrations" at all State Exhibitions, we cannot believe that more customers for our teas, and permanent ones too, would not have been won, than by the policy actually pursued. We know advertising was partially tried, chiefly through dealers—so gaining a temporary trade in our teas; but the object should have been to gain the notice of the masses in the way in which every great advertiser with a good article goes to work.

TRADE IN CEYLON: COLOMBO AND GALLE.

We have received the following remarks on the present condition of Ceylon trade, more especially among the natives, which come to us

from a correspondent at the leading port of the South:—

"The article on Madras steamer freights reproduced from the Madras Mail in the *Observer* of the 24th ult. affords some interesting information re the cute Bombay trader. It appears he has encroached on the Piece Goods trade of the Madras Presidency; and in Ceylon, too, we find the same element in active competition with the ubiquitous Moorish trader. The latter complains that he can make no profit on his cotton goods, although he imports them direct from Europe, so long as the Bombay trader can afford to undersell him. It was thought at one time that inferior goods, unsaleable in Bombay, were sent to Galle; but the secret leaks out now. 'J W' explains that the Dealers' Association contract price from Manchester to Bombay is 10s 6d per ton measurement with ten per cent primage. With such cheap freight, the Indian merchant is well able to secure a margin, notwithstanding the additional expense entailed on re-shipments to Galle or Colombo.

"The Maldives' trade, which was formerly in the hands of the Moormen and gave them very lucrative returns, is now monopolised by Bombay capitalists. These latter have their representatives in Galle and Colombo, and carry on an extensive business in coconut oil, Bombay flour, curry-stuffs, etc.

"Since the Indian coasting steamers commenced to bring regular supplies of rice from Calcutta and the coast, the Chittagong rice trade has been extinguished. The Chittagong crafts traded regularly between that port, Galle, the Maldives, and Calcutta, and found here a ready market for their rice and paddy—but at present the grain trade is mostly in the hands of Chetty firms with agencies in all the principal rice ports, who effectually combine to discourage outside competition.

"Another feature of local trade is, that of late, with the acquisition of capital acquired during the plumbago boom, Sinhalese dealers have entered into keen competition with the Moormen and Parawas in the retail shop-keeping line.

"It is obvious therefore that our friend, the Tamby, is being gradually ousted from many of his happy hunting grounds. Even the trade in precious stones which has enriched so many Moor dealers is doomed—if the large finds of rubies and blue sapphires reported as having been discovered in the United States and Canada prove to be equal to the Ceylon specimens."

With regard to what is said above we have made enquiries in a reliable quarter and have found everything that is said confirmed. What is stated is only too true. Freights from Manchester to Bombay are a half, or a third, of what we have to pay to Ceylon. The quantity sent out to the former place being so enormous, the rates are low, and thus the dealers have a pull. With regard to remarks about the local trade and Sinhalese dealers having entered into keen competition, as a result of the plumbago boom at Galle, the same may be said of Colombo. During the last year or two, travellers for European houses have come to Colombo in large numbers, showing samples through native agents, and taking orders for quantities of goods far in excess of what the market could take off.

We understand that the Banks in London are much to blame for granting facilities for

over-trading, by buying bills on natives in the way they have done; the consequence is that the place is full of goods, for which there is a limited sale. Bills cannot be met, and large stocks are held practically in pawn, stocks which should never have been imported. The best thing those interested could do with them would be to send them back to Europe.

CEYLON DIRECTORS AND COMBINATION.

(To the Editor, *Home and Colonial Mail*.)

SIR,—The remarks from the chair at the recent meetings of Ceylon tea companies, so far as they refer to the question of over-production of tea, are singularly unsatisfactory: They bring into prominence the question of whether directors are justified in taking upon themselves and imposing upon their constituents the risks involved by ignoring the present and prospective perilous position of the tea industry. The statistics of the last half-dozen years show, in spite of increased consumption, that there has been during that period a continually increasing excess of production over consumption to the extent of upwards of 50 million pounds of tea. The leading brokers are urging upon producers to take note of the Board of Trade returns, and warn them that, if surplus production is to go on increasing on the present scale, prices are likely to be even further reduced. Yet, with these and other equally serious facts before them, what was the attitude of the directors at the recent meetings? Several advocate a policy of drift, glibly disposing of, the difficulty by stating that matters will right themselves by the simple law of supply and demand; a simple law, certainly, though, in the sense they intend it, not one to be contemplated with equanimity by shareholders. Then with regard to the late proposal to curtail output by mutual agreement as a remedy—which, by-the-by, has fallen through entirely from the supine indifference or active opposition of Ceylon planters—some directors excuse themselves by expressing the opinion that it was not practicable, that it is difficult to get planters to combine for such a purpose. Indian planters showed that it was quite possible. Others were of opinion that there would be a sufficiently reduced yield, because a system of plucking finer leaf would be adopted by planters, though a reference to their own estimates of yield for the current season showed that they had framed estimates for an equal or increased yield. Expression was given to an opinion that it was even doubtful whether times were so bad that any combined effort to alter the position of the tea market was necessary. It would be interesting in this connection to know at what point such combination would become necessary. It is said there are some 70 or 75 per cent. of Indian and Ceylon tea companies that are not paying. Some companies are calling up the unpaid balances on shares, others are re-arranging their capital. Bankers are hesitating about giving facilities for credit to companies. Large areas of new plants are coming into bearing. As no agreement exists among planters as to output, the current season's crop may be as heavy as, or even heavier than, the last, for probabilities are that those planters who commenced the season by plucking finer leaf in order to reduce output may revert to coarser plucking and a larger yield if prices should

not sufficiently improve, and in the face of the present vast accumulation of tea in stock it is most likely prices, even for fine teas, may be disappointing.

Can such a state of things be considered as not sufficiently serious to render some co-operative movement necessary?

It was remarked by one director—whose utterances, however, were somewhat of the hot and cold order—that “planters have it absolutely in their own hands, on the day they combine, to alter the whole complexion of the tea market.” Let planters then see to it that they combine, lest the tea market alter the whole complexion of the planting community.

There need be no denying the fact, indiscriminate rivalry—in other words, cut-throat competition—has reached its limit. We have passed the days of long profits, when wild and reckless rivalry was possible. We are now in a period of close-margin profits, when all kinds of combination among buyers, carriers, &c., beset the industry on all sides.

Shareholders are usually slow to attribute blame to those who represent them, except in times of disaster, when, of course, it is too late. They are, however, becoming anxious. It has even been suggested that a shareholders' league might be serviceable.—Yours faithfully,

JAMES HODGES.

Birmingham, May 21, 1901.

[Our correspondent is in error in stating that the excess of production over consumption is to the extent of upwards of 50 million lb. Last year it was 20 million lb. in excess, and the previous year 14 million lb.]

GREEN TEAS FOR EGYPT AND NORTH AFRICA.

A colonist recalls an enquiry made of him in Egypt ten years ago for “green teas” which were said to be in great request for the Soudan. He wishes to know if samples of Ceylons are being sent to Egypt, Tunis, Algeria and Morocco?

A CURE FOR DYSENTERY.—Dr. Mougeot, whose investigations into the subject of a cure for dysentery have been attracting attention in Saigon for some time past, now claims to have discovered a remedy for the disease. This is the seed of the plant named *Brucca Sumatrana*, belonging to the family *Simarubaceæ*, which is found in those parts of Southern China, Lower India, the island of Sunda and tropical America where the malady prevails in its more virulent form. Both the tree and its seed are known in the vernacular of its habitat by the name of *kosu* or *kosam*. It may be remembered that several years ago the scientist Roger discovered a bacillus which was held to be the cause of dysentery. In experiments which he conducted upon animals, Dr. Mougeot found that, wherever these bacteria were most numerous in the bowels, the use of the *kosu* seed, which, by the way, is about a centimetre in length and lies hidden within a small oily kernel, led to their utter destruction. He usually administered from six to ten seeds on the first day and twelve on the second, in which time a change for the better generally became apparent. Dr. Mougeot claims that 871 out of 879 cases experimented upon proved successful.—*Pioneer*, June 2.

ROYAL COLONIAL TOUR. TEA CULTIVATION IN CEYLON.

(From Our Special Correspondent.)

H. M. S. ST. GEORGE, Singapore, April 22.

It is one of the penalties of a visit to Ceylon that a great feeling of regret arises when the day of departure arrives, tempered, it is true, by the hope that in the future one's eyes may again rest on a land so fair and beautiful. One of the leading residents of the island remarked recently, at some function, "that it is the opinion of the present Governor, Sir J. West Ridgeway, and of the leading Colonists and officials, that Ceylon only needs to be better and more widely known to be still more appreciated." This is a true sentiment, and the Royal visit should do much to enhance the popularity of the most prosperous of the Crown Colonies. It possesses features that should attract all. As the island is today, those travelling for pleasure will find much to gratify their tastes in the rich and glorious scenery, the simple, quiet, and inoffensive habits of the native races, and in the hill districts a climate which has the reputation of being one of the most enjoyable in the world. To the student of book-lore there is no lack of opportunity for interesting research. The several races which now form the native population have woven in the past a fascinating record in which many of the blackest spots are, it is sad to say, due to the presence of unscrupulous European adventurers. In the wonderful ruins, which the archæologist delights to unearth for his own instruction and that of mankind, are signs that in the earlier days of the world Ceylon was inhabited by a noble race, of high intelligence and capabilities.

The point of prosperity to which the island of Ceylon has attained at the commencement

OF THE 20TH CENTURY

is the more remarkable and praiseworthy since less than twenty years ago it was nigh sick unto death through a trade disease, brought about by the failure of the coffee berry in 1874, from which, thanks to the dauntless spirit and enterprise of the planters, whose salvation came with the planting of the tea-shrub, a recovery so rapid and marvellous has been made. It is true that the tea plant was first introduced into Ceylon as early as 1842, when a field was laid out in the Ramboda Pass, but no serious attempt at its cultivation was made till the collapse of coffee gave it the opening wanted. Happily, in this hour of tribulation, the planters did not despair. Like men they put their backs to the wheel, and shoved hard, until once more the cart of their fortunes no longer travelled brake-less down the road of ruin. A brilliant and most accomplished Governor, Sir Arthur Gordon, afterwards Lord Stanmore, was there to aid their efforts, and until the cultivation of tea came to maturity the evil years were tided over by the cultivation of cinchona, a tree from whose bark is produced the febrifuge, quinine. Its rise and fall forms a short chapter in the agricultural history of Ceylon, but it bridged over the most disastrous period.

The development of

TEA CULTIVATION

has been marvellous. Wherein, then, lies the secret of the marvellous diversion of a staple trade from an old-established centre to new and younger rivals, who,

moreover, were handicapped in their dealings, owing to the artificial rise in the value of the rupee, due to legislation, which operated to the disadvantage of the Indian and Ceylon planter in competition with the Chinese manufacturer? The secret will be found in the value, purity, and cleanliness of the tea manufactured under European supervision, and scientifically prepared by machinery, as compared with the primitive methods of Chinese hand labour. It is said by those speaking with knowledge that, if people at home knew how the China tea was prepared for the market, they would never drink it again. It is not my intention to enter into any detailed description of tea-growing and manufacture. Although passing a few estates, the journey to Kandy only takes the traveller to the border of the tea country, which lies more or less in a semi-circle running north and south to the east of this town; but as many of those with whom we came in contact during our stay were connected with the industry, it is obvious that with such an interesting subject for discussion our knowledge of tea cultivation was materially increased.

Of Colombo our glimpse was too brief to convey more than a pleasurable impression. It contains many modern and handsome buildings, and, further, possesses the reputation of having several of the best hotels in the East.

Although I fear I have written at too considerable length, for which the interest of my subject can be my only excuse, mention must be made of the

FAMOUS BOTANICAL GARDENS

at Peradeniya, some four miles from Kandy. Here, in a large space of 150 acres, most carefully laid out, and with its well-trimmed turf recalling at times the precincts of an English park land, is stored a marvellous wealth of tropical vegetation, such as is, perhaps, to be found in no other spot on earth. The utmost care is lavished on the growth and cultivation of the plants, with the result that one may wander for hours through avenues of stately beauty. Scientific instruction has not been allowed to overrule picturesque effect, and the feelings of the visitor are in a manner largely reflected by the remark of one who said his taste for an English hothouse had been absolutely spoiled by the view of this wonderful garden. Perhaps, in the midst of all the marvels of the earth's raiment none is more remarkable than the Talipot palm. The screw pine, the banyan tree, with its weird roots crawling like pythons over the ground, clumps of bamboos, which soar with tufted feathery crests a hundred feet or more above ground, and many others are all beautiful, but the Talipot palm outdoes them all. In its early growth for the first ten years it spreads out great fan-shaped leaves, and then the trunk begins to form. The natives compute the uses to which the tree can be put as 801, of which the foremost are a rain-cloak and a sunshade. Some of the leaves will shade or keep dry twenty men: three or four make an excellent tent. Like the papyrus of the ancients, the Talipot leaves when boiled and dried are used for writing under the native term of ola. On strips of ola historical records and religious codes have been handed down from time immemorial. There exist manuscripts 2,000 years old in a perfect state of preservation, with the Pali characters as clear and distinct as when

first graven. When the palm approaches full maturity, it develops a great bud, which in due course bursts with a report, and lovely white blossoms unfold and spread in a pyramid shape of creamy flowers. But like the swan's song, the flowering of the Talipot announces its doom. Within a year it has drooped and dried.—*Daily Telegraph*, May 22.

MR. THOMAS CHRISTY OF LONDON ON HIS TRAVELS.

SOAP-MAKING AND COCONUT OIL: A NEW PATENT.

IMPROVED ORANGE CULTURE FOR EGYPT—WHY NOT FOR CEYLON?

There are few more enterprising, inventive or interesting men of business in the City of London than Mr. Thomas Christy, the head of the well-known drugs and new plants and products' importing house, the inventor of the Rubber-separating machine, and of many more useful little articles, and the first to utilise several new plants for medicinal, art or industrial purposes. We have just received two chatty letters from him, telling of a recent visit to Egypt where the temperature was so unusually cold that many of his old China friends on board the steamer pressed him to go on to Ceylon; but he could not spare the time. We venture to quote the purport of his letter regarding Egypt, dated 14th May:—

"While in Egypt I carried on my researches in that wonderful country, and I think, from what I can see, that it will come out one of the richest countries connected with England,—the people are so hard-working and they use their brains to arrive at a result. I take advantage of the present note to ask if you can help me in a matter. I believe that there are oil mills in certain parts of Ceylon; I want to know what class of oil they press, and if they turn any of it into soap; further, if the manufacture of soap direct from the oil would be a matter worth following up for Ceylon. The reason of my troubling you is that in Egypt some of the soap-makers complained that they were not successful in working the cotton-seed oil. I promised them that I would at once look into the matter, and I conferred with chemists in this country who have worked at it, and I believe we have hit off a very inexpensive process. If it works well in Egypt it will also be applicable for Ceylon.

"ORANGES.—I worked considerably at this, and was interested to find out why the oranges were so degenerating and becoming full of core and pips instead of being fine, large, juicy oranges. I learned that the natives were grafting plants yielding the red or blood orange on to grafts from their own varieties of oranges. This resulted in an orange that looks very well on the barrow or in the shop windows, and keeps its color for some length of time, but the natives will not allow the oranges to properly ripen; this is a very bad feature. The first-class orange that we know of in this country, and which stands the journey well from California, is the Waval Orange, and I have written to my friends in Egypt to try and secure plants and cuttings of these, and do away with the dry-cored, hard orange without juice. While on this question of the red or blood orange, I may say that with the assistance of Admiral Blomfield I threshed out this subject. The old idea was that the pomegranate pollen, impregnating that of the orange, caused the blood red color. This is a botanical impossibility, so I don't go into that matter further; but

I learned that it is the red pomelo which is found in the island of Labnan, and which is a species of orange; these pomelos were sent to Amoy and as Malta is supposed to be the origin of the red Maltese Blood Orange, I was anxious to find out how it was that this occurred. I learned that the Jesuits had sent the pomelo and orange trees home to Europe and they had sent them to Malta; hence the idea of the Malta blood orange being unique, whereas this red orange is now to be found all along the shores of the Mediterranean and in many instances has greatly deteriorated the fruit and it has also been largely sent to Egypt. People often express their disappointment when they see on a barrow or in a shop, especially abroad, a fine orange, very black in the centre, and on securing some from the same pile find that they are not nearly so red as the decoys put outside. I learned in Egypt that these decoys are produced by allowing the orange to thoroughly ripen on the tree, when it takes up a much deeper shade of color. Further, if it is desired to increase the size and the depth of color they manure the tree heavily. This will give them a good yield of large (decoy) fruit.

"I was enabled to secure some very fine oranges in Egypt. One of the dealers packed me a large basket, and when I went on board the steamer I handed it over to the second steward, who put it in the cool room. These oranges arrived in England in perfect condition and were very much appreciated for their fine flavour. I do not know if it has occurred to any of your merchants in Ceylon to purchase oranges at a low price and try shipping them in cold chambers to London. The Navel orange sells in the shops here for 3s, 4s, and 5s each, and there is a great demand for them.

"In Egypt the orange is being cultivated to an extent that is almost incredible; gardens of 300 to 400 acres each are not uncommon, and already the landed proprietors are seeking to get into connection with steamship owners to follow the example of the Jamaica firms of shipping their fruit to England, but in Egypt they have another great advantage, and that is that the country produces the most magnificent vegetables.

Alas! that Ceylon should be so far behind with its fruit cultivation, and that of oranges in particular; but Mr. Christy's letter affords encouragement to any planters who have gone in for Mr. Pearson's offer to supply reliable kinds, and we trust to hear of improvement and success in culture. Meantime, why should not a Rangala, Hewaheta or Maturata planter try a case of his oranges—such as they are—to the London market. Sent in the cold room, they should arrive in good order and possibly to a good market.

As regards coconut-oil and soap-making in Ceylon we have no very encouraging story to relate; but first let us hear what Mr. Christy has to tell us in a second letter, dated 17th May:—

"I send you by sample post a specimen of soap made in five minutes from coconut oil. I thought it would interest you to have a specimen that you could show, because it probably will become a valuable process, especially in countries where oil exists in quantities but yet is difficult of transport. I may say that the process is very inexpensive and most simple and it is done without heat. My friend, the chemist, labels it "process almost instantaneous," but I put it down at 5 minutes. Use it in any way and put it to any test you like; I can easily send you more at any time. I send you copy of the letter with sample that I received this morning."

(From the Chemist to Mr. Christy.)

"By this post I am sending you a sample of pure coconut oil saponified by my rapid cold process. Nothing beyond very ordinary mixing arrangements are re-

quired for the purpose. It would remain sufficiently liquid to allow of being run into barrels or boxes, and it would quickly set as hard as a rock. The packages need not be expensive, as no ordinary atmospheric temperature would re-melt it. This appears to me the best way of packing this product, as in the raw condition the loss is enormous. Of course in this condition it would only be suitable for the soap-makers. But this trade uses the bulk of the production and in addition to the saving in waste they would have the advantage of having a ready-made soap which only requires mixing."

The specimen of soap sent to us is rather crude, and we fancy the article that used to be manufactured at the Hultsdorf local coconut oil mills was much superior. In 1890 we exported 660 cwt of local manufacture, chiefly to Mauritius: but all this manufacture and trade has died away; and we import now over R220,000 (£15,000) worth of soap each year, although we suppose more coconut oil is shipped from Colombo than from any other port in the world.

CITRONELLA AND LEMON-GRASS OIL.

From the Semi-Annual Report of Messrs. Schimmel & Co. (Fritzsche Brothers), Miltitz, near Leipzig, London and New York, April-May, 1901, we quote some paragraphs of local interest:—

CINNAMON OIL, CEYLON.—In consequence of insufficient demand, it has at last been decided at Colombo to reduce the price of larger parcels of fine chips. The reason why the sellers of these chips have given way is no doubt partly due to the favourable prices which they have recently obtained for the cinnamon quill shipments.

CITRONELLA OIL.—The value of this important perfume has, during the last six months, undergone a further decline to about 9½d per lb., at which figure it has now stood for three or four months. All reports agree that a further reduction is impossible. It is much more probable that there will be a decided rise: for it is stated in authoritative quarters that, owing to the unprofitable prices, the cultivation of citronella grass has been entirely given up on many large plantations in the Akuressa and Baddegama districts, and has been superseded by tea plantations which yield much more profitable results. Our correspondent estimates the falling-off in the production at at least 25 per cent. If this estimate comes true, which we do not doubt, the reduced production would probably soon affect the quotations. In spite of the low price, this article is constantly being adulterated in a most unheard-of manner. To the usual method of adulteration with kerosene has now been added that with camphor oil; in fact, no other article gives so much work to our analytical laboratory. In what condition should we be, if there were no means of checking the quality! The fine Java quality, specially distilled for us, is more and more appreciated, and is also purchased by many practical experts, who are well able to estimate a thing at its proper value. The yield of this quality is enormous, the perfume exquisite. For fine honey soaps only this oil should be used. We received recently several very interesting photographs of plantations and distilling installations supplying this oil, and hope to reproduce them, for the benefit of our readers, in our next Report.

LEMONGRASS OIL.—The value of this article has risen during the last few months to 4½d per ounce, which would be about equal to a quotation of 1½ marks. Whereas the annual export from Cochin usually comes to between 2000 and 3000 cases, the export in 1900 only amounted to 1600 cases, a quantity which is decidedly too small for the present consumption, since the manufacture of citral has placed this article in a totally different position. A return to the previous values is not to be relied upon. The opportune importation of large quantities has placed us in a position to accept orders below the present quotations.

VARIORUM.

RAFIA FIBRE IN MADAGASCAR.—Rafia, or as it is generally spelt, "rafia," is the Malagasy name of a Palm which furnishes a staple article of commerce, called rafia fibre. It is indigenous to Madagascar, and it is to be met with everywhere on the coasts, needing neither cultivation nor attention of any kind. It is not a stately Palm, but sends its enormous branches from near the ground; in a fine specimen one branch is almost a tree in itself. The rib on each branch is as much as 20 feet long, of a pearly grey colour, smooth and shiny, flat on the inner surface, but otherwise round, without any knobs, and so exceedingly hard. At the base it is as large as an ordinary champagne-bottle and tapers to a point at the top. The inside consists of a light pith, which can be split into layers of any thickness. Possibly, says the United States Consul at Tamatave, it is this or an analogous production, which is used for making pith helmets in the East. Naturally these ribs combine great strength with wonderful lightness and are used for shafts for "flanjanas" or palanquins, ladders or other purposes, but otherwise have no particular commercial value. It is the pinnate leaves which produce the rafia fibre of commerce. One Palm frond will produce eighty or one hundred long green leaflets, from 2 to 5 feet in length, like the leaves of the Sugar-cane, but of a dark, lustrous green, and both thicker and stiffer. These again contain a round and pliant rib, which the natives utilise for making baskets and dredges for catching small fish and shrimps in the rivers after they have stripped off the green part which furnishes the fibre. The under part of this green leaf (which is not exposed to the light, as it remains folded), is of a pale greenish-yellow colour, and from that side the inner skin can be peeled off in the same manner as the skin on the outside of a Pea-pod, except that it peels off straight to the tip without breaking. It is then of the palest green, and after being dried in the sun assumes a light straw colour. This is the rafia fibre of commerce. It was originally sought for by the natives for use in articles of clothing. The men bring in the fronds, and women and girls weave it on hand-looms, of any coarseness or fineness. Woven just as it is peeled off from the fronds, it forms a kind of sacking used for wrapping goods, while the perfection of the art, as known by the Hovas only, is to weave a tissue of which the warp is rafia fibre split very fine, and the weft of white silk. This gives an article called silk lamba, which fetches fancy prices in Europe and America. The coast tribes use it for clothing, but of moderate fineness, with dyed stripes of indigo, saffron, black, and a dirty green. It is a cold, comfortless-looking material, and refuses to adapt itself to any folds that a sculptor would care to copy. Rafia fibre is used in Madagascar by nurserymen, gardeners, &c., for tying up vines and flowers, and possibly for grafting. It possesses the advantage of being as soft as silk, and is not affected by moisture or change of temperature so as to risk cutting or wounding the most delicate tendrils, and it does not break or ravel when folded or knotted. These qualities bring it into use all over Europe, and consequently maintain its price. It is

virtually inexhaustible in Madagascar, the supply being limited only by the scarcity of labour. For export the fibre is merely collected in large skeins, twisted up or plaited, and then baled like raw cotton, Madagascar exports about 20,000 bales annually.—*Journal of the Society of Arts*.

THE MANUFACTURE OF COCONUT BUTTER IN GERMANY.

The manufacture of coconut butter is an industry of some importance in the City of Mannheim. The Mannheim factory is said to be the only one of any considerable size in Germany; it has an output of about 10 tons of butter a day. The product is sold under the name of "Palmin"—a registered trade name—or coconut butter ("Kokosnuss butter"). It is manufactured from the kernels of coconuts, and is used as a substitute for butter and lard in cooking. Consul Harris of Mannheim says that, as sold, it is generally white in colour, almost tasteless, melts at about 80° Fahr., and is of about the consistency of mutton or beef tallow. When desired by retail customers who are bakers, confectioners, &c., the product is coloured to resemble ordinary butter: When furnished to dealers it is unlawful to colour it. The proprietors of the factory at Mannheim, referred to above, claim that an analysis of their product shows it to contain more than 90 per cent. of vegetable fat, with but a slight trace of water, while ordinary butter contains about 85 per cent. of fat and nearly 15 per cent. of water. It is stated that the substance does not become rancid easily, that it will keep for three or four months in a cool room, and that it is much more wholesome and easily digested than the ordinary fats used for baking and cooking. For this reason the product has met with considerable favour in German hospitals and other institutions, and for use in army camps. Coconut butter is generally put up in square packages, wrapped in parchment paper, a small percentage being sold in tin cans. The latter are hermetically sealed for shipment during hot weather. The product is sold at one price throughout Germany, namely, about eight-pence per pound, or about half the price of ordinary butter. The kernel of the coconut is imported in thoroughly dried strips, forming the "copra" of commerce. It is subjected to various refining processes, by which all the free acids and other substances are separated, leaving only the vegetable fat. In the latter stages of the manufacture the product resembles ordinary butter recently churned. It is placed in machines, similar to the separators used in creameries, in which the water and other foreign substances are separated by centrifugal force. In the manufacture of coconut butter a by-product, consisting of free acids and other substances, is obtained, and sold to soap manufacturers.—*Journal of the Society of Arts*, May 24.

RUBBER NOTES.

Experiments in the cultivation of the ficus elastica at Katha, in Upper Burmah, have not been very successful, only eighty-two out of 370 seedlings planted survived at the end of the past year. It is stated that the Rubber Trade in the Lagos district has almost reached a position of complete standstill. This anxiety is well founded, and there are some substantial reasons for believing that other causes than the failure of the rubber trees are operating, to obstruct and kill the trade.—*India Rubber Journal*, May 13.

SEYCHELLES NOTES.

VANILLA.—Our next year's vanilla crop promises to be a very good one. The rains in November, however, prevented it being the bumper crop it then

appeared to promise. The owners of the mountain-vanilla estates were the heaviest losers, owing to the rain. It came down steadily just a day or two before the great flowering days, the result being that thousands of flowers were not fecundated. The area under vanilla in the Colony is steadily increasing. There are a good many diseased vines about all over the islands, but now, owing to each vine being kept distinctly separate from its neighbour, the fell vanilla-disease cannot cause the ruin of our plantations as it did in 1889 and following years.

SOAP.—The exports of soap from the Seychelles per the British India steamers to Zanzibar and the East Coast of Africa continue to expand. Consequently caustic soda is being imported here in increasing quantities. The bulk of it comes from Newcastle-on-Tyne. One of the chief causes of the flourishing state of our soap industry is the low price at which coconut oil has been selling. This oil is only worth now about 1'60 r per velt (1½ gal.), instead of over 2r a year or two ago.

GUANO.—The exports of so-called "guano" from the Admirantes Islands (a dependency of Seychelles) are also increasing. Shiploads have been sent recently from Remire Island to Durban and Mauritius. As I think I already told you, this stuff is only rich in phosphates, but it is an excellent material to use as a basis with which to mix other kinds of fertilisers.—A Seychelles *Cor.* to the *Chemist and Druggist* or May 11.

THE TRADE ON TEA:

(To the Editor, *Grocers' Journal*.)

SIR,—In your capital leading article on "The Trade in Tea," in last week's *Grocers' Journal*, you say that tea is still, as it always has been, the chief glory of a grocer's business. This is certainly what it ought to be, but I must confess that it is difficult to see where the glory comes in. Selling a strong, dark, bitter, dyspeptic Assam, with a little tasteless refreshing Ceylon thrown into the blend, and perhaps some uncommonly common China (not to improve the flavour but to make a little more profit), in possibly a very handsomely decorated caudex, at an impossible price, does not, in my opinion, add largely to the glory of the tea trade. Neither is it likely to assist the public to value or enjoy the infusion. It is true there is "nothing like tea" when you get fine China tea properly made, and I have proved over and over again that ninety-five people out of a hundred appreciate such tea, which refreshes them more than cocoa or chocolate, and is palatable without milk and sugar. This is more than can be said of common Indian tea, which is not only injurious to health and temperance, but is decidedly nasty. I agree with you that China tea has long been under a cloud. This has been brought about through the trade, as a body, shirking the trouble of selecting China tea when they got strong liquoring Assams at low prices. These latter produced a dark-coloured liquor, and were puffed as more economical than China at the same price; and it was asserted that three-quarters of a pound made as much liquor as a pound of China at the same price. Old-fashioned people who knew anything about tea were not gulled by this specious argument, and did not give up drinking pure China tea; but gradually it became more and more troublesome to get a pound of tea anywhere that was not heavily dosed with Assam, which ultimately swamped all the old flavour of China tea out of the blend, and then the trade (all but a few old houses) bought and sold nothing but a mixture of Indian and Ceylon, to save trouble and secure a profit. At the present time it is almost impossible to find a grocer who has a pound of really fine China tea in stock, and equally impossible to find a customer who has any knowledge of the quality he gets for his money. Whisky and tobacco have not improved the public palate, or the teas now supplied by the bulk of the trade would

command a very limited sale. I again agree with your remark about the complaint "I can't drink tea" being so common now, but this mostly comes from people over forty, who are wise enough not to swallow a tea that would give them dyspepsia, or from the young who have not tasted a really enjoyable cup of choice China tea, and are quite disgusted with the bitter burnt flavour of cheap Indian tea.—I am, yours, etc.,

CINQUE PORTS.
Boswell House, Bolt Court, E. C., May 20, 1901.
—*Grocers' Journal*, May 25.

CINCHONA IN JAVA AND PROSPECTS.

The condition of cinchona cultivation in Java is not altogether that of an open book, at least so far as knowledge in the London market is concerned, for it is a prey to all sorts of rumours, especially as to cultivation being on the decline. We have during the past ten days had the opportunity of getting authentic information on the matter from two gentlemen who are not primarily interested in cinchona production. One resided in Java for nearly ten years, following a scientific pursuit, and the other spent nearly two months in the island investigating the cinchona question. Both agree that cinchona cultivation is on the up grade in Java, and that the cultivation of ledger trees there may be said to be in its infancy. Everything is giving way to ledger trees, which are all planted as graftings upon succirubra seedlings. These compound plants flourish exceedingly in the well-cultivated soil, which is kept as clean as any Surrey market-garden. There is no sign of any plantations going out of cultivation; rather the contrary, as the whole tendency is to get bark of high quinine percentage. Much interest is taken by the planters in the Bandung Quinine-factory, and, as the planters can with advantage get their highest-yielding barks worked up there, they do not export the best barks. The factory is now the only one in Java, and it is slowly making its influence felt on the market. Last year it sold 900,000 oz. of quinine by auction locally, the bulk of it going to the United States. We may note that the exports of quinine from Germany to the United States decreased 1,000,000 oz. last year. It has often been asserted that the Java planters have the quinine situation in their own hands, if they would come to some agreement to restrict the output or control the supply of bark. This is just what they cannot, or will not, do. On the contrary, they ship larger quantities every season. For instance, the shipments for 1898-1900 have averaged over 11,000,000 Amsterdam lb. per annum, against an average of 9,000,000 for 1895-1897. During the first four months of this year the shipments also show the large increase of nearly 1,000,000 Amsterdam lb. To this fact, taken together with the heavy London stock of quinine, is attributed the recent depression of the market and want of confidence among speculators. During this week there has been a slight revival, but it is thought to be merely a "move" with the idea of giving a fillip to the bark auctions at Amsterdam at which the quantity offered is again large, representing nearly 1,080,000 oz. quinine in the bark, or over 30 tons. The result of these auctions will be found in our Trade Report, and will be eagerly awaited by quinine speculators and dealers generally, for upon it depends the immediate course of the quinine market. According to the drug statistics there was a stock of 3,330,000 oz of quinine in the London warehouses at the end of April, and, although this is slightly less than the

stock at the corresponding period of 1900, it has none the less disheartened speculators. The deliveries for April were only 37,000 oz., while the imports reached the respectable total of 218,480 oz. The above stock is a heavy one, and the figures since the beginning of the year, month by month, show that it is normal in recent history:—

	1901	1900
	oz.	oz.
January	3,300,000	2,800,000
February	3,100,000	3,090,000
March	3,150,000	3,320,000
April	3,330,000	3,430,000

We may repeat, in regard to the heavy shipments of cinchona from Java, that they are not a matter of uprooting trees or anything of that kind, but are simply the natural outcome of a culture which is carried on with excessively cheap native labour, and under the best possible scientific conditions. There is no evidence, as far as we can gather, that this is done at a loss to the planters, and they are not in the slightest interested in what will suit quinine speculators.—*Chemist and Druggist*, May 11th.

PLANTING NOTES.

PISCICULTURE.—We are obliged to Mr. Farr for his suggestive note on this subject. To improve the fish supply of the island, to stock our large rivers, tanks, and lakes with new and suitable species, is a matter of as much importance to the Colony at large, in its own proportion, as to spend large sums on "irrigation" or "railways." Let our Legislative Councillors bestir themselves.

A NEW LOBELIA.—Mr W V Fitzgerald has published in the *West Australian* a description of a new species of lobelia, named *L Gouldii*, after Mr L H L Gould, of Mt. Malcolm, who forwarded the specimens from which the species is determined. It flowers profusely late in September, forms large patches in ferruginous, gravelly, or sandy soil, and would be of horticultural value where a bedding-plant of violet colour was required. It is a little plant, two inches to four inches high, with large violet flowers, singly terminating in large branch-like peduncles. The corolla is three-quarters of an inch to nearly one inch long.—*Chemist and Druggist*.

TOMATOES ARE MOST HELPFUL TO THE SYSTEM—when eaten raw, as the volatile oil they contain is dissipated by the heat of cooking. Green vegetables, such as spinach and cabbage, are invaluable as medical articles of diet, as they possess blood-purifying properties and act indirectly on the liver. Turnips, are nutritious, while the young turnip-tops are possessed of tonic properties. Parsley is a blood purifier, and should be eaten both raw and cooked. An almost exclusive diet of fruit and vegetables is supposed to induce purity of complexion.—*Indian Agriculturist*, June 1.

THE CULTIVATION OF TEA IN NATAL.—Some ten years since we gave a few figures respecting the growth of Tea in Natal, supplied by the head of the Agricultural Department. At that time it was thought that a good market could be found in this country and at the Cape for all that could be spared after satisfying the needs of the proprietors of the Tea plantation. Progress has certainly been made, but not by leaps and bounds. The estimate for the supply of 1901 is 1½ million of pounds, or an increase over the production of last year of 250,000 lbs.—*Gardeners' Chronicle*, May 25,

BRICKS FROM SLAG.

The problem of what to do with slag seems to have been solved by the George-Marien Mining and Smelting Company, at Osnabruck, where the granulated slag from blast furnaces is mixed with slag cement in the proportion of one part of slag to eight parts of cement, and the mixture is compressed into bricks weighing 7½ lb. After two or three months' exposure to the air these bricks are suitable for building purposes. Whilst they are newly made they can be cut to any shape desired, and their rough surface facilitates their use with a minimum of mortar. These bricks will sustain a pressure of 1,500 lb per square inch, and are very suitable for resisting the high temperature of factory chimneys. The slag finely granulated and mixed with cement in the proportions of eleven to one furnishes excellent mortar.—*Sell's Commercial Intelligence.*

TEA IN SICILY.—We learn from *Nature* that an attempt was made to grow the tea bush in Sicily (from Japan plants) so far back as 1872; but not much success attended the cultivation, and, as nothing has been heard of it since, we suppose the trial was abandoned,

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for July :—

Vol. XIII.]

JULY, 1901.

[No. 1.

OURSELVES.

THE present number of the *Agricultural Magazine* begins a new volume. With the issue of the last number, the publication completed the 12th year of its existence, and is therefore now entering upon its 13th—a good age for a Ceylon Magazine. There may be ventures of a similar character that have been carried on for longer periods, but we fear that these will be found to have passed through occasional seasons of hibernation, while our own monthly has appeared for a dozen years without a break. A bound collection of past volumes should, to the local agriculturist, prove as full as the proverbial egg; and in saying this we make no boast to ourselves, though we would wish to impress upon those for whom we labour (with no recompense to speak of) that they are bound to learn much and to derive much help by taking in the *Agricultural Magazine*, the subscription to which is the modest sum of Rs. 3 per annum. We have endeavoured with each new volume to increase the usefulness of its contents to our readers, and we hope to make the present volume still more useful by furnishing information on home industries and practical hints connected therewith, in addition to papers concerned with practical Agriculture and Horticulture.

We take this occasion, on the opening of a new volume, to thank our contemporaries for their kind countenance and our readers for their support and encouragement.

THE EDITOR,

RAINFALL TAKEN AT THE SCHOOL OF AGRICULTURE DURING THE MONTH OF JUNE, 1901.

Greatest amount of rainfall registered in 24 hours on the 8th inst. 1.53 inches.

Recorded by C. DRIEBERG.

OCCASIONAL NOTES.

The *Queensland Agricultural Gazette* refers to the decision of the Ceylon Government to carry on agricultural work through rural schools with connected school gardens as "a step forward." Let us hope that the progression will continue,

The village industry of desiccating the pulp and seeds of the jak fruit is larger than is generally supposed; in fact, though most people are familiar with the jak nuts that have been dried and stowed away in sand—treatment which permits of the seeds being kept for future use, and which at the same time improves their flavour—few have probably seen the sun-dried pulp (dried with or without previous boiling) which is a convenient form of reserve food to be soaked and cooked (like apple chips) whenever required,

There are many parts (such as the Kesbewe district) in which the industry is common, and where it is found to be rather a profitable business. We have been informed that when jaks are plentiful they sell for 3 cents (equivalent to a $\frac{1}{2}$ d.) each, and that in seasons when they are scarce the dry stuff fetches as much as 6 cts. per lb., and jak fruits may weigh anything from 6 to 60 lbs.

Among our latest visitors from abroad (and there are many that call at the Colombo School of Agriculture—now, alas! only so in name) was Dr. F. Stuhlmann of German East Africa, who has lately been touring in India, Java, and the East generally. The doctor is a most interesting personage, and has a fund of information to entertain one with, not merely regarding his own African experiences—botanical and agricultural—but also with reference to the various countries he has been so fortunate as to visit with a view to studying their economic conditions. We are making a fairly representative collection of the vegetable products of the Island which Doctor Stuhlmann wants for a museum in which he is interested.

An Australian exchange in taking over an article on the composition of Indian cows' and buffaloes' milk remarks that some information regarding the quantity of milk yielded by milch buffaloes would be desirable. In north-west India the buffalo as a milk animal is found at its best. Mr. Mollison, late of the Poona Farm, in his paper on the Management of Dairy Cattle in India, speaks of buffaloes "giving over 30 lbs. of milk per day (a quantity sufficient to make 3 lbs. of butter), and of an average animal yielding 18 lbs. per day while suckling her calf. In his report on the Poona Farm for 1893, the same authority records that the best buffaloes yielded during the period of lactation (371 days) 6,959 lbs. of milk, and the worst (during 227 days) 1,971 lbs." This will give some idea of the milking capacity of the Indian buffalo. At the time of our visit to the Poona Dairy in 1893, the best buffalo was giving 36 lbs. per day.

In this connection it would be interesting to compare the yield of certain animals at the Allahabad Dairy Farm. In a recent account of a visit to this institution mention is made of a buffalo giving 32 seers of milk (a seer = 2 lbs.) equal to 5 lbs. of butter per day, and of a cow of the Hansi breed yielding 26 quarts of milk per day. We shall say more about the Allahabad Dairy and its successful work in another issue.

Mr. George Weerakoon, Mudaliyar of Wellaboda Pattu, Matara, draws our attention to the reported extraordinary flowering of the bamboo in Central India. The area over which the flowering extends is estimated at 1,200 sq. miles, and with the exception of a few isolated clumps the flowering is said to be universal. The extraordinary point is that clumps of all ages are seen in flower. Last year, it is said, the drought brought about flowering in the Dhaba

Range of this district, where the bamboo produced a kind of manna, the seeds keeping thousands in food for some weeks; so that this year it is expected that the entire population will flock, in a short time, to gather the seed. To the people in the vicinity it is said the result of flowering will be serious owing to the impending death of the bamboos. The oldest inhabitants recall the gregarious flowering of bamboos over fairly large areas some 60 years ago, a circumstance which points to the not unlikely fact that the bamboo found in the district flowers at intervals of about 30 years.

Mr. Weerakoon states that he remembers seeing a sample of the bamboo seed brought from Bintenue in the Badulla district some 35 years ago. The "paddy" as well as the "rice" resembled the products of *oryza sativa*, and in taste resembled el-wí or hill paddy. It would be interesting, as our correspondent remarks, to ascertain from Bintenue how often seed has been produced since then, and if it is procurable at present. We trust some of our readers will give the desired information.

Since writing the above we find a reference to the extraordinary flowering of bamboos in the last (June) number of the *Indian Agriculturist*. The approximate area over which the flowering is taking place is put down at "75,000 acres extending 50 miles from North to South, along belts 3 to 8 miles broad." Cart loads of bamboo grain are now seen plying along the roads, and no action is taken to arrest collection by the natives, as the deficiency of rain has produced scarcity of ordinary food grains, while this same drought has no doubt brought about the seeding of bamboos. The flour is either mixed with "Jowari" (*Sorghum vulgare*) or eaten by itself after preparation into flour cakes. It is considered nutritious by the natives, but it would be interesting to ascertain (as we hope to do) its chemical composition, and its true value as food.

MORE ABOUT AGRICULTURAL EDUCATION FOR COUNTRY DISTRICTS.

In the April number of the *Queensland Agricultural Journal* Mr. F. W. Teck deals with the question of Agricultural Education for our country districts, and many of the arguments in his paper apply forcibly to local conditions.

It is no wonder, says the writer, that with the conditions of life as it is generally found among the cultivating classes, our young country folk get dissatisfied with their isolated position and crowd into towns where life is made to appear more pleasant if not so healthy and independent. The pleasures of a town life and the alluring fixed period of work per day tend to attract the sons of the soil, who should be brought up to have a stronger liking for agricultural pursuits by better systems of education and by practical teaching. And how, it is asked, are the children of the rural districts brought up? As soon as they are old enough they are expected

to follow in the old-fashioned ways, the old "Jig-Jog" of their parents, while the school teacher has to do all he can to prevent their absence from school. But what little is learnt in the school is soon forgotten, and that little is of small service to the rustic. No difference is made between the teaching in town and in country schools in the midst of agricultural districts. Nothing is done to meet the difficulties in which the people of these latter districts are placed. The system of teaching and the curriculum laid down by educational authorities are undoubtedly good, but so far as our country districts are concerned, are susceptible of much improvement, as the curriculum is more applicable to town children. What is desired is an education in our country schools by which children may be instructed in such matters as have a bearing on their every day life. The writer suggests the introduction of a series of Agricultural Readers, forming a continuous upward course of instruction. These, he says, would be of great value, while being attractive and interesting.

Again, the writer, recommends object lessons and cultivated school plots for the teaching and practical illustration of the rudiments and elementary science of agriculture. It is also suggested that prizes should be offered for the best-kept home or school garden and for essays on subjects of agricultural and rural importance. Though he is ready to admit that he may not have hit upon the best methods of teaching, he believes that the general outlines he has traced would be most suitable for the children's calling in after life. It will no doubt be stated by those engaged in teaching and those connected with the educational staff that there is no room for teaching agricultural subjects, the daily routine of work being already crowded and the teacher's time taxed to the utmost. Granted, but are there not some subjects that could be easily dispensed with in country schools, especially during the later years of school life when the system of practical instruction should take the foremost place in the curriculum? One of England's greatest statesmen is quoted to have said that "the successful pursuit of Agriculture demands the exercise of a broader intelligence than any other calling." But do our educational arbiters recognise this fact at all?

COCONUTS.

The Benefits of Mulching.—Mr. J. T. Last, F.R.C.S. writes as follows upon the benefits of cultivation as he has found them at Mangapwani:—"There are at Mangapwani about 300 bearing palms from which the nuts are gathered every three months. About three years ago I had the ground well dug up for some six feet round the base of each tree, and then packed round the tree any manure, grass or vegetable matter I could get, covering the same up with soil. This has been repeated every year. The result of these operations is that the number of nuts gathered has greatly increased.

Yield of Nuts.—Formerly the three-monthly gathering would average about 3,000 nuts, now more than double that amount is obtained. The

last gathering reached the number of 7,033. Since I started mulching the trees there have always been one or more trees at each three-monthly gathering from which I obtained 100 nuts. At this gathering 110 nuts were gathered from one tree, 100 from two, 91 from one, 89 from one, 86 from one, and 80 from one, making a total of 656 nuts from seven trees.

I think, judging from the above results, we could fairly expect that with proper attention a healthy full-grown coconut tree will produce 100 nuts a year.

Coconuts in Zanzibar.—The average yield of nuts in Zanzibar Island is from 25 to 30 per tree. Calculating the price at Rs. 20 per 1,000 and the yield at 30, there will be a gross return of 9½ annas per tree. Gathering may be set down at Rs. 4 per 1,000, which leaves a net return of about 7½ annas or half a rupee per tree.

Pemba trees yield less, the average being probably less than 15 nuts per tree per annum. But labour is cheaper and cost of gathering less, about Rs. 3 per 1,000; so that the net return works out about 4½ annas per tree.

Planting Nuts.—Dr. Krapp in his Swahili Dictionary has the following note:—"The natives plant the coconut on the 14th day of the moon, because the moon is then at her full power. This takes place before the rain. They take care that the bud is placed downwards in the pit which is dug to the depth of a cubit. The tree (like the mango) requires five years' growth before it bears fruit.

The generally accepted way of planting a nut is to lay it on its side in a trench about 7-8 inches deep (its own depth.) It has been rightly pointed out that if a nut be planted eyes downwards, the young shoot may rot before it reaches the surface; on the other hand if planted eyes upwards the milk inside, which is especially provided for the first nourishment of the germ, will settle at the bottom of the nut and the young shoot will then run a risk of being dried up. Nature seems to have especially pointed both ends of the nut so that having fallen from the tree it shall remain upon its side to germinate. In the case of the mangrove the young seedling drops from the parent tree upon its pointed end and sticks in the mud and grows forthwith. But the bottom of the coconut could not have been pointed to enable it likewise to stick in the sand and germinate, because a nut always falls upon its side. This is well shown by dropping a few nuts from the roof of a high house. If the nut is suspended by the stalk, in the way it hangs upon a tree, and dropped, it will turn half over and fall sideways. The same thing happens if the nut be held upside down. If it be held horizontally it will maintain this position till it reaches the ground. Nature is always a safe guide. Allow a space of nine inches or a foot between the nuts in the trench, and 18 inches between the trenches. This gives plenty of room to lift the nuts when the time comes for them to be planted out, without doing much damage to the roots. April is the best time to plant out the seedlings, when they should be 5 or 6 months old. Hence the nuts should be planted in the nursery in November. But no hard and fast rule need be laid down, especially as our

seasons are uncertain. 35 feet by 35 feet is a good distance for them to be placed in the plantation. This gives 35 trees to the acre.

[The above notes are culled from *The Shamba*.—Ed. A.M.]

MILKING.

[The following interesting Prize-essay on milking was written by Mr. J. Petersen, of Dalum Agricultural College, Denmark, and translated for the Cape Colony Agricultural Journal by Mr. Arthur Muller of Clare College, Cambridge].—

CHAPTER I.—INTRODUCTORY.

The udder is, from the point of view of the milker, the most important part of the cow. That a proper use develops the living instrument is a maxim that applies to the udder of a cow as well as to a multitude of other things.

That use develops the instrument is easily shown by example. A workman knows that unusual labour causes a strain at first. The sower feels tired in his right arm, the harvester tired in the back, the milker tired in his arms and hands, etc., but before long they accomplish the one-sided work without feeling much strain or tiredness. Only the use which causes considerable exertion brings on further development. The way to exert the udder is to milk it completely dry. The milker should imitate the greedy calf, which sucks the last drop of milk out; this causes a greater flow of blood to the glands of the udder, and it is from the blood that all material for further development and for the forming of more milk must be sought.

It is in the above facts that one finds an explanation of the case (so common in Denmark) of the agricultural labourer's wife getting quite a lot of milk from her cow, which on a large farm would be found useless for the dairy. Whoever undertakes milking should certainly know the above facts.

CHAPTER II.—HOW TO MILK.

The object of milking is to empty—as completely as possible—all the milk present in the udder, and in such a way that the cow finds it a pleasant sensation, and that the milk is kept clean.

The cow is by nature meant to nourish its young. We ought therefore to learn from the calf. The latter does not suck its mother in a brutal manner; on the contrary, it knows by instinct that if it wants milk it must behave properly. Therefore it never grabs a teat at once, but asks, by touching the belly and then the udder, if it may.

The milker ought to begin by speaking kindly to the cow, patting it, and afterwards with the back of the hand rubbing it gently on the belly and udder. By this means one not only puts the cow into a good temper, but the rubbing helps to get rid of loose hairs, scales and dust, etc., which otherwise easily find their way into the milk pail.

Next the milk pail is placed under the udder (always on the same side of the same cow), and the work is begun by catching hold round both the front teats with the whole hands. The hands are now in turn moved up against the udder with a gentle pressure, and they are then closed slowly and softly (likewise in turn) about the teat, the

closing beginning at the top and extending downwards.

These gentle movements should be continued until one notices that the cow lets the milk "come." The milk must now be emptied out in long unbroken jets by means of the same movements of the hands as before, but applied with more vigour than at the beginning. For every fresh grip the hand ought to exert a new pressure up against the udder, while at the same moment the first finger and thumb should grasp that portion of the udder which lies exactly above the teat. During this part of the milking the conscientious milker ought to fix the whole of his attention on his work, since every interruption means a loss of milk. Hence all loud talk or noise, which disturbs the cow as well as the man, is to be strictly avoided. A good enlivening song need not, however, be out of place.

When the front teats give no more milk, the work is carried on—without the preliminaries of patting, rubbing and so on—in the same way as regards the back teats.

The milk must be *squeezed*—not dragged—out of the teat. The teat should therefore be grasped with the whole hand, and the latter must not slide up and down the teat more than necessary. The sort of milking which is carried out by grasping the top of the teat with the thumb and first finger or thumb and second finger (the latter is the worse) and then pressing the fingers together and dragging them down the teat, is very bad indeed. The cow does not like it since it irritates the skin on the teat, and easily causes sores, and it is really much harder work for the milker.

In the case of those heifers, however, whose teats are too short for the whole hand to grasp them, the fingers must of course be used.

The milking is not over, even when the back teats (or the last milked) give no more milk. *A vigorous second milking must now take place.* After one has again changed a few times from the first milked to the last milked teat and back again, the udder must be thoroughly "worked" by means of gentle handling and afterwards the last drops of milk must be squeezed out of the teats.

Here we could also learn from Nature. Look at the lamb, when it sucks! See how it pushes its mother's udder when the teat gives too little milk.

The little pig also can be seen poking its mother by means of its soft snout, so as to get all the milk possible.

One would almost think that they found the last milk sweeter than the first! So they no doubt do, as it has been proved by a number of investigations that it is *by far* the richest.

If the first half pounds of milk are mixed (equal amounts being taken from the four teats) from each of say 40 cows, the 20 pounds of milk thus collected will as a rule not even produce half a pound of butter.

But if in the same way one were to collect the last half pounds, which after inadequate milking can still be worked out of the udders of the same 40 cows, nearly 2 pounds of butter can be got out of the 20 pounds of milk.

Any milker can roughly prove this for himself. Collect the first jet from a teat in a small glass,

and the last jet (or the last drops) which can be squeezed out of the same teat in another glass. Place the two small glasses in a cool place; and after 24 hours it is astonishing to see the great difference there is in the layer of cream. The first milk is only good skimmed milk, while the last is nearly their cream. Getting out all the possible milk is therefore of importance not only for the development of the cow's power of giving milk, but also for obtaining rich milk. Thus the milker who does not take sufficient time to milk the cow quite dry, either does not know her or his work, or is not carrying it out conscientiously.

After the milking is finished the cow should again be patted in a soothing way, and a kind word may again be said to her. The milker should always keep an eye on the state of health of the udder and teats. If swellings or lumps or tenderness in the udder, sores on the teats or blocked milk channels are observed, or the milk looks unnatural (for example, lumpy, reddish, etc.), the owner or other responsible person should be at once informed.

As disease of the udder and teats are often infectious, such cows should always be milked last, and the milk from the diseased udder should be carefully put in a separate pail and thoroughly disinfected (and then thrown away, of course) or thrown away where it cannot spread the infection.

The milk canal inside the teat is occasionally very narrow or has a frequent tendency to get blocked. To make use of a straw or such means to clear it, is very wrong, as it can set up inflammation in the corresponding gland. A teat with a blocked milk canal should be rolled gently between the hands held out flat and then carefully milked.

After the first calf the heifer is apt to feel tender and hence inclined to object the milker's touch. This tenderness lasts, in a few cases, to the later years. In such cases one must set about milking with even greater gentleness and care. Nothing but kindness should be used unless the cow is very "wicked."

To milk quite dry, as a means of milk-giving power to a cow, is especially important in the case of a heifer after its first calf; since it acts with even greater power on the heifer than on the older cow.

It would be a good thing if every milker was provided with two smocks of washable material, one being always in the wash or clean, so that a clean one may be put on at least once a week. As one ought to milk with bare arms, these blouses should have short sleeves and be made so that they can easily be slipped on over the ordinary dress.

In wet weather, when milking is done out of doors, a waterproof cloak is almost a necessity. It should be a point of honour for the milker to see that all pails, etc., in which the milk is collected should be absolutely clean. This scrupulous cleanliness is of course a necessity. The pails, etc., are best made of tin-plated steel and must not be allowed to rust.

Complete cleaning is best and most easily done as follows:—Immediately they are finished with, the pails are washed with two or three lots of cold water; afterwards they are completely covered both inside and outside with thick lime water,

then scrubbed with cold water, rinsed and washed again two or three times in clean cold water, and finally in clean boiling water, and then allowed to drain dry in the open air; they must *not* be wiped with a cloth nor with anything else.

Be it morning, noon, or evening, the hands must be carefully washed before going to milking, and if the milking is done indoors one should also wash and dry the hands whenever they get at all dirty. For the sake of cleanliness it is best to milk with dry hands.

(To be concluded.)

AGRICULTURE IN THE TRANSVAAL AND ORANGE RIVER COLONIES.

[The following reference to Agriculture in the Transvaal and Orange River Colonies is taken from a reprint of a lecture delivered by Prof. Wallace on Agriculture in South Africa, delivered at the Royal Colonial Institute on March 12th last. The reference should prove interesting at the present time when so large a number of the late inhabitants of these colonies is in our midst. We shall probably make further extracts from this interesting paper.—Ed. A.M.]

The Transvaal and the Orange River Colonies are grassy, pastoral, and essentially cattle countries. The area of the Transvaal is similar to that of France, while that of the Orange River Colony is less in the proportion of about 70 to 114.

Witwatersrand, or White Waters Ridge, is the watershed of two great river systems, being the highest surface traversing for about 300 miles, in an east to west direction, the elevated plateau of the "Hoogeveld" or High Veld of which the Transvaal forms a part. All the water to the north discharges into the Limpopo, the northern boundary of the Colony, and that to the south into the Vaal. The name Transvaal implies the position of the Vaal as the southern boundary. Johannesburg on the highest part of the "Rand," as it is curly designated, is 5,735 feet above sea level (at Park Railway Station). To the north as well as to the south the elevation falls away pretty rapidly, so that Pretoria, the capital, only 35 miles to the north, is 1,600 feet lower, and Heidelberg, which is almost a like distance to the south-east, stands at only 4,900 feet. Kimberley, to the west of the Orange River State, has an elevation of 4,012 feet. The climate of Johannesburg is one of the coolest in Africa, the hot weather lasting for barely four months, while at Kimberley it extends to eight months in the year.

The high country—4,000 feet or upwards above sea level—occupies the southern section of the Colony.

North of this is the Bush-veld or bush country, at a lower level and having a warmer climate. In places it is broken by a series of hills, and it is covered with high grass, bush, and trees.

The south-eastern parts, including New Scotland, are specially suitable for sheep-breeding as well as for agriculture, the high central area for cattle and corn, the northern and lower elevations for coffee and sugar plantations and for tropical fruit

culture. Good tobacco is largely grown in the Transvaal for export to other districts of South Africa. Maize, Kafir corn and other tropical or semi-tropical crops are grown in summer when rains are abundant.

In some parts, as near Pretoria, maize, the most extensively cultivated crop of all, only grows well on river banks, in the alluvial soil found there. European cereals suffer from rust and from hailstorms during the summer or wet season, and probably only one crop in five years could be secured. Oats are not so much injured as wheat. A variety known as the Sidonian oat, brought from Australia by way of Natal, is not affected by rust and is grown during summer. Planted in December and January, it is ripe in April and May. The Boer oat grows in suitable soils or where irrigation is possible during the dry season of winter.

Potatoes grow freely, and lucerne does remarkably well, and when planted in alluvial soil that can be irrigated during the dry weather, after frosts have disappeared, it can be cut as many as eight times in one year. Turnips and swedes, which suffer from the attacks of fungi, especially in a very dry season, do not always prosper, but mangels do better. Frosts are liable to do considerable damage, especially in the low-lying areas.

The high-veld plateau, healthy for cattle and sheep in summer, is too cold in winter when the grass is dry and hard, and the animals are moved off in May to the lower and warmer country, where sweet grass and shelter are both more abundant in the "Bankenveld," or terrace country to the eastern side of the Drakensberg range on the Natal and Swaziland borders, or to the north of the Magaliesberg mountains, to return in September after rain falls. The dry and withered grass on immense areas of the high-weld is burnt off during September, chiefly with the object of destroying ticks which swarm in countless myriads on cattle from land which has escaped burning. The ticks are then so numerous that the cattle cannot thrive, and moreover are liable to suffer from red-water or Texas fever. The periodical burning is of recent introduction, since ticks were brought into the country by "transport riders" (cattle-waggon carriers) from Natal, and the practice has so much injured the pastures that fewer cattle can now be kept than formerly on a given area, and the quality has also gone back in consequence.

Horses are bred on the high-veld, especially to the south-east, but they do not exceed more than two to five per cent. of the live stock. In Baustoland, the greatest horse-breeding centre of South Africa, they number from ten to twenty-five per cent. of the live stock. On the low ground of all the Colonies and other dependencies, and in the valleys even at considerable elevations, horses and also mules are subject especially during summer (February being the worst month) to uncertain and intermittent outbreaks of the deadly horse-sickness, a disease peculiar to South Africa. It is contracted by them at night when they are exposed in the open air. They take into their circulatory systems the germs of a filamentous fungus, *Edema mycosis*, of the form of a beer barrel,

which are carried by thin streaks of mist rising from the veld when climatic conditions are suitable for their propagation. About eight or nine days after such an exposure, or after eating grass from which the moisture deposited by the mist had not been dried up by the sun, very few affected animals escape death by suffocation induced by serum escaping into the air passages from the affected lung structure.

The Transvaal is now outside the area which is recognised to be affected by "tsetse fly," though at one time the river valleys, especially to the north and north-east, were included in it. The pest has disappeared from the whole of South Africa south of the lower area of the valley of the Limpopo and a comparatively narrow belt of coast country surrounding Delagoa Bay and terminating in the south at St. Lucia Bay.

The wholesale destruction of the large wild game, more especially the South African buffalo, has conferred this solitary advantage upon the country as a solatium for the injury which has thereby resulted.

A good deal of a mild type of malarial fever exists, especially in summer in the low and humid parts, but it is not confined to these areas. It was present at Pretoria when the waterworks were formed, on the surface of the hard dry land above the city being broken.

The country is well provided with springs of good water.

The Orange River Colony occupies the important area of high-veld lying to the south of the Transvaal. In the eastern part of the Colony the Drakensberg and subordinate ranges of mountains occur. The great breadth of the country is a rolling, grassy plain, with a general trend to the west and north-west. Like the Transvaal, it at one time grew coarse grass, and supported immense herds of antelopes and other species of wild game, very few of which remain. But now finer and sweeter grasses prevail, and the country is stocked chiefly with cattle and a few horses, and in certain places with sheep. From the higher and more exposed parts stock require to be removed to lower and more sheltered and more succulent pastures during winter. In what is known as the "Conquered Territory," to the south-east of the centre of the Colony, is the chief agricultural district, about 100 miles in length and 30 miles in breadth. The soil is rich and capable of growing good crops of cereals of all kinds, including wheat, without being manured or irrigated. It may be looked upon as a continuation of Basutoland—the granary of South Africa. Wheat produces 30 up to 80 fold even on land which has grown grain crops successively for a number of years. Farms usually range in extent from 1,000 to 3,000 acres, and the value of the land with buildings upon it is about £1 per acre. Considerable numbers of both sheep and cattle of improved types are bred in the district.

ABOUT MANGOES.

(Concluded.)

Mr. Knight certainly deserves the sincerest thanks of all mango growers for making known

his process and experience. If others can achieve a like success we need not long have inferior mangoes in Queensland, for every bad tree can be converted into a good one. Mr. Knight says:—"It has been suggested that there is some room for improvements in our mangoes, and the writer is of that opinion also." Undoubtedly there is, and no time should be lost. Even in the West Indies, where so many fine kinds exist, it is thought desirable to import new strains from the East Indies. The following is from No. 24, *Trinidad Bulletin*:—"It has been thought advisable to import once more a number of selected varieties from the East, and to this end application was made to the Indian authorities for the best kinds from the various provinces, and cases of plants have been ordered from the Bombay, Bengal, and Madras Presidencies. It is almost certain we do not possess all the types of various strains of mango grown in the East, and although our number of seedling varieties is legion, yet it is probable the introduction of further East Indian kinds will be of great advantage in the endeavour to improve the strains now cultivated in the Western World."

We are not half as far from India as Trinidad is, and we have frequent and speedy steam communication. How much easier, then, for Queensland to get supplied than the West Indies.

When mango plants are next imported, a trial might be made of branches for grafting by Mr. Knight's method. He says:—"Experiments have proved beyond a doubt that sections of the mango-tree will keep good for grafting purposes from three to six months' time, according to variety and to the constitution of the tree from which they are obtained. This gives us the opportunity to import sections of the most desirable class of tree from any part of the globe with a certainty of their growing when properly prepared and tied on."

May not Mr. Knight be induced to go to India and procure a quantity of branches and plants of the choicest varieties? His doing so would be an inestimable boon to Australia. Branches in Wardian cases or simply in boxes having holes perforated at the sides near the top to admit air might easily be imported. I have in this way received fruit trees from California in first-rate condition, all of which grew; indeed, they could not have been better had they come from Sydney or Melbourne.

I have heard it remarked in Melbourne and in Sydney, "You Queenslanders keep your good mangoes for yourselves and send us your rubbish." My reply was, "This is not so; you have much the same mangoes as are sold in our shops, most of which are poor." Those who make mango growing a business should bestow particular attention on the keeping properties of their fruit, as well as excellence in other directions; also to careful grading and packing. Greater care should also be taken in transit. I have seen cases standing on their side and on end, and very roughly handled. This, I must say, has not been in our market. The carriage of mangoes long distances is a problem that is not yet been satisfactorily solved. I have eaten mangoes in London

from the West Indies, and in New Zealand from the Islands; they were wretchedly poor. The cause was probably owing to the necessity for picking them unripe.

I noticed on a visit to the market recently quantities of mangoes being sold by auction; 3s. per case was the highest price realised. I saw a couple of hours afterwards, at a fruiterer's, two cases, for which he informed me he had paid 7s. a case. They were certainly a very fine sample, in excellent condition, fairly large, clean, and not over-ripe; he was confident they would keep good a week or more if necessary; he expected to realise 2d. each for all of them. This is an instance of how desirable it is to cultivate only good varieties.

There are various points that go to make a good mango—on the outside, size, form, colour and texture of skin; inside, freedom from fibre, size of stone, and, most important of all, flavour. It is very rare to find all these conditions in the same fruit. The finest-flavoured mango I ever tasted was at the Island of St. Helena, South Atlantic; but it possessed no other condition of excellence, the price it realised was one shilling each. This and other fruit trees were brought to the island by Captain Bligh in H.M.S. "Providence" from Timor and the South Seas in 1792. I never saw a handsomer mango than one grown at Wickham terrace; it was entirely free from fibre, but had an enormous stone, was destitute of flavour and otherwise worthless. In marked contrast was one produced here, of fine form and colour, and without a blemish. It weighed 18 oz., the stone $\frac{3}{4}$ oz.; it was quite free from fibre, and of delicious flavour. The tree is a shy bearer, and is this year without fruit. The specimen described was exceptional, the next being a bad second in size, though equal in other respects.

The nomenclature of mangoes seems to be in a hopeless state of confusion. This is greatly owing to the immense variety we have, and to our ignorance on the subject. I have seen several distinct kinds called the "Bombay." As well may we speak of the strawberry as the "London," simply because it originally came from London, or an apple the "English" because it came from England. Eight or nine distinct varieties are known as the "Apple" and as many as the "Strawberry," though why they are so named it is difficult to tell. They do not resemble the apple or strawberry in appearance, flavour, or anything else. Mr. Parker, who has given considerable attention to the cultivation of mangoes, has this season been fortunate in producing a new variety; it is of peculiar form, fairly large, of good colour, free from fibre, small stone, and of excellent flavour. The mango is so good that it is thought worthy of being named "Bobs."

FIRST STEPS IN AGRICULTURE.

First Stage—2nd Lesson.

BY A. J. B.

In our last lesson I explained to you the necessity of ploughing and otherwise working the soil, which work is included in the word "culti-

vation." You know that the farmer is not always ploughing his land. If he were to do nothing else but plough, he would not be able to sow any crops. There are certain times and seasons when ploughing has to be done, and there are seasons when the farmer and his men attend to other work.

You are not too young to understand why some crops grow best during the winter and others during the summer. I will therefore give you a short lesson on what I will call the "seasonable" work on the farm.

There are few Queensland children who do not know what maize is; only they know it by the name of "corn." Well, maize does not like cold weather. On a right frosty morning you like to get near a good fire, or, if you go out, you like to have a warm coat on. But a maize plant or a sugar-cane plant has no warm coat to protect it from the cold, so, if either of them happen to have been planted at a wrong season, its tender green leaves exposed to the frosty air of night become frost-bitten, and the whole plant dries up when the hot sun shines on it, and it withers away. Then, such plants as cauliflowers and cabbages love the cold weather, and if they are planted out of their season—that is, if they are exposed to the blazing heat of our summer—they will not thrive, and the greatest care has to be taken to make them grow at all. Then, again, the climate of Queensland changes. If you live away in the far North—at Cairns, Cooktown, or Thursday Island—you find that the weather is very hot almost all the year round; so it is on the coasts of the Gulf of Carpentaria, which you see on your map. But up in the country above the Main Range it is very cold in winter, even at Herberton in the North. So you see that all over Queensland the farmers have to remember the climate they live in, and so arrange the time for ploughing and sowing. On the Darling Downs they begin sowing the wheat in April—that is, in autumn. Then the wheat, which loves the cool weather, comes up, and if it gets sufficient rain at the proper time the farmer will expect a good crop, unless something happens which you will hear about in a future lesson.

The maize crop, on the contrary, loves the hot weather, so the farmers plough their corn land in July and August—that is, in the winter—and, as soon as there is no more fear of frost, they sow the maize, and soon the fields are covered with the beautiful dark-green maize plants, which produce their golden cobs in the height of summer.

Now, here is an easy lesson for you to learn. Remember that all the common vegetables—such as cabbages, cauliflowers, carrots, turnips, and many European vegetables—are best grown during the cold winter weather; and that sugar-cane, rice, yams, maize, melons, pumpkins, and other, what are called tropical, plants must be grown during the hot months of summer.

I told you that the farmer is not always busy ploughing the land. When his crops are sown, he has to keep the weeds down for the reasons I gave you in your first lesson. So he stops ploughing and cultivates the soil among his grow-

ing crops in order to supply them with plenty of plant food.

Then by and by his time is occupied with gathering in the harvest. In November he is busy harvesting his wheat and barley crops. In December and right up to April and May he pulls his corn. Then he has to dig his potatoes twice in a year, besides gathering vegetables. And again he has fields of lucerne to cut and turn into hay. And so, all the year round, each season brings its round of duties, and the farmer who does not watch the seasons, and who does not plough, sow, and plant at the proper time, will lose a great deal of time and money.

Now, having explained to you the necessity for watching the seasons, you can easily understand how a farmer may lose a great deal by ploughing and sowing too late. If he puts in a crop in June which should have been sown in April, he is a bad farmer, and almost deserves to lose his time and reap a bad crop. And if he is too great a hurry and hopes to get his crop out before his neighbour, and so plants in April instead of in August, he is just as bad a farmer, and can blame nobody but himself for his want of success.

Before we finish this lesson, I must tell you that all soils, although close to each other, are not alike. I may have a farm of which the soil is rich, and deep, and warm, and sheltered from cold and violent winds. My neighbour's farm has a stiff, cold soil exposed to the strong winds. If my neighbour and I were to cultivate our farms in exactly the same way, one of us would be doing wrong, and would suffer for our want of knowledge. If his farm is wet and cold, he must do something to the soil to get rid of the wet, and to warm it. If mine is too dry and too light, I must do something to retain the moisture and to make the land less loose and porous. So you see that every farmer has to learn what to do to his land so that it may yield him good crops.

Here are eleven more questions, the answers to which you can supply from what I have just told you.

Questions on Lesson 2.

- 1.—Why does the farmer not spend all his time in ploughing the land?
- 2.—Name the seasons.
- 3.—What is meant by seasonable work?
- 4.—Name any plants which thrive best in hot weather?
- 5.—Name some that grow best in winter?
- 6.—Name the warm and cool portions of the colony?
- 7.—In what months does the farmer plant sugar-cane, sow rice, maize, wheat, barley, and kitchen vegetables?
- 8.—When does he begin to harvest maize and wheat?
- 9.—Why should the farmer watch the seasons?
- 10.—Is the soil on all farms of the same quality?
- 11.—Describe two different kinds of soil?

(To be continued.)

COLOMBO, AUGUST 1ST, 1901.

No. 2.]

BASIC SUPERPHOSPHATE: ITS PREPARATION AND USE AS A MANURE.

BY JOHN HUGHES, F.L.C.,

Reprinted from the Journal of the Society of Chemical Industry, 30 April, 1901. No. 1. Vol. XX.

THE manufacture of superphosphate in this country may be considered to have commenced in 1842, when the late Sir John Bennett Lawes, F.R.S., obtained a patent for treating ground mineral phosphates with sulphuric acid.

The chemical theory then enunciated may be briefly expressed, namely, that the agricultural value of phosphate manures depended upon the extent to which the phosphoric acid they contained was rendered soluble in water through the aid of sulphuric acid.

It was contended that this solubility in water insured the most complete diffusion through the soil that could possibly be obtained, and this theory in itself is still regarded as correct.

At first the treatment of ground coprolites with commercial sulphuric acid was carried on in a cautious manner; only a portion of the phosphates, amounting perhaps to 20 per cent., was converted into what was known as soluble phosphates; and frequently as much as 8 to 10 per cent. was still left as undissolved phosphates.

The manure so produced was in an excellent dry condition. Indeed in those days complaints respecting damp condition were of rare occurrence.

When acid, however, became cheaper, as the result of improved manufacture, and as competition increased, the utmost amount of soluble phosphate was got out of the manure, so that only 2 or 3 per cent. of phosphate was left in a condition not soluble in water.

Superphosphates then became damper and more acid, so that complaints respecting the condition were of frequent occurrence, because the farmer could not obtain uniform distribution from the manure clogging in the drill.

Superphosphate when first introduced was chiefly applied as a manure for root crops, such as turnips and swedes, which were usually raised on good arable land containing a fair quantity of lime.

Indeed as early as 1863 the late Dr. Augustus Voelcker, writing in the journal of the Royal Agricultural Society upon "Phosphatic Manures for Root Crops," writes:—

"Superphosphates of lime applied to root crops has a different practical effect on different soils.

"The more rapidly and completely the soluble phosphate in commercial superphosphate and turnip manures is precipitated and rendered insoluble in the soil, the more energetic will be its effect upon the turnip crop.

"Purely mineral superphosphates fail to produce good turnip crops on light sandy soils.

"Bone dust partially dissolved by acid is a better manure on light soil than a purely mineral, superphosphate.

"It has indeed been observed that the exclusive use of superphosphate, however beneficial it may be in the majority of instances, has in some soils led to complete or partial failure or the presence of disease in the turnip crop.

"The reconversion of soluble into insoluble phosphate perhaps may appear undesirable, but in reality it is not only beneficial, but absolutely necessary to healthy and luxuriant development both of turnips and of all other crops to which superphosphate is applied.

"No acid combination as such can enter into plants without doing them serious damage; even free vegetable acids, such as humic and ulmic acids,

are injurious to all crops cultivated for food for the use of man or beast; and unless these acids, which are always present in what practical men call sour humus, are neutralised by lime, or marl, or earth, none but the roughest and most innutritious herbage can be grown.

"Free mineral acids are, I believe, still more injurious to all farm crops, and perhaps to all plants, than the free organic acids that are found in humus.

"A very dilute solution of sulphuric acid—say 1 part in 1,000 of water—may be used with advantage for killing grass in gravel walks made with flint or quartz sand; after one or two applications the weeds will be destroyed and will not reappear for a long time.

"But if the walks are made with limestone gravel, the application of a much stronger acid has little or no effect on the grass or weeds; after some time the latter indeed seem to grow all the better for having had a taste of dilute sulphuric acid.

"In reality, however, no acid enters these plants, but on coming into contact with the limestone gravel unites with the lime to form that useful fertilizer sulphate of lime or gypsum."

The above paragraphs express the opinion of one who was rightly regarded as an authority upon the properties and application of artificial manures.

In 1875 the Aberdeenshire experiments, conducted by Professor Jamieson, were instituted, and continued for some years.

The published results excited much interest, for they demonstrated by actual field experiments that insoluble, or more properly termed undissolved, phosphates, if applied in a finely ground state and in sufficient quantity, were of very considerable value as a manure, whereas according to the previously held theory they were supposed to possess no practical value at all.

Further, these experiments proved that on certain soils ordinary soluble phosphate, that is to say, phosphate of lime rendered soluble by acid, was not superior in its action to undissolved phosphate to anything like the extent that had hitherto been generally supposed.

Not unnaturally, these results, being opposed to the theory hitherto held, excited a considerable amount of hostile criticism, which, however, time and more extended enquiry has proved to have been unreasonable.

The experiments were carried out at five stations situated in different parts of the country, and the soils are described as being black mould resting upon a granite subsoil, and the analyses show that in every case they were specially deficient in lime.

The figures for lime at these five stations being respectively 0.08, 0.17, 0.21, 0.33, and 0.38 per 100 parts of the dry soil.

Such soils were, in fact, exactly those upon which soluble phosphate, as supplied by superphosphate, would not be likely to exert its full benefit, while the vegetable acids present in the black mould would be certain to dissolve the finely-ground mineral phosphate to a very considerable extent.

In short, the conditions were most favourable to the action of dissolved phosphates.

About the year 1883 the now well-known Thomas phosphate powder, prepared from basic slag, was introduced to the agricultural world as an entirely new manure.

At first, agricultural chemists of high repute were disinclined to place any agricultural value upon this material, which was really only the refuse in the manufacture of iron from ores which, by reason of containing much phosphorous and silica, required additional lime to be specially added to remove the same.

Little by little, however, farmers were induced to take small quantities for trial, chiefly on their old grass lands, and the practical results were so good on certain soils, rich in vegetable remains but

poor in lime, that scientific authorities were soon compelled to recognise the value of this manure when applied to suitable soils.

In this country the importance of fine grinding has been fully recognised as a test of the probable manurial value; but in Germany Prof. Paul Wagner of the agricultural station of Darmstadt has insisted upon the solubility in citric acid as a further test of probable manurial value, and it is to be hoped that the attention recently directed to this test by Mr. F. J. Lloyd will accentuate the importance of adopting some such additional test, rather than to confine the examination to a statement of the total phosphate of lime and the fineness of the grinding.

The author, however, had already adopted this citric acid method of testing the probable manurial value; but instead of employing the 2 per cent. cold solution of citric acid used by Wagner, or the 1 per cent. cold solution recommended by Dr. Bernard Dyer in his paper "On the Determination of probably available Mineral Plant Food in Soils" (Journal of the Chemical Society, 1894), he prefers to use a solution very much weaker, and in his opinion more nearly resembling the acidity of soil water.

The solution employed is 1 in 1,000, namely 1 gm. of citric acid to 1 litre of cold distilled water, taking 1 gm. of the slag or ground phosphate, and allowing the same to be exhausted with occasional stirring for 24 hours.

On referring to Table I. the relative solubility of five different kinds of ground phosphate is compared with that of basic slag.

The Peace River, with a fineness of 93.61, shows the highest figures for phosphoric acid dissolved out, namely 9.90 as against 8.70 in the basic slag; but as regards lime the latter shows 22.17 as against 15.23 in the former.

The French phosphate, specially rich in carbonate of lime, upon which the citric acid first acts, shows 15.34 of lime and only 2.85 phosphoric acid.

TABLE I.

Solubility in a Weak Solution of Citric Acid

1 gm. phosphate powder
1 gm. citric acid
1,000 c.c. cold distilled water.

Allowed to stand 24 hours, with occasional stirring; then filtered, the insoluble portion weighed, and the solution analysed.

	1 French	2 Algerian	3 Florida	4 Tennessee	5 Peace River	6 Basic Slag
Containing phosphate of lime per cent.	50.36	55.99	78.26	79.57	61.23	28.97
Fine powder passed through 100-hole sieve.	76.21	67.69	72.37	91.63	93.61	83.8
Portion soluble in citric acid solution	30.00	30.00	22.60	22.80	31.40	38.80
* Containing—						
Lime.....	15.34	13.66	11.87	11.64	15.23	22.17
Phosphoric acid.	2.85	6.35	8.25	8.40	9.90	8.70
Equal to phosphate of lime.	6.22	13.86	18.01	18.34	21.61	18.99

These results certainly go to prove that much of the good effects of basic slag must be ascribed to the ready supply of lime rather than to the supply of phosphoric acid. Further, that the solubility in citric acid solution depends upon the character of the phosphate, the fineness of the grinding, the strength and quantity of the solvent, and the time allowed for the treatment.

It has been stated that ordinary basic slag contains as much as 20 per cent. of free caustic lime, but this is not the case, and obviously so, because any such excess of lime would indicate a wasteful method

of manufacture, for lime is only added in sufficient quantity to remove the phosphorus and silica existing in the original iron ore,

Probably 2 or 3 per cent. of caustic lime is the utmost present, for most of the lime not combined with phosphoric acid exists as silicate of lime in a form readily soluble in weak solutions of vegetable acids, but not soluble in ordinary water, as may be easily demonstrated by actual trial.

The Preparation of Basic Superphosphate.—Bearing all the before-mentioned points in mind it occurred to the author that a manure, superior to ordinary basic slag in regard to its solubility, and at the same time combining its alkaline character, could be prepared by the addition of lime, preferably slaked lime, to ordinary superphosphate in sufficient quantity to convert such acid superphosphate into alkaline or basic superphosphate.

Experiments were accordingly made, and, it being found that the addition of lime in proper proportions did not render the soluble phosphates insoluble in very weak cold solutions of citric acid (1 in 1,000), such as might be expected to exist in certain soils, a provisional specification was at once filed and eventually a patent as granted.

The preparation in theory is very simple, but in practice there are certain mechanical difficulties to be overcome in order to effect a uniform and complete admixture of the acid superphosphate with the caustic lime.

The quantity of slaked lime required to be added depends upon its quality and the care with which it has been burned in the kiln. No particular degree of purity is necessary, but by preference the best commercially available is to be employed.

The original specimen of basic super was prepared from a super having the following composition:—

	Per Cent.
Soluble phosphate	27.72
Insoluble phosphate	4.82

This would be regarded as a somewhat wastefully made quality, having nearly 5 per cent. of undissolved phosphate; but it was found that a considerable portion of such phosphate, though insoluble in ordinary water, was readily soluble in weak solution of citric acid (1 in 1,000).

About 35 parts of the super were thoroughly mixed with 15 parts of good slaked lime and allowed to remain in a heap for fully 24 hours. Next day 1 gm. of the maure, with 1 litre of standard solution containing 1 gm. of citric acid, was placed in a large beaker, and, with occasional stirring, was allowed to stand for 24 hours, no artificial heat whatever being applied. On the following day the solution was filtered, the portion left insoluble was burned and weighed, and the filtrate carefully analysed for lime and phosphoric acid, with the following results:—

* Portion soluble in citric acid solution	94.70
† Portion insoluble (after burning) in citric solution	5.30
* Containing—	
do soluble lime	34.66
do phosphoric acid	12.00
Equal to phosphate of lime	26.19
† Containing—	
do insoluble lime	2.40
do phosphoric acid	0.65
Equal to phosphate of lime	1.41

According to calculation the sample so prepared should have contained—

Ordinary soluble phosphate	23.56
Ordinary insoluble phosphate	4.09

But the actual results obtained by treatment with the standard citric acid solution were—

Soluble phosphate	26.19
Insoluble phosphate	1.41

Consequently 2.68 per cent. of the phosphate originally insoluble in warm water was found to be readily soluble in the cold weak citric acid solution employed.

TABLE II.

Works Samples of Basic Superphosphate as actually prepared in England, Ireland, and Scotland.

	1	2	3	4
* Portion soluble in weak citric acid solution.	94.60	94.20	93.00	92.60
Portion insoluble in same (after burning).	5.40	5.80	7.00	7.40
* Containing—				
Soluble lime.....	33.92	36.73	32.53	29.56
Soluble phosphoric acid.....	13.60	13.35	12.00	12.45
Equal to phosphate of lime.....	29.68	29.14	26.19	27.18

Manufacturers hitherto have never been paid anything on account of the so-called insoluble phosphate in superphosphate.

When made from materials like Tennessee rock phosphate, containing 4 to 4½ per cent. of oxide of iron and alumina, there must always be a considerable proportion of phosphoric acid retained in a form insoluble in water, but readily soluble in weak vegetable acids, and therefore probably available as plant food.

It is intended that the quality sent out shall average 25 to 27 per cent. of such so-called soluble phosphate, and that the manure shall always have a distinctly alkaline reaction.

Basic super is much more soluble in ordinary water than basic slag, as may be easily ascertained by treating 1 gm. of each with a litre of cold distilled water, allowing the same to remain in contact for 48 hours, with occasional stirring, and subsequently filtering off the insoluble portions and analysing the filtrate as follows:—

TABLE III.

Relative Solubility in Cold Water after 48 hours,

	Basic Super	Basic Slag
* Portion soluble.....	66.80	6.60
Portion insoluble (after burning)	33.20	93.40
* Containing—		
Soluble lime.....	22.28	4.70

No phosphate soluble in water.

These results demonstrate the superior solubility of basic super and also may explain why basic slag fails on soils which do not contain an excessive proportion of accumulated vegetable matter.

It is not ordinary water, but water largely impregnated with vegetable acids, that is capable of dissolving a hard fused mass like slag. Ordinary water has but a slight action on slag, however finely ground it may be.

In this case the slag was very well ground, having a fineness of 83.88 and containing 38.97 per cent. of phosphate of lime.

TABLE IV.

Comparative Solubility in Ammoniacal Citrate of Ammonia

Taking 1 gm. of phosphate, 2½ grms. citrate of ammonia, and 100 c.c. water, gradually raised to boiling point and filtered, and the insoluble portion burned and weighed.

	Basic Super	Basic Slag
* Portion soluble.....	86.70	28.90
Portion insoluble (after burning)	13.30	71.10
* Containing—		
Soluble lime.....	32.03	14.72
Soluble phosphoric acid...	10.20	3.35
Equal to phosphate of lime	22.27	7.31

The above results show that basic super is very readily dissolved by citrate of ammonia solution (slightly ammoniacal), while basic slag is only very slightly dissolved, though containing originally a higher percentage of phosphate of lime.

Mechanical Condition.—As may be expected, the condition of basic super is excellent, being a dry powder easily distributed either by hand or machine; and the farmer need not fear that clogging in the drill, resulting from damp condition, which is such a difficult matter to overcome.

The light bulky character of the material as compared with the heavy nature of slag may be con-

veniently illustrated by placing the same weight in two $\frac{5}{8}$ inch diameter glass tubes, about 1 foot long, when it will be seen that the basic super occupies a space of 11 inches, as compared with only 4½ inches occupied by the basic slag the relation being as 100 to 40

This greater bulk in itself ensures a more perfect distribution, and will be appreciated by farmers who have already recognised the difficulty of obtaining a uniform delivery of slag, especially when applied by hand, for the heavy gritty powder falls between the fingers before complete delivery can be effected.

Its use as a Manure.—Basic super is not intended to supersede ordinary superphosphate on good arable land containing plenty of lime, but is intended to be applied on soils that are either deficient in lime or contain an excessive quantity of vegetable acids, such as sour pastures do.

It is also recommended as specially suitable as a fertiliser for turnips grown on land subject to the disease known as "finger and toe."

Manure manufacturers have suffered seriously from competition with basic slag, because on sour grass land acid manures were unsuccessful, but now, by the simple addition of slaked lime, ordinary superphosphate can be converted into a manure particularly adapted to all sour soils.

Field Experiments.—Of course, as the provisional specification was only filed on the 1st November last, no field experiments have yet been made, but during the coming season a fair trial will be made upon a great variety of soils throughout the United Kingdom, and upon the results so obtained the future success of manures will depend.

It may, however, be interesting, and tend to engender confidence in the new manure, if attention is directed to the reports of certain field experiments in which superphosphate and lime were applied separately with most satisfactory results.

In the joint report of Prof. Carruthers and Dr. John Voelcker on the improvement of grass land, published in the Journal of the Royal Agricultural Society for March 1898, the following statement occurs in reference to an experiment in Lincolnshire upon a soil containing only 0.17 per cent. of lime.

The soil is of a very light character, with a subsoil of clay; it is deficient in vegetable matter, and has not much potash, but is fairly supplied with phosphoric acid; and, from the analysis, lime would appear to be the great requisite.

Half the experimental plot was limed in January 1895 at the rate of four tons of lime per acre, and the other half received no lime.

On the limed portion mineral superphosphate was applied in February at the rate of 4 cwt. per acre; and on the unlimed portion, basic slag, at the rate of 8 cwt. per acre, was applied also in February.

The report states that "the entire half that had been limed has shown marked improvement."

"Basic slag used alone has produced more clover, but is hardly as good as mineral superphosphate with lime."

In the Journal of the Board of Agriculture, December 1900, Dr. Somerville, in a paper "On the Influence of Manures on the Production of Mutton," resulting from experiments carried out on Cockle Park Farm, in Northumberland, writes, respecting the grass plot that had received a dressing of 7 cwt. superphosphate in 1897 and 1900, and 10 cwt. of ground lime for 1897 and again for 1899:—

"This is a plot in which the interest increases each season, and this year it merits special notice, as it has produced the greatest aggregate increase of all.

The results are further favourably contrasted with those obtained from two other plots, one of which had received a dressing of 7 cwt. superphosphate, but no lime; and the other had received as much as 4 tons per acre of ordinary burned lime, but no superphosphate. He writes:—

"The main reason for this difference in the effect of lime is that where used alone its action is limited by the want of phosphates, in which the soil is very deficient; whereas in the presence of a phosphatic

dressing it is able to exert its full, or nearly its full effect."

"On the other hand, phosphates, used alone, have not been able to exercise the maximum influence because of the want of lime."

The practical results obtained by Dr. Somerville agree so well with the opinions expressed by the late Dr. Augustus Voelcker in 1863 that the author has a reasonable hope that basic superphosphate will prove a useful and economical manure on the particular kinds of soils already mentioned.

Instead of going to the expense of liming a field so thoroughly that every square inch of soil shall contain sufficient lime to neutralise the acid superphosphate that may be afterwards applied, it is proposed to add sufficient lime to the super before application, and thus secure a very important economical saving both of time and money.

If superphosphate can be thus adapted for application to sour soils, a great increase in the demand may in a few years be expected.

Moreover, the superphosphate employed may be made from materials containing more oxide of iron and alumina than usual.

Phosphates which have once been rendered soluble in water by treatment with sulphuric acid are superior, and must always remain superior, in their action to all raw phosphates, which are merely mechanically divided, however finely ground.

Though the total phosphates supplied by basic super may be less in actual amount than that existing in ordinary basic slag, they will be found much more certain and effectual in their results.

Mr. D. Wilson, D. Sc., of Carbeth, Killearn, very truly remarked, in a recent lecture on the manuring of farm crops; "Artificial manures should be so arranged as to yield a profit on the first crop, and should be of a quick-acting class, and limited in quantity to the requirements of the particular crop."

Basic super may be regarded as a quick-acting manure, and may be used with advantage quite late in the season, with a reasonable expectation that under favourable climatic conditions satisfactory and economical results may be obtained.

(To be concluded.)

THE COCO-NUT—INSECT ATTACKS AND THE VITALITY OF PLANTS &c.,

Coconuts are largely grown in Trinidad, but little attention, generally speaking, is paid to their requirements in the way of manure. At times they are stricken with disease, when the soil, the climate, an insect, or a fungus is sure to be blamed for the trouble; and in most cases special "remedies" are applied, which are expected to act "like a charm" in the removal of the mischief. Many instances could be cited where this has occurred, but it would be invidious to particularise. The scale insect is one which has generally been combated with potions, poisons, or "remedies," and yet it still exists and is said to kill out the trees. Now there can be little doubt that ill health is one of the primary causes which lead to insect attack in the vegetable world; and, therefore, a due examination should be made of the soil and climate of the district in which the plants are growing for the purpose of ascertaining whether they are in reality getting all they require in the form of nutriment for the maintenance of healthy growth. From our personal observation it would appear that, if a soil is deficient in certain constituents, there is always a want of vigour in the plant cultivated and, in most cases, insect attack follows—and also follows where there is want of moisture, or too much of it, viz., drought and bad drainage. Instances have been seen where Coco-nut trees and other plants attacked by scale insects have completely recovered by being heavily manured, (i.e.,) supplied with those ingredients necessary for the plant to maintain itself in a healthy state. Although it may be quite clear that insect attack always follows bad health, it would be too

much to argue that plants are never otherwise attacked; for it may be freely admitted that there are insects of a predatory or predatory character, which destroy plants in good health, without affecting the point, which is, that attacks are invited by a condition of bad health, arising through weakness of constitution, induced by unsuitable conditions of climate or season and frequently by starvation. In many plants constitutional weakness can be shown to exist, which is adequately proved by their passing out of existence in the struggle for life, and no amount of skill in cultivation or manuring could possibly give them the vigour or vitality of their surviving brethren. Such plants may at times have qualities which make them of value to the cultivator, and if they are grown for economic purposes, cultivation becomes one interminable fight against such weaknesses. Where special products are desired, it is always better to raise and select seedlings possessed of such vitality or vigour of constitution as will suit the climate or soil in which they are grown, and this may be generally effected by the common processes of artificial selection. In this way we find that in the United States and other places plants are being raised, the progenitors of which could not stand certain climates. The publication of the proceedings of the Hybrid Conference recently held by the Royal Horticultural Society in London makes it clear there is every reason to hope that strains or varieties of plants may be raised by taking certain precautions, which possess a vigour or suitability of constitution enabling them to stand the extremes of either hot or cold climates. Now, while we may not expect any immediate or present advantage to the Coco-nut from these methods, yet it is to be clearly pointed out that a method of selection may be followed, even with this plant, by taking seed nuts only from those trees which show they possess a vigorous constitution and mature nuts of saleable size in paying quantity. It is not to be expected, however, that individuals will do much with a plant which would take so long a time before results could be observed, and therefore in this, as in many other cases, the work is best performed by Experiment Stations that the objects in view may be carried on through a series of years. Many years ago I recommended the practice of selection for the Coco-nut but was met by the argument from a Trinidad grower that "the smaller nut had most meat" or as much "meat" as the larger one. Even if this is granted it is an indisputable fact that the larger nut sells better than the smaller one, always has done, and probably always will do. A Coco-nut tree planted in an unsuitable position will soon show signs that it is not getting all it requires and much may be done by the cultivator to ascertain and supply what is actually needed. In the Queensland Agricultural Journal for April, 1900, there is published a complete analysis by Dr. F. Bachofen of Mr. A. Bain's chemical Laboratory at the Ceylon Manure Works. Mr. Bain* writes:—

"Though there exist several analyses of parts of the Coco-nut, no one seems to have undertaken the task of getting a complete analysis made with the view of ascertaining the actual demand made by the Coco-nut upon the mineral constituents of the soil. Yet this knowledge is of paramount importance to those going in for manuring."

Dr. Bachofen's tables and analysis of quantities taken out of the ground by 1,000 nuts are here given as valuable addition to our knowledge.—*Trinidad Bulletin*.

COCOA IN TRINIDAD.

From now on we pass to the newer industry of cocoa, although, so far as Trinidad is concerned, this is by no means a new industry. There are plantations in

existence, the starting of which can be traced to over a hundred years ago. The development of this industry has certainly been remarkable. Forty years ago there were only some 7,000 acres of cocoa in cultivation. The total exports for the year 1899 amounted to the very large figure of 29,225,504 pounds—an increase in ten years of over fourteen million pounds. The cultivation is still being extended. The system of cultivation in Trinidad is a very interesting one. The present large estates have been made by the gathering together of the smaller areas under cultivation. These small areas have been started under what is known as the contract system. The contractors have generally been the descendants of the Spaniards and the French, and now to this class has got to added the coolie. The proprietor pays the cost of cutting down the forest, and when so cleaned the land is turned over to the contractor, who cultivates upon it plantains, tannias, (our cocones, bananas and pigeon-peas, for a period of five or six or ten years, in return for this he undertakes to plant land with cocoa and shade trees, and when he gives the land up, the proprietor gives him a shilling for every tree planted. The laws in protection both of the contractor, and of the proprietor who gives the contract are well drawn, enabling the contractor to get justice and at the same time safeguarding the rights of the proprietor under the contract. There is not much to be seen of cocoa cultivation from the roadside, but undoubtedly it is an ideal cultivation for a European in the tropics. In Trinidad the soil is of such a nature that it easily cakes and dries under the sun; and consequently it is necessary—in Jamaica, I understand, it is not so necessary—to plant permanent shade trees. In starting the plantation, after the trees have been raised in the nursery they are planted out, each tree being surrounded by four banana suckers. The banana which is principally used for this purpose in Trinidad is the so-called fig-banana plant producing a much smaller variety of fruit than ours. These young bananas form the shade for the young cocoa, but at the same time there has to be planted the permanent shade tree, and by the consensus of all opinion the tree that is best adapted for this purpose of permanent shade is the Immortelle, known by the Spaniards as the *Madre de Cocoa*, or the "Mother of Cocoa." This tree grows very rapidly, much more rapidly than the cocoa itself, and grows to a great height. By the time it is necessary for the cocoa to have shade the Immortelle is there. The protecting influence of this shade has given it the name it so well deserves of the "Mother of Cocoa." The Immortelle is a tree that does not throw deep roots into the ground, and apparently takes nothing from the soil which the cocoa needs. The falling of its flowers and leaves seems to supply a valuable manure to the soil. It is almost impossible to conceive a more beautiful sight than the hillside one mass of beautiful red when the Immortelle is in bloom for it bears a red flower. Walking through the cocoa plantations when the blossoms are falling, one treads on a carpet of fallen blooms. There are other shade trees that are spoken of, notably the hog-plum, the sand-box, and that variety of the rubber plant known as the *Castilloa*. The Immortelle, unfortunately, is easily blown down, and with the immense length does considerable damage to the cocoa trees when falling. As a rule, however, when it falls it is very largely rotten, and the decayed vegetable matter forms an important manure. The best authorities agree that the cocoa fields should be kept as free as possible from all grass, although of course, as in everything else, there are people who dispute this. The trees have to be pruned regularly and carefully, and it is interesting to state here that a very large percentage of the cocoa planters firmly believe that only at certain phases of the moon should this be done, the running of the sap in the trees being affected by the action

* Sic. Mr. A. Baur, of course.—Ed. T.A.

of the moon. This has been disputed by scientific authorities, such as Mr. Hart, of the Botanic Gardens; but still the belief exists among the planters who personally told me that, though they can find no scientific reason for it, nevertheless they are right. It is necessary on cocoa estates to have good drainage, and the drains must be kept clear so that the land shall not get soured by the accumulation of water. A large quantity of moss is all the time gathering on the trees, and this moss has to be taken off by the process known as "brushing," brushes made of stiff fibre being used for the purpose. The moss, of course, accumulates on the trees with varying rapidity, according to the moisture of the climate, but it is generally conceded that in most districts the trees require brushing once in three years.

HOW PREPARED FOR MARKET.—It may, no doubt, be of interest to some of my readers to know just how the cocoa is picked and prepared for market in Trinidad, and the following account, I think, about covers it. Picking is started, say, on Monday, and the pods when picked are gathered in piles which are left there until Friday morning or afternoon, according to the quantity picked. The breaking or opening of the pods commences either on Friday or Saturday morning. The pods are opened at the pile and the beans taken out and "crooked" to the sweat-box that is to say carried in baskets on mule-back to the sweat-box. The reasons for not breaking and taking the beans in every night are many:—(1) Because it would be expensive. (2) Because the fruit is too fresh from the tree. (3) Because the sweating would not be regular and it would not be possible to get a regular kind of cocoa both as to size and colour. (4) Because too many sweat-boxes would be required.

By allowing cocoa to remain in the pod for four or five days in the field before breaking, it is found that fermentation gradually begins, and the fruit benefits from all the aroma there may be in the pod. Once in the sweat-box, the beans are covered with plantain leaves, and in a couple of days fermentation is very strong. The sweat-boxes, on properly arranged estates, are fixed in a series so that, when fermentation commences, the beans are changed from one box to another, and this process is allowed to go on for four, five, or six days, according to the quantity of the cocoa it is desired to produce. Highly fermented cocoa formerly fetched very high prices, but to-day the difference in price is so little that the planters are seriously considering the question as to whether it is wise to waste the time and extra loss of weight that is required for extreme fermentation—though it is only right for me to state here that there is a great divergence of opinion as to whether after a certain period there is any extra loss of weight by fermentation. From the sweat-box the cocoa is put in the sun and spread out very thin, and while it is in that state, labourers, principally coolies, are employed to walk on the cocoa, or, as it is called, to "mash" it. Whilst the labourers are walking over the beans they are also busy picking off any pieces of fibre which may adhere to them from the pods. During the first day the beans are carefully watched and turned about so as to let the sun get at all of them. If the sun is too hot, the cocoa-house is closed and the cocoa heaped up. In the afternoon, it is opened out until sunset. After this process is over, the cocoa is "danced" for two or three days. That is to say, coolies are employed to perform a dance on top of the cocoa. This must be done when the beans are still soft, as when half-dry it is too late and the cocoa is apt to get spoiled. The cocoa is cured in eight days, provided there is sufficient sun. The cocoa drying-house is an interesting building and requires some explanation to the uninitiated. Posts are firmly driven into the ground at distances, say, of about four or six feet apart. On these are laid beams, and on the beams is put an iron rail.

The roof is a pitched roof covered with corrugated iron, and is made in two sections, the sheets of one slightly overlapping the sheets of the other. Underneath the beams, forming the sides of the roof, are wheels, which run on to rails. If the cocoa house is 60 feet long, then 15 feet on either side are left unfloored, whilst 30 feet in the middle are floored. The roof covers this centre part, but when the cocoa is to be exposed to the sun the two parts of the roof are pushed apart, leaving the boards bare to the sun. A couple of men can open or close the house, and they watch for every sign of rain in order to do this. On many well-regulated estates, underneath the cocoa house are situated all the rooms necessary for the cocoa—the sweat-boxes, the packing-room, etc. A good many of the estates, especially those in districts where there is a good deal of rain, are adopting artificial curing by means of hot air, but practically all are agreed that there is nothing like Nature for doing the work thoroughly and properly. In case of some of the finer grades of cocoa, during the dancing process a particular kind of red clay is sprinkled on the beans, which gives them a bright, shining, brown appearance. No cocoa is prepared by our method of washing, although this is sometimes done when the beans happen to get "weathered." A good many of the estates are situated in the highlands, and at present there are very few good roads, so that all the cocoa has to come down on mule-back either to the railway station or to the commencement of the cart road.

As regards the future of cocoa in the markets of the world, it is difficult to say. For many years the consumption of cocoa was comparatively a small one, and the article fetched a very high price. The fall which took place fifteen years ago called the attention of many people to the enormous profits being made by cocoa manufacturers. There was a sudden development of the industry and the consumption has been greatly increased. Unlike coffee and tea, cocoa has still large areas of cultivation to conquer, and, uniting in itself, as it does, the properties of a valuable beverage and a wonderfully sustaining food, it does look as though the future of cocoa is a good one. It must not be forgotten that large areas have been placed under cultivation recently, and enormous quantities are being grown in many parts of the world. The island of San Thome, off the African coast, which was practically unknown a few years ago, is now supplying vast quantities of cocoa. The only thing that can be said is that, at the present price, cocoa is an enormously remunerative industry, and that it can bear a considerable fall in price without its arriving at a point where it could not be cultivated. In Trinidad it is estimated that the cost of production of a fair bag of cocoa is \$8, the bag weighing 168 lb. The value of that bag of cocoa to-day is about \$21.

Nearly every day one is hearing of some new use to which cocoa is being put. This is largely owing to the advertising genius of the manufacturers. One can hardly open any magazine or newspaper without coming across some advertisement of cocoa or chocolate. It has been discovered that the article is of great nutritive value, and therefore it is constantly being put to some new use. It has been largely used by the British troops in South Africa, and has been found wonderfully sustaining under hard conditions of campaigning, with the additional advantage that a large quantity of nutriment can be compressed into a very small space. But of course I would say to Trinidad what I would say to Jamaica—that it is a bad thing to rely upon one article of export.

The life of a cocoa planter in Trinidad is certainly most pleasant, and work among the beautiful shaded cocoa trees is possible to a European without unduly suffering from the rays of the tropical sun. A walk through the cocoa plantations when the trees are bearing is a most beautiful sight. The same tree has on it flowers, buds, and pods, in every stage of

development, and one can practically from day to day watch the maturing of the crop.—*The Journal of the Jamaica Agricultural Society.*

SIMPLE METHOD OF STRIKING CUTTINGS.

The accompanying illustration of a simple method of striking cuttings, which we take from *Farm and Home*, will commend itself to all horticulturists. We have tried a plan somewhat similar and find it of great advantage. The *Journal* in question, replying to a correspondent, says of the method:—It has been recommended to us by an experienced gardener. It is made and used thus: Take two flower pots, one large and one a few sizes smaller. Place in the larger one a layer of pebbles, broken bricks, &c., a few inches of black earth. With a good cork plug the drain hole of the smaller pot and put it inside the larger one, centring it upon the layer of mould. Fill it with water, and fill the circular space between the pots with more mould. Insert the cuttings all round, and without further attention they will strike roots and thrive in a way calculated to make the floriculturist's heart glad within him. The roots and fibres make straight for the sides of the water reservoir, through which all the moisture they require is absorbed. If the packing of the earth in the larger pot has been properly done, the smaller pot can be lifted out now and then, and the process of root formation readily observed. Seeds can also be germinated readily in a simple contrivance of this kind. Choose fine sandy loam for striking the cuttings. If the weather outdoors is very cold, stand the pot in the kitchen, particularly at nights.—*Queensland Agricultural Journal.*

THE PINEAPPLE INDUSTRY.

Pineapples attain to greatest size in the West Indies, some weighing 12 to 13 pounds. Great care is taken in packing them to secure their arriving in England in sound condition. The stalk is cut several inches below the fruit; an ordinary large-sized flower pot is then filled with mould, into which the stalk is inserted in such a manner that a casual observer would almost take it to be the way it was grown. Each pine is then put into a skeleton wooden case made just enough to hold it, so that it can be safely handled without the risk of being bruised or injured.

Pineapple culture is yet in its infancy in Florida, but the success that it has already met with in some parts of the State promises to establish it as one of its most profitable industries. The following varieties have given the best satisfaction: Spanish, Sugar Loaf, Cayenne noted for its large fruit and the absence of stickers on its leaves, and the Egyptian Queen or Trinidad. This latter is probably the first variety grown in Florida: the fruit is of large size, superior quality, and with an almost entire absence of the toughness noticeable in some varieties. Cotton seed meal is found to be the best fertiliser, and generally fifteen thousand plants are put to the acre, yielding an average of ten thousand fruits. Three or four annual crops are produced without replanting. Last year a crop of Egyptian Queen yielded to the planter a net income of seven hundred dollars per acre. The lowest returns the same individual ever received were three hundred dollars. The net price received is from three cents to twelve cents each, depending upon size, quality, season, and condition of the market. But the pineapple area is limited. The bulletin of

the agricultural division of the Census Bureau states that there are now 23,496,000 bearing plants in Florida, which is the only State in the Union where it is cultivated.

MEXICO.—In the tropical districts of this country the culture of the pineapple is being rapidly promoted owing to the increased demand from the United States. Experiments made last year demonstrated that it was better to have the plants wider apart (say 8,000 to 10,000 per acre) as they then produced larger pines. The close planting hitherto practised is the cause of the larger quantity of small fruit that floods the markets. Between the rows of pines they planted corn, the product of which more than compensated for the necessary labour in caring for the pines. The pineapple not needing a very rich soil and only moderate food was benefitted rather than retarded by the corn: it was discovered that too much fertilizing actually retarded the growth of the pines, for being allied to air plants a large share of its nutriment is drawn from the air, leaving the roots, but little to do.

OTHER COUNTRIES.—In Ceylon, there are about 9,000 acres covered with pineapples, in Cochin China about 8,000 acres and in India enormous quantities are grown in great ranges in Assam, in Rangoon, in the Tenasserim provinces and at the foot of the Himalayas. But it is mostly consumed locally and does not figure in foreign exports. From Acapulco there are annually shipped to San Francisco about 800,000 pineapples realising about \$6 per 100. Cultivation is increasing, owing to the large demand from the Pacific Coast.

Honduras annually exports to the United States about 150,000 of three kinds—the horse, cherku and sugar-loaf.

Antigua exports to England about 5,000 barrels annually of the black-pine pineapple.

Havana exports principally to the United States the surplus over local consumption, about 60,000 barrels each containing 35 pines of first, 45 of second, or 50 of third cuttings. The average price per barrel ready for shipment is \$6 \$5, and \$4, for each quality respectively, and the freight to New York is 30c. to 50c. per barrel. There is a continued increase of production.

The annual import into the United States from the West Indies is over 5,000,000 pineapples.

PRESERVES.—In Florida an excellent wine and cider are made of the pineapple; and in the Azores wine and alcohol are largely made.

In Nassau the local demand of fruit for tinning equals the amount of fresh fruit exported. The operation of peeling and slicing is performed on tables in the yards near the waterside. The cans are carried to the warehouse on wooden trays (each containing fifteen), to be immersed in syrup. The tops of the cans are soldered on, and they are lowered in an iron framework, 400 and 500 at a time, into the steam boiling vats. After boiling, the cans are perforated at the top to allow the steam to escape. They are then hermetically sealed and spread over the yard to cool. Each can of fruit, before the syrup is added, weighs two pounds.

All the apparatus and the tins used in the canning factories are imported from New York.

Almost every modern cook book furnishes receipts for making jellies, marmalade and preserves from the pineapple. The following, which

has been tested by the writer, is a receipt largely used in Florida for making pineapple marmalade for family use or in large quantities for trade. "Select large sugar-loaf pineapples, peel them, take out the eyes, which are not very deep in the sugar-loaf, and grate them on a porcelain grater into an earthen dish. Do not grate the core. Weigh the juice and pulp and measure out to every pound three-quarters of a pound of sugar. Mix the sugar with the pulp and boil it for an hour to an hour and three-quarters, until it is a smooth, clean paste and firm."

Chichi or pineapple wine is a delightful and favourite drink made of the pineapple in Mexico and other tropical countries. A small quantity is made as follows: Over the peelings of two pineapples pour one quart of boiling water: allow it to steep until cold, then sweeten to taste, strain and bottle. Tie down the cork and place the bottle on its side; if placed in a warm place it will be ripe in 24 hours. A small piece of ginger placed in each bottle will improve the flavour. If made in large quantities the whole pineapple chopped should be used.

PINEAPPLE FIBRE.—The plant affords fine fibre of practical utility from the leaves, which are about 3 feet long by $1\frac{1}{2}$ to 2 inches wide, strongly edged with spines except in the one variety known as the smoothleaved Cayenne. Besides the fineness of the fibre for textile fabrics, it is remarkably strong when made into cordage. A government test made in India proved that a rope $3\frac{1}{2}$ inches in circumference would bear a weight of 42 cwt., it actually breaking with 57 cwt. We quote from published reports concerning this fibre. This fibre however is produced chiefly from a species of wild pineapple, though the fibre of the cultivated plant is of excellent utility.

"The pineapple grows in great abundance in the Philippine Islands, but produces only a small dry fruit. We require, however, more precise information to enable us to determine whether this is actually the plant escaped from cultivation. Mr. Penelet, of Pondicherry, considers it a distinct species, and has named it *Bormelia pigra*.

"In preparing the fibre for weaving, the fruit is not allowed to ripen early; its removal causes the leaves to increase considerably both in length and in breadth. A woman places a board on the ground, and upon it a leaf with the hollow side upwards. Sitting at one end of the board, she holds the leaf firmly with her toes, and scrapes its outer surface with a potsherd, not with the sharp fractured edge, but with the blunt side of the rim; and thus the leaf is reduced to rags. In this manner a stratum of coarse longitudinal fibre is disclosed, and the operator, placing her thumbnail beneath it, lifts it up and draws it away in a compact strip, after which she scrapes again until a second fine layer of fibre is laid bare. Then turning the leaf round, she scrapes its back, down to the lacer of fibre, which she seizes with her hand and draws at once, to its full length, away from the back of the leaf. When the fibre has been washed, it is dried in the sun. It is afterward combed with a suitable comb, sorted into four classes, tied together, and treated like the fibre of the lupi. In this crude manner are obtained the threads for the celebrated web "nipis de pina," which is considered by experts the finest in the world.

"In the Philippines, where the fineness of the work is best understood and appreciated, richly

embroidered costumes of this description have fetched about £200 each.

"This fine muslin-like fabric is also embroidered by the nuns of the convents in Manila with great skill and taste.

"The manufacture of the pina fabric is carried on in the metropolitan province of Fondo. From the extraordinary facility with which the pineapple is grown in the vicinity of the equator, it seems almost certain that, by the application of modern skill to the process of separating the fibre from the pulpy matter of the leaf, a valuable raw material composed of it might be obtained for the nations of Europe. The fibre by the hackling process could be rendered fit for the finest fabrics. The leaf consists of two different structures, the upper side being of a soft or pulpy character, easy of removal; and the under side, of a harder or more ligneous nature, and more difficult to separate. These two external bodies hold the fibre between them.

"In the Straits Settlements the Chinese laborers have taken kindly to this new and promising branch of industry. The process they adopt in preparing the fibre appears to be much the same as that pursued in the Philippines. After being scraped with a bamboo plane they are steeped in water and washed and then laid out to bleach on rude frames of split bamboo. The process of steeping, washing, exposing to the sun is repeated for some days, until the fibres are considered properly bleached. Without further preparation they are sent into towu for exportation to China."

Nearly all the islands near Singapore are more or less planted with pineapples, covering an extent of about 2,000 acres. But the manufacture of the fibre or trade in fruit does not amount to much.

"The wild brother of the pineapple has a larger leaf and longer fibre. It is common in the Antilles, growing in the most arid spots. It makes excellent mats, hammocks, and ropes. Almost all the fishing tackle of the American mercantile marine is made of it.

"The leaves are 5 to 8 feet long, and from $1\frac{1}{2}$ to 3 inches wide, thin and lined with a tough fibre. The plant is self propagating, and left to itself in an open field will soon cover the ground. In Central America, but particularly in Nicaragua, it is so abundant in the forests as to be a serious obstruction to man or beast. It is largely cultivated in the districts of Mexico. It is indifferent to soil, climate and season, while the simplicity of its culture, and the facility of extracting and preparing its products render it of universal use. From it is fabricated thread and cordage, mats, bagging, clothing and hammocks."—*Hawaiian Planter's Monthly*.

BANANA MEAL.—We call attention to the letter of Messrs. Haddon & Company, of London, in Correspondence Column, and their offer to take Banana Meal at from 30s. to 35s. per cwt. It will just pay at the price, when the maker is in a good banana district, and yet is far from shipping places, and so can get plenty of bananas at his own door cheap; when also he goes into the business properly with artificial driers and other facilities for saving time and labour. At 30s. the price per lb. runs to about $3\frac{1}{2}$ d., at 35s. the price is $3\frac{1}{2}$ d., and at the latter figure there is a good working margin.—*Journal of the Jamaica Agricultural Society*.

IMPERIAL GARDENS FOR FRUIT-TREE DISSEMINATION THROUGHOUT THE EMPIRE.

By Dr. BONAVIA, F. R. H. S.

[Reprinted from the JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY. Vol. XXV. Part 3.]

It is gratifying to learn that the two noble Bananas of India—or Plantains, as the English there call them—have been at last introduced into the Royal Gardens at Kew.

The *Ram Kela* and the *Champa* Bananas must have been known to the British in India for perhaps a hundred years, and yet nobody, until recently, has ever thought of introducing these fine things either into England or to any of our colonies.

I do not think there are many plants the stools of which—like bulbs—can be taken long distances without any special care. The Banana is such a plant.

The way it is grown in Northern India is this:—

A trench is dug, three feet deep and as many broad. The bottom of the trench is manured, and the bulbous roots, with their sprouts, planted there, four or five feet from each other. Then every year a lot of fresh cow-dung is thrown round the stems, until the trench is filled up in the course of years, when the site is changed and the same process repeated. The Banana requires plenty of water, except in rainy seasons.

In Northern India the choicest varieties cannot be cultivated, as both the hot winds and the cold winter nights are unfavourable to them. Bombay, Madras, and Bengal are the districts that suit them.

The comparatively inferior variety now so largely grown in the West Indies cannot be compared with the choicer ones of India.

It is surprising that wealthy persons in the United Kingdom have never devoted a special glass-house to the cultivation of these indubitably fine varieties of Plantain.

The introduction of these choice Bananas into England is a movement in the right direction. Eventually they can be disseminated throughout the tropical dependencies of Great Britain.

But this is not enough.

There is room for two or three Imperial Gardens, where some of the choicest fruit-trees of the world could be collected, studied, and not only disseminated throughout the Empire, but new ones evolved by seed variation and cross-fertilisation; for it is idle to suppose that all these choice fruits were originally contained in the "Garden of Eden."

Let us take them:—

(a) ONE OR TWO GARDENS FOR THE CITRUS GENUS.

There are so many fine and distinct varieties of this wonderful genus—some of which are very little known out of the localities in which they are grown—that it would be an advantage to the people of the Empire, and also to mankind in general, to have them collected for the study of their botanical and horticultural characteristics and commercial values.

THE PORTUGAL ORANGE GROUP.

The Portugal Orange, of which the British markets are now full, with its variations, the seedless oval Orange of Malta, and the oval Orange of Jaffa, also seedless, and the Blood Orange, &c., are sufficiently well-known to need no description.

I am informed that in Malta there exists a unique Orange of the same group, but which is never sour from beginning to end, but sweet and juicy. It is called there "Loommi-Laenij." I have never met with an Orange of this description in India. It would be worth while getting hold of it for the purpose of multiplying it and bringing it into commerce. Such a unique Orange, I believe, has never appeared in the English market.

In India I met with two varieties of this group; both are fine and worthy of being more generally known. The one is the "Bändir" of Tanjore, a large Orange,

12 in. in girth or so, with a yellowish-orange skin when ripe. The other is the "Mussémbi" of Poona. Its name is evidently a corruption of Mozambique, and it goes to the Bombay market. The exterior is orange-yellow, and is covered with longitudinal furrows from base to tip. Natives say this can be kept on the tree for a whole year without deteriorating.

THE SUNTARA GROUP OF INDIA.

The loose-skinned "Süntärä" Orange of India, as far as I know, has only appeared once in the London shops. There is a considerable trade in this Orange in India itself.

There are two widely spread varieties of it. The one is called "Nagpore" Orange, some of which find their way to Bombay. It is this, I believe, which, on one occasion, was sent to London.

The other is the "Syhet" Orange, which mainly goes to Calcutta, and is grown *solely* from seed.

The fruit of the two differs little, but the tree of the former has a spreading form; while that of the latter is upright, somewhat in the fashion of a Lombardy Poplar, although, of course, not so tall by any means.

There are other good varieties of this group which are little known. One is grown in Lahore, the fruit of which is distinctly pyriform (see *Oranges and Lemons of India and Ceylon*, Plate cix.) It is wrongly called 'Kärna' in Lahore. Another is the 'Jäwanarun' of Ceylon, resembling a purse with a much, puckered surface.

A still more interesting variety is the green Orange of Ceylon, called there 'Könda-närün.' It is invariably eaten in its green state. Rumphius mentions an Orange which is green when quite mature, and if left on the tree till it colours becomes, he says, worthless. But in an experiment which I made with these green Oranges in 1884, I found them better flavoured and more juicy as they turned yellow.

Both the 'Jäwanärün' and the green 'Könda-närün' are pictured in Miss North's Gallery at Kew, No. 266.

In Ceylon, a number of the varieties of the 'Süntärä' group are called Mandarins, but the only true Mandarins I ever saw there were a few on a neglected tree which the late Dr. Trimen showed me in Peradeniya.

The Tangerines of the London shops are no other than Mandarins. * I never could discover one in London worth eating. To enjoy it you must grow it yourself, and take it off the tree when fully ripe. The perfume of its peel is not to be found in any other Orange.

To the 'Süntärä' group belongs a small Orange grown almost wild on the borders of Nepal, north of Goruckpore. It is the sweetest Orange I ever came across, perhaps a little too sweet. It is locally known by the name of *Santolah*.

Another important Indian Orange belongs to what I consider a subgroup of the 'Suntara.' It goes by the name *Könda* or *Kämala*. Its exterior is of a deep lobster-red, and even when quite coloured is sourish, but if left for a long time on the tree it sweetens. It is the latest of all Indian Oranges.

The *Läroo* of Poona is, I consider, a variety of the foregoing. It is flat and very loose skinned, so much so that the pulp-ball can be made to rattle within the skin.

I have enumerated all the Indian Oranges that could, I think, be made marketable, although there are several others.

It is not easy to find a place for an Imperial Orange Garden, where all the Orange varieties of the Citrus genus could be studied, for one kind of soil might not suit them all. The Mediterranean climate would probably suit all varieties, and Cyprus or Egypt might perhaps be mentioned as an eligible locality. It must be a place where water could be easily procured, and not subject to frost.

(b) A MANGO GARDEN.

An Imperial Garden for Mango trees of the choicest varieties, for the study, propagation, and dissemina-

* Perhaps they may be a seed variety, and a little smaller than the true Mandarin.

tion of this noble fruit. There are at least about fifty choice varieties of this unique fruit, some of which cannot be bought, but are grown in the orchards of native gentlemen, and kept for presentation to important officials and select friends.

The Mango is the one fruit in which the native of India takes a real interest. You may mention to him many other fruits, but he will tell you "They don't come up to the Mango."

No one who has not lived some time in India, and has discovered what a choice Mango, just ripe, means, can form any adequate idea of the exquisite flavour of this fruit.

New arrivals in India, having heard of the Mahgo, very often get hold of seedling bazaar Mangoes, and pronounce them a fine combination of tow and turpentine. They have a sort of turpentine flavour, and the inferior varieties are very stringy, and can only be sucked. Nevertheless, there are often exquisite flavours even among these.

The Mango is never allowed to ripen on the tree, but is plucked at a certain stage and packed in large jars among straw. This operation is called putting the fruit in *pál*. The reason given for this is that the Mango ripens more evenly and thorough than on the tree. In England Pears are treated in much the same way. When taken off the tree they are not fit to eat, and many kinds of Pears require to be kept a long time before they are fit to eat.

This characteristic of the Mango fruit would prove advantageous for exportation, as it would ripen on the voyage.

All the choice varieties most probably originated by seed-variation, and their good qualities are kept up by proper cultivation.

All the fine varieties are propagated by grafting them on seedlings of the ordinary ones.

The Mango tree cannot be grown successfully in localities subject to severe frost. On one occasion, in Lucknow; in the first week of January, five degrees of frost were registered. All the Poinsettias in the Horticultural Garden were, of course, killed outright; the young seedling Mango plants in the nursery prepared for grafting were killed; and up to six feet from the ground all the leaves of the large Mango trees were blackened, but above that line no leaves were touched.

In the hot dry weather the trees want regular watering.

Some place in India not subject to frost, and where water can be easily got at, and with good soil, would be suitable for a garden such as is here suggested.

There are so many exquisite varieties of Mango that they could not readily be studied, and their characteristics found out, without being collected in one garden. From thence they could be disseminated to all parts of the Empire where the climate would be likely to suit them.

I have often tried those that sometimes appear in the London shops from the West Indies and other Atlantic islands. I never found one worth eating. They would not be looked at by an Indian Mango connoisseur.

I have often wondered why wealthy English gentlemen, with extensive gardens and acres of glass-houses, have never, that I am aware of, undertaken to build a special house for the reception and growth of the trees that produce one of the finest fruits in the world.

It is the same with oranges. The British markets are flooded with foreign Oranges, which are often unripe and sour. When ripe they are mostly stale, and not infrequently have a flavor of onions or tar. The flavour of tar is acquired from the ship-hold, and that of onions comes from a mixed cargo of oranges and onions!

To eat an Orange off the tree when perfectly ripe would be a revelation to persons who have not been in Orange countries, and the difference between those imported and those taken off the tree at the right time is something like the difference between night and day.

And yet one never hears of any wealthy gentleman undertaking to erect a special house for Oranges, and

to collect these fine things which are to be found in various parts of the world.

There is such a thing as a movable glass-house on rails. Such contrivances would be very useful in England, where foreign fruit trees might be kept warm under glass in winter, and the house wheeled off them in summer to expose them to direct sunlight and rain, both being very invigorating to all trees.

If the present movable house is somewhat cumbersome it could be made in sections; and surely the engineers who have built the bridge over the Forth, and have done other wonderful things, would be equal to inventing a house that could be easily drawn away by either horse, steam, or hydraulic power.

Then I am told that the reason why Orange trees are not popular in England is that their leaves have to be washed, which is a great bother. I am afraid, however, that sufficient experiments have not been tried, with washes syringed over the leaves, to rid them of that curious sooty, powdery parasite that more or less covers them. There is the ammoniated sulphate of copper, used successfully by the French to combat mildew on vines; there is a carbolic soap, and petroleum, and other combinations that might be tried.

I must not forget, however, that I am writing about Imperial Gardens for the dissemination of fruit trees which are little known, and not about private gardens.

Where Mango trees in India can be grown, Guavas, Lichis, and Bananas can be also grown.

Of Guavas there are two forms, the globular and the pyriform. Those sold in bazaars are not choice, but they make one of the finest fruit jellies in existence. You have to eat Guava jelly, freshly made, with clotted cream, on toast, to understand what this fine thing means.

All Guavas make a capital stew—peeled, with the seeds scooped out, and stewed in sugar and a little water. They are excellent, with a *sui generis* flavour.

The raw fruits are not much relished by the English in India, owing to their strong scent; some cannot tolerate them in a room. But there are Guavas and Guavas. The choice varieties would be worthy of cultivation in an Imperial Garden. There is one fine variety which I came across in Lucknow. It was presented to me by a native gentleman, and strange to say, it had the flavour of Strawberries! It is curious that this flavour should be imitated by two such distinct fruits as the Grape and the Guava.

Of the Persimmon I know nothing, except what I read of it. Of the Mangosteen I know nothing from personal experience. Everyone who has eaten it declares it to be a delicious fruit. I was informed that it had been introduced into the lower ranges of the Nilgiri Hills. Why they have not introduced it into Ceylon and cultivated it for commercial purposes is a mystery.

I think I have enumerated all the choice fruit trees of which I have experience, and which might be grown in Imperial Gardens for dissemination throughout suitable places in the Empire. In such gardens these trees could be studied, and the best mode of cultivating them and propagating them discovered. Moreover, it is only in such institutions that new varieties could be evolved from seed, for no private garden could possibly undertake the creation of new varieties of the fruits herein mentioned on the scale that would be required for success.

It might be said, especially with regard to Oranges—why undertake such a troublesome and expensive job, when shiploads of Oranges are already imported from various places? Well, no one will say that Apples are not grown in this country in large quantities—the bewildering number of varieties at the shows testifies to this—yet shiploads of Apples come from Canada and the United States.

What is being done in America with regard to fruit trees should be a lesson to the rulers of the British Empire.

I have left out of consideration a large number of varieties of the Citrus tribe which are to be found in India, such as Lemons, Limes, and Citrons &c. The latter might be utilised in India and elsewhere for making candied citron-peel. On one occasion I gave some Citrons to a lady friend, and explained to her how this preserve was made. She turned out a candied peel which was much finer than any I could obtain in the shops, and the late Mr. Philip Crowley of Waddon always had most excellent home-made citron-peel.

The number of varieties of Citron to be found in India is astonishing, as a glance at the 'Oranges and Lemons of India and Ceylon' will show.

There is one fruit which must not be omitted in this sketch. It is the red-fleshed Pummelo of Bombay. When cut across, its pulp is of the colour of raw beef, and it is the thinnest-skinned Pummelo that I ever came across. It is fine-flavoured and juicy, and when the large juice vesicles are taken out and mixed with sugar they are delicious. This Pummelo is of the size of a child's head, and sometimes of the size of a child's head affected with hydrocephalus?

I have done with these fine fruits, but there is one plant which should be grown largely in India itself—I mean the Date Palm. In Imperial Gardens experiments might be systematically undertaken with the innumerable varieties of the Date Palm which are known in Asia and Africa; about 150 at least, although not all of first-class quality. The success obtained with these trees by the Superintendent of the Saharunpore Garden proves undoubtedly that the notion that the Date tree cannot be grown successfully in India for its fruit is an antiquated superstition. India is written with five letters, but it is as large as Europe without Russia? The Date tree experiments, if undertaken, should be under the care of a practical Date-grower imported from the Persian Gulf.

It is not intended in this sketch that Imperial Gardens should have anything to do with growing flower-plants and vegetables. That is already done in provincial horticultural gardens. The object should be to collect in one place, and under one supervision, as many of the choice fruit trees that can be grown in that locality, for the purpose of studying them, describing them, classifying them, and discovering the best mode of cultivating them, with the object of disseminating them throughout the Empire in suitable localities, for the health and enjoyment of the people, and for commercial purposes.—Reprinted from the *Journal of the Royal Horticultural Society*.

IRRIGATED COFFEE.

The subject of improved coffee culture having been freely discussed in our columns, we requested Mr. Meenashaya, a retired Judge of the Mysore Chief Court, and now engaged in the interesting occupation of growing coffee under a system of irrigation at Gouripuram, near Tumkur, Mysore, to favour us with a description of his estate, methods of culture and other particulars. He has very kindly complied with our request, and we feel sure that all coffee planters will be interested in what he has to say. His estate is a small one of 40 acres and when the trees are mature he estimates that he will obtain 12 tons of coffee a year. The value of the crop he places at the modest figure of Rs. 10,000, or say Rs. 40 (53s) per cwt., while the cost of production, including everything, is estimated at only Rs. 3,600 or Rs. 2,700 under tank irrigation. Thus the net profit on the 40 acres is Rs. 6,400 or Rs. 7,300 per annum. Multiplied by 5, to make 200 acres, which ought not to be difficult to obtain under tanks, and the profit is Rs. 36,500. This does not, of course, include capital account and the necessary adjustments, but is the net profit of a matured estate. There are many other details

which prospective irrigation coffee planters would have to look into for themselves; but even if we halve the prospective net gain the return is still at the rate of say Rs. 1,500 a month, a profit that is not to be despised. Of course, it remains to be seen what the life of coffee trees will be under the irrigation system, but it does not seem unreasonable to calculate upon at least as long a life as trees which have to depend solely upon the life-giving rains for their vitality. How irrigated coffee would fare in a famine year is another question that remains to be solved; but even in famine years all the rivers do not run dry, and the Cauvery certainly is a perennial stream whose waters might be always relied upon. The prospect of irrigated coffee certainly pleases, but the performances, on a large scale, may, conceivably, be vile. However, "nothing venture, nothing win" is a maxim that has a good deal to commend it, and as the capital necessary to start a fair-sized irrigated coffee estate would not be very large, if the worst came to the worst the loss would not be very heavy. At all events the subject seems to merit the attention of practical planters, and we hope that, if any of them resolve to make the plunge, they will be rewarded on a scale proportionate to their merits.

Mr. C. Meenashaya writes:—

I have an experience of about 15 years in the culture of coffee under irrigation, both in Bangalore (Rock-Dale Park), and in Gouripuram, near Tumkur, where I now reside. In Bangalore I had planted 15 acres, and here, during the last five years, I have planted 40 acres. Having sold Rock-Dale Park six years ago, I have no precise information about the state of the coffee there. But, as far as my experience goes, the results have proved to my satisfaction that, with a never-failing supply of water and careful management, an acre of coffee trees planted 6ft. apart, and five years old, ought to yield from 6 to 7 cwt. The plants when three years old give a crop of from 4 to 5 cwt. an acre, a crop much too large and exhausting for their age; the next year they rest for recuperation, producing little or no crop; and from the following year they give a steady crop of 6 to 7 cwt. year after year. Of the 40 acres I have planted here, eight are 5 years old, ten 4 years and five 3 years; the remaining 15 acres need not be considered, being too young. My five-years-old 8 acres gave me in 1898 a crop of 2 tons, *i.e.*, at the rate of 5 cwt. for the whole eight acres, and this year I hope to get about 3 tons. My 4-year-old 10 acres gave me last year a ton and half, at the rate of 3½ cwt., but I hardly hope to get more than 10 or 12 cwt. this year, but the trees have thrown out an immense quantity of excellent wood, and are just now looking so healthy that even a crop of 4 tons next year would not surprise me. My three-year-old plants (5 acres) have a crop in different stages which I estimate at about 1 ton. My experiments in Bangalore produced similar results.

My system of cultivation is as follows. I plant my coffee 6ft. apart, and plant simultaneously quick-growing shade-tree seedlings, silver-oak etc.. Coffee grows more sturdily and with a much larger number of primaries under the shade, but when the trees begin to bear the shade-trees grow sufficiently high to afford protection. After two or three good showers in the South-West Monsoon I get the plantation dug up like a potato garden or apple orchard. When that is completed, the plants are manured pretty heavily with a compound of cattle manure, tank-silt, and leaf-sweepings. When the North-East Monsoon sets in I give oil-cake, about a ton for five acres; but this is given only to plants which have commenced to bear. I start irrigation in the latter part of January and each plant is watered once a week. The irrigation is stopped with the advent of the South-West Monsoon. I commence picking in July, and this lasts off and on till January. But I must admit that the berries picked till about the

middle or end of August are comparatively smaller and poorer-looking than those picked subsequently. As the heavy pickings are from September to January, and as the quantity picked previously seldom comes up to even one-twentieth of the total outturn, there is practically no loss worth mentioning. This extended period for picking saves me the necessity of employing cooly-labour. My permanent staff of servants, who are at that period relieved from irrigation work, do the picking and pulping. As to the quality of my coffee, Messrs. Binny and Co., through whom I sent a consignment to England, will bear testimony. In 1898, when the London market was exceedingly dull, my good kinds fetched 82 and 78 shillings per cwt. Dr. Lehmann, Agricultural Chemist to the Mysore Government, visited my plantation three weeks ago, and Mr. Cameron, of Lal Bagh reputation, so recently as the 4th instant, and both were greatly pleased with the condition of the plants, to say the least.

Assuming that my calculations will be realised in the future also, (and I am sanguine about this) my 40 acres ought to give me from two years hence about 12 tons a year, or at the rate of 6 cwts. an acre, and this means, at a modest estimate, R10,000. Now comes the most important question, viz., what it would cost me to raise this crop. The purchase of land and sinking wells or other means of irrigation will be capital laid out, and this will vary according to local circumstances. I may mention here that when the plants are four years old and upwards, I water them once in three weeks or a month only, according to their condition, and this relieves the irrigation works to a large extent. I have a permanent establishment which costs me R200 a month, including my head maistry, which would suffice for even double the acreage, as in a couple of years more the irrigation work of the present plantation will abate considerably. I have an oil-mill of my own, which after paying its own expenses, gives me the requisite oil-cake. In addition to the above R2,400 a year, I spend about R200 for manure, and a margin of R100 for contingencies is allowed, making a total annual expenditure of R2,700, which ought to enable me from two years hence to raise a crop of 12 tons, which means a ton at an outlay of R225. But I have special facilities for collecting, for the mere trouble of collecting, a large quantity of cattle manure from short distances where the cattle of neighbouring villages are sent out to graze, and I fortunately possess a spring the water of which flows throughout the year from elevated ground into my plantation and irrigates about 15 acres by gravitation. But R900 a year will more than adequately represent the money value of these special advantages, which additional item, in the case of others, will bring up the outlay for raising a ton to R300. This cheapness in production ought to defy more than one Brazil and the threatened French Customs duty.

Having said so much about coffee under irrigation, I must frankly admit that there is one important source of danger to this industry under well-irrigation. It is patent that water-springs in some localities are gradually failing, especially where a large number of wells are worked. A 50-acre plantation would require not less than 10 ordinary-sized wells. The constant drawing of water from so many wells must necessarily affect the under-ground springs in course of time, whereas a well or two only would cause no diminution. For a small plantation of five or even ten acres, unless in specially-favoured localities, well-irrigation will answer all purposes, and such specially favoured localities can be had by careful enquiry. But there ought to be no fear of future failure of water supply if lands are taken up for large plantations under any one of the magnificent tanks which the Mysore Government has constructed and is constructing. I feel confident that the the Durbar, in its policy of progress under the sympathetic advice of the distinguished British

Resident, will encourage the development of the coffee industry under such gigantic tanks at Biiunakavay and Marikanavay by granting lands under special concessions. One very great advantage in raising plantations under such tanks will be that they could be irrigated by gravitation, and the expenses of sinking wells will be saved. Instead of "putting all his eggs in one basket" the planter could also grow various fruit trees.—*Madras Mail.*

BANANAS.

We have seen it stated that the Banana is one of the most extravagant plants known in its demands upon the soil, and very speedily exhausts it. We do not think so at all; on the contrary, there is comparatively very little taken from the land in a banana-walk by the crop,—not so much as by a crop of corn, and very much less than by sweet potato^{es} or any root crop, not so much even as Sugar Cane, and less than half a crop of tobacco does,—in fact we know of no common crop, except peas, which makes so light a demand. In saying so we may astonish many, but we adduce proof. The banana plant grows from a large bulb, it spreads a number of roots superficially and very widely; it builds up a stem or stalk ten or twelve feet high and a foot to six inches in diameter from bottom to top; this breaks into six or eight leaves, nine or ten feet long, and about a foot broad; it shoots forth a bunch of nine hands or say 120 bananas on a stem three feet long and, say, three inches in circumference at the thickest, tapering to one and a-half inch. Now all that is taken away from the field is this bunch with the stem to which the hands are attached, and the trash or withered leaves which is used as packing to prevent damage to the fruit. If a planter is wise, he brings back all this trash or as much of it as the buyers do not use for packing the fruit on the railway waggon. All the old bulb root and the long feeding roots through the soil remain to rot, the 10 or 12 feet of stem and the long broad leaves are chopped up and are dug or ploughed in around the growing suckers, and the young roots of the ratoons thus find plenty of available food at once. In a wet climate so much rank, juicy matter dug into the soil may cause some sourness, but there is usually, in banana walks, enough lime in the soil to counteract this, and at any rate, the stems and leaves are not generally dug in at once, but lie drying and weathering for a time; besides, the banana is as rank and gross a feeder as a cabbage (and it would thrive on a dung-hill) and it takes a deal of rough feeding to give it indigestion. Then again, bananas have usually—until lately,—been planted as widely as 14 or 15 feet apart, even 16 in Portland, and when we consider how fast weeds and grass grow here, and that four to six hoeings are given a year, we can easily see how great a quantity of humus is being turned in from weedings, in an area of seven feet round each root. To be sure all this stuff—the stalks, leaves and weeds,—is not really an addition to the soil; it is not manure in the sense of stable manure carted on to the land, but still the point is how really little is taken from a banana walk; at any rate, the rotting stalks and weeds form plaut food in a very available form for the roots of the growing plants to feed upon; and that the roots appreciate such, rather than having to search through the soil to get inorganic food in litters, we have only to turn over a heap of rotten weeds that have been hoed out a month or two and left to decay. We should find a crowd of banana roots right under and through the heap. We think that when old banana walks begin to flag, even when cultivated, that they should be replanted in the middle of the old rows, and a free application of lime given to counteract probable acidity from the decaying of the old roots and stems and also to hasten decay. Or if this replanting may not be done, half a bushel of lime flang

round and into the old stool would have quite a rejuvenating effect. If anybody would place his nose near to the heart of an old stool, when one or two old roots are decaying surrounded by ratoons, the sour smell would soon convince him of the good a sweetener like lime could do.—*Journal of the Jamaica Agricultural Society.*

COFFEE-TEA.

To the Editor *Queensland Agricultural Journal.*

As you invited experiences re coffee-tea in the *Queensland Agricultural Journal* of March last, I am very pleased to send you mine. I acquired it when on a selection, on the road to Emu Park from Rockhampton. Having then an experimental plot of about twenty coffee-trees growing, and reading that tea made from coffee-leaves dried was very highly esteemed in some coffee countries, I determined trying it for myself. First, I dried leaves in the sun, but the product was disagreeably tasted when tried. Finally, I dried some leaves in a camp-oven, slung so as to swing over a fire, keeping them constantly stirred until they were dry and fairly crisp. Tea made from them was much enjoyed by all who tasted it; and one who did was the editor of the *Rockhampton Bulletin* at that time, but dead now for years past. He greatly enjoyed it, and my wife and I liked it better than any tea we could purchase. I intend growing a few coffee-trees for the leaves only where I am now, as I am sure if it be only dried properly we could dispense with tea, provided we had sufficient coffee leaves to make our own tea from. To dry it properly is everything. It must be done quickly, and done to a turn; then it has an aroma and flavour that any lover of tea would enjoy.

THEODORE WRIGHT.

Wellington Point, 1st May, 1901.—*Queensland Agricultural Journal.*

DURABILITY OF AUSTRALIAN TIMBER.

The durability of timber in a structure will depend very largely upon the season when the trees are felled. As matters stand in Queensland, timber of all sorts is felled and hauled to the mills during the whole year round. Now, it stands to reason that some of this timber, when worked up, will not stand as long as others, for the simple reason that, at one period of the year, the tree is in full growing vigour, and the sap in full flow. In such a case it is easy to understand that, in the necessary process of seasoning, timber cut in this condition will shrink considerably, and will be weaker than it would have been had it been cut when at rest, *i.e.*, when the sap is down and the growth diminished. We see railway bridges and culverts built of timber often felled close to the line, and squared on the spot. Directly afterwards, this dressed timber is built into the structure. Then it is tarred or painted. Now, what is the result? The timber is full of moisture. This moisture is confined by the tar or paint, and fungoid diseases are provided with an excellent breeding ground at every joint. Then begins dry-rot. Instead of the logs, after or before dressing, being allowed to season and shrink by evaporation of the moisture contained in them, the shrinking goes on after the beams have been fitted in their places. Hence they warp and twist and open their joints, and the element of danger to the structure comes in.

Mr. James Mann, assistant to the Professor of Engineering at the University of Melbourne in his excellent work on Australian timber, says on this point:—

A slightly better condition is that of putting into the structure timber which has been felled during its dormant condition. It then contains the minimum moisture a live tree can contain; but it is only better in that it has completed its cycle of structural work, and is in the best condition for felling. It

contains far too much moisture to admit of being placed in any important position.

Partly seasoned lies mid-way between unseasoned and well-seasoned timber. The latter, of course, is less likely to encourage fungus growth than any. But there are other advantages to be gained:—

1. There is little or no shrinkage. If green timber be used the amount of shrinkage is enormous, requiring the constant attention of a man to put in wedges and screw up bolts. This is almost unnecessary when seasoned timber is used.
2. The whole may be finished, tarred, or painted, without incurring the danger of dry-rot.
3. The timber also may be stronger.

The same authority says that one of the peculiarities of Australian timber is the great oxidizing effect it has upon iron. Place an iron bolt through a piece of partially seasoned eucalyptus, and in a few days there will be a very considerable coating of rust, while the bolt-hole will be blackened all round.

It is only natural that one should ask the question: *How shall we prevent this decay?* In the first place, *use seasoned timber*; it lengthens the life of the timber 100 per cent. Where seasoned timber cannot be used, *protect those points where decay will first appear*, and use every precaution in order to allow the timber to dry while in position.

Coal-tar and paint, while preventing the water from soaking into the wood, also repel the attacks of insects. Hence, *a coating at the joints when dry will retard decay*. Do not paint unseasoned timber except at the joints.

If trees cannot be felled at the proper time, they may be ring-barked, and allowed to drain naturally. When felled they will be better than green timber.

As there seems to be a great diversity of opinion as to the necessity for tarring decks, beams, and piles, it may be stated that all the reports received of timbers that have been so treated confirm the opinion that *tarring increases the life of a structure*.—*Queensland Agricultural Journal.*

COST OF PRODUCTION OF COFFEE.

The following correspondence has appeared in the *New York Journal of Commerce*, in which the cost of production in Mexico and Brazil is compared:

"According to the owners' statements the cost of producing Santos coffee on the Fazendas Schmidt and Dumont, which probably have more coffee trees than any other plantations in the world, is four cents per pound bagged, ready for shipment on the plantation; five cents per pound in Santos; six cents per pound in warehouse in New York. At this price nobody makes any money except the brokers, railway companies and steamship lines. These figures are based on the average product of the plantation, which would probably be somewhere between numbers five and six, New York exchange standards.

"Of course, the smaller plantations cannot produce at the same price as the larger ones and the question of the survival of the coffee planter is getting to be largely a matter of transportation. Undoubtedly many coffee planters will be forced out of business from mere inability to pay their labourers for the picking of the coffee and the care of the plantation. Probably the first decrease in production will come from this reason. The planter whose shipping facilities are close to a railroad can perhaps make expenses at the above figures, but the one who must cart his product five or twenty-five miles to a railroad station must go to the wall. Of course, this applies with greater force to those planters in Mexico, Venezuela and Columbia, who must put a couple of bags of coffee on a "burro" and take anywhere from one day to five days' journey before they can reach a shipping point. All of them are at present losing money largely and it is only a question of time when they must stop.

"On the other hand those large plantations along the line of the Tehuantepec railroad in Mexico have a rate of freight of 60 cents per hundred pounds from the plantation to New York, as against 250 cents for the planter in Sao Paulo. These Tehuantepec plantations claim that they can put washed Oaxaca coffee in New York at a cost of five and one-half cents per pound. Now suppose the Brazilian planter receives nothing at all for his coffee on the plantation. It still costs him two and one-half cents per pound in New York in actual transportation expenses. It is probable that no one will dispute the statement that washed Oaxaca will always bring at least three cents per pound more than the average Brazil coffee. Consequently, while the Brazilian was getting two and a-half cents per pound for his coffee which would only pay the transportation expenses, the Tehuantepec planter would obtain five and one-half cents for his coffee at which price he could live, but not pay any dividends on his stock. There is no place in the world that can compete with him in coffee production, largely on account of his superior transportation facilities, and the superior quality of his product. Moreover, he can also raise rubber, pineapples, sugar, oranges, lemons and other products which pay a profit to reduce the cost of coffee production. A rubber tree shades his coffee tree and it costs him five cents per pound to produce the rubber after the tree is matured. The rubber sells for 65 cents. A handsome profit surely.

"Fortunately for the Brazilian the area suitable for coffee planting in this region is limited or the Brazilian would have harder competition than he ever had before. There is no doubt but that, were there area enough in Mexico along the line of this railway, all other coffee planters would be driven out of business, and no one in the world could compete with such plantations as the "Doa Rios" and "Uberos," run by American capital on American business principles, with a stable government and a railway depot on the plantation itself. Moreover they have two outlets, one by way of Coatzacoalcas to New York and Europe, and the other via Salina Cruz to San Francisco and the Pacific Coast. This road is now being four-tracked so that it will be able to handle all the freight which is presented to it with facility, even to the extent of competing with a Panama canal, because the saving in ocean travel is several days in favour of the more northern route.

"The practical question of decrease in coffee is: "How long is the purse of the planter? and how long will he fight against what appear to be hopeless odds? and how can he pay his labourers for picking his product?"

Note by Ed. B. R.—The cost of production of coffee as of everything else is a relative and not a positive quantity, and is a function of general local prices. The price of any commodity is entirely distinct from its cost of production, and is determined by the ratio of supply to demand. But if price decline in such a manner as to fall under the cost of production, it is clear that either the cost must be reduced or production fall off. If, on the contrary, as is the case with Brazilian coffee, production instead of decreasing increase, the only logical conclusion that can be arrived at is that, however low prices may have fallen, they have not yet reached the limit at which production becomes impossible.

Because the cost of production may have ruled 4, 5 or 6 cents per lb. at one time, it does not follow that it will always do so, or even that it does so now. As exchange rises the cost of production declines, and the fact that Brazilian coffee has been sold as low as 5 cents in New York without stopping but rather stimulating production shows that the premises on which the whole argument of this correspondent is founded are unreliable. We do not pretend that at 5 or 5 1/2 cents planting can be very profitable. Indeed, if it leaves any profit at present it must be a very bare margin. But it does not,

therefore, follow that it must be always so, or that, by reduction of cost the margin may not be considerably widened in a manner that would be probably, impracticable elsewhere.

In the first place a readjustment of charges to the altered circumstances created by the rise of exchange is ultimately inevitable. Not only must the current rates of wages be reduced, but railways and intermediaries of all kinds will be forced to reduce their charges also. Half a loaf is better than no bread: and if, as is stated, coffee at current prices is so unprofitable to the planter as to leave him only losses, the time cannot, evidently, be far off when they must be reduced or he must give up planting altogether and there will be nothing for the railway to carry? Long before that could happen, if, as the correspondent of the "Journal of Commerce" states, railway freights really represent a charge of 2 1/2 cents per lb or 100% on the prime cost of the coffee, there must be a tremendous margin for reduction in that item alone.

The interest of the railways are identified with those of the planter to the extent that they depend exclusively on coffee for their traffic, and would work at the bare cost of maintenance rather than shut up altogether. The very causes that are at present prejudicing the planter, viz, the rise of exchange and "overproduction", are a source of profit to the railways and make it easier for them ultimately to reduce their charges.

As regards the cost of delivery from the plantation in Mexico at New York, we have no means of verifying the statement that it rules only 50 cents per hundred lb, but it seems extremely low and probably, if correct, applies only to a limited area and does not include the cost of handling at all. Anyhow, the cost of delivery from Sao Paulo plantations which is put down at 250 cents per 100 lbs. is grossly exaggerated. The maximum freight charged in the Paulista railway, for example, is only 1\$ 500 per arroba of 15 kilos, equivalent, at even the relatively high exchange of 12d., to only 112 cents per 100 lb, whilst, at 35 cents a bag, ocean freight amounts to 26 cents, thus bringing up the total to 138 in lieu of 250 cents per 100 lbs. We do not include duties and other charges as they have evidently not been included in the calculation of the comparative cost of delivery estimated for Mexico.

The railways engaged here in this traffic nearly all earn handsome dividends of 12 to 14% and could, in Sao Paulo at least, probably reduce rates to half without losing money. On the other hand, coffee has been constantly carried to New York at 10 cents per bag without loss and could be again if necessary. So that, altogether, a reduction of carrying charges from 112 to 60 or 70 cents per 100 lb. is by no means an impossibility. The method of estimating the cost of production followed by the correspondent of the "Journal of Commerce" is, however, misleading and arbitrary. Brazilian coffee is now selling in New York at little over 6 cents, or 1/2 cent under what he estimates to be the cost of delivery, and has before been sold at 5 cents, the price he estimates as the cost of delivery at Santos. In spite of such low prices, however, coffee does not cease to be produced nor to be shipped, which certainly would be the case had the price really fallen under the cost of delivery. At 5 or 6 cents per lb, coffee may not leave much profit to planters, but before Brazilian coffees could be driven from the markets, there are wide margins yet to be reduced not only in the prime cost of production but of freight and handling. Should extensive cultivation prove too costly, it must be made intensive and labour replace planters as proprietors, as was the case with cotton in the Southern States. But, come what may, coffee will never cease to be profitably produced, because Brazil possesses an almost unlimited area and climate suitable for growing coffee such as no other country enjoys.—*The Brazilian Review.*

FRUITS IN EGYPT.

(Annual Report: British Chamber of Commerce
of Egypt.)

A tree of the orange tribe, known in India as the "Bael fruit," or Bengal Quince, (*Egle marmelos*, Corr.), is very rarely seen in Egyptian gardens, but should be extensively cultivated if only for its long-recognised merits as an invaluable remedy in India in cases of dysentery and allied complaints. Its sun-dried nripe fruits, so common in Indian bazaars, do not seem to have found their way to Alexandria or Cairo though the liquid extract is official in the Indian Pharmacopœia. Another medicinal tree belonging to a different natural order (Leguminosæ) the "Khyar Shambar" of the Arabs (*Cassia fistula* L.) of which Hugh Liudschoten the traveller tells us he saw more than a thousand trees in Egypt in 1580 A. D., mostly near Damietta, has almost disappeared, although an avenue of them is still to be seen in flower in the island of Rodah in June. Its laburnum-like flowers are highly ornamental and fragrant, whilst the pulp in its long cylindrical pods is a valuable laxative. The "Habel Molook," or Physic nut (*Jatropha curcas* L.) is also rare in Egyptian gardens.

The "Mozz," Adam's fig or Tropical banana (*Musa sapientium* L.), with some of its many varieties, including the Plantain (*M. S. V. paradisiaca*), has been cultivated in Egypt for many centuries, principally about Damietta, but with no pains to improve the quality of the fruit. This lofty species cannot be grown with success at Alexandria or anywhere near the sea in Egypt, without the protection of a very high wall, on account of continuous salt-laden sea breezes, and its cultivation has of late years been almost abandoned. During the last ten or fifteen years the low-growing Chinese species (*Musa Cavendishii* Lamb.) which grows to a height of only 6 or 8 feet, and is extremely prolific, has been cultivated with considerable success near Alexandria and in the interior. It is well-adapted to the climate, and fruit of excellent flavour has been produced. The Chinese banana is much cultivated in the Canary Islands.

Dr. Seeman (1) tells us that the species was taken to the Samoan or Navigator Islands by John Williams, the missionary martyr of Eromanga, from the Duke of Devonshire's seat at Chatsworth, and was carried thence in 1847 by the Rev. G. Pritchard to the Friendly and Fiji Islands where its introduction put an effectual stop to the famines which previously were experienced. It has now spread over the whole of Polynesia and has almost supplanted the "*Musa Sapientum*."

Of the latter species Simmonds (2) tells us that there are 17,000 acres under plantain gardens in the Madras Presidency of India and 24,000 acres of bananas in Ceylon.

Sufficient bananas are already cultivated to supply the Egyptian market, and export has commenced; but it seems that the fruit from the Canaries, which makes a better show but is inferior in quality as regards flavour, is preferred to the Egyptian bananas in the French market. Direct export to England has not yet been attempted.

The import of bananas into the U. S. A. in 1892 was 13,000,000 bunches, valued at £2,000,000, mostly from Honduras, Jamaica and Central America.

The Mango (*Mangifera indica* L. is one of the best of Indian fruits, and, although unadapted to the Alexandria climate, has been for some years cultivated with success in the neighbourhood of Cairo and Ismailia; fruit of excellent flavour, although smaller than that grown in India, has been produced, and the markets are well supplied with it in August at a charge of from P. T. 1 to P. T. 2 per fruit.

As mangoes arrive in Egypt from Bombay in perfect condition, when wrapped in tissue paper and packed in boxes in such a manner as to prevent contact between the fruits, it is probable that a more extended

cultivation would repay export to the Continent and Great Britain.

Dates are not cultivated in Egypt to such an extent beyond the requirements of the population as to become an important article of export. The varieties are numerous, some being of the size and form of a lemon, and others of a banana; but there is much room for improvement by the extended and careful cultivation of the best kinds which are rare. Of the Nakhlet el Basha or Vanilla date, (*facile princeps* in Egypt), Figari Bey tells us there were only, in 1865, four trees in the Ghizeh district near Bedra-sheen, "Safr el Dunyeh" or Sultani, a large dry kind cultivated near Belbeis and Zagazig and of excellent flavour, is also rare elsewhere.

The average quantity of dates exported during the 15 years 1884-98 was 645 tons per annum, valued at £11,864 or at nearly L.E. 18 per ton. The export in 1899 was...892 tons valued at L. E. 14.221 and in 1900 " ...834 " " 13,849

or at about L.E. 16 per ton. Of these Great Britain took more than one half, Turkey about 1/6 and Austria about 1/9. The import of dates is somewhat larger than the export; probably from the cheapness of inferior qualities from Turkish ports.

Out of a total import in 1899 of 1,061 tons valued at L.E. 8,187, 967 tons of Turkish dates were valued at L.E. 6982 or at a little over L.E. 7 per ton. On the other hand the superior quality of Tunisian dates of the best kind is evinced by 21 tons out of the above 1,061 tons imported from Tunisia being valued at about L.E. 657, or at about L.E. 31 per ton.

Shammam gawoon, &c., or melons (*Cucumis melo* L.) and Batteekh, or water melons, (*Citrullus vulgaris* Schrad), although cultivated on a tolerably large scale (about 15,000 feddans in Upper Egypt and more than 20,000 in the Delta, much of the latter being sandy desert), are not sufficient to supply the Egyptian market at all seasons, and there is a considerable import of them. This amounted in 1899 to 2,492,863 fruits, valued at L.E. 23, 249 or at less than 1 P.T. each, all from Syrian or Turkish ports.

Of other fresh fruit in general, although strawberries during the last fifteen years have been abundant and of good quality in the market, there is much to be done in the way of improved cultivation and of acclimatizing new kinds. The loquat (*Eriobotrya japonica* Lindl) is much cultivated but the fruit is of inferior quality and not worth eating. The Guava (*Psidium pomiferum* L. and *P. pyriforme* L.) is no better) whilst the Pope's Apricot (*Diospyros kaki*, Thunb) of Japan is scarcely more than a botanical curiosity. The Roumman or Pomegranate (*Punica granatum* L.) which has been cultivated since the days of the Pharaohs all over Egypt, and as far South as Khartoum, and is of good quality in the Delta, especially near Rosetta and Damietta, ripens too late in the season (August and September) for the European market, and is more appreciated for the beauty of its flowers and fruit (especially the double-flowered "gulnar") than for the flavour of the latter. But as an economic plant it is most valuable, the powdered rind being in great request for tanning, and dyeing yellow Morocco leather, and as an astringent remedy in dysentery; whilst the root bark is considered a specific for tapeworm.

The Kishta or sweet sop (*Anona squamosa*, L.) is in common cultivation and of good quality; but the better species of Anona, viz., the Cherimolia (*A. Cherimolia* Mill.) the Custard apple (*A. reticulata* L.) and the Bullock's heart or soursop (*A. muricata* L.) are never seen.

The Papaw apple (*Carica papaya* L.), which has a commercial value in the drug market from the "papayotin" extracted from the milk of its half-ripe fruits, and is a by-no-means unpalatable fruit to eat when at its best, thrives in Egyptian gardens, but is grown more for the sake of its handsome foliage than for the market.

The Barbadoes gooseberry (*Pereskia aculeata* Mill.); the Granadilla (*Passiflora quadrangularis*, L.); the Water lemon (*Passiflora latifolia* L.) the Cape Gooseberry (*Physalis peruviana* L.) and the Cucumber Custard apple (*Monstera deliciosa*, Liebm.) are all cultivated in gardens, but, with the exception of the last two, only for ornamental purposes, although they should all be market produce. Of the Sapodilla or naseberry tree (*Achras sapota*, L.), a good fruit, sold in the Calcutta bazaars under the name of "mangos-teen," which it somewhat resembles but cannot be compared to for flavour, a fine old tree exists in the island of Roda which fruits annually; no other exists in Egypt.

The "Tamar Hindî", or Tamarind (*Tamarindus indica* L.), is cultivated in gardens and flowers well, but cannot ripen its fruit in the Egyptian climate. Two fruit trees which might be introduced advantageously are the Avocado Pear or subaltern's butter (*Persea gratissima* Gortn.) an excellent fruit, and the Litchee of China (*Nephelium Litchi* Camb.); the former is abundant in Algeria.

The total import of fresh fruit into Egypt is very considerable, and in 1899, omitting dates, melons and water-melons amounted to 51,691 tons valued at L.E. 44,079; more than 1/5 of the whole came from Malta and Gibraltar, the same from Italy and about 2/5 from Turkish ports.

Although a humble annual, the "Ful Soudani" or earthnut (*Arachis hyogæa*, L.), claims our attention as a larger export produce than dates from Egypt; and its cultivation, which only dates from the last twenty years, does not, as might be imagined from the Arabic name, belong to the Sudan, but to the Fayoum and Delta, especially in the Province of Charkieh. It is of South American origin although much cultivated in Central Africa and throughout the tropical world. The export from Egypt was in

1899 ...	1926 tons valued at L.E. 22,225	and in
1900 ...	1431	" 16,753 or

at about L.E. 12 per ton. Almost the whole export went to Turkish ports.

"The consumption of this seed," says Simonds, (1) "is held in such estimation for eating in the U.S.A. (where it is known as the peanut) that flourishing sale stands are seen at almost every street-corner of New York. They are not much appreciated in England except by children. In America 3½ million of bushels are sold annually. There are full 750,000 bushels (18,750 tons) sold yearly in the city of New York alone. Previous to 1860 the product of peanuts in the U.S.A. did not amount to more than 150,000 bushels (3,950 tons), and of this total nearly 5/6 were from North Carolina. It was estimated that Virginia, Tennessee, Georgia and Carolina, sent conjointly over 3,000,000 bushels (75,000 tons) to market in 1886, of which 1/4 went to New York. As much as 10/- to 12/- is paid for the bushel (£20 to £24 per ton). The yield is from 80 to 120 bushels per acre." Apart from the question of food the earthnut is a valuable plant for the oil contained in its seeds and pods, the former containing 45 0/0 and the latter 30 0/0 of oil; they make an excellent but expensive oilcake for feeding cattle.

The cultivation of Henna (*Lawsonia inermis*, L. and *L. spinosa*, L.) represents about the same export importance as dates and earthnuts. It is cultivated, like the latter, almost entirely in the Delta and province of Charkieh. The average export of the powdered leaves during the 15 years 1884-98 was 1,115 tons per annum, valued at L.E. 15,025 or about L.E. 13½ per ton.

1899 ...	1178 tons valued at L.E. 18,246	and in
1900 ...	1234	" 21,036 or

at from L.E. 16 to L.E. 17 per ton. Nearly the whole of this went to Turkey, Tunisia and Algeria. None goes direct to Great Britain but a portion of the small export to Malta, valued at L.E. 74, may find its way there for the purpose of making hair-dye. The Henna is cultivated throughout India, as a hedge plant and in gardens, for the same purposes as in Egypt, and also as a hair dye. The glossy jet-black

colour of the hair so prized in the East is obtained by dyeing first with henna and then with indigo powder, each being made into a paste for that purpose, with a subsequent application of castor oil. Certain Moslems prefer only the first part of the operation and leave the hair of a brilliant red, dyeing the manes and tails of their horses of the same colour.—*The Egyptian Gazette*.

THE COMMON DATE PALM.

CAN IT BE GRAFTED?

TO THE EDITOR OF THE EGYPTIAN GAZETTE.

Sir,—I shall be glad if any of your correspondents can inform me, by means of your columns, of an instance they have known of a successful attempt to graft the common date palm. An Algerian agriculturist, Count de F.—who makes the cultivation of this tree a speciality—has recently pointed out to a traveller at Biskra a date palm which he said he had himself grafted in the ordinary way when it was between five and six years old; this tree has now three branches or stems at its summit. The count informed the traveller that, for the purpose of grafting, he had made use of the young shoots, known to the Arabs as "ragab," which, occasionally, are found in the axils of the lower leaves near the base of the tree and are much smaller than those arising from the rhizomes beneath the ground (known as "jobar") which are the usual means of propagating the date palm. The fact of the existence of the triple-crowned stem is indisputable; but that it has resulted from the ordinary process of grafting appears almost incredible.

The curious mode in use in Egypt of continuing by "layering" (marcottage) the propagation of a valuable kind of date palm, which is deteriorating without any young shoots by which to replace it, has been accurately described by Figari Bey in his "Scientific Studies in Egypt." In this case, a cylindrical hole is bored, horizontally, in the stem, about six inches in diameter, at twelve feet from the summit of the tree; in this is placed a corresponding piece of wood, projecting at each end, to which is attached, below, a sort of sack, made of matting and filled with good earth and manure, which is carefully watered every few days for nine or ten months; the upper portion of the trunk is secured by ropes to neighbouring trees during the above-mentioned period. When the new roots are well formed (after expiration of ten months) the tree is sawn through near the base, and carefully lowered down, the newly rooted part being then removed and planted in the place previously prepared for it. In two years, if not too old, it will give excellent fruit of precisely the quality of the original tree. With care, date-palms forty or fifty years old may be safely transplanted. But "grafting" a palm tree is a long way in advance of any such process as the above, and I should like to be convinced.—*Egyptian Gazette*.

I am, etc.,
APPELLA.

TO PRESERVE YOUNG LIMES.—Millions of limes go to waste every year in this island, which with very little trouble and slight cost could be made into a delicious and very saleable preserve. The following method of preserving young limes will be found useful:—Use limes not over ¾ inches in diameter. Prepare brine by dissolving salt in water until an egg will float, in which place the limes for from ten to fourteen days; then cut these in halves and scoop out the pulp; boil the skins in two or more waters until the salt and essential oil are removed; stew them in syrup made from white granulated sugar. If crystallised limes are required, after they are stewed dry them and dip them several times in thick syrup, drying them after each dipping.—*Journal of the Jamaica Agricultural Society*.

CEYLON AND JAPAN TEAS IN CANADA.

I.

The following letter, signed "P C Larkin, Toronto," appears in the *Canadian Grocer* :—

"We read with much interest in this week's issue your article headed 'Japan Tea Market Injured.' In it you state that the Japan tea market has been 'difficult to understand,' and you go on to state that, in spite of the material diminution in the amount of imports, the market has weakened rather than stiffened." We personally, and without prejudice, cannot see that there is any reason for surprise. It is quite apparent to us that you have overlooked the strongest factor of all in bringing about the decrease of the demand for Japan tea, and that is, the green teas of Ceylon. Every wholesale house has, by this time, recognised the fact that there is no future for Japans, and that there is a great future for Ceylon greens in Canada. Consequently, not only the wholesale houses, but every bright retailer as well, are afraid to stock up with Japan teas, wishing rather to adopt a hand-to-mouth policy.—*Home and Colonial Mail*, May 31.

II

(To the Editor of the "*Home and Colonial Mail*.")

DEAR SIR,—Being an old Indian planter, and having been engaged in the Indian and Ceylon tea business in Toronto (Canada) for many years back, I have taken a great deal of interest in the many proposals made to better the state of the tea market. And while watching with much interest the very energetic campaign that has been carried on by Ceylon for some years, and which has shown such great results, especially here in Canada, I have been surprised, as well as disappointed, that as much, at least, has not been done by India. They did have an energetic and able representative in the United States for three or four years, with a small amount of money at his command with which to advertise; and he effected wonders, I think, with the amount at his disposal. But what is wanted to turn the consumption of the one hundred million pounds of Japan and China tea, that is now consumed annually in the United States, into a consumption of Indian and Ceylon tea, is the expenditure in advertising, for the next three or four years, of at least forty or fifty thousand pounds sterling per annum. This, well spent in the daily press, would force Indian teas on the attention of all tea drinkers; and I venture to say that in five years from now over fifty million pounds of Indian tea per annum would be consumed in the United States.

You will ask how this money is to be raised. Well, why can it not be raised as I understand the planters of Ceylon have raised theirs for years back? The imposition of an export duty of one-sixteenth of a penny per pound on all tea exported from India would create a revenue of £45,000 per annum; this is, basing the calculation on the output of Indian tea last year, and the expenditure of such a sum would enhance the value of Indian tea twenty-fold the amount expended.

It may be said that the planter is not in a position to stand this one-sixteenth of a penny per pound. The question just occurs to me, who

would pay it? Would not the consumer pay it in the long run, instead of the grower or exporter?

In any case I consider that a real live campaign carried on in the United States is the only feasible plan that will bring about the position so much desired by us all.

If one wants to see a recent result of advertising, I have only to point out the progress which Ceylon green teas have made in Canada during the past eighteen months. One firm to my knowledge, the "Salada" Tea Company, has for months back taken, on regular orders from one garden in Ceylon, over four hundred half-chests per month. Practically every wholesale house in Canada is now handling Ceylon green teas, and they are all predicting that they will entirely displace Japan teas. This has been brought about, first, by superior quality, and, secondly, by the tremendous advertising that "Ceylon green tea" has received. To the Indian planter the moral is: "Go thou and do likewise."—Yours faithfully,

ROSS W. HAYTER.

50, Front Street, East, Toronto.

May 16, 1901.

WHY NOT FIGHT MATE TEA IN SOUTH AMERICA?

80 TO 100 MILLION LB. OF THIS "HOLLY" MATÉ TEA CONSUMED.

It may come as a surprise to many people to learn that no fewer than from 80 to 100 million lb. of the indigenous tea of Brazil and Paraguay are consumed in the South American Continent. From Brazil alone 30 millions lb. are said to be "exported"—that is to countries farther south, such as Argentina, where the consumption of Maté is said to reach to 15 lb. a head per annum. All this we learn from the account we republish in our daily and *T.A.* of "Maté," from the latest edition of the "Encyclopædia Britannica." [The new edition or Supplement now in course of preparation will no doubt have later information.] It will be observed that Maté tea is really made from a kind of ilex or holly and, as apparently there is no cultivation of the plant, even the widespread forests of Brazil and Paraguay cannot supply groves of the ilex for ever, although perhaps the cutting of branches in the manner described, by the Indians, does not do permanent injury to the trees. Be that as it may, we cannot see why the people of the South American States—in Argentina especially—should not by degrees be won over from Maté to Ceylon and Indian teas. Already a few million lb. of our teas as reported by Messrs. Gow, Wilson & Stanton, are taken for South America and, if some trouble were taken to exploit the States concerned, or their capitals at least, with samples of our stronger teas, it is quite possible that the supersession of the indigenous article, Maté, might go on a good deal quicker and that no inconsiderable quantity of our teas, and one yearly increasing, might be taken by South America. We commend the subject to the attention of the "Thirty Committee."

CEYLON GREENS FOR AMERICA.

HOW THEY MUST BE MADE: TO WIN FAVOUR IN THE WEST.

We have pleasure in giving prominence to the following letter to a Colombo firm from its Agents in the United States, in which it will be seen that valuable suggestions are made for the manufacture of green teas to suit the American market. We feel sure that all engaged in making greens so far will give them their careful attention, even if the time be not yet ripe for the measure suggested. With the expansion in our trade in green teas, the Ceylon Planters' Association should certainly consider the proposal made, more especially if the market for black teas is not to recover, as at present it shows signs of doing. The imitation of Japans, however, would not be confined to greens only, as the last paragraph shows:—

May 20th.

We note from late advices that the proposal of the India and Ceylon Association for the reduction of out-put has fallen through, and therefore the importance of finding other outlets for India and Ceylon Teas will become a matter of extreme importance to those interested in India and Ceylon Teas. Of late a good many so-called Ceylon Greens have been sent to this market, and have attracted some attention, but we feel convinced that there will not be a ready sale for this new description of Tea unless their manufacture is somewhat altered. If the leaf can be made to closely imitate Japan Teas, both basket-fired and pan-fired, we believe that there would be a great opportunity and a small fortune for those who are first in the field. To accomplish this, it would be necessary to have a firing establishment in say Colombo (and Calcutta, if the Indian Teas prove serviceable for the purpose) the same as exists in Yokohama and Kobé. The leaf would be brought down in the semi-raw state, viz., once fired, and then treated and manipulated in the same manner as Japan Teas. It would also be necessary to have the Teas packed in half chests, matted, and faced in the same way that Japan Teas are treated. We are forwarding to Ceylon a small quantity of Japan Green Tea for the purpose of ascertaining whether they can manufacture this leaf to imitate closely in appearance Japan Teas. If they can do so, the cup quality of Ceylons would certainly give them a distinct advantage over Japans. The annual export of Japan teas is approximately 40,000,000 lb., and if this trade can be diverted to Ceylon and India, the Associations interested in these classes of tea would certainly be greatly benefited. Our suggestion is that a Company be organised for the purpose of establishing firing establishments in both Calcutta and Colombo, provided, of course, that we are able to ascertain by experiment that our suggestion to imitate Japan teas is a feasible one. In a venture of this kind, we should be willing to subscribe liberally, and we think that both the India and Ceylon Associations should make some considerable concessions to the pioneers. The question is as to the best and most expeditious method of taking up such a venture. It seems to us that it would be necessary to form a small Company of those interested and obtain some skilled Japanese labor to initiate and start the manu-

facture. Speaking in general terms, we think that the export of such teas should be confined to one or two houses in the States and Canada.

We are sending you, by today's mail, samples of Japan teas that we suggest imitating. You will notice that one is a long black leaf tea called "Basket-fired" and the other is the regular style so-called "Pan-fired." We feel sure that the latter can be imitated very closely. Whether or not leaf is obtainable in Ceylon and India similar to the Basket-fired, is another question, of which you are the best judge. Please advise us as promptly as possible what suggestions you have in this matter.

PLANTING RUBBER IN BRAZIL.

An occasional correspondent to our contemporary, *The South American Journal*, writing from Para, advocates the cultivation of rubber trees as follows:—The Government of this State could do very much to draw large amounts of foreign capital here by offering sufficient inducements for the establishment of rubber plantations. At present all the rubber exported is collected from the virgin forests; the trees are widely scattered, and the collecting of the rubber takes much time. If plantations were made, ten trees could be placed in an area now occupied by only one, so that a man collecting could work four or five times the number of trees that he can attend to now, resulting in a much greater production of rubber per man, consequently more profit to all concerned. Here is the natural home of the rubber tree, and the quality of the rubber is the best in the world.

About four or five years ago, a law was passed by the Legislature of the State, offering a premium of one conto of reis for every two thousand trees planted; that it has had little or no effect shows that the inducements offered are not sufficient; that it would be well if the Government would offer more. Suppose the Government were to offer, in addition to that now offered, half the export duties of all rubber from such plantations for a term of years, and exemption from all taxes of whatever sort for the same length of time, and make these terms known throughout the world. It seems credible that it only requires something of the sort to draw large amounts of foreign capital here to establish rubbish plantations. Millions of dollars have been invested in such plantations in Mexico and other places, and millions of trees have been and are now being planted every year; if something of the sort is not commenced here pretty soon, this country may have an unpleasant surprise some day not very distant. With sufficient inducements, millions of pounds would pour into this State to establish rubber plantations, which would revolutionise the whole rubber business of the world. Public land can at present be bought from the State on very favourable terms, from one milrei per hectare up, according to location and quantity of land required. The Government would not be required to spend any money in this enterprise for some years to come, and compared with the benefits to be derived, the sum to be paid in the future is very little. It is certain that it is worth all the privileges that might be offered as above, because Nature alone and unaided will never establish such plantations; they will only be planted by enterprising men, backed by large capital, and with the hope and expectation of large gains.—*India Rubber Journal*, May 13.

INDIAN TEA EXEMPTED FROM FRENCH IMPORT DUTY.

Private telegrams received in Pondichery state that the French Government has decided to exempt

tea and coffee imported into France from British India from the prohibitive tariff, which comes into force next January. The favourable solution of this important subject—which will be hailed with thanksgiving by the large community of planters throughout India—is in a great measure due to the exertions of Monsieur Yves Guyot, editor of the Paris *Siècle*, who has thoroughly studied the conditions of the case.—*M. Mail*.

BENGAL AND MADRAS INDIGO.

THE CUSTOMS DUTY IN EGYPT.

Calcutta, May 14.—The Bengal Chamber of Commerce has addressed the Government of India, drawing attention to the very heavy incidence of the Customs duty in Egypt on Bengal indigo as compared with the duty imposed on Madras indigo, which has worked adversely to the interests of Bengal indigo, and requests that a fairer basis of assessment should be arrived at, more in accordance with the relative values of the two descriptions of indigo. The difference in the tariff rate between the two descriptions of indigo is extremely disproportionate to the prices ruling for the past three years. The average price of superior Madras qualities has been R50 to R55, while the average price for ordinary Bengal qualities has been R60 to R65 per maund of 25lb. The difference between the ruling rates of the two qualities is under 17 per cent., while the difference in the tariff rates on which duty is charged is about 45 per cent., thus giving the Madras dye an enormous advantage over the Bengal product. The Committee is informed that the Customs duty in Egypt on all foreign goods and produce is 8 per cent. *ad valorem*, and it is clearly apparent that Bengal dye is valued too high for the purpose of levying duty. The equivalent of 8 per cent. on 48 piastres, the Egyptian valuation for Customs purposes of Bengal indigo, is nearly 4 piastres per kilogramme, while the equivalent of 8 per cent. on 28 piastres, the Egyptian valuation for Customs purposes of Madras indigo, is only a little over 2 piastres per kilogramme. The method of assessing duty on indigo which at present prevails in Egypt is unfair and requires re-adjustment. The Committee does not ask any concession in favour of indigo cultivated in one Province to the detriment of that cultivated in another. It simply desires that the whole of the indigo exported from India to Egypt should be placed on the same footing as regards assessment of duty in the latter country.—*Madras Mail*.

MEDICAL INVESTIGATIONS IN INDIA.

THE MALARIA COMMITTEE.

The delegates of the Malaria Committee of the Royal Society, Doctors Stephens and Christopher, whose main object in visiting India is to seek for and investigate cases of black-water fever, a most deadly disease to Europeans in Central and West Africa, and some cases of which have been reported from the Dooars, Sylhet, and other malarious localities in India, are now at Simla, where the following plan of work has been arranged, in consultation with the Sanitary Commissioner with the Government of India:—Dr.

Christopher goes to Mian Meer and Amritsar to make preliminary arrangements for the autumn campaign (in co-operation with the Medical Officers of those military Cantonnements) against malaria. He then joins Dr. Stephens in Calcutta, by which time Captain S P James, I.M.S., will have returned from China. All three will then go to Darjeeling, the Terai, and the Dooars to investigate the black-water fever.—*Madras Mail*, June 19.

CINNAMON IN LONDON.

The information which the last English mail has brought does not disclose any special features in the Quarterly Auction of Cinnamon held in London on the 20th ultimo. The tone of the sale was quiet; and naturally so, in view of the large leavings from the heavy catalogues of February, when 2,132 bales had offered. The offerings last month were a fairly average quantity, having been 1,088 bales, against 1,058 at the corresponding auction last year. It was, therefore, scarcely to be expected that the fall in prices experienced in February would be recovered, the more so as heavy shipments of bark continue from this side, although the amount is not as large as it was last year. Unless there is a rush soon, following the big harvest which is now fairly on, prices may be expected to recover somewhat. It would be something, even if they were maintained, looking to the dullness of trade and the unhinging of business through the prolongation of the troubles in South Africa and China, the shuffling which there has been in the home duties on produce, and the recent scares in Wall Street and the London Stock Exchange.

As it was, more than half the quantity of spice offered was sold at prices which were on the whole satisfactory, and should pay producers. Whether they leave any profit to middlemen is another matter. Local traders are rather fond of paying fancy prices when there is a demand, hoping to make a profit by mixing with coarse bark, and they often burn their fingers, as London buyers are wide awake. The fate of shipments of wild cinnamon is proof of this. It may take some time for traders to recover who have embarked in "wild," but with stocks fairly easy in London, there is room for legitimate trade.

We quote as follows from the Report of Messrs. Forbes, Forbes & Co., Limited:—

London, May 21.

CINNAMON.—The periodical auctions were held yesterday and went off with a very quiet tone. The total offering was 1,088 bales plantation quill, compared with 2,132 bales at the February sales, and 1,058 bales at this period last year. Of this supply only 77 bales were good and fine "worked" quill. The steamer "Stentor" with fresh parcels of fine &c., some 240 bales, only arrived in the river yesterday, *via* Amsterdam, and her shipments were consequently shut out.

There was scarcely any change in prices, the 77 bales "worked" realising about last sales' rates and 621 bales "unworked" going irregularly and occasionally easier.

"Worked" firsts brought 11d to 1s 6d, seconds 9d to 1s 5d, thirds 1s 1d to 1s 4d and fourths 7½d to 11d per lb.

"Unworked" firsts sold at 9d to 1s; seconds, 8d to 10½d, thirds 7½d to 10d, fourths 7½d to 9½d per lb.

Of about 850 bags chips &c., only a few bags sold at 2½d per lb. for coarse.

WILD CINNAMON.—About 212 bales and 578 bags were offered and passed without bids. Present stocks 3,197 bales Ceylon, 2,666 bales "wild," 3,515 bales chips and 8,373 bales of wild bark, &c.

The next sales will be held 28th August.

PLANTING IN TRINIDAD. CACAO—RUBBER—COCONUTS.

From "Trinidad and its Future Possibilities,"—a paper read by Sir Hubert Jermingham, ex Governor, before the Royal Colonial Institute, we quote:—

Trinidadians have every reason to take time by the forelock, for they possess a soil which can grow anything and everything. The cacao trade, which comes next in importance to the sugar trade, is one which, however remunerative, does not give work to many hands, though fortunately it is one in which the native Creoles take an interest, and the coolies are beginning to invest their savings. It is a trade which flourished in Trinidad up to 1827, when, owing to the fall in prices, it gradually dwindled to nothing, until in 1856 there were no more than 7,000 acres under cultivation. As the average yield per acre is 600 lb, or 2 lb per tree, some idea of the development it has now reached can be gathered from the fact that there are at the present time nominally 498 cacao estates, yielding 173,000 bags, or 29 million pounds of cacao, hence representing some 48,000 acres under cultivation. It is estimated that the cost of production of a bag of cacao containing 165 lb is 34s, while the sale price average for the last two years has been 75s a bag, representing a total of more than £600,000, of which half was clear profit and half was expended in the Colony. The demand is so much on the increase that prices maintain themselves in spite of accumulations and of old methods of growth; and the providential dispensation which places Trinidad outside the hurricane zone is also the guarantee of her future prosperity from this one article, if she had no other to rely on; but a great impulse has been given within the last three years to the cultivation of rubber, and this important article of commerce is expected to rank eventually as one of the most remunerative of the Colony's resources. Thanks to a Swedish Professor of botany and natural history, Professor Bovallius of the University of Upsala, who was introduced to me by letter from the Secretary of State, I modestly hope that I have had a slight share in the impetus given to this new industry from which so much is expected.

Professor Bovallius assured me that he had not seen along the Orinoco river any land better suited to the growth of Hevea or Castilloa than that which Trinidad affords, and he has since proved his confidence in the soil by the purchase of some 4,000 acres of Government land and the launching of the Narva Estates Co., Ltd., for the cultivation of rubber, cacao, and indigenous products.

I wish I had the time to explain to you how these estates, situated in, I think, the loveliest parts of the island, and selected with the greatest care and knowledge, are expected to give returns in the

eight year, when the rubber-trees yield their milk, which are simply astounding to one who, like myself, has no money to invest.

But as the company is formed on what, I think, is the safest basis of investment in land, when the investor does not reside on the spot, viz., on a syndicate system, in which dividends are paid *pro rata* of the shares held after a lapse of half the time necessary for the produce plants to bear, it may be useful to point out that, in the case of a rubber plantation, which takes eight years, the coconut trees, the bearing cacao trees, the hardwood and the corn are made to pay full interest on the capital for four years, and a dividend after. On the Narva Estate, for instance, I see by the prospectus that at the start there are sixty acres of bearing cacao, equivalent to £1,200 a year, and coconut trees yielding nuts worth £750; while hardwood is expected to realise £400, and fifty acres of corn a further £200, in all £2,550, which is more than necessary to pay 8 per cent on the gross capital of the company in question, viz. £25,000; that this revenue increases to £3,000 the second year, £3,450 the third year, £4,800 the fourth year, and to £7,300 the fifth year, owing to enlarged acres of both bearing cacao and coconut trees. In the fifth year it exceeds, by £2,500 the cost of working the estate in that year, that cost, inclusive of interest, being estimated at £3,475 the first year, £3,930 the second year, £4,360 the third year, £4,915 the fourth year, and about the same in the fifth.

However correct these figures may be, they are so far reliable that, provided the cacao trees are bearing as well as the coconut trees, 8 per cent interest on capital is secure, though a deficit on working expenses, averaging £700 a year for four years, is expected.

But in the fifth year the balance of revenue covers that deficit and a dividend of 9 per cent becomes possible. The prospectus after that becomes aggressively alluring. Before the rubber adds its 100 per cent, the sixth year gives a dividend of 33 per cent, and the seventh year 44 per cent, and, although I am not quite capable of understanding such high profits, there is no reason, with the prices which cacao and rubber command, that this should not be realised, seeing especially that cacao is daily becoming more popular throughout the world as a nutritive beverage, and the demand for pure rubber is far in excess of the supply; and it will be interesting to note when the time comes how wise they have been who have asked of the soil and vegetation of Trinidad for returns equivalent to those of the best minerals elsewhere.

I have mentioned coconuts, and most people do not realise their value in the economy of nature.

In Trinidad these trees thrive particularly well, and especially so in the district of Mayaro, where the finest cocal, or coconut walk has curiously planted itself from nuts originally cast ashore from a wrecked vessel.

These trees bring forth a bunch of nuts every month, and the bunches average nine nuts each. Sixty good nuts go to a gallon of oil, and this gallon averages \$1, or 4s 2d. The yearly value of a coconut tree is therefore roughly set down at \$1, from which it will be seen that 9,600 coconut trees are sufficient of themselves to pay £2,000 interest, at 8 per cent, on £25,000.

In 1899 some 13,000,000 nuts were exported, representing 118,000 trees at least, and £45,000. As there are sixty nominal coconut estates in Trini-

dad, each estate exported on an average produce of the value of £740, and this sum, at 8 per cent, is interest on £9,250, a fact not to be despised when a coconut walk is advertised for sale.

I will not weary you with Indian corn or maize, which gives two crops a year, and is only inferior to wheat as a nutritive aliment; or with rice, which is imported to the extent of £150,000 a year, and could be raised in the island for more than twice that value, were there proper appliances to thresh and clean the grain; or with coffee, every grain of which finds a sale in the local market, as Verdant Vale can testify; or with tobacco, which has been pronounced as good as the Havana leaf: alas! the secret of the curing rests with the Cubans and no one else—nor of the fruit, which is a drug in the markets of the Colony, and awaiting the success of Messrs. Elder, Dempster & Co.'s plucky venture in Jamaica; nor, indeed, of the spices, vegetables, and other riches which the marvellous soil offers eagerly to all who seek them; but I will point out in a few words the mineral wealth of which the Colony can also boast.—*Journal of the Royal Colonial Institute.*

SCHOOL GARDENS AND NATURE STUDY.

MR. J. C. WILLIS' EDUCATIONAL LECTURE.

(Special Report.)

Mr. J. C. Willis, Director of the Botanical Gardens, Peradeniya, lectured to a large audience at the School of Agriculture last night on *School Gardens and Nature Study*. The chair was taken by the Bishop of Colombo. The lecture was of a different kind to those of the educational series that preceded it. It did not deal with the best and most practical methods of teaching particular subjects to junior classes: but had an altogether wider scope. It dealt with a new scheme for the teaching of Agriculture in Ceylon, a scheme already drawn up and ready to be put in practice. The lecturer did not begin at once by unfolding this scheme.

Mr. WILLIS began by laying stress on the need for improvement in agriculture in Ceylon, and by pointing out what sort of character must be developed before any improvement could take place. He said that at present all the efforts made by his Department to push the cultivation of plants that could with advantage be grown more largely here, such as cacao and cinchona, were unavailing owing to the resistance they met with through the ignorance of the people. There was also a constant waste of materials owing to this want of knowledge. In Jaffna, where there was less ignorance, the scanty soil was made to produce more than was produced by the richer soil of the South-Western Province. Constant complaints were being received by Mr. Green against insects as pests, when, in fact, these very insects were often not only harmless but actually beneficial to the plants. The only way to combat these and the many other evils of ignorance was by

THE TRAINING UP OF A MORE SCIENTIFIC SPIRIT.

There must be developed a capacity for taking accurate observations,

and for drawing accurate conclusions from them. It might be remembered, said the lecturer, that it was by close and accurate observation that Sherlock Holmes spun those wonderful theories of his, whose correctness was proved so conclusively in the Police Courts! For a proper scientific training there should be first accurate observation, then the collection of facts, then their classification, and lastly the deductions drawn from them and their application to life. The Germans were much ahead of us in their application of science to practical things. By their superiority in this, they had succeeded in crushing out the aniline dye trade in England, and they would very soon succeed in crushing the Indian Indigo industry as well.* Both with nations as well as with individuals, those who chose to neglect science must be content to fall behind in the world's race. It was in the training of those still at school that the greatest hope of improvement lay. Children were by nature more observant than adults, and their faculties of observation should be encouraged. It was with a view to this that

A SCHEME FOR SCHOOL GARDENS

had been brought forward by the Director of Public Instruction in conjunction with the Director of the Botanical Gardens. Though the scheme was new here, it was not in New York where Professor Bailey (?) of the Cornell University had made it a great success. The gardens should be quite small, and useful and ornamental plants should both be grown. The seeds would be supplied by the Botanical Gardens, and a travelling Superintendent would be sent to visit and examine these gardens from time to time. They should be made to look as pretty as possible, and every scholar should grow a plant by himself. Circulars as to the laying out of the gardens, and leaflets with lists of plants would be supplied by his Department, and the master and pupils should make out the plan of their gardens together. The products of the garden should be studied for object lessons. Leaflets to assist the teachers in this would be sent them. The object lessons would need preparation and should be as informal as possible. The pupils should also be taken out into the fields and jungle and should be made to describe the things that they had seen. If they made inaccurate observations, they should not be corrected, but should be sent back to examine the things afresh. No other person's observations should be accepted by them without their being proved by themselves.

FORMER SCHEMES

for agricultural teaching in rural schools had failed because too much had been attempted. Another reason had been that

* The German Company here referred to, is, we have ascertained, the Badische Co. Staufenfels. It employs 148 skilled chemists, 75 engineers, and 305 clerks, and makes a substitute for indigo by a synthetic chemical process. This product does not decay nor change its colour, and can be made much more cheaply than indigo can be grown.—This is how Germans make use of their technical education!—*Ed. T.A.*

that prices will improve. How is it—we ask—that the only scheme which met with any pronounced favour—the reduction scheme—has been so universally condemned? We have absolutely come to the end of our tether as regards quality. We can, and do, change the quality of our teas to meet the requirements of the markets, but we invariably make a thorough mess of it. The market howled for coarse tea and paid up to 6d. for it; with great joy, we responded. The extra duty was imposed, but tons of coarse tea were on the sea and in our tea houses—it had to go on.

Then came such foul abuse regarding quality that every decent manager began to blush, and it ended up by Mr. Skrine setting up a cry of "stinking fish." He got a special man to find microbes on *dry* tea. The tea they got hold of was dry, yet rotten. May the Lord help us and give us peace because, as the sentence goes, "there is none other to fight for us." I am speaking on behalf of tea managers, myself included.

I have done all that *can* be done. I have reduced my expenditure, and forfeited the greater part of my commission. If this state of affairs lasts much longer, the quality of my tea must suffer. I shall have to reduce rolling, and fuel, and labour in the tea house. My garden receives the minimum of cultivation, and will have to do with less. I shall soon have to reduce my own pay, or look for fresh work.

None of this is *my* fault, (I speak for hundreds of managers); the fault lies with *you*, (the owners). I tell you out straight that, unless you get a Cess, and a heavy Cess, your properties will be closed. Some of you, like Mr Rutherford, own properties that may weather *any* storm. Will you refuse help to us who have been less fortunate. Some of you have helped in the past, and are willing to help in the future, but naturally you do not move heaven and earth for redress. When it comes to the vote will you help us?

There is room for all, and for double our present area of tea. If Ceylon and India will combine and have a Cess worthy of the Industry we shall be able to conquer the Tea world.

If Ceylon will let good Indian tea in free of duty, she would be able to blend her poor teas and make them valuable.

COLOMBO SHOULD BE OUR DISTRIBUTING CENTRE FOR AMERICA AND AUSTRALIA AND RUSSIA IN EUROPE.

If it comes to a fight, India is *much* stronger than Ceylon. We shall be able, by means of cheaper labour, and bigger ventures, to crowd you out. You supply 37 per cent to our 53 per cent to British consumption. We shall be able to run you down—down—down as we did China, by being more capable of expansion than you are. It will be a dreadful fight, but we are bound to win. "We don't want to fight but by jingo if we do!" &c. &c. Again I appeal as a manager—to the owners; why cannot you agree? and pull together, and make our work *certain*?

Up to now, you—the owners directors, agents, of tea properties—have pocketed the proceeds. It is time now to think, and to think seriously; to formulate some plan and *stick to it*. In the past your managers have pulled you through each crisis as it came up. I have recently learnt the reason why we cannot help you any more. It is because there is only seven million pounds of China tea to be displaced in British markets.

We can no more prevent our expansion than can the school-boy. We stick out at each end and our chests are cramped by our clothes. You have to get us a new suit, and if you imagine that a new suit costing seven lakhs of rupees will cover our partial nudity you are mistaken. But it will relieve the pressure on the chest and let us breathe. I beg to be excused if I am too outspoken, or frivolous, or for any other fault. I understand that there is a crisis, a bitter fight for existence. I cannot understand this lethargy, this utter apathy, this heathenish way of sitting down to meet our fate.

We, the managers, have *trusted* the owners to find a solution of the difficulty. If they will not or cannot find it, we shall be better employed in serving men who *can* manage their business. If another war was to the fore, I believe that we could organize a managers' strike, and take the best brains out of the country. At present men are *waiting*; some of them will lose their reason from the strain, many their lives, and more their employment; a large proportion of owners and shareholders will lose their properties. A few will gain in the end, and tea will become an industry of bloated properties and trusts. Am I placing more than the truth before you? If so, the papers lie. I glean my forebodings from them. Have I exceeded my station by an inch? If so, it is for the benefit of my fellow-managers. We, the managers, cannot "strike," but let us speak out, and blow the consequences; nothing worse can happen than what we *have* to face in 1901, if our owners are asleep.

A. C.

COFFEE IN COSTA RICA.

(From an ex-Ceylon resident.)

Costa Rica, April, 1901.

Coffee planting and curing are carried on in this country in ways and under conditions peculiar to it. The only one which resembles it in some respects is the sister republic, San Salvador, as regards the size of the farms, and their being owned principally by native farmers who with few exceptions do all the manual labor necessary on their own lands, besides going out to look for work on larger estates when not too far off. The farmer sells his crop to different curing stations, and between these a lively competition has at all times existed, thus securing to the producer a lion's share of the profits, which would be much greater if he were to undertake to increase the productiveness of his land by an effective system of manuring, which alas is almost unheard-of, and cannot be hoped for. The present generation shut their eyes and ears to the most convincing of practical proofs. By this it can be inferred that coffee culture in general is not in a prosperous condition as regards crops produced, or prices of the same; the world's markets naturally being the cause of the drop in these of late years. With some exceptions, in the neighbourhood of the cities, the land under cultivation is owned by the small farmer who plants his coffee in lots which range from one acre upwards, and cultivates it in a manner which can well be termed orthodox, his principal implement being the broad shovel, in the handling of which he is an adept, so much so that no imported labour is employed to any extent, as all trials in this direction have resulted in failures. The cost of keeping up a manzana (1½ acre) is between 30 and 40 colones per annum and means four cleanings a

year in most cases, the colon being worth 46½ cents American gold; this means to larger estates where a day's work is the way labor is employed and paid for. In the centre of the republic native labor is scarce only at certain times—in June when the maize-fields have to be cleaned, and in October when summer beans are planted,—the labourer prefers to work in these districts for less wages than are paid on banana farms or in districts nearer the coast line.

MANURING AND PRUNING UNKNOWN.

As manuring may be considered almost an unknown feature, the same is true of trimming or pruning, it being almost impossible to follow the native farmer when at this kind of work, and establish a fixed idea, the tree in most parts being *shuck*, which becomes more scraggy in appearance as each succeeding crop is taken from it. There are ideas prevalent that the introduction of plantains and different kinds of shade trees are of benefit to the plantation, the first being an article of food, and therefore the origin of the idea; the latter, though planted with the object of giving shade to the coffee, is useful principally as a wind-break, during the dry months from Dec. to April, when the northerly winds are most violent, and also for firewood in some cases. Both however have their disadvantages, as at all times the plantain needs constant care to see that the stalks do not fall on the coffee, to say nothing of their being exhaustive of the fertility of the soil; while the cutting of firewood is also attended with damage to the coffee tree.

One crop of coffee is hardly picked and sold, before the farmer begins to think of

RAISING A LOAN

on the coming one, and has immediate recourse to some curing station, where it has long been the custom to make these advances for the purpose of securing as much as possible of the crops. This transaction, barring some risk, gives most of its advantages to the money-lender whose rate of interest is often 1½ per cent a month, sometimes more; capital and interest payable in coffee of stipulated good quality in fruit at current prices, the failure to deliver this incurs an additional fine of 20 per cent or more in case cash is taken instead of coffee; a backer's signature and pledge is exacted in all cases. This borrowing in advance has sent many a poor farmer to the wall, legal prosecution often following the non-fulfilment of such agreements.

Perhaps the most onerous laid on the farmer is the government

EXPORT TAX

which is levied when the coffee is shipped out of the country; it amounts to about one cent American gold per pound which means a considerable fraction of its value as prices are at present. No complaints are heard of, however on this point from the farmer, as it does not come from his pocket direct, but is paid by the exporter on whom he lays the blame of all reductions in his selling price. The daily papers often publish inflammatory articles in the same strain. When coffee begins to ripen, everybody is on the alert in ascertaining prices paid in the neighbouring stations, to make sure of not having to sell at a lower price than is possible, and soon afterwards men, women and children are out with baskets and cloths, some picking from higher branches, others from lower branches and what is on the ground, and everything is delivered to the

stations all of a rush, which puts some of the receivers into a squeeze to know how they can take care of it all. Picking is done in December on the lower levels of 2,500 and 3,000 on the Pacific slope, and in January on the upper levels of about 4,000 feet elevation.

The disheartening effects of

THE FALL IN PRICES

of coffee are felt alike by farmers and purchasers, many manzanas being abandoned of late years, on account of low prices and small crops; the first is unavoidable; the second, however, seems to have found a remedy in what few farms have practised,—chemical manuring. Coffee manured thus by a brand of manure well known in the London market yields 30 fanegas to the manzana, of high quality (the fanega, equal to 4 hectolitres giving 116 lb. of cleaned coffee), leaving clear profit of 300 colones upwards to the manzana. Taking coffee at its current price, as delivered in fruit, this cannot be called a low return, and is only an exceptional case on account of the use of manure. This being so, many owners of coffee estates near the capital have realised similar returns from land that was supposed to be exhausted long ago. The introduction of manures into the country is free of duty, and obtains also 33 per cent reduction in railroad freight. What is wanted, as Professor Voorhees expresses himself in the preface to his "First Principles of Agriculture," is the teaching of the use of manures in public schools according to practice and theory: every inhabitant of the country could have a manzana of his own whose yield would not alter the markets of the world one single point. As it is, the farmer in despair has abandoned some or all of his coffee, and has devoted himself to sugar-cane and yucca, the produce of which has to be sold in the Republic, both of them following the downward drop in prices. Indeed, some are at their wits' end to know what to plant, and talk about leaving off pants and taking to long shirts like the aborigines. In the interior of the country coffee may be said to be the only exportable product, and this is the part of the country where the farmer will always live if he can.

When coffee was at a good price, four and five years ago, several large lots of land were taken up on the Atlantic slope close to the railroad by capitalised firms, principally in the Turrialba and Juan Ninias districts: at elevations of 2,500 and 3000 feet. The climate, one of almost continuously daily rainfall all the year round, is not favourable to the development of a single uniform crop, as on the Pacific slope, but has to be picked two or three times a year. The price of labour is here fifty per cent and seventy-five per cent higher also; and last, but not least, the quality of the produce after a few crops does not fetch such good prices as at the start, blights in the crops being often heard of.

[There is no hope for coffee, we fear, until Brazil abates her enormous crops, larger this year than ever before. But has our correspondent never seen "cacao" in Costa Rica? It is said to be the home of certain kinds and that the people cannot grow enough for local consumption, so keen is the demand in the towns. That then (*Theobroma Cacao*—the cocoa or "chocolate" plant) ought to be a profitable product in rich soil, though it cannot stand wind.—ED. T.A.]

THE "MASHEER" IN NORTHERN INDIA.

Local fishermen have heard of the Mahseer, if they have not all seen it; and although there have been many proposals in the past to introduce the fish into our streams from India, we do not think that any have been successfully carried out. It may interest members of our Fishing Club and other sportsmen, however, to learn that sportsmen in Northern India have been obliged to take steps to protect the Mahseer from extinction in the rivers of the Punjab, where they have been systematically netted for years at all seasons, with disastrous effects on the supply. The Giri river is nominally preserved by the Sirmoor Fishing Club; and as the income of the Club had for several years fallen short of the expenditure—probably through the forgetfulness which obtains here, too, on the part of many members to pay their subscriptions,—the Committee resorted to the extraordinary expedient of letting portions of the river to netting contractors! As was to be expected, the contractors went beyond the contract, and outsiders joined in the game, until the river was almost depleted. Netting has now been prohibited, the Club has improved its financial position, and the Sirmoor State, to which the Club pays heavy rental, has been asked to lend a helping hand to stop poaching.

The river Poonch, which once had a large stock of the largest Mahseer in India, is in a worse state; and there, writes an Indian contemporary:—

"For the past two years a contractor has come from Jhelum, armed with a permit signed by some local official in the Jammu State, and has proceeded to net the whole of the pools and runs between Tangrot and Nar, a portion of the river in which nine-tenths of the mahseer in the Poonch hibernates. With the last closing showers of the monsoon the fish drop down from the upper waters, and the long reaches below Nar, the Pota pools, the famous water below the fantastic cliffs of Palak, and, above all, the Jungoo pool close to Tangrot, are their refuges. In the cold weather the Jungoo pool presents a wonderful spectacle, being filled with thousands of huge mahseer in a semi-comatose state, packed as close as sardines. They begin to assemble in September, and by the end of October the pool is full. Late in February, or more usually about the middle of March, the first slight spates come down the Poonch, and this is the signal for the mahseer at Jungoo to begin to work upwards. The same state of things holds good in the other pools of the lower portion of the Poonch. When, therefore, a band of men armed with nets, and with unlimited time at their disposal, proceed to clean out pool after pool, sparing nothing, it is easy to conjecture the enormous damage done to the river. During the summer time the large mahseer would probably succeed in breaking all ordinary nets; but in the winter they are overtaken by a strange species of lethargy, and lie for days together at the bottom of the pools without moving."

The Mahseer weighs up to 50 lb and affords excellent sport, and we can sympathise with those who complain of operations which sweep one pool after another of all fish. No less than 200 maunds of Mahseer are said to have been taken by nets out of two pools

last winter. The local Government should help our sportsmen to establish the Mahseer in some of our Ceylon rivers?

"MATÉ" TEA.

(From the *Encyclopædia Britannica*.)

Maté, or Paraguay Tea, consists of the dried leaves of *Ilex paraguayensis*, St Hil.,* an evergreen shrub or small tree belonging to the same natural order as the common holly, a plant to which it bears some resemblance in size and habit. The leaves are from 6 to 8 inches long, short-stalked, oblong, wedge shaped, rounded at upper end, and finely toothed at the margin. The small white flowers grow in forked clusters in the axils of the leaves; the sepals, petals, and stamens are four in number; and the berry is 4-seeded. The plant grows abundantly in Paraguay, Corrientes, Chaco, and the South of Brazil, forming woods called *yerbales*. One of the principal centres of the maté industry is the Villa Real, a small town above Asuncion on the Paraguay river; another in the Villa de San Xavier, in the district between the rivers Uruguay and Parana.

Although maté appears to have been used from time immemorial by the Indians, the Jesuits were the first to attempt its cultivation. This was commenced at their branch missions in Paraguay and the province of Rio Grande de Sau Pedro, where some plantations still exist and furnish the best tea that is made. From this circumstance the names Jesuits' tea, tea of the Missions, St Bartholomew's tea, &c., are sometimes applied to maté. Under cultivation the quality of the tea improves, but the plant remains a small shrub with numerous stems, instead of forming, as in the wild state, a tree with a rounded head. From cultivated plants the leaves are gathered every two or three years, that interval being necessary for restoration to vigorous growth. The collection of maté is, however, chiefly effected by Indians employed for that purpose by merchants, who pay a money consideration to Government for the privilege.

When a yerbal or maté wood is found, the Indians, who usually travel in companies of about twenty-five in number, build wigwams and settle down to the work for about six months. Their first operation is to prepare an open space, called a *tatacua*, about 6 feet square, in which the surface of the soil is beaten hard and smooth with mallets. The leafy branches of the maté are then cut down and placed on the *tatacua*, where they undergo a preliminary roasting from a fire kindled around it. An arch of poles, or of hurdles, is then erected above it, on which the maté is placed, a fire being lighted underneath. This part of the process demands some care, since by it the leaves have to be rendered brittle enough to be easily pulverised, and the aroma has to be developed, the necessary amount of heat being only learned by experience. After

* Mr J Miers has proved that *I. cuitibensis*, *I. gigantea*, *I. ovalifolia* *I. Humboldtiana*, and *I. nigropunctata*, besides several varieties of these species, are in general use for preparing maté.

drying, the leaves are reduced to coarse powder in mortars formed of pits in the earth well rammed. Maté so prepared is called *caa gazu* or *yerva do polos*, and is chiefly used in Brazil. In Paraguay and the province of Parana in the Argentine Republic the leaves are deprived of the midrib before roasting; this called *caa miri*. A very superior quality, or *caa cuys*, is also prepared in Paraguay from the scarcely expanded buds. More recently a different method of drying maté has been adopted, the leaves being heated in large cast iron pans set in brickwork, in the same way that tea is dried in China; it is afterwards powdered by machinery.

The different methods of preparation influence to a certain extent the value of the product, the maté prepared in Paraguay being considered the best, that of Oran and Paranagua very inferior. The leaves when dried are packed tightly in serons or oblong packages made of raw hides, which are then carefully sewed up. These shrink by exposure to the sun, and in a couple of days form compact parcels each containing about 200 lb of tea; in this form it keeps well. The tea is generally prepared for use in a small silver-mounted calabash, made of the fruit of *Crescentia Curate* (Cuca) or of *Cucurbita lagenaria* (Cabaco), usually about the size of a large orange, the tapering end of the latter serving for a handle. In the top of the calabash, or *maté*,* a circular hole about the size of a florin is made, and through this opening the tea is sucked by means of a bombilla. This instrument consists of a small tube 6 or 7 inches long, formed either of metal or reed, which has at one end a bulb made either of extremely fine basket-work or of metal perforated with minute holes, so as to prevent the particles of the tea leaves from being drawn up into the mouth. Some sugar and a little hot water are first placed in the gourd, the yerva is then added, and finally the vessel is filled to the brim with boiled water, or milk previously heated by a spirit lamp. A little burnt sugar or lemon juice is sometimes added instead of milk. The beverage is then handed round to the company, each person being furnished with a bombilla. The leaves will bear steeping about three times. The infusion, if not drunk soon after it is made, rapidly turns black. Persons who are fond of maté drink it before every meal, and consume about 1 oz. of the leaves per day. In the neighbourhood of Parana it is prepared and drunk like Chinese tea. Maté is generally considered disagreeable by those unaccustomed to it, having a somewhat bitter taste; moreover, it is the custom to drink it so hot as to be unpleasant. But in the south-eastern republics it is a much-prized article of luxury, and is the first thing offered to visitors. The *gaucho* of the plains will travel on horseback for weeks, asking no better fare than dried beef washed down with copious draughts of maté, and for it he will forego any other luxury, such as sugar, rice, or biscuit. Maté acts as a restorative after great fatigue in the same manner as tea. Since it does not lose its flavour so quickly as tea by exposure to the air and damp, it is more valuable to travellers.

* The word *caa* signified the plant in the native Indian language. The Spaniards gave it a similar name, *yerva*. *Mate* comes from the language of the Incas, and originally means a calabash. The Paraguay tea was called at first *yerva do mate*, and then, the yerva being dropped, the name *mate* came to signify the same thing.

Some writers attribute deleterious effects to its use, while others praise it to an almost incredible degree. Its physiological action does not appear to have been carefully worked out, but its extensive use in countries where tea and coffee are known seems to indicate that it may possess virtues peculiar to itself.

Its properties appear to be chiefly due to theine or caffeine. Analysed by Dr H Byasson, 100 grains were found to yield.

	Grains.
Caffeine	1·850
Glutinous substance or peculiar fatty matter and colouring matter ...	3·870
Complex glucoside	2·380
Resin	0·630
Inorganic salts, including iron ...	3·920
Malic acid not estimated.	

According to analyses made by Alonzo Robbins it also contains about 1·5 of a peculiar tannin which does not precipitate potassiotartrate of antimony, nor tan leather. The glutinous substance resembles in consistence common birdlime, and is considered by Byasson to be a compound ether, the alcohol of which would be near cholesterin. Since the beginning of the 17th century maté has been drunk by all classes in Paraguay, and it is now used throughout Brazil and the neighbouring countries. In 1855 the amount of maté annually consumed in South America was estimated by Von Bibra at 15,000,000 lb, and the consumption is now probably three or four times as great; in Brazil it brings in a revenue of about £410,000. In the Argentine Republic alone the consumption is not less than 27,000,000 lb per annum, or about 13 lb per head, while the proportion of tea and coffee consumed is only about 2 lb of the former and $\frac{1}{4}$ lb of the latter per head. The export of maté from Brazil to foreign countries has also increased from 2,720,475 kilos in 1840 to 5,236,485 kilos in 1850, 6,808,056 kilos in 1860, 9,507,086 kilos in 1870, and 14,063,731 kilos in 1879-80.

TEA SEED OIL.

We are much indebted to Mr. Collett for his opportune letter on the subject of tea seed oil. We had rather more than a little doubt as to the prospect of its proving a more paying product than tea in even a few cases; but Mr. Collett finds from practical experience that not only is it not advisable to change non-paying tea-fields into seed-bearing plots for the purpose of oil production, but that even the plucking of the seed and production of oil from abandoned fields will not yield a profitable return. It will, in view of these results in Ceylon, much surprise us if Mr. Drummond Deane obtains satisfactory returns and we await the news of how his forthcoming shipment of tea-seed oil is received, with considerable interest. The *Encyclopædia Britannica* speaks of the oil as follows:—

Tea-seed oil is a commercial product in China, where it is used for food, lighting, and soap-making. It is said to yield a fine hard soap. The oil contains 75 per cent. of olein and 25 parts of stearin, has a yellow colour, and is destitute of taste and smell.

PRODUCE, PLANTING AND
COMMERCIAL NOTES.

An endeavour is being made in the United States by firms prominently identified with the Japanese tea trade to form a big combination in order to control the market. We learn from one American journal that the object is to "do away with the ruinous competition which the trade has recently been undergoing, which has placed Japan tea at a distinct disadvantage with the China and other teas which are fired and packed by natives." We like the term "other teas"; perhaps the firms who wish to establish a Japanese tea trust are sensitive on the subject of Indian and Ceylon tea in general and the green tea movement in particular.

The following letter from Mr P C Larkin, of Toronto, written to Mr Mackenzie, on reading in our columns the report of the Ceylon Commissioner on the American tea market, is of interest. He says:—"I have read with a great deal of interest your letter in the *Home & Colonial Mail* of May 17th. Mr Drummond, of the Anglo-American Direct Tea Trading Company, Limited, was good enough to bring it over to me. With regard to the figures which you gave as being the quantity of greens we take per month from Whittall and Co., you could have increased these one-fifth, as they ship us every month at least 24,000 lb. of Ceylon green tea. In addition to their shipments, we have bought many hundreds of chests from Odell, Crosfield and Lampard, and others. You know what I have been predicting for the last eighteen months; that is, that these Ceylon greens will entirely displace Japans in America. This is surely coming to pass. It may take twenty-five years or five years, just as the planters wish. If the Indian planter would do just as I, and dozens of other advertisers, do, viz., advertise, advertise, advertise, it would bring about the desired state of affairs in a very short time. If they don't advertise it will take them a mighty long time, however superior their goods may be in quality. I have shown you an instance up in North Bay. There is a firm up there who, under great persuasion, took a few pounds of Ceylon green tea with their black tea order. We got a list of names of Japan tea drinking customers, and sent out sample lead packets to them. This brought about sales, and made them fairly enthusiastic about our Ceylon greens, as they had been about our "Salada" blacks for some years. They said they could sell very large quantities of the greens, and displace Japans with them, if we would do something towards advertising. Well, I've shown you what we did. We subsidised them to advertise in their local paper, and you have seen the full pages and half-pages they have taken at different times to advertise our Ceylon greens. What has been the consequence? They have had three 500 lb. orders, the originals of which have all been sent on to you. Now that is only one very, very small point in our whole territory; and we cannot afford to subsidise all over, as you know; but it should be done by the Ceylon and Indian planters from one end of America to the other. There is a whole district around about North Bay now where the people are interested in Ceylon green tea, and who are drinking it; and Japan teas there have been displaced. It was experimental on our part, the subsidising of this firm, and we have shown

you the results. It may be said that the planters cannot afford to advertise. Neither can I afford to do so, but I can still afford less to drivel. I note some remarks in your letter about 40,000'00 dols or 50,000'00 dols per year. It is not forty or fifty thousand dollars per year you want to exploit the United States and Canada properly, but six times forty or fifty thousand dollars, so that every newspaper will be full of Ceylon and Indian Tea, samples will abound, and so that the matter will be forced upon the attention of the whole people of the country in a very short period. This would bring about such a relief to the London market that teas would be a penny per pound higher than they otherwise would be. I am awfully glad that you look favourably on my suggestion of Ceylon teas of Oolong flavour. If this can be done it will be making our path still easier, and when they have succeeded in making such admirable greens I fancy they can produce anything in the tea line. If we had had greens in Canada here nine years ago, when I took up blacks, what an easy path we would have had, compared with what we have experienced. The same may be said of the last four or five years in the United States. Our sales there would have been at least double what they are now. A drinker of Oolong is just as much wedded to his peculiar kind of tea as a drinker of Japan is to his kind, or as a drinker of black is to his, and they can only be weaned away from their kinds by the greatest efforts, and it requires but one-fiftieth of the efforts to produce results when you are offering them a tea of a similar flavour and kind."

Last week we quoted some comments from the *Globe*, referring to Indian and Ceylon tea companies. These comments have called forth the following reply from Mr. George Seton, who, writing to the *Globe*, says: "A paragraph in your issue of the 28th instant with reference to Indian and Ceylon tea companies seems likely to lead to misapprehension. Owing to excessive extensions of the plantations during the good times, and to consequent over-production, tea prices have dropped very low, and results to tea companies last year are poorer than previously. Estates producing high-class tea, and those with a low cost of production, have done pretty well; but those with a weak financial position, or whose expenses of administration were high, have done poorly. The home market is at present over-supplied with tea, but foreign and colonial markets are every year taking off increasing quantities, and this was especially the case last year. British investors who purchased shares at top prices are no doubt disappointed, but up to 1898 they received good dividends, and they will doubtless do so again. Dividends, recently announced for 1900, have ranged from 15 per cent. down to nil. Share capital of 45 representative companies, whose market value rose in 1897 to 12½ millions sterling, has now dropped to little over seven millions! An endeavour has been made to collectively restrict production, but it has been found impossible to form a combination, as has been done in the nitrate-producing trade. Restriction of output, however, is being largely adopted by the leading companies, and all extensions, it is believed, have been stopped. Under these circumstances, then, the trade is likely, eventually, to recover its prosperous condition."

DISEASE IN PLANTS.

When a doctor is summoned to the bed-side of a patient, he listens attentively to the narrative given by the sick man or his friends, forming meanwhile his own general impressions from the aspect of the patient, and from what he sees and hears. These preliminary proceedings are generally quite inadequate, and, so far as the account and especially the theories framed by the patient are concerned, almost always misleading if not wholly incorrect. Having gained as much information as possible in this way, and having made the necessary allowances, the doctor proceeds to investigate "the case" for himself. He learns all he can about the family history, mode of life, and "constitution" of his patient; what previous illness he may have suffered from; when, and in what manner the present sickness began, and what has been its progress. Having thus obtained a general knowledge of the state of affairs, the doctor proceeds to investigate, in due and regular sequence, the condition and working of the several organs of the body. And not till he has made this through investigation of "signs" that he sees and can personally detect, and of "symptoms" that are made known to him by the patient, does he venture on either diagnosis, or prognosis; still less, unless he be a quack, on methods of treatment.

Neither the patient nor his friends desire, or could in most cases appreciate, the inductions that the doctor makes. They wish to know, in general terms only, what is the matter, what are the prospects of recovery, and what are the measures to be taken to secure that end.

Plant doctors up to this time have been too communicative, and not sufficiently practical. If they see a fungus they forthwith measure its spores in fractions of a millimetre, they compare it with other organisms of a similar nature, and they draw up a highly technical description, which is quite unintelligible and equally useless to the persons for whose benefit it is supposed to be framed. Now, we are far from wishing to depreciate these proceedings. For purposes of scientific research they are absolutely essential. It is likewise essential that the fungi be cultivated by the plant doctor, and their life-history accurately studied, as upon the information so obtained depend in most cases our methods of combating disease or preventing its onset. This cultivation takes time, and hence it is not always possible to give an immediate or even a speedy answer to enquirers. But the details to which we have alluded are appropriate only to the student. The busy cultivator has not the time nor the means to make the necessary investigations. He wants general results, and specially indications for treatment.

Many, perhaps we may say most, treatises and papers hitherto written have been drawn up by experts, with too little attention to the requirements of cultivators. A book now before us proceeds to a large extent on different lines.* The very title, "*Disease in Plants*" (the italics are ours), indicates this. No one is more competent to compile such a book as this than Prof. Marshall Ward. The work is apparently based on a series of lectures, though we are not expressly told so; nevertheless, the following passage shows the intention of the writer:—"The purpose of these essays [is] to treat the subject of disease in plants with special reference to the patient itself, and to describe the symptoms [signs] it exhibits and the course of the malady, with only such references to the agents which induce or cause disease as are necessary to an intelligent understanding of the subject, and of the kind of treatment called for." The first part is devoted to an admirably clear and concise account of the living plant and what it does, to the biology of the soil—a comparatively new but most important subject, and to a short account of hybridisation and selection.

* *Disease in Plants*. By H. Marshall Ward, Sc. D. (Macmillan & Co.)

Part II. is devoted to diseases in plants, their causes, nature, diffusion, and the remedial measures to be adopted. Sundry chapters are given to "symptoms" of disease, which in medical phraseology should be "signs," and these should be attentively read by cultivators. The inclusion of scale-insects among symptoms seems rather incongruous, but this is a matter of little moment. "Silver leaf" disease, characterised by the detachment of the epidermis from the subjacent tissues is, in our experience, confined to members of the Rosaceæ, and is as common out-of-doors as under glass, so that we do not think it has any special connection with hot summers. Not only are plants considered in their medical aspects, but their surgical injuries are also discussed, such as wounds of various kinds, including the burrowing excavations made by certain insects in leaf or branch. Among excrescences we do not find mention made of the warts on the under surface of Vine-leaves, which are so common in vineries where the proper balance between temperature, moisture, and ventilation is not maintained. Under "Gummosis," we do not find any reference to Beijerinck's observations on *Coryneum*.

The chapter on Life and Death is full of suggestive matter; the more so, as we know of but one book intended for the use of cultivators that deals with this subject, and in that only in a much less complete manner than in Prof. Ward's book.

The book has copious references to the literature of the subject, but these are not always sufficiently explicit; for instance, to cite the *Gardeners' Chronicle* without specifying the date of publication and page, is simply to embarrass the enquirer. The author has evidently been hampered by his desire to keep the book within convenient limits, a circumstance which has led to undue concision; but, on the whole, we have nothing but praise to bestow upon a book which will be so useful to the intelligent cultivator that no garden library should be without it.—*Gardeners' Chronicle*, May 18.

MOSQUITOS AND EUCALYPTUS.

The *British Medical Journal* doubts the wisdom of the proposal by the Sanitary Department of Havana to plant eucalyptus trees in all the marshy and malarial districts in and around Havana as a mosquito deterrent. The journal in question points out that in a paper by Prof. Celli, which appeared in the *Journal of the Sanitary Institute* for January, that distinguished authority says that the eucalyptus, so far from being protection, is, like other trees, rather a shelter for mosquitos, and in the neighbourhood of dwelling-houses adds to the danger of malarial infection.—*Globe*, June 7.

CEYLON VERSUS BAVARIAN GRAPHITE.

This mineral, which is now much in request as a lubricator of machinery, is one of the most valuable products of Bavaria, the only formidable competitor in the supply of natural graphite being Ceylon. The production of graphite in Ceylon has, however, diminished, causing a great rise in prices, as the deficit could not be made good from other sources. The Bavarian graphite is inferior to the Ceylon product, as, while the latter is nearly pure, the former has about sixty to seventy-five per cent. of earthy substances mixed with it. With Bavarian methods, it is stated, there is a great waste of raw material, and it is alleged that nearly ninety per cent of the mineral is absolutely thrown away, owing to the short-sighted and unscientific system of working.—*United States Consular Report*.

AGRICULTURAL EDUCATION IN CEYLON.

(Extract from Report of Director of Public
Instruction for 1900.)

SCHOOL GARDENS AND ELEMENTARY HORTI- CULTURE.

An order was issued several years ago that every Government school was to have a garden, but nothing was done to introduce method into the general scheme, and, although a few of the most intelligent schoolmasters set to work on practical lines, in the large majority of cases the effort stopped short at a few unsuccessful crotons. The scheme now gradually being developed is (1) to select in each Province those schools where, owing to climatic circumstances and space, a garden can be profitably developed and to let the other schools alone for the present, (2) to keep two objects in view, the picturesque and the utilitarian: to cultivate the ideas of taste, neatness, pleasant surroundings on the one hand, and on the other, in consultation with the revenue officer and headmen, to discover what economic products do best in or ought to be introduced into the neighbourhood, and to devote a large section of the garden to these, (3) to start supply gardens at various centres for the issue of seeds, cuttings, &c., (4) to appoint a special Inspector of Gardens who will take charge of the supply gardens, visit all the selected school gardens in turn, instruct the teachers how to instruct the pupils and what points to pay special attention to, and give a few elementary lessons in school on practical horticulture and botany. The Director of the Royal Botanic Gardens has given the scheme his warm support and his advice has been closely followed. The matter is one of great and growing importance. Whatever may be argued as to teaching the natives agriculture, there can be little doubt that in horticulture (especially as concerns manure, rotation, new products, &c.), there is a great deal they can be profitably taught if the education is practical and the scheme removes from our State educational system one of the chief reproaches levelled against it,—that it is mere book-learning and of no practical utility.

SCHOOL OF AGRICULTURE: BY MR. C. DRIEBERG.

The number of students on the roll was, as in the past few years, kept low by the continued uncertainty as to the future of the institution, and the persistent rumours of its impending abolition. For the year under review it was 16, made up of 6 seniors and 10 juniors. On the results of the final examination held in November, two students became entitled to first-class certificates granted by the Department of Public Instruction, and one to a second class certificate. M.D.S.A. Wijeyenayaka and E. Jayatilak, old boys of the school, have been appointed stock inspectors.

Another Commission, distinct from that referred to in my last report, was appointed to deal specially with the question of the continuance of the school.

The recommendation of this Commission was to the effect that the School of Agriculture, as at present constituted, should be closed at the earliest opportunity; this will probably be on the 31st March, the end of the first school term of the year.

A scheme for establishing an experimental garden, and, possibly, scientific agricultural classes, in connection with the Royal Botanic Gardens (the staff of which has been augmented by the appointment of a number of scientific experts), and another distinct scheme for agricultural instruction through the children of village schools, by means of nature study lessons and school gardens, are under consideration. The developments under either scheme will be for further reports to deal with.

The experiment in bee-keeping continues, as must needs be with a pioneer industry, slowly, but with it a knowledge of the habits and instincts of our Ceylon bees is gradually acquired.

The school premises became the headquarters of the Paris Exhibition Committee's operations. I myself was connected with the Committee as Assistant to the Secretary-General (afterwards Delegate for the Ceylon Government at Paris). The work of organization, and particularly the collection and classification of the vegetable products of the island, proved of special interest, and served as a useful medium of instruction to the students of the year, who themselves helped me a good deal.

The "Agricultural Magazine" completed half its 12th volume at the end of the year.

The rainfall registered at the school was as follows:—January 4.83, February 3.50, March 1.17, April 16.01, May 11.11, June 7.71, July 7.47, August 79.6, September 7.12, October 11.85, November 6.98, December 6.95. This makes a total of 91.02 inches for the year. For purposes of comparison I give the rainfall as recorded in the Fort, viz., 83.63.

Of the forty acres originally attached to the Dairy about six acres were put up for public sale by the Government Agent of the Western Province, and the land sold (about four acres) realized Rs. 3000 per acre. The land is to be utilized for building purposes.

SCHOOL GARDENS, NATURE STUDY, AND AGRICULTURAL TEACHING.

By Mr. J. C. Willis.

The most practical means of influencing the agricultural practice of the country for the better, and of introducing new products and ideas, is by working through the children at school. I think a system of school gardens, supplied from the Royal Botanic Gardens with the best kinds of plants, cultivated by the teachers and students, and used as object lessons by the former, aided by leaflets issued by the staff of the gardens for their guidance, and, if it can be arranged later, by actual lessons given by the staff to teachers, offers fair prospects of success and usefulness.

The opening of these school gardens and their stocking with good fruit, vegetables, &c., is sure to lead to the gradual introduction of new cultivations into the villages, and the stocking of the gardens from the Royal Botanic Gardens will ensure that these new introductions are good of their kind. In so far as these cultivations are concerned, the school gardens may be used to give a certain definite amount of agricultural instruction, but in general they should never be regarded as organizations for the teaching of agriculture. The teachers are not themselves sufficiently qualified to teach agriculture or to criticise methods already in use in the villages. The aim of the gardens should rather be what is now called "Nature Study," the inculcation of habits of observation and induction among the pupils. Such training will render such pupils much more capable when older of appreciating definite agricultural instruction, and will render them able to criticise intelligently the methods they employ in the actual cultivations that they may carry on in after life. They may be taught the reasons why such or such an operation is performed, and performed in such or such a way, but they should never be given definite instruction in the cultivation of staple products; to do so will be fatal to the success of the scheme.

School gardens should cultivate ornamental as well as useful plants, and pupils should be encouraged to do the same. A few gardens should first be selected for trial; these might be visited by the officers of the Royal Botanic Gardens, and the general plan of laying out and gardening decided. The seeds and plants should be supplied from the Botanic Gardens, planted and attended to according to instructions by the school teachers and scholars. Object lessons should be given at occasional intervals, and experiments carried on upon lines to be indicated in leaflets previously issued, and the teachers should never try to give these lessons or try the experiments with the pupils till they themselves have previously mastered them.

The following titles are suggested for such leaflets:—

How a pumpkin plant gets out of the seed.	The soil.
Cuttings.	Seed travellers.
Children's gardens.	Why must plants be watered?
Annual flowers.	The growth of a rice plant.
The planting of school grounds.	The flower, what it is.

Many interesting entomological subjects can also be used.

Only a few kinds of plants should be cultivated in any one garden, and new ones should only, as a rule, be distributed one kind at a time.

Children should be encouraged to grow plants at home, and new kinds be given to those who do well. The work done should not be made the subject of examinations. Children should be encouraged to observe accurately, and to record in writing and with drawings what they observe.

A book should be kept at school in which the dates of planting and the subsequent history of all the important products may be recorded. Much valuable information about the districts, climates, and soils suitable for such products may thus be collected.

One-third of the produce of each garden should be the property of the teachers in charge, another third be given to the pupils, and the remainder, after deducting what is needed for seed in the following season, be the property of the Department of Public Instruction, for distribution to other schools. What is not wanted for this purpose should be returned to the Botanical Gardens.

TROUT, DEER, AND INDIAN ELK IN NEW ZEALAND.

There were liberated in rivers in the Wellington acclimatisation district this year 46,000 brown trout and 15,000 rainbow trout—a total of 61,000. There were 80,500 fry sold to other societies—29,000 brown, 39,000 rainbow, and 12,500 Loch Leven. The total quantity of ova collected by the curator of the Masterton ponds was 700,000. Of these 10,000 were from "fontinalis," 25,000 from Loch Leven, 65,000 from "rainbow," and 600,000 from brown trout.

Mr. Grogan, the African traveller, it was stated at the meeting of the Wellington Acclimatisation Society last night, is very much struck with the extent of waste country in New Zealand suitable for such animals as African deer, and as it is the intention of the society to import deer of this description, the council will probably interview Mr. Grogan on the subject when he returns to Wellington.

The annual report of the Wellington Acclimatisation Society states that sambar (or Indian elk) were liberated on Carnarvon estate many years ago. The herd is now reported to number about 100, but there is good reason to think that they are really more numerous. That they are slowly but surely distributing themselves over the country most suitable for them is evidenced by a report just received by the Auckland Acclimatisation Society to the effect that a pair of sambar antlers had been found on the hills near Cambridge, and that two sambar had been shot there. No sambar have been liberated in the North Island except at Carnarvon, and these deer must of necessity have travelled overland from there, a distance of about 200 miles. The four moose imported by the Government, and liberated near Hokitika, have been seen several times, and are

reported to be looking well. The society's council contemplate importing some varieties of deer from South Africa, and hope to be able to get the Government to assist them in this venture.—*N. Z. Mail*, May 23.

PLANTING MANUALS AND OTHER LOCAL PUBLICATIONS.

Taking advantage of his freedom from the daily treadmill, Mr J Ferguson has been revising the manuals on "All about Spices" (Pepper, Cubebs, Nutmegs, Cloves, Ginger, Vanilla, Pimento and Cinnamon) and "All about Tobacco-growing and preparation"—both of which have been out of print for some time. He is also desirous of completing a Paper on the "Rise and Progress of Coconut Palm Cultivation in Ceylon,"—the material for which he has been collecting for a long time past. Any further information bearing on the above products or subjects from planters and others will be very welcome and may be addressed to "Naseby House, Nuwara Eliya."—The completion of a new edition of the popular Handbook to "Ceylon" (Ceylon in 1902) must come later. Copies of the recent editions of the Manuals on "Rubber and Gutta Percha" and on "Coconut Planting" are still available. The *Observer* Press is at present busy with reprints of two very useful little works, namely,—a new (the Fourth) edition of Dr. Vanderstraaten's well-known "Index of the Diseases of Children in Ceylon and their Treatment" with several additional Notes by the author; and also a Fourth Edition of "Cookery for Ceylon"—locally compiled, the recipes being given in Sinhalese and English, the *brochure* being dedicated to all house-keepers, cooks, &c—A new edition is also required of the handy pamphlet, published at the *Observer* Office, on "Gardening Vegetables, Flowers and Fruit in Ceylon" in the compilation of which the late Messrs. W Ferguson, F.L.S., and H Sims and Messrs. W Cameron and W Nock took a part. Due notice will be given of the completion of these works.

THE TEA TRADE.

MESSRS. THOMPSON'S ANNUAL REVIEW.

38, Mincing Lane, June, 1901.

In the statistical record of the twelve months, ending 31st May, which we print at foot, will be found much that is of interest, and even a little that is encouraging amidst the disappointments which so many have suffered.

The figures show the great producing powers of Indian and Ceylon plantations; unlooked for vitality in China's export trade; a larger volume of business than ever before, but—a decline in the average value of our product, so considerable as to seriously affect the welfare of nearly everyone connected with the Industry.

As a year ago, so now, the statistics relating to Home Consumption have been disturbed by the heavy clearances before the Budget, and do not enable us to gauge what increase there has been, if any. We incline to the opinion, however, that consumption is increasing, notwithstanding the raising of retail prices, necessitated by the advance in the duty. That the proportion of British-grown tea used has increased is certain.

But important as this would be if supply and demand were evenly balanced, it is of comparative insignificance at the present juncture, for production has outstripped the combined requirements of home and foreign markets, and a limit has been found, for the present, to the quantity that can be taken at prices that will pay the producer.

To this untoward fact the decline in value must be directly attributed. The fall would probably have taken place eighteen months ago, if it had not been for the heavy speculative transactions in anticipation of the Budget of 1900; it has been accentuated by the re-assertion which followed, by the strain upon the Traders' resources caused by the high duty, by the heavy and poor crop, and to some extent by the use of unsuitable chests.

An opinion is held by some that economy has perhaps been pushed further than is wise, but we do not propose to tread upon this debatable ground, or to dwell upon market fluctuations, exchange, the rainfall or the temperature, or to discuss those details of administration and manufacture which rightly occupy the attention of Managers—preferring to pass to the consideration of broader issues.

Stated in the fewest words these issues are—improvement of quality, restriction of quantity, consolidation of interests, the development of new markets, and the outlook for our home and export trade.

To revert to a higher standard of quality, where it is possible, appears to us of primary importance. The stocks held everywhere consisting of inferior tea, the turn for a finer crop has come; London and Provincial buyers ask for it and will handle it with more confidence, whereas they regard with foreboding the possibility of another large and common one. It is quite true that trade has been stimulated in the past by abundant and cheap supplies, but a low quotation alone, without merit in the tea itself, no longer brings new customers, and a larger business without profit benefits no one but the shipowner, the warehouse-keeper, and the Custom House.

We emphasise the need of listening to what the Home Trade say, because they are in touch with consumers; while taking, as they do, 80 per cent. of the total output of India and Ceylon they ultimately determine the value of the whole, wherever sold or however distributed.

Methodical and deliberate curtailment of quantity is of almost equal importance. An agreement between a large number of planters to effect it would have been a useful addition to the measures which others are going to take in their own interest; but the reasons of those who were unable to bind themselves in the manner suggested are quite intelligible, and after all, it might have failed of its purpose if it had led managers to regard it as the one panacea for all ills, and to relax their efforts to make better quality. Its failure, however, is an additional reason for those who know that they can make finer and more valuable tea to do so, and not be turned from their purpose if they hear that a shorter supply has improved the position of low-priced teas without benefiting fine—an eventuality for which they must be prepared. It may be that, if managers were not required to make estimates before the season has commenced, or at least if their estimates were not published, they would be less tempted to realise them at all costs, when, perhaps, they ought to be doing just the reverse.

The amalgamation of separate and sometimes of conflicting interests might make it easier to unite in pursuit of a common policy. The process is capable of development—not necessarily in the form of a Trust but preferably on the lines of some of the older associations under one strong central management and control which have proved successful in Ceylon and India. The risk being distributed in this way over wider areas, and between estates yielding both high-priced and low-priced tea, the investment of capital becomes more secure, financing is made easier, and the shareholder has a more liquid asset.

We pass on to consider the markets outside the United Kingdom open to us, and the best means of gaining entrance to them. The fact that of the tea used at home only 5 per cent. now comes from China shows how little margin there is for increased sale here of British-grown tea, and illustrates the importance of finding customers elsewhere.

Useful and even necessary as advertisement, subsidy, and the intelligent work of special agents have been in countries where our tea was practically unknown, we have now to rely upon ourselves; expanding through the regular channels of trade, to work upon a commercial basis, and to trust to our ability to sell cheaper and better tea than can be obtained from other sources.

There is not room for a much larger business with Australia, which already draws from Calcutta and Colombo 80 per cent. of its supply (leaving only some 6 or 7 million lb. of China tea to be displaced), and can obtain from those markets all it wants, as London buyers will probably be ordering less this year. Canada takes about 45 per cent. of its import from us, leaving some 13 or 14 millions of Japan and China tea to be displaced. The trade with Asia is becoming useful, as it takes tea of which there is sometimes an over-supply, thus relieving this market. Germany, South America, and South Africa are still small outlets though steadily growing.

There remain the great markets of Russia and the United States, using annually some 180 million lb. Of these, the Russian is the more hopeful, because it requires black tea, appreciates quality, and is taking more from us every year, by direct importation or from London; it, too, is calling for better tea. Our trade with America continues to disappoint some who had not grasped the difficulty of persuading people who prefer tea uncoloured or green to drink our strong black sorts. The attempt to manufacture tea to suit their tastes is enterprising, but we fear lest it be made in a way which will give trouble and bring disappointment to a number of individual growers, without substantial benefit to anyone. It will take a decade to create a trade worth anything to us by means of specimens unlike in make or flavour; for large distributors hesitate to introduce a new kind of tea to their customers unless they can rely upon a regular, uniform and free supply. We think if Americans had this matter in hand on their own account they would rent for a term of years estates capable of producing, at the lowest possible cost, millions of pounds per annum, have it all made uniformly into two or three grades, procure men and materials from China for packing it in the way Americans like, give a constant supply, and undersell their rivals until the trade was made. It would cost money, but it might prove the cheapest and most effectual way of making a market—assuming, of course, that we can make unfermented tea that Americans will drink. Seeing that we have obtained less than 10 per cent. of a trade amounting to 84 million lb. per annum, after twenty years of heavy expenditure by planters and strenuous effort by the agents of London Dealers, it is obvious that other means must be tried. It has been said that tea is not likely to become in America the popular beverage that it is here and in the Colonies; but it may be that the small and declining consumption in the United States—now only 1½ lb. per head per annum—is due to the astringent and unsatisfying nature of the Japan and China teas principally used, as compared with the softer and richer teas of India and Ceylon which other races of Anglo-Saxon origin find such a cheap and wholesome article of diet that their annual consumption has reached the rate of nearly 6 lb. per head. It should be noted how largely the use of tea here has increased since the introduction of our own in place of Chinese growths.

As regards the Home Trade—which is the most important factor, inasmuch as our 42 millions of people, taking their 250 million lb. per annum, use nearly as

much as the rest of the world put together—its position is financially sound. The tendency continues for business to come into the hands of the large specialists, whether Dealers, Blenders, or Distributors, who, by absorption or purchase, seem to be getting the trade under their control at the expense of the smaller vendors. If this entails risk of possible combination of buyers against sellers, it finds some compensation in the larger financial resources they command and their greater power of holding stocks.

It is of importance to growers that those who buy and pay for their produce should be financially strong and doing a profitable business; and we believe the Trade have had a good year, though just now they are overstocked. Retailers having raised their prices to the extent of the rise in duty a year ago, and having bought the crops for about 1d. per lb. less than before, it might be thought that they had made 1d. per lb. more profit on all they have sold to the public; but they have not done that, for although their quotations may be 2d. higher the average of their sales is not. A great number of consumers pay no more now than when the duty was 4d., and it is owing to this that the increased tax has injured the growers; consumers in the aggregate are only paying a portion of it and producers are paying the rest; the middlemen are untouched while those of them who took the 40 million lb. out of bond before the Budget last year and have filled their stores with free sugar have made additional profits.

Our Export Trade is also healthy and growing; it is larger, indeed, than it has been for many years, notwithstanding that we have lost so much of the China trade that used to pass through London, but is now done direct. Nine years ago the total was about 37 million lb., of which only 7 million lb. were Indian or Ceylon; in the interval the volume of business has been gradually contracting but during the past season it has risen to 43 million lb., 28½ millions of this being British-grown tea.

We have said there is encouragement for producers even in the statistics of such a bad season as the last has been: we find it in the fact that the world is now largely dependent upon India and Ceylon and in the evidence that the use of our tea is increasing. It is, therefore, not an exaggeration to say that Planters hold the key to the position, and by combined action, resolutely followed on the lines indicated, have it in their power to recover a considerable degree of prosperity.

PARASITIC PLANTS.

A LECTURE AT THE ROYAL INSTITUTION.

At the Royal Institution, on Saturday, Professor J B Farmer gave the first of two lectures on the "Biological Characters of Epiphytic Plants." Epiphytes, he explained, differed from parasites in demanding only lodging from their host, without also exacting a food supply. Permanent humidity was necessary for them, and they were found at their best in tropical forests. From their mode of life they derived the advantages that they were raised up to the light and were enabled to occupy a space which every kind of plant was not qualified to fill; the great disadvantage was the precariousness of the water supply. Plants could only manufacture food when the light was sufficiently strong and their cells were turgid. If the water-supply was scanty or intermittent they could either expose less green foliage and so lessen transpiration, or store water, or in rare cases endure being quite dried up. In one cactus (*Phyllocactus*) there were no leaves, the green stems taking on their functions. In *Peperomia* the leaves were fleshy, with a water-jacket on the upper surface. The band of green tissue was thin, and above it were numerous rows of water-holding

cells; as the water was used these collapsed and the leaf became thinner, thus preventing the entrance of air. Many orchids had two kinds of roots, one for attachment, the other for the storage of water. The latter were covered with a coat of strong-walled cells which would soak up water like a sponge. Pseudobulbs, *i. e.*, thickenings at the base of the stem and leaves, contained mucilaginous cells, which also retained water. When *Myrmecodia* was discovered in Java it was thought to be an ant's nest which had turned into a vegetable. Its tuberous base was channelled with galleries inhabited by ants, which were supposed to protect the plant from enemies. This theory, however, would not hold, for seeds grown at Kew developed plants with galleries and openings to the exterior, although no ants were present. The real use of the galleries was to aid respiration. Another orchid had fleshy leaves, some slimy inside and others modified into pitchers which caught the drops of water falling from the boughs on which the plant grew. By means of a root, running from the base of each leaf into this pitcher, the plant could utilise the water in times of drought.—*London Times*, June 3.

THE MANIA FOR CHEAP PRODUCTION OF TEA.

WHERE THE LONDON AGENTS AND DIRECTORS DO HARM.

This wild mania for cheap production swamps everything, without looking at ulterior results. What does it matter what it costs a manager to turn out his teas, so long as he gives a profit? Why look to cheapness if it is obtained at a loss in the price realized? It is this incessant desk work of irresponsible Directors without experience that has ruined half the big companies in India, and brought some to the verge of bankruptcy; and, unless stopped, will bring more. The manager of an estate is the best judge of how much money he should require, and, as long as it reveals a decent profit on overturn, should not be interfered with, unless in a fair honest way; in fact, as a rule, should require little or no criticism. What does it matter if A's tea cost 5 annas to make, if it realises 6, whilst B's costing 4 annas, sells for 3½? Some of our readers may quibble at our remarks, but let them follow the result of gardens last year, and they will find every word we have written verified. In the case of one company, which paid a dividend upon the prospective prices of the remainder of its crop, and afterwards revealed a loss, the Directors make as an excuse the exceedingly had prices realised, the fault, they say, of the unfortunate manager, entirely forgetting that they had told him plainly how much tea he had to make, *not asking him*. If any one will mark the changes in the Directorate of many of our leading companies during the last year or two, a noticeable feature, they will find, will be the eager way in which old, retired and successful planters are pounced upon as a panacea for the present troubles; and in many cases, no doubt, they have done an immensity of good in restraining the spirit of government by mandate, which has of late years but too much made itself evident in the instructions communicated by London Boards to the local management. Of course there are exceptions to this, as in everything else; but we speak

of the matter in a broad sense, and the London school of Directors have been for many years gravitating towards the Government style of voluminous reports and tables of statistics that take a long time to make up, and are practically nullified for this very reason. There is no reason why a manager should not have the question put in a fair and square way.—How much tea can you make at such and such a figure, and how much profit would you expect? or, Can you do better? if so, we are willing to entertain your views. It is also utterly absurd a man in an armchair in a London office saying, Oh! that's all nonsense, you must make so much tea per acre, and at so much, and unless you do this we will get another man. What is the result? The poor manager must try, and, as must be the case, he either makes his tea at the price named, and drops a penny per pound; or he falls far short of the quantity, aiming to keep quality up, and *finis*—gets the sack. Until the London Agents and Directors leave a little more to the judgment of their local managers, and treat them as sensible human beings, doing their utmost for their employers, so long will we have rubbish to contend with in the market, and the only ones to blame will be the Agents and Directors, more especially at Home, as those in Calcutta understand the position and often themselves share in the mud thrown at the manager.—*Indian Planters' Gazette*, June 22.

A DISTINGUISHED GERMAN COLONIAL BOTANIST.

HIS VISIT TO CEYLON.

We have omitted to make special reference to the departure of Dr. Stuhlmann, a distinguished German Botanist who has been visiting Ceylon and who left for East Africa via Aden in the "Hamburg" on the 24th inst., after having travelled all over India, collecting information which might be of use in the German Colonies. Dr. Stuhlmann had visited Java as well, buying seeds and plants for experiments to be started by the Government at Dar-es-Salaam, the promising capital of German East Africa—Dr. Stuhlmann is not only a prominent botanist, but also one of the leading officials in German East Africa. He has even been Acting Governor there. Dr. Stuhlmann is one of the few, if not the only one, remaining of the first generation of pioneers in German East Africa, his time of service extending over 14 years. He accompanied the well-known Emin Pasha on an exploring expedition into the interior of Africa, on which he afterwards wrote a book of world-wide fame.

RICE CULTIVATION AND PRACTICAL EXPERIENCE.

We are indebted to Mr. Elliott for giving our readers the results of his experience as regards one important department—the supply of water—in paddy cultivation. Irrigation Engineers would no doubt be all the better for a course of training in the actual growing of paddy. They have something to learn in regard to the best means of utilising water, and Mr. Elliott questions if the growing paddy or rice plant can have too much water? He instances the case of Burma with its abundant rains and heavy crops; but we

suspect the latter are due even more to the rich alluvial soil than to the heavy rain. Still, a full water supply is undoubtedly necessary, and it is well to have the result of Mr. Elliott's personal experience as a rice-cultivator.

AFRICAN MARKET FOR CEYLON TEA INTERESTING INTERVIEW WITH SIR HARRY JOHNSTONE, COMMISSIONER FOR UGANDA.

RELIEF FOR THE OVER-BURDENED MARKET: SUGGESTION TO EXPLOIT PORTUGAL.

A FIRM BELIEVER IN TEA-DRINKING AND THE PERMANENCY OF THE TEA-INDUSTRY.

On the O.R.M.S. "Orizaba" at Naples,

19th June, 1901.

We arrived here early this morning. The weather is lovely now, the sea like a mill-pond all the way from Port Said, and it is expected we shall reach London about 21st.

I had an interesting chat with Sir Harry Johnstone, Governor of Uganda, who joined the ship at Port Said *en route* to England, on furlough. His ideas on the tea industry are distinctly refreshing in these times, and I think worth consideration.

To begin with, he takes a keen interest in planting, studies the *Tropical Agriculturist* and the *Observer*, and has tried growing various products, including tobacco and tea; this last with but small success. In his opinion this depression in the tea trade will not last, it cannot last, and when it passes over, as assuredly it must, tea will be in as sound a position as ever. Moreover, if he had money to invest, he would have

NO HESITATION IN INVESTING IN CEYLON TEA PROPERTY.

Regarding the question of over-production, Sir Harry declares that Africa will be a great tea-drinking country—already the native tribes are taking to it; and provided tea is good, cheap, and easy to get, Africa, now only in its infancy, will do away with the fear of over-production; and there will be no question, he believes, of glutting the market with India, Ceylon or China teas. Africa, for various reasons, will never compete with recognised tea-producing countries, like India, Ceylon, and China.

Talking of the "Thirty Committee," why on earth, he said, do they not

EXPLOIT PORTUGAL?

There is a good field there for tea shops. Portugal, unlike Spain and France, is not a coffee and chocolate drinking country. It drinks tea, and drank tea long before we did ourselves, but tea is dearer there than it ought to be. Then Morocco is another country where tea is drunk all day long, and the "Thirty Committee" would do well to turn their attention to it. The other day

IN SOMALILAND

he stopped at a café, and asked for some coffee; they told him they had only tea, and he was served with a delicious cup of tea.

There were great possibilities for opening up a trade in packet teas with the Arabs who of late have taken to drinking tea. If India and Ceylon turned their attention to these parts of the world, over-production would cease to cause alarm. Asked about the increased duty on tea, Sir Harry said he would have taxed fifty other things before he touched tea; he would have clapped the duty on, say, champagne, velvets, silks, and various foreign importations. Sir Harry, himself a good judge of tea, is a confirmed tea-drinker, and believes that tea is

DISTINCTLY BENEFICIAL, ESPECIALLY IN
MALARIOUS REGIONS.

"Bad for the nerves and digestion, the Doctors say? Well, it has not injured mine," said Sir Harry, "and I don't care a rap for Doctors' fads. Much of the illness in Uganda is caused by scarcity of good cooks and good food, with too free and too frequent use of alcohol."

"EPIPHYTIC PLANTS."

SECOND LECTURE AT THE ROYAL INSTITUTION.

Professor J. B. Farmer gave the second and last of his lectures on the "Biological Characters of Epiphytic Plants" at the Royal Institution last Saturday. Some plants, he explained, began life as epiphytes, and later made connexion with the earth. The seed of the common india-rubber fig usually germinated in the fork of a tree; the roots grew down the trunk to the soil and were firmly glued to the bark by a cementing substance; any excess of cement was re-absorbed, the roots coalesced and soon enclosed the tree, causing its death. The fig continued its existence as an individual. In one epiphytic, *Anthurium*, the leaves formed a sort of funnel in which vegetable detritus accumulated, sometimes to the amount of 20 or 30 pounds, and in this solid matter the roots ramified. In a fern called *Drymoglossum* the root hairs stood absolute drying up, and when moistened new root hairs sprang from the bases of the old. In *Polypodium quercifolium* one kind of leaf manufactured carbohydrate food, while another kind resembling oak leaves were adpressed to the bark, forming pockets in which humus accumulated and in which the roots ramified. *Platyserium* also had two sorts of leaves; one for assimilation and one which, though becoming dead and brown, collected nutriment and water. Liverworts showed very diverse adaptations and occurred wherever there were epiphytes; they covered leaves or even grew on one another. In *Gottschea* the leaves folded over one another and held water by capillary attraction. In one species of *Physolium* the leaves consisted of two lobes; one, acting as a gutter, conveyed water into the other, which was hollowed out and provided with a valve to prevent the escape of water. In *Physolium acinosum* there were large sacs at the apex of the stem, which in most species contained the spore-bearing organisms, but had here become for the most part water reservoirs. *Frullania*, in addition to ordinary leaves, had pitcher-like leaves, which held water and in which small organisms lived. Lichens endured unlimited drying, and very little moisture served to swell them out and make them gelatinous. Only plants with small seeds or spores could attain to an epiphytic

existence. After Krakatoa was blown up, the whole island was covered with red-hot cinders. Three years after these were overgrown with a gelatinous *alga*, in which new vegetation, chiefly ferns, had taken root. The spores had had a distance of 25 miles to cover, and only the smallest kinds could be borne so far. Few, even of small-seeded plants, could become epiphytes; success depended on the adaptability of the individual to change of environment.—*London Times*, June 11.

TEA DISTRIBUTION AMONG NATIVES.

AN APPEAL TO CAPITALISTS.

Up to date only some 300,000 lb. of tea have been subscribed to the scheme for disseminating our teas among the natives in this country. To ensure the project being a success, one million eight hundred and seventy thousand pounds is wanted; but, as is usual, in all matters relating to the welfare of the tea industry in this land, utter apathy is being evinced by those whose interests are most at stake. It is difficult to fathom the reasons for this only too apparent indifference, but one of the motives assigned is that the larger and more substantial proprietors (who are in a position to pull through the crisis and stand a prolonged strain, having ample means at their back) do not wish their weaker brethren to pull through, as it will be to their advantage if they fall in the struggle and go to the wall. In such cases it is the essence of selfishness which is at the bottom of the great want of support, which is at present so conspicuous. To eliminate self-greed is impossible, and we fear that the small concerns, with no reserves in the way of capital to help them to pull through, will ultimately have to cave in and give up a hopeless contest against adverse circumstances. This is the age for great things, for colossal undertakings, but compressed into one word they simply mean "Money." Without capital nothing can be done; with capital there is nothing that cannot be done. It is hopeless, therefore, for those who have not capital to try and compete with those who have. But this is no reason why capitalists should hold back at the present juncture; yet, we are told they are doing so, in the hope that they will thereby wipe the indigent concerns out of existence.—*J.P.G.*, June 8th.

THE POSITION IN CASSAVA.

A recent analysis made by Professor Carmody, Government Analyst, confirms the previous work of Francis as to the presence of Prussic acid in sweet cassava, the proportion found varying from 0.005 to 0.019 per cent. The skin was found to yield from 0.014 to 0.042 per cent., while the inner part gave only 0.003 to 0.015 per cent. The interior part of bitter cassava yielded 0.013 to 0.037 per cent., while the skin and outer layer yielded from 0.012 to 0.035 per cent. Peeling sweet cassava before cooking is therefore a wise precaution. Professor Carmody also suggests that the acid may in part be formed by fermentative change.—*Trinidad Bulletin*.

NEW ZEALAND FOR HONEY.—A shipment of honey recently made by a Poverty Bay (N.Z.) settler realised £42 10s per ton in the London market. The settler in question has been obtaining an average yield of 90 lb. honey per hive during the season.—*Sydney Mail*, June 1.

SUNSPOTS AND CLIMATE :

J. NORMAN LOCKYER ON THE
RECENT "SUNSPOT";
ITS BEARING ON LOCAL
METEOROLOGY.

Sir J. Norman Lockyer first took an active interest in the climate of India and the application of the Sunspot and Rainfall Cycle theory, when he came out to the East to observe the Eclipse of 1871. In a long paper to *Nature* of December 12th, 1872, on the "Meteorology of the Future," the distinguished Astronomer mentioned how, while preparing to go to India, he got valuable information from the editor of the *Ceylon Observer* (the late Mr. A. M. Ferguson) who happened to be in London, —as to the time of year at which the monsoons broke up in the island. "Nor was this all; he added"—said the Astronomer—"that everybody in Ceylon recognised a cycle of about 13 years or so in the intensity of the monsoon, that the rainfall and cloudy weather were more intense every 13 years or so. This, of course, set one interested in solar matters thinking; and I said to him: 'But are you sure the cycle recurs every 13 years? Are you sure it is not every 11 years?'—adding as a reason that the sunspot period was one of 11 years or thereabouts and that, in the regular weather of the tropics, if anywhere, this should come out."

Our senior sent us out an account of his conversation with Mr. Lockyer, as he was then, and on our publishing it in the *Observer*, the late Mr. R. B. Tytler—who in his too dry Dumbara Valley paid great attention to Meteorology—wrote to us to point out that Mr. Lockyer was right, that the cycle period in Ceylon was one of 11 years—five or six years dry and five or six years wet—although occasionally thirteen years might more accurately represent local experience. This statement was sent to Mr. Lockyer who at once paid special attention to our local records, getting also corroborative returns from Mr. Meldrum of Mauritius, from Brisbane and Adelaide, and later from Madras and the Cape. These he worked up in a paper for *Nature* on "The Meteorology of the Future." Recognising the eleven-year cycle, he declared that the true cause had yet to be discovered and for this two things were necessary: an accurate knowledge of the currents of the sun, and, secondly, of the currents of the earth. Photography and Spectrum Analysis were necessary for the former and for the latter the pursuit of Meteorology as a physical science.

Ever since that time, now thirty years ago, we have, in our "Ceylon Handbook and Directory," endeavoured, in our "Meteorological," to meet the requirements of the "Director of Solar Physics," so far as the maintenance of local statistics and observations is concerned. The dates of the advent of successive monsoons and of the annual rainfall are complete for well-nigh fifty years and we have had Mr. Archibald analysing the same with a view to shew the close connection between the Sunspot Cycle and the advent and magnitude of the Monsoon. The subject is, of course, of far more practical im-

portance to India—so often the scene of famine—than to Ceylon; but it is not without a good deal more than theoretical interest even in this favoured island. For, in respect of coconut and paddy cultivation (as well as a good deal of fruit and root culture in certain districts,) a poor monsoon or a dry season makes a world of difference.

We cannot say, however, that much progress has been made during the past thirty years in arriving at the results desiderated by Sir Norman Lockyer in 1872. But that gentleman has never lost his interest in a subject which is, of course, so closely related to his daily work as the "Director of Solar Physics Observatory, South Kensington"; and in *Black and White* of June 15th, we find an illustrated article headed "The Dream of a Great Scientist: what a Sunspot may mean for the human race." The veteran Astronomer is a firmer believer than ever as to the relation of solar influence upon terrestrial meteorology, and he has even now gone so far as to express the hope that, in a few years' time, meteorologists will be able, as the result of observation of solar phenomena, to predict the time, and even perhaps the place, in India, in which famine may be expected, so enabling precautions to be taken against loss of life; and that they will also be able to give warning of high and low floods in Egypt. Of more immediate importance is the following statement made in the course of this interview:—

The sunspot observed lately he regards as of the greatest importance. "It shows us, beyond all question, I think," he informed the writer, "that the minimum is past. And that is a very important matter. It is very remarkable that a spot in the minimum period, apparently the first spot of a new cycle, should be of such magnitude. We are working at it, but cannot say anything definite for the moment. It will take some time before any certain pronouncement can be made, but it looks very much as if it will enable us to fix the period of the minimum, which before was uncertain to a year. If we can fix that, it will be very helpful for subsequent work."

We take it that, in saying "the minimum is past," Sir Norman Lockyer means the period of dry or short rainfall years, more especially in India. We have not the figures of rainfall for the Central or North-West Provinces of India before us as we write; and the Madras Presidency has had no trouble with famine or short crops of late years, or, a study of our meteorological returns might be of interest. But, as a matter of fact, in respect of Colombo at least, our rainfall is more distinguished for alternate years of heavy and light returns than for the periodicity of the larger cycles of dry and wet years. Thus, beginning with 1890, we get the following alternation:—

Year.	Rainfall inches.	Year.	Rainfall inches.
1890	72.80	1895	92.23
1891	119.03	1896	101.06
1892	60.83	1897	82.73
1893	89.67	1898	103.11
1894	77.46	1899	73.43
		1900	83.68

It will be seen that 1896 breaks the alternation and a new series then begins, although

the fall of 1900 must be reckoned short (by five inches, of the average, and therefore we ought, with two scanty years in succession, to have an unusually heavy rainfall for 1901. That does not always follow, however, for in the "seventies" we had four years in succession with an abnormally low rainfall:—

	inches.		inches.
1871 ...	65.09	...	1873 ... 85.62
1872 ...	62.07	..	1874 ... 57.03

Total... 269.81

Normal Annual Average: 88.03 inches \times 4 = 352.12

Deficiency in 4 years ... 82.31

But to expect two more years—1901-2—of abnormally low rainfall in Colombo, would be contrary to the Astronomer's declaration that "the minimum is past" (and we suppose that he has no fear of a recurrence of famine in India for some years at least.) So far as the present year has gone, the first half shows a fall well up to the average, and by the end of December the prospect may well be of a total which will bear out Sir Norman Lockyer's belief that "the minimum is past." So mote it be, we say, in the interests of local paddy and coconut farmers; but still more with reference to the vastly more important claims of India throughout its length and breadth.

It only remains to be mentioned that taking our Colombo Rainfall returns from 1870—the year when the late Colonel Fyers established the Colombo Observatory (although it remains for Governor Ridgeway to place it on a proper footing before he leaves us)—the average for the eleven years 1870-1880 was 86.82 inches (a dry cycle comparatively) and of the next series 1881-1891, the average was 92.16 (or 4 inches above the average); while for the current cycle the average for the nine years expired is 84.58, pointing to another dry period and so far maintaining the law of the eleven-year cycle and its alternations, although in the case of the South West division of Ceylon—situated in the pathway of both monsoons—the difference between a wet and dry period, as illustrated above,—86.82, 92.16, 84.58 inches—is comparatively slight. Nevertheless, when we recall the fact that in 1874 the total rainfall was so low as 57.03 inches, and in 1878 so high as 139.70, we must bear in mind that, highly favoured as Colombo is, it is not beyond the influence of a tryingly dry season, involving poor crops of coconuts, rice, vegetables and fruit generally, or again of a season of heavy continuous rainfall—with all the injury which sudden and persistent flooding means to thousands of the people in the low-lying Colombo and neighbouring districts.

RAW RUBBER NOTES.

NICARAGUA.—Mr. Consul Chambers, in his report of trade in Nicaragua for 1900, states:—Rubber is getting more scarce every year, and the planting of rubber trees has not been taken up to any extent, possibly through the long time necessary before any result is seen, and the difficulty of preventing stealing. The Government allows a bonus of 1 dollar

currency (about 1s 5d) on every rubber tree planted in certain districts, also 5c currency (1d) for coffee trees, 20c currency (3½d) for every cocoa tree, and 10c currency (1¼d) for every pound of indigo exported. During the year 1900, in order to benefit agriculture, the Government allowed the free transport of coffee to Corinto on the railway, also free transport of maize and plantains, when solicited, for the use of the estates. Through this concession, it is estimated, the Government lost 135,829 dollars 5c currency (100,611) in freight.

BRAZIL.—The report of Mr Acting-Consul Temple on the trade of Para and district for the year 1900 has just come to hand. In it he comments upon the commercial crisis which has occurred in the Amazon Valley during the past year, and, although many similar crises have occurred in past years, none has been experienced so disastrous or so wide reaching in its effects as that which developed during the spring of last year. Rubber, which still maintains its position as the chief item of export from Para, continues to show a steady increase in the total exported from the Amazon Valley, including Bolivia and Peru. In twenty years the total quantity has more than trebled the export in 1880 amounting to 8,635 tons, while that for 1900 amounted to 26,693 tons. Only in 1897 did the amount of any year fall short of the preceding one, and this was only about sixty tons. A considerable stir has been caused by the recent re-enactment on the part of the Congress at Manaus of a law which was referred to in our issue on the 1st ult, whereby all rubber produced in the State of Amazonas must be disembarked in Manaus, examined, classified, reweighed and boxed up. This would entail a great quantity of rubber, which has hitherto been dealt with at Para, being treated at Manaus, and shipped direct from there without touching the port of Para. The Consul in his report says:—Trade has, however, a conservative tendency; in addition to this, the fact that the subfervid cable which connects Manaus with Para has up to the present been so liable to interruption that no reliance could be placed upon it, and has caused a large proportion of the trade, which would naturally go to Manaus, to remain at Para. In justification of this law, the Legislature states that the Revenue collectors are not able to calculate the export duties in a satisfactory manner, whilst the rubber is in "pelles," and that it is necessary, in order to secure the interests of the Treasury, that fine rubber should be separated from the inferior grades before leaving the State. A land cable has been suggested, but it has been considered almost impossible, owing to the luxuriance of the forest growth which would cause as many interruptions as occur to the cable in the bed of the river. As Manaus is, therefore, not in such close touch with the exchange and produce markets, the merchants buying at Manaus must always risk a large loss, especially with an article like rubber, which is subject to such rapid fluctuations.

Although the effect of the Amazonas rubber being handled at Manaus would deprive Para of a considerable amount of trade, yet it must not be supposed that Para would be entirely eclipsed. Taking the total crop to be about twenty-six thousand tons per annum, eleven thousand tons of up-river would probably be handled at Manaus, and nine thousand tons of island at Para. Of the remaining six thousand tons coming from Bolivia and Peru, a certain quantity would still be handled at Para, thus bringing up the trade of the latter port to about the same total as the former. The probabilities of increase in production are about the same for both States. The total crop of rubber shipped from the Amazon Valley during the year was 26,881 tons, of which 12,474 tons went to the United States, and 14,407 tons to Europe. Of this quantity, the State of Para produced 5,000 tons, Amazonas 4,300 tons, Peru 123 tons Bolivia 465 tons, making a total of 9,888 tons, of fine

with a total value of £1,906,000. Of this 5,100 tons went to the United States, 4,466 tons to the United Kingdom, 260 tons to France, fifty tons to Italy, and twelve tons to other European countries. The total export of entrefine amounted to 1,124 tons, with a value of £402,000. This was about equally divided between the United Kingdom and the United States, a small quantity going to France and Italy. The State of Para produced 4,000 tons of Sernamby, Amazonas 913 tons, Peru forty tons, Bolivia 235 tons, making a total of 5,188 tons, valued at £901,000. Of this amount the United States received 4,398 tons, the United Kingdom 664 tons, France 115 tons, and Italy eleven tons. Of Caucho amounting to 1,092 tons, valued at £210,000, chiefly produced in the State of Amazonas, about one-half went to the United States and Europe.—*India-Rubber Trades' Journal*, May 13.

THE ALDABRA ISLANDS.

AN OUTPOST OF EMPIRE: LEASED FROM THE SEYCHELLES GOVERNMENT.

The curious group of islandlying north-west of Madagascar, and known as the Aldabra group, have recently changed hands. The Government of the Seychelles Islands, of which politically Aldabra forms part, has leased the group for a term of thirty years to Messrs Bates, Bergne & Co., acting for the Hon. Walter Rothschild, M.P., and themselves. Mr Rothschild's interest in the islands is probably derived from their remarkable fauna. Aldabra is almost the sole habitat of that antediluvian relic, the gigantic land tortoise, and is certainly the only spot in the world where that reptile flourishes. Some of these tortoises might have been seen in the Bombay Dockyard last September on their way to Mr Rothschild's zoological gardens at Tring Park. Certain birds and insects, too, are believed to be peculiar to these islands. Besides Aldabra proper, which consists of a ring of land broken by channels and surrounding a lagoon about fifty square miles in extent, the group includes Cormoleo, an atoll of similar formation Astove and Assumption Islands. At the west end of the Aldabra lagoon there is a fine land locked harbour named after H.M.S. Euphrates, and capable of giving shelter to the largest fleet. Owing to the large volume of water in the lagoon and the lack of sufficient outlet the tides are at times very strong, which is rather a drawback. Aldabra itself contains little land capable of cultivation; on the other islands, however, there are hundreds of acres suitable for coconut plantation, and the lagoons and coasts of the whole group swarm with fish and turtle, including the hawksbill variety, the source of the so-called tortoise-shell. An interest attaches to these islands from another point of view. In 1894 the French flag was hoisted on Glorioso Island, less than one hundred miles south of Astove. Before that date Glorioso, with some adjacent islets, had been considered British territory and was included in the list of the Dependencies of Mauritius. Aldabra is now the outpost of the British Empire to the west of the Indian Ocean, with the Comoro Islands, Glorioso and Madagascar stretching in a French semicircle from the south-west to the south-east. Glorioso was

lost, it is said, solely from the lack of a British flag or from the neglect to hoist it; it is to be hoped that the lessees of Aldabra will take proper precautions against similar aggression.—*Times of India*, July 1st.

TROUT AND GAME IN NEW ZEALAND.

The Auckland Acclimatisation Society is doing its best to stock with trout all the suitable streams in the district, but their efforts are greatly discounted by the devastations of shags. If, therefore, the country settlers desire to profit by the efforts of the society, they would do well to further their intention by the destruction of these voracious birds. Few people are aware of the havoc they make. The number of young fish they destroy is almost incredible; some persons put the number they devour as high as 50 per cent of those distributed.—*Auckland Weekly News*, June 7.

Mr. Ernest Grogan, the African explorer, has been in communication with the Wellington Acclimatisation Society, and has informed it that there are many varieties of African game which would adapt themselves admirably to a New Zealand environment, and indeed thrive vigorously on the vast waste spaces of the north. He is insistent, however, that any importation of the best varieties which are projected must immediately be undertaken, because several of the species are on the verge of extinction. Indeed, he says, the transportation of these species to the colonies is the only means to prevent them being entirely lost sight of.

Mr. Avson, Inspector of Fisheries, is circularising the various Acclimatisation Societies of the colony, asking them to co-operate with the Government in securing the importation of South African game of different varieties, as recommended by Mr. Ernest Grogan.—*New Zealand Mail* (Wellington) June 6.

BRAZILIAN "RUBBER" FARMS FOR SALE.

We have before us descriptions of several "rubber farms" in the Amazon river country that are for sale. Some of them are offered by the proprietors, and others by banks at Para, which, having made advances to the owners of the "farms," have taken over the properties in default of payment. We do not know the merit of these particular opportunities for investment, but the fact that they exist suggests several points of interest.

In the first place, the rubber gathering business probably is better organized than most of us hitherto have supposed. It appears that the 50,000,000 pounds or more of rubber annually exported from the Amazon is not gathered mainly by half-savages, roaming in vast forests, tapping at random such rubber trees as they may chance to find. It would require more than such haphazard methods to form the basis for the business of the banks and mercantile houses of Para and Manaos, the hundred or more steamers on the Amazon, and the rubber-carrying ships on the Atlantic which transport not infrequently a cargo of rubber worth \$1,000,000 or more.

On the contrary, each of the "rubber farms" is described as consisting of a definite number of *estradas* (paths, or roads), marked out so as to give ready and certain access to the particular rubber trees to be

tapped, the approximate number of trees also being given. This preliminary work of road making is not done for a single season, but is meant to be permanent so that, when a plentiful supply of prolific trees is once located on a navigable stream, they may be visited season after season, with an assurance of a yield that will prove profitable. From one description we quote: "This farm was marked off five years ago, for which service was paid 40 contos of reis (equivalent today to \$10,000)." The number of trees on this estate is estimated at 20,000. There are also said to be on the farm wooden buildings, cattle, etc., besides which four steam launches are owned. Doubtless on an estate where the business of rubber gathering has been prepared for with so much forethought and at such expense, we might today see a force of workers established all the year round, but for the fact that the annual rising of the rivers scatters the rubber hunters for a certain period. As it is, the crop season, during which the trees are tapped daily, is something more than six months in the year.

It may be asked why, in the face of such preparations and the presence of rubber in paying quantities, the owners of these farms should want to sell. The reason given is the financial depression from which all Brazil is suffering. Any manufacturer who buys Para rubber is prepared to believe that somewhere, between the forest and the factory, good profits are made on it. The owners of many of these farms have profited largely, but their money has been made too easily for any thought to have been taken for the morrow. Hence the beginning of each new season finds most of them with nothing but their *extra as*, waiting to be worked. They must send for workers, and provide for them until the proceeds of the year's crop come to hand, all of which makes necessary advances from merchants or bankers who are generally at a distance. Whatever may be the prime cause, money is now a scarce article in the rubber country, the rate of exchange is most unfavourable, and credits have become contracted to an extent which leaves the weaker operators helpless. It is quite possible that the number of persons in the rubber gathering business, and the number of estates, affected by the Brazilian financial crisis will be so great as to curtail seriously the production of rubber during the coming season.

All of which leads to the thought that, if the Para rubber already produced has come to an important extent from systematically marked out farms, visited year after year by workers under the same control—albeit the general management of these estates may have been wasteful and improvident—there may be a good opportunity for the investment of capital by outsiders, on a basis of cash capital instead of advances of goods and credit, in very large tracts of rubber lands, to the profit of the investors, while rendering the supplies of rubber more stable and the ultimate cost to the manufacturer lower.—*India Rubber World* June 1.

THE RUBBER PLANTING INTEREST.

RUBBER PLANTING IN SOCONUSCO.

The Soconusco Rubber Plantation Co., incorporated under California laws, October 16, 1900, to develop a plantation in the Soconusco department in the state of Chiapas, in the extreme southern portion of Mexico, was organized by Mr. Charles G. Cano, C.E., who is its general manager. The company own 17,858 acres and are preparing to plant rubber on an extensive scale. They expect to ship considerable rubber this year from native trees on the property. This property is near the estates of La Zucualpa Rubber Plantation Co., comprising 18,791 acres, and which has been mentioned several times in *The India Rubber World*. This company, besides planting largely on their own account, have acquired a plantation formed ten years ago or more, from which some rubber has been shipped. In the same region is the rubber estate Los Cerritos, on which 40,000 trees were planted eleven

years ago, and which was sold recently by Rafael Ortega to Louis Tomalen for a large sum. Still another enterprise there is the Dona Maria Rubber Plantation Co., with 5,288 acres, owned by F. A. Quimby. Mr. Cano, mentioned above, has also interested eastern capitalists recently in forming the Pacific Rubber Co., for planting rubber, which has just been incorporated under Maryland laws. Mr. Cano is interested in the sale of other lands, on a large or small scale, suited for rubber planting, either alone or in connection with other crops, and may be addressed for the present to the care of *The India Rubber World*.

It is in this department, by the way, that the late Mexican ambassador, Senor Romero, made a rubber plantation in 1873. Some of the trees then planted still survive, in spite of long neglect, and rubber gathered from them formed a part of the Mexican exhibit at the Paris Exposition of 1900. The identical lands are now under control of Mr. Cano.

PLANTING "LANDOLPHIA" IN AFRICA.

The Compagnie Anversoise des Plantations de Lubefu, formed in Belgium in 1897 to trade in Africa, with 600,000 francs capital, and which have been shipping considerable rubber from the Congo, are reported in *Congo Belge* as having commenced a plantation of *Landolphia* rubber vines on the river Luofu, to cover 1,000 hectares = 2,471 acres besides which the company have an option on 4,000 hectares more, for the same purpose.—*India Rubber World*, June 1.

FAILURE OF THE CAMPHOR MONOPOLY IN FORMOSA.

OWING TO INCREASE OF PRODUCTION IN JAPAN

The failure of the camphor monopoly in Formosa is supposed to be caused by the unexpected increase in the production of the staple in the interior of Japan, with the result that the markets in Japan and abroad have been considerably affected. It was therefore thought necessary by the last Cabinet to extend the monopoly to Japan, so as to maintain the price of the staple and protect the monopoly in Formosa. A proposal to this effect was agreed to by the last Cabinet. Viscount Katsura, the Premier of the new Cabinet, is reported to take special interest in the finances of the territory, as he was for a time the Governor-General of Formosa, and it is believed he will take up the proposal of the last Cabinet and favour the extension of the camphor monopoly to Japan. The *Kobe Chronicle* says:—It is stated that, if such a Monopoly Bill is passed, the export of camphor from Japan will be undertaken by the Agricultural and Commercial Department; and that Monopoly Offices will be established at Nagasaki and Kobe, the head office being at Kobe. The purchase price of camphor will be fixed at 75 yen per picul for Kobe, and 65 yen per picul for Nagasaki, while the sale price will be 85 yen per picul. From these particulars it would appear the Government has practically decided to introduce such a Bill.—*Hongkong Press*, June 22.

THE ORANGE INDUSTRY.—It is said that more oranges are grown at Riverside, Cal., than in any other city of equal area on the face of the earth. Out of fifty-six square miles, which is the area of Riverside, thirty square miles have been converted into orange groves. This means that the coming season's product will "aggregate," as Americans say, about 3,200,000 boxes of oranges. This represents a money value of 6,000,000 dollars.—*Morning Leader*, June 15.

THE AGRICULTURAL SOCIETY OF MADRAS was established in 1835 and has had a useful career. From the annual report just to hand, we quote:—

RECEIPTS AND EXPENDITURE.—The receipts from various sources, viz:—Sale of seeds, plants, sundries, admission tickets at the Flower show, subscription from Members, and Government grants amounted to Rs.1,872-3-3 and the expenditure by way of establishments, purchase of seeds, plants, erecting palm house, cisterns, printing advertising, &c Rs.1,329-5-3, leaving a balance of Rs.542-14-0.

BREAD FRUIT (seedless)—The one sent to us from the Peradeniya gardens, planted out near a water channel, is now about 25 feet high and bearing fruits for the last 4 years. The other plant from the Lacadives planted in an open place and getting only a scanty supply of water is not more than 8 feet high and bears a sickly appearance—now dead.—LANDOLPHIAS—L Kirkin and L Florida, two African rubber climbers. The former is a delicate twining plant producing fruits in profusion, and the latter is a giant, covered up four trees already but did not fruit as yet. FICUS VOGELII—This rubber plant has made no progress yet. Evidently the climate does not suit it.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop, August-September delivery 1901; booking necessary before the end of April; quantities of 100,000 and over at special low rates. Plants available all the year round. 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year."

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery, 1901, booking necessary before the end of March; large quantities on special terms; Plants in Wardian cases.

Manihot Glaziovii—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter, in sending an order for this seed, wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Kickxia Elastica.—(*Funtumia Elastica*).—Seeds and Plants, orders booked. (Lagos rubber.)

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Urceola Esculentia and U. Elastica.—Same as above. (Burma rubber.)

Parameria Glandulifera.—Orders booked for seeds for January-February delivery; also plants; immediate booking necessary. (A good rubber creeper of Malacca.)

Landolphia Kirkii.—Seeds in July August, early booking necessary. Plants can be supplied all the year round. (A highly-recommended species.)

Chonemorpha Macrophylla.—Seeds and Plants; orders booked. (A very valuable rubber-yielding creeper.)

Memusops Globosa and Payena Leerii.—Seeds and plants in July-August, booking necessary before April.

Achras Sapota, Willughbeia Firma, W. Edulis and other Rubber and Gutta Percha yielding Trees and Creepers, Seeds and Plants.

Cinnamomum Zeylanicum (Cinnamon superior variety). New crop of seed in April to June, booking necessary before the end of February; also plants.

Coffea Arabica, Liberian Hybrid and Maragogipe Hybrid.—New crop March-April; immediate booking necessary.

Cinchona Ledgeriana.—Seeds now ready, also other varieties.

Seeds and Plants of Nutmeg, Clove, Sandalwood (white and red), Pepper, Cardamom, Vanilla, Cacao, Tea, Coea, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products of Foreign countries for 1901-1902, now being prepared, and will be ready in a few months.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Price List of Seeds and Plants for CEYLON use, post free, on application.

Our new Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms &c., Timber Trees, Trees for Avenues, Hedges, Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Orchids, Bulbs, Dracenas, now being prepared, and will be ready shortly.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

PLANTING IN NYASSALAND: B. C.
AFRICA.FRIGHTENED AGAINST PLANTING TEA: CHILLIES
TO THE FRONT.

M'lanje, May 9.

DEAR SIR,—The prices Ceylon tea is now fetching frightens one from extending much here on that product. Over-production and low prices usually, in time, find a remedy. Low coffee prices and short crops in B. C. Africa are causing a great funk, and planters are going in for tobacco and chillies at a great rate. I hear of thousands of acres being put under the latter product.

Chillies may be over-done, but tobacco won't I am sure. I am getting 1s per pound, for all I can produce, in the South African market. —I cannot go in extensively for this product for want of a steady supply of labour. We have now got established a Labour Bureau which is doing good work. I have had thirty men sent down during the last month. There is labour galore in this country, but owing to the interference of Government Officials, and the unscrupulous recruiting by native *kapatns* belonging to Transport Companies and planters, the people are afraid to leave their homes.

H. B.

P. S.—So the Nyassaland Company is likely to close down, and I hear Lochnagar Estate is abandoned. It had bad treatment indeed.—H. B.

INTERESTING INFORMATION FROM
PARIS IN RESPECT OF GUTTA
PERCHA AND RUBBER.

Paris, May 25th.

DEAR SIR,—You will receive by this mail a little sample of Gutta Percha; submit it to any expert and he will report—'Gutta Percha fine quality.' And yet, I can certify that neither *Dichopsis*, *Paladium*, *Isonandra*, *Payena*, nor any other plant yielding Gutta Percha has any thing to do with this sample.

This little sample is perhaps the solution of an urgent problem, the certitude of the supply of this substance for the future. All the Gutta Percha yielders from the "Insulande,"* are localised, and the crop will be quickly exhausted. Their product is slowly obtained; the trees require four years and more and give 1 or 2 lb of marketable gum. The extraction from the leaves has proved till now a failure, and has not been accepted by the manufacturer of electric cables; extraction from the bark is on trial and I cannot say anything about it yet.

But chemists have recognised the presence of gutta percha in a number of plants growing in all parts of the tropical world. All the *Mimusops* contain Gutta; and *M Balata* and *M Globosa* are reported to yield 60 to 70 per cent of pure Gutta in the gum. *M Schimpen* of Abyssinia and very probably the species from Asia, contains a limited quantity of the product. I know that other

* Sic. What does our correspondent exactly mean by this?—Ed. T.A.

Sapotaceous plants and a few *Euphorbiaceous* are in the same case. The sample I send you has been obtained from Balata, *Mimusops Balata*.

I do not know the process, but I know it is a very simple and economical one. One kilo of Balata gives 700 grammes of Gutta. As the sample is valued at 7 francs per kilo, one can obtain 700 grammes of a substance easily sold at 14 francs for 700 grammes or 20 fis. per kilo. The chemist says that, all expenses paid, the kilo comes out at 12 to 12½ francs the kilo. This sample is sold here at a much higher price, for 30 francs have been paid in every case, so you can judge of the commercial value of the substance.

But just now I write with another point in view. I write only to planters, and I say all the gutta-yielders actually known are trees, slow-growing, requiring a special soil and climate, and very few will try the culture of the trees out of the regions where nature has sown *Dichopsis*, *Isonandra*, &c.,

But amongst the numerous species containing gutta, mixed with other substances, many are easy to propagate and to grow in very varied conditions of temperature, soil, and moisture. So it will be of enormous interest to know what percentage of Gutta all these plants contain, and to see beforehand if the culture can be remunerative. Till now the process has been a secret, but I believe it will not be so for long. But never mind, if this gutta-yielder becomes the subject of a great enterprise, Balata gum will jump high, so the grower will be interested in trying some other gutta-yielders. *Balata* (*Mimusops Balata*) is a tree more easily grown than *Isonandra* or others from the same region, and other sorts of *Mimusops* are largely spread over the world.

Any chemist will give you the percentage of true gutta the trees contain; do not take any notice if the chemist says it will be too expensive to isolate the gutta. My inventor says that his process allows him to make a profit from the gums containing only 10 per cent. of true gutta. But we will speak of that again some day or other.

I received a few days ago two plants in a very bad state from the centre of the Orenoque region. One of these plants has begun to show a few leaves and I was very ashamed when I identified it with the numerous varieties of *Sapium Biglandulosum*. The travellers reported:—Big tree, yielding a large quantity of the rubber exported under the name of Para rubber.

I know that Para rubber is not the product of *Hevea* alone, and an Englishman sent me a few years ago a sample of rubber made from *Micrandra*. But *Sapium* from the hot countries has always been reported to yield Rubber of very inferior quality. Strange to say, I have had in my hands plants collected by one of my collectors, M Guillot, from English Guiana, known by such an authority as Mr Jenmann as a bad yielder; others from Columbia, giving the virgin Caucho known as a very fine sort; others from Ecuador, just at the limit where the *Castilloa* is met: all these sorts are exactly the same in general appearance. But the area where *Sapium* gives good rubber is immense, nearly as large as its competitors, *Hevea* or *Castilloa*.

I have not been able till now to identify that new Rubber yielder from San Luiz Potosi, Mexico. I know that the plant is a very common one in all the dry countries of the Mexican region, but I

do not know its botanical name. My correspondent told me that the plant was known under the name of *Synanthera prepennia*, but *Synanthera* is not the name of a botanical genus, so I believe this species has been determined as a plant of the *Synanthera* family, which will also be called part of the "composite" family. The sample I have had in hand is really a plant of this family, but I have not had any flower, so I can say nothing more. As the region where the plant grows presents many plants suitable for the dry countries of North Africa, it has great interest for us.

After many trials I have received in good order seeds of the *Mangiaba* rubber (*Ilencornia speciosa*). These reached me in the forests, packed in saw-dust, but I believe it will never pay to import the seeds. All insects are fond of these seeds, and I have been obliged to place the pots on supports with the feet of these supports in Lysol to avoid the incursions of ants. It is a common proceeding in your countries, but not here. The seeds begin to germinate in a few days. The plants remain very delicate in our houses, but are easily propagated by cuttings.

I trust some of your planters will be enterprising and kind enough to send me through you a few samples of the gum from *sapotaceous* plants from your fine country, and if possible latex from the same. The latter must be packed in bottles mixed with 2 per cent of formol.* I believe that will be sufficient for avoiding the coagulation of the latex, for I can do nothing with coagulated latex.—
Truly yours
A. GODEFROY LEBEUF.

[The following are the trees of the order *Sapotaceæ*, mentioned in Trimen's "Handbook of the Flora of Ceylon," of which the author says that 'all contain a milky juice, which, after evaporation of its liquid portion, affords that variety of Caoutchouc known as Guttapercha:—(1) *Chrysophyllum*; (2) *Sideroxylon*; (3) *Isandra*; (4) *Bassia*; (5) *Palaquium* and (6) *Mimusops*—ED. T.A.]

TEA SEED FROM NATAL.

AN INTERESTING HYBRID.

Ifafa, Alexandra County, Natal, May 28.

DEAR SIR,—At the request of the late Mr. John Fraser, of Umzimkulu, formerly well-known to you as of the "Brae Group" of Gardens, Ceylon, I have taken the liberty of sending you, through Messrs. King and Sons of Durban, a small box of tea seed. Mr. Fraser had a quantity of the seed from me and mentioned that there would probably be an opening for seed in Ceylon, so pleased was he with the jât. All the seed on my place I have imported—some from Darjeeling, some from the Kodanaard (Nilgiris) and some from Ceylon (from a Mr. Inglis.) Consequently the seed I am sending you is a hybrid I shall take it as a great favor if you would kindly ask one of your friends to try the seed and let me know what you think of it. Our seed is ready for shipment February-April. Thanking you in anticipation, I beg to remain, yours truly,

JAS. A. McMILLAN.

[We will get the seed tried at once, but there is certainly no opening for tea seed in Ceylon!—ED. T.A.]

* ? Ether or some acid.—ED. T.A.

THE OLDEST TEA-TREE,

A SCOTTISH EX-PROPRIETOR'S CONFIRMATION.

Edinburgh, May 28.

DEAR SIR,—A letter appears in your Overland issue of 9th May by Mr. Cottam from Pen-y-lan estate, headed "Have we found the oldest tea-tree?" I think so: for on reading the name "Llewellyn" and "Pen-y-lan," a dormant memory of the decade forty is awakened. I remember Mr. Llewellyn (senr.) visiting Captain Reddie at "The Eagle's Nest" bungalow on Karagastenne estate, somewhere in the middle of the "forty decade," and of his saying either that he was about to experiment in planting tea, or that he had done so on his estate in Dolosbage. The tea-tree mentioned by Mr. Cottam cannot be under 55 years old—probably more, if it could be found out in what year Mr. Llewellyn bought and settled on Pen-y-lan.—Yours truly,
P. D. MILLIE.

"TEA SEED OIL":

MR. DRUMMOND DEANE'S LATEST EXPERIMENT.

Travancore, S. India, June 16.

DEAR SIR,—I have read with interest the extracts you give of Mr. Thomas Christy's letter asking for information about Ceylon oils. Now I have been recently experimenting with tea seed oil, the seed taken from "China" and hybrid bushes, and am in correspondence with my London agents about it and am sending them a sample gallon of oil and also some of the poonac by next steamer from Cochin. The poonac when potash is added "lathers" freely and has the cleansing properties of scap. The oil is clear and not unlike olive oil; 1 lb. of clean seed gives, so far as my experiments go, 20 lb. clean oil, but I think if the poonac were boiled and oil taken out, it would be quite 25. Tea seed oil has been used in China from time immemorial for burning purposes; for light, it burns well and gives little smoke.

I am unaware that it has ever been tried as an article of commerce, but the yield in low jât fields if not pruned frequently is very large and possibly it might pay planters to abandon such fields for the purpose of converting the seed into oil. Next hot season I intend gathering off a field of low jât tea systematically, with the object of testing fully the cost of production.—I am, sir, yours faithfully,

H. DRUMMOND DEANE.

P.S.—Before reading your article I was in correspondence with "Indian Gardening" and the "I.T.A." on this subject, and no doubt that paper will shortly have something to say about the matter, as I sent samples of oil and poonac for analysis. I am posting you a small bottle of ordinary oil. Some I have sent London is much clearer. Also a small piece of poonac in case you think it worth while to have them analysed for your readers' information.

H. D. D.

"ACACIA DECURRENS": AS A
"NEW" PRODUCT FOR CEYLON.

Albion, Nuwara Eliya, June 20.

DEAR SIR,—Your paragraph in *Observer* of 17th instant, re *acacia decurrens* as a possible new product for Ceylon, is likely to give anyone interested the impression that it has not yet had a trial. I first planted *acacia decurrens* here in 1887 on very ordinary patana soil, and there is no doubt as to its being a success, as I have marketed several tons of bark from a small belt, and during the past few years have sold (mostly locally), over 300 lb. of seed, the produce of my older trees; while a sample of bark that was sent to the last Paris Exhibition was awarded a medal. (The tree that produced it was raised from my own seed.) To make it a really paying concern it should be grown on a large scale for export, and if in a locality where the timber would command a sale (fuel), that item would add considerably to the profits. You might publish some of the detailed estimates given in Maidan's "Wattles and Wattlebarks;" and if a syndicate could be formed to take the matter up, Government might reasonably be asked to lease or grant free for a term of 10 or 12 years, a few thousand acres of the now useless patanas, not only in Uva but say between Nannoya and Summit Level. Mr. Thomas Kent "discovered" the virtues of minosa bark extract and received as a reward (10,000) ten thousand acres of the richest land he could find in Tasmania.—
Yours faithfully, A. J. KELLOW.

BASIC SUPERPHOSPHATE AND "HUGHES
PATENT."

London, June 21st, 1901.

DEAR SIR,—The *Overland Observer* received this week contains a criticism on the above from a planter who, you state, "has paid a good deal of attention to the subject of the proper manure for tea."

It would be very out of place for me to occupy your space with a view to supporting the merits of a manure introduced by myself. Basic Superphosphate must succeed on its own merits, and it will be sufficient to mention that the material has been devised upon chemical principles in order to supply phosphate of lime in a readily available form, for application to soils naturally deficient in lime, upon which ordinary Acid Superphosphate, when used alone, cannot exert its full benefit.

The practical value of the invention has been recognised by the formation last January of a syndicate consisting of six of the largest manure firms in the United Kingdom who have taken up the patent rights, and the manure is now being prepared and sold in considerable quantities. Ceylon planters, who are shrewd men of business, will properly appreciate the above facts and I now proceed to briefly reply to the points of objection raised by the planter already referred to. He states that, unless Basic Superphosphate is cheaper than Basic Slag, he does not think there will be much sale for it in Ceylon. In reply I can assure him that this is no reason whatever, because the new manure

is of superior solubility in regard to its composition and therefore should command a higher price per ton.

I quite agree with the planter that tea only requires Phosphoric Acid in comparatively small proportion, but it requires to get it in a form readily available as plant food, and not in the condition of a hard fused mass like slag, however finely the latter may be ground.

"Planter" rather contradicts himself in first stating that Tea only requires Phosphoric Acid as an essential ingredient to a moderate extent, and then going on to state that Basic Slag which contains fully 38 to 40 per cent of Phosphate of lime is more effective as a material for burying with prunings than even burnt and slaked lime which practically contains no Phosphate of lime at all.

The cost of Basic Superphosphate in England is about £2 10s per ton for the usual quality which contains 26 per cent of Phosphate of lime soluble in a weak solution of Citric Acid (1 in 1,000 parts of water.) For foreign shipment it has the great advantage over Acid Superphosphate that, being Alkaline in character, there is no danger of the bags being rotted during the voyage; and importers will fully appreciate what immunity from damage in that respect means.

"Planter" evidently recognises the value of the invention when he concludes his letter by remarking that concentrated Superphosphate of lime could be mixed with finely-slaked coral lime, and might be found a cheaper form for restoring the balance to crops which are annuals, but he adds, for Tea the problem is more complicated.

My patent consists in the conversion of Acid Superphosphate into alkaline or Basic Superphosphate by the use of lime, and I am not restricted to any particular strength or quality of the respective ingredients; so that the most concentrated Superphosphate can be treated with lime prior to shipment, and thus all the annoyance of damage, through the rotting of the bags during transit, will be avoided and the manure will arrive in a fine, dry, powdery condition admirably adapted for mixing with the other ingredients necessary to form a suitable complete compound fertiliser for Tea or Coffee.

I enclose you an official reprint of my paper read before the Society of Chemical Industry at Burlington House on April 1st, which also gives an account of the discussion which followed the same.

JOHN HUGHES,

Agricultural Analyst.

TEA SEED OIL.

AN ACCOUNT OF SOME EXPERIMENTS.

Mount Lavinia, June 22.

DEAR SIR,—In answer to your request for some information regarding tea seed oil, perhaps the following notes may be useful:—

Some five years since, I experimented with this oil, which was extracted in two different ways:—(1) by pressing the seed in a "chekku" and (2) by boiling the seed, when the oil was removed by skimming the surface of the liquor. The first kind was like fine olive oil in appearance; and, according to the City Analyst, to whom I submitted samples, it was possessed of many of the latter's properties. It made an excellent illuminant, being in that respect fully equal to coconut oil; and was also very useful as a lubricant for machinery, being equal to the

best vegetable oils used for that purpose. I used it in the tea factory for some time, and gave samples to my neighbours, who spoke well of it. Tea seed oil has been used for centuries by the Chinese and Japanese for lighting, cooking and varnishing purposes. Our estate coolies use it for lighting and cooking, and also for anointing their bodies. The boiled oil gives a good stain and polish to wood work of all kinds, and would make a very fair varnish; and the poonac after the oil has been extracted from it would most probably make an excellent fertilizer for tea.

The raw oil is specially well suited for purposes of soap manufacture, and would in this respect undoubtedly rival coconut-oil, if it could be produced at the same cost. But here is the rub!—and I came to the conclusion, after going carefully into the question of production, etc., that, excepting perhaps upon land already abandoned (i.e. unweeded and uncultivated), it would not be harvested with profit. And even then the seed would inevitably deteriorate in quantity and quality as the bushes become gradually enveloped in new jungle growth. In South India the conditions may perhaps be different.

I published an account of my experiments in "Planting Opinion" for (I think) June or July 1896, but at present I am away from my notes. On my return to the estate, I will furnish Mr. Deane with a copy of Mr. Cochran's report.—Yours faithfully,

OLIVER COLLETT.

TEA-GROWING IN SOUTH CAROLINA.

To the Editor, *The Tropical Agriculturist*.

Office of Special Agent, Tea Culture, U.S. Dept. Agriculture, "Pinehurst," Summerville, S.C., June 6th, 1901.

SIR,—I note in the May No. of your ever-instructive and welcome journal your apparent surprise that the article written by Mrs. Ellis for the "Review of Reviews" did not allude "to the part played by an old Ceylon planter—Mr. Henry Cottam" in the local experimentation. Aside from the fact that the work was that of another, it is but justice to Mr. Cottam and myself to state that his visit to Pinehurst was most agreeable, inspiring, and advantageous to me; although the first cold winter caused me to abandon, as unsuitable to this climate, the Ceylonese methods of cultivation of which, very naturally, Mr. Cottam was the enthusiastic exponent. And I might add that experience has demonstrated that it is better to conform to the taste of the buyer than to attempt to convert him.—Yours very truly,

CHARLES U. SHEPARD.

MR. A. COOKE'S SCHEME FOR A
TEA RESERVE

Watawala, July 8.

DEAR SIR.—Referring to Mr. A. Cooke's scheme—I see no reason why it should not be quite workable, with good agents in Calcutta and Colombo; provided that it receives sufficient support in India and Ceylon. Of course, there would be a tug of war, for

some months after its inauguration, between the buyers and the Syndicate; and the side that holds on longest wins.—Yours faithfully,
D. K.

SOURCES OF TIMBER SUPPLY ON THE
NILGIRIS.

SIR,—A Forest Conservator in 1876 declared that, if forest conservancy on the Nilgiris was efficiently carried out and an adequate number of 'exotic' trees, Australian gums and acacias, planted, thousands of tons of timber would be available annually to send down the ghaut for locomotive purposes, sleepers, building, etc.; adding that *eucalyptus globulus*, though inferior to teak for the interior fitting of houses, is known to be a valuable building material and used in Australia for beams, joists, rafters, and in outdoor work for piers, bridges, fences, rails, railway sleepers and shafts and spokes, and other purposes. Twenty-five years have elapsed since this was said, and the sanguine expectations of this enthusiastic forest official remain unrealised, for no hill-grown timber finds its way down the ghaut and the Nilgiri Railway burns coal and refuses to depend for its sleepers on a local supply.

It was not so long ago either, that an indent for timber from Calicut could not be supplied from the Mudumallay forest for the reason that none was available.

Mudumallay, referred to, is a forest lying to the north-west of the Nilgiris on the Mysore frontier, extending from Tibbakadu northwards beyond the Mudumallay Hill, until it joins the Wainad teak hill. It is approximately 300 square miles in extent, of which 200 square miles have been leased by Government from the Tirumalaped of Nilambur, for 99 years, at a rental of rupees 3,500, beginning with the year 1862. Before that date a five years' lease existed of the same forest, from which the supply of teak for the construction of the Wellington barracks was drawn. This forest contains much teak and other timber, but is so remote that such timber really has little marketable value, except for the Nilgiri plateau and for Mysore, and communication with the former is by a ghaut of stiff gradient; and with the latter the road is some 80 miles in length.

The teak planted at Mudumallay by the Forest Department in 1868-69, is not promising—being too far away from the influence of the South-West Monsoon; in fact, experience has shown that teak planting in mountainous countries does not promise so well as when planted in rich valleys, though the mountain timber is regarded as superior to the produce of richer and moister soils.

There is another teak forest on the confines of the Nilgiri District, though strictly speaking no part of it, named Bennie. It is 80 square miles in extent, and the property of Government, very similar to Mudumallay in contents, but more exposed to the South-West Monsoon, for which reason its growth of teak is judged to be finer.

Barring the above, there are really no indigenous timber forests on the Nilgiris. Officially planted Australian gums and acacias amount to something like 1 000 acres in extent—but they have no appreciable effect on the house building of the plateau, where the gum is found to be too stringy and wanting in durability—though I have heard the District Board Engineer say that a

timber bridge of blue gum piers that had stood in the water for 15 or 20 years were found on lifting to be as sound as when put down. This, however, has not been the experience of others, and the fact remains that no one who can afford teak or vengay will build with blue gum.

The 1,000 acres of planted blue gum and acacia above mentioned are in 21 plantations, but beyond using these plantations for fuel the Forest Department has no demand for their growths. Most of them are not more than 20 years old, and this may be a reason why the capability of the exotics are not known and appreciated.

Of the blue gum—the Forest authority above quoted says that from measurements made he can state that 25 tons of dry timber per acre per annum are sure of being returned,—but a proviso is added that the growths in most if not all the plantations are very uneven and variable—mere spindlings being interspersed with trees of 2 and 2½ feet diameter.

The 21 plantations are scattered over a wide area,—and are in some instances 20 miles apart, so that every aspect and soil has been tried.

Private owners have done a great deal in the way of growing blue gums, but no single planter that I know of will admit that he is growing the tree for timber, all being satisfied with it for fuel, and more particularly for shelter, for which latter purpose it is admirably adapted.

I was told the other day by the Forest Officer of the Nilgiris, that the unrestricted growth of blue gum was seriously menacing the water-supply of the district, and thus stultifying the purpose for which conservancy was being carried out. That purpose will be understood when I tell you that, at present, no less than 369 square miles of forest are close reserves, and proposals are now under consideration to add 5 or 6 more square miles to the area. The proportion thus represented in a small district of only 957 square miles, with 124 square miles of unculturable waste, is simply unprecedented. The only benefit this officer claims for such wholesale reservation is the alleged regularity and abundance of the waterflow in the Cauvery River. But as this river has two other confluent, one from Coorg and the other from the Annamalais—it is hardly fair for the Nilgiri Forest Officer to take all the credit—even if the water-supply in the Cauvery River has been as he claims it to be. The late scarcity and drought in the Southern Presidency was attributed to the deficiency of irrigation water—then how can the river flow be what is claimed for it?

A. M. I. C. E.

—*Indian Engineering*, June 22.

THE TEA OVERPRODUCTION QUESTION:

MR. A. COOKE OF CHOTA NAGPORE
ON WHAT IS BEST TO BE DONE;

A BOLD SCHEME FOR TEA GROWERS;

HIS PAST ADVICE IN RESPECT OF AMERICA.

DEAR SIR,—In the pages of "Indian Gardening and Planting" I proposed a scheme for the use of the Cess: at that time (April) there had been such strong recommendations for a Cess from the majority of those who spoke at public meetings that it appeared a certainty.

But as week followed week and nothing was done, I continued my exertions to get a Cess, and acting under advice I confined my endeavours to

rousing the tea public to vote for the Cess. My friends said that we must first catch the Cess before we cook it. It is different in Ceylon. You have a Cess, and are open to receive proposals for the use of it, and so perhaps your planters will receive my idea without scoffing. I strongly hold the doctrine that an absolute reduction of yield would be fatal, but that the prices of tea at the open sales could be raised by withdrawing the *surplus*; that is to say if the buyers want 1,000 pounds or mannds, or tons, and 1,100 are offered, prices will be low; but if the surplus of 100 can be withdrawn the buyers will have to pay the price we want.

Some time ago your planters offered to reduce the yield by three million lb. and my advice is to make that three million, but withdraw it as required by the rates ruling at the sales. If prices are extremely low it might be necessary to withdraw 20% from each sale for three or four successive sales, and as prices improved the amount to be withdrawn would become less until absolute equilibrium should be established. "Equilibrium" means a price which would pay for production and also for selling, the producer and buyer would both get their *legitimate* profits.

I may note here that a *reserve* of tea would enable us to fill up any temporary deficiency which otherwise would force the buyer to pay a price that left him no margin of profit.

Any sensible scheme *must* protect the interests of the buyer.

To return to the promised reduction of offerings, I proposed that the tea should be made, but the cost of making it would have to be repaid to those who join the scheme.

The cost of making tea in India, *i. e.* plucking, manufacture, fuel, boxes, freight to Calcutta and sale charges, comes to about R12½ per maund of 80 lbs, *i. e.* 2½ annas per pound of Tea.*

I advised Indian Planters to put on a Cess of 2 pies per pound which would give a revenue of from 19 to 20 lakhs of rupees; the cost of 10 million lbs of tea at 2½ annas comes to about 15½ lakhs, and leaves 3½ to 4½ lakhs for expenses of distribution. I recommended that percentage of tea should be drawn from the sales of each class of tea, not only the lowest, but of *all* classes. Thus according to the orders for the amount of tea to be withdrawn, each garden would reserve one out of 20 or one out of 30 or 40 chests of *each* class of tea. This reserve could be forwarded on demand to the Association for disposal, and would be paid for at 2½ annas per pound out of the Cess.

The tea thus reserved would be credited to the garden at the prices actually obtained at the sale for the unreserved tea.

The reserved tea would be sent to new markets and disposed of.

If it is *given* away, there would be no return, but supposing it to be sold at 2½ annas, clear of all expenses, that sum would be refunded to the gardens.

By this means a certain proportion would refund the cost of the Cess itself. The Cess on 1,000 pounds at 2 pies comes to R10/6/0. 66 lb of tea at 2½ annas is also R10/6/0, and 66 is about 5½ per cent of 1,000, so that 5½ per cent of tea reserved and sold at 2½ annas would recover the cost of the Cess at 2 pies per pound on the whole crop. There is an old saying that

* Fifteen cents per lb., to which cost of cultivation has to be added.—*Exp. T.A.*

you get nothing for nothing and very little for a ha'penny. Apparently I want to propose that the Cess shall pay itself and thus cost nothing. But in this case we gain by *unity* and efficiency. The mere fact of union amongst tea owners with a *sufficient* capital at their backs, will, to begin with, force the buyers to pay the Cess. The *first* two pies increase in prices will pay for the Cess. That sum of money, instead of being distributed amongst the producers, will be collected for the *general good*. It will buy *average* tea which will be sent forward to create a demand. When you *give* your surplus to the dealers they reserve the best tea for their ordinary customers, and they send forward the lowest classes to create a demand.

I have thus shown that, by *pretending* to pay a Cess of two pies per pound, we shall force the buyers to pay it, and we shall be able to extend our markets with *average* tea at cost price instead of with low-class rubbish at double that price.

Our *average* tea will be placed on new markets at 2½ annas at Calcutta, say 3½ annas anywhere in the world, and the present low-class tea bought in Calcutta at 2 annas is placed on those markets at about 4 to 5 annas. Does it not follow that better tea at half price would do more to create a demand than worse tea at double the price?

To put it in a clearer light, we could transfer the profit from the buyer in Calcutta or London to the pockets of the actual tea dealer in the new market; and he, having placed the new tea at a big profit, would go to Calcutta or London and get more of it.

In armed conflicts the one who can *show* overwhelming force is not compelled to *use* it; it is only necessary to send a commissioner or two to take possession of the desired territory.

In our case we can show an overwhelming force by paying a cess of 2 pies per pound on the *first few invoices of tea*, and we compel the buyer to refund that, and to go on paying this heavy cess, which we use in recovering that territory which the force of circumstances has made over to him. We shall recover the two annas per pound of tea which we do *not* get now, and which is *due* to us, and which the buyer and consumer have taken from us.

I have provided for the greatest difficulty, which is the *storage* of the reserved tea, by proposing that the reserves shall be kept (sealed) on the gardens till required. We can expect so much loyalty from managers that they will *honestly* reserve the tea, and not fill up the chests with bad tea or sand.

Even if all is granted there will be a minority who will refuse to reserve any tea. They will benefit by selling their *whole* crop at the improved rates. The *only* method of preventing this illicit gain would be to impose a Cess at a rate that would cover the gain in prices, and to refund the surplus funds to those who subscribed to any generally approved movement, but this of course is not practicable.

I fear that I exhibit a daring which may be considered folly in lightly mentioning sums of 20 lakhs of rupees per annum, but I have endeavoured to show that we shall *not actually have* to pay it ourselves, and these sums are small compared with the amount of gain to be obtained.

Our Indian crop, when it reaches 190 millions, at one anna per pound represents 118½ lakhs of rupees, and an actual expenditure of 20 lakhs would be cheap for such a return. And then I have stated

that we shall be able to recover *two annas* per pound, which comes to 237½ lakhs.

You in Ceylon spend about two to three lakhs of rupees per annum, and you do *not* get the buyers to pay it, because India has no Cess and the prices cannot be *forced* up. Let us suppose that you get a return of 200 per cent. on your expenditure, that is to say, you profit to the extent of 20 or 30 lakhs of rupees; that is real good business, but what is the use of this paltry profit divided amongst all tea owners?

It seems to me to be useless to struggle unless we, the tea makers, get the absolute command of the situation, and I reckon that 20 lakhs in India and 14 to 15 in Ceylon would effect this.

Unlike the simile used above, we send an insufficient force to capture the desired territory, and that force is cut up, and we remain vanquished; we remain the absolute slaves of the buyers. They will allow us only sufficient food to keep us alive.

By using ten times our present force we *shall* conquer and make up for lost time, and the tea world will belong to us; and China and Japan will retire into their own borders.

This scheme of mine surpasses even Mr. Mackenzie's aspirations. You could let him handle millions of pounds of *good* tea. Several years ago I ("1874") advised you to make "Green Tea," and to send big lots of tea to America to sell for what they would fetch; but Mr. Mackenzie would not dare to be years ahead of his time.

I understand that your Associations are feeling sore with him, but in point of fact you set him to an impossible task; you wanted to get a return of one anna per pound on your tea for an expenditure of two lakhs of rupees.—Yours,

A. COOKE.

GUTTA PERCHA AND RUBBER.—There can be no doubt that in these we have two products, the demand for which is bound to go on increasing for many years; while it is very doubtful if the present supply from the natural forests of South America, Africa, the Malayan archipelago and India can be maintained. Planters in suitable regions are bound more and more to study all available information about Rubber, &c., and to go in for the cultivation as far as possible. In this connection we call attention to an interesting suggestive letter from our correspondent, Mr. Godefroy-Lebeuf, of Paris, accompanied by a very fine sample of raw gutta percha, due to some process not yet generally known, although the tree is a well known one in the Straits. In other respects, the information of our correspondent is interesting, as when he speaks of rubber-yielding trees suitable to a dry climate and soil, such as prevails in Algiers and Tunis, and which might therefore be of service in Northern Ceylon. We hope to hear more on this subject. A great deal of information respecting *Mimusops balata* is given in our Manual, "All about Rubber." As to gutta-yielding trees, we fear there are few in Ceylon—none yet grown by planters (?) we believe—though the late Dr. Trimen did much to promote the growth of the best (*Dichopsis gutta*) in the Peradeniya and Henaratgoda Gardens. We should be glad to have any sample of "gum" or "latex" to send to our correspondent in Paris.

PLANTING NOTES.

GETTING RID OF COUCH GRASS.—The following method is reported to be entirely successful:—Plough during mid-summer, and keep couch from getting much headway by occasional harrowing during autumn months. Cross-plough in spring, harrow thoroughly, and sow some strong-growing crop in drills. Hoe constantly until crop is mature. Then repeat first year's proceedings. At the close of the second year not a vestige of couch will remain.—*Agricultural Gazette of New South Wales.*

COCONUTS.—The question has recently been raised as to the largest number of nuts of all sizes which a coco palm can have on it at one time? Some one mentions 500 to 700; but we are inclined to think this too much. Has any one ever taken the trouble to count?—Then again, what was the largest number ever got at one plucking from a single tree? At Zanzibar we see that in one case, where quarterly pluckings were observed, over 100 nuts (110 in one case) were got from several trees. Is that unusual?

TIMBER ON THE NILGIRIS—Some interesting notes on the timber supply of the Nilgiris appear in our daily and *T. A.* It is pointed out that the exotics, Australian gums and acacias, though extensively planted, are not held in much favour for timber, but are rather grown for fuel and shelter. Wood for timber is usually drawn from the teak forests of the Nilgiris. A drawback to gums and acacias is their great capacity for the exhaustion of moisture.

ROYAL HORTICULTURAL SOCIETY: ORCHIDS.—The fortnightly show of the Royal Horticultural Society was held yesterday at the Drill hall, James-street, Westminster. The orchids made a beautiful show, and nearly every collection included numerous specimens of *Cattleya Mossiae*. Sir F Wigan sent a group which contained some fine *Miltonias*, with a few *Masdevallias*, a pretty example of *Sobralia macrantha alba*, white with a tinge of yellow in the throat, and two plants of the *Thunia Marshalliana*, bearing white blooms with variegated hairy lips, on the top of flag-like foliage. Messrs. Veitch and Sons' group included three *Oncidiums* of the divaricatum variety, having long sprays of small yellow flowers. Among the orchids staged by Mr J Colman, of Gatton-park, Reigate, there was a well-grown *Cymbidium* and many excellent *Odontoglossums*. Mr H Smee, of the Grange, Hackbridge, and Messrs. H. J. Sow and Co. exhibited some handsome *Cattleyas*. Mr H T Pitt's collection included a splendid *Odontoglossum Crispum Pittianum*, well marked with brown blotches on white; Messrs. Stanley, Ashton, and Co. sent a large variety, one of the orchids which took an award of merit being a pretty *Cattleya Mossiae* of the "Mrs F W Ashton" variety, which had white petals, prettily crimped lip, with very light crimson-purple markings, and a rim of yellow round the middle of the lobe; and Mr H F Simmonds, of Beckenham, staged a beautiful group. All the above exhibitors were awarded medals, and Mr R H Murray, of Great Marlow, received "cultural commendation" for a grand plant of *Dendrobium thysiflorum*. Among the miscellaneous groups there were several charming displays of hardy flowers.—*London Times*, June 5th.

GAMBOGE FRUITS.—Mr. Gutteridge, the Curator of the Liverpool Botanic Gardens, obligingly sends us fruits of the tree yielding the gum known as Gamboge. We do not remember to have seen them previously. They are globose, the size of a small Apple or *Diosyros kaki*, and of a yellow colour. We may allude to them on a future occasion.—*Gardeners' Chronicle*, May 25.

COFFEE IN COSTA RICA—is the subject of a second contribution in our daily and *T. A.* from a planter who owes his birth if not his training to Ceylon and who has a good deal to tell us about the mode of working in the Central American Republic; but strange to say, as our note to the letter mentions, nothing is said about Cacao which we understand to be a great crop in Costa Rica for local consumption.

TEA SEED OIL. Mr Drummond Deane's letter elsewhere opens up a happy vista for the proprietor with abandoned or anything but paying tea fields. Tea seed oil may figure in our Chamber of Commerce exports by this time two years hence! But we have first to await the result of the experiments Mr. Deane is making, unless any planters in Ceylon will experiment for themselves. We shall be glad, if so, to hear of their results.

A COFFEE EXCHANGE IN RIO DE JANEIRO.—It is proposed to establish a Coffee Exchange in Rio de Janeiro, with branches and depôts in Santos, Bahia and Victoria. A petition has already been made to the President of the Republic. This Exchange is to be managed by seven directors to be chosen by parties interested in the trade, except the chairman, who is to be nominated by the Government. It is also proposed to establish agencies to furnish statistics of the production and consumption of coffee, in order to establish a basis for arranging the prices.—*Handel's Museum.*

OVERPRODUCTION AND THE FUNCTION OF GOVERNMENT.—There is a curious remark in a recent London market Report in reference to the Overproduction of Brazilian Coffee which we do not think has been noticed locally. The writer says:—

'In December last, the popular figure was 9,500,000 bags receipts for the season, today 10,500,000 bags is likely to be nearer the mark. Another object lesson is that, even half way through a crop, estimates are anything but infallible. It is curious that, whilst modern Governments can take away from the individual in money, for the benefit of himself and his country, they cannot take away from him in kind, for the same benevolent purpose. We hear of Government bounties to stimulate production, but we never hear of Government action to check the same. If the Brazilian Government were to destroy a percentage of the Brazilian Coffee Planters' production, the individual and the Government would benefit, and why, if it be wise to stimulate, it should be foolish to check, we cannot understand.'

This has reference to the fact that the current season's Brazil Coffee Crop—or rather Rio and Santos exports—are to reach 11 to 12 million bags, whereas the world (according to W H Crossman & Brothers) only wants 8½ million bags of "Rio and Santos."

THE DUMONT COFFEE CO., LTD.

DIRECTORS IN LONDON.—P R Buchanan (Chairman), H K Rutherford, Hon. H A Lawrence, G A Talbot, R Hart, and S Boulnois.

DIRECTORS IN BRAZIL.—John Buchanan and Senhor Rodolfo Miranda.

AUDITORS.—Messrs. Jackson, Pixley, Browning, Husey & Co.

SECRETARIES AND MANAGING AGENTS.—Messrs. P R Buchanan & Co.

OFFICES.—45, Leadenhall Street, London, E.C.

Report to be presented at the Fifth Annual General Meeting of the Dumont Coffee Company, Limited, to be held at Winchester House, Old Broad Street, London, E.C., on Monday, the 24th day of June, 1901, at 12 noon. The Directors submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1900.

The Gross Profit for the year, exclusive of	
£7,097 12s 8d brought forward from	
previous year, amounted to	£58,495
And the London Charges were	3,340
	<hr/>
Leaving a Nett Profit of	£55,155
Amount brought forward from 1899	7,098
	<hr/>
	£62,253

Interest at 5½ per cent. per annum (less Income Tax) has been paid on the Debentures, amounting to	£20,981
Income Tax on same	1,008
A payment of 2½ per cent. (less Income Tax) was made on 19th April, 1901, on account of arrears of Dividend on the Preference Shares	9,500
Income Tax on same	500
	<hr/>
	31,989

Leaving a balance of	£30,264
It is proposed to place to a Reserve Account	20,000
	<hr/>

And to carry forward a balance of £10,264 The Crop, which was estimated at 75,000 cwt., amounted to 81,781 cwt. Of this quantity, 70,478 cwt. were sold in London, and the remainder in Santos and New York.

The gross average price realised for the whole crop was equivalent to 40/2 per cwt. landed in London, as against 29/4½ per cwt. the previous year, but owing to the adverse milreis Exchange the cost in London was 6/10 per cwt. more than in 1899.

The spot price of "good average Santos Coffee," during the period of the year in which the Company's crop was sold, was 35/8 per cwt., while the average price realised for the Company's pulped Coffee, of which there were 22,760 cwts., was 47/7, and for the Company's unpulped Coffee 37/4 per cwt.

Owing to the increased production of Coffee from Brazil during the year under review, the price of ordinary Santos Coffee has now fallen to 29/ per cwt., and with the Exchange at about 11½d per milreis, the margin of profit is considerably diminished, causing the position of growers to be one of anxiety at the present time.

Under these circumstances, and in view of the necessity of providing working capital, the Directors, after serious consideration, do not feel justified in recommending the distribution of any further dividend, but consider it prudent to place the sum of £20,000 to Reserve Account, carrying forward £10,263 15s 7d.

With regard to the condition of the Estate and of crop prospects, the Manager writes, under date the 8th April:—

"GENERAL APPEARANCE OF PROPERTY.—This continues most satisfactory, and there is lots of wood to give another good crop in 1902. I suppose that Bourbon Coffee at Agua Vermelha and Paty will

give less, as it seems only to yield well every second year, but all the old Coffee looks as well as ever it did, and the young fields at Guerra, Iguae, and Paty have very much improved and ought to bear well next year."

* The Coffee crop harvested to 31st ultimo was 38,000 cwts., as against 23,300 cwts. to same date last year, and the Manager's latest estimate of the current crop is 120,000 cwts.

Mr. R Hart and Hon. H A Lawrence are the retiring Directors, and, being eligible, offer themselves for re-election.

The Auditors, Messrs. Jackson, Pixley, Browning, Husey & Co., also retire, and again offer themselves for re-election.—By order of the Board, P. R BUCHANAN & Co., Secretaries.

12th June, 1901.

PITIAGAMA CINCHONA COMPANY.

Minutes of general meeting held at No. 11 Queen Street, Colombo, at 12 noon on Saturday the 29th June, 1901.

Present.—Messrs S Bois, H G Bois and C E H Symons.

Minutes of last general meeting were read and confirmed.

Notice convening the meeting was read.

Proposed by Mr H G Bois and seconded by Mr C E H Symons:—That the Report and accounts for the 13 months ending 31st January 1901 be adopted.—Carried.

Proposed by Mr C E H Symons and seconded by Mr F W Bois' attorney:—That Mr Stanley Bois be re-elected Director.

Proposed by Mr. C. E. H. Symons and seconded by Miss W. Cross Buchanan's attorney, that Mr. E. M. Shattock be re-appointed auditor on a fee not exceeding R50.

The report was as follows:—

The Directors herewith beg to submit their Report and Balance Sheet for the thirteen months ended 31st January, 1901.

The total quantity of Tea manufactured during the period under review amounted to 106,948 lb., of which 101,195 lb. was secured during the twelve months to 31st December last, against an estimate of 77,000 lb ; the average price per lb. realised being cents. 33·02, against cents 38·33 in 1899.

The Directors have to point out that the amount of R23,206·68 appearing in last year's account as in suspense has been transferred, which accounts for the balance of the Profit and Loss Account (viz., R27,765 64, as will be seen from the accounts) being so considerably in excess of that for the year 1899.

As previously intimated to the Shareholders, the estate has now been leased for a term of ten years, with the option to the Lessee of discontinuing same after the expiry of seven years as from the 1st February, 1901.

The Lessee is to have the option of purchase at any time during the currency of the lease for the sum of £7,000—less £500 to be spent by him in putting the Estate and Factory into good working order—i.e., for £6,500 sterling nett.

Mr Stanley Bois retires from the board, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the meeting.

THE BOGAWANTALAWA DISTRICT TEA COMPANY, LIMITED.

ANNUAL REPORT.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st March 1901, duly audited.

The yield of Tea largely exceeded the estimate in spite of finer plucking during the last three months of the season, and the cost of production, though slightly higher than last year, is still moderate. The average price obtained for the Tea is again lower, owing to the unsatisfactory state of the market during the year. The expenditure includes that incurred on New Clearings, Buildings, and Machinery.

The total yield was 1,236,272 lb. Tea plucked off 2,185 acres, being at the rate of 565 lb. per acre all round, costing free on board at Colombo 23·92 cents or 3·93d per lb. The gross average price of the 1,220,246 lb. sold in London was 7·51 per lb.

The crops for the current season owing to finer plucking are estimated at 1,188,000 lb. tea.

The gross average at which drafts were negotiated was 1s 4½d per Rupee against 1s 4 5-16d in the previous season.

The Directors desire to place on record their appreciation of the services of their Manager and his staff in Ceylon.

STATEMENT SHEWING RESULTS OF WORKING FOR THE FOUR YEARS ENDING 31ST MARCH, 1901.

Season.	Acres.	Total Tea Crop. lb.	Yield per acre. lb.	Cost of Crop per lb. at f.o.b. Colombo.	Gross Average per lb. Tea sold in London.	Average Rate of Exchange per Rupee.	Preference.	Dividends Ordinary.
1897-98	2,041	994,413	487	4·22	8·20	1/3 9-16	6 6	
1898-99	2,081	1,031,782	495	4·12	8·71	1/4 5-32	6 7½	
1899-00	2,185	1,209,451	553	3·69	7·98	1/4 5-16	6 7½	
1900-91	2,185	1,236,272	565	3·93	7·51	1/4½	6 6	

The Profit for the year amounts to	£13,290	5	11
To which has to be added Interest	132	7	11
And the Balance from last year of	952	10	5
	<hr/>		
	£14,375	4	3

Interest on the Mortgage Debentures has been paid, less Income Tax .. 399 0 0

Dividends on the 6 per cent. Preference Shares for the 12 months were paid on the 3rd October 1900, and 3rd April 1901, less Tax .. 5,301 0 0

An Interim Dividend of 1½ per cent. on the Ordinary Shares was paid, less Tax, on the 9th January, 1901 .. 1,425 0 0

Income Tax to April 1901 has been paid .. 722 2 0

IT IS PROPOSED—

To pay a final Dividend of 4½ per cent. on the Ordinary Shares, making 6 per cent. for the year, which will require, less Tax, .. 4,275 0 0

To transfer to Reserve (increasing this account to £4,500) .. 1,500 0 0

And to carry forward to next year the balance of .. 753 2 3

£14,375 4 3

The Director retiring on this occasion is Mr Charles Petherstonhaugh and, being eligible, he offers himself for re-election.

Mr. John Smith, the Auditor, also retires and offer himself for re-election.

By Order of the Board, ROBERTSON, BOIS & Co., Agents and Secretaries.

12, Fenchurch Street, London, E.C., 18th June, 1901.

SCHEDULE OF THE COMPANY'S ESTATES.

Estates.	Tea, full bearing.	Tea, not in bearing.	Forest.	Grass.	Chena and Patana.	Total.
Kirkoswald	756	35	74	12	—	877
Bridwell	382	36	35	5	15	473
Elbedde	705	—	27	15	—	747
Bogawana	342	26	44	6	18	436
Total	2,185	97	180	38	33	2,533 acres.

PLANTING NOTES.

OTTERY TEA COMPANY.—This Company will be wound up shortly and the purchasers of the property of the Company ought to make a good bargain.

GREEN TEAS.—We call attention to the weekly report of Messrs. Walker, Lambe & Co. on another page. The quantity of Ceylon green teas sent is said to have been so insignificant as not to make it worth buyers' while to attend to it.

A BIOLOGICAL STATION FOR CEYLON.—Referring to the appointment of Professor Herdman to report on the Pearl Fisheries of Ceylon, unofficially announced by us, Mr. Collett looks forward to its consummation in that it will probably lead to the establishment of a Biological station for the island, whither students will come from all parts of the world, a station such as is found at Naples today. Fees from such students, it was pointed out to us, would go a good way towards paying for the expense of the station.

"ACACIA DECURRENS."—We have pleasure in publishing today the letter sent us by Mr. A. J. Kellow of Albion estate Nuwara-Eliya, giving his experience of growing "acacia decurrens." His experiment has been attended with undoubted success, and he thinks the cultivation of this plant could be made a really paying concern if it were carried out on a large scale for the purpose of export. This could be done by a syndicate and the reasonable suggestion is made that Government might be asked to lease or grant a few thousand acres of the patnas in Uva and between Nanuoya and Summit Level.

MANURING BANANAS.—Mr R H Elworthy, of Priestman's River, took 5 acres of his coast lands in Portland, red soil which, he states, does not grow bananas; he manured one acre with sheep manure and on this acre the bananas made luxuriant growth, and came in earliest, but bore small bunches of seven and eight hands. On one acre rotten coconut husks were dug in, and here the fruit came slow, with less stem and head growth than the acre with sheep manure, but the bunches were larger and fairly good on the whole. On the remaining three acres no manure was applied, and the bananas grew very poorly, producing, when they produced fruit at all, small bunches and poor fruit.—*Journal of the Dept. of Agriculture of Western Australia* for June.

ADVERTISING TEA.—Mr. P. C. Larkin's letter to Mr. Mackenzie provides very sound reading and his battle-cry, "advertise," is well spoken. As to the progress of Greens in the West, it rests with the planters, as Mr. Larkin says. But for pushing *black teas* Mr. Larkin's argument applies equally, except in so far as an established taste has to be changed, and it is only wholesale advertising, thus getting at the consumer, that will make a way for Ceylon black teas in America.

"BASIC SUPERPHOSPHATE."—We direct attention to Mr. John Hughes' reply to the criticism which has appeared in our columns. The contents of the accompanying pamphlet, we shall give in our *Tropical Agriculturist*, more particularly because the discussion—where Mr. Hughes' views met with a good deal of criticism, though on the whole he carried the experts present with him,—is exceptionally interesting. It is curious to read that "some years ago (Mr. D. A. Louis, a pupil in Rothamstead Laboratory, is speaking) "Dr. Augustus Voelcker, Sir John Lawes and Sir Henry Gilbert all set their faces against basic slag and considered it absolutely valueless." Again, later on, Dr. John Voelcker considered it worthless. The latter afterwards pointed out that the basic slag as now used was a very different body from the slag that was first introduced.—But all the same, we infer from the discussion that the first agricultural chemists of the age were mistaken at first as to the future before basic slag—and why not possibly in some other matters? We live to learn.

THE INDIAN TEA ASSOCIATION IN CALCUTTA—is inclined to be bitter against the Ceylon Planters or their Association for reasons which will be found in their proceedings given elsewhere. If we could only have foreseen war and a war-tax in 1898, doubtless the course taken in Ceylon that year in regard to the Tea Duty would have been very different.—On the other hand we have been urging the Indian Tea Association and planters for half-a-dozen years back to establish a "Tea Cess" after the example of Ceylon; and only now do they realise the necessity and importance; and yet, still, we may ask, where is the Memorial to the Viceroy, signed by every Tea or Planters' Association Chairman and Secretary—or better still by every planter—in India? Instead of a move of this kind, all the planters' energy seems to be spent in writing to the press, and we have even appeals to us in Ceylon, to help them to get a Tea Cess! So strongly do we feel in the matter that we would have our P.A. last year to ask the Governor of Ceylon to mention the importance of the matter to Lord Curzon; but there is a certain degree of local jealousy; and it is far more important that the Indian Tea Planters should memorialise on their own account. Cannot so prolific a writer as "A.C." draft a brief pithy Memorial of half-a-dozen paragraphs at most? Then, if such were approved in Calcutta, printed and circulated with sheets for signature, the whole business could be done in a month or so.

MIDLANDS RAMIE SPINNING Co., LTD.—Registered June 13th, with a capital of £10,000, in £1 shares, to adopt an agreement with E A Wallis and W Watson, to acquire any patents, inventions, and the like, and to carry on the business of ramie manufacturers, growers and merchants, etc. No initial public issue. The number of directors is not to be less than 2 nor more than 5; the subscribers are to appoint the first qualification, £100; remuneration as fixed by the company. Registered by Fullilove & Co., 120, Cannon St E C.

COFFEE IN BRAZIL.—In his message to the Congress of the State of S. Paulo, the President refers to "the financial crisis through which the whole country is passing aggravated by the low price of coffee." He shows that, in 1892, 245½ millions of kilograms of coffee shipped were officially valued at close on 252 million dollars; and, in 1900, about 267 millions only was the value of as much as 387 million kilograms! He then goes on:—

Undoubtedly other coffee-producing countries will likewise feel the fall and have to contend with difficulties as great as ours. Planters in Java and Sumatra already complain of the damage inflicted by the over-production of this country and maintain that the future of coffee will be everywhere controlled by conditions here. In Mexico, the West Indies and Central America complaints are also heard that coffee is no longer profitable in consequence of our competition. After spending so much labour and money on raising the coffee industry to its present proportions, it would be a tremendous mistake to abandon the struggle when the exceptionally favourable conditions and the fertility of our soil and the tenacity of our planters are the most certain guarantee of ultimate success. If coffee cultivation has to be abandoned anywhere, it will not be in S. Paulo, where the conditions of resistance are better than anywhere else!

What is wanted is that planters, merchants and Government should work all together and harmoniously, for the common end and give no attention to fanciful measures that can effect no real remedy and only make things worse.

To cut down working expenses, improve their process and secure permanent and steady labour, should be the aim of planters thus imitating the example of countries where production is far more insignificant, but better prices are secured by better products. On the side of *commissarios*, they should aim at extending old markets and opening new ones as well as at organising local elements of resistance to speculation, and the elimination of needless middlemen and consequent reduction of commission and direct dealing with consumers. The Santos market, important as it is, is now too narrow for operations so vast and branches of several exporting houses have, we are informed, been already started in America and Europe, whilst a few planters have commenced selling direct to consumers with good results. Energy and agitation cannot fail to produce good results for planters, if persisted in. By *Le Brésil* I observe that during the last few days a new house for exclusive sale of São Paulo coffees was opened in Paris by Snr. Conceição, with the object of promoting consumption and raising the reputation of Brazilian coffees so unjustly depreciated by retailers.

The responsibility of the government, deriving as it does nearly all its revenue from coffee, cannot and has not been overlooked. By promoting immigration, improving the means of transport, reducing railway charges, funding agricultural schools and encouraging mortgage banks and other cognate measures, the government has already done much to benefit the planting interest.

There is much here that is applicable to planters, merchants and the Government in Ceylon in reference to tea.

IMPROVED AGRICULTURE FOR THE PRESENT AND NEXT GENERATION.

SCHOOL GARDENS AND THE SINHALESE AND TAMILS :

A KACHCHERI EXPERIMENTAL GARDEN IN EVERY REVENUE DISTRICT.

The Director of the Royal Botanic Gardens, in his lecture on Thursday the 13th inst., laid a sound foundation for all agricultural instruction and training with reference to the rising generation of Ceylonese. The educating (educating) and training of the powers of observation among young people has long been recognised as of much greater importance than the "cramming" with facts, whether of grammar, geography or history or the learning of lessons "by heart"; and it has also been recognised that no branch of study is better fitted to educate and train the observing power of children than "botany"—the study of plants. In this connection we may say there is immense encouragement in dealing with oriental pupils, at any rate in rural districts; from the simple fact that all Sinhalese and Tamil villagers, as a rule, know a great deal more about the plants and vegetables around them, and their various uses, than do the same class of people in the United Kingdom or perhaps anywhere in Europe, save in France where the peasantry cultivate a very close and practical acquaintance with nearly every plant within their reach. Dependent, as the rural Ceylonese are, on the products of the soil for their food and medicine, they know far more in their own way regarding a great many plants than Europeans usually give them credit for. Waring's "Bazaar Medicines of India" is a standing proof of the wonderful extent to which the people in Ceylon (as in India), under the guidance of their Vedarālas, utilise the vegetation of all degrees within their reach, from the stately tamarind tree or palm to the lowliest of roots or mosses. Such information and experience trickles down from father to son; and therefore it is that schoolmasters interested in their agricultural work, and well-equipped themselves, should find apt pupils among Sinhalese and Tamil lads and lasses as they teach them about plants, how best to cultivate, observe, and utilise them, with a view to gardens of their own in days to come.

But a generation must pass before the fruit of such a course of study can be seen, even if Mr. Burrows had at hand the qualified and interested schoolmasters; and this fact brings us to another side of agricultural progress among the people, which, we trust, will not be lost sight of by Mr. Willis, the Revenue Officers, or the Government. Just as every Village School ought to have its Garden for experiment, teaching and observation, so ought every Kachcheri in the island to have an Experimental Garden attached to it, specially with a view to the introduction of new products, but also for the improvement of existing plants and fruits. Such Gardens should be under the direction of the Revenue Officers (with trained gardeners from Peradeniya?) and they should be periodically inspected

by Mr. Willis or a member of his Staff. Moreover, once a year there should be an Agri-Horticultural Show—an occasion as well for holiday-making and games—at the headquarters of each revenue division, such Show to be confined to the products of the district, with prizes in cash, medals, and even higher honours (costing nothing!) for exceptionally meritorious cases. The expense of an annual Show, if carried on after a modest and practical fashion, and specially in the interest of the native cultivators and their headmen, should be very little; while the good achieved, through stirring up emulation as to field and garden produce and live-stock, could not fail to be considerable and to increase year by year, more especially when the annual gathering afforded the opportunity for comparing the villagers' products with those from the Kachcheri Experimental Garden, Cattle &c. Establishment; and for observing and trying useful new vegetables, fruits or other products.

We do not overlook the progress already made in multiplying Gardens, at Badulla as well as Heneratgoda, at Anuradhapura, and Jaffna. But why not in the same way at the capital of each province and each district? If Revenue Officers bestir themselves to make a start with their Kachcheri Headmen, we feel sure the Peradeniya authorities will help them with plants, seed and personal aid—and that for this the sanction of H.E. the Governor in executive Council can readily be obtained. In this way, every Kachcheri might have an Experimental Garden begun before the present year expired; and if we were Governor we should take special note, in reading the Provincial and District Administration Reports for 1901, of any mention made of such Gardens and the progress attained with them. In this way, we feel certain a great advance could be made in and around our rural villages, even in the present generation. Recalling the great interest taken by Sir West Ridgeway in this subject of improved Agriculture and His Excellency's evident desire to see the well-equipped Peradeniya Scientific Staff fully utilised for the benefit of local industries, the multiplication of Experimental Gardens or Stations must have the Governor's fullest approval. They cost little (comparatively a trifle); but may achieve much.

THE PRACTICAL FARMER (Price 1s.)—A *Vade Mecum* of Grasses, Roots and Forage crops.—Messrs. James Carter & Co. have issued a valuable pamphlet book, which will be helpful in the selection of suitable grass seed as well as for its directions for the preparation of grass land. Numerous illustrations make it easy to recognise the kinds common in Ceylon. One chapter is devoted to "Pernicious Weeds likely to occur in uncleaned samples of grass and clover seeds," and another to Furze, Gorse or Whin. From the latter we learn that Gorse as a young plant is useful as forage, being especially valuable for milch cows as causing an increasing yield of milk; but the Gorse must be young and well bruised. Other chapters are devoted to Crop Pests; Root cultivation; the cabbage as a field crop; a description of the soils of Great Britain (Agricultural and Geological); Permanent Pastures.

THE BANDONG QUININE FACTORY.

The annual report of the Bandong quinine-factory expresses much satisfaction with the results of the Batavia quinine-auctions, and states that new contracts have been made with the planters, which ensure a full supply of bark for this year. As the whole of the Company's capital is invested in the buildings, plant, and stock, it is proposed to issue six per cent debentures for 6,250*l.*, redeemable in six years, in order to provide the necessary working capital; the whole of this issue has practically been applied for. After allowing for depreciation there remains a net profit sufficient to pay a dividend of four per cent which the Directors propose.

The Board refers to the great assistance rendered by Mr. P. van Leersum, who superintends the work on behalf of the Government, and to whose advice the improvement in the manufacturing process is due.—*Chemist and Druggist*, June 22.

CARDAMOMS IN BRITISH CENTRAL AFRICA.

(To the Editor of the Central African Times.)

Dear Sir,—In Mr Hastings' very interesting article on cotton cultivation it is suggested to plant cotton between coffee, which reminds us once more that up till the present no planter has given a proper trial to Cardamoms.

It has been said that some Mlanje planters have gone in for them, but I gather it is only the wild specimen that has been exported. From the fact of their presence here in a wild state one may surely assume that the cultivation of the marketable quality is practicable. A circumstance to be observed in general produce reports is that Malabar and Mysore are the only qualities ever quoted, and this would lead one to the conclusion that countries such as Brazil and the West Coast of Africa cannot produce the Cardamom. A great drawback to a trial has probably been the difficulty of importing seeds from India, but it should be possible to obtain them from Kew. I regret I am unable to give statistics as to the yield per acre, but I have, in Calcutta, sold Cardamoms from Ceylon at prices from three to seven rupees per seer (2 and 1-7th lb); home quotations are from 1s 6d to 4s per lb. The plant is, I understand, of the vine species and is planted between six by six coffee. The picking season immediately follows the coffee crop. I am aware that this information is unfortunately very meagre; but Mr Hastings having suggested that a few acres of cotton at an estimated price of 5d per lb will do no planter any harm, I think that cardamoms, at a possible 4s per lb deserve also to be experimented with, especially as owing to our present crude and expensive transport methods only the higher-priced products can be profitably handled. Few more valuable items than cardamoms can be found in the produce market reports.—Yours, etc., J W KIRK

INDIAN AND CEYLON TEA SHARES.

"TEA" ON RECOVERY IN VALUES AND SPECULATIVE TENDENCY.

June 15, 1901.

GENERAL REMARKS.—As I said in my last report, only those companies which have conserved their financial position are likely to see their way comfortably through the present crisis. In the future a closer criticism of non-effective charges must be made, and directors will be wise in limiting their dividend distributions in such a way as to leave something "up their sleeves." Some of the companies appear to be feeling the pinch of finance, as witness the Imperial Company with its recent issue of debentures, and the Dooras Company seeking power from its share-

holders to create fresh preference capital. In regard to the immediate market prospect for the produce, it is satisfactory to note that from Ceylon the exports appear recently to be tending smaller, while in India, owing to drought in some of the districts, the opening of the season has been backward, and no great bulk of tea is likely to come to the market here until about a month later than usual. In regard to the question of shares, there appear to be indications to an increasing extent of speculative enquiry for the cheaper as well as for the more solid issues, and shares on the whole are difficult to obtain.

At the present juncture it is interesting to note that of Indian and Ceylon companies registered in this country with sterling capital, there are altogether nearly 150, with a share and debenture capital amounting to between fifteen and twenty millions sterling. The figures compiled by Mr. George Seton, of 120, Bishopsgate Street, relating to the values of the shares of 45 representative companies, and to which we refer elsewhere, will show the depreciation on a portion of this capital—some £9,000,000. On the whole amount the loss would probably be proportionately the same, or even more so.—*Tea* for June.

FIBRE IN GERMAN EAST AFRICA.

It is expected that the cultivation of fibre will be very profitable. There are at present over 800,000 *Poucroya gigantea* plants and 750,000 *Agave sisalana*. Compared to other products, the cultivation of fibre is very simple and inexpensive. The only fear is that, owing to over-production, the price will fall considerably, and the article will become a drug in the market. Within the last few months Fourcroya hemp has fallen from 33s to 25s per cwt. The first Sisal Agave bulbs were introduced by the German East Africa Company in 1891, forty-six being brought from Yucatan and planted in the Kikogwe estate. From the original forty-six plants over 700,000 have been obtained in nine years. At Kikogwe alone there are 640,000 covering an area of 1000 acres, whilst 65,000 have been distributed amongst the German East Africa Company's other estates. The Sisal Agave at Kikogwe only lives for five or six years when allowed to go to seed. When the leaves are regularly cut, the life of the plants will probably be considerably longer. The annual produce of each plant is about forty leaves, or 2½ lb of dry fibre. During the year under review a sample of 100 cwt of fibre was sent out and sold for 50s per cwt.—*British Acting Vice-Consul at Dar-es-Salaam*.—*British Trade Journal*.

"ANNALS OF THE R. B. GARDENS, PERADENIYA"

We have to give a hearty welcome to this new periodical, edited by Mr. Willis as Director and to be representative of the work of himself and the full scientific staff now attached to his department. We have already published the prospectus, and the first part opens very appropriately with a succinct and interesting history of the Ceylon Botanic Gardens, from the days of Governor North onwards, from the pen of the Director. It is interesting to be reminded that J. G. Lear who was in charge of the Gardens from 1837 to 1840 (and many of whose letters are reproduced in our *Literary Register*) planted

tea at Nuwara Eliya so early as 1837! He also laid out the beautiful group of palms at the entrance to the Peradeniya Gardens.

A second paper by Mr. Willis is on 'the Royal Botanic Gardens of Ceylon as a centre for Botanical Study and Research,' a popular statement which ought to be the means of bringing many scientific visitors to Ceylon. It is mentioned, *inter alia*, that a resthouse is shortly to be opened at Peradeniya and other accommodation is often available.

It will be understood that the "Annals" are to be devoted chiefly to scientific botanical papers (some in French and German) and will not interfere with the appearance from time to time of the Gardens "Circulars" on planting topics which have hitherto been so much appreciated, and most of which have been reproduced in our *Tropical Agriculturist*. In conclusion we may quote the following particulars from the History of the Gardens:—

The present organization and staff of the Department is as follows:—

Director: J. C. Willis, M.A., F.L.S.

Chief Clerk: R. H. Pereira.

SCIENTIFIC DEPARTMENT.

Botanist: The Director.
 Assistant Director and Mycologist: J. B. Carruthers, F.L.S.
 Entomologist: E. E. Green, F.E.S.
 Agricultural Chemist: M. K. Bamber, F.C.S.
 Assistant: H. Wright, A.R.C.S.
 Draughtsman: W. de Alwis, Mubandiram.
 Herbarium and Laboratory Attendants, and two Plant Collectors.

BOTANIC GARDENS DEPARTMENT.

Peradeniya.—Curator: H. F. Macmillan, and native staff.

Hakgala.—Superintendent: W. Nock, and native staff.

Henaratgoda.—Conductor: S. de Silva, and coolies.
 Anuradhapura.—Conductor: D. F. de Silva, and coolies.

Badulla.—Conductor: D. D. Fernando, and coolies.

PROPOSED EXPERIMENTAL GARDENS DEPARTMENT AND AGRICULTURAL SCHOOL.

(Not yet organised.)

Superintendent, foremen, and coolies.

Teaching Staff: The Officers of the Department.

GREEN TEA REPORT.

(FOR THE WEEK ENDING 6TH JUNE, 1901.)

CEYLON GREEN TEA.—The prices paid are a little stronger than at last sales, full-sized breaks being competed for, but so many of the teas arrive in quantity so insignificant as not to make it worth buyers while to attend to them: twenty lots this week totalled only 103 packages, only one line exceeding 13 chests, many being but one to three chests or halves: the prices consequently being very low, one invoice averaging 2½d per lb.

WALKER, LAMBE & Co.

THE DEAF HEAR.—No. 479 of *The Illustrated World* of 626, Chiswick High Road, London, W., England, contains a description of a Remarkable Cure for Deafness and Head Noises which may be carried out at the patient's home, and which is said to be a certain cure. This number will be sent free to any deaf persons sending their address to the Editor.

INDIA AND FRENCH IMPORT DUTIES.

EXTENSION OF THE MINIMUM TARIFF.

Simla, July 10.—The following has been issued by the Finance Department:—"By a Decree published on the 27th December, 1900, the French Government continued till the 30th June, 1901, their minimum tariff for Colonial produce of various countries, including British possessions. Intimation has been received from the Secretary of State for India, that the minimum tariff has been further prolonged till the 23rd Feb. next."

NO FRENCH COUNTER-PROPOSALS.

Simla, July 11.—No special proposals from the French Government have reached the Government of India for relaxing the Indian import duties in favour of France, or facilitating coolie emigration to Madagascar, in return for continuing the present French tariff.—*Madras Mail*.

NEGRI SEMBILAN.

(Extracts from the Annual Report for the year 1900.)

THE REVENUE collected during the year amounted to \$1,251,366.14, as against \$1,085,015 collected in 1899. The total value of trade amounted to no less than \$11,330,000, being an increase of \$2,489,000 over that of the previous year. The export of coffee, tapioca, and tin showed a considerable increase, but in the case of gambier and pepper there was a decrease.

COFFEE.—The price of coffee, which showed some little improvement in March, has again fallen to a figure which can only be remunerative to the most economically managed, as well as the most productive, estates. To make matters worse, in June, a veritable plague of caterpillars, the larvæ of *Gephenodes hylas*, one of the bee hawk moths, was found to be infesting many estates. Previous experience in Selangor has shown that the only remedy likely to be of use was to pick the caterpillars off by hand, and to enable this to be promptly done the Government lent as much labour as was available. Many estates were attacked, most were rescued after a large expenditure, but one had to be cut down and burnt. The owner of the latter, a Chinaman, was compensated by the grant of a tract of mining land. The Resident of Selangor rendered much assistance to Negri Sembilan by sending Mr. Butler, the Curator of the Selangor Museum, who had experience of previous outbreaks in Selangor, to advise and assist in the extermination of the caterpillars. I desire to record the thanks of this Government to both the above gentlemen. More than one estate went out of cultivation during the year, which has been one of great severity to all coffee estate owners.

PADI.—The crop of padi just harvested has proved generally poor. This is attributed to a prolonged drought, which set in soon after the young plants were transplanted to the fields, and to the absence, through the ravages of rinderpest, of a sufficient number of buffaloes when the fields were prepared. In parts, rats are said to have done much damage. Next season it is proposed to experiment with Löffler's typhimurim bacillus, which, if successful, should prove a great boon to the native community. In the Coast district steps were taken to encourage the settlement of some Banjarese padi planters, but nothing has yet been settled. These people have shown themselves most expert padi planters in the Krian district of Perak and their settlement in Negri Sembilan is greatly to be desired.

TAPIOCA.—Applications continue to come in for lands for tapioca cultivation, and attempts, not altogether successful, have been made to insist on some

form of permanent cultivation on lands to be planted with this product. I doubt whether the results would in any case be commensurate with the outlay involved. Chinese who understand the cultivation of tapioca do not necessarily understand the planting of coconuts or rubber, and are consequently loth to undertake such cultivation.

COCONUTS.—I am glad to say that the cultivation of coconuts has received much attention and many new plantations have been started, more especially in the Coast district, which is the most suited to them. Coconut planters, like other agriculturists, have their troubles. In new plantations wild pig do enormous damage by rooting up and eating the seed coconuts. Nothing seems to be quite effective against their ravages, although both barbed wire fencing and deep ditches have been tried. Again, when the trees have grown, the boring beetles (*Oryctes rhinoceros* and *Rhynchophorus ferrugineus*), by eating the heart of the trees, kill large numbers. A special enactment has been provided to compel owners of trees to keep them clean and free from the larvæ of these beetles. The provisions of this enactment were carefully enforced by the Forest Officer and Inspector. The District Officers write in favourable terms of the work done by the Inspector, who visited upwards of three thousand gardens during the year.

THE NEW GRAFFE-LIKE ANIMAL.

SKIN AND TWO SKULLS RECEIVED IN LONDON.

Prof. Ray Lankester has now received the case, shipped at Mombassa on April 19th, containing the skin and two skulls of the remarkable new giraffe-like animal obtained from the Semliki forest by Sir Harry Johnston, and sent by him for preservation in the Natural History Department of the British Museum. Writing to the *Times* with reference to the specimens, Prof. Lankester says:—"The animal is a giraffe-like creature devoid of horns, with relatively short neck and with colour stripes on the limbs, but nowhere showing spots or areolæ like those of the giraffe. Sir Harry Johnston was amply justified in assimilating the animal to the extinct Helladotherium, but after an examination of the skulls I am of opinion that the 'Okapi' (the native name by which the new animal is known) cannot be referred to the genus of the Helladotherium, but must be placed in a new genus. I must say that, although the horny hoofs are not present, yet the double bony supports of the hoofs are preserved with the skin, and leave no doubt, even without reference to the accompanying skulls, that the animal which bore the skin was not a horse-like creature, but one with cloven hoofs."—*Nature*, June 20.

A LONG PERIOD SUNSPOT VARIATION.*

It has long been known, and Dr. Rudolf Wolf of Zurich was the first to draw attention to it, that the length of a sunspot period is only in the *mean* eleven years, and that the real length of any one period might differ from this value by as much as \pm two years. Another fact of observation is that the times of maxima do not occur a constant number of years after a preceding minimum, and Dr. Wolf determined the *mean* interval as 4.5 years. The minimum also follows the maximum in a *mean* interval of 6.5 years

It has further been noticed that the intensity of each period, *i.e.* the total amount of spotted area, included between one minimum and the next, was not constant. Dr. Wolf held that these quantities indicated a certain periodicity, and at first suggested a period of 178 years, and later 55.5 years, or a period extending over five eleven-year periods ($11.1 \times 5 = 55.5$).

The present investigation was limited to the interval of time, namely, 1833-1900, over which *systematic* observations of the sun's surface have been regularly made, and, as Dr. Wolf's relative numbers agree well with the actual facts of observation over this period, these numbers have been employed.

Since then, in addition to the well-known eleven-year period of sunspot frequency, there is another cycle which extends over about thirty-five years, and which is indicated clearly, as has been shown, both by the changes in the times of the occurrence of the epochs of maxima and in the variations in area included in consecutive eleven-year periods of both sunspot and magnetic curves, it is only natural to suppose that this long-period variation is the effect of a cycle of disturbances in the sun's atmosphere itself.

Such a cycle, if of sufficient intensity, should cause a variation from the normal circulation of the earth's atmosphere, and should be indicated in all meteorological and like phenomena.

We are indebted to Prof. Ed. Brückner for the great work on the changes in climates, and in this investigation he sought variations in the observations of the height of the waters in inland seas, lakes, and rivers; in the observations of rainfall, pressure, and temperature; in the movements of glaciers; in the frequency of cold winters; growth of vines, &c.

The result of the whole of the investigation led him to the conclusion that there is a *periodical variation in the climates over the whole earth, the mean length of this period being 34.8 ± 0.7 years.*

Prof. Brückner was so convinced of the undoubted climate variations which he deduced, and so certain that such variations could only be caused by an external influence, that he investigated Wolf's sunspot numbers to see whether such a cycle was indicated. Not finding any, he was led to make the bold suggestion that such a variation as he sought must really exist in the sun, but might possibly be independent of sunspots. He finally concluded that the climate variations are the first symptom of a long-period variation in the sun, which probably will be discovered later.

In the light of the secular period of solar activity dealt with in this article, Prof. Brückner's conclusions are of great interest, because not only does the length of the period, but the critical epochs of his cycle, completely harmonise with those found in the present discussion of the sunspot and magnetic curves.

Prof. Ed. Richter, in a detailed investigation of the movement of glaciers, has also found a cycle of thirty-five years, and he pointed out that the variations agreed generally with Brückner's climate variations, the glacier movement being accelerated during the wet and cool periods.

Again, Mr Charles Egeson not only finds a secular period of about thirty-three to thirty-four years in the occurrence of rainfall, thunderstorms, and westerly winds in the month of April for

* Extracts from a paper, "The Solar Activity 1833-1900," read before the Royal Society on May 23rd, by Dr. William J. S. Lockyer.

Sydney, but the epochs of maxima of the two latter harmonise with the epochs of the thirty-five-yearly period deduced for sunspots.

There seems little doubt that, during the interval of time covered by the present sunspot discussion, the meteorological phenomena, number of auroræ, and magnetic storms show secular variations of a period of about thirty-five years, the epochs of which harmonise with those of the secular variations of sunspots. As we are now beginning to approach another maximum of sunspots which should correspond both in intensity and in time of occurrence after the epoch of the present minimum with that of 1870-8, it will be interesting to observe whether all the solar, meteorological and magnetical phenomena of that period will be repeated.

WILLIAM J. S. LOCKYER.

—*Nature*, June 20.

RAW RUBBER NOTES.

LAGOS.

The exports of rubber from Lagos show a marked falling off since 1896; the figures for the past five years are as follows:—1895, £269,892; 1896, £347,721; 1897, £283,184; 1898, £285,409; 1899, £160,315. The decrease in the export of rubber, from £347,721 in 1896 to £160,315 in 1899, is clearly due to the reckless and unskillful manner in which rubber was collected, which resulted in killing the majority of the trees. The collecting of rubber has been prohibited for a period of two years, to give time to the trees that survived to recover themselves. Planting is also being encouraged. Concessions of timber lands are being granted to Europeans and natives, with exclusive timber-cutting rights, on the condition that certain payments are made to the native authorities, and young trees planted to take the place of those cut down.

In places where the native authorities are unwilling to protect the timber, trees continue to be felled recklessly, and no attempt is made at replanting. But it is hoped in time to overcome these difficulties and extend the protected areas. Vigorous action is being taken to suppress the ruthless tapping of the rubber trees, and every assistance is being given with regard to planting. By these means there are possibilities in the future of reviving this industry.

PARAGUAY.

Rubber is not found in the wild state to any great extent in Paraguay, but attempts are being made to cultivate it, and it is thought that the most suitable species for artificial cultivation will be the manicoba of Brazil, owing to its rapid growth and general hardiness. The manicoba is said to have given excellent results in Brazil and in Central America, and it is stated that the Paraguayan Government intends to offer special inducements to agriculturists in order to develop this industry.

GUTTA-PERCHA FROM CENTRAL AMERICA.

Dr. Paul Preuss has found plentifully in the west of Central America, especially in Nicaragua, Salvador, Guatemala, and Mexico, a plant with strange-shaped leaves, which the natives called "Cojon de pierco." Its real name is *Tabernaemontana Donnell Smithii* Rose, and it belongs to the family of the Apocynaceæ; it grows mostly as bushes, but often attains the height of trees, and can therefore be used as a shade to coffee and cocoa trees in regions up to 700 metres above sea level. The leaves, bark, and especially the fruits, produce a great quantity of milk, which does not change in a solution of salt, acetic acid, or cold citric acid, but is coagulated by cooking in water into a yellow-white, and later on yellow-brown, mass, that gets hard in the open air slowly, and is soft

and kneadable again in warm water. By order of the Colonial Committee of Berlin, the plant has been cultivated from the seeds in the botanic gardens at Berlin and Victoria (in the Cameroons), and it is pretty sure that it will be introduced into the Cameroons on a large scale. About 6 gr. of the coagulated milk have been analysed in the Pharmaceutical Laboratory at Berlin by Professor Dr. Thoms and Dr. Mannich, and no substantial distinction has been noted between this product and the real guttapercha. Fifty per cent. of the coagulated stuff is soluble in acetone, but Dr. Mannich does not think this bad, as many descriptions of gutta-percha in the market do not contain less resin. As the power of resistance against solutions of salt especially is all right, it may be well used as a substitute for gutta-percha. Dr. Preuss thinks that this discovery is of a great and practical importance, for in his opinion there is nothing in the way of cultivating the plant. The first fruits are received after four to five years, whereas the growing of the Sapotaceæ, which furnishes us at present with gutta-percha, takes a much longer time. With regard to the high prices of gutta-percha, it may be recommended to ascertain the quantity of gutta-percha in the dried leaves, bark, and fruits of this plant in order to effect the most advantageous method of cultivation.

BOLIVIA.

The German Consul in Cochabamba, in his recent report, states that the export of caoutchouc has much increased during recent years. According to the port of shipment, Bolivia is divided into different regions: (1) The region of the Acre River takes the first place on account of the quantity of caoutchouc exported. Villa Bella has been appointed by the Bolivian-Brazilian Government as the port of shipment for this district, a town about 4½ miles from the Brazilian frontier. (2) The region of the rivers Madidi, Beni, Orton, Manurini, Tahuamann, and other small rivers, which are of great importance to the caoutchouc trade. (3) The region of the forests belonging to La Paz—namely, Challana, Songo, Mapiri, Huanay, Coroica, and the province of Carpolican partly. The export of these districts goes chiefly *via* Puerto Perez (Chillilaya), on the Titicaca Sea, Puno, and Mollendo. (4) The region in the north and east of the department Santa Cruz, with the Velasco and Magdalena provinces. The regions round the Paragua and Verde rivers are the principal districts in this part, and they are not much explored on account of the bad lines of communication. But these districts will doubtless gain some importance later on. The export goes mostly *via* Puerto Suarez, on the Paraguay River, and only a small quantity comes *via* Cochabamba. Many caoutchouc trees have recently been discovered in Yuracares, Puerto, Santa Rosa, etc., in the Cochabamba departments, and the right to explore these forests has been granted. These districts will also be of great importance in later years. The export *via* Puerto Perez, Villa Bella, and Puerto Suarez amounted in 1895 to 820,410 kilos., in 1896 to 1,140,712 kilos., in 1897 to 1,674,216 kilos., and in 1898 to 3,155,955 kilos. —*India-Rubber Trades Journal*, June 10.

THE "VOANDZOU" is a bean from tropical Africa which, by the analysis of M. Balland, communicated to the Academie des Sciences, Paris, consists of 10 per cent water; 19 of nitrogenous matter, 6 of fatty matter, 5 of amylaceous matter, and 4 of cellulose or sugar. A kilogram of voandzu contains the food required to support a man each day, namely, 120 to 150 grammes of nitrogenous matter, 56 grammes of fat, and 500 grammes of hydrate of carbon. The conclusion is that voandzu is a complete food in itself, and would be serviceable for troops in the field. It could, no doubt, be cultivated in most of our tropical or even hot countries.—*Globe*.

“THE TROPICAL AGRICULTURIST.”

The twentieth annual volume of this periodical was completed with the June number; but the title page, index, &c. for the same are included with the first issue of a new year, the July number, and we give the same as a Supplement today. We began the *Tropical Agriculturist* in 1881 (“Timehri” in British Guiana began a year later), and we do not know of any similar publication in the British Dependencies, at any rate within the tropics, that has lasted so long, or been so generally appreciated by the constituency for whose benefit it was started. It has carried the name and reputation of Ceylon and its planters far and wide, and the copies officially filed in the West Indian, African, and some of the Australian Colonies afford evidence of the value attached to its contents. Of late years, not the least flattering testimony has come from French and German Dependencies; but the greatest compliment was that paid by the Agricultural Department in Washington where, on our visit in 1884, the “T.A.” file was brought forward as including one of their most treasured foreign receipts, and we were even asked if we knew of the existence of this Magazine from the East Indies! Of course, primarily, the periodical has been begun and continued with reference to Ceylon, Southern India and the Straits, and there are certain features—the London and Colombo Sales of Produce, Reports of Tea Limited Companies, &c.,—which make the periodical specially useful for local reference, so that it has been well said a copy should be filed in each large Tea Factory or on all plantations, especially where several products are being cultivated.

Having concluded a third series of “Planting Pioneers” in our monthly, we cried “halt” for a time; but we have been urged to resume, as there are several names of departed and living worthies still available, that ought to be embodied. The new volume is likely, therefore, to include several for a new or fourth series. But what is now wanted is a more concise and yet general Dictionary of Biography for Ceylon, to embrace, say, all the notable men of the past century in connection with the Colony with brief accounts of their career, somewhat after the fashion of Mr. Henniker-Heaton’s Australian compilation, or of “Who’s Who.” Believing that such a work would be widely appreciated, and having a great deal of the material at hand, we are anxious to put one through our press.

Meantime as regards the *Tropical Agriculturist*, the chief desideratum will now be a Topical Index to the twenty volumes, and this is hastening to completion, and will enable all who possess the set (or a goodly number) of the volumes, to refer very quickly to information in respect of any product or subject treated.

A RECORD BLOCK OF MICA.

A block of pure mica, measuring a cube of six feet, has been found in Canada. This is the largest piece ever discovered, and is to be exhibited at the Pan-American Exhibition at Buffalo.—*Globe*, May 31st.

“ANNALS OF THE ROYAL BOTANIC GARDENS.”

A new Official periodical makes its appearance on the scene with the second half-year of 1901, and we have to thank Mr Willis for the first issue to hand. It is introduced thus in a Circular from the Royal Botanic Gardens, Peradeniya, dated June 1901. “Commencing with the present year it is intended to issue a new Botanical Periodical, to be called ‘The Annals of the Royal Botanic Gardens, Peradeniya.’ It will be a journal of pure and applied Botany and will contain chiefly the results of work performed wholly or in part in the laboratories and herbarium of the Ceylon Botanic Gardens, or upon materials supplied by the gardens. It will also contain notes, papers, and reviews dealing with general tropical Botany and its applications. While in general conception it thus resembles the well-known “Annales du Jardin Botanique de Buitenzorg,” it will include a somewhat wider range of matter. As in that journal, papers written in French or German will at times be included. It will be issued by the Government Printer, Ceylon, in an octavo form equal in size of page to the “Annals of Botany,” and will be illustrated as required.

The “Annals” will appear at irregular intervals, each paper of any considerable size being published separately as soon as ready. The number of pages that may appear in one year will be variable, probably at first between 250 and 300. When sufficient matter has been published to make a volume of convenient size, the Index and Title Page will be issued; there will not necessarily be annual volumes.

It is not of course possible to mark out in advance the exact line to be followed by such a publication. One great object in view is the keeping together of the large amount of work dealing with Ceylon Botany, and the fostering of an *esprit de corps* among the workers in the Research Institute now established in the Colony. In the pursuit of this object, not merely will original papers be inserted, but also reviews of other papers and books and summaries of preceding work. It is intended also to publish short floras of special districts or of biological areas in Ceylon, and figures and descriptions of the less-known species of the Ceylon Flora. The following list of papers that may probably appear within the first two years will help to indicate the scope of the journal:—

A History of the Botanical Department in Ceylon, by the Editor.

The Research Institute of the Royal Botanic Gardens of Ceylon, by the Editor.

The Life-History of the Cacao Canker, by J B Carruthers.

A Revised Catalogue of the Phanerogamic Flora of Ceylon, by J C Willis.

A Revision of the Podostemaceæ of India and Ceylon, by J C Willis.

The Ceylon Ebonaceæ and their Timbers: a Systematic and Anatomical Monograph, by H Wright.

A Botany of the Maldivé Islands, by J C Willis and J Stanley Gardiner.

Notes on *Hemileia vastatrix*, the Coffee Leaf Fungus, by C Holtermann.

The Citronella Oil Industry of Ceylon, by J C Willis and M K Bamber.

Notes on the Sapotaceæ of Ceylon and the *Guttaperchas* yielded by them, by H Wright.

Studies in the Phylogeny of the Sympetalæ, by J C Willie.

The Growth in Thickness of Tropical Trees, by H Wright.

STATISTICS OF THE PRODUCTION OF TEA IN INDIA.

THE OFFICIAL RECORD FOR 1900.

AREA.—The area under tea in India at the end of 1900 extended over 522,487 acres, nearly two-thirds (64·6 per cent.) being in the valleys of the Brahmaputra and Surma, which contain as much as 337,327 acres, namely, 204,985 in Assam (the Brahmaputra Valley) and 132,342 in Cachar and Sylhet (the Surma Valley). In extent of cultivation Bengal comes next, the area under tea being 134,572 acres; or 25·8 per cent. of the whole, and a little more than that in the Surma Valley.

The production of tea is, therefore, to the extent of nine-tenths of the whole area, limited to the two provinces of Assam and Bengal.

The other tenth is divided between Northern and Southern India, thus:—

NORTHERN INDIA—		SOUTHERN INDIA—	
	Acres.		Acres
North-West Provinces ..	8,055	Madras ..	6,107
Punjab ..	9,745	Travancore ...	25,202
Total ...	17,800	Total ..	31,309

The principal localities in each province where tea is grown are these:—

IN ASSAM.		IN THE NORTH-WESTERN PROVINCES.	
	Acres.		Acres.
Surma Valley:		Kamaun ..	2,921
Cachar ..	60,852	Dehra Dun ..	5,134
Sylhet ..	71,490		
Brahmaputra Valley.		IN THE PANJAB.	
Sibsagar ...	78,422	Kangra ..	9,645
Lakhimpur ..	67,509		
Darrang ..	41,708	IN SOUTHERN INDIA.	
Nowgong ..	12,673	Nilgiris ...	2,542
Kamrup ..	3,973	Malabar ..	3,053
		Travancore ...	25,202
IN BENGAL.			
Darjeeling ..	50,769		
Jalpaiguri ...	76,278		
Chittagong ..	4,146		
Ranchi and			
Hazaribagh ..	3,284		

There is a small area of 1,479 acres in Upper Burma, but in this province the leaf which is produced is not made into tea, but is pickled to be eaten by the Burmans, and the area and production may therefore be left out of account.

Tea cultivation in India has been mainly concentrated in tracts where a heavy rainfall and a humid and equable climate permit of repeated flushes and pluckings of the leaf. In the valleys of the Brahmaputra and Surma the yield averages about 468lb to the acre; in Jalpaiguri (the Dooars) 484lb. in Darjeeling about 279lb in the North-Western Provinces it is 309lb. In Travancore it is stated at 360lb. Elsewhere it is much lower.

The area under tea has expanded from year to year without a pause during the sixteen years comprised in the statistics appended. In 1885 the area was about 284,000 acres; in 1900 it had increased to 522,487 acres, the increase being in the ratio of 84 per cent.

The number of acres added to the tea-grower area each year has been:—

	Acres		A
1886 ..	14,294	1893 ..	20 ¹ / ₂
1887 ..	14,584	1894 ..	4 ⁹ / ₁₆
1888 ..	11,524	1895 ..	15 ⁶ / ₁₆
1889 ..	9,374	1896 ..	17 ³ / ₁₆
1890 ..	11,126	1897 ..	36 ⁶ / ₁₆
1891 ..	17,610	1898 ..	31 ⁶ / ₁₆
1892 ..	12,432	1899 ..	137
		1900 ..	6 ³ / ₈

It appears then that as much as about 107,000 acres have been added to the area under tea during the last five years. This area, in full bearing, will yield at least 40 million pounds of tea a year.

The plantations vary greatly in size. In Assam, where the industry is mainly carried on by Europeans with ample capital, where fusions of estates have been in progress for some years in view of economy of management, and where most plantations have large unplanted areas attached to them, the area of a plantation averages as much as 1,318 acres. In Bengal the average area of a plantation is 734 acres; in the North-Western Provinces the average falls to 121 acres; while in the Panjab, where natives grow tea extensively in the Kangra Valley, there are only about four acres to each plantation. In Madras the average is about 172 acres, and in Travancore 445 acres.

PRODUCTION.—The quantity of tea produced has increased in much greater ratio than the area under cultivation, for while the area has increased by 84 per cent, the increase in production had been 176 per cent.

Representing the area and production in 1885 by 100 in each case, the ratio of increase is stated below, the actual increase of production each year over the production of the preceding year being also stated:—

	Area	Quantity produced	Actual increase annually in lb.
1885 ..	100	100	..
1886 ..	105	115	10,899,835
1887 ..	110	129	9,826,270
1888 ..	114	139	7,540,462
1889 ..	117	149	7,250,331
1890 ..	121	156	4,993,531
1891 ..	127	173	11,831,496
1892 ..	132	170	-1,873,628
1893 ..	139	185	10,253,626
1894 ..	141	188	2,465,144
1895 ..	146	200	8,694,783
1896 ..	152	219	13,018,227
1897 ..	165	215	-2,643,846
1898 ..	177	222	3,693,192
1899 ..	182	254	24,322,055
1900 ..	184	276	15,663,209

PERSONS EMPLOYED.—The number of persons employed in the tea industry in 1900 is returned at 621,287 (permanently) and 98,446 (temporarily), or altogether a little below three-quarters of a million (719,733 persons), which would work out to about 1·38 persons to the acre.

EXPORTS AND CONSUMPTION.—The tea produced in India is exported, mainly to the United Kingdom, to the extent of about 96·6 per cent. of the average production. The subjoined figures give approximately the quantity of tea consumed in India, the figures representing the average of the last five years:—

INDIAN TEA.	Produced ..	170,509,067
	Exported ..	164,634,913
FOREIGN TEA.	Left in India ..	5,874,154
	Imported ..	5,801,241
	Re-exported ..	2,563,029
	Left in India ...	3,238,212

Thus more than 9 million pounds were left in India on the average, of which 5·87 millions were Indian and 3·24 millions foreign, the bulk of the foreign tea being Chinese, though a substantial quantity consists of Ceylon tea. More than a million pounds are purchased annually for the British army, and a larger quantity must be consumed by the European and Eurasian civil population, as also by natives who, in some of the larger towns, are adopting the tea-drinking habit.

The principal markets for Indian tea are stated hereunder, with the quantity exported (in lb.) to each country in the last five years:—

	1896-97	1897-98	1898-99
United Kingdom..	135,456,884	137,655,957	139,245,995
Australia ..	6,155,895	6,792,654	6,306,135
United States and Canada	1,607,731	1,523,236	2,457,880
Persia ..	1,993,823	1,464,394	3,456,791
Russia ..	457,634	689,271	500,889
	1899-1900	1900-01	
United Kingdom ..	154,161,492	166,171,556	
Australia ..	8,362,797	10,438,984	
United States and Canada	4,677,797	3,490,451	
Persia ..	1,953,900	2,429,140	
Russia ..	467,451	772,495	

TRANS-FRONTIER—

	1896-97	1897-98	1898-99
Kabul, Kashmir, & other countries on the North-Western Frontier ..	1,498,672	867,888	1,040,704
Other trans-frontier countries ..	13,552	18,144	23,968
	1899-1900	1900-01	
Kabul, Kashmir, & other countries on the North-Western Frontier ..	2,099,328	1,942,640	
Other trans-frontier countries ..	25,312	25,760	

The production of tea in India and Ceylon has increased so much more rapidly than the consumption in the United Kingdom, which is the principal market for these teas, that there has been a heavy fall in price and the tea industry is at the moment in a position of great embarrassment. Producers are busily engaged seeking relief from the introduction of economies and from the enlargement of markets other than that in the United Kingdom.

PRICES.—The course of prices of tea in Calcutta is illustrated in the appended figures in which the price in March 1873 is taken as equal to 100.

They represent the course of prices of fine Pekoe in January of each year as given by the Bengal Chamber of Commerce. It will be observed that the price in January 1901 fell to the lowest level yet known:

1873 ..	100	1888 ..	84
1874 ..	123	1889 ..	77
1875 ..	123	1890 ..	63
1876 ..	136	1891 ..	81
1877 ..	148	1892 ..	71
1878 ..	135	1893 ..	87
1879 ..	129	1894 ..	52
1880 ..	126	1895 ..	97
1881 ..	135	1896 ..	84
1882 ..	126	1897 ..	64
1883 ..	110	1898 ..	61
1884 ..	116	1899 ..	58
1885 ..	90	1900 ..	64
1886 ..	90	1901 ..	45
1887 ..	77		

In the Statistical Department the average prices of the various descriptions of tea sold at the public sales held in Calcutta during the tea season have been computed for some years past. From these accounts the figures below are taken, being the prices in annas and pies per pound of the three descriptions which form the largest proportion of the tea sold and the variations in the prices, the average price of 1888 being represented by 100:—

	Broken Pekoe		Pekoe		Pekoe Sou.						
	Price	Variation	Price	Variation	Price	Variation					
	As.	Pies.	As.	Pies.	As.	Pies.					
1888..	10	3	100	8	1	100	6	3	100		
1889..	9	9	95	7	5	92	5	7	89		
1890..	8	10 ³ / ₄	87	7	2	89	5	8 ¹ / ₂	91		
1891..	8	7 ¹ / ₂	85	7	0 ¹ / ₂	87	5	3 ³ / ₄	184		
1892..	11	3 ³ / ₄	110	8	9	108	6	5 ¹ / ₂	103		
1893..	9	2	4·5	90	7	2 ³ / ₄	90	5	4	4·5	87

J. E. O'CONNOR,
Director-General of Statistics.
—Capital, July 14th.

GREEN TEA REPORT.

[FOR THE WEEK ENDING JULY 4, 1901.]
(Walker, Lamb & Co.)

London, July 5, 1901, E.C.

Owing to the small supply left in importers' hands, there has been no auction sale this week, but privately there have been a few transactions at fully late rates.

CEYLON GREEN TEAS.

The only offerings have been three small lines of very nice cup teas, which, being in such small quantity, buyers neglected and they sold very cheaply at from 4d to 6¹/₂d. Buyers are remarking that, having taken trouble to introduce these teas, the supply is not continuous enough to meet the enquiries which have followed from the earlier sales, and that, as it is put by some, "They will have to do the work of introducing them all over again."

THE RUBBER INDUSTRY IN NATAL.

A few months ago the Government advertised for a man capable of carrying on experiments in connection with the institution of a "rubber" industry, and for a man competent to point out where rubber trees existed in a wild state, or where imported trees might grow. It is understood that such a man could not be found in South Africa. Messrs. Medley Wood and Maurice S Evans interested themselves in the subject, and it is probable that a Commission will start, when the labours of the session are over, for a part of the Colony in which it is probable good rubber soil will be found.—*Natal Mercury*, June 24.

CASTOR OIL TREES IN NATAL.—The General Manager, Natal G. R., has seen that the new engine-sheds on the Zwaartkop Road have been constructed near large plantations of castor oil trees, and it is rumoured that a castor oil factory is to be started near the City, with the N.G.R. as chief consumer.—*Natal Witness*, June 18.

ABYSSINIAN 'TEF' (*poa abyssinica*) is the seed of a grass which the people consume (see Sagot's 'Manuel des Cultures Tropicales'). By analysis it contains $8\frac{1}{2}$ per cent of nitrogenous matter, $75\frac{1}{2}$ per cent of amylaceous, and nearly 2 of fatty matter, besides nearly 2 of cellulose. It is, therefore, a grain worthy of attention in other hot countries.—*Globe*.

BURMA RUBY MINES CO.— $16\frac{1}{2}$ PER CENT.—The report of the Burma Ruby Mines Co., for the year ended February 28th shows a profit of £33,845, from which the percentage payable to the Government of India, amounting to £12,440, has to be deducted. Including £8,881, brought forward, there is a total balance of £36,286. The Directors recommend a dividend of $16\frac{1}{2}$ per cent., free of tax, on the ordinary shares for the year, leaving a balance of £10,123 to be carried forward. During the year under review 947,444 loads of ruby earth were washed at an average cost of 10-39d., as compared with 888,135 loads in the previous year.

MR. A. COOKE'S SCHEME FOR A TEA RESERVE.—So far we have had but three opinions vouchsafed to us upon the striking scheme for a great tea Indo-Ceylon reserve and an immense increase to the forces available for exploiting foreign markets. One of them is that the proposals are quite impracticable. Another, which we shall publish tomorrow, comes from a planter who adds that he "cannot see that Mr. Cooke's scheme is practicable at present. What we want is more money to encourage Traders in foreign countries to hold and make known by advertising and other methods the high qualities of our teas." The third appears elsewhere. This scheme is not one that can leap into popular favour at once and will require a good deal of backing before it can be put into forces. But it cannot be denied that the exploitation of foreign markets will have to be taken up on a good deal larger scale than now if cultivation continues to increase with the opening up of new land—outside the countries where it is the leading product today.

Fiji.—The Receiver-General's annual report on the trade and commerce of Fiji shows that the exports from the colony for 1900 were valued at £619,836, as against \$481,856 for the previous year. The imports were £349,890 (including £6,027 for re-exportation) as compared with £263,044 for 1899; and the total trade of £969,726, as compared with £744,900. The improvement in the export is mainly due to the greatly increased production of copra. The import of live stock amounted to £23,358, as against £8,292 for 1899. The Customs duties levied for 1900 were £65,932 11s 5d, an increase of £13,305 16s 11d on the previous year. Included in the exports were 32,961 tons of sugar, 15,605 tons of copra, 158,224 gallons of distilled spirit, and 396,242 bunches and 46,224 cases of green fruit. The export of copra exceeds that of any previous year by 7,000 tons. Minor exports show no tendency to increase. Of the total trade the port of Suva contributed £770,266 and Levuka £199,460. The wharves at the former port are now being extended. There are in the islands 68 European-owned vessels aggregating 1,106 tons, and 105 native-owned vessels aggregating 893 tons.—*London Times*, June 19.

ANGLO-CEYLON AND GENERAL ESTATES COMPANY.—We direct attention to the full report of the past year's working of this Company which we give on our sixth page today, having been kindly placed at our disposal by the Hon. Mr. J. N. Campbell. The very wise precaution has been taken of strengthening the reserve fund and, making allowance for a dividend of 4 per cent on the consolidated stock, there is the substantial balance to be carried forward of over £13,000 in order to meet contingencies in view of the unsettled state of the market. The price of the Company's tea has, we are glad to see, been well maintained. A fairly good account is also given of the Mauritius sugar estates as well as of the rubber, coconuts and other products in Selangor.

INDIAN AND FRENCH IMPORT DUTIES.—Indian and perhaps Ceylon planters will be glad to read the Notification of the Finance Department, issued on Wednesday, to the effect that the French Government has decided to prolong till the end of February next the minimum tariff for tea, coffee, pepper, etc. The fact that the minimum tariff has merely been prolonged temporarily for eight months shows that the French Government has not yet altogether made up its mind in the matter. The truth seems to be, as was lately pointed out, that the French Government has a *quid pro quo* in view; and it has prolonged the *status quo* for eight months longer in order that there may be time to negotiate with the British Government. There seems to be no room for doubt that the principal "compensation" that France is seeking is British Indian coolie emigration for Madagascar, where such labour is urgently required. Already one batch—says the *Madras Mail*—of Indian coolies has been sent there from Pondicherry, as the result of a private recruiting venture.

"NATURE STUDY" IN RURAL SCHOOLS.—The Technical Instruction Committee of the Bedfordshire County Council have this year arranged, for the assistance of elementary teachers in rural districts, a series of 12 lectures on Saturday mornings upon "Naked-Eye Botany," supplemented on six of the Saturday afternoons by field excursions under the direction of local botanists at which "attention was specially directed to the commonest and most widely representative examples." Both the lecturer and excursion guides, we are told, disclaimed as an end in view the collection of rare specimens or minute scheduling of variations, their object being to encourage in young teachers such a knowledge of the common plants of the countryside as may enable them to stimulate in their pupils "an interest in the vital processes and in the leading characters of the vegetation of both farm and garden." Those who attend are invited to answer weekly questions on paper, and also to forward specimens of plants for identification to their excursion guides—an invitation that might conceivably encourage the spoliation of rare flora, that is complained of elsewhere. But the scheme, speaking generally, seems carefully designed to avoid such a result; and is stated thus far to have been much appreciated.—*London Times*, June 21.

THE EXPORT OF CAOUTCHOUC—from French Tonquin last year—amounted to 300,400 kilos, says the *India Rubber Journal*, the greatest part of which went via Hongkong, only a small quantity being shipped from Haiphong direct to Europe.

A NEW PROCESS FOR MOULDING SWEET BISCUITS is being worked in Philadelphia, which includes the use of rubber. It consists in placing a thin sheet of tough elastic India-rubber between the moulding dies and a layer of dough. When the die cutter is forced into the dough the rubber conforms exactly to the design in the die by minutely reproducing the same through the rubber upon the dough. By this process very thin wafer-like biscuits, with a highly embossed surface, can be turned out at much greater speed than ordinary methods.—*Indus-rubber Trades' Journal*, July 24.

PLANTERS AND NEW PRODUCTS.—A correspondent writes:—"We tried making tea seed oil and the oil was successfully made, but the cost was prohibitive. I was reading somewhere about sunflower-seed oil being valuable. Now sunflowers grow like weeds here and our patanas could soon be full of them, if some one with means and leisure would kindly experiment and give less fortunate planters the benefit of his experience?" We fear neither sunflower nor tea seed oil will pay to make in Ceylon. But sunflower seed is said to be valuable for feeding stock. The time is approaching when systematic experiments can be made at the new Government Farm, Gangaroowa, under the auspices of Mr. Director Willis and staff.

COMPANY REPORTS.—We publish on page 121 the annual report of the Bogawantalawa Company. The yield of tea largely exceeded the estimate in spite of finer plucking during the last three months of the season, and the cost of production, though slightly higher than last year, is still moderate. The expenditure includes that incurred on new clearings, buildings, and machinery. The total yield was 1,236,272 lb. tea plucked off 2,185 acres, being at the rate of 565 lb. per acre all round, costing free on board at Colombo 23/92 cents or 3.93 d. per lb. The gross average price of the 1,220,246 lb. sold in London was 7/51d. per lb. The crops for the current season owing to finer plucking are estimated at 1,188,000 lb. tea. The gross average at which drafts were negotiated was 1s. 4½d. per rupee against 1s. 4/5-16d. in the previous season. The profit for the year amounts to £13,290 5s. 11d., to which has been added interest, £152 7s. 11d., and the balance from last year of £952 10s. 5d. It is proposed to pay a final dividend of 4½ per cent. on the ordinary shares making 6 per cent. for the year, which will acquire less tax, £4,275; to transfer to reserve (increasing this account to £4,500) £1,500 and to carry forward to next year the balance of £753 2s. 3d.—We also give the report of the Dumont Coffee Company in which Ceylon men are interested. The causes are explained, which have led to a considerable diminution of profit. As the result of this the directors have considered it advisable, instead of declaring a further dividend, to place the sum of £20,000 to reserve account and carry forward £10,263 15s. 7d. The property of the Company seems to be in a satisfactory condition.

THE FRENCH INDO-CHINA CONSULAR REPORT for 1900, sent here May 8th, states that the exports of gutta-percha for 1900 amounted to 39,000 kilos, against 58,813 kilos in 1899. The gutta percha comes chiefly from Annam and Laos. A picul of good quality is worth about £13. The rubber and gutta-percha are subject to an export duty per 100 kilos of 100 francs—equal to £4.—*India-rubber Trades' Journal*, July 24.

SUGAR-GROWING IN THE STRAITS.—It appears that sugar planters are prepared to take up thousands of acres in the Selinsing division, if the Government will grant the land for that purpose. A large sugar factory of the latest type was opened on the Gedong Estate late in the year, where over a thousand acres are under cultivation. There is no doubt a great future before sugar in this district, if difficulties be not thrown in the way of its cultivation.—*Official Report for 1900*.

PLANTING IN THE STRAITS.—The Collector of Klang reports high prices prevailing for land in the neighbourhood of Kuala Klang, on which he has reason to believe the present owners propose to erect permanent buildings, and, although there is a tendency to surrender the unopened land on some European-owned estates, agricultural land is still in request by both European and Native planters. Coconuts, rubber and coffee are the principal products at present under cultivation.—*Official Report for 1900*.

BOLIVIAN EXPLORATION.—Reuter's Agency is informed that an expedition sailed yesterday for the Isthmus of Panama, whence it will proceed to Bolivia for the purpose of continuing the exploration work in that country which was begun by Sir Martin Conway. The region to be explored lies between the crest of the Andes and the great Amazonian plain, and between the rivers Kaka and Beni and the river Pando or Tambopata, an area of over 10,000 square miles. The expedition is equipped and sent out by Sir Martin Conway. Its leader is Mr John W Evans, D.Sc., a well-known geologist and traveller, who has previously done good work in the western part of Brazil. With him go Mr John Turle, assistant geologist, and Mr Gerard A Watney, B.A., surveyor. They will be joined by an experienced botanist from the United States and by a zoologist already in the country. The expedition is fully equipped with all needful scientific appliances, and will spend one year in making a thorough scientific examination of the region. They will make as complete scientific collections as possible, and, if expectations are realised, will bring back valuable observations and maps of general scientific and geographical importance. The collections will ultimately be presented to the public museums of London and New York, and it is hoped that they may fill a gap in the national collections on both sides of the Atlantic. The country to be explored cannot be described as wholly unknown, but it is for the most part unmapped; it has never been scientifically explored, and great areas of it have only been visited by native prospectors. In this region are the fertile valleys of Las Yungas and the famous gorges of the Tipuani, Mapiiri, and Coroico, whence so large a part of the gold of the Incas was brought. The hill-sides produce every kind of tropical and sub-tropical crop, Yungas coffee being in the opinion of many experts the best in the world. Indeed, all the products of the Yungas valleys are not merely rich, but of singular excellence.—*London Times*, June 27.

TEAK PRICES.—The rise in the price of Teak timber is thus discussed by an Indian paper.—“The large rise which has taken place in the price of teak-wood is attributed to a number of causes, of which, curiously enough, the experiments conducted with the “Belleisle” is one. The last Report of the Burma Forest Department, in discussing the state of the market for this timber in London and on the Continent of Europe, states: “Planks have been in even greater request than before, owing to new sources of demand for carpentry and decorative and electrical purposes. The satisfactory results reached with H M S “Belleisle” as to the degree of inflammability of teak have tended to increase the demand for this wood by the British Admiralty.” So great was the effect of these various causes that the price of teak rose in the London market, in twelve months, from £10 to £17 per load, and the Conservator of Forests, Pegu Circle, writes:—“Every indication points to a continued increase in demand and to steady maintenance, or even enhancement, of present prices.”

THE
AGRICULTURAL MAGAZINE,
COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for August:—

Vol. XIII.]

AUGUST, 1901.

[No. 2.

NATURE STUDY.

We have placed ourselves in communication with the authorities who are conducting the agricultural extension work in connection with Cornell University College of Agriculture with so much success, and are extremely gratified at the encouragement we have received at their hands. In addition to a letter of welcome to us to join in the movement for the promotion of Nature Study, we have also received a collection of very useful publications that have been issued by that body. These consist of leaflets of instructions to teachers for the preparation of lessons in Nature Study, with directions for the laying out of school gardens, numbers of the Nature Study Quarterly and Junior Naturalist Monthly, and reading-lessons for farmers, all of which have furnished us with most entertaining information, inasmuch as we are only just beginning to work on the same lines in connection with our village schools in Ceylon, where, we venture to think the new movement for the promotion of agriculture is particularly well adapted, and that if persisted in without too great an anxiety for speedy results, which it would indeed be absurd to expect, would be attended with a full measure of success.

We have to thank Mr. J. C. Willis for bringing the Cornell University Organization for Nature Study to our notice. We now proceed to cull from the papers referred to above with a view to laying before our readers the aim and object of Nature Study.

Nature Study consists in a word, of seeing the things which one looks at, and drawing proper conclusions therefrom. It is not the study of a science as of botany, geology, and the like. That it takes the things at hand and endeavours to understand them, without reference to the systematic order or relationship of the objects. Indeed, it is wholly informal and unsystematic, the same as the objects are which one sees. It is therefore supremely natural. It simply trains the eye and the mind to see and to comprehend the common things of life; and the result is not directly the acquirement of science but the establishing of a living sympathy with everything that is.

If the objects to be studied are informal, the methods of teaching should be the same. If Nature Study were made a stated part of a curriculum, its purpose would be defeated. The chief difficulty with our present school methods is the necessary formality of the courses and the hours. Tasks are set, and are as a rule, hard on a learner. The only way to teach Nature Study is with no course laid down, but by taking up and studying natural objects, as far as possible as we find them, and it is the pupils who must do the work under the eye of the teacher, and the exercise should not be long. It should, indeed, come as a real exercise, (if possible whenever the pupils become listless), and above all, the exercise should not be looked upon as a recitation, and there should never be an examination. The teacher must studiously avoid definitions and types. For instance, he must not speak of the model flower which indeed does not

exist in Nature, he should begin with things and not with ideas; in other words, the ideas should be suggested by the things, and not the things by the ideas and proceed from the known to the unknown.

This will give some ideas of the *raison d'être* of Nature Study, about which a great deal more might be said, if necessary, but sufficient has been said, we think, to show that the intention of the new movement (for it is little known outside America) are such as to commend Nature Study as the most rational method of enlarging the minds of children, giving them a new interest in life, and placing them in closer sympathy with Nature, results which will at once be admitted by all to be most worthy of attainment under any circumstances, and especially so in the case of village children.

Greatest amount of rainfall registered in 24 hours on the 6th July 1.16 inches.

Recorded by C. DRIEBERG.

OCCASIONAL NOTES.

On 1st July last the Government Dairy was transferred from the Department of Public Instruction to the Veterinary Department. Presumably, the change was necessitated by the fact that the late Superintendent (who was the Superintendent of the School of Agriculture as well) is now doing duty as Inspector of School Gardens, an office which calls for his frequent absence from Colombo.

Mr. P. Samaranyake, late manager of the Colombo Stock Garden, has been appointed clerk to the Colonial Veterinary Surgeon.

It is intended to establish typical school gardens at Murugampola, Kahatuduwa, Jambureliya, Kirriwattuduwa, Panala, Handapangoda, Kumbaloluwa, Danowita and Matugama schools during the present half year.

On June 15th, Mr J. C. Willis, Director of Botanic Gardens, Ceylon, delivered a lecture on School Gardens and Nature Study at the School of Agriculture, Colombo.

Mr. J. H. Barber of the "Grove" cacao estate, Ukuwala, Ceylon, and the only local manufacturer of chocolate and cocoa essence, has left on a tour through the Australian Colonies with a view to establishing a business in the chief cities there.

FIRST STEPS IN AGRICULTURE.

First Stage—3rd Lesson.

BY A. J. B.

In the last lesson you were told something about the soil. We will continue that subject and find out what soils are made up of. If you go into the country and look round you, you will notice that in some places the soil is black, in others it is red; further on you find brown or chocolate-coloured soil; on the open hillside you will often observe stony, gravelly soil; and, lastly, you will meet with soils which contain a good deal of sand (this is called a sandy loam), or others, again, which are composed entirely of pure sand. It is too soon to explain to you what it is that gives the various colours to all these soils. That you will learn when you are more advanced in the subject. Now, if a farmer were looking for a good piece of land which will yield him good crops, he would not be content with merely looking at the surface. You have already seen that the roots of many farm crops run deeply into the ground, so the farmer wants to know what sort of soil there is beneath the surface. To find this out he must dig down into it for at least two feet. The surface may be composed of rich soil, but just below it there may be very bad soil, which would prevent the land from yielding heavy crops.

A rich soil, you told me the other day, is such as is found in scrubs and on the black and red soil plains of the Darling Downs. What is it that makes scrub soils, as a rule, so rich and fertile? If you were to examine scrub soil by the help of a microscope, you would find that it is principally made up of decomposed (that is rotten) leaves, sticks, and trees, which have fallen to the ground during a number of years, probably for many hundreds of years. Mixed with this rotted matter called "humus," there is a quantity of lime. This lime is derived from countless thousands of snail shells, which you can find in most scrubs. If you have ever seen the great mounds heaped up by the scrub turkeys, you must have noticed the ground surrounding them strewn with these shells. The mother turkey has gathered them day after day to feed her little chickens until they are able to run about and hunt for their own food. At a future time you will learn that lime is very valuable to the farmer. Then, in addition to the humus and the lime, there is a certain quantity of fine sand and slime washed on to the land during floods. These scrub soils are often of great depth, and the deeper a soil is the better it is able to supply plant food to the crops.

The great black and red soil plains are not formed in the same manner. Most of them are what is called volcanic soils. Their great fertility is not derived from decomposed vegetable substances, but from decomposed mineral matters. This also will form a subject for future lessons.

The soil which lies below the surface is often very different to that on the surface. It is called the "subsoil" from a Latin word which means "under." So remember that the soil immediately below the surface is called the *subsoil*. This subsoil consists sometimes of stiff clay, sometimes of gravel, and in very rich lands is as good as the surface soil when it is turned up by the plough and allowed to sweeten in the air. Well, the farmer who is looking for good land will first of all examine the surface, and will then look below it to see what the subsoil is like. Perhaps he finds a stiff clay close to the surface. This he passes by, because a shallow soil, no matter how rich it is, resting on stiff clay will not yield good crops without a great deal of labour. When heavy rains come, the water sinks through the shallow upper soil, but it cannot sink through the clay, so, if the land is at all flat, the water lies upon the clay, and when the roots of the plant pass into it they begin to turn sickly, and if the root is sick the whole plant suffers and at last dies. Just think how you would feel if you had to sit all day with your feet on a cold wet floor. You would soon become ill, and if something were not done to dry and warm the floor, you would die. So it is with the plant. If its roots are resting on a cold, wet, sour, clay subsoil, it soon turns yellow and dies. But clay soils can be cultivated and made to yield large crops, especially of turnips. The work of making such soils fertile is, however, very expensive, and only farmers with plenty of money can afford to cultivate them. You will learn as we go along how these soils are treated. Now, I am not going to tell you at this stage all about subsoils, because it is a very difficult subject, and there is no need for you to know much about it at present. All you need learn now is that a good farmer will always try and find out what lies below the surface, and by knowing that, amongst other things, he knows whether the land he is examining will be suitable for growing good crops or not.

You have seen farms which are perfectly flat, and others which lie on a hillside. Land which is flat is exposed to the sun all day long, and it is also exposed to every wind that blows. But land on hillsides running north and south can only receive the sun's rays either in the early morning and during a great part of the day, or else it does not receive the morning sun until late, owing to the height of the hills towards the east in which direction the sun rises.

On the other hand it has the benefit of the evening sun. The position of the land with regard to the sun is called its "aspect." If it faces the rising sun, it is said to have an easterly aspect, and if it faces the setting sun, the aspect is called westerly.

The aspect of a farm is a very important matter. In cold countries like Scotland and Denmark and North America, farmers always try to avoid a northern or a north-western (sometimes a north-

eastern) aspect. The reason for this is that the cold cutting winds from those directions cause injury to the crops. The soil remains cold and wet until far into the spring, when the farmers should be sowing his crops, and the cold winter sets in earlier than it does in more sheltered localities. You will easily understand how this comes about. When a strong, cold, westerly wind is blowing, place yourself on that side of the house facing the wind. You soon begin to feel cold. Now go to the opposite side of the house. Here you are sheltered from the cutting wind and you do not suffer from the cold. Now imagine the house to be a range of hills. The hillsides facing the west are exposed to the full force of the cold wind, whilst the opposite slope is entirely sheltered. From this you can at once see that a farm on the western side in this State must be much colder than one on the eastern side in the winter time, and that consequently the planting season will be later, and the hot weather of shorter duration on the western than on the eastern slopes. There is one more little thing I may mention to you in connection with aspect. The rays of the morning sun are more beneficial to plant growth than those of the setting sun, and in case I may forget to tell you later on, it is always well in sowing a crop of corn or potatoes, or in planting any crop in rows, to arrange the rows so that the rays of the morning sun may pass along them. Such an arrangement has been found to result in better crops than if the rows cross the sun's rays. Why this is so is not for us to consider here.

Now, we will close this lesson, and I will, as before, give you some questions to answer.

Questions on Lesson 3.

1. Of what materials is a rich scrub soil composed?
2. What is meant by a sandy loam?
3. Why should a farmer want to know the kind of soil beneath the surface?
4. What is a "subsoil"? Why is it called a subsoil?
5. Of what does a subsoil usually consist?
6. Why is clay subsoil bad for field plants?
7. Can land with a clay subsoil be cultivated?
8. What is meant by the aspect of land?
9. What aspect is the best with respect to crops?
10. Why is this so?

—*Queensland Agricultural Journal.*

POULTRY NOTES.

(Culled from various sources.)

When poultry are at liberty, animal food need not be given them, especially in warm weather. Indeed, it is quite out of place. The birds get as much healthy insect and animal food as they require, and a sufficiency of nutritious green food to balance it and act as a corrective. Birds kept always in confinement may have an occasional allowance, even in warm weather, as they have no chance of securing insect life for themselves, and when there is an abundance of green food supplied at the same time no harm is likely to result. But the animal food should not be too strong and coarse for use in warm weather. Boiled and grated

liver and fish food are the best for such times. There are few things more detrimental to the well-being of poultry than an excess of animal food. Birds become listless and unhealthy and cease to lay regularly under such treatment.

If the poultry-keeper has no idea of raising his or her chicks to renew or increase his stock, no males whatever need be kept. Many people imagine that males are necessary for the production of eggs; whereas the males are only needed for fertilising the eggs for hatching. Indeed, the hen will do a trifle better in laying if no male is present. This uselessness of the male should be noted by all poultry-keepers who want eggs only, as sometimes the male is an absolute annoyance and hinders egg production to a much greater extent than is commonly believed. For egg production the so-called "non-sitters" should be chosen, viz., Leghorns, Hamburgs, Houdans, Polish, Spanish, and Minorcas. The white Leghorn, Minorca, and Houdan lay the largest eggs; Hamburgs the smallest of any of the breeds named.

The sterility of eggs may arise from various causes. Over-feeding is a very common one, especially over-feeding penned-up fowls with Indian-corn. If some of the eggs be fertile and others clear, the cause may be, amongst others, either neglect on the part of the cock or some fault of the hen. In some cases the average of the fertility of the eggs may be improved by taking away to another pen those hens which lay fertile eggs, when they are known, for a day or two, and then putting them back for a like period, and so on until some improvement is noticed. The pens should be as much alike as possible, so that the fowls may feel at home, and obviously they should be kept isolated from a cock. This temporary absence is at times quite beneficial to some hens, which become weakened by the too constant attention of the cock, and they, in consequence, begin to lay clear eggs. Sometimes one hen is the favourite of the cock, to the neglect of the others; in this case the hen should be taken away for a time. This may be suspected if only a small percentage of the eggs are fertile, especially if those eggs look as if they had been laid by one hen, and often the question may be settled by watching the fowls in the pen. Sterility may sometimes be overcome by removing the cock during the day and putting him back at evening feeding time, or keeping him away altogether for a couple of days at a time, and then giving only a few hours' run with the hens. When all kinds of dodges have been tried, and the feeding and housing are not at fault, and yet the eggs are clear, you may conclude the fowls will not breed together in the way they are mated. Some cocks will not breed with certain hens, and some hens will not breed with certain cocks. In such extreme cases the sexes should be separated for quite a fortnight, and then an entirely different mating be tried, the fowls being put together even in a different pen if any way possible.

In an article on the "British Egg Supply" in the *Royal Agricultural Society's Journal*, the

writer classifies the breeds thus:—Non-sitting varieties are Hamburgs, Minorcas, Campines, Leghorns, Anconas, Andalusians, Redcaps, Houdans, Scotch Greys, and Barbezheux. General purpose varieties are Plymouth Rocks, Wyandottes, Langshans, Orpingtons, and Brahmans.

Says an American Bulletin:—Poultry are quite susceptible to diseases of the brain. Commonly, symptoms of brain disorder are due to indigestion or intestinal worms. The removal of these causes may lead to recovery; otherwise no remedy can be applied. Vertigo, due to congestion of the brain with blood, shows itself in an unsteady, staggering gait, the bird walking backward, sideways, or turning in a circle. Sometimes this giddiness is followed by epileptiform attacks. As treatment, apply ice to the head until thoroughly cooled. Then open the bowels with a purgative, as Epsom salts 30 grains, or calomel $1\frac{1}{2}$ grains. Keep the bird in a quiet, shady place. If this method is not successful, administer bromide of potassium in 1 to 5 grain doses three times a day. If the trouble is due to intestinal worms, treat the fowl for worms. Epilepsy, commonly known as fits, is occasionally seen in fowls. Birds attacked may fall and may lie on either the back or the abdomen, the eyes opening and closing. After a time the attack subsides. Unless due to intestinal worms, no reliable treatment is known.

W. B. Tegetmeier, the well-known authority on poultry, says:—One of the fallacies of the present day is that the production of eggs can be increased by the use of highly-spiced stimulating foods. These are consequently advertised by the makers very extensively. The slightest acquaintance with anatomy and physiology would prove the absurdity of such a belief. Animals cannot be made more fertile by giving them an unnatural diet and irritating their digestive organs with food which they do not obtain in a natural state. Some of these substances which are sold as egg producers are fiery and stimulating to the highest degree, and cannot possibly tend to increase. I have recently received several complaints of the ill-health of birds that had been fed on spiced foods. If the natural diet of a fowl is taken into consideration, it will be found that the bird never takes voluntarily any substance of the kind. The production of eggs in quantity requires that the fowls shall be provided with the materials out of which they can be secreted or made, and certainly turmeric and cheap waste peppers do not furnish these substances.

We give the following extract from *Station, Farm, and Garden*:—Much of the foraging done by fowls is more for grit than for food. Do not content yourself with the fact that your hens have a gravel run, for hens do not pick up gravel for grit unless it is sharp. They may be but a week on a gravel bed, and yet in that short time a large flock will clear it of the material they require, as is shown by their constant search for sharp material, which they always need. Yet there are those who have kept hens in large numbers on one place for years, without supply-

ing them with any, and when the hens become sick from indigestion they resort to poisonous nostrums. Keep a box of pounded glass where your hens can always get at it. Perhaps some may smile when advised to give pounded glass to the hens, but try it and notice how readily they will eat it, and you will wait quite a long while if you expect any of them to die from eating the glass. Anything that is hard and sharp will answer. The hard pearly-ports of oyster-shells make an excellent grit, but they lack hardness, though they are better than nothing at all. Pounded bones are a delicacy to any flock of hens, and this is a material which is available at the cost of a little trouble in every household. Remember, fowls cannot lay well unless kept healthy, and cannot be kept healthy without grit.

A writer in the *Field* writes to prove that Shakespeare knew even the merits of poultry! When Master Robert Shallow orders a dinner for Fulstaff, he is made to say "Some pigeons Davy, a couple of short-legged hens, a joint of mutton, and any pretty little kickshaws." This passage, it is said, shows that even in Shakespeare's time short-legged hens were regarded as being, what they undoubtedly are, the best and plumpest for the table. At that time the fancy breeds were unknown, and the farm-yard fowls that were regarded as the most valuable were those that had, like the Dorking and the present Surrey and Sussex fowls, short legs. Many fancy breeds are characterised by long legs produced by unnatural selection, until some enormities such as the long-legged game, Langshaws, &c., have resulted, the former being so obviously useless as table fowl that they have been excluded from the schedules of the Royal and other Agricultural Societies.

MILKING.

(Concluded from last number.)

CHAPTER III.

Whoever has the care of the cows, it should be their object to keep them clean. If the udder is in a filthy condition it must, before milking is begun, be washed clean with lukewarm water and rubbed dry with a piece of cloth.

Milk has great capacity for absorbing gases from the air, and since it offers an extensive surface as it passes in jets through the air between the teat and the pail, the air in the shed should—especially during milking—be kept as pure as one can possibly keep it. For this reason, if the cows are indoors, they should be made to stand up a little while before milking begins. They will then probably get rid of their manure. Afterwards all available doors and windows should be opened for a few minutes, the litter is arranged and things are put in order, so that everything is as it should be when the milking is to begin.

Light helps to keep the air pure, so one should always have plenty of daylight in the shed; and if the cows are milked indoors in the dark winter

mornings and evenings, plenty of lantern light gives a better chance of good clean milking.

MILKING TIMES.

If a cow is milked three times in every twenty-four hours the milk obtained is both more abundant and richer than if milking takes place only twice a day. But whether one milks three times or only twice daily, the times between the milkings should always be as nearly as possible of the same length.

The cow is a creature of habit; its udder works steadily and regularly. Hence the milking times should be most carefully kept, and the same pair of hands should milk the same cows in the same order. If milking is begun too late the cow becomes restless, and as regards those which give much milk the tension in the udder can give pain—in all cases milk is lost.

Altogether it ought to be clearly realized that the cow repays all unpleasantness by giving less milk.

GOOD ADVICE (IN BRIEF).

- (1) *The cow is a living creature.*
Use her kindly and you get more milk from her.
- (2) *Use develops the living instrument.*
 - a. Milk dry! Milking dry develops the udder and consequently the power of giving milk.
 - b. And one obtains richer milk, since the very last milk is by far the richest.
- (3) *Milk in the right manner.*
 - a. Grasp the teat with the whole hand.
 - b. Press the milk out.
 - c. Don't forget the gentle push up against the udder.
 - d. Never stop nor let the work be interrupted when milk is "coming."
 - e. Remember the second milking and the last drops.
 - f. Pat the cow when you have finished milking.
- (4) *Cleanly milking.*
 - a. Have clean pails (to milk into and for carrying the milk).
 - b. Wash your hands before and (in the shed) during milking.
 - e. It is best to milk with dry hands.
 - d. Milk in a suitable and clean smock.
- (5) *The state of health of the udder.*
 - a. Tenderness or hard lumps in the udder or on the teats.
 - b. Blocked milk channel, etc., or
 - e. Unnatural looking milk—should all be at once reported to the owner or other responsible person.
- (6) *Milking Times.*
 - a. Begin at a fixed time.
 - b. Milk the same cows in the same order.

To whoever has charge of the cows:—

- (1) Clean cows.
- (2) Good air in the shed.
- (3) Plenty of light.

—*Agricultural Journal of Cape Colony.*

AGRICULTURAL PROGRESS IN ZANZIBAR.

We have to acknowledge with thanks receipt of a copy of the Annual Report (dated the 24th Feby., 1900) of the Agricultural Department of Zanzibar.

Among the more important crops referred to are

1. CLOVES.—The year is reported to have been a bad one for this product, the general crop of the island having been about $3\frac{1}{2}$ -tenths of last season.

2. COCONUTS.—At Dunga the average number of nuts per tree is put down at 31 per annum; the price varied between Rs. 18 and 25 per thousand. A new plantation of 1,579 trees is said to have been laid out in April and May, the palms being put 35 feet apart. Mr. Herbert Lister's report on Tundana plantation puts down the total yield at 14,300 nuts, an average of 18 nuts per tree, showing an increase of 2,400 last year, and 4,400 over 1897. The price at the end of the year was Rs. 24 per thousand.

3. COFFEE.—A small beginning has been made with both the Arabian and Liberian variety, both of which are reported to be doing well, particularly the latter. Snails seem to be the chief enemies.

4. TEA has been grown experimentally, seed having been procured from Horagalla, Ceylon. The experiment has so far proved successful, and the opinion is expressed that Zanzibar should be able before long to meet all local demands, though there is not sufficient suitable land for an export trade.

5. CACAO.—The verdict as to cacao is "Cacao is a most disheartening product to grow; it is the most delicate of all the economics . . . nearly every insect attacks it, &c." It is evident that the requisite conditions for cacao growing are wanting in Zanzibar. There are few plants more particular as regards its natural conditions, but given these conditions it will grow like a forest tree if not interfered with. The area under cacao is comparatively small owing to the unsuitability of the greater part of our planting areas to the growth of the plant; and it is rather misleading to read "Cacao does well down to sea-level in Ceylon," which, indeed, it does not do. As suitable shade—not referred to in the report—we might mention *Erythrina indica* and *E. lithosperma*.

6. RUBBER.—The summing up of the experiment in growing this product is that the experience has so far been unfavourable both in Zanzibar and Pemba.

7. VANILLA.—The plantation of Vanilla is favourably reported on. There is little to report regarding rhea which is only being grown on a "small plot." As regards chillies it is a surprise to read that "there is no doubt that in Zanzibar these do not pay to cultivate, except for the native to whom time is no object." As a "Catch crop" it has given excellent results on a large scale here.

THE GOVERNMENT DAIRY FARM.

This institution has had a record year of success. It still continues under the good management of Mr. J. A. G. Rodrigo, whose experience of dairy

cattle and of breeding, gained during the eight years he has been in charge of the farm might be considered mature, and therefore particularly valuable. The expenditure during the year on the dairy was Rs. 21,207.62, and the receipts Rs. 26,838.86, so that the nett profits from the working of the institution as a milk dairy was Rs. 5,631.24 (*vide* Statement A.).

Two lots of cows were purchased and added to the dairy herd on 31st March and 22nd December. The first consisted of 15 Scinde cows which were imported with the help of Veterinary Surgeon Haji of Karachi, no special officer having been sent from here to effect the purchase. The second batch of animals was secured in Madras by Mr. Rodrigo himself, who was sent to India for the purpose, Mr. Wijenayaka acting for him in the dairy. These latter were principally of the Nellore breed, and the new departure of purchasing other than Scinde cows (which have proved so satisfactory) was necessitated by the great advance in the market value of our favourite breed, chiefly owing to the losses resulting from famine in North-West India. The new animals are good of their kind, but certainly not as good as our old stock, and the calves bred from them will, I fear, be of small value in the eyes of stock owners, among whom the young Scinde animals bred in the dairy are highly prized for improving their own herds. It is hoped that we shall be able to get future supplies of cows from Scinde, so as to preserve the uniformity of the dairy herd, which certainly cannot be improved by the addition of South Indian cattle, though the introduction of a good English milking strain should prove an advantage. The first purchased batch cost the dairy Rs. 2,375.99 and the second Rs. 2,514.98.

The sales were held in the dairy on 30th March and 8th June. At these sales 10 cows and 27 calves were disposed of for Rs. 1,955.86. The average price per calf (taking both sales into consideration) was Rs. 50; at the first sale of rather old animals it was Rs. 62. As a result the Scinde breed is being introduced into the Western, Southern, and North-Western Provinces. No public sales were held at provincial centres as in past years, but three bull calves were sold to the Government Agent, Ratnapura, for Rs. 320; two to the Assistant Government Agent, Kogalla, for Rs. 220; one to the Government Agent, North-Central Province, for Rs. 100; and one heifer to the Government Agent, Northern Province, for Rs. 60. These animals were the pick of the older lot of calves, and are intended for breeding purposes under Government auspices. The dairy has been most fortunate in the matter of casualties, only one cow and one calf having died from ordinary ailments during the year. The calves suffered from a peculiar affection during the latter part of November and beginning of December. This disease, which attacked the most thrifty animals of about two years of age, was considered by the Government Veterinary Surgeon to be "quarter ill," which though as a rule very fatal in England did not cause the death of a single animal in the dairy herd. I have no doubt that Mr. Sturgess will refer fully to this outbreak in his report, so that I need not give any further particulars with regard to it.

Considering that both rinderpest and foot-and-mouth diseases prevailed in the near neighbourhood during the year, it speaks well for the management that these contagious diseases did not reach our herd.

Though the lease of the Havelock Racecourse grounds (for which the dairy pays Rs. 60 per mensem) secures distinct advantages in the way of providing pasture and exercise for the stock, the difficulty of checking cattle trespass under the conditions of the lease is much to be deplored, as it will be readily understood what serious risks are run in permitting our cattle to graze over pasture at the disposal of outside cattle all night, and sometimes also by day. I trust that in the interests of the dairy, with its excellent herd, put together at so much cost and pains, and forming a valuable asset (potentially if not so intrinsically), some means will be found to cope with the evil complained of. A much needed addition to the building was made by the erection of a small detached block of two rooms to be used as a food store. Hitherto much trouble and some loss was experienced by the incursions of rats that persistently burrowed beneath the foundation to reach the cattle food, and so formed excavations which affected the stability of the dairy walls. After trying various remedies it was decided to erect a separate building in the open, as a surer means of watching for and preventing the nuisance caused by the rats.

Model Farm.

As shown by Statement B. appended, the gross receipts for the year were Rs. 3,980.20, the expenses Rs. 240.35, and the profits, after deducting a sum of £s. 1,350 paid as rent to the Government Agent, Western Province, Rs. 2,389.85.

The Kelani Valley Railway runs through the farm, and to meet the requirements of Government in this connection about five acres of cultivated grass land were appropriated for the railway. The reduction in the revenue as compared with last year is attributable to our giving up this land as well as the digging for cabook and gravel.

An extent of 11 acres was given over with the sanction of Government to Messrs. W. H. Davies & Co., who have acquired the land on a 25 years' lease and a rental of Rs. 1,000 per annum for the first ten years, and Rs. 1,500 for the fifteen years following.

As appendices to this report are annexed the following statements:—

A.—Receipts and expenditure of the Government Dairy for the year 1900.

B.—Receipts and expenditure of the Model Farm for the year 1900.

C.—Financial statement of the Government Dairy and Model Farm for the year 1900.

D.—Capital Account of the Government Dairy, 1900.

E.—Balance Sheet showing the position of the Government Dairy attained of 1900.

F.—Live-stock return of the Government Dairy for the year 1900.

A.—Receipts and Expenditure of the Dairy for the Year 1900.

* Six calves were transferred to the list of cows.

INTRODUCTION TO ENTOMOLOGY.

(MISS ELEANOR A. ORMEROD.)

Classification of Insects.

Opinions of different writers vary much as to the most desirable form, but the method appears to be the most simple and comprehensive in which are divided into thirteen orders, arranged according to general similarity in the early stages, and also in the general appearance of the perfect insects composing each order; also according to the number or nature of the wings or the method in which they are folded beneath the wing-cases.

In the table the orders are arranged accordingly in the classification given in Prof. Westwood's Introduction to Entomology, these thirteen orders being formed into two great tribes of Mandibulata and Haustellata, according to whether they feed by means of jaws (mandibles) as in the case of beetles, or by means of some kind of sucker (haustellum) as in the case with butterflies, aphides, &c.

These orders are placed in succession according to the nearest resemblance which the insects of one order bear to the one preceding or following; and the reader will notice that the two last syllables of the name of each order are Ptera, meaning

"wings," from the Greek word *Petron*, a wing. The preceding part of the word signifies the nature of the wing.

Mandibulata.

- Coleoptera—Sheath-winged—Beetles.
- Euplexoptera—Tightly-folded-winged—Ear wings.
- Orthoptera—Straight-winged—Cockroaches, Crickets, Grasshoppers, &c.
- Thysanoptera—Fringe-winged—Thrips.
- Neuroptera—Nerve-winged—White ants, May flies, Dragon flies.
- Trichoptera—Hairy-winged—Caddice flies.
- Hymenoptera—Membrane-winged—Saw-flies, Gall flies, Ichneumon flies, ants, wasps, bees, &c.
- Strepsiptera—Twisted-wings—Bee parasites.

Haustellata.

- Lepidoptera—Scale-winged—Butterflies, moths.
- Homoptera—Similar-winged—Lantern flies, Cuckoo-spit flies, aphides, scale insects, &c.
- Heteroptera—Dissimilar-winged—Plant bugs, &c.
- Aphaniptera—Imperceptible-winged—Fleas.
- Diptera—Two-winged gnats—Dabby, long-legs, gad flies, bot flies, flesh flies, &c.

GENERAL ITEMS.

Perjeval-ky's horse is the name given to what has not been decided to be a distinct species of the horse in the desert region of Central Asia. Further specimens of the animal have lately been secured and the characteristics of the animal have been well studied. It has much shorter ears than any species of ass. In its shape it resembles the horse, with thicker legs and broader and sounder hoofs than the ass. The colour is dun with a yellow tinge on the back, but without a stripe down the centre. Under the belly it is almost white. The hair, which is long, is brick red on the head, cheeks and jaw, the muzzle is white. There is no forelock but an upright hogged mane, which extends to the withers and is of a dark brown colour. The tail is thicker at the root than that of the ass, and has long dark brown hair at the end. The legs are

brow near the hoof—a character never found in the wild ass.

A well-known English Veterinary Surgeon gives the following recipe in reply to a correspondent in the *Farmer and Stockbreeder*—In general use among horses where some obstruction is likely enough to be the cause of gripe there is a good formula, but a horse given the mixture should not be worked the following day though apparently well :

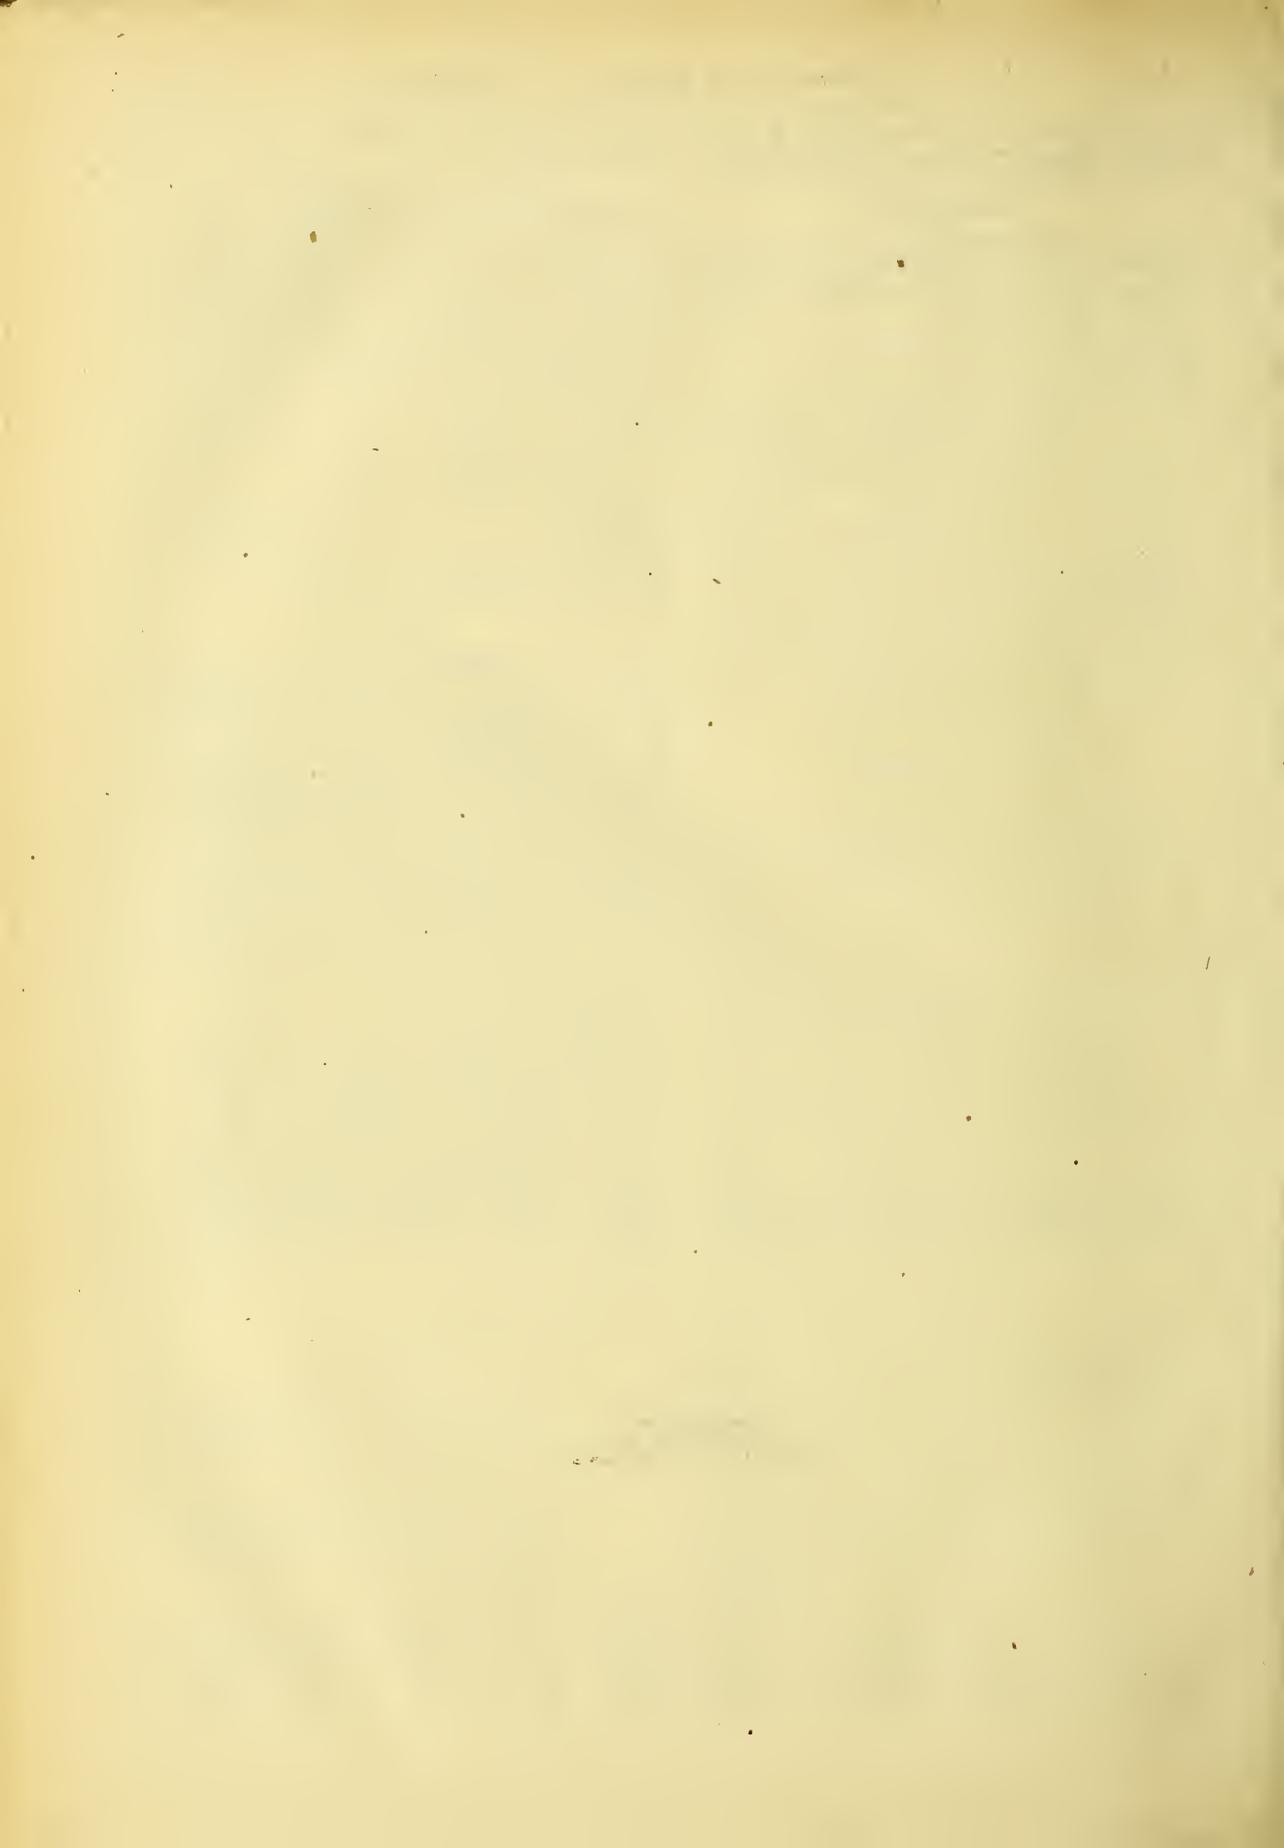

Barbadoes aloes in solution	...	6 dr.
Spirits of turpentine	...	2 ozs
Sweat spirit of nitre	...	1 oz.
Compound tincture of Morphia
and Chloroform	...	4 drs.
Linseed oil	½ pt.

Mix with a pint of thin gruel and dreuch slowly. If the animal's bowels are known to be in soft condition leave out the aloes.

The Hush tomato (of which the botanical name is not available to us) is the latest reported novelty. It is like the ordinary tomato, a native of the new world (coming from Mexico) and has been successfully introduced into the Channel Isles. It is described as no bigger than a horse chesnut and enclosed in a hard skin which dries as the fruit ripens, so that it is easily pulled off. It is never eaten raw in the land of its origin, but is most palatable when properly cooked, and is especially good when prepared as a conserve. The *Farmer and Stockbreeder* thinks that it will doubtless be in considerable evidence before many seasons are past.

The *Exchange* says:—There are hundreds of horses and thousands of cattle in the Hawaiian Islands which never take a drink of water throughout the whole course of their lives. The cattle runs are in the upper altitudes of the mountains, and here they run wild. Excepting possibly two or three months in the rainy season, there are no pools or streams in these parts, but everywhere there grows a recumbent pointed grass known as the "maninia" which is both food and drink to the animals.

No. 3.

SCHOOL, BUNGALOW, AND REST- HOUSE GARDENS, AND SOME HINTS ON HOW TO PLANT THEM.

(Circular, Royal Botanic Gardens, Ceylon.
Series 1.—No. 22, July 1901.)

THE general scheme for the working of school gardens, as has been set forth elsewhere, is to have small gardens at the schools, worked by the personal labour of the masters, and scholars, who may divide two-thirds of the produce between them, and to give the scholars simple lessons in "Nature Study," using as objects of study the simpler operations of the garden, and the innumerable natural objects and phenomena around them. In providing these gardens with plants, the object to be kept in view is to provide only the best varieties of each kind, so far as possible. There is no great variety of plants in most of our villages; what is cultivated in the school gardens will gradually diffuse into the neighbourhood; hence it should be the best possible of its kind. In the second place, the village teacher is not qualified to teach agriculture, nor to criticise intelligently the agricultural operations of the district: he must carefully avoid trying to grow the staple crops of the neighbourhood, lest he fail—as he probably will—to do as well as the villagers and thus bring himself into ridicule. Hence the school garden must cultivate in general things not common in the district.

Every child in the school should help in the garden, and if possible grow a few plants him or herself. We want all the children to learn something about plants, to grow them as well as they

can, and to come to love them. The school garden and perhaps more especially that part that is worked by the joint labour of masters and scholars, will of course contain many useful plants, but we do not want the children to look upon all cultivation for the sake simply of the rupees it may bring in and ornamental plants should be grown also. There are other interests in life than mere money-making. The child who grows up to love nature, and the beauty of natural objects and phenomena, and to observe what goes on around him, will live a happier life than the one who gives himself up from the first to the consideration of monetary gain; in the long run, too, he will probably be the richer in actual money, and he will be less liable to spend his earnings on coarse and expensive pleasures.

Let, then, the school garden, in addition to the useful plants in the narrower sense, cultivate as many as possible of the ornamental. Let it be laid out as beautifully as possible with the means at disposal. Let masters and scholars take a pride in the prettiness of their garden. An attractive school garden will be a great benefit to the neighbourhood in many ways; it will make school more attractive to the scholars, will promote in them good taste and a love of natural beauty, and will stimulate the neighbours to do likewise.

The remarks made below apply equally to rest-house or private bungalow gardens. Parents should encourage their children to work in the garden and take an intelligent interest in it and in the plants growing in it.

The first point to be borne in mind is that the beauty of a garden depends, not on the particular plants it may contain, but mainly on the skill with which it is laid out, its natural advantages further improved and emphasised, and its defects lessened or concealed. The world-famous beauty of the

Peradeniya Gardens depends partly on the natural advantage of the site, with its broad river and mountain background, but quite as much on the great skill and taste with which it was laid out and planted by Dr. Gardner and others. The plants with which the beautiful scenic and gardening effects are produced are nearly all the same as the common ones that one may see in almost every large garden in the Island, but by skill in grouping and laying out so fine an effect is produced that it is often difficult to get people to believe this.

In an ordinary native garden the planting is not ornamental, because the object is to obtain as much monetary return from the land as is possible, and the ground is thickly planted up with useful trees and plants with no attempt at artistic grouping. The bulk of the trees are usually coconuts. Individually or in clumps these are very beautiful trees, but their effect in great plantations is wearisome, depressing, and inartistic. We do not want our school gardens to be mere monotonous coconut groves: we want some variety, some taste in laying out, some pretty flowers, something which will make the garden pleasant to look at. If, as, in some cases, the land is already a dense coconut grove, then, unless some of the trees can be cut down, not much can be done, for few things will grow in the shade of coconut palms.

Let us now consider some general principles of laying out, which are applicable equally to any garden on a small scale, such as a resthouse or bungalow garden. The first great thing to remember in ornamental planting is the provision of open spaces: not merely are these pleasant in themselves, and useful as lungs and playgrounds, but the trees and shrubs, as well as the flowers, have room to be seen to advantage, and make much better growth, forming leafy masses, instead of growing up tall and spindly with all their leaves at the top. Put the larger trees and shrubs near to the sides of the ground. Especially put them on the sides that will protect the central parts from the wind in the monsoons, *i.e.*, in most localities put them on the south-west and the north-east. But do not have too many trees—give them room to grow and spread out so to show themselves to the best advantage.

Plant the trees and shrubs in clumps or singly, as the case demands, not in rows or belts. Contrast the ugliness of the wind belts in the tea estates with the beauty of the irregular patches of natural jungle. The latter are also made up of different kinds of trees, and this is an important feature in their beauty. In mixing trees, however, do not mix those which differ too radically in form and habit; do not mix many palms among ordinary leafy trees of conical or spherical form; palms lend themselves very well indeed to massing in groups of palms and cycads, with the larger in the middle or at the back and the smaller near the edge or the front, as in the beautiful groups at Peradeniya. Remember, too, in mixing trees, the colour of their flowers, and do not put trees whose flowers are of inharmonious colours together. For instance, do not put a pink-flowered *Cassia* beside a red *Plamboyant* or grow a purple *Bougainvillæa* or an *Amherstia*. If the trees do not flower at the same time of year, this is of less importance.

Before you begin to plant, look at your ground from all sides and think how to use it to the best advantage. Draw a rough plan of it on the blackboard, and mark out on this as you think best the way in which you mean to plant your ground. Make the most of its natural advantages. If there is an unpleasing view or building in any direction, plant so as to conceal or diminish its ugliness, but if there is a pretty view do not hide it, but give it a good foreground, *i.e.*, one clear of trees and shrubs or flower beds in the centre, so as not to interfere with the view, but prettily framed with trees or shrubs at the sides; bamboos make especially pretty

frames to a good view, but there are many ways in which the object can be attained. If there are any steep banks in the ground do not, if you can help it, plant them with trees; they lend themselves well to small plants, especially if rocky. Bring up all the stones that interfere with the work in other parts of the garden, and put them in natural positions on the bank, and plant the bank with ferns, mosses and flowers. When it is planted put the smaller stones close together in the surface earth between the plants, and this will keep the earth from being washed away by the heavy rain. Go out into the country round and see how beautiful nature makes these steep banks at the sides of the roads and elsewhere with ferns, mosses, and other little plants, provided it be shady enough. Try to imitate nature; bring in pretty plants from the banks of the roads and put them in places as like those they came from as you can. The success of a gardener depends on his being able to give to his plants the nearest possible imitation of the conditions under which they do well in nature. Let each child have a little piece of the garden if there is room for it, and let him try to imitate nature, bringing in wild plants and trying to grow them successfully. If the bank in the garden is not shady enough, plant some trees near it, but not upon it. If it is too high for convenient working, make a terrace out of it. Otherwise make pockets in it and put the plants in these.

We must also, if possible, find room for some shrubs as well as trees. A close shrubbery makes an excellent screen for outhouses or for ngly surroundings outside the school grounds, and serves as a good background for flower beds. Shrubs and trees may be mixed together; some shrubs will do well in the shade of trees and may be put right among them, others must be put at the edges of the groups of trees. Do not, however, plant shrubs among or around all the tree clumps. Leave most of these as they are. Large flowering or foliage plants may often be mixed among shrubberies with great advantage: *caladiums*, *alocasias*, *cannas*, &c., are especially suitable under this head.

Ceylon gardens are famous for their pretty flowering creepers, and we must not forget these very effective plants, if we have an old tree, or a trellis, or a side wall to plant them on; but do not have many in a school garden, and do not cover the building with large loose-growing creepers. *Ficus repens*, which clings closer than ivy, is very suitable for the walls of the building. Remember the colours of the flowers of the creepers you plant, and do not have a *Bougainvillæa*, as it is too overpowering for a small garden, and to make it effective from an artistic point of view everything else must be subordinated to it, even the dresses of the people frequenting the garden.

The garden must have some flower beds. Flower beds should not be put without a background in the middle of the lawn or open space—flowers want a dark background to show up their bright colours, so we must put them against a mass of trees or shrubs or against a wall with creepers on it, or near the house, or against the dark shadow of a mass of trees at a little distance. If you put them near the school house wall, be careful that the drip from the eaves is taken away by guttering; otherwise, they will not thrive.

In laying out flower beds, do not put the plants in stiff rows but in groups and clumps, and fill up the ground as much as possible; nature does not leave patches of bare earth between her plants, and if such are left the best part of the soil is washed away and the plants are injured by mud splashed upon them. Let the plants grow as they will till they fill up the spaces, and keep away weeds, and trim the plants carefully to keep them in their places when they have filled those places. Use as many different kinds of flowers as you can, and bring

in pretty wild flowers from similar situations as regards light and soil and plant these. Remember not to mix inharmonious colours. Put the small plants at the front and the larger at the back.

Do not make the beds more than three feet wide, so that the children can easily get at all the plants in them. When first making them dig out the soil to a good depth and remove all the roots of trees from it; break up the soil finely with the mamoty and the fork if you have such a tool, and mix with it a supply of well-rotted manure if you have any. If you have not, make a pit in some out-of-the-way corner of the garden and begin a leaf mould store putting into it all the dead leaves and other garden rubbish and keeping it covered from the rain as well as possible. Put your flower beds in well-drained places, not in the lowest parts of the garden. The digging up and manuring should be a yearly operation and in some cases even more frequent.

We must not forget the walks in laying out our garden. Do not, as a rule, make straight ones, unless the distance is short or between points where short cuts are possible. If the walks are in the open spaces of the garden let them be walks only, do not plant flower beds beside them.

Do not leave the schoolhouse or bungalow a bare exposed building in the middle of an open space; group your trees so as to make a picture in which the schoolhouse shall be the prominent feature as seen from the principal road. For instance, put a clump of trees near to the house on one side and tapering away into the open area, but do not let the line of the trees be at right angles to that of the building. Put some flower beds near the building in suitable positions. Avoid exact regularity in the arrangement of the garden on the two sides of the building, from whatever direction it may be seen.

Now, let us turn to the consideration of the economic or more strictly useful plants of the garden. Many of these will be trees or shrubs, *e.g.*, cloves, nutmegs, sago, oranges, cacao, limes, mangoes, coffee. These may be planted, with strict regard to the principles of ornamental gardening laid down above in the places best suited to them. Cacao must be in the shade of other trees, also coffee, but not very dense shade is required. Sago palms must be put in damp or even swampy places. The other trees will do very well almost anywhere and may be planted in clumps, but oranges and limes, which are small trees, must not be put in the centre of the clumps.

Such economics as are climbing plants may be put among the trees or shrubs on suitable supports if they require shade, or out in the edges of the clumps if they require sunshine, as the case may be. Pepper and vanilla need a good shade, but many yams, &c., prefer some sunshine. Other economics, such as yams of some varieties, pineapples, ginger, maize, guinea corn, cassava, arrowroot, sweet potatoes, and other vegetables, are herbaceous or only small shrubby plants, and are best cultivated in special beds laid out in rows. These beds should be in good sheltered parts of the garden, but need not be obtusive. They must of course be prepared and cultivated with special care.

Lastly, we must have a nursery in which we may start our trees and shrubs, and even some of the smaller plants. This also must be in a good soil, well-drained, in a sheltered but not too shady part of the garden, and must be the object of special care and attention.

Now, in conclusion, let us sum up the main points to be attended to. First attend to the broad general features of the garden, then to the details. Go over all the ground, dig holes here and there if necessary to see what kind and depth of soil you have in different parts, and make a rough plan showing the house and boundaries, and any other unalterable features of the land, such as neighbouring houses visible from the ground, pretty views &c. Decide the position of your clumps of trees, with

reference to the making of screens from wind, hiding ugly views or buildings, emphasizing pretty ones, making a good setting for the schoolhouse, &c. Then settle the position of the shrubberies, vegetable garden, nursery, and flower beds, and see that the most is made of steep banks or of other good natural features, such as rivers, streams, or ponds. Then, as your plants come on in the nursery, plant them out according to your pre-arranged plans, of which you should keep a copy, but do not try to arrange everything in an hour or two. Go into the garden again and again on different days and think everything over carefully, and look at everything from all sides and decide what will be best.

Attention must always be paid to the special local or other conditions of the particular garden. For example, in the case of railway gardens, or of bungalows which have merely a narrow strip of garden along the front or side, the provision of open spaces is impracticable in the sense described above. With a railway garden, the object to be aimed at is to provide for travellers by the passing trains and for people walking along the platform, a succession of small pictures of the greatest possible beauty. A long platform garden is perhaps best treated by being laid out in irregular smaller plots open to the platform, and with a few trees and shrubs at the back and sides of these and flower beds and creepers in suitable places. In the case of a bungalow with only a strip in front, it must be decided whether privacy shall be aimed at, or a pretty appearance as seen from the road. In the one case shrubs and trees must be planted along the road, and the space between them and the house laid out to make the best possible effect as seen from the latter. In the other case the house should be used as the centre of a picture as seen from the road, and shrubs and trees planted near it as required, the clumps tapering away down the sides of the plot towards the road.

JOHN C. WILLIS,
Director, Royal Botanic Gardens,
Peradeniya, June 25, 1901.

BASIC SUPERPHOSPHATE: ITS PREPARATION AND USE AS A MANURE.

BY JOHN HUGHES, F.I.C.,

(Reprinted from the *Journal of the Society of Chemical Industry*, 30 April, 1901. No. 4. Vol. XX.)

(Continued from page 73.)

DISCUSSION.

Dr. J. A. VOELCKER said that not many weeks ago a lecture had been read to chemical manufacturers, and more especially to manufacturers of superphosphates, to the effect that they must "put their house in order." Now they had another warning—they must no longer use dissolved phosphates; that seemed to him a retrograde step, for, when one considered the great benefits to agriculturists which had come from the introduction of dissolved phosphates, one could not but wonder at the proposal to dissolve phosphate first and then precipitate it again; in other words, to go to the trouble of undoing the work already done. Mr. Hughes had referred to the labours of his (the speaker's) father on the subject: but it was necessary to consider the present question in its different aspects, and to remember also the attitude taken up by the late Dr. Voelcker with regard to the comparative values of dissolved and undissolved phosphates. Mr. Hughes had referred to one point which the late Dr. Voelcker had always insisted upon, *viz.*, the very fine state of division of the phosphate when superphosphate was washed into the soil by rain; but Dr. Voelcker was always decidedly opposed to the views

held by Mr. Jamieson, of Aberdeen, as regards the harm done to the soil by the use of superphosphate. On his farm at Woburn he (the speaker) had a plot of land which had been manured yearly with superphosphate for the last 24 years to his own knowledge. The soil had, at the commencement, a very small amount of lime, 0.25 per cent. of carbonate of lime only, but the plot had not yet suffered from deficiency of lime. There were other plots in the same field which had, indeed, so suffered, the lime having been removed to a very great extent by the continued use of soluble nitrogenous manures. He could not, therefore, altogether agree with Mr. Hughes as to the great necessity for a manure which had the acid character taken away by admixture with such a substance as finely ground lime. He had certainly come across soils which were so poor in lime as to require nothing so much as a good dressing of lime; he had not yet had experience with the new material which Mr. Hughes had just introduced, and so did not know whether that purpose might be well served by it; but, if so, he ventured to suggest that it could be done without the necessity of buying a patent manufactured manure. He was not going to discuss the question of citric acid, and how far it was a test of the availability of phosphatic materials; but, as they had just heard the use of hot water mentioned for determining the amount of phosphate available, and had been reminded that it did not occur in the soil, he might equally well point out that they did not have citric acid in the soil either. With regard to basic slag he did not think they had yet arrived at a solution of the cause of its utility. Attempts had been made to estimate this by the solubility in citric acid solution; but there were many other things in the soil which might exercise an influence on the solubility of the materials applied to it. He would like to have seen some comparison given between basic slag and basic superphosphate with regard to their respective solubilities in citric acid solutions of different strength. What was the behaviour of each in a solution of the strength likely to be met with in soils? It might be taken for granted that there were soils which were sorely in need of lime, and where superphosphate might do harm; but he would ask Mr. Hughes where was the advantage of using superphosphate mixed with lime as compared with the use of a material like precipitated phosphate, which was just as soluble in citric acid as was Mr. Hughes' mixture. And then, even if it were granted that the mixture had advantages, what was there to prevent the farmer from buying the lime and the superphosphate separately and mixing them together himself? If Mr. Hughes said that a farmer could not do this, but would be bound to buy a patent manure, ready mixed, he (the speaker) had still to learn that such a patent was of any value when it was taken out. If the farmer thought it a good thing to neutralise superphosphate by lime he would mix the two materials together, patent or no patent. There was, to his mind, a further disadvantage, inasmuch as Mr. Hughes did not sufficiently imitate the action of the soil in the mixing together of the two materials. If superphosphate was taken and ground lime added to it, the lime did not work through the whole mass, but there was only a superficial action, the external portion being neutralised and the inner left as it was. So one did not get a thorough neutralisation and distribution of precipitated phosphate purely by a mechanical mixing of the ground lime and superphosphate. The only advantage apparent to him was that there might be some places abroad or in the colonies where lime was not obtainable, or where it was so expensive that its use in any quantity was practically out of the question. If soils in such places were very deficient in lime one might certainly get some advantage by using lime and superphosphate together, but, for that matter, he did not see the advantage which the new

material had over precipitated phosphate in this respect, nor why one should not get the materials separately and mix them for himself.

Mr. F. J. LLOYD said that it was now about a quarter of a century since any new manure was brought before the agricultural world and that was a sufficient reason for thanking Mr. Hughes for having brought before them a new manure. Whether it would prove of value or not, time only could show. The author had given two reasons why it might prove valuable: first, because from the empirical tests made there was every reason to suppose that the phosphate of lime would be quite as available to the plant as the phosphate in superphosphate, and more available than that in basic slag, which for the last twenty years had proved a valuable and effective manure; and, secondly, because it was not acid, and therefore suitable for soils of an acid character or deficient in lime. There was another reason, in his own opinion, why Mr. Hughes' mixture should be a valuable manure. The progress of science in agriculture had of late years been mainly bacteriological. As lecturer on agriculture at King's College, it was his duty to explain why we manure the land. Formerly there were only two reasons: one, to supply a deficiency of any material in the soil; and the other to supply material of a nutritive character to the particular crop to be grown. But science had recently shown a third reason of considerable importance, and one which threw light on the action of manures hitherto difficult to explain. The soil was full of bacteria, and many of the plants grown in the soil were affected by bacteria. These bacteria must be fed in order to carry on the functions of their life. Taking the bacteria most studied, those which produced nitrification in the soil, it had been proved that they were most active in a material of an alkaline nature, and did not act and grow, except slowly, in any material of an acid nature; therefore, if one added something to the soil which, while it supplied the plant with one variety of food, also supplied conditions which enable the bacteria to supply another form of food, and helped the nitrifying organisms to carry on their work, that manure served a double purpose. Basic slag had had that effect, because of the double action brought into play—the supply of nitrogenous matter to the plant as well as phosphatic food. Arguing *a priori*, there was every reason to suppose that this basic superphosphate would have the same effect, and he really believed that they had to thank Mr. Hughes for the introduction of a material of considerable value. It was all very well to say that, if the soil contained lime and acid, superphosphate did no injury; but they had to deal with the British farmer, and he was a peculiar man. For the last twenty years liming had gone out of fashion, and the soil was deprived of lime as much by the use of nitrogenous manures as by superphosphate. Consequently, the soils of the country were becoming more and more deficient in lime, and an acid superphosphate, was not, in his opinion, likely to have the same effect as a basic superphosphate, which gave the farmer the lime and available phosphates at the same time. He would not enter into the question of the estimation of the value of this material; but he did hope, as an official agricultural analyst having to carry out the Fertilisers Act, that those who put the manure on the market would give a distinct guarantee as to what it should contain. He was sure they would find it beneficial to themselves, and it would be a subject for future discussion to determine whether that guarantee was a satisfactory one or not. He felt personally grateful to Mr. Hughes for bringing this valuable communication forward.

Mr. J. RUFFLE agreed with the last speaker. He was not surprised that Dr. Voelcker should throw cold water on this new idea, for it was just what happened on the introduction of basic slag 20 year

ago. One after another the authorities refuse to have anything to do with it, and he got a wiggling because he suggested that it would have a manurial value. The fact was that basic slag had become a very useful manure both in England and on the continent. Dr. Voelcker asked, Why should not a farmer take his superphosphate and add lime to himself? He might, but he would not do so well as a manufacturer. But would one gain anything by taking superphosphate and adding lime to it? He ventured to think one would, wherever an alkaline phosphate would be useful; also because the ordinary acid superphosphate was, after all, not on the average in a very fine condition; it would hardly go through a 10-hole sieve. But after mixing it with lime, one could send the mixture through a 30- or 40-hole sieve. Taking the relative surfaces which the increased fineness yielded, one would find very great advantage by that superior subdivision, so that in many cases it would be found quite equal to the ordinary acid superphosphate, even where this article was successfully used. One advantage it had was that it was more readily distributed, and that it would allow of the simultaneous use of nitrate of soda, and where it was desirable to put them together that could be done. One point had not been touched upon which he thought the makers of this article would find desirable, namely, the degree of hydration of the lime to be added to the superphosphate. If they took quicklime and added it after grinding, they would get tricalcic phosphate, but if they hydrated it with as much water as it would carry, they would get a finely divided powder; this, added as Mr. Hughes directed, was one that produced a hydrated mono- or dicalcic phosphate which was far more soluble. Therefore he suggested that they should take a lime that would take two-thirds of its weight of water, and hydrate it at that rate; this would break down readily. If they took lime and water in those proportions, namely, one of lime (CaO) to two of water (H₂O), when added to the superphosphate it would form a body which would be more soluble than with a greater number of molecules of lime (CaO) only. He believed it would prove to be more valuable as a manure than even basic slag had been.

Dr. BERNARD DYER said that it was interesting to think that the author of the paper before them, Dr. Voelcker, Mr. Lloyd, Mr. Ruffs, and himself were all old pupils of the same grand old master, and he could not help thinking that most of what was best in the knowledge of all of them had been derived from him. For really the quotations that Mr. Hughes had made from the early paper by Dr. Voelcker went to the heart of this matter. The great value of a superphosphate lay in its diffusibility, and the utmost value to be derived from this quality could only be realised in those soils which had a satisfactory proportion of carbonate of lime. He had tried to persuade farmers to use more discrimination as to the kind of phosphatic manure they employed, and had laid it down as a rule for guidance that, if they had a soil that would effervesce when hydrochloric acid was poured on it, an acid or dissolved phosphatic manure was the most valuable one they could use; but that, when no such effervescence took place, they should have recourse to some other form, such as bonemeal, guano, or basic slag. There was another material which was manufactured to a large extent some years ago, and was referred to by Dr. Voelcker, namely, precipitated phosphate. Large quantities of it were made on the Rhine by precipitating a solution of phosphoric acid with lime, and it was suitable for use on soils which were deficient in lime. What Mr. Hughes made was precipitated phosphate. He felt inclined to quarrel with his term "basic." He really made a precipitated phosphate, and he probably made it more cheaply by this "dry" process than it could be made by the "wet" method of precipitation. But

the manufacture of precipitated phosphate by the "wet" process had almost entirely disappeared since the efficacy of basic slag had been recognised, and basic slag had quite taken its place. That fact was presumably due to questions of cost. The question now was whether it was more economical to dissolve phosphate by the process of Mr. Hughes, and then use lime to neutralise it. He took it that the unit price of the phosphoric acid in this material would be higher than in some other forms of manure; and they had yet to learn whether it was so much more useful as to warrant that higher price. Following the teaching of Dr. Voelcker, he had recommended farmers having soils poor in lime to buy superphosphate and bone-meal, and make a compost of it and also neutralise it. It occurred to him that it might possibly be more economical to use finely ground phosphate itself instead of lime. One would thus be retaining in an available form all the phosphate already dissolved, and the free phosphoric acid which existed in the phosphate would react on the fresh quantity and make some of that available, as well as being itself converted into the non-acid form. What Mr. Lloyd had said with regard to farmers being reluctant to use lime was quite true. He did not think, however, it was due to obstinacy, but rather to poverty; for to lime soil in some districts was very expensive, and in the present time the farmer had to look at every source of expense. He had no doubt that Mr. Hughes' mixture would be a very useful and valuable manure; his only doubt was as to its economy. He had shown it to be more soluble than slag phosphate in such weak solutions of citric acid as he had taken; but he feared that, if he took acids of such strength as were used on the continent, those great differences would disappear. As to the doubt which Dr. Voelcker had thrown on the validity of Mr. Hughes' patent, he would not like to express an opinion. Patent law was very complicated, and there was no knowing what the result of litigation on such a subject might be. He should think the case would go right up to the House of Lords, and that a great many experts would be found on each side of the question.

Mr. A. G. BLOXAM presumed that the 27.7 soluble in Mr. Hughes' table represented that percentage of tricalcium phosphate rendered soluble. Mr. Hughes treated the same sample of superphosphate with lime, and found 94 per cent. soluble in citric acid. Did he mean to say that the calcium sulphate and all dissolved up? If so, the comparison appeared to the speaker to be valueless. Then, with regard to that same determination, the sample mixed with lime was washed with water and citric acid, the soluble matter weighed, and the residue ignited and weighed; the whole then added up to 100. Was that so?

Mr. HUGHES replied that it was so.

Mr. D. A. LOUIS said it might interest the meeting to hear the views of one who had not had the advantage of being in the late Dr. Voelcker's laboratory. Some years ago, however, he had been in the laboratory at Rothamsted and he remembered the position taken up by Dr. Augustus Voelcker, Sir John Lowes, and Sir Henry Gilbert in connection with basic slag. They all persistently set their faces against it, considered it absolutely valueless, and even refused for some time to experiment with it. It was thought to contain deleterious ingredients, and the phosphoric acid to be in an unsuitable condition, and that it could be valuable as a plant food seemed to them an impossibility. He remembered discussing the subject with Dr. John Voelcker some years ago, who, too, considered it quite worthless. In course of time, however, all these gentlemen came to recognise basic slag as an important manurial agent. That fact showed the position that some of our dear old agricultural friends were liable to take up when anything novel was presented to them, although

one would think it would be wiser to suspend judgment until experimental evidence was forthcoming. By Mr. Hughes' suggestion it seemed that a factor which rendered superphosphates unsuitable for certain soils was removed in a very simple manner, and at the same time yielded a mixture in a convenient form for use on the farm, which, moreover, on the face of it, might prove of high manurial value; but, of course, this point could only be decided by trustworthy experiments, to which the speaker, amongst others, would look forward with interest. As chemists, of course, they must all admit that in these mixtures they had sulphuric acid, phosphoric acid and lime, and these bodies had always been the constituents of such artificial manures from the beginning. When Mr. Hughes told him of his invention, it struck him that the proposal was somewhat retrogressive, and he suggested that to him; and further, that on putting lime into the manure the phosphoric acid would possibly assume a reverted condition, that was, go back to tribasic phosphate. However, in practice things did not always happen as we expected them to happen, and so perhaps in this case the expected might not happen. He would like to ask Mr. Hughes how long the mixture given on the table had been prepared, so as to yield 66.8 of soluble matter, inasmuch as if it consisted of phosphate, it would at once put out of court Dr. Dyer's argument, as there was no dibasic phosphate that would give that solubility in water.

Mr. HUGHES: Table III. represents the portion soluble in water. The whole of the phosphates were rendered insoluble in water, and therefore it did not appear on the table.

Mr. Louis, continuing, said, if that were the case, Dr. Dyer's contention might be right. Then there was the other point mentioned by Mr. Lloyd, and admitted by all who knew, that without any doubt it was valuable to add lime in some soils; and, as Dr. Voelcker held, the farmer might be free to buy the lime and phosphate separately and mix them himself; but the farmer would not do that; he liked things made easy for him, and liked to buy his materials ready for use as "wheat manure," "barley manure," and so forth. The farmer, for want of means, would not put lime on his soil, but he knew that he must put some phosphate; and if he could conveniently buy the lime at a moderate price along with the phosphate, he would very likely do so, especially if he got it in a form convenient for handling, and could by one sowing and one expenditure introduce two valuable factors into his soil. He was sorry to learn from the author that the 63.8 was not the material one would have liked to see soluble and suitable for plant food, though it might prove suitable for Mr. Lloyd's bacteria, and probably do good in that way.

Note.—At the time of speaking Mr. Louis was not aware of the fact that excess of lime was employed in Mr. Hughes' mixture.

The CHAIRMAN had no wish to stand as umpire between two contending parties. No doubt each of these materials had its value in the right place, and each of them was useless in the wrong place. If Mr. Hughes's mixture could be made at such a price as to be as cheap as other phosphates, he thought it had a considerable future before it. But when he considered that first in the making of the superphosphate the original raw phosphate got diluted by sulphuric acid, and then still further diluted by the addition of lime, the net result was a mixture containing only a fraction of the tribasic calcium phosphate present in the raw material; and it was difficult to see how such a mixture could compete with a material like Thomas slag, which had not to undergo those processes of dilution. Assuming that the material of Mr. Hughes was more soluble and more available than soluble Thomas meal, the question was, how could such a material, which had to stand the cost of grinding, treatment with sulphu-

ric acid, lime, and carriage on a reduced percentage of phosphoric acid, hope to compete with basic slag? If, however, Mr. Hughes could give satisfactory assurances on that point he had rendered a service to agriculture.

Mr. RUFFLE said that Dr. Voelcker had referred to the precipitated phosphate made on the Rhine, and had questioned whether Mr. Hughes' material would be able to compete with it. Was that precipitated phosphate hydrated? He believed it was a very rich tricalcic phosphate, but not hydrated. Mr. Hughes' proposal really was to take the hydrated P_2O_5 in the superphosphate; to that he added hydrated lime, and thus got a hydrated compound of phosphoric acid and lime. Would not that hydration give it such a start of superiority that it would answer where the precipitated phosphate would not?

The CHAIRMAN: Does Mr. Ruffle assume that a different compound would be obtained by adding calcium hydroxide instead of calcium oxide? Is there any chemical evidence to that effect? No matter what form the lime may be in, the same product would probably result.

Mr. RUFFLE said he thought one would get Mr. Hughes's compound by putting 15 to 20 per cent. of hydrated lime. One would want more than that to form a tricalcic phosphate; but by adding 17 per cent. one got a phosphate which had some water and some lime. In fact, Hughes produces an alkaline hydrated dicalcium phosphate in the superphosphate (P_2O_5 , CaO , H_2O), plus a slight excess of $CaO \cdot 2H_2O$ for alkalinity.

Mr. STEWART remarked that if one added calcium oxide there was a danger of forming pyrophosphate of lime. Did Mr. Hughes confine himself to producing dibasic phosphate? Was there just sufficient lime to form two of CaO to one of PO_5 ?

Mr. HUGHES, in reply, said he was pleased to find that he had very little to answer. Dr. Voelcker had suggested that farmers would add lime to superphosphate themselves. They were quite welcome to do so, for it would increase the sale of superphosphate; but they would find a difficulty in preparing a perfectly uniform mixture. Further, it was a fact that in those parts of the country where lime did not occur in sufficient quantity in the soil, the farmer would have to purchase it from a distance and at considerable cost; therefore the application of lime where it was most required was generally neglected. Moreover, instead of purchasing superphosphate and lime separately, the farmer could purchase basic super, and so supply both available phosphates and lime at one dressing. With regard to precipitated phosphate, which had been referred to, it was well known that it was an expensive material, prepared by a wet process, whereas basic super was a comparatively cheap material prepared as a *dry* mixing, so that any manufacturer could make it; consequently there was no fear of competition with precipitated phosphate. Bearing in mind the opposition that basic slag had originally met with at the hands of scientific men, and knowing the immense quantities of it that were now used, he took encouragement that, even if his material met with similar opposition now, he felt confident that the practical results in the field would be satisfactory.

Dr. VOELCKER, interposing, said he thought it ought in justice to be pointed out that basic slag as it was known now was a very different body from the slag that was first introduced, and the results now obtained could not have been obtained by the material then condemned and rightly condemned.

Mr. HUGHES, resuming, said that the only improvement that had taken place in the quality of slag was due to improved grinding; and he would like to refer to Table I., in which the Peace River phosphate, with a grinding of 93.61 fineness, actually showed a greater amount of phosphate of lime dissolved by the weak solution of citric acid than was shown by the basic slag, the figures being 21.61 as against 18.99. He ventured to think that

had the Aberdeenshire experiments been carried out more extensively in this country the actual value of finely ground raw phosphates would have been demonstrated long ago. Basic slag being, however, introduced just when these experiments in the north had terminated, attention was naturally concentrated upon it, especially as the cost was then so low, and it naturally became the favoured material for field experiments, with increasing success; though, as will be seen from Table I., its solubility was greatly inferior to that of basic super.

Dr. DYER: But the solubility of basic slag in a stronger solution, such as 1 per cent, was much greater than that referred to in Table I.

Mr. HUGHES, continuing, said no doubt a 1 in 100 solution, would dissolve out more than his weaker solution, 1 to 1,000; but the relative solubility was still against basic slag and in favour of basic super, as the following figures clearly indicated:—

Comparison of Solubility.

1 grm. of each of these materials was treated respectively with 200 c.c. of 1 per cent. solution of citric acid, 400 c.c. of 0.5 per cent., 1,000 c.c. of 0.1 per cent., and 2,000 c.c. of 0.05 per cent.; allowed to stand 24 hours, with occasional stirring.

	Basic Super.	Basic Slag.
Portion soluble in 200 c.c. 1 per cent. .	94.70	64.70
" " 40 " 0.5 " ..	95.30	54.50
" " 1,000 " 0.1 " ...	95.70	33.30
" " 2,000 " 0.05 " ...	92.40	30.30

It would be seen that, while the solubility of the basic super remained practically constant up to a dilution of only one part of citric acid in 2,000 parts cold water, the solubility of the basic slag declined with the dilution enormously. He could not agree with Dr. Dyer's suggestion that perhaps it would be more economical to use ground phosphate instead of slaked lime. The lime was hydrated and in a very soluble form, whereas the raw ground phosphate would be coarse or fine according to the grinding, and the action of the acid in the superphosphate would be directed rather upon the carbonate of lime than upon the phosphate of lime. In conclusion he would say that the new manure must stand upon its own merits; and it only remained for him to thank those gentlemen who had supported him in expressing their opinion that the manure would prove useful. Experience had shown that basic slag was a very valuable manure, and if his manure was still more soluble and rapidly available, as was indicated by its much greater solubility in the particularly weak solution of citric acid (1 in 1,000), he had every reason to hope that the field experiments would prove it to be a quick-acting and reliable manure, which was just what the farmer wanted.—*Journal of the Society of Chemical Industry.*

To encourage the oil seed industry the Department gave a bonus of £2 per acre to farmers to cultivate the seed for three years, and extracted the oil for them at a nominal cost, refining and packing the oil ready for the market.

If the Ceylon Government would do likewise, the planters would only be too glad to try some new industry to help them over the present very hard time.

Sunflower seed: 8 lbs. of seed per acre is enough to plant, the oil cake is excellent as a food for horses, cattle, pigs, &c., and is worth about £6 per ton for feeding purposes.

The best to grow for oil is the small black variety (*grandiflora*) as it yields the larger percentage of oil, 20 to 25 per cent of good oil, almost equal to the best olive oil; it is a first class table oil and there is always a good market for it if properly refined. When in Colombo I could let you see samples of the above oils if you care to inspect them. I hope to be down in a week or so.

Since writing the above, I see another correspondent asks information about the castor oil plant. There are two kinds of this seed that I have manufactured into oil, the large and small variety. The small is the best, as it contains from 40 to 42 per cent. oil; the price of the seed varies from R5 to R6 per cwt. It can be obtained in Bombay, and is grown in the Gujarat district; castor cake is worth from R40 to R50 per ton, and it is an excellent manure, as it contains a large percentage of nitrogen. It should find a ready market in Ceylon.

For "Palma Christi's" information:—

(1) In my opinion it is better to put in seed say 3' x 3"—two seeds in a hole about 2.

(2) Bombay, that which is grown in Gujarat district is the best.

(3) After the seed is ripe enough, it is cut off in clusters, allowed to dry and then trampled on by bullocks, same as puddy, then collected and cleaned.

(4) About 40 bushels per acre, or more on good soil.

(5) There is a good market both in England and France for good castor seed, also oil; seed is worth say in Colombo from R5 to R6 per cwt. Castor cake should bring at least R40 to R50 per ton.

(6) By hydraulic pressure, a small plant could be got for £500 or 600, but this would depend on what power could be got on owner's property.

(7) In my opinion plants grown as an annual give best value. After seed is sown, there is little or no attention required until seed is ready for plucking.

(8) The plants would certainly crop best grown alone.

When in Colombo I could give you more information than by writing, such as cost of machinery, refining oil, &c.—Yours, &c.,

E. WILSON,

Engineer, Finlay Muir & Co.

Katugastota Estate, Katugastota, August 10th.—
"Local Times."

CULTIVATION OF SEEDS FOR OIL AND CAKE EXTRACTION.

SUNFLOWER AND CASTOR OIL PLANT.

SR.—Seeing that there are some planters thinking of going in for the cultivation of sunflower seed (for oil extraction), I thought it might not be out of place to give a few particulars with reference to the growing and treatment of the seed to be converted into oil.

I think a valuable vegetable oil industry might be carried on in Ceylon if the planters would go in for the cultivation of the various kinds of oil plants, such as castor oil, sunflower seed, pea nuts, mustard, cotton seed, gingelly, and even olives, I think, might be grown to advantage.

I have extracted a very large quantity of oil from the above variety of seeds, grown in Victoria by the Department of Agriculture, in whose services I was for several years as manager of the department's mills,

WEEDS.—On new and unexhausted lands the bad effects of weed growth are doubtless due fully as much to the waste of moisture going on through their leaves as to the competition with the crop for plant-food. Hence all good orchardists are very careful about keeping their ground clear in summer; but it must not be forgotten that by doing so they quickly deplete their lands of vegetable matter which requires systematic replacement by green manuring if production is to continue normally, yet of the two evils, the loss of moisture is more to be dreaded, and very generally in practice the more difficult to remedy.—PROFESSOR HILGARD. Weeds in a dry country waste enormous quantities of soil moisture, each pound of weeds reducing the growth of corn by two pounds. Clean farming conserves moisture for the useful plants and useful plants produce more bulk as well as more value from a given amount if available moisture.—W. M. HAYS, Minnesota. Agricultural Experiment Station.—*Agricultural Gazette of N. S. Wales.*

*Containing nitrogen N 0.137 0.100 0.504

Thus of the more important ingredients of the soil 1,000 nuts remove the following:—

	IN LBS.				HUSK, SHELL, KERNEL, MILK.				TOTAL LBS.				
Nitrogen N	3.7017	0.5460	4.4100	...	8.6577								
Phosphoric acid P O	0.8456	0.0735	1.4053	0.1279	2.4523								
Potash K ₂ O	13.5235	0.7127	3.7362	0.7783	18.7527								
Lime Ca O	1.8234	0.0991	0.2143	0.1674	2.3042								
Sodium chloride Na CL	20.2375	0.2464	0.3563	0.5431	21.4233								

It will be seen that sodium chloride is found in the Coco-nut at 21 lb. to 1,000 nuts, and shows therefore that common salt should enter largely into all manurial material applied to this tree. One of the best and cheapest methods of applying this is to use the waste pickle of the salt provision stores, such as that from herring and pork barrels, &c. Other constituents should be supplied in a suitable manner, or in a form that comes cheapest. Chemists tell us, however, that we should not depend upon a single analysis, which is undoubtedly true, and therefore growers should know whether nuts of Trinidad, nuts of Tobago, nuts of Grenada, &c., &c., would give the same results in the Laboratory as those obtained in Ceylon. It is reputed that the water or milk of the Coco-nut is a powerful diuretic, but to which of its constituents this property is due is not stated.

It is clear from the analysis that it is not sufficient merely to bury the nut in earth or sea sand to succeed in raising fig trees, but that such cultivation requires considerable attention, and the trees are benefitted, like all other plants, by the application of suitable manures when necessary. The want of such applications, where the plant food is deficient, undoubtedly leads to ill-health and subsequent insect attack.

The question of vitality in plants is not generally well understood, but it means everything to the cultivator. The Pine Apple in the English hot-house is ruined by an attack of mealy-bug—but growing in the open under natural conditions and with all its requirements at command, the Pine Apple laughs at and despises the attack of this insect. Some stools of seedling sugar cane succumb to the attack of fungus and insect pests, while growing under exactly the same conditions as to culture, soil, and general attention, as their untouched stronger brothers (i.e.) their vitality is low and their constitution weak, which renders them unable to survive. This vitality is also seen in fields newly planted, among cane

cuttings planted on the same day on the same lands and under exactly the same conditions. One row will have but very few misses, while another variety will require supplying to the extent of 40 or 50 per cent. In some cases this is due, as is well known, to the condition of the cane; for joints or tops containing a large amount of glucose are much quicker in developing growth than the hard or ripened joints which contain a major portion of sucrose. It may be argued that plants, if well cultivated, can have no weakness of constitution; but nevertheless, it can be shown in hundreds of instances that, where plants are exotics, it is a difficult matter to get them to thrive; and their adaptability for culture often depends upon their power of becoming acclimatised (i.e.) acquiring a strong constitution. Some plants never appear to acclimatise, and others are apparently ubiquitous and appear to adapt themselves to change of climate with greatest facility. From those facts it is fairly clear that the constitution plants possess is affected and also weakened or strengthened by several conditions.

1st, by inheritance; 2nd, by temperature; 3rd, by humidity; 4th, by want of nutriment; 5th, by unsuitable lands; and 6th, by persistent attacks of fungoid or insect pests. So far as it is yet known, the best course to be followed, instead of using the nostrums often advocated, is to secure by hybridization and seminal selection, varieties possessing a vitality and strength of constitution which will enable them to overcome attacks of fungoid or insect enemies. It is of course admitted that the application of insecticides is often of the greatest service when the plant suffers from special invasions not due to want of cultivation, plant food, or lessened vitality, but the cultivator should be careful in discriminating between attacks caused by these wants, and attacks having a special character or cause. In the latter, insecticide can be used with advantage—in the former, even endless repetition of their use will not render them effective.—*Trinidad Bulletin.*

FIG GROWING IN SMYRNA,

In his report on the trade of Smyrna, Mr. Vice-Consul Hampson gives some information as to the cultivation of figs in Smyrna. He says that the fig district lies almost entirely along the Smyrna-Ardin Railway, the best quality of fruit called "erbeilli" coming from Inovasi, while those from Nasil and Sntlan Hissar are also much valued, though their skins are thicker and lighter. There are two kinds of figs, both from the same tree: those for eating and those for distilling purposes (hurdas). The fruit of trees growing on the plains is larger and richer in saccharine matter: but, on the other hand, the trees in the plains often suffer from excess of moisture in a wet season, which those on higher ground escape owing to facilities for draining. The trees begin to bear in their sixth year, and are in full vigour in their 15th year. The fruit ripens about the middle of August, when it is picked and dried in the open air for from three to six days. It is then packed in sacks of about 250lb. each, two of which constitute a load for each camel, by which means figs are carried to the nearest station to be conveyed by train to Caravan Bridge, Smyrna. Thence the sacks are again conveyed by camels to the depots of the purchasers. An attempt was made to employ carts (arabias) in the place of camels, but it was found that the fruit was damaged if the sacks were piled one on the other. The arrival of the camel load of figs in Smyrna each season is celebrated as a popular festival, as the washing, drying and packing of the fruit gives employment to thousands of families. The sale of dried figs for food takes place from the end of August till the beginning of November, after which the sales are almost entirely of "hurdas" (figs for distilling.) A certain quantity of these latter are also sent to Austria-Hungary, where they are used as a substitute for chicory.

PRUNING FRUIT TREES.

The general principles of pruning have already been discussed in the previous issue of the *Journal of the Department of Agriculture*, and to these the reader must be referred. Several of the most approved methods of vine pruning have also been reviewed and illustrated by means of diagrams in the same publication. In this chapter the shaping and the pruning of the several varieties of those temperate climate fruit trees grown in our orchards will be more particularly referred to.

GENERAL PRINCIPLES.

There are a few rules, however, which are applicable in every circumstance, and which should be borne in mind whatever the system of training or the kind of tree to be pruned may be. Thus, when pruning, cut off all dead wood; also one of any two branches which may happen to cross and rub against each other, thus chafing the bark and injuring the limb. Suppress water shoots and suckers. When cutting to a bud do not leave a stump above the bud; but on the other hand do not cut the wood off too close to that bud. When compelled to cut large limbs, pare off the wound with a sharp knife, and cover the wound with some dressing, such as already recommended in the previous chapter on pruning (p. 316), or even with clay, which, while preventing the air and the dampness from drying and rotting the wood, will not prevent the young bark overgrowing the wound and gradually healing it. Before cutting the limb off try to see what the result of your action is likely to be a few years hence, and thus save at an early stage the possible necessity of having to cut large limbs at some future period.

Should it be found necessary to cut a large limb, saw it a short distance from the bottom first. Then saw down from above, and the limb can be removed without fear of splitting off below. Under the climatic conditions which prevail here, it is better to err on the side of cutting hard back, so as to keep the tree low, than on the side of sparing the tree the first year of its growth, and letting it run up a high stem, topped with long lanky branches.

SYSTEMS OF TRAINING AND SHAPING FRUIT TREES.

Climatic conditions to a great extent influence the methods of training trees. Thus in colder climates they often trained *Cordon* fashion, or in *Espaliers*. Then again the *Pyramid* shape was for a long time a favorite in warmer climates, until the *Low Standard* or *Vase* system supplanted it.

This latter method of training fruit trees has been found by long experience to be the form best suited to the Australian climate; it is also the one best adapted to Californian conditions. Unlike the *pyramid* shape, which has the cone pointing upwards, the *vase*, *goblet* or *wine-glass* form, as it is at times

called, rests on its cone, and directs its branches upwards and outwards.

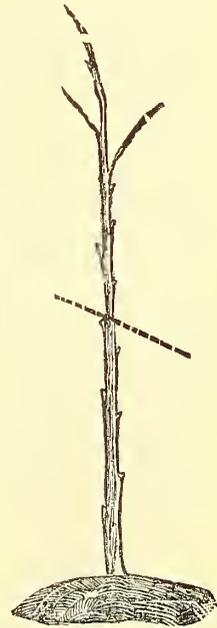

Amongst the advantages it offers it is simple to understand and to master; it is applicable to all kinds of fruit trees; it is suitable to all localities where fruit trees can be grown out in the open without artificial shelter; it forms a vigorous, stocky tree, well balanced, easy to prune, spray and pick; it efficiently shelters the stem against sun scald; it resists the onslaughts of heavy gusts of wind better than the other forms of training; it requires less space than the *pyramid* form; it offers greater facility of approach to the stems by the horses when cultivating.

FIRST PRUNING.

Young budded trees in nursery rows present the first season of their growth the appearance of a straight switch, with good buds all along the stem.

Sometimes they grow so vigorously that they throw out laterals. Both such young trees are found in nurseries. As their customers like to see as much growth as possible, nurserymen generally send out their trees without cutting them back.

Experienced orchard owners generally prefer, when ordering from the nursery, one year old trees, which are merely straight switches with good buds all along the stem. These they can cut back to the height they prefer, with a length of stem pretty well uniformly the same all through the orchard. If they plant trees with a head ready formed in the nursery they cut it short back on the laterals. Those who, on the other hand, have little or no experience of fruit growing, would do wisely to select from the nursery trees with their heads ready formed. When cutting back, especially in the warmer and drier localities, a stem, 12 to 18 inches high, will be found the best. In the cooler districts it can be given a height of 18 to 24 inches. Cut back to a good bud, care having been taken that the tree has not been planted too deeply, but

WITHOUT BRANCHES.

The cross line shows where to cut back when planting.—BARRY.

that its collar, or point of junction between the roots and the stem, be as nearly as possible flush with the surface of the ground. If the tree has suffered much, and the buds are very small, the bark leathery and wrinkled, the stem somewhat dried and the roots much injured, it is advisable to cut the stem lower still, say at a height of about 9 inches from the ground, or even lower, but in every case above the graft. In such cases, however, the proper height should be given to the stem, either by pinching the straight shoot which will grow from it, as soon as it reaches that desired height, or by cutting it back later on at the time of winter pruning. From stem topped to a height of 15 to 18

inches, several short shoots will be sent up from the upper buds; of these three or four of the best shoots, placed symmetrically round the stem, are allowed to grow, all superfluous vegetation being rubbed off. These three or four shoots, which will form the main limbs of the tree, should be placed in such a manner that they form a well-balanced head, and do not all come out together, but spring out of the stem with an interval of an inch or two between them. This knits them better to the trunk, and they are thus less liable to split, as they sometimes do in windy weather, when grown in forks and laden with fruit. The apricot more especially, with buds very close together, has a tendency to grow its limbs all in a bunch.

Three limbs growing symmetrically round the stem are better than four. During the first season, these three or four shoots are left to grow without interference, so as to favor as good a root system as possible. Should one of the rods, however, grow with such exuberant vigor that it draws all the sap for its own use, to the detriment of the other two or three, it would be advisable to pinch it off and check it, so as to maintain a fairly equal growth of the head. A tree is very easily thrown off its balance at this stage of its growth, and unless properly trained and watched it might be difficult subsequently to re-establish the harmony of growth between the main branches that constitute the head.

SECOND PRUNING.

During the summer following the first pruning, the young tree should be allowed to grow unchecked, so as to ensure a good root development. Some young trees, however, at times persist in sending up one solitary shoot. Should this be the case, the tender growth is pinched back when it has reached a length of five or six inches, and this will excite the bud immediately underneath into life, with the result that the three or four limbs required to form a well-balanced head will be secured.

The reverse at other times happens, the young trees sending up a bunch of shoots of such vigorous and luxuriant shoots that there is danger of the stems splitting. To guard against this, it is in such case also, although for a different purpose, advisable to take in the sails, and relieve the plant of any excess of shoots, or of its threatening top weight.

During the first winter following the planting of a young tree, the three shoots, or may be the four, which constitute its head, are shortened to four to ten inches, according as to whether these shoots are feeble, or strong and vigorous. Fruit-growers often get their trees from the nursery at this stage of their growth, and the accompanying figure illustrates their shape after pruning. This operation excites the somewhat dormant buds at the base of the shoot into active life. As previously said, the terminal bud should be a plump and healthy one. It should be directed either upwards, downwards, or sideways, so as to prolong the growth of branch outwards or inwards, or towards a lateral blank space.

The growth of the main shoots is regulated by pinching, and should a third or fourth twig grow amongst them between the forks they are rubbed off. When the tree is ready for pruning a third time it has then, if three main limbs only, six branches, which, at the time of the

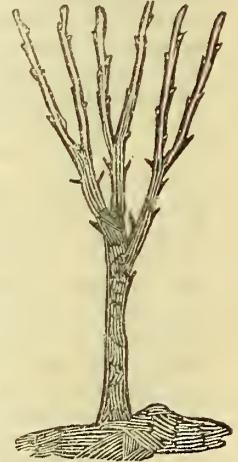

THIRD PRUNING

Are cut back to 6 to 12 inches, according to their strength. Two of the top shoots on each of these branches with an upward direction are left, and the lateral shoots from the other buds on the limbs below are pinched back in the summer time, when they are a few inches long, to four or five leaves.

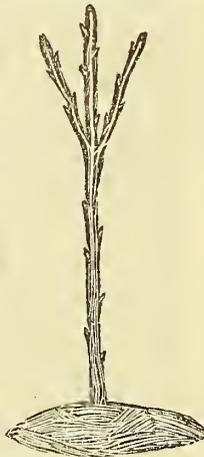

These little tufts of leaves shelter the branches, strengthen them by covering sap into woody tissues, and ultimately develop fruit spurs. Branches which approach the vertical line most are cut shorter than those inclined to an angle, to thus force the buds at the base to grow.

FOURTH PRUNING.

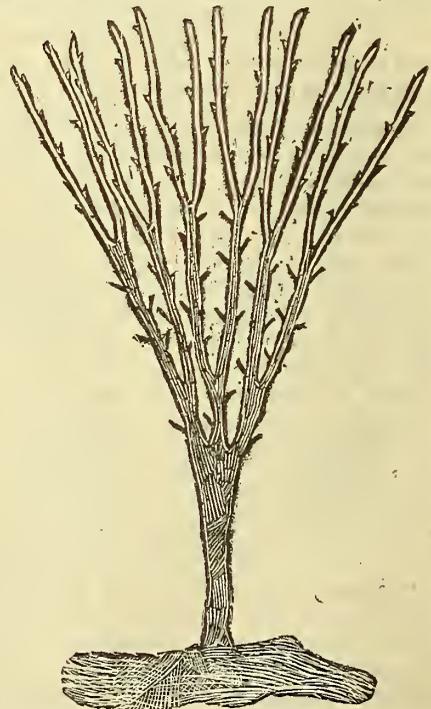

The same treatment described in the case of the first, second and third pruning is applied in the case of the fourth pruning, and generally at this age the tree will begin to bear readily. At this period a stocky, low standard tree will have been formed, which will have a well-balanced head, constituted of branches growing in an upward direction, and carrying fruit spurs all along their length. Such a tree will resist high winds well, can easily be approached by horse and implements, so that comparatively little hand-labour will be required to keep the orchard in a high state of cultivation; the crop will be evenly carried along the main branches, which will not stand in need of artificial props, lest they should break down under the load of fruit which, at this

Winter Pruning of a tree three years from the bud.—BARRY.

Pruning of a two-year-old tree from the bud.—BARRY.

Young standard tree, four years from the bud, after pruning.—BARRY.

early stage, they will begin to carry. The pinching of the superabundant laterals is best done in the early autumn, when buds, which would otherwise have remained sterile, are transformed into fruit buds. This operation will besides save much butchering in the winter time, as, by suppressing either entirely or partly an undesirable shoot at an early stage, much sap, which would be turned into wood growth, destined to be cut off in the winter, is saved, and the energy and the vitality of the plant thrown into more useful channels. This practice leads to the enunciation of the fact that severe winter pruning induces wood growth, while summer pruning tends to fruit production. Thus, if a tree is stunted, and for some obscure reason does not make much wood, but shows a tendency to produce more fruit buds than it can safely carry, prune close in the winter; if, on the other hand, a tree grows so quickly that all its energy is wasted in wood and leaves, and does not pause to produce fruit, either summer pruning or root pruning will throw it into bearing. By such means the plant realising, while in full flow of sap, that its constitution has been attacked and its life menaced, will make an effort to reproduce its kind forthwith and the result will be the evolution of leaf buds into fruit-bearing spurs. Subsequent prunings consist mostly in rubbing off water shoots, in suppressing branches that cross and rub against one another, and trimming the twigs and the fresh growth made during the season's growth. As this stage the tree will have ceased making much wood, and will begin the business of setting and carrying fruit.

REDUCTION OF SWELLINGS AND HIDE-BOUND TREES.

At the time of pruning swellings are occasionally noticed on the stems or limbs of trees. These swellings are either due to the disproportionate growth of the scion or fruiting part, compared with the stock or root end of the tree.

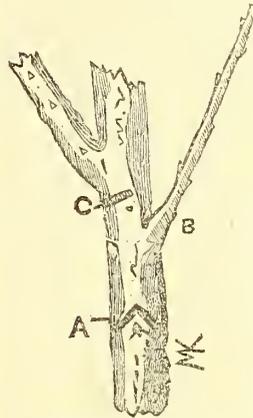

They may also be due to strings used in previous seasons as ties, which have cut through the bark. These swellings, which interfere with the free circulation of the sap, must be reduced. This is best done by running longitudinal incisions from C downwards to the stock B. The bark will thus expand, and, should the deformity continue the next season, these incisions should be renewed.

Trees which have been neglected, or whose growth has been stunted by the presence of moss and lichen, scale insects for other pests, or by want of drainage of the soil, by the aridity and poverty of the ground, or are debilitated in consequence of having been allowed to bear too early, often show a miserable, sickly appearance. Their growth is stopped, the bark becomes tough and leathery; they are hide-bound. The cause of the mischief may have already been removed, and still they will make no growth.

Such trees should be similarly treated at the time of pruning. They should be cut hard back and at pruning time the knife should be run longitudinally through the bark, from the beel to the top of the stem, and even along the main limbs. It is also advisable to whitewash the stems of such trees. Lime, in the shape of whitewash, is well known to be beneficial in most bark diseases.

Under this treatment the stunted trees of last season are seen to spring into fresh and healthier growth. The cambium or growing wood layers force the strip of leathery bark apart, the stems and limbs are soon seen to swell, the sap runs freely from the roots to the top branches of the plant and the whole growth looks healthier.

INCISIONS TO CONTROL THE GROWTH OF SHOOTS AND BUDS.

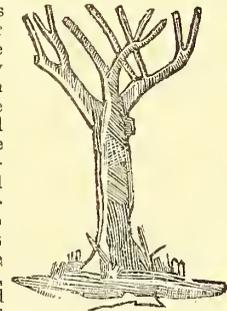

INCISIONS.—DU BRENIL.

Should, during the preceding growing season, any one of the lateral branches have been imperfectly developed, it should be cut back lightly when pruning, and, if it is much too small compared with the others, it is sometimes advisable to make immediately above the point of attachment to the branch (B) a notch or small incision through the outside layers of growing wood, so as to force the sap to run up the branch and develop it. The cut should be prevented from healing too rapidly. It is also sometimes desirable for the symmetry of the tree to force a dormant bud into growth, and in that case an incision as shown at A will be found useful. On the other hand, should a strong branch become uncontrollable in spite of heading back, it may, in extreme cases, be advisable to check the flow of sap towards it by making an incision as shown at C, immediately below its point of attachment to the stem.

Thus we have a means of transforming wood bud into a fruit bud and vice versa, by making a cut below the rudimentary bud if we want a fruit bud, or above if it we want a wood bud. These methods should, however, be only used with discrimination, else more harm than good will ensue.

RENOVATING OLD TREES.

Fruit trees, planted in good soil and possessed of a good stem, are susceptible of living to a great age. It, however, often happens that through years of neglect their branches have grown to excessive length and are, to a great extent, deprived of fruit shoots, or that the crop is carried up too high, hence adding considerably to cost of gathering; or again the trees are diseased, and in order to successfully combat the pests which infect them they must be shortened in. Again the variety of fruit the tree bears may be unsuitable, and it may be expedient to change the variety by means of budding or of grafting. In all these cases it may be desirable, or even imperative, to shorten the tree and head it back. For that purpose the saw is called into requisition, and the cuts smoothly pared with a sharp knife, the wound being then smeared with clay, or with the shellac paint, or some of the other paint already referred to.

Top of an old plum tree headed back for the purpose of renovating.

The figure illustrates an old plum tree which has thus been renovated. The plum, better than most other fruit trees, stands cutting back hard to old wood without showing symptoms of dying back, which, under similar conditions, are often shown by apples and more particularly peaches and nectarines.

Early in the spring, the roots of the tree, which may be good for many years more, become active, the sap commences to move upwards and a number of hidden and dormant buds are excited into life. Shoots burst out of the old stumps and as they grow they should be thinned out to the number of three or four only, well placed and likely to form a

Incisions to reduce the swelling of the graft or the stem.

symmetrical head. Should these few shoots, which are destined to serve as main limbs, grow too rankly, they may be pinched or cut back during the summer and laterals will grow on the tree, which will be shortened at the time of winter pruning. Should, however, these shoots show only a moderate growth, they are better left alone until the pruning season, when they are cut back and treated as directed under the heading "First and Second Pruning."

Except in the case of plum trees referred to already, it is inadvisable to cut back trees in the process of renovation to blind stumps, but this should always be done just above a young branch or a small shoot, so situated that it can be used for giving start to the fresh growth. Old apple trees, apricots, and especially peaches are at times killed through overlooking this detail. The sap becomes stagnant, a dying-back process sets in, and carries off the limb. Peach trees more particularly must be cut back with judiciousness when it is intended to renovate them, the reason being that fewer buds are found on the old bark of peaches and nectarines than on the old bark of pippins, and what few buds there may be left are less easily thrown into active life again than buds of apple and pear trees. In the case of peach trees, indeed, the basal buds are frequently bloom-buds which blossom and then die off, leaving no wood buds to spring into life at a later period and send up fresh growing shoots.

When renovating trees of the citrus tribe, it is also advisable to cut large limbs above on young, fresh growth, although in their case this is not so essential as in the case of peaches. These trees are fairly well stocked with miniature, dormant buds, which are thrown into life whenever the emergency arises.—*Journal of the Department of Agriculture.*

A FEW NOTES ON CITRUS TREES AND ALSO WORKING OVER WORTHLESS OLD ORANGE AND PEACH TREES,

W. J. ALLEN.

In many of our citrus orchards are frequently found a few or perhaps a good number of trees which do not bear as well as they should, or it may be that the fruit is of such inferior quality as to be of comparatively little value. In such cases it would pay the grower, if the trees are vigorous, to cut them back and graft or bud the new shoots to varieties which have been found thriving and bearing well in the particular district. In California many good old seedling and other orange orchards have been treated in this way and worked largely to the Washington Navel, which is the most popular orange grown there.

While many growers in the Cumberland district might deem it advisable to rework some of their trees, there are but few who would care to bud to the navel, as, up to the present, most of those who have done so have found to their sorrow that the navel orange has proved a shy bearer with them, and consequently these feel disposed to rework such trees with other varieties which bear regular crops of fruit. The grower should be most careful that the buds or scions intended for use are taken from good trees, and not from young immature trees which have not yet justified their existence in the orchard.

In the orchard at the Hawkesbury Agricultural College I have been, and am even now, getting some of our worthless trees worked over to better varieties, and from time to time the Department is importing some of the best Californian varieties. In the accompanying illustrations I have had the artist photograph one specimen of each of the following Mandarins, viz.:—The Emperor, Scarlet, and Thorny—these three being largely grown throughout

our citrus-growing districts. At some future time I hope to have the Beauty of Glen Retreat illustrated. Other illustrations show the progress made from year to year by worthless trees which have been cut back and reworked at the same orchard.

Fig. No. 1 (a) is a typical Emperor Mandarin tree, which is carrying a heavy crop of fruit. Up to the present time it has been found that this is one of the most profitable varieties to grow, and is a good mid-season variety. If held on the trees too long the fruit is likely to become very puffy in many districts. Should the Beauty of Glen Retreat prove to be a constant, heavy bearer it will no doubt supersede this and other varieties.

Fig. No. 1 (b) shows another style of Emperor Mandarin tree, started out nearer the ground and trained to spread wider, and not allowed to grow as high as fig. No. 1. The tree is carrying a very heavy crop of fruit. The fruit is more easily picked from this tree, and the process of fumigating for the destruction of scale is carried out more easily in the case of this tree than in that fig. No. 1.

Fig. No. 2, a Scarlet Mandarin tree, heavily laden with fruit. The tree grows more upright than the Thorny and not so tall as the Emperor. A good cropper, fruit rather large and flat, but inclined to go puffy when kept on the tree any length of time. This variety has not found the same favour with growers as the Thorny and Emperor.

Fig. No. 3 shows the Thorny Mandarin tree. A very heavy cropper. Fruit small and rather flat. One of the best flavoured of all the Mandarins, and very much liked by the public. Ripens about the same time as the other varieties. The tree shown is a typical one, but at the time of photographing it was bending in all directions with the weight of its fruit, which, however, being green, does not show.

Fig. No. 4 shows an orange-tree cut down to force out new shoots preparatory to budding, which method I prefer to grafting. The tree will throw out numerous shoots, but as these grow the surplus ones should be removed, and only a few should be left, and these in positions where the new main limbs are required. If this work is carried on early in the spring there will be some good strong limbs by the fall, ready to receive the buds, which should be inserted about the first week in March, or just sufficiently late that they will not start into growth that autumn, but lie dormant until the following spring, when they will push out and form a very good tree by the next autumn, and in all probability some of them would carry a little fruit the second year.

Fig. No. 5 shows the tree at the time of budding, the buds being inserted at the base of the new growth.

Fig. No. 6 shows a tree after the new buds have made their first year's growth.

Fig. No. 7 is a Washington Navel tree two years after budding. Five fine oranges were picked from it this season, but owing to the visitation of night birds of prey it was thought advisable to pick them before they were coloured, and in consequence they do not show to advantage, as the rind would have been much thinner and the cells finer if the fruit could have been allowed to hang until properly ripe. It will, however, be seen that the size is all that could be desired. Fig. No. 8 shows the fruit before being cut, and fig. No. 9 shows the same orange cut in halves.

Fig. No. 10 shows an assorted row of best varieties of imported orange trees, two years from the dormant bud, and consisting of the following varieties, viz.:—Washington Navel Paper Rind, St. Michael, Mediterranean Sweet, Valencia Late, Egg-shaped St. Michael, and a few other varieties.

Fig. No. 11 shows part of a consignment of orange trees procured from California twelve months ago. All arrived in good condition and are doing well

The trees shown in figures 10 and 11 are worked on orange stocks, as were also the parent trees from which the buds were taken to work these trees, so that when they come into bearing it will give us a good idea as to their suitability for this district. The object in importing these trees was to ascertain which were the best and most profitable varieties to grow in this State, as also to prove whether it is the true Washington or some other variety of navel which has proved such a shy bearer with us.

As there are thousands of peach trees bearing poor fruit in the State, it will be of interest to many to have the reworking of such trees demonstrated. Fig. No. 12 shows a large peach-tree cut back during winter's pruning. If the grower wishes, however, he may leave them until the latter part of August, when they can be cut back and grafts inserted, by splitting the bark down the side, then raising the bark and inserting a scion between the wood and bark. Bind firmly with waxed cloth, and cover the cut with a thin coating of grafting wax. Should any of the grafts miss, buds may be inserted the following February in the new growth. All surplus growth should be rubbed off, leaving young shoots in such positions as are most desirable to start main branches, the latter to have buds inserted in the exact places where main branches are required. It is generally found best to bud on the outside of the tree as that generally gives the tree a good crown, whereas, if the buds are put on the inner side of the branches, the limbs grow towards the centre of the tree, making a very close and undesirable crown.

Fig. No. 13 is the same tree after it has made six months' growth. The buds will be inserted within a few inches of the base of the new growth. The top will be well cut back in the winter at pruning time, and the growth forced into the buds so that they will form a good crown.

Fig. No. 14. A tree which has been cut back and budded—the buds showing the first summer's growth.

Fig. No. 15. The same tree as in fig. 14, two years after budding. It will be seen that this tree had longer arms left on it at time of cutting back than fig. No. 12, and consequently the tree is not nearly so well shaped as it would have been had the main branches been well cut back in the first place.

It will be seen that in treating a tree intended for reworking to better varieties it is best to cut it back to within 6 inches of the trunk rather than to leave arms 2 feet or more in length.—*Agricultural Gazette of N. S. Wales.*

CULTIVATION OF RUBBER TREES,

Some people may be surprised to learn that there is still a raw product that man finds just as difficult to obtain as it was a hundred years ago, and that it is harder to obtain than ever. It is the milk of a very insignificant-looking tree, growing in great quantities over a large tract of territory. The tree itself is generous; liquid follows the incision; a wait of a few hours for the milk to harden and a man has the equivalent of a day's wages. This white liquid, after exposure to heat, and many species to that of the sun alone, and without any further treatment, gives thirty per cent of its bulk in pure rubber. Despite this, the world cannot obtain a tithe of the supply it needs. The simple reason for this state of affairs is that the tree, although generous itself, elects to grow in regions which for the most part are death to white men, and are removed from civilization by thousands of miles of swamp and jungle.

To alter this condition of this two sets of men are working on opposite lines. They are engaged in a sort of race for a very high stake—an unassally

high stake indeed, as the pure rubber is now selling for something more than \$1 a pound. One set are chemists, who have been trying their best for the last twenty-five years to find a substitute for rubber. So far there has not been an unqualified success among their attempts, and there are experts who go so far as to say that chemically it is impossible to combine for the market a substitute having the different properties of pure rubber. Be that as it may, hardly a day passes but the long-expected substitute is brought forward and the company formed to exploit the perfect substitute of the year before goes into the hands of a receiver.

The field of activity of the other set of men is very different. It is found in a few farms in Mexico and Central America, and in a few government stations, notably in Jamaica and Ceylon. There are a small number of farms where something like a systematic attempt is being made to farm rubber on a large scale; some half dozen in the Isthmus to Tehuantepec and a very few more in Nicaragua, Costa Rica and the rest of Central America.

The difficulties which confront this handful of farmers are peculiar. In the first place, no one ever tried before to make rubber grow as a crop for the market. There are no data, no facts of even the simplest kind to tell these men whether their ideas are the right ones. The natives of the country take no interest in this outside their own particular business, and a mau about to establish a plantation has had to start fresh, with his own ideas to guide him! and these latter cannot be said as yet to have become authoritative; for none of the farms are more than six years old, and the trees must be up that time before the question of growing them can be settled. Rubber planting, then, is not only an absolutely untried undertaking, but there has been nothing of tradition or general knowledge of the subject with which to make a start. If rubber were a delicate tree, or difficult to cultivate, the outlook would be disheartening indeed.

Second, the general conditions are against the planter. The nature of the country throws him entirely upon his own resources, and the climate is apt to be enervating, to say the least. Transportation is a great problem. Labour is scarce and not easy to handle, the native peon of Central America being a mixture of childishness and independence, and a hard drinker to boot. Although strong and active as young men, excellent axemen and better with a spade than any other labourers in the world, they become debilitated very early in life. They have no constitution and must be cared for like children. Furthermore, they look to the patron, or owner, for the settlement of every ill, spiritual or temporal. You must keep them sober, get them out of debt, make peace between them and their wives, arrange any infelicities that may occur between them and their neighbours' wives, doctor the whole family and educate the children, if you have time. For the peon is essentially a creature formed for the patriarchal system. With a chief or employer whom they know or respect the better class of peons become in many essentials ideal labourers—steady, careful, hard-working, quick to catch an idea, faithful to follow it out, entirely honest; their employer's interests become their own. But in order to obtain this desirable state of things a farmer should be a first-rate judge of capacity and character, a fair lawyer, physician and man of business.

A third problem before the farmer of rubber is where to plant. *Castilloa elastica*, for practical purposes the only rubber in Central America, has an extremely varied habitat. It is found at all elevations up to 2,000 feet and in a great variety of soils and locations, with a consequent variation of rainfall. So, here, again, the farmer must make a choice, and one upon which his success will probably depend, with nothing to guide him in the making. As regards location, it is conceded that *Castilloa* needs a tropical climate, a rainfall that

can be depended upon, a good drainage, and an elevation of less than 1,500 feet, but these conditions have great latitude of choice.

The most important of the questions relative to the method of planting rubber is the one about which the farmers are most divided, and is probably the most vital connected with its cultivation. It is the question whether to plant in groves, in the open, or under forest shade. The advocate of the former system says that in any other part of the world, if one wants to get a particular crop, it is customary to give the tree or plant all the chance possible. One clears the ground, turns it up, and after the tree is planted keeps all weeds from encroaching upon its light and food space. Why not apply these elementary principles to rubber and plant in plowed and open land, in groves, like an apple orchard?

The advocate of the forestry system points, however, to the manner in which the tree grows naturally and says that rubber is found thriving best under shade, in a cool, wet spot, and by "thriving" he says he means gives the most rubber. The tree will grow, it is quite true, faster in the open than in the forest, and you will get your groves of rubber trees more quickly, but the question is, Will you get the milk from them? For it does seem to be a fact that rubber found in open pastures will not yield so much milk as those trees growing in the forest, where it is cooler and moister. If it could be ascertained exactly what function the milk of the tree performed, one would probably be able to tell how much sun and how much rain would produce the tree with the largest quantity of rubber. The milk is not a sap, but a latex, which is carried just under the outer bark, and the slightest nick from a pen-knife will be followed by a thick liquid, which if caught on the finger dries at once, leaving a shred or two of pure rubber, like small elastic bands.

There are farms established by exponents of each theory. One can see in Mexico rows of young trees in open cleared land, in every respect like a coffee or orange plantation; and again in Costa Rica the farm consists of rubber trees planted in among the forest trees, only cleared where the growth is very thick, though of course the bush is kept down by cutting twice a year. Those who are following these two theories will be relieved when they get their first crop. But at present they are having rather an anxious time of it, for on the one hand it will be expensive business, not to say impossible, to plant shade among those trees in the open, and the rubber may be ruined before the shade comes up. But this course would be imperative should the advocates of the orchard theory find themselves in the wrong. On the other hand, should the forestry people be at fault, it will require considerable skill for the owner of the rubber growing in the forest to cut out the trees and let in the sun without injuring the rubber. Ringing trees at the right phases of the moon, some eminent scientists to the contrary notwithstanding, will go far toward solving the problem for the grower of rubber in the forest and make his position the stronger of the two, on the whole, in that he runs the lesser risk, as it is easier to cut out the shade than to put it back.

As for the rubber planter's profits nothing definite can be said about them as yet. A man might buy a thousand acres of good rubber land for \$5,000, and he might plant it and bring it to production for \$45,000 more—\$50,000 in all. But now as to the returns, it is like figuring on the chicken industry; one becomes alarmed at the rate chickens, eggs and profits pile up. In the same way it is estimated that rubber will produce a handsome return every year at the end of the sixth year from planting. Anyone can work out for himself the following sum in multiplication for the profits of the eighth year: One thousand acres with 200 trees to the acre, one pound of rubber to the tree each year, sold at a net profit of 50 cents a pound.—*Agricultural Gazette*.

VANILLA CULTIVATION.

To judge by occasional notes, which appear in our planting journals, this product appears to be having its full share of attention at the hands of those planters who are on the alert for anything in the shape of a profitable auxiliary to the main crop they may be growing. In certain planting districts it is being propagated year by year with the view of raising a sufficient number of plants to form a plantation of an acre or so, in order that a regular squad of people may be told off specially to look after the plants. This is absolutely necessary, and is the right way to go about the matter,—where there are only a few plants scattered here and there about a compound, they cannot get that special attention which is necessary to forming an opinion as to whether the raising of them on a larger scale will be a profitable undertaking. Of course there is always the probability of over-production, and this ought to be steadily kept in view, and nothing but the very best quality of pods put upon the market. If we may take South Sylhet, for instance, which, by the way, we are inclined to place in the very first front rank amongst planting communities, in the matter of the introducing and cultivating of valuable plants from other regions with an analogous climate and habitat, we can see no reason whatever why that district should not make a name for itself for a good quality of vanilla.

The large majority of our planting districts in Assam will grow vanilla. There are a few districts in Upper Assam, which are sometimes too cold and damp during the winter months, and the plants get what is known as "spot." This is not what we should call a disease, but simply a "hurt" caused by water resting upon the leaf when the atmosphere is at a low temperature. The vanilla "plant" will stand a much lower temperature than any we ever get in the valley of Assam, but it will not tolerate dampness as well. Even in the South Sylhet district, where we never get such a degree of cold as is usually experienced in Upper Assam, vanilla will not succeed in a lowly situation where there is sufficient moisture during the dry season to cause a continual raw feeling during the day.

That it grows, flowers, sets and grows pods of a good quality as are produced in the Seychelles Islands has been already proved. The prices have been well maintained for many years past, despite the invention of vanilla (the coal tar product) which has not commended itself as anything likely to be a competitor, where the real vegetable product is to be had. There are lands more suitable for its cultivation than others, but any ordinary forest land with a good surface accumulation of vegetable mould will be found adaptable for the cultivation of vanilla. At the same time, vanilla-growing, being one of the most concentrated of Agri-Horticultural industries, can be grown upon the most barren of lands, in the absence of other unfavourable conditions. The writer is not aware as to what size the vanilla plantations of Reunion and Mauritius run, but we may take it that a 5-acre vanilla garden would be considered a very large "auxiliary" indeed to a 500-acre tea garden. And if 5 acres of first-class forest land could not be had, 5 acres of scrub jungle could very easily be made almost as suitable by carrying fresh jungle soil to plant the vanilla plants in. It would cost no more than it does to make large pits and fill them with fresh soil—a necessary work when filling tea vacancies if any measure of success is to be counted upon. The Mexican system of allowing the vines to grow under trees nearly wild appears to be almost universally adopted now, and is a decided improvement on the old system of training the vine on artificial supports. According to a report on the

vanilla growing in Seychelles nothing pays better than vanilla. Its production costs the planter about Rs. 3 per lb., and as prices vary from Rs. 8 to Rs. 16 per lb., a net profit of from Rs. 5 to Rs. 13 is the result. The average price was Rs. 15 in 1898, and at the present time runs much about the same. The yield may safely be taken to be 200 lbs. an acre according to the report above alluded to. "Taking, therefore, an average of Rs. 10 only, an acre of vanilla should produce Rs. 2,000." Five acres of vanilla at this rate would not come amiss to plenty of large tea concerns, to say nothing of small ones.

It would even pay them to keep a European who thoroughly understood the plant, its growth, fertilisation (which has to be done artificially) and last, but by no means least, the curing, sizing, and packing. The object of this article is not to make planters believe that they have nothing to do but procure vanilla plants, stick them in and wait for the pods to come. We may go the length of asserting that out of every 100 planters who attempted vanilla growing 98 would very probably not succeed. It requires special knowledge all through as to the habits of the plants and its requirements. The curing alone requires considerable study, care and experience. The plant when growing, although preferring to take its own sweet will during its adolescence, is entirely helpless when it comes to maturity. It will keep on growing certainly, but is quite incapable without human aid of reproducing its own species; consequently, if this process is not understood, the growers will have no produce in the shape of the fragrant vanilla pods of commerce.

Whatever may happen in the future the industry is not suffering at present from over-production to the extent of affecting the profitable nature of the industry. In 1898 the vanilla crop of the Seychelles amounted to 63,000 lb., and was sold for Rs. 936,000. It cannot be gainsaid that the large output of vanilla has given a fresh impetus to its cultivators, and large quantities have been planted during the last two years. Still, according to the chemist and druggist, the consumption of vanilla pods is increasing every year and likely to continue to do so far a long time.—"A. P." in *Capital*.

COFFEE CULTIVATION IN BRITISH CENTRAL AFRICA,

To the flowering of coffee the planter looks for a forecast of the season's crop. Naturally one would expect this to be correct, but, for several reasons, it cannot always be depended upon. It is now well known that *Antestia variegata* is responsible for the reduction of both the flower and the berries after they have been formed. Drought was supposed to do considerable damage also, and, in fact, is the reason given for the failure of so much crop. I assumed this as correct, and, by some notes on the subject to the *Central African Times*, I concluded that, with the destruction of *Antestia variegata*, and a system of irrigation, our success in coffee production was assured. Now I must admit I have been misled, and, therefore, made a mistake. My views of the subject now are that irrigation would do very little good, and that it is not the roots that require moisture, but the plant above ground. This drought which we get occasionally is not directly the cause of our failure of crop, or the burnt-up or dead appearance of our plants, but of course it is so indirectly.

From my observations I with no hesitation declare thrips to be almost the sole cause of this damage put down to sun and heat. Damage caused by sun and heat is relatively so immaterial that little account need be taken of it. We have thrips every dry season, and it is only the want of rain or a drought which helps to bring them forth in such

vast numbers. At the beginning of the dry season they are few and far between, but become more conspicuous towards its close. Some time before the wet season commences, I should say, they are found at the very least to average a dozen larvæ to every leaf, and the whole of the underside of that leaf is sucked and discoloured completely. The time when the destruction is disastrous is immediately after the coffee has flowered. Here are tender berries much superior in the estimation of thrips to leaves months old, or leaves that they have been living on and sucked from the under side, giving them the appearance of pieces of brown paper hanging from the branches instead of leaves, and now discarded for berries. Ultimately these leaves fall off, leaving the branch and berries black and dead.

Thrips are first seen as minute red insects generally with a drop of dark fluid or excrement attached to their abdomen; they afterwards change to a lighter green than the colour of the leaf; a few of the imago or perfect insect with wings and dark body are also observed. The elongated abdomen of the larvæ gives them the appearance of minute worms or caterpillars. In fact, there is sometimes seen on the coffee leaves a grub resembling them which is not unlike the larva of a fly. Wherever they are they darken the leaf, tender stem, and berries by their puncture and excrement.

As to the possibility and feasibility of destroying or keeping thrips in check by hand picking in their initial stages, I am not in a position to say at present.

Besides hand-picking we have another alternative; we are aware that some seasons we get a shower every month; those showers and everything else being favourable, we get a good crop; in other seasons these beneficial showers fail to come, and our crop is more or less a failure. Now those monthly showers have been the means of keeping the thrips in check. Likewise the wet season almost completely overwhelms them. From these facts we may conclude that spraying with a syringe or a garden engine is the next best thing, and with the addition of tobacco juice or any other insecticide less spraying may be required.

There can be little doubt as to thrips being indigenous, and possibly new to science. The nearest approach I can get to the species of thrips on coffee, is one found on grass, which may be the same species or quite different. To me it appears smaller or shorter. The result of thrips on grass is that they are accompanied by a fungus. This fungus is red, and can be easily noticed; it is on the under side of the blade, but can be seen from the top, so that grass with thrips can be easily detected. This grass had not been burnt in the previous year with bush fires; on grass that had been burnt, or grass grown from seed, I have not noticed them. The appearance of this fungus in most cases resembles the larvæ of thrips in their red stage.

The next nearest approach to the species found on coffee is one found on a shrub, *Dissotis princeps*, growing in our marshes.

Thrips belong to the Thysanoptera order, and like our plant bugs imbibe the juice of plants by suction. At the recommendation of Dr. Sharp, F.R.S., Cambridge University, I have sent all the specimens of thrips, &c., to Miss Embleton, Balfour Laboratory of the above University, for identification, and any advice which may be of use to us in the matter.

KENNETH J. CAMERON.

Namasi, Feb. 26th, 1901.

SHIKAR AND TRAVEL : ONLY A CUP.

That there was a tigress in the jungles somewhere near my camp I knew, but she could not be persuaded to kill any of the baits that I had had tied up for

her. Her tracks one morning showed that she had gone along a nullah not ten yards from one of the tied-up bullocks, but she had not touched it, and it seemed as if she fed on game only, as no damage to any of the cattle herds in the neighbourhood had been reported. I had quite given up all hope of getting a shot at her, and had, on my last day at the village of A., arranged for coolies to be collected to beat through a hill near my camp which was a sure find for bear if only they could be persuaded to break which was not always the case, as there were so many caves in the hillside, when word was brought that a kill had taken place in a nullah between the bear's hill and my camp. On going to inspect the place where this had happened, I found that the carcass had only been dragged a short way from the nullah into the jungle along its banks, and but little of it had been eaten. The tracks showed that there was a cub with the tigress—a fact of which I had not been aware, and the tracks further showed that after their meal the two animals had separated, the cub remaining in the jungle near by while its mother had returned by the way she had come to the kill. For about two miles we followed her tracks which led us away from the nullah, and then they struck a small village path and we lost them. This was disappointing; but there was the chance that the tigress had gone round by some other way to join its cub, so I gave up all thought of having a bear beat, and instead made arrangements to beat along the foot of the hill on both sides of the nullah for the cub, and, if possible, for its mother too. The spot that I selected for my station was on the side of a small dried-up stream (a tributary in the rainy season of the nullah where the kill had taken place); all around me was grass jungle with scattered trees, and about 400 yards to my left was the bear's hill. Directly behind me, about 600 yards away, was another hill, for which it was anticipated the tigers would make on being disturbed. It was necessary, in such a grass jungle to have a large number of stops, for although the grass was high and thick it was not matted, and a tiger could get through it easily anywhere, so I selected forty of the least stupid-looking from among the coolies assembled and placed twenty on each side of me, those on the left extending up to the foot of the hill. While laying the stops on the left my "shikari" came face to face with the tigress who was sleeping alone—the cub not being with her, at least my "shikari" did not see it—in a small depression at the foot of the hill. Fortunately, on being disturbed, she hounded off into the forest through which the beaters were to pass.

I had waited about two hours in my *machan* before I heard the welcome sound of the beaters advancing and, as I lifted up and cocked my rifle, I scared a covey of bush quail, that had allowed me to watch them feeding among the sal leaves below me and they scurried away across the dry stream and into the grass on my right. Ten minutes later I heard the sound of an animal coming towards me on my right; at first I thought it must be the tigress as it made so much noise among the dry leaves in the nullah, but it was only a four-horned antelope buck that stood and looked at me and offered a most tempting shot at twenty yards which, of course, I did not take. Then after another wait of 10 or 15 minutes, the tiger-cub appeared. It came towards me across the bed of the nullah at a good rate, and I fired, when it was almost below me, between the shoulders, killing it at once.

All this time I was not aware that the tigress was in the beat, as my *shikari* did not tell me till afterwards that he had almost stumbled upon her as he was laying out the stops, and I was consequently very pleased to hear a low growl that could only come from her, soon after I had shot the cub. I heard her moving about the bed of the

nullah, apparently coming and recrossing it, and though I imagine she saw me, I never caught a glimpse of her, until the beaters were nearly up to her, and then she sprang across the nullah and through the grass to my left offering me two snap shots, both of which were unfortunately missed. They were both difficult shots: the first among the trees, and as there was a bend in the nullah when she crossed it, I could not get a clear view of her; and the second, in the long grass. The latter I ought to have made fairly sure of, but as I was on the point of firing I noticed that one of the stops, who was in a low tree to my left and rather below me, was almost in the line of fire, and I had to hold my fire until the tigress got well clear of this line. This delay put me off my shot, and, in all probability, accounted for my miss. After the beaters had come up, and I had searched carefully to see if either of my shots at the tigress had taken effect, I decided on another beat, through the low hill that I have already said was situated behind where I had been stationed. The tigress' track lay straight in this direction, and it appeared as if she must be lying up there; but the beat which was a miserable, uncomfortable one, as a drizzling rain set in while the stops were being placed, proved blank, and we found that the tigress had made for this hill; but instead of ascending it, she had skirted along its foot and gone thence to some thick jungle and hills to the south-west. It was too late then to think of trying to hunt her up there, for I had 8 miles to go to my next camp and the sun was then very near the horizon, so I had to be contented with the cub I had bagged, and leave the mother for some future occasion.

ANTONG, Raipur, C.P.

LONG TOM.

Indian Forester.

GLASGOW EXHIBITION; BLACKMAN EXPORT COMPANY LTD.—The Blackman Company's Exhibit 700 sq. feet is an interesting one. Seventeen of their well-known Blackman Fans are shown in motion, the largest of which, 96 inches in diameter, is driven from the shafting overhead by means of a belt; others varying from 72 " to 12 " in diameter are driven direct by electric current, these Fans being combined with Electric Motors of the Company's own manufacture, especially designed for this class of work. Four of the Fans deliver air, warm or cold at pleasure, from the four sides of the upper part of a central column or Kiosk, which is a prominent feature of the stand. On this stand there is also a Model Drying Installation consisting of a drying compartment arranged in conjunction with a Blackman Electric Fan 24 " in diameter and suitable Radiators for heating the air. The main advantages gained by the Blackman System of drying is that almost every class of material and produce is effectively and rapidly treated with the greatest economy both in cost of drying and in the space occupied by the drying chambers whilst the quality of the material so dried is much superior to that baked or stewed in closed stoves. Twenty-four Blackman Electric Fans are used for ventilating the Restaurants in different parts of the exhibition. Messrs. McKillip & McKenzie have 14 of them, from 24 " to 42 " in diameter, in Restaurants Nos. 1, 2 and 3, where their cooling and ventilating effect is highly appreciated. Four others of similar sizes are used by Mr. Jenkins, in Restaurant No. 5: two more in the Indian Theatre, and two in the Bernaline Model Bakery. An imposing addition to the Exhibit is a large assortment of Keith's patent Hydraulic Rams and pumps, heating Apparatus, and High Pressure Gas lamps of great brilliancy, for which the Blackman Export Company Ltd., of 70, Finchbury Pavement, London, E. C., are the Exporting Agents,

RHODODENDRONS.

After the floral flood-tide of early spring, there is a brief but perceptible ebb in the beauty of the lawn and garden-border. The ever-welcome bulbs, whose gay but not deep colourings remind us a little of the tremulous winter sunshine, have had their hardy day, and Nature pauses as if to gather strength for the production of the richer and riper beauties of the glowing summer. But this wonderful pause is garlanded for us with a magnificent display of flowers, which belong to the landscape rather than the parterre. They do not easily lend themselves to the restrictions of "interiors," nor to the narrow embraces of the flower-vase. But when a dry May-month gives them their opportunity the tree flowers are not to be surpassed for the veritable enchantment which they work upon the scene. The half-dozen homely kinds upon which we customarily rely for this magical effect have been this year close confederates and have conspired to delight us by an almost simultaneous effort. The white and pink of the chestnuts have challenged the white and pink of the hawthorn. Honours are fairly easy, but, as if to abate any nascent feeling of rivalry, the softer syringa with its white and "lilac" has held a commanding position between its loftier fellows. And the golden tassels of the laburnum have so brightened and relieved the competition that the wide sylvan stage has been a scene of the most refreshing variety and enjoyment.

Flora thus descends to our meadows and pastures by way of the trees; and true to time and season, and her own good will, she finally alights upon the lawn in a blaze of triumph lighted among the dark evergreen leaves of the rhododendrons. The fire has been smouldering for some days, but the punctuality of the plants in "lighting up" is proverbial. They seem to claim the early days of June as their special prerogative, and seldom indeed do they disappoint us. As handsome evergreen shrubs they do splendid service all through the year: and when their too-fleeting glories have passed away, we may enter the portals of the garden proper, with all its marvellous assortment of "bedded-out" plants, making themselves at home, and gradually expanding into blossom. But for the moment, the rhododendrons hold us; nor are we in the least doubt as to the point of view from which they are, and should be, popularly regarded. The botanist tells us—in the seemingly callous, but perhaps necessary, way which makes so many persons shrink from him—that "the rhododendron is a genus of glabrous, pubescent, tomentose, or lepidotod shrub." Not even Mrs Gamp herself would have been provoked into a "deniging" of this proposition. But a pleasant voice floats across the lawn freighted with a dictum much more germane to the occasion. "Are they not perfectly lovely?" The precise value of which phrase lies in the intonation, which, unhappily is not producible in print. But it is true—so far as it goes. Critics, indeed, might demur to it, as placing the rhododendron on the same plane of comparison as its latest fanciful imitation in ladies' headgear. But that is a captious objection. The flowers are lovely. The mere man only employs a more square-set word when he calls them magnificent.

When the early settlers in Virginia had time to look about them their first astonishment was at the splendour of the autumnal forest tints. Against the dark livery of the pines were set the golden yellow of the beech, the red foliage of the maple,

and the glories of the scarlet oak. But another natural feature presently drew their eyes downward. The mountain-sides and valleys were thickly covered with a handsome shrub which they soon learned to call the mountain laurel, and which in its season bore abundant flowers of a "pale blush." This was simply the quite unauthorised American edition of the rhododendron, which does not appear to have found its way to England much before the beginning of the last century. Even its great Oriental predecessor, the Pontic rhododendron, from which so many of our present varieties have sprung, was little known among us before the early years of the 18th century. Since that time, however, the florists have found the tribe so very teachable that they have devoted much time and skill to their higher instruction. Both the oleander and azalea are scientifically included in the family, which even at the beginning of its school career was one of the greatest promise. And now in the parks of town and country rhododendrons have long been flowers of course. Planted "walks" have enlivened the more sombre vistas of forest scenery, and no garden which attains to the dignity of a lawn can now afford to dispense with them. The very severity of their dark, leathery, but always attractive, leafage affords only the greater contrast to the vivid splendour of the flowers. The colours of the more delicate greenhouse kinds are a wonderful feast for the eye, passing from white to silvery, and through the softest sulphur-shades to yellow and deepest orange. In another direction we are led through the gradations of rose and mauve to the most gorgeous depths of crimson and purple. Nor are their open-air sisters much behind them, though here we are scarcely in the mood for nice discrimination. The flowers strike us by their splendid massing, and the one truth which impresses us is that they are the glory of the lawn in early June.

Travellers take pleasure in assuring us that we know but little of the possibilities of the rhododendrons until we have seen their lavish beauties in the Himalayas. It may well be so, but then the entire natural scale differs accordingly, and contrast is only greater or less by the sum of its surroundings. We are standing on a verdant stretch of English turf, and, at least for the moment, are willing to leave comparisons to those who seek them. Our own varieties are "beautiful exceedingly," and that suffices. The plants yield their blossoms freely; there is nothing of the coyness and reluctance which seems a natural, though not always unpleasant, feature of so many of our English beauties. But this is mainly due to the shrub's natural habit. When once the rhododendron is in flower, it seems to be all flower, because the innumerable blooms are so completely unveiled. Every flower-head is a mass of separate flowers, the calyx of each being so very slight that the whole beauty of the bloom is unfolded. Let us gaze at the rhododendrons while we may. Fast fleets their transient beauty, and the greater perhaps is the delight of its return.—*Globe*, June 10th.

A TYPICAL MEXICAN RUBBER PLANTER.

The "India Rubber World" has published so much in the last few months regarding the planting of India-rubber in Mexico, that further information regarding the individuals who have made a study of this question should be of interest to its readers

The following is a brief sketch regarding Mr. Maxwell Riddle who is now acting as general manager and treasurer of the Republic Development Co., which is engaged in planting a large property for the Obispo Rubber Plantation Co., on the isthmus of Tehuantepec.

Mr. Riddle was born in Ravenna, Ohio, where his father has been engaged in the manufacture of carriages for nearly half a century. On leaving college Mr Riddle entered his father's office and started to learn the details of carriage manufacturing. During the course of the six years which he devoted to this business, he became much impressed with the increasing use of rubber in rubber tyres, which led him to a study of the sources of supply for the crude product, and then to the question of rubber planting, in the investigation of which he was assisted greatly by the Bureau of American Republics in Washington, the various foreign consuls, and the late Minister Romero. After studying the question for more than a year, he started on a trip through Central America to learn for himself the facts regarding this interesting question.

After a long trip through Central America he visited various localities in Mexico, making a particularly thorough examination of the plantations in the states of Vera Cruz, Oaxaca, Chiapas and Tabasco. He found that the true rubber belt in Mexico was a narrow strip of land following the border of the states of Vera Cruz and Oaxaca and continuing along the border of the states of Chiapas and Tabasco. This narrow strip having been enriched for centuries by the wash from the mountains behind it, and being drenched by the continuous rains due to its proximity to the great plateau, made it ideal for the cultivation of tropical products. He decided to purchase a property near the border of Oaxaca and Vera Cruz. After returning to the United States for a short trip, he went back to Mexico and started planting his property in earnest, and has now set out more than 100,000 trees, which he reports are doing magnificently. During the year 1899 he became interested with Chicago capitalists, chief of whom was Mr Alfred Bishop Mason, president of the Vera Cruz and Pacific railway, in the purchase of a tract of 2,500 acres in the state of Vera Cruz to be planted in rubber and sugar cane and pasturage for cattle. This company have already succeeded in putting their plantation on a dividend-paying basis and are anticipating very large returns when their rubber is in bearing.

Some months ago some capitalists in New York, recognizing the value of Mr Riddle's practical experience as a planter, induced him to become associated with them as general manager of the Republic Development Co., now planting about 1,500,000 trees on their Obispo plantation in Oaxaca. Mr Riddle is compelled to make frequent trips between Mexico and the United States, and the proper management of this plantation, as well as his private place, keeps him very busy. He reports that they have had no difficulty in getting all the labor they could use up to the present time, and anticipates no difficulty in the immediate future, as the large town of Tuxtepec is within walking distance of the plantation, and the men much prefer to work on a place where they can get into town to see their friends on Sunday. He reports also that the town of Tuxtepec ships a large amount of crude rubber every year, much of it coming from the region immediately adjoining their plantation. Although their system of planting requires the burning of the timber and the underbrush, they are in hopes of saving many of the wild trees, the returns from which will assist materially in paying dividends.

It is encouraging to see people of Mr Riddle's business experience engage in this important undertaking. The question is becoming recognized as of vital importance to the rubber manufacturers, and when men of training and experience take hold of it, its ultimate success seems assured.—*India Rubber World*, June 1.

AFTER CROCODILES IN CEYLON.

[BY TOM-TIT.]

To the sportsman who has time and means to spend amongst elephants, buffalo, and deer, the attractions offered by the crocodile will perchance not be very great. But, as elephants and buffalo are scarce, and the pursuit of them an enjoyment entailing great expenditure and much equipment, there are many who are glad indeed to spend a day or two after the crafty saurian, especially as these days are usually attended by a little diversion among the innumerable wild owl which share their haunts. The two species that will most interest the sportsman in Ceylon or India are the estuarine and the marsh crocodile. The former are ferocious brutes, which frequent the mouths of rivers and salt-water lakes by the sea, feeding on anything from a bird to a bullock, and only too often on human beings. The marsh crocodile is very common in Ceylon, and is to be found in most rivers and lakes all over the country. It grows to an enormous size, though to shoot anything over 15 feet is not common. The "mugger," as it is often called, seldom attacks man, unless it is wounded or its nest molested, when it becomes a savage and dangerous customer.

Most crocodiles feed and roam at night, returning to the water before dawn, and leaving it again to bask when the sun is at its hottest, about noon. Their favourite basking haunts are on shelving rocks and mounds of sand or mud that have silted up during flood time; and in tidal waters on mudbanks left by the receding tide. In unfrequented localities it is easy to approach crocodiles in a canoe at mid-day, as they are then usually asleep or dozing on the sand spits and rocks, and can be shot before reaching the water. They become very wary, however, if often molested.

Crocodile shooting, if not the highest form of sport, is at least exceedingly good fun. The outfit required for an expedition of a few days is by no means extensive; a folding canoe, a double or repeating rifle, a tent, some rope, and a sharp grappling iron, skinning knives, food and cooking apparatus about make up the list. When staying with a coconut planter near Batticaloa some years ago, I was much attracted by the wonderful lake or fresh water lagoon which extends over thirty miles along the coast—a perfect chaos of islets, river mouths, and mangrove swamps. This lake teems with fish and wildfowl, and some parts of its serrated edges literally swarm with crocodiles. Cranes, pelicans, duck, snipe, and endless varieties of aquatic birds find sanctuary on the many islands and swampy nooks: while at night the place is alive with crabs, crocodiles, and snakes, which seek their food to the tune of mysterious "musical shell fish," which live at the bottom of the lagoon, and tinkle away all night, the effect in toto of these myriads of tiny voices vibrating to the surface of the still water being very impressive.

But to return to the crocodiles, which range in size from a few inches to twenty feet. I soon found out the whereabouts of some of the monsters—the old ones frequent the same spot for years—and we decided to have a good try for some of them. My host, who was an old hand at the game, sent a couple of coolies on with our tent etc. in a bullock cart giving them some instructions about mosquito nets

the value of which I afterwards appreciated. When we arrived all was ready, the coolies having, at my friend's dictation, arranged some very effective bait, consisting of two dead dogs, cut open and secured to the ground by stakes about twenty yards apart. When it was dark, and just before the moon rose, we crept down to within a few yards of our baits, and, taking the best cover we could find, waited for whatever might turn up. After a little time our friends began to show themselves—and ugly beggars they looked in the moonlight, slowly crawling out of the water, with that hideous, jerky motion peculiar to the saurian. It was not long before our dainty offerings, which were about fifteen yards from the water's edge, were discovered. One, and then another, approached the bait opposite me, and as the creeping monsters drew nearer I became conscious of a feeling of nausea I had never felt before. But the excitement of the moment soon overcame any other emotion, and, picking out the longest reptile, I covered him and waited for the signal from my companion. That wait must have made my hand unsteady, for when the signal came and we both fired, I saw my gentleman turn and make for the water as hard as he could shuffle. I was using a Colt 44 repeater, and gave him two more before he splashed into the water after the others. My companion had done better, having placed a 450 bullet slap in the brain of his beast which was a fine one.

We left the coolies to skin him and anchor his carcass in a suitable spot as an enticement to his cannibal brethren to return, and, launching the canoe, started off for another place, where we were pretty sure of a find. But the moon clouded over, and we had to give it up and turn in, which I did in anything but a good mood. However, next morning I had the satisfaction of finding my crocodile belly upwards at the bottom of the water a few yards out. He was fished up, and had been hit twice—in the jaw, and by a lucky fluke also in the spine, which was broken.

Before it was time to start in the canoe to pot baskers, I took my rifle and wandered along the reedy banks, intent on killing something. There were birds galore, but nothing for a rifle could I find till I came upon a mound of rotten leaves, the sight of which sent my heart into my mouth. It was the first crocodile's nest I had ever seen, and I knew the owner was not far off, lying in watch for intruders. I pitched stones about in every direction, but did not move in the thick reeds, having no fancy to be taken by the leg. At last, a slight movement in the rushes at my side betrayed the presence of the lady. There she was, a few yards off, with one wicked eye fixed unflinchingly on me. I moved quietly round till I could see the other; then, taking careful aim between them, relieved her of her brains.

That morning we had good sport. Paddling quietly along the banks we came across some monsters. Though numerous, they were very wary, and, while apparently asleep, at the slightest sound glided into the water and disappeared. However, we got some good shots, the best being at one that was crawling out of the water on to a bank, and which I shot through the head as he was half in and half out, and just as he spotted us.

In shooting on tidal waters it is essential to kill dead, as otherwise the beast will scramble into the water, sink, then be carried away and lost. A dead crocodile rises to the surface after about fifteen to twenty hours, but by that time

is not a pleasant object to approach. Speaking of the keeping propensities of the tribe reminds me of a young subaltern, newly quartered in Colombo, who was very anxious to shoot his first crocodile. He returned one day in a state of high excitement, with a reptile in a state of still higher condition. It had been shot ten hours before, and he could get nobody to take it to the local taxidermist, one Lazarus. Ultimately, by the help of the all-powerful rupee, a man was induced to take it in his rickshaw, which he did, with its tail tied to its head like a whiting. What the good Lazarus said when it arrived I never heard, but he skinned and set it up, and, after all, our young friend had not yet shot his first crocodile—it was a harmless iguana!—*Shooting Times and British Sportsman*, June 15.

BLACK PEPPER (PIPER NIGRUM.)

This does not get the attention in Assam and its sub-districts of Cachar and Sylhet as it ought to. I don't know what amount of this spice is annually imported into Assam, but it must be enormous. Everybody uses it, from the highest to the lowest. Assam used to be in former years, a very large producer and now it is only found in *barris* here and there up and down the country. We have a variety of it growing in South Sylhet, but it must be the Bengal variety, as it does not compare in either pungency or flavour with the true Assam plant. So much is this the case that I am inclined to think that it is an entirely different species. The Bengal species has got into Upper Assam too and the real old original Assam Black Pepper plant is exceedingly rare, and anyone who has once used it will never think of using any other that the writer is acquainted with. This plant should not only be better known commercially, but from a botanical point of view it is well worthy of the closest attention. I don't know whether the pepper growers of Malabar or Sumatra are aware that *Piper Nigrum* is a dioecious plant, but Marsden never mentions it being so in his "History of Sumatra," and it does not appear to have been generally known in Roxburgh's time. But there is every reason to think that this plant, like many thousands more, is in its transitory stage, and little if any perceptible change in such a plant will take place in the comparatively short period of one hundred years. So we may conclude that the plant occurs in some instances in a complete dioecious state, sometimes in the monoecious and probably most often in the hermaphrodite condition. When these circumstances are taken into consideration the intending planter of Black Pepper will do well to bear in mind that he has more chance of having a good well developed crop of cerns when he plants his vines three or four together round their supporting tree. Coffee and pepper are eminently adapted for growing with each other, because the shade trees can be utilised for the vines. Such I believe is the common practice in Southern India. I tried Vanilla upon our shade trees, but it would not answer owing to the difficulty in fertilising them. The pepper of course presents no such difficulty, as it is capable of fertilising itself. We have no less than three species which we are going to try and cross fertilise in order to get a bigger corn, at the same time retaining the far-famed Assam flavour and pungency.—*South Sylhet Notes*, June 22.

FISHING IN NEW GUINEA.

BY CHARLES PROTHEROE.

The methods of fishing in different parts of the South Sea Islands are manifold, and some of them would surprise the disciples of Izaak Walton. One of the most ingenious may be laid claim to by the natives of a portion of British New Guinea, namely, Dawson Straits. Here, the web

of a spider made use of in conjunction with a kite affords a novel and successful method of fish catching.

On first visiting these islands, and seeing the natives kite flying, I thought I had dropped among them whilst at play. I was mistaken, for upon investigation I found they were engaged in fishing.

On shore many of the trees are covered with cobwebs, spun by huge spiders. The kite is made of the dry leaves of the sago palm, stitched together and ribbed. It is furnished with two wings, and when flying looks not unlike a good-sized bat. To this is attached a long tail, having, at the extreme end, cobweb gathered from the trees and rolled into a ball. The native paddles out in his canoe against the wind, his kite made fast to the canoe, and flying behind him. The craft, being propelled gently, keeps the kite flying at a certain altitude, and the ball of cobweb, fast to the tail, is kept bobbing on the water. The fish common in these waters, a long narrow kind, not unlike barracouta, or like our garfish, but much bigger, and often two or three feet long, jump at anything moving. They no doubt take the cobweb for a flying-fish, and getting their teeth into it are unable to withdraw them, and so fall an easy prey. The native then pulls in the kite and fish together. As the fish are plentiful, and seldom miss anything they jump at, a few hours of this sport well repays the native for his labour.

About thirty miles from Dawson Straits the natives make use of the cobweb in another kind of fishing, and catch flying-fish during certain months of the year—from December to March, which is the calm season of the year, as you know. Coconuts grow in bunches, and, after they are plucked, the pliant, tough, elastic stem, with perhaps twenty or thirty shoots along it on which the nuts once grew, is brought into use. A lot of these stems are covered with cobweb, and thrust into long narrow baskets made out of the coconut leaf. A long line is made fast to the basket, and after paddling perhaps a mile or so from the land the basket is thrown out, and allowed to drift astern. The flying-fish, to escape from their voracious enemies, which are numerous, seek refuge in these baskets, and, once in, the cobweb effectually prevents them from coming out again. The basket as it gets wet sinks just below the surface of the water; then, after it has been out some time, the native pulls it in, empties the contents, and then repeats this operation. The craft most used in this part for flying-fish catching is the catamaran, just three logs of cedar, roughly shaped and lashed together, and cut away underneath at the ends, to cause less resistance on being driven through the water. You may meet them three or four miles from the shore when engaged in this occupation, lazily floating, and going with the tide.

This sort of fishing appeals to the native mind, for there is no real work about it, the only exertion required being to haul the basket in from time to time. He is a keen trader, and is always willing to do a deal with you for his flying-fish, which are excellent eating. The size of the fish range from a few inches to a foot; the biggest one I ever saw was little short of two feet long. Their lot is not, I should think, a very happy one, the big fish driving them up from below, and a flock of sea-birds waiting to pounce upon them as soon as they show above the surface. The larger fish give them no rest, and you can

tell the course they are taking by the birds which hover about and follow them for miles. The flying-fish use their wings when startled or in danger, which indeed seems to be their chronic state in the day time. Their flight is limited to six or seven hundred yards, for, as soon as their wings dry, the fish drop into the water again, and do not continue their flight unless compelled to. The picture shows a party of New Guinea men net-fishing. The way the natives keep their equilibrium, standing upright on the catamaran, is an acrobatic feat only to be attained by practice. The confident manner in which they move about on their primitive craft gives one the impression that it is easy. I thought so myself until I tried it, but was glad to drop gingerly on to my hands and knees until I came within reach of something more solid, which in this instance took the shape of a thirty-ton cutter. When engaged in fishing each catamaran carries two men and a pile of netting. This is shot and laid out on the water in the form of a horse-shoe. Two catamarans are then paddled up the centre of this net, the natives on them beating the water with long poles, and making a violent noise so as to frighten the fish into their net.

The mode of fishing in favour with the white people in New Guinea, when they do not use the ordinary baited hook and line, is quicker and more simple than any of the native methods. At the same time it is more brutal and destructive, and the man who makes use of it without absolute necessity should be looked upon in the same light as a sportsman would regard a person who shot at a sitting bird. When a shoal of fish is sighted in shore they go out in a dinghy, or small boat, the fisherman having a fire-stick in one hand and a charge of dynamite in the other. Shepherding the fish round for a time until he gets them in a favourable position, he touches the fuse that is inserted in the dynamite with his fire-stick and throws it in the midst of the shoal. The fish, instead of taking fright at the splash caused by the cartridge falling among them, rush towards it. A dull explosion follows, and hundreds of fish rise to the surface, but quickly sink again. Some people believe that dynamited fish float on the water, but such is not the case; the shock having stunned them, and burst their swimming bladders, they immediately find the bottom. The natives then dive and pick the fish up with both hands, the dynamiter having taken care that they were not in more than three or four fathoms of water when the charge was thrown among them. I fired a charge one day, and the boys (natives) had gone down in this usual manner to pick the fish up. Looking over the side of the boat I was horrified to see five or six large sharks quietly picking up the fish on their own account, and taking not the slightest notice of the boys, who were close enough to have touched them with their hands. The immunity enjoyed by the natives in this respect is remarkable. They are constantly in the water, but for one of them to be attacked, or bitten by a shark, is almost an unheard-of occurrence. This is explained, I think, by the fact that the island shark finds plenty of food in the fish which abound, and so is never very hungry. A white person, however, does not enjoy the same immunity as the native, perhaps because the colour of his skin is more attractive. The mid-ocean shark, on the contrary, will tackle anything, and is no respecter of persons, black or white.

Having to travel a long way for what food he picks up he is always in a savage state of hunger, and I doubt if it is ever fully satisfied.

The native simply delights in dynamite-fishing. The noise, the splash, and the result all appeal to him, and give him the idea that they are just what they should be. He would give anything to possess the explosive, but fortunately a wise and paternal government has stepped in, and made it a punishable offence to supply natives with fire-arms or explosives. The man who is foolish enough to furnish them with the means of blowing up themselves or their friends will find himself liable to a fine of a hundred pounds. A spice of danger about dynamite-fishing is perhaps answerable to some extent for its use. With the trader dynamite is looked upon as an essential part of his outfit, and he would almost as soon think of leaving port without a mainmast as start on a cruise without a supply.

Familiarity breeds contempt. In the handling of dynamite it generates carelessness. The man who understands it, and has used it frequently, is usually caught in the end, and the old saw of the pitcher that goes often to the well is fully justified. One could hardly imagine a man throwing away the fire-stick and retaining the cartridge in his hand. Yet that is what one man I know did, in his excitement and absent-mindedness, with the result of losing his arm; and had not a friend been on the spot, with surgical knowledge enough to amputate the limb above the elbow, he must have lost his life. As it is, he adds one more to the long list of one-armed and one-handed men in the islands, maintained through the careless use of dynamite, I was once lying at a place called 'Senapa,' on the north-east coast of New Guinea. A small trading-vessel called in one day, and the trader after the usual fashion started fishing. Putting half a dozen cartridges down, and turning his back for a moment, the natives, who were expert thieves, purloined one of them. It was impossible to recover it from among such a crowd, so my friend sailed away and left it in their hands. I came back to the place some few days after, and then I heard what had happened. The man who had stolen the cartridge, when the coast was clear, invited his friends to come and witness him dynamite fish in the same manner as the white man. Poor fellow! he didn't know much about the article he was handling, and it is certain he never will. The dynamite was a double charge; it was two days since he had given his exhibition, and they hadn't found all of him then. After witnessing many accidents, dynamite strikes me as being a splendid article—for what it is intended for, that is mining purposes in the hands of experts.

The sort of fishing practised by the native women is mostly done from the beach, or in shallow water. A number of them, each provided with large two-handed nets, will wade out at different points, meeting when up to their armpits in something like a half-circle. The fish, if any remain visible, are then frightend into the nets by the women who remain on shore. As many as fifty will sometimes take part in this kind of fishing, furnishing a most animated scene. The only wonder is that they catch anything at all, for the shouting and laughter that goes on should be sufficient, one would think, to frighten fish that were half a mile away.

Tow-line-fishing is too well known to need much description. When you are sailing, a hook covered with a piece of red and white rag is stowed over the stern with a good length of line, and proves a tempting bait for the king fish. Fifteen to twenty pounds is the average size of this fish, which in appearance is something like a salmon, but white flashed, and remarkably good eating.

The canoe on the beach is a sailing craft, used by the natives to go from one island to another, and long journeys are undertaken in such boats when used on trading expeditions. The bottom is a large cedar log hollowed out, the flat sides being built up with sago palm slabs, sewn together with cane, and made watertight with a gluey substance extracted from certain trees. A large mat, made of sago leaves, and oval in shape, is hoisted on the mast as a sail, and the way these canoes lie in the wind and travel is nothing short of marvellous. There is a platform for deck, and an outrigger stretching five or six feet out on one side, the outrigger being a light log lashed to two poles that are fastened to the main canoe. This outrigger gives such stability that it is impossible to capsize the boat, and altogether they are a most seaworthy craft. Another good point in them is that when they are required to go in an opposite direction to what you have been sailing there is no need to turn them round. Both ends being alike the natives simply slues the sail about, and what was the stern then becomes the bow. Great care is taken of this class of canoe, and some of the carving on the ends is really a work of art. They are also decorated with cowrie shells along the water line, and on the stem and stern posts.—*Badminton Magazine* for July.

ORANGE CULTIVATION IN EGYPT.

There is no doubt but that the cultivation of oranges is a far too neglected branch of horticulture in Egypt, which has been especially recommended by experts as one of the best suited spots for the establishment of a garden for oranges and other fruits of its class. Although much progress has recently been made in its cultivation in this country, there is still room for much greater extension. At present the export of oranges only amounts to about one-eleventh of the import, and, fortunately for those in the orange trade, the fruit comes in at the same time of the year as the annual influx of visitors, much to their mutual satisfaction. The "Yussuf Effendi" is the variety most extensively grown here. These are mostly sold locally or at neighbouring large towns at a fair price. Although a nicely-flavoured and satisfactory fruit it has been cultivated too exclusively. The smaller variety, sold in England as Tangerines, fetch about the same price as the best Jaffas. They should prove very remunerative to growers here for export. Belonging to the same loose-skinned group are the "Nagpore" of Bombay and "Sylhet" of Calcutta. Both of these are grown very largely in India and are very much alike. The "Nagpore" tree is a spreading variety while the "Sylhet" is an upright tree, grows higher, and is only grown from seed. Both are excellent varieties for exportation. Two other varieties which should do well here are the "Suntolah" and the "Keonla." The former orange is very small but extremely sweet. It grows almost wild in the hot, humid part of India between the Himalayas and the Ganges. It should be suitable for those parts of Egypt or the Soudan which have a similar climate but should, of course, be tried in any part which can be kept well supplied with water throughout the year. Naturally, it requires very little attention. As novelties are always acceptable in English markets

and as it is sweet almost before it is quite yellow, it promises well. The "Keonla," another Indian orange, is to be greatly recommended on account of its lateness. On comparing one of these trees with the "Yussf Effendi" one would imagine that, as both oranges were of the same hue and size, they would both be ripe. This, however, is not so. Long after the other oranges have been gathered the "Keonla" stays on the tree until at last its colour is a beautiful dark red, and not till then is sweet. Of course, in Egypt, this should be ready for gathering just as the "Yussf Effendi" is over and when the "Portugal" is dearest, at about the end of April. Many other varieties of the Suntara group, grown in India, Ceylon, South China, and East Indies, and Australasia, might be tried. The Australians have for two or three years been sending oranges to England. They are mostly of the Portugal variety and have reddish skins. This is, of course, rather an attraction, and so they sell at about two or three times the price of the ordinary ones. Considering that it takes three times as long for ships to reach England from Australia than from Egypt, this should greatly encourage growers here.

Belonging to the Portugal group there are many kinds which ought to be grown here with great success. Already Egypt has successfully reproduced the blood orange from seed—a feat apparently as yet unaccomplished in any other country. Other varieties have been grown well in private gardens. There should, therefore, be a great extension in the growth of the seedless egg-shaped orange of Malta, the Jaffa seedless varieties, and the "Bisray," which is grown from seed, and is one of the best of Jaffa oranges. All of these are too well known to need description. The great advantage of this class of orange is its keeping qualities. With careful packing it will keep for two or even three months. The British Chamber of Commerce in Egypt reports that the egg orange has been introduced into Florida and has been so successfully cultivated that it is probably now more extensively plauted there than any other kind. In Malta there is said to be also a unique orange of the same group which is never sour from beginning to end but sweet and juicy. It is there called "Loomi Larenj." Such an orange should be well worth cultivating and should always command a good price. Another orange sold in Bombay, the "Mussembi," is brought from Poona, and it is said that it can be kept on the trees for a whole year without deteriorating. The Chamber of Commerce rightly complain that the "Lemoun Hindi," often exhibited at our horticultural shows, is not properly cultivated. To obtain a really delicious fruit the trees must have, as nearly as possible, conditions of soil, heat, and humidity similar to what they have in the island of Labuan and at Amoy, where they grow to perfection.

As regards the treatment of the orange tree, practical experience, combined with logical reasoning, is of far more value than theoretical book information. Nevertheless, it is both interesting and very useful to read of the results of others' experiments and work, and to profit by their successes and failures. The number of trees per feddan should be, to obtain the best results, one hundred. At Jaffa, however, as many as six hundred per feddan are generally to be found. Abundance of irrigation water is the *sine qua non* of a plantation and the watering should be done continually. The fruit, consisting of over 90 per cent water, it will be understood that without a sufficient supply the tree cannot possibly do well. The average of several analyses of the orange shews that there are four parts each of nitrogen, phosphoric acid, and potash per thousand. Calculating from this, 1,000 kilos of oranges will contain 4 kilos of each of these three constituents. Growers generally fail to supply this amount again to the soil, and consequently it gets weaker and the produce of oranges less. To obtain theoretically this amount each of the trees supplying the thousand kilos of fruit should receive $2\frac{1}{2}$, $2\frac{1}{2}$, and

$\frac{3}{4}$ kilos respectively of nitrate of soda, superphosphate of lime, and sulphate of potash in return, besides an additional quantity for their growth of wood and leaves. Manure is one of the absolute necessities of the orange tree if it is to produce well. Every piastre properly expended in well manuring the trees brings much over a piastre's worth of extra fruit, either numerically or in size, besides giving a better flavour to it. The soil of Egypt is admirably suited to the physical requirements of the orange tree. A perfect soil is a mixture of sand and a little clay and lime. The lightness of this soil allows the water to sink in easily and the roots to spread out well. Now, if there be added to this good food for the tree, it can of course do well. The Nile mud, like the "loess" of China, is a typical fertiliser. But growers must remember that where the deposit is thin or absent, cultivation cannot be carried on profitably without abundance of artificial manures. Speaking in a simple way, nitrogen produces wood and leaves, phosphates produce fecundity, and potash produces sweetness and flavour. Lime is absolutely necessary for the orange tree, which absorbs great quantities of it. If not present in the soil it should be supplied in the form of Gypsum. If too abundant the sap will not run freely, but $\frac{1}{2}$ kilo of sulphate of iron for each thousand kilos of fruit produced will correct it. The Gypsum and iron sulphate also help to fix the fruit on the tree. Seeds should not be treated with mineral fertilisers but should be given plenty of organic food. Stable refuse is excellent for the seed beds, but it should be passed through a very coarse sieve and the big straws taken away. Most people in Egypt make the mistake of digging holes round their trees and filling these with water. Instead of a hole, in the middle of which stands the tree, a ring should be made so that neither fertiliser nor water will touch the trunk. One very successful orchard owner bores holes in the ground in a circle round the tree varying in size, depth, and distance from the stem according to the size of the trees. These he frequently fills with liquid fertilisers so that the roots thus receive a greater benefit and the tree can better keep its upright position. The best time to apply the manures is about a month after the gathering of the crop and again when the fruit is about half-grown. Thus the first part will strengthen the tree for producing the fruit and the other part will supply the nourishment for the fruit when growing.

Lemons, limes, citrons, and other trees of the Citrus group require almost the same treatment. The lemon and citron need more nitrogenous manures than the orange to the extent of about 12 per cent, and the other sour fruits of about 10 per cent. Lemons in this country are smaller but more juicy than others and limes are very inferior. Both would repay generously more liberal feeding. A few only of the best and most suitable kinds of oranges have been named. There are many others which might be grown to advantage. Young trees and picked seeds can generally be obtained from the nurserymen and horticulturist in the different countries. Those who are anxious to obtain them would no doubt be able to get information and help from their respective Consuls. It is to be hoped that orange growers will take "Excelsior" as their motto and that we shall soon see a great development in the orange trade. With a little experimenting and care, many new varieties should be well established and both quantity and quality improved. Those who prefer to keep to their present variety should at any rate spend a little on improving it. One thing is certain, any expenditure the growers may make in doing either or both will prove a good investment.—*Egyptian Gazette*, July 1.

RUSSIAN TEA.

A PRINCE'S ENTERPRISE ON THE BLACK SEA.
It is not generally known that Russia—next to England the greatest tea-drinking country

in Europe—is making great efforts to grow a portion of her own tea in Russia. Along the eastern shore of the Black Sea, a district favoured with a suitable soil and climate, a number of Russian landowners, at their head Prince Voronzoff, have begun tea-planting on a considerable scale, and the result of their efforts encourages them to persevere. One planter has about 40,000 acres which he is carefully preparing for tea culture. This year's harvest promises to be about six tons, but each year, as the plants grow older, the harvests will increase. On Prince Voronzoff's estate it is expected that next year a harvest of twenty-five tons will be gathered. These are only small beginnings, but it has now been proved that tea will grow in that favoured locality, and that its growth will pay. The quality of the tea grown on the Black Sea coasts is said to be of the purest. —M.A.M. —*Leisure Hour*, (July.)

THE M. P.'S ORCHID.

“*Odontoglossum crispum* var *Triomphe de Rambouillet*.” This is the name of an orchid for which Mr J Rutherford, M P for the Darwin division of Lancashire, paid the Land Horticole Coloniale of Brussels £80 in November 1899. According to the diagram supplied by the sellers the flower had a pinkish ground, dark red marks and spots, and a pure white lip. Instead of this, when the plant flowered in 1900 it had, said Mr Rutherford, a muddy yellow ground with brown spots. Yesterday Mr Rutherford sued the Land Horticole Coloniale to recover damages for breach of warranty in regard to the sale. The defendants admitted the warranty, but contended that a genuine *Rambouillet* had been sent and that Mr Rutherford must have got his orchids mixed. John Lupton, Mr Rutherford's gardener, said that, had this orchid blossomed as represented, it would have been worth £150. As it actually bloomed it was worth something under £5. The case was adjourned.—*Daily Mail*, July 3.

CINCHONA PLANTATIONS IN BURMAH.

It would be interesting to learn what has become of the cinchona plantations spoken of in 1880 as existing in the Toungoo district by Major Spearman in his *Gazetteer*. In December 1863 a small plantation was commenced on Plo'o-ma-do hill, south-east of Toungoo at an elevation of 2,100 feet. One hundred and eighty plants of the “*Succirubra*,” or red bark variety, were planted, of which 128 were living twelve years afterwards. Two plants of the same species planted on Bogale hill at an altitude of 2,800 feet, but in rather an exposed situation, had attained a height of nine and ten feet in thirteen years. A plantation was formed in 1871-2 at Thandaung, eighteen miles east of Toungoo, at an elevation of 3,700 feet. The red bark variety is the only one of the different species tried which has succeeded at all. Plants of this species, though vigorous enough, have a bushy and gnarled appearance, and were covered with seed though only about ten to fifteen feet high. The other variety, planted over two-thirds of the whole area of 100 acres, failed. The plants grew well for two or three years but then began to sicken and die. Plants were gratuitously distributed to heads of Christian Missions. We have not noticed in any Forest Department report any account of these cinchona plantations, the oldest of which were planted from thirty to thirty-five years ago. It would be interesting to learn what has become of them.—*Rangoon Gazette*, July 15.

SISAL HEMP INDUSTRY.

Dr. Morris [in a letter dated Barbados, January 28th] has estimated that under favourable conditions the cost of cultivating and extracting the fibre should not exceed about £10 or £12 per ton. The market price, however, is very variable. It has been as low as about £13 per ton; on the other hand, it has, for one or two years continuously, been as high as £39 to £49 per ton, or even higher. The plant will undoubtedly grow in Trinidad and Tobago. There are already a large number of plants running wild in the latter island. It is to be remembered that it is not a cultivation for small proprietors. It is carried on on very much the same lines as cane cultivation. I estimate that it requires a capital of about £7,000 to £10,000 to start and maintain a plantation, say, of 1,000 acres in regular working. Anything less than the area above given would not keep the scutching machines in full working, and thus add to the cost of management and the up-keep of the plantations. As only about three per cent of the weight of leaves is returned in fibre, there is a heavy cartage of these to the factory. On an estate turning out, say, 500 tons of fibre, not less than about 15,000 tons of leaves have to be brought to the mill. This necessarily involves considerable expenditure in carts and stock, or in estate tramways. It is stated that in very rich soils the fibre is not so strong and abundant as in comparatively poor soils in dry climates. Again, in the Bahamas, it was found that absolutely barren land was quite useless and led to disappointment and loss.—*Proceedings of the Jamaica Agricultural Society*.

TOBACCO GROWING IN NORTH NEW ZEALAND.

Mr. G F Sutherland, of Fiji, who was commissioned by the Government of New Zealand to report upon the suitability of the North Island for growing tobacco as a commercial crop, has just sent in his report. Mr. Sutherland has had 23 years' experience as a tobacco-grower in India, Australia, and Fiji. He has on the present occasion visited the whole of the North Island, and we understand that his report is generally of a favourable character. He deals with the questions of soil, climate, economic conditions, former experiments, and the reasons why they failed. Mr. Sutherland leaves on the 26th inst. for Fiji.—*Auckland News*, June 21.

TEA IN MAURITIUS—According to a report recently received at the Colonial Office from the Government of Mauritius and Rodriguez, there are four factories of tea in that colony and several plantations, covering approximately 200 acres. The tea made is nearly all consumed in the colony. In 1898 there were five factories and 367 acres under cultivation. The average selling price in 1898 and 1899 was R1-20 per kilo. The approximate quantity manufactured in 1899 was 27,000 kilos., of which only 2,585 were exported, chiefly to the United Kingdom. In 1898 it was 40,000 kilos., of which 7,266 kilos. were exported, chiefly to Madagascar. The year 1899 shows an approximate decrease of 13,000 kilos.—*Tea* (May.)

THE PROPOSED TEA GROWERS' ASSOCIATION.

[To the Editor, HOME AND COLONIAL MAIL]

SIR,—As a private proprietor in Ceylon, I am more than pleased to see Mr Sholto G D Skrine's resolution at the meeting this last week of the Ceylon Association in London to form a "Tea Growers' Association," and if it is to be a success we must get India to join us and look to the support of all the large companies in India and Ceylon; the smaller proprietors, I am sure, will follow. I am plucking finer this year and throwing away all leaf three rounds at least after pruning. What has it benefited me up to date? A yield of 3,500lb less tea and lower price per lb. It is no good to say that some of the "tea companies" have done well, and therefore they cannot join a "Tea Growers' Association," or some such scheme of this sort. The small proprietors might equally say the same. No, we must all help one another by joining in some such scheme as this for the common good, and the sooner the better.—Yours faithfully,

CHARLES E. G HATHERELL.

Radford House, near Leawington.
July 1, 1901.

—H and C Mail, July 5.

COCONUTS AND TAPIOCA IN PAHANG, STRAITS.

In the Pekan districts 3,000 acres of land on the coast have been alienated to a Syndicate (for planting coconuts, I understand), of which about 500 acres have been cleared and are being fenced. A block of another 2,000 acres, alienated for tapioca cultivation, will probably revert to the Government, no work having been begun on the block.—*Official Report, 1901.*

PRODUCE, PLANTING AND COMMERCIAL NOTES.

Although the tea industry is under a cloud, which we hope is but temporary, the attendance at the Annual Assam Dinner last week was remarkably good, nor were there any marked signs of depression observable in the tone of the speeches. These festive gatherings are of ancient standing now. The first took place in 1883, and since then death has claimed some of those who were wont to be so regular in their attendance. It seems long, although it is but really only a short time, since the late Mr John Berry White was a conspicuous figure at these gatherings, of which he was one of the chief founders, and his cheery "Hear, hear," when one or another of the speakers referred to the old Assam days or touched a chord of memory, still ring in one's ears. But although several of the veterans no longer grace the festive board, the attendance does not diminish, and the chairman of last Thursday was as full of eloquence and enthusiasm as in the good old days when tea was higher by some pence per lb. If some of the old familiar faces were absent those present were fairly representative of all departments of the industry, and the dinner was a great success. We trust that when next Assam planters meet to dine the outlook for tea will be brighter. A special feature of this occasion was the presence of Lieutenant-Colonel D M Lumsden, of Lumsden's Horse, who, needless to say, received a very hearty welcome.

Commenting upon the position of the tea market in the Dominion, the "Canadian Grocer" says:—"Japan teas are in a somewhat unique position at present, they being strong in price, while those of other countries are weak. The chief factor in this is the buying on

United States account. If the present high price of Japan tea is maintained, benefit will certainly accrue to Ceylon greens."

America took considerably more Indian and Ceylon tea in the first three months of 1901 than during the corresponding period last year—5,112,871 lb., against 4,043,062 lb., an increase of 1,069,809 lb. As the main increase was received from London, there is no doubt, say Messrs. Gow, Wilson and Stanton, in their last report, that low prices have been the cause, and the expansion has therefore been in black tea. To capture the North American market for green, unfermented, and Oolong teas is more important, say they, than ever. There seems no reason why this should not be done, now that absolute necessity demands it and it has been proved that suitable tea can be made.

In view of the fluctuating fortunes, in the past ten years, of the Assam Frontier Tea Company, the directors are no doubt acting prudently in the policy they will recommend to their shareholders for adoption at the coming meeting. The available surplus for the year 1900, after providing for the six per cent. dividend on the Preference shares, is equal to a distribution of 7 per cent. on the Ordinary; but they propose to pay 3 per cent. thereon, and to devote £4,454 in part payment of the upkeep of recent new extensions, leaving £1,229 to be carried forward, as against £2,873. Last year the Ordinary shares got 8 per cent., previous dividends having been (reading backwards) 4, nil, 6, 6, 3, nil, 2½, 7½ and 11, this last being for the company's first year.—*Home and Colonial Mail.*

RAILWAY ENTERPRISE IN ECUADOR.—Our Guayaquil Correspondent writes under date May 13:—"The extension of the Railway from Guayaquil to Chimbo and the capital of Ecuador has made some substantial progress in the course of the past year. A large quantity of rails and other material for the construction of the line has recently been received. Some 25 miles of earthworks have been built, and over the first half-dozen miles the track is now laid. The remaining portion of about 100 miles, however, presents greater difficulties than any hitherto encountered by the contractors. Before Quito is reached many steep valleys must be crossed, and innumerable rivers and streams bridged. The construction will be costly and calls for engineering skill of no mean order to carry the undertaking to a successful issue. While the line may prove to be a benefit to Ecuador from a political point of view, inasmuch as it will give easy access to the national capital from the seaboard, the commercial prospects of the undertaking are not brilliant. The city of Quito contains 1800 inhabited houses and 40,000 may, therefore, be regarded as a most liberal estimate for the population. The route followed by the line traverses no thickly settled districts, nor does it tap a country where the natural resources promise any great future development for mining or agricultural industry. The climate throughout the regions lying between Chimbo and Quito is totally unfitted for the settlement of immigrants from Europe. In the vicinity of Quito there is little production of any kind, except of such food-stuffs as are required to meet the demand of the local markets. In these circumstances it is impossible to see where the traffic is to be obtained to support the railway on any satisfactory commercial basis. Unfortunately it is British capital, largely subscribed in Glasgow, that has been invited in this enterprise.—*London Times.* June 17.

PLANTING IN JOHORE.

The following information respecting the State of Johore has recently been received from the Corresponding Agent of the Imperial Institute, the Hon. Dato James Meldrum, F. R. G. S. :—

The cultivation of gambier is beginning to languish, owing to the distance planters require to go from the water before they can find virgin forest and fresh land for new plantations. This industry is entirely in the hands of Chinese. The destruction of valuable forest trees is to be regretted—thousands of acres have been cut down by gambier planters, who, when the soil is exhausted, seek for "fresh fields and pastures new." Some have gone to Raja Brooke's territory, Sarawak; some have gone to British North Borneo.

The cultivation of tea has practically ceased, owing to want of cheap labour; otherwise, the frequent rains and heat are favourable for leaf crops.

A new steam saw-mill has been erected by Chinese assisted by Johore officials. The Johore Steam Saw mills, erected in 1886, are in full work; supplies are now brought from greater distances. Ballow, sometimes called Johore teak, has become scarce; this wood was admitted by Lloyd's for "all parts in ships of the highest grade"; it is harder and heavier than *Tectona grandis*, and nearly double the strength.

No planting of gutta percha trees has been attempted; the supply cannot be kept up much longer. As regards forest trees, there are no private individuals in Johore to undertake such planting; indeed it is only Government who can perform this important duty.—*London and China Express*, July 5.

THE MANURIAL RELATIONS OF THE BOIS IMMORTELE AND CACAO TREES.

With reference to the Analysis of Bois Immortelle Flowers made in the Government Laboratory, and recently published by command of H.E. the Governor as a Council Paper (No. 38 of 1901), we quote as follows: I have the honour to add for the information of the Agricultural Society that these flowers appear to supply all the Nitrogen permanently removed from the soil by the cacao beans. And in support of this I submit the following figures:—

	Nitrogen per acre.
250 Cacao Trees—500 lb cured cocoa containing 2½ per cent of Nitrogen	12½ lb
50 Immortelle—500 lb dry flowers containing (say) 4% of Nitrogen	20 lb

In making this estimate, I have allowed for a full yield of cacao; and I believe I have not overestimated the yield of Flowers.

The Flowers lose their Nitrogen rapidly as the following results show:—

	Nitrogen %
1st Analysis (fresh flowers)	.. 6.32
2nd do (2 days old)	.. 5.16
3rd do (5 days old)	... 4.14

I recommend the attention of cacao cultivators to these results which appear to me to be of considerable importance.

BOIS IMMORTELE AND OTHER FLOWERS, MANURIAL VALUE OF.

Source of Flowers	% of Nitrogen in dry Flowers.
Saman fresh 4.40
Do same sample older 3.55
Poui 4.55
Sugar Cane (old flowers)	.. 1.43
Hibiscus 2.71
Water Lily 4.63

Immortelle (anauca) from Tacarigua	6.30 fresh flowers
Do same sample older	4.05
Do do	.. 3.96
Do from Tortuga	... 6.32 fresh flowers
Do same sample 2 days later	5.16
Do do	5 do 4.14
Do do	6 do 3.91
Do from Botanic Gardens	4.21 fresh flowers
Do do Cascade Valley	4.81 do
Do do Caroni	.. 3.25 do
Immortelle (Bocare) from Cunipia	4.93 (2 or 3 d'ys old)
Do do Caroni	3.84 fresh flowers
Immortelle leaves	... 2.87
Locust Beans (from Saman tree)	3.07

P. CARMODY, Government Analyst, Trinidad,
14th March, 1901.

BRAZIL AND OVERPRODUCTION OF COFFEE.

THE LABOUR SUPPLY—RAILWAYS—GOVERNMENT PAPER—FOOD SUPPLIES—THE RUBBER INDUSTRY—SUGAR AND RUM—COTTON AND WEAVING—AMERICAN FARMERS—GERMAN SETTLERS—ITALIAN LABOUR—BRAZILIAN EXCHANGE—PURCHASING POWER OF THE MILREIS.

Great changes have taken place in Brazil during the past twenty five years. The coffee crop has doubled in quantity and improved in quality. Many of the coffee planters of Brazil have put up improved machinery and take great pains to cure their coffee properly and endeavour to improve prices. The great difficulty is that a large number of the planters still harvest their crops in a slipshod manner, stripping off the green coffee with the matured berries, and leave the cherry too long on the ground before raking it up and sifting the coffee from the rubbish. The consequence is that, however much trouble and extra expense the leading coffee planters take to improve their prices, the small farmers undo all by their slovenly work and, instead of improved prices, Brazilian coffee still bears a bad reputation and the middlemen make capital out of the producer's want of co-operation and want of system in preparing their coffee crops for the markets of the world.

Attractive labels are printed for the grocers, calling the ordinary Santos and Rio Coffee "Old Java" or rather "Old Government Java and Mocha" and the conservative old ladies in all parts of the world still believe they are using the genuine article and get quite angry if anything but "Old Government Java and Mocha Coffee" is offered to them.

The origin of the brand "Old Government Java" was, I believe, brought about by the Java Dutch Government leasing land to the farmers of Java on condition that the coffee crop was sold to them.

The Dutch would in all probability receive the bulk of such coffee and, after Amsterdam and Rotterdam were served, there would be very little left for the United Kingdom, Canada, and the United States of America.

Then again the Brazilian planters call their pea-berry "Mocha" and it is duly shipped from Santos and Rio de Janeiro as Mocha coffee! "What's in a name? The rose by any other name would smell as sweet," and so does Indian and China tea when labelled Ceylon!

The overproduction of tea is a very serious thing and so is the over-production of coffee. Will the cheapness of coffee as compared with tea lead to the return of some of your tea-drinkers to coffee?

Will the wholesale adulteration of coffee still continue when Brazil has despatched her twelve millions of sacks or fifteen millions of hundred-weight?

I remember a nice old German coffee-dealer in Canada who was one day very busy mixing roasted barley with his coffee. The perfume was delicious, and he looked up with a grim smile and said, "It is good for dare stomachs. When I give dem pure coffee, day say it give dem de headache and now day say my coffee is de best day ever drink it."

There will be plenty of Brazilian coffee with the addition of chicory, beans, and barley, converted into fine "old Government Java and Mocha."

It was thought that, when the slaves of Brazil were withdrawn from cotton and sugar culture and concentrated on coffee growing in Brazil, the coffee crops would reach their zenith and diminish with the dying out of the two-and-a-half million of slaves; but this is not the case, for the Brazilian Government imported European labourers from Germany, Austria, Spain, and Italy; hence the large area planted by the poor slaves, who have disappeared from the face of the earth, is now harvested at great expense by Italians and Spaniards.

I have no sympathy with the latter race who rose to grandeur by slavery in South and Central America and now substitute themselves in the place of the dead and departed slave in Brazil.

Before the railways were made many colonists made a footing in the country by the carrying of coffee, on mules and by bullock-carts, to the shipping ports.

The Germans are small farmers and form snug settlements both inland and on the coast—some are engaged in cattle-farming at Rio Grande de Sul and many keep hotels. The making of the railways employed thousands, many of whom are now well-to-do coffee planters and storekeepers in the numerous Brazilian cities, such as Rio de Janeiro—Santos—San Paulo—Campinas—Rio Claro—San Carlos de Pinhal—Araraquara—Jabatababal—and many other thriving townships scattered throughout the coffee district. It is true that, through the rise in the value of the milreis or paper money of Brazil, many colonists take advantage of the cheapness of gold to visit their homes in Europe and therefore labour is very scarce just at the moment when the big crop is coming in with a rush.

Food supplies are much dependent upon the weather; the corn and bean crops are often failures through prolonged droughts in Brazil; each estate or Fazenda grows corn and beans, manioc and tobacco, between the rows of coffee as well as separate fields ploughed and harrowed for reserve supplies of food.

It is a melancholy fact that in Brazil one travels hundreds of miles through monotonous country without seeing villages or market gardens. Everybody must work for the coffee planter and nobody is allowed any ease or independence in that country where the slaves were locked up at night inside an enclosure by the planter's house and coffee stores.

Out of the coffee region there are rubber collectors who recruit men and make them advances of food and money. The export of rubber from Brazil is very considerable, but they have a wasteful way of harvesting by cutting down the rubber-bearing trees and leaving them to rot on the ground.

Sugar is largely cultivated, chiefly for the making of a cheap rum called "Pinga," largely used by all sorts and conditions of men in Brazil; it is so cheap that everybody can drink it, sometimes only two millreis per gallon or about four pence per bottle on the estate.

Cotton was once largely exported from Pernambuco and other parts of Brazil and weaving establishments were making money from the ready sale of cloth. At Santa Barbara a number of Americans grew cotton for a mill located in Santa Barbara, but they discontinued growing cotton and cultivated melons. Near Santa Barbara in the Province of Sao Paulo; there is a German Settlement called Limea where a number of pretty fruit gardens and orange and lemon groves may be seen by the traveller journeying from the city of Sao Paulo to Rio Claro, many pretty flower gardens round their neat little cottages bordering the railway track. All the railway stations are crowded with a miscellaneous crew of every nationality under the sun, but chiefly Italians with their wives and numerous families going and coming to and from Italy. The rise in exchange and the cheapness of gold in Brazil is the main cause of so many Italians returning to Italy where they buy a small farm and place some relation in charge of it, then returning to Brazil and taking more contracts to cultivate and harvest coffee on the Fazendas.

The Italian seems to be the only colonist that thrives in Brazil; he grows grapes and makes his own wine—keeps pigs and goats—grows his own Indian corn and beans—does a little trade in tobacco and rum (Pinga); he even receives his regular mail and is well up in the rise or fall of Exchange, discusses the War in South Africa and is a sea lawyer generally, being quite a match for his master, the coffee Planter or Fazendero. The stay-at-home storekeeper is a very different kind of animal; he likes his pipe of strong tobacco, his pinga, and his dirty cards, does not bother about Exchange, the purchasing power of the milreis not affecting him; his prices are always the same to his customers, and he laughs and grows fat.

The prosperity of Brazil depends on the labour supply from Italy. HENRY COTTAM.

NEW PRODUCTS IN THE WEST INDIES.

In the course of a lecture before the Royal Colonial Institute on "Impressions of the British West Indies," Mr. Henry de R. Walker, a visitor from England to several of our Colonies (with a view to qualifying himself to speak on Colonial subjects when he goes into Parliament), made the following interesting references to products cultivated in Ceylon:—

The most salient feature (after sugar) is the enormous increase in the cultivation of cocoa* and bananas. Grenada has so largely replaced sugar by cocoa that it no longer grows enough of the former for its own requirements. Dominica, from its physical configuration, should never have placed its confidence in sugar. It was not introduced until the beginning of last century, and has never thriven as well as the coffee for which it was substituted. At present cocoa, limes, and coffee are in the ascendant. Trinidad divides its allegiance between sugar and cocoa; but, whereas the output of sugar products other than rum

* More properly cacao; but I have preferred the popular designation.

has fallen during the last fifteen years, that of cocoa has nearly doubled, and two-thirds of the amount goes to Europe. This is an additional proof, if any were needed, that, under fair competition, the British West Indies are able to hold their own. Equal success might be anticipated with fruit if the facilities enjoyed by Jamaica for the transport of perishable produce could be extended to some of the other islands. The Royal Commission recommended, as a start in that direction, that Dominica and St. Vincent should be placed by a subsidised service in direct communication with New York. But the Secretary of State has preferred to persuade the Imperial Parliament to pay £13,500 annually for a connection between the Lesser Antilles, British Guiana, and Canada. The experiment has not been altogether a success; one of the ships was wrecked on the coast of Grenada under circumstances which were the reverse of creditable.

The only other subsidised service, with the exception of the Royal Mail Steam Packet Company, which has been in existence for nearly sixty years, is the direct line between Jamaica and Bristol, which has been inaugurated so recently that its value cannot adequately be determined. Its object is to encourage the growth of fruit in Jamaica, and especially of bananas and oranges. The extent to which the cultivation of bananas has already been carried is an exemplification of the results following from the judicious application of brains and capital. Two extracts will show the transformation undergone by a district in the north of the island.

In 1861, after a personal visit, Trollope wrote that Port Antonio was once a goodly town, and the country round it, the parish of Portland, as fertile as any in the island. But now there is hardly a sugar estate in the whole parish. It is given up to the growth of yams and plantains. It has become a provision ground for Negroes, and the palmy days of the town are of course gone.

Twenty-six years later Dr. Morris could write the following glowing report:—At first the fruit was purchased in small quantities from Negro peasants in the neighbourhood of Port Antonio. There was practically no capital invested in the cultivation. The settlers were induced to grow bananas in small patches of an acre or two and to deliver the fruit at the port of shipment. In the aggregate these small patches produced bananas sufficient to fill all the first ships engaged in the trade. The fruit trade in Jamaica is now the means of circulating nearly £500,000 annually amongst all classes of the community, and this large sum is immediately available in establishing other and more permanent industries. Bananas come into bearing at the latest in about fifteen or eighteen months from the time of planting, and, as the return is usually from £10 to £20 per acre, the planter is able, with a comparatively small capital, to establish his land in cocoa, coffee, nutmegs, limes, oranges, and coconuts, which, when the bananas are exhausted, will remain a permanent source of revenue. It is on this account that the fruit trade has always been regarded as capable of building up, little by little, an improved condition for the people, not only of Jamaica, but of other West Indian Islands suitable for the industry. Latterly, many sugar estates have been converted into banana walks, and all sections of the community have taken part in the enterprise.

This vast improvement is entirely due to the Boston (now United) Fruit Company, which, during the season, which lasts from March to August, despatches as many as six or eight steamers weekly to Boston, Philadelphia, and New York. And the progress has been well maintained, eight million bunches having been exported in 1899 as against four and a quarter in 1895. When it is considered that each bunch contains more than 100 bananas, some idea may be formed of the magnitude of the trade.

For the present the Bristol to Jamaica line will operate on a much smaller scale than the United Fruit Company; but it is understood that Messrs. Elder, Dempster & Co. are prepared to extend their under-

taking as soon as success is assured. We should welcome this scheme, not only because it fosters trade between the Mother Country and a British Colony, but because it affords to that Colony access to a secure market. It is an open secret that Jamaica desired a Reciprocal Treaty with the United States, not so much for the sake of the sugar industry as in order to obviate the danger of a duty upon its bananas. Citrus fruits are heavily taxed in the interests of the growers of California and Florida, and it is feared that a similar fate may befall bananas if Cuba and the Philippines are admitted, similarly with Puerto Rico and Hawaii, into the American commercial union. It is almost superfluous to point out that the present policy of the United States is to impose heavy duties upon all articles which are, or might be, produced within its borders. And in Cuba and Puerto Rico, however it may be in the Philippines, are many districts thoroughly suited to the cultivation of bananas. The new line is, therefore, a most wise form of insurance; nor can Jamaicans grumble at the annual charge of £20,000 when the Imperial Parliament pays an equal amount.

Mr. Walker had much to say about "sugar" and the work of Dr. Morris, and here is a curious paragraph:—

I wish to touch upon a somewhat delicate matter. There is not the cordiality of relationship between the Department and the planters which might be expected in view of its principal aim and object. To this extent its utility is impaired; but, while I sympathise with Dr. Morris and his subordinates, I cannot altogether blame the planters if I am right in seeing herein the cloven hoof of the bounties. They argue, I take it, that an increase in the productivity of the cane might be counterbalanced by higher bounties, and that it could have no effect in improving the credit of the industry, the lack of which is its greatest misfortune, while it might be held to weaken the claim to countervailing duties. In any case, the protected cane-sugar growers of Louisiana are equally able to profit by the work of the Department, and they do not hesitate to do so.

THE AFRICAN ELEPHANT QUITE TAMABLE

(To the Editor of the *Times*.)

Sir,—In several journals I have lately read allusions to the supposed fact that the African elephant cannot be tamed, or, at all events, that all modern attempts to use it in the same way as its Indian relative have failed. I venture to ask the authors of these paragraphs (which appear to have been derived from Belgian authority) to pay a visit to this society's gardens, where they may see every afternoon a full-grown elephant of the African species engaged in carrying women and children up and down the principal parade. So far as the experience of this society goes, the African elephant, if proper measures are taken, is as easily-trained and reduced to obedience as the Indian elephant, although the males of both species, when they attain fully adult age, become, in some instances, liable to occasional fits of ill-temper.

It is desirable that the fact of the African elephant being perfectly tamable should be more widely known, because the belief that the contrary is the case may tend to interfere with the very laudable efforts now being made in several of our African protectorates for the preservation of this noble beast.—Yours, &c.,

July 3rd.—*London Times*, July 5,

PRODUCE, PLANTING, AND COMMERCIAL NOTES.

Last week the long threatened movement for establishing private sales of tea in Mincing Laue took practical shape. The object is, of course, the securing of secrecy as to the price paid, and this does not at all suit the retail tea trade. The "Grocer" warns its readers to be very careful in making any purchases of Ceylon tea, otherwise they will probably find that they have been paying the dealers the very large profits that these secret tea auctions are desired to effect, with the result that their tea trade will be seriously damaged.

Referring to these private sales, which opened last week it says: "Last Tuesday the usual public sales of Ceylon tea took place, but the result was more or less a fiasco, as several leading buyers decided to abstain from active operations pending Thursday's private sales, and the greater portion was withdrawn, although the various parcels have been since dealt with privately without material change in values. On Thursday 9,839 packages Ceylon were offered at the private auction, which quantity was sold with fair competition at, on the whole, steady rates, showing no alteration from the public sales of last week. The attendance was very large, many being doubtless present from curiosity. In answer to the question whether buying brokers were to be allowed to circulate their lists of bought-over teas amongst buyers, it was stated that no objection would be raised, and beyond this there was no discussion. Some further private auctions are announced for next week besides the usual public ones, but so far Indian tea has not been included. The success of these private auctions depends on whether all those whom it is intended to benefit are able to see their expectations realised, but it would appear as if the majority of buyers were dubious as to its ultimate good effects. Merchants doubtless expect that by joining this experiment they will get better prices for their teas, but most buyers are keenly alive to the importance of purchasing in the cheapest market, and it is unlikely that an artificial rate of profit can be maintained. It must be refreshing to buying brokers to know that their presence at these sales is tolerated, especially in depressed times, when they have often proved to be the backbone of the market, as other important operators are content for the moment to fill the role of spectators, whilst upon buying brokers the principal burden has fallen of carrying over stock and taking their chance of selling it later with commission only."

At the conference held last week at Brighton of the Federation of Grocers' Associations, Mr. Collis Clark proposed the following resolution on behalf of the Metropolitan Association:—"That in the opinion of this conference the proposals which have recently been made to hold private auctions for tea sales, and so to establish a private tea exchange, is undesirable, and appears to be an attempt to bring about a corner in tea." Mr. Palmer Bryant (London), in seconding the resolution, said he did not think they had anything to fear from the scheme. He believed it would die out very shortly. The resolution was carried, and the Secretary was instructed to forward a copy to the Tea Brokers' Association.

The French Government has again postponed the application of the law of February 24th, 1901, which provided for the imposition of the French maximum tariff on foreign colonial produce. This latest postponement is to February 23rd next.—*H. and C. Mail*, July 12.

THE UNITED STATES TO RAISE THEIR OWN COFFEE.

The United States is a wonderful country and Americans a wonderful people worthy of their origin but there are some things that cannot be done, not even by electricity, and one of them is to grow coffee

on the sea. We do not know to a nicety what the area of the American "possessions" suitable for coffee growing may be, but are willing to risk a guess that, even with Cuba thrown in, it would not reach a quarter of what is already under cultivation here. There is, of course, the resource that we refer to in another column of building plantations out on trestles into the sea, but short of that, however anxious Americans may be to raise everything they consume within their own borders, it is impossible just at present. Besides, why be in a hurry? Is it not written that, in the fulness of time, when American markets are surfeited with their own products and the power of the Trusts is waning, Americans will enter on the fulness of the vast inheritance reserved by Monroe and annex South America in a lump with Brazil and her coffee plantations, all ready made, without any complicated engineering at all? Meanwhile, why alienate the sympathies of a possible possession by so cruelly usurping functions so alien? Let Brazil grow her coffee and sell it to the beneficent protector of South Americans—at a price—and be thankful it is no lower.

No doubt the programme of raising everything you consume is attractive enough to some minds, but, unless it can be completed by consuming all you raise, it has its weak points. It is all very well to assert that, come what may, decrepit Europe must take the States' produce at any price; but, if Europe is to go on buying without selling, she must soon have nothing left to buy with and be bankrupt, when we suppose the U. States would supply everything gratis, out of pure philanthropy. All the same, Brazil has a few advantages in the coffee line that defy competition and will enable her, in the expressive American vernacular, to lick not only the States, but the whole creation. Every time more Revenue is required, or a commercial treaty with this country is involved, pressure is brought to bear and Brazil warned of the awful consequences that obduracy may entail. Its undisguised official origin is sufficient this time to show that, like its predecessors, the present is but another attempt to bluff reluctant Brazil into reciprocity. We can see no use or advantage in so tying our hands. No commercial treaty would prevent Americans from cultivating coffee in their "colonies", if it pays; and, if it doesn't, we require no treaty to give currency to our products in the States; because, if as they are so fond of saying, Europe cannot do without their cereals, the States cannot do without coffee, and in that particular line we boss the show!—*The Brazilian Review*, June 18.

GERMANY AND SPAIN; AND FERNANDO PO.

THE RIGHT OF PRE-EMPTION ACQUIRED.

(London *Times* correspondent.)

Berlin, July 10.

The report of the acquisition by Germany of the right of pre-emption of Fernando Po is confirmed by the *Coloniale Correspondenz*, which states that the agreement in question was made while the former Conservative Ministry of Senor Silveira was still in power. The value of the island, according to the same authority, consists in its cocoa and coffee plantations. These, which at the present moment are about 140 in number, are in the hands of half-breeds, Spaniards, Englishmen, and in some cases Germans. The trade is concentrated in the port of Santa Isabel, and is carried on almost exclusively by Spaniards and Englishmen. The British firms of Holt and the Amba Bay Trading Company have each an establishment at Santa Isabel, with branch offices on the coast. At present almost all the goods imported

come either from Spain or from England, but it is hoped that German goods will find a market if they are once introduced. A "Fernando Po Committee" is being formed in Berlin for the purpose of promoting German trade and of directing the attention of German manufacturers and merchants to the commercial possibilities of the island.

**A BOER PRISONER—EX-JAVA PLANTER
—ON COFFEE CULTIVATION.**

SIR,—Having, from past experience of tea and coffee planting in Java, always retained a strong interest in these important branches of tropical agriculture—I could not help noticing in your issue of the 16th instant the article, "Wynaad Planting Notes" and the reprint from the *Ceylon Observer* headed "Coffee in Brazil." What struck me more particularly in the first-named article was the reference made therein to a seemingly enthusiastically advocated system of leaving coffee plantations (old ones, I presume) unweeded. "Weedy" gardens must be detrimental to the production of the crop. This at least is my experience both in Java and Sumatra, while during a visit in 1895 to an important coffee-growing district in Mexico I had ample opportunity to see the superiority of weeded over unweeded coffee gardens illustrated, and that under climatological conditions and nature of soil vastly differing from those of Java and Sumatra, Ceylon and, I should say, the Nilgiris as well. In Swaziland (South Africa) I visited a small coffee plantation, started by some enterprising Scotchman (but unfortunately guided by a West Indian planter of limited experience), where the three year-old trees were only fit to be pulled up by the roots, standing in almost a forest of weeds, and black and shrivelled up by the *Hemelleia vastatrix*. Although unacquainted with the state of the coffee industry in India, I should say that the words of the President of the State of San Paulo, as quoted by you from the *Ceylon Observer*, might be studied with advantage by "Herobollollos." To "give no attention to fanciful measures that can effect no real remedy and only make things worse," is sound advice to coffee planters in every part of the world, where the enormous output of the Brazilian article threatens the very existence of the local industry, a danger only to be warded off by studying quality rather than quantity, and which so far has enabled Java coffee planters to maintain their foothold, and prevented their being swamped by the ever-increasing flood of the Santos article. While in charge of the Java exhibit at the World's Columbian Exhibition in Chicago, during 1893, I noticed the strenuous efforts made by the Ceylon Tea Growers' Association for the capture of the American markets, and which I saw repeated at the Brussels Exposition in 1897. The brazen audacity of modern advertising speaks volumes in this revolution of the world's tea markets, which towards the end of the first half of the 19th century was still in the hands of the Chinese and Japanese. Let us hope for the honour of the civilised

world's palate that the tea history does not repeat itself in the future of coffee; for in that case we may expect to see some day the Liberia coffee holding the same position in the civilised world over the coffee Arabica which Assam tea holds at present over the Chinese article—and why not, with these respective articles running on almost parallel lines. The Liberia coffee has more body and less flavour than the Arabica, and the same qualities hold good in the case of Assam *versus* Chinese teas. However, Arabica will last our day, and I think that I am expressing the spirit of our times when I exclaim, *Après nous le déluge!* This deluge, however, might arrive a little "too previous" at those plantations which indulge in "weedy gardens,"—*pour revenir a nos moutons!*

THE INDIAN TEA TRADE IN 1900.

MR. J. E. O'CONNOR'S OFFICIAL REVIEW.

To producers and all concerned in the trade, the year was one of anxiety and depression resulting from the decline of prices to a level much lower than the lowest ever before touched. The statement appended of the prices realised at the public sales in Calcutta illustrates the depth of the descent (annas and pies per pound):

	Or. (& bro or.) pek.	Bro. pek.	Pekoe.	Pek. fans.	Pek. sou.	Bro. sou.	Average.
1895-96..	11-1½	9	7-3 4/7	6	5-11	5-6 4/5	8-9
1896-97..	9-11½	8-7½	6-9 9/10	5-9½	5-5½	5-3 5/6	8-8
1897-98..	8-9 5/8	7-5 5/7	6 0¼	5	4-10½	4-6½	8-5
1898-99..	8-1 2/5	7	5-8	4-8½	4-7	4-3 3/7	8-1
1899-1900	7-9 1/10	6-9½	5-8½	5-2½	5-0½	4-11	8-3
1900-01..	7	6	5	3-11½	4-1½	3-9½	7-11

While prices were falling so heavily, the imposition of the additional duty of 2d a lb in April 1900 on tea imported into the United Kingdom also filled the minds of producers with dread that the additional cost to the consumer would have the effect of reducing consumption, and the alarm was revived towards the end of the year when it was rumoured, but untrue, that the duty was to be increased. The fall in prices reduced profits on all tea estates so materially that dividends were paid to shareholders in but few cases and then on a very reduced scale. The reduction of prices was the consequence of overproduction, that is, of production expanded in excess of the expansion of consumption in the strictly limited market which now exists for Indian and Ceylon tea. According to the returns made by the owners and managers of tea estates for 1900, it appears that in the five years ending with that year about 107,000 acres were added to the area under tea in India, being an increase of about 26 per cent. This area, in full bearing, can produce at least 40 million pounds of tea. Unfortunately, while reduced prices were the consequence of over-production, they also became the cause of the continuance of over-production, for, to compensate for the fall in prices, as much leaf as possible was taken from the plant, and the quantity was increased

at the cost of the quality. This operation again, by lowering the quality, had the effect of maintaining and accentuating the fall in prices. It is not intended here to tender advice to producers in respect of their own business, or to join in the lively controversy on the merits of "coarse" plucking *versus* "fine" plucking. It is only intended to record the conclusion that, when prices fell because tea was produced in excess, the fall induced directors to endeavour, by further increasing production, to continue dividends to shareholders, and that this endeavour to increase quantity was inevitably attended by a reduction in quality, the combination of the two bringing about a further fall in prices. The obvious inference is that the remedy is inefficacious, and that the quantity produced must be proportionate to the consuming capacity of the market which the tea enters. Either the market must be enlarged, or that area in which tea is produced at the greatest cost, whether by reason of the nature of the soil or of the remoteness and inaccessibility of markets, must necessarily be abandoned and some of the existing tea estates be thrown out of cultivation. The extent to which the supply of Indian and Ceylon tea has exceeded the demand is thus presented by the well-known London brokers, Messrs. Gow, Wilson, and Stanton, in a recent circular (lb):

	Imports.	Consumption.	Excess.
1895 ..	233,834,519	227,806,249	6,028,270
1896 ..	253,141,438	246,607,478	6,533,960
1897 ..	268,865,989	261,875,872	6,990,117
1898 ..	276,437,473	279,031,828	-2,594,355
1899 ..	302,590,293	288,695,931	13,894,362
1900 ..	334,072,942	314,230,316	19,842,626

It appears from these figures that the quantity thrown on the market during these six years has exceeded the demand by over fifty million pounds, and that the excess of the last two years has been quite remarkable, amounting to 33½ million pounds. As the firm who issue the figures justly observe, there is in this excess supply "abundant reason for the present severe depression in price." If nine-tenths of the Indian and probably a similar proportion of Ceylon production are sent to the United Kingdom, and if the exports increase as they have done from year to year for the last ten years, it is not easy to see how a further fall in prices can be avoided. There is no circle of people in the United Kingdom to whom the advantages of drinking tea are unknown, and it is probably not going in any way beyond the facts to say that every person in the British islands who desires to drink tea can and does obtain of it as much as he or she wishes to consume or can safely consume. It is indeed likely that some, women especially, drink more tea than is good for them. No material expansion of consumption can therefore be looked for amongst the population of those islands beyond that which is the consequence of waste when the article consumed is very cheap, and that which follows the annual increase of population, but the rate at which the population increases is far slower than the rate at which the production of tea increases. For a material increase in consumption, therefore, the Indian producer must look to the further exclusion from the British market of the remnant—some 35 or 40 million lb.—of non-Indian (or Ceylon) tea still taken in that market. He must also depend upon the capture of markets other than that of the United Kingdom. Some progress has been made

in this direction, but it is not flattering to our self-esteem to find that in this campaign the producers of Ceylon have made much more headway than Indian producers. The following figures are quoted from a circular issued by Messrs. Gow, Wilson, and Stanton last month, in which they printed a table to show the expansion in foreign and colonial markets of Indian and Ceylon tea:

	Indian.	Ceylon.
1896 ..	19,226,789	23,222,434
1897 ..	22,440,687	29,074,498
1898 ..	25,892,985	36,353,643
1899 ..	29,651,933	38,778,595
1900 ..	33,566,241	49,255,833

It appears then that the increased consumption of Indian tea in markets outside the British islands between 1896 and 1900 was over 14 million pounds, but the increase of exports from India in the same years was over 41 million pounds. The principal consumers in these markets are:

	million lb.
Australia ..	9.58
United States and Canada ..	6.96
Turkey and Persia ..	7.71
Germany and Russia ..	5.58
South Africa ..	1.27

The owners of Indian tea estates, while striving to gain possession of such markets as these, also recognise, somewhat late in the day, the importance of creating a market in India and in the countries across the Indian frontiers. They have sent a small venture overland from Quetta to Seistan, and are considering arrangements to place packets of tea for sale in the bazaars of Indian cities, at railway stations, and other places where consumers are likely to be found. As these arrangements will be undertaken by an enterprising and substantial mercantile firm in Calcutta, there is reason to anticipate that the business will be done in a manner to deserve success.

The exports of tea have expanded without a pause since 1893-94.

	lb	R
	(000 omitted)	
1893-94 ..	126,332	6,58,58,355
1894-95 ..	129,099	7,55,57,447
1895-96 ..	137,710	7,66,48,887
1896-97 ..	148,908	8,12,45,480
1897-98 ..	151,452	8,05,86,233
1898-99 ..	157,471	8,04,48,038
1899-1900 ..	175,038	9,09,21,120
1900-01 ..	190,305	9,55,09,301

Last year's exports were directed as follows:—

	lb
	(000 omitted)
United Kingdom ..	166,171
Australia ..	10,439
Turkey, Asiatic ..	3,240
" European ..	618
Persia ..	2,429
Canada ..	1,725
Hongkong ..	1,143
Germany ..	838
Russia ..	772

These are direct exports as declared in India and do not include re-exports from the United Kingdom.

RUBBER SUBSTITUTE.—The following appears in the American Rubber paper:—For Sale, the American patent of a new substitute (floating, white) superior to the best on the market, and already appreciated in Europe. Enormous profit for the manufacturer. Address Substitute, care of the *India Rubber World*.

THE "SHOT-HOLE" BORER. ADVICE TO THE PUSSELLAWA PLANTERS.

WHAT THE GOVERNMENT ENTOMOLOGIST THINKS OF
THE PEST.

At yesterday's meeting of the Pussellawa Planters Association, Mr. E. Ernest Green, the Government Entomologist, attended and gave the members some valuable information regarding the "shot-hole" borer, a beetle which does damage to tea plants.

The CHAIRMAN (Mr. G. C. Bliss) said Mr. Green had been making extensive enquiries regarding the "shot-hole" borer, and his information would be valuable to planters. The pest was undoubtedly one of the most serious that attacked the tea plant, and he had offered Mr. Green opportunities of studying it on the Atgalla estate.

Mr. GREEN said the insect was a minute beetle known to scientists by the name of *xyloborus fornicatus*, and belonged to the family of scolytidae. It was popularly known as the "shot-hole" borer. He had known the pest in question for about twelve years in the Nawalapitiya district and probably all those present were well acquainted with it. They would see from the specimens of tea trees that were on the table that the beetle bored holes in the wood, which very much resembled a single shot. It seemed to affect the tree from the top to the bottom practically. Its *modus operandi* was to commence from the base and go on to one of the branches; it almost went through the branch, and then took a spiral turn round which girdled the branch just above where it went in. It then went back and made another girdle below the original circle. The object of the beetle was to choke the flow of sap and enable it to go on breeding without having too much moisture. The way that it had affected whole fields showed that it had been going on for a very large number of years. It was very difficult to do anything with it when it had got to that stage. If it was noticed in the beginning, the way to treat it was by cutting and burning the prunings. Where the beetle had affected the whole field, of course, to prune would not be worth while, as it would be necessary to practically hack the bush away; he thought the best thing to be done under such circumstances was to leave as much bearing weight as possible and to stimulate the tree by manuring, producing more sap to counteract the effect of the beetle. In fields where the beetle had only just appeared it certainly should be possible to control it by cutting down below the place wherever the beetle had been, and carefully collecting and burning the clippings. It would be a great pity in young clearings to let the thing get a hold from the commencement. It was absolutely necessary to burn the clippings. Their Chairman had very kindly consented to undertake any experiments that he (Mr Green) might suggest; it was, however, more or less working in the dark, excepting that they would have to try all sorts of things likely and unlikely. Probably they would have to try and find some deterrent which would render the bushes more or less obnoxious if attacked after pruning, and he proposed experimenting in that way. He would put the result of what would be done in black and white for the benefit of the planters, and he hoped to be able to himself find the time to supervise the experiments and see how they were going on. His main object at present was to point out the gravity of the pest. When it had got to the stage in which it was at present on many fields they never knew where it would stop. After pruning, they would find that a certain number of the branches did not throw out any shoots, or at any rate they were very much retarded and might appear a month or six weeks after the main part of the bush. That was because of the beetle, and they could easily see that there was no limit to its ravages. It had thoroughly infected the estates around Nawalapitiya and Gampola, and it had also appeared sporadically on one or two estates up-country. Many

people had an idea that it had got into the estates from the grevillea trees; he (Mr Green) had examined those trees and came to the conclusion that it was much more probable that it had got into the grevillea trees from the tea. With the assistance their Chairman had been good enough to offer, he hoped to be able to do something. (Hear, hear.)

Mr. Green produced specimens of the male and female beetles, which were examined with interest. The beetle was allied to the true weevil, but it had not the long snout. The weevils were very dangerous, but as a rule they preferred dead wood to any other. The shot-hole borer unfortunately, preferred the half-living wood, for, as soon as the branch was absolutely dead, it seemed to desert it, or at all events did not continue to breed in the dead wood.

Mr. CHRISTIE enquired whether the beetle was able to fly and whether it did fly.

Mr. GREEN said the female insect flew about, but the male insect had no wings. The male insect was very much smaller than the female.

Mr. CHRISTIE asked whether Mr. Green would recommend the prunings to be burned green, or would it be sufficient to burn them afterwards, as there was, of course, a difficulty in burning the green prunings.

Mr. GREEN said it was most important that the prunings should be burned as soon after being cut as possible. It would be a great mistake to let the branches dry, and if the branches were only scorched when green and not entirely consumed, it might be enough. He had made experiments to try and attract the beetle by light and also with a preparation of alcohol, but the only result was the inebriation of ants. (Laughter.) It was a very bad night for the experiment, as there was a very bright moon and few insects were flying about, and as he did not consider it by any means conclusive, he meant trying again under more favourable circumstances.

The CHAIRMAN thanked Mr Green for the information he had given the meeting. There was no doubt that the shot-hole borer was a very serious pest, he would say the most serious pest that they had. The best return they could make to Mr Green for his kindness in attending the meeting and giving them information as he had done was to thoroughly try every suggestion that he made, and thus cooperate in the attempt to exterminate the pest.—Local "Times," July 26.

A BOOK ON MOSQUITOS.

Dr. Howard, Chief Entomologist of the United States Department of Agriculture, has published a book on Mosquitos, in which the fly and the remedies to be used against the infection of malaria and yellow fever are fully treated. It is published by McClure, Phillips, and Co, New York.—*Globe*.

QUININE-INJECTIONS.—M. Emery-Desbrouesses reports that during the Madagascar expedition the military physicians found themselves frequently obliged to administer quinine hypodermically to soldiers with fever. It was found, however, that patients who had received the injections of quinine developed tetanus. The injections had been made in the limbs, and were then ordered to be made under antiseptic conditions in the abdomen and sides, with the result that no further case of tetanus was produced. These facts suggest that tetanus may have a non-microbic origin, the cause being probably aneuritis, due to irritation caused by the quinine solution.—*Chemist and Druggist*, July 13.

TEA, RUBBER AND CLOVES IN THE STRAITS.

A resident of Malacca, on a visit to Singapore, states that the tea industry is making headway there by leaps and bounds. It is now just over nine years ago since the first seed was planted upon the soil of the Peninsula, and the enterprise of those who have pioneered the country has been well rewarded. The area under cultivation on one estate is 500 acres. Tea, together with para rubber and cloves, which have a great future before them, will soon, it is said, form important items of export from Malacca. Already, four thousand pounds of tea a month are exported, and the demand for the leaf is growing.—*I. P. G.*, Aug. 3.

YIELD OF TEA PER ACRE IN CEYLON.

The question has been asked us by Mr. Bamber:—Is the average yield of tea in Ceylon per acre increasing or diminishing? It is not easy to find out exactly; but if we begin with 1896, the export of that year of 108,141,000 lb. must have come from about 273,000 acres, making an average of 396 lb. an acre; in 1897 our crop was 116,054,000 from 288,000 acres, giving 403 lb.; in 1898, we find 305,000 acres giving about 120 million lb., or very close on 400 lb.; then 1899 we had very nearly 130 million lb. from 330,000 acres which again works out as nearly as possible to an average of 400 lb.; while last year our crop of 148,431,000 lb. must be reckoned as from 350,000 acres which would give an average of 424 lb.—so that manure has not done much more than maintain the average for the past five years, and evidently “fertilisers” will be required to keep up a large number of the older plantations especially.

PLANTING NOTES.

RUBBER.—The “India Rubber World” has been applied to, through the consulate of Salvador at New York, for information bearing upon the suitability of the Ceara rubber tree for cultivation in that republic. A late issue of the Salvador *Boletim de Agricultura* prints an advertisement of Ceara rubber seeds for sale in San Salvador, and also mentions the planting at San Miguel of seeds of *Sapium biglandulosum*, an important rubber tree of Columbia.—*India Rubber World*, July 1.

ODONTOGLOSSUM CRISPUM PITTIANUM—is the name of the famous orchid, which was in flower at Mr. Horace Pitt's place, Rosslyn, Stamford Hill, when last mail left, and has won the highest prizes at home. It was discovered three years ago by the agents of Mr. John Corder, the collector, in the Columbian Woods, flowered near London last year for the first time in Europe, and stands only second to Baron Schroder's anatum.

MANURE FOR TOBACCO.—Where wattle ashes can be procured, they are said to form an excellent manure for tobacco. Mr. J. M. Van Leenhoff, tobacco expert in Natal, states that they may be used for procuring a mild, good-burning tobacco. The ashes should be ploughed in very shallow, four or five months before planting.—*Queensland Agricultural Journal*.

THE REPORT ON THE GOVERNMENT HORTICULTURAL GARDENS, Lucknow, for the year ending 31st March 1901—does not contain much of interest to Ceylon readers; but we quote on fruit culture:—

The principal fruit crop in the garden (from a revenue point of view) viz. the mango crop, was almost a complete failure. Pine apples were fairly good. Nearly all sections of the citrus family did well, the Sylhet oranges and pummelos bore good crops of fruit; peaches and *alubukharas* were moderate crops, but *aluchas* were bad, *loquatas* were a light crop, while figs and *leechis* were fair crops. The seedling Malta orange trees again bore well, and a large amount of seeds was secured from the fruit and sown with the object of raising a good stock of seedlings, among which possibly new varieties may eventually be found.

CINCHONA BARK PROSPECTS.—Messrs. C. M. and C. Woodhouse report on 9th July, favourably, as follows:—

In spite of the temporary depression in the Quinine market, the present statistical position, taken as a whole, cannot be considered unfavourable. On the one hand, the exports of Bark from Java for first six months show an increase of about 1,100,000 Amst. lb. compared with last year, and 130,000 lb. compared with 1899, but this is probably more than balanced by decrease in exports from British India. It will be noticed that during the last three years the exports from Java during the last six months of the year have been nearly the same as a total, though they have differed very much month by month. They have averaged slightly over 1,000,000 lb. per month. The Stocks of Bark in London (which are now 11,107 packages, against 16,598 packages in 1900) were reduced by 7,600 packages last year between 1st July and 31st October. A similar reduction this year would not leave London with much stock. The Stock of Quinine is now slightly the largest of recent years, but as Importations since 1st January are 200,000 oz. less and deliveries 100,000 oz. more, it is evident that it runs compare more favourably with last year now than it did on 31st December. After all it only represents about three months of world's consumption, and in the absence of stocks of Bark it forms the only reserve to meet any extra demand that might arise. Consumption shows a marked increase this year, especially in United States, British India and Italy.

A COLONIAL GARDEN AT PARIS.—Do Englishmen appreciate Kew? What is certain is that foreigners envy them their superb botanical garden. The Dalham Gardens at Potsdam are probably known to German tourists, and an interesting brochure about the Kolozvar Gardens (Hungarian University) was distributed to the members at the Paris 1900 Botanical Congress. The Paris Jardin des Plantes is a small, starved affair. The Colonial Garden at Nogent-sur-Marne, near Paris, is a new and interesting experiment by the French Government. M. Dybowski, the superintendent, is an African explorer and an ex-director of agriculture in Tunis. Many interesting studies and experiments are carried out in his pleasant leafy gardens, near the Bois de Vincennes. Naturally there is a laboratory, to which any explorer from the French colonies has only to submit his specimens and a scientific analysis will be made gratis. The results may be exploited by the explorer, and the Garden does not interfere with his commercial rights. As a consequence of this, it is reported that two kinds of wood from the Congo were shown at the 1900 Exhibition, and examined by the laboratory. From these a new perfume is now made, which, if properly pushed and advertised, may be worth a fortune. We have Congo soap: why not Congo perfume?—*Chemist and Druggist*.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop, August-September delivery 1901; booking necessary before the end of April; quantities of 100,000 and over at special low rates. Plants available all the year round. 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 29th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year."

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery, 1901, booking necessary before the end of March; large quantities on special terms; Plants in Wardian cases.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter, in sending an order for this seed, wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Kickxia Elastica.—(*Funtumia Elastica*).—Seeds and Plants, orders booked. (Lagos rubber.)

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Urceola Esculenta and **U. Elastica.**—Same as above. (Burma rubber.)

Parameria Glandulifera.—Orders booked for seeds for January-February delivery; also plants; immediate booking necessary. (A good rubber creeper of Malacca.)

Landolphia Kirkii.—Seeds in July-August, early booking necessary. Plants can be supplied all the year round. (A highly-recommended species.)

Chonemorpha Macrophylla.—Seeds and Plants; orders booked. (A very valuable rubber-yielding creeper.)

Memusops Globosa and **Payena Leerii.**—Seeds and plants in July-August, booking necessary before April.

Achras Sapota, Willughbeia Firma, W. Edulis and other Rubber and Gutta Percha yielding Trees and Creepers, Seeds and Plants.

Cinnamomum Zeylanicum (Cinnamon superior variety). New crop of seed in April to June, booking necessary before the end of February; also plants.

Coffea Arabica, Liberian Hybrid and **Maragogipe Hybrid.**—New crop March-April; immediate booking necessary.

Cinchona Ledgeriana.—Seeds now ready, also other varieties.

Seeds and Plants of Nutmeg, Clove, Sandalwood (white and red), Pepper, Cardamom, Vanilla, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products of Foreign countries for 1901-1902, now being prepared, and will be ready in a few months.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Price List of Seeds and Plants for CEYLON use, post free, on application.

Our new Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms &c., Timber Trees, Trees for Avenues, Hedges, Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Orchids, Bulbs, Dracenas, now being prepared, and will be ready shortly.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

Agents in London :—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon :—E. B. CREASY, Esq.

Telegraphic Address :

WILLIAM, VEYANGODA, CEYLON.

Tropical Seed Merchants,

Lieber's, A.I. and A.B.C. Codes used,

HENARATGODA, CEYLON.

THE INDIAN TEA ASSOCIATION
(LONDON).

The following is from the annual report of the Association:—

The General Committee of the Indian Tea Association (London) have the pleasure to submit to members the following statement on the conclusion of the twenty-first year of its operations.

THE INDIAN TEA CROP OF 1900.

The estimate of the crop issued by the Indian Tea Association in Calcutta on September 8, 1900, which was based on the actual outturns of tea to August 15, 1900, was in round figures as given below, the final results being alongside for comparison:—

District.	Estimated. million lb.	Actual Crop. million lb.
Assam ...	66½	68
Cachar and Sylhet ...	60½	61
Darjeeling and Terai ...	10½	11
Dooars ...	23	30
Kangra Valley, Dehra Dun, Chittagong, Ku- maon, and Chota Nag- pore ...	6	6½
Private and Native Gar- dens, including those from which no returns were received ...	16	11½
	182	187½

Owing to incomplete returns, about five millions pounds of tea were included in the last item of the estimated crop which should have been added to the figures furnished for Dooars.

The crop of 1899 was 175 million lb, the increase in outturn last year being therefore 12½ million lb, exclusive of the tea produced in Southern India, of which no reliable statistics are obtainable.

GREEN TEA.

As mentioned in last year's report, a bonus of 1½ anna per lb. was offered to planters who were prepared to manufacture green tea for the American market, but the committee regret to say that few applications were received for the same, and it is not, therefore, as yet definitely ascertained how far tea of this description can be made in India to take the place of the China and Japan greens, now so largely consumed in America. A misunderstanding also arose in Calcutta as to the terms on which the gardens applying for the bonus were entitled to receive it, and the proposed 200,000 lb were not made. The offer of a bonus at the same rate has been renewed for the present year, and it is hoped that in view of the great importance which attaches to the securing of this outlet for Indian teas, more advantage will be taken of the offer.

The terms of the committee's resolution on the subject were as follows:—

"That 1½ anna per lb, up to a maximum of 200,000 lb to be manufactured this season, be allowed out of the funds of the levy on shipments of green tea to the American market sent there direct from India, such funds to be distributed as a bounty at the discretion of the Calcutta Committee, the definition of the term 'green tea' for the receipt of the bounty being taken to be tea made from the ordinary leaf plucked on the gardens such as would ordinarily be made into black tea, but which in its altered manufactured state would not compete with the sale of black tea in America or elsewhere.

The bounty to be paid on the same quantity as before sanctioned, viz., 200,000 lb, until it is seen what success is attained in the manufacture of green tea.

"The Association in Calcutta to be requested to notify the committee promptly if a larger quantity than 200,000 lb is likely to be specially prepared for shipment to America."

In a report furnished by Mr. William Mackenzie in connection with a recent visit to America, he says that of green teas and partly fermented Oologs and Formosas the imports are about as follows:—

	lb.
Green Japans ..	36,000,000
Green China ..	15,000,000
	<hr/>
	51,000,000
Oologs and Formosas ..	17,000,000
	<hr/>
	68,000,000 lb.

[Then follows Mr Mackenzie's statement as to winning the market for green teas, familiar to our readers.—Ed. C. O.]

To attain success, however, Mr Mackenzie recommends a syndicate being formed in Calcutta and another in Colombo, to take over the green teas manufactured, and to blend and pack the same in uniform and attractive packages, making regular shipments to one or more firms in America, so as to ensure continuous supplies of teas of standard qualities. The committee have advised that steps should be taken in Calcutta to carry out Mr Mackenzie's commendation.

It is essential also, the Committee consider, that Indian planters should make greater efforts to produce the class of tea required, which, so far, they do not generally appear to have succeeded in doing.

LEVY FOR 1901.

The large increase in the crops of British grown tea in 1900 has rendered it imperatively necessary that continued efforts should be made to find new outlets for the growing output, and as will be seen by the lately issued report on the operations in America and other foreign markets for the year ending May 31, 1901, it has been decided to call for a levy for 1901 on the same basis as in previous years, viz.:—4 annas per acre of cultivation and ½ anna per maund of tea manufactured, to be paid as usual in Calcutta, and the Committee earnestly beg that all interested in the welfare of the industry will subscribe to the fund.

WORK ON THE CONTINENT.

Mr. J E M Harrington, as mentioned in last year's report, was deputed to visit Italy, Turkey, Austria, and Germany to inquire as to the prospects for Indian teas in those countries, and the best means of increasing their sale. Mr. Harrington afterwards visited Belgium, and extracts from his reports are annexed:—The tea rooms in Rome, which were subsidised on Mr. Harrington's recommendation, have since been successful in enlarging their sphere of operations, and branches have been opened by the proprietors in Florence and Naples, where a taste for Indian teas appears to be developing. The question of opening tea rooms in Berlin and Frankfort is now under consideration, as well as the establishment of an agency in Antwerp.

The committee have come to the conclusion that now is the time to make a strong effort to develop the market in Russia for Indian teas.

Messrs W J and H Thompson in their last annual report point out that Russia is a most hopeful market; "because it requires black tea, appreciates quality, and is taking more from us every year by direct importation, or from London; it, too, is calling for better tea."

The committee are now in negotiation with an agent who has been in the tea business for many years, and who, it is thought, will prove a good medium for carrying out the measures which may be considered desirable in order to push the sale of our teas in Russia.

TEA SAMPLES BY POST.

Further correspondence has taken place between your committee and the Postmaster-General on the subject of permitting samples of tea to be sent by the sample post in hermetically sealed tin boxes so as to fully preserve their condition. Unfortunately, it appears that the department is precluded under the conditions settled by the last Congress of the Postal Union, which met at Berne, and which will not reassemble until the year 1903, from allowing samples of tea to be sent at the sample-post rate of postage, except when packed in such a manner that the contents can be examined. The Postmaster-General has therefore been asked to take the earliest possible opportunity to get this particular rule amended.

DOCK TRUST FOR THE PORT OF LONDON.

As was mentioned in last year's report, it was considered advisable, in the interests of the tea industry, to support the opposition to the proposals of the dock companies, and a donation of £10 10s. was given to the London Chamber of Commerce towards the necessary expenses. The Royal Commission appointed to consider the whole question of dock accommodation for the Port of London is now engaged in taking evidence on the subject.

PRIVATE AUCTIONS

Importers having been approached by the buyers with a view to the restriction of the publication of prices realized at auctions, a meeting was held on December 11, 1900, to consider the question. It was then suggested that the printing of garden marks in the catalogues might be discontinued, but this proposal was not approved of by the Association.

Afterwards a proposal to establish a Tea Exchange was put forward, and a meeting of the committee was held to discuss the matter on April 23 last. Considerable divergence of opinion was found to exist on the subject, and no decision was come to.

As an outcome, however, of these proposals, some importers, with a view to meet the wishes of the tea buyers, expressed their willingness to the experiment of offering their teas at private auctions, and the Tea Brokers' Association was asked to draw up rules for holding these. These rules have now been formulated, and the first sale under them took place on July 4, when a quantity of Ceylon tea was catalogued.

[Reference is also made in the report to the following subjects, all of which have been fully dealt with in our columns during the past few months—Reduction of output; the import duty on tea; the Labour Bill; Consular reports on the position of the tea trade in various countries; Indian tea at the Paris Exhibition; regulation of sales; and tea statistics.]

TEA BLIGHTS, &C.: THE DISTRIBUTION OF FUNGI SPORES.

A USEFUL SCHEDULE FOR OBSERVATIONS.

The following schedule of observations to be taken by the co-observers in the tabernacle experiments, planned to gain information as to the distribution by wind, insects and other agencies of spores of parasitic fungi, has been issued from the Scientific Department at Peradeniya Gardens:—

The Mycologist, while wishing to reduce the amount of trouble taken by each observer, will be glad to receive as complete answers as possible. If the terms suggested in the footnotes only are used the comparisons of the observations at the different stations will be simplified. When convenient the returns should be sent to Peradeniya next day, so that the diseased leaves can be examined with little delay. All the diseased leaves should be sent unless too bulky, when they should be weighed and the weight sent, with as many of the leaves as possible. The tabernacle should be kept closed and only the kangany or cooly who is to pluck the bushes admitted.

Name of Estate; Date of Plucking; Weather Conditions (very wet, rainy, no rain, no sun, sunny, hot sun); Wind (no wind, little wind, variable, constant wind, strong wind); Weight of leaf plucked from enclosed bushes (green); Approximate number of bushes from which the diseased leaves came; Conditions of nearest bushes on north side of tabernacle; Condition of nearest bushes on south side of tabernacle; Does the flush on enclosed bushes fairly agree with the rest of the field? Remarks or Observations.

[The tabernacles are all erected or will be by the end of September. They are at various heights from 50 to 5,000 feet above sea level and in various districts in which the areas over which the wind has passed is different. Nothing has been done to solve some of the knotty questions as to spore distribution by wind, heretofore, and as this has a most important bearing on the spread of diseases caused by parasitic fungi, all knowledge gained by these experimental screens will be valuable.—ED T.A.]

PEARL OYSTER INSPECTION.

Captain Donnan's last inspection was a very full and exhaustive one and his Report is now published in a Sessional paper, the summing up of which runs:—

The result of the inspection may be summed up thus. There are nine pearl banks with oyster beds on them aggregating 8,338 acres in area, and estimated to contain nearly 543 millions of oysters, most of which have survived their first year on the beds, which is the most disastrous period to young pearl oysters. Of the nine banks the two chief and largest ones, the Cheval and Mutuvaratu, attract the most attention. Both of these banks are now largely stocked with young oysters, and judging by their present condition they ought to be capable of giving two large fisheries in succession each, the first one coming off in March 1903, by which time the large number of oysters now estimated to be on them will no doubt be much reduced, probably by half. Of the remaining seven minor banks the Periya Paar Karrai, Kondatchi, Paar, Karaitivu Paar, and Alautura Paar may probably keep a due proportion of the oysters now on them until they arrive at maturity but the times remaining banks I have no faith in.

Captain Donnan concludes that rock fish running from 5 to 15 lb. weight each, are responsible for the destruction of young oysters. As regards the conservation and culture of oysters, there is the following interesting paragraph:—

A few months ago in Colombo I had a visit from Dr. H. Lyster Jameson, Fishery expert, on his way home from Conflict Group, British New Guinea, where he had been studying the subject of pearl oyster cultivation on behalf of a London Company, which had sent him out for that special purpose. Dr. Jameson told me that the oyster he had to deal with is commonly named the black lip, a different class of oyster to that of the Gulf of Mannar, but he had no doubt the system of cultivation or preservation that would suit the black lip oyster would also be found suitable for the Gulf of Mannar oyster. He also said that after studying the question for some time, he had come to the conclusion that the only successful way of dealing with the black lip oyster would be by placing the young oysters in baskets made of wire meshing, of a suitable size of mesh, and then placing the baskets on the oysters' natural beds and keeping them there until they were old enough to be able to resist attacks of their enemies; then to take them out of the baskets and lay them back on their natural home without the baskets. And he was of opinion that beds similar arrangement would be likely to prove the most successful in dealing with the Gulf of Mannar oysters. I quite agree with Dr. Jameson that his plan would be likely to prove quite successful as regards preserving the oysters, but I am inclined to believe that by the time such oysters came to yield a fishery, what with the cost of the number of wire baskets that would be required to cover the bottom of a pearl bank—say, half a mile square or more—the cost of a staff of boats and divers required to place the baskets on the bottom, and to take them up again after (say) two years, remove the oysters, and place them back again without the baskets, there would not be much profit left from the fishery. Mr. Jameson (who called upon us) had much the same experience as Mr. Savile-Kent. No doubt, Professor Herdman, F.R.S., who is coming out in charge of the Ceylon investigation, will inquire into all that has already been done off the Australian coast with a view to its bearing on the conditions found in the Pearl-oyster Banks of Ceylon.

PROPOSED 'TEA-GROWERS' ASSOCIATION IN LONDON.

THE MEETING OF IMPORTERS.

(Special Report.)

LONDON, July 19.

There was a meeting of some 20 of the largest Tea importers at Winchester House on 17th inst, to discuss a proposal to form an Association with a capital of £1,000,000 to protect Indian and Ceylon Teas in the London and other markets.

Mr. THOMSON of Messrs. Whittall & Co. was in the chair and briefly explained the scheme which was, he said, to regulate the quantity of tea for the Trade by purchasing any quantity in excess of actual requirements and holding the same—until required. Some discussion was begun by those present on the details of the scheme, when Mr. H. K. RUTHERFORD pointed out that it would be advisable, before they went on to discuss the details, that the meeting should come to a decision whether such a gigantic combination was necessary in the interests of growers at the present time. He said that, after giving the matter his

most careful consideration, he regretted he did not see how he could support the scheme. The present state of affairs solely hinged on the question of supply and demand, and he firmly believed, with the influences now at work, that supply and demand would become more evenly balanced in a shorter time than most of them seemed to think. The proposed scheme did not strike at the root of the existing evil; as it would still leave the surplus tea in existence and act as a drag on the market, whereas he contended, if a remedy was necessary, it could only be found at the fountain head and that was either in the non-production of the tea or the opening out of new markets, or a combination of both, and not in simply holding the tea off the market for a given period. Poor lands going out of cultivation would, he thought, counterbalance the crops from new areas coming into bearing; the unlikelihood of a favorable season taking place concurrently in India and Ceylon in 1900 and the expansion of new markets coupled with the severe lesson planters had learned from coarse plucking last year, would inevitably tend to bring supply and demand into closer relationship, and prosperity would return. This scheme, which was to protect the grower, instead of diminishing the output would have the tendency to increase it, as the proprietor with a non-paying estate would make as much tea as he could if he were assured of protection to even $\frac{1}{2}$ d per lb over the cost of production. We were undoubtedly, as had been pointed out by Mr Thomson, at the present time in the hands of the buyers, as regards the price of our teas. This was only the natural position, for, when there was an over-supply of a commodity, the purchaser had the seller under his control, but the position becomes reversed when the supply is not in excess of the demand. This altered situation was bound to come about in the tea industry in time, and we could not force that period by any such scheme as the one proposed as it did not permanently get rid of the tea. He concluded by saying that, once this crisis of over-production was over, which he ventured to predict was not far off, we would gradually enter a period of remunerative prices, and he did not think that in our time at least we would again suffer from over-production.

MR ALFRED BROWN said he regretted he could not share Mr Rutherford's views, and he also had given this matter a great deal of thought, and willingly hailed the proposal for the promotion of such an Association. The buyers had combined and were strong, and unless we also combined we would continue to be in their grasp even if there was no over-production. It would require a very great margin between supply and demand to make them compete and pay up for our teas. He asked how it was that, before we heard so much about over-production, indeed since 1890, the price of teas had gone steadily down, entirely in his opinion through the workings of the dealers' combination to keep down prices, and we would never be right until we put combination against combination. He certainly thought that some combination was necessary.

Mr. W. MCKENZIE pointed out that the gradual fall in the price of tea dated from the time of the packet-tea man, and that Lipton Ltd. made nearly the entire profit of their business out of tea, selling most of their other commodities

at cost, or under. He could not agree with Mr Rutherford in his opinion that Ceylon had practically reached its maximum production. Ceylon, if prices improved, could double its yield by manuring, so the question was a wider one than that of excessive areas of new land coming into bearing. With reference to green tea, there was an enormous field for their energies in America and Canada; but he regretted to say, while they talked of combination between India and Ceylon, the former had started to undersell the latter in green teas, and this, he understood, arose from India giving a higher bounty than Ceylon. This state of affairs should not be allowed to go on.

Mr. JAS. SINCLAIR said he would like to know if any one present could authoritatively say there was a combination among dealers or whether the low prices of our teas were solely due to excessive supplies.

Mr. MAGOR (Williamson and Magor) gave it as his opinion that what importers suffered from was the want of combination to give the trade the quantity required at the proper time. At one time of the year we throw thousands of chests at them, and sell regardless of price. At another time we have nothing on the market. He thought if an Association could be formed to "carry" the tea it would be a good thing, and he also thought it was necessary to have such an Association. He believed, if the great mass of importers came to this conclusion, then he was sure the money would be forthcoming.

Messrs. Macleod, Bryans and others spoke in favor of something being done, if not exactly on the lines proposed, in some way that would limit the offerings to the buyers.

It was finally decided to appoint a Committee of eight, four representing India and four Ceylon, to consider the whole question and report.

BRAZIL'S ECONOMIC POSITION.

TOO MUCH COFFEE.

The production of coffee in Brazil is so severely felt, says Mr. Consul Rhind in his report on the financial economic situation in Brazil, that a strong opinion has gained ground that a 20 per cent. reduction in output is necessary and that compulsory destruction of the crops to that proportion should be insisted on.

It is stated that the world's production of coffee now attains 16,500,000 bags per annum, while the consumption is only 14,500,000, the excess of 2,000,000 bags being attributed entirely to Brazil; and it is felt that this surplus should be done away with.

Happily, other action of a more practical nature has, in the meantime, been taken to relieve the agriculturists, in the form of reducing the railway freights and conceding extension of time for foreclosure of mortgages on agricultural estates. The improvement in the valuation of Brazil's fiduciary currency by the recent funding operations is incontestable, and the appreciation attained, in combination with the system applied in the collection of duties, more than balances, from the importer's point of view, the additional gold taxation now imposed. In demonstration of this fact the following table may be instructive.

It is intended to show the relative cost in milreis of a parcel of goods invoiced at £5 and paying duties to the amount of 30 milreis at the higher exchanges of the present time, as compared with the local cost of a similar value at the time when the Funding Loan was arranged.

Year.	Rate of Exchange per Milreis.	Currency Value of £5	Proportion of 30 Milreis Duties Payable in Paper.	Proportion of 30 Milreis Duties Payable in Gold.	Total Cost of £, with Duties of 30 Milreis included.
d	Reis.	Per cent.	Reis.	Per cent.	Reis.
1893	6	21 0/100	100	31 8/100	2308 0/100
1899	7 7-16	161 3/40	91	27 0/100	199 2/100
1900	8 1/2	137 1/40	80	25 5/100	156 4/100
1901	12 1/2	56 0/100	75	22 5/100	134 7/100

On a transaction, therefore, as here imagined, there would be, at the rate of 12 1/2d per milreis, a reduction of 95\$300 reis in comparison with the conditions prevailing in 1893.

Unfortunately the necessity for increased taxation has shown itself simultaneously with a great local depreciation in the value of the national produce, which depreciation, strange as the statement may seem, is in great measure due to the enhanced sterling value of the currency. It is not always realised that, although expenditure within the country has naturally to be liquidated in paper currency, the exports, which represent the marketable wealth of the community, are valued according to the sterling value on consuming markets.

Thus, a bag of coffee which, when exchange is at 6d per milreis, may be worth in London 30s, is still worth there only the same amount if exchange be at 12d, but locally the 30s represents 60 milreis when exchange is at 6d and only 30 milreis when exchange is at 12d. With the rise of exchange, therefore, the local value will have diminished by 50 per cent. This is exactly the position of coffee at the present time.

Altogether it is a trying time for Brazil, and there is a general absence of prosperity amongst the community at large.—*Sell's "Commercial Intelligence."*

"NIGERIA AND ITS TRADE"—is the subject of a paper in Murray's "Monthly Review" from which we quote:—

Practically speaking, the exports of Nigeria are confined to palm-oil and kernels. A little rubber comes out—there will be more some day, though at present Lagos holds the monopoly—but to all intents and purposes a little nut accounts directly or indirectly for the white man's presence in Nigeria. It grows beneath the curving fronds of a palm in clusters which, although it is not a very good simile, resemble a pineapple, and when detached it looks like a plum painted scarlet and saffron. Under the thin skin lies a layer of scented grease, which is scraped off, and boiled to extract the fibre, and the result is palm-oil, indispensable in many manufactures, and worth from £20 to £25 a ton. Then there remains a thin-shelled nut, which is cracked, and its two back kernels thrown into baskets, to be shipped by thousands of tons to Europe for oil-extraction. It is a simple process, for it must be remembered that the tribesman, who makes no attempt at cultivation, merely gathers what Nature lavishly provides, but it is probable that every few puncheons cost a human life. The possession of favourite native markets is periodically fought for, petty robber chieftains waylay the oil-carriers going down stream, or exact illegal blackmail, until an expedition is sent up against them, while the mortality among the white men who purchase the oil is very heavy.

THE TRAGEDY OF COFFEE.

We drink our coffee as a matter of course for breakfast; we sip it contentedly after luncheon and dinner; but never a thought passes through our minds of the tragedy that may lie in the accustomed cup. Yet many a brave British heart has been broken, and many a British life sacrificed in the struggle for the berry which we buy complacently from our grocer, and grumble over when, over-roasted or badly prepared, the beverage turns out too bitter for our taste. If our coffee be bitter, we ring the bell and the servant takes it away. If their coffee proves bitter they have to drink that bitter drink to the last dregs, waiting silently until death shall remove them out of the loneliness of exile and close their eyes to the hopeless wreck of all youth's golden dreams. They—those well-plucked British coffee-planters—have suffered defeat through no fault of their own. It was just the luck of life. They had to battle against Nature; Nature was too strong for them: she remained the conqueror. Woe to the conquered!

Most of the coffee consumed in the United Kingdom comes from Ceylon and Southern India. Five-and-twenty years ago Ceylon was practically ruined as a coffee-producing country. Men, who two or three years previously had been accounted almost millionaires, found themselves face to face with absolute poverty. This was due to the appearance of a red fungus called the "hemileia vastatrix," which wasted thousands of acres under coffee. The long and glorious records of the Empire hold no more splendid illustration of grit and iron determination than the final triumph of Ceylon over this overwhelming disaster. There was no wailing, no thought of retreat, but first cinchona cultivation was tried, then tea-growing, and new methods were introduced on the few surviving coffee plantations, until at last the tide turned, and prosperity reflowed, but in fuller flood than before. In South India the story of coffee growing reads the same, but with this difference. In the isle of spices the whole community suffered simultaneously, on the mainland individuals have fallen one by one.

Coffee and tea belong to the same natural order of plants, but, whereas tea is the easiest plant possible to cultivate, coffee is the most difficult. It needs a peculiar climate, one free from extremes of heat and of moisture. If too dry the shrub will not blossom freely, if too wet after a few years it falls an easy prey to one of the many pests that beset it. In India the virgin forest that clothed the Western ghats were selected. Young fellows with capital at their backs and enthusiasm in their hearts threw themselves gladly into the enterprise. The life was lonely but adventurous, and visions of fortune danced before their eyes. Only a few, a very few lucky ones, ever realised them. The forest soil was sodden with malaria. In the early days a mud hut, grass thatched, was the recognised planter's home. When the rains came, and for weeks the hills were enveloped in cloud and mist, he lived perpetually in sopping raiment. There was no leaving the work then, for it was the time for planting out. So in utter loneliness he shivered and sweated when the fever gripped him; no doctor within fifty miles; his next-door neighbour five miles away. He vainly hoped for better days. One would die before his capital

was half expended, another would live on till all his money was gone, his property mortgaged to the hilt. Then followed foreclosure. Perhaps he would receive a pittance to manage what he had formerly owned, or else the plantations on which his life's work had been spent, and to which health and fortune had been freely given, would be again swallowed up in the jungle. There are valleys in Southern India into which literally tens of thousands of pounds sterling have been poured, and from which not a dozen good crops have been picked. A more melancholy prospect than an abandoned coffee district can hardly be imagined, and the sadness of the scene deepens when it is remembered that every ruined plantation means at least one brave life broken in exile.

The contrast between a thriving and a deserted district is not a whit greater than between life and death. There is no happier prospect than a planting district in full working order. Every acre has been won labouriously, and at risk of death in the jungle. Until the European planter came, these acres of dark-green coffee bushes were the haunt of wild elephant, tiger and bear, and where to-day go up the sound of the healthful toil and the bright laughter of children, formerly the silence was only broken by the booming cry of the black monkey and the hideous laughter of the solitary jackal. The coffee planter has done well for the land of his adoption, cruel step-mother though she has often proved herself. He has created a new industry; he has given work at high wages to thousands who needed it; has practically populated the solitudes, drawing the people from areas already too thickly crowded—war against nature no less than war against man has its roll of martyrs, of victims, and of heroes, and the roll of coffee planting is brilliantly illustrated with many bright deeds of which the world has never heard and never will hear anything. The good work still goes forward in Ceylon and in South Africa, and has also now been extended to Central Africa. On the Shiré Highlands coffee plantations have been opened by Europeans, and there again the white planter is proving himself a true philanthropist.

Of recent years the coffee planter's life has been brighter. His bungalow nowadays is a pleasant brick house, embosomed in trees and surrounded by a garden. An epoch of prosperity, all too brief, enabled him to make himself comfortable. Many married. But there has been a return of bad times. Prices have fallen when the seasons have been good, and short crops have not raised them. Tragedy still lurks in those hospitable bungalows. Coffee is a bitter brew for many a planter today. He seldom grumbles at fate, though constantly at the weather. He fights on to the last without a thought of surrender, and when the end comes, leaves behind a memory of silent endurance and unflinching courage, which all who knew him love to cherish. Over the lintel of the coffee planter's bungalow might be engraved those lines from Kipling's sorrowful song of exile:—

"Oh, the toil that knows no breaking! Oh, the
heimweh ceaseless aching!

Oh, the black dividing Sea and alien Plain!
Youth was cheap—wherefore we sold it; Gold was
good—we hoped to hold it;

And today we know the fulness of our gain."
—Globe, July 9.

TEA CROPS AND MANURE.

It may be of interest to mention the imports and transport (by Railway) of manure, for the series of years corresponding to those for which we have reckoned the average yield of tea per acre. Taking the country as a whole, it is not easy to say on what particular crop, within one, two or three years, an application of manure has most effect. But for a rough comparison it will do to contrast the "manure" figures for any particular twelve months with the succeeding year's yield, thus:—

Average yield of tea per acre.		Imports of Manure.		Carried by Rail:	
		tons.			
1895 ...	396 lb;	12,487	7,213	1896 ...	11,576
1896 ...	403 lb;	10,874	8,431	1897 ...	12,745
1897 ...	400 lb;	14,200	11,126	1898 ...	20,341
1898 ...	400 lb;			1899 ..	
1899 ..	424 lb;			1900 ..	

It may be said that the increased yield per acre last year corresponded with an increased application of manure in the previous twelve months; but the most striking fact is the enormous increase in imports and carriage upcountry of fertilizers during the past year. With "fine plucking" following on "liberal cultivation," estates should continue in very good order for some time.

SUB-TROPICAL CULTURE IN QUEENSLAND. VITICULTURE.

The area under vine cultivation in Queensland last year was nearly 2,000 acres, showing an increase of about 300 acres on the two preceding years. To judge from the demands made on this department for cuttings this season, the area is being rapidly extended, applications for upwards of 8,000 cuttings in excess of last season having already been made. Fruit-growers are beginning to find out that a vineyard properly looked after is a paying undertaking, and that the demand for grapes exceeds the supply. If table grapes are sold at as low as 1d per lb., the return from an acre of vines is not less than £18; and if sold at 2d per lb., a common price, the return is £36 per acre. Wine grapes would return not less than £10 and turned into wine by the grower himself would realise much more. The cost of cultivation in both cases is about £3 per acre, if labour is employed. Much of the grape crop for 1899 was injured by frost, yet it totalled £3,230 627 lb. weight of grapes, which, calculating the value of the wine made from the wine grapes, has a total value of £46,000. Experiments are being carried on at the State farms with a view to establishing in Queensland one or more of the Almeria varieties; if successful, a large export trade in grapes to Canada and Great Britain would grow up. Experiments in currant growing and drying are being also carried on; the imports of currants into the State for 1899 were 1,636,185 lb., with a value of £13,646.

Some of the finest varieties of European wine grapes have been imported by the Department for propagation and distribution, which should eventually materially assist in improving the quality of Queensland wines. With regard to winemaking, we have a satisfactory proof that some of our vigneron appreciate the assistance given them by the Viticulturist, one winemaker having written to the Department to the effect that £500 a year had been put into his pocket by Mr. Rainford's services. Improvement in

the quality of table grapes and wine is evident, although in the latter case the result is obtained most slowly.

TOBACCO.

Since the last meeting of this Conference, an experiment farm for tobacco has been established at Texas, and 9½ acres of desirable leaf has been successfully grown, housed and cured. The varieties grown are those producing the favourite tobacco for the British and United States markets of the heavy pipe-smoking sorts. The results, so far, have been satisfactory. The industry is growing, and may be said to be in a fairly prosperous condition. White men are going more into the cultivation as they realise the value of the crop. New South Wales buyers have entered the market, and, if the product proves satisfactory to them, and there is every reason to believe it will, the future of the industry is most promising. It is to be regretted that an interest has not been manifested in cigar tobacco, as under federation, Sydney and Melbourne would give an outlet for considerable quantities and at a fair price. These tobaccos can be grown on many of the alluvial soils north of Brisbane, below the Range, the crop being suitable for both the large and the small farmer.

COFFEE.

In view of the great demand for coffee, and of the suitability of a large portion of Queensland for its cultivation, nothing has been left undone to place the coffee-growing industry on a sound basis, and to bring before the growers the latest and most effective methods of production. For years the Department scattered broadcast the best literature on the subject, and in 1899 appointed a most competent expert to give practical assistance and instruction to the planters, with the result that at present coffee-growing, though not conducted on a very extensive scale or in all the localities adapted for it, is one of the most prosperous of our industries. So favourable, indeed, is our seaboard from Rockhampton northward, so far as climate and soil are concerned, for the cultivation of coffee of the best kind, that Queensland within the next decade will be able to supply the coffee required for the whole population of the Australian Commonwealth.—*Queensland Agricultural Journal*, June 1.

JAMAICA ORANGES.

The "Fruitman's Guide" of New York publishes the following interesting figures on the receipts of Jamaica oranges in that city from September to March:—

Month.	Boxes.
September	12,700
October	51,200
November	105,200
December	19,300
January	4,700
February	800—193,900

This amounts to over 530 carloads, and indicates that Jamaica is quite a factor in the orange market, in spite of the tariff. The crop was a light one this year and under normal conditions with a lower tariff the island could easily put one thousand or even two thousand carloads of oranges into New York. Naturally the California orange grower does not enthuse over any reciprocity treaty that will increase imports from Jamaica.—*Cal. Cultivator in the Hawaiian Planters' Monthly* for June 1901.

ALOE: A NEW INDUSTRY IN SOUTH INDIA.

SIR,—It may interest your readers to know that a new planting industry is being opened up in our midst and one which may help the much distressed tea and coffee planters out of their

difficulties. I refer to Agave, or as it is commonly known Aloe, planting and the extracting of fibre therefrom on a commercial scale. A Syndicate has been formed in this Presidency under the designation of "The South Indian Fibre Syndicate" and the Manager has taken, on its behalf, for a period of years, all the aloe plants belonging to the Forest Department and the Local Fund Board along the various roads in the Anantapur District, in all perhaps some 300 miles. Probably, if all India were searched, no such extent of aloe hedging could be found, and therefore the concession is of priceless value to the Syndicate, for money could not purchase it in any other part of India, or it is simply not to be had. Further, it has secured through its Manager a grant of 20,000 acres of land for planting purposes. The Syndicate is now turning out fibre superior to anything that is produced by the Bahamas or Mexico, the two chief fibre-producing countries. I hear from a reliable source that a gentleman named Gribble has, on behalf of a Company at Home, offered to purchase the rights and property of the South Indian Fibre Syndicate for a sum of £60,000, and I should say, from all I hear, that the property is fully worth this or more to any Company in England with capital, and that they are getting a cheap bargain. I may mention that the fibre now being manufactured by the South Indian Fibre Syndicate has been reported upon by experts at Home as superior in every way to that received from other countries.

AGAVE.

—*Madras Mail*, Aug. 6.

PLANTING NOTES.

THE REPORT on the progress and condition of the Government Botanical Gardens, Saharanpur and Arnigadh, for the year ending 31st March 1901, shows that certain drugs—Colocynthis fruit, Kamela powder and extract or dried leaves of Hyoscymus—are given and supplied to the Indian Medical Department. Could this not be done in the same way in Ceylon? In regard to fruits and palms we quote:—

Seedling trees of the coarse stringy mangoes bore heavy crops in some of the groves in the district, but the crop carried by the choice grafted kinds grown in the garden was very light. Pears, figs, liches, loquats, peaches, country pears and country plums were somewhat better in yield; but in no single instance was the crop sufficiently heavy to be classed as good. Oranges, limes, lemons, and grapes all gave very light crops, and so very light in the case of the lime that considerable difficulty was experienced in collecting sufficient seed to meet the wants of our nurseries for sowing purposes.

Arabian Date Palm (Phoenix dactylifera).—The date palms, with some few exceptions, are making excellent growth, but the yield of fruit is still insignificantly small. Fruit of excellent quality was produced by 17 trees, but the bunches were all too small to be of any value for market purposes. The trees which were noted in the last annual report as having been treated to a cart-load of manure apiece threw out a magnificent crop of leaves, but those which fruited did not bear larger bunches of fruit than trees which were not manured. The manured trees are however without question stronger and healthier-looking plants than those which have not been manured, and are almost sure to respond to the manuring given by yielding larger-sized bunches of fruit within the next year or two.

"THE WAX-PALM OF BRAZIL"—referred to by a correspondent the other day—is thus noticed in the "Treasury of Botany":—

The Carnaüba or Wax-Palm of Brazil, *C. cerifera*, grows about forty feet high, and has a trunk six or eight inches thick, composed of very hard wood, which is commonly employed in Brazil for building and other purposes, and is sometimes sent to this country and used for veneering. The upper part of the young stems, however, is soft, and yields a kind of sago; and the bitter fruits are eaten by the Indians. The young leaves are coated with wax, called carnaüba wax, which is detached by shaking them, and then melted and run into cakes; it is harder than bees' wax, and has been used by Price and Co. for making candles, but, as no process of bleaching has been discovered, they retain the lemon-coloured tint of the raw wax. The leaves are also used for thatching, making hats, &c., and while young as fodder for horses.—A.S.

COCONUTS AND RICE IN THE SOUTHERN PROVINCE CEYLON.—Here is an interesting paragraph from Mr. Fowler's able Administration Report just received today:—

NEW AREAS OF CULTIVATION.—The extension of coconut cultivation progresses rapidly, and the sale of land affords a fairly correct index of the extent annually brought under cultivation. Tea planting is at a stand-still, and very little additional land has been planted with citronella. Most of the small lots are cultivated as gardens, and the total area of these is very considerable. A large extent of paddy land can be sold if the purchasers are allowed to buy under Sir Henry Ward's Minute, payment being made in four instalments, and I expect to be able shortly to submit applications. Mr Elliott has favoured me with some notes on his interesting experiment at Walawe, and it is pleasant to hear that experience has not affected his belief in paddy cultivation as a paying investment. He has found that working with hired labour, as on an estate upcountry, is impracticable. It is contrary to all Sinhalese traditions and customs. No reasonable wages would secure the services of the regular cultivators, and he could only get men who took no interest in their work. He then adopted the customary share system, and had then no difficulty in securing any number of the regular "goyas," and only the want of sufficient buffaloes has prevented him from securing a highly satisfactory return. Ploughs cannot be used on newly-opened land, and buffaloes, for which a high rate of hire must be paid, are indispensable. The area now under cultivation is nearly 500 acres, and the yield per acre was about 30 to 35 bushels. His experience shows that, exclusive of cost of land, a sum of 6 cents represents the working expenses in producing a bushel of paddy, including European supervision. As the price of paddy varies from Rs 1.33 to Rs 1.56 per bushel, the return on a large acreage is sufficient to justify Mr. Elliott's faith in his enterprise, and it may be hoped that the time will come when European capital will be largely invested in the production of rice waiting under so many restored tanks and channels. It is possible that in the Hambantota District cotton-planting may prove to be remunerative. On a circuit in that district in company with Mr. Brown, the Conservator of Forests, we found cotton growing apparently wild in the jungle and bearing freely. Mr. Brown took specimens of the pods which proved to be those of a cultivated variety gone wild. As the locality was far from any existing village of any importance, it must have been planted very many years ago, a proof that the soil and climate are congenial.

Correspondence.

To the Editor.

HOW TO CAPTURE THE UNITED STATES MARKET FOR THE TEAS OF INDIA AND CEYLON.

ADVERTISE—WIDELY AND BOLDLY.
MESSRS. P. C. LARKIN & CO.'S VIEWS.

Toronto, June 12th.

DEAR SIR,—We are enclosing herewith a copy of a letter which we have written to the *Home and Colonial Mail* of London, England, as we thought it might be of interest to your readers also.—Yours very truly,

P. C. LARKIN & CO.

(To the Editor "the Home & Colonial Mail.")

June 12th,

DEAR SIR,—I have been reading with a great deal of interest the many suggestions made by the friends of the tea trade, to bring that industry into a better condition than it has been in of late. I read with special interest the letter signed "Ross W. Hayter," and agree with everything Mr. Hayter says. In the first place I believe that the only cure-all India and Ceylon can find is in the conversion of the hundred million pounds of Japan and China Tea, used in the United States annually, to the consumption of the products of India and Ceylon. That this is feasible is beyond question, and is best evidenced by the progress that has been made in the United States during the past six or seven years, for I consider that wonderful progress has been made for the amount of money that has been expended. Surely the newspaper writers, who occasionally give expression to their unsatisfied expectations, can know little of business, and less of this Continent, when they expect such wonderful results (as they apparently do) from the small efforts, in the shape of expenditure, that have been put forth by these two tea-growing countries. No sum less than Mr Hayter mentioned, viz.—forty or fifty thousand pounds sterling per year, and continued for at least five years, can have the effect of converting this Continent to the use of Indian and Ceylon Tea. And to put this into the hands of an inexperienced man, and allow him to purchase his experience on arrival here, would be a great waste. The money should be given to a man with a wide experience. To give you an idea of what amounts are expended by single firms, who exploit much more insignificant articles than tea, we might quote what is a well-known fact among advertisers; and it is that the Royal Baking Powder Co. spends in the United States and Canada five hundred thousand dollars, or one hundred thousand pounds sterling, annually in exploiting "Royal Baking Powder"; and they have done it consistently for years, and have found it most profitable. In our small way,

IN CANADA,

we spend and have for many years past, an average of twenty-five thousand dollars per

year on newspaper advertising alone. In addition to this we expend large sums on sampling, showcards, street-car advertisements, demonstrations, etc., etc. Now, if we, in our small way, find this profitable (and the best evidence of the fact that we have found it so is that we are at it today, after nine years) how very much more profitable could the Planters of India find it, if they took the matter up in a whole-souled manner. Mr. Hayter suggests the collecting of one-sixteenth of a penny per pound on all exports from India, which would amount, roughly speaking, to about forty thousand pounds sterling per annum. This sum would be excellent, and, if continued for five years, would have a wonderful effect. But I venture to say that, if, instead of one-sixteenth, one-eighth of a penny was collected, the much desired state of affairs would be brought around much more quickly; for not only would the London market be relieved of an enormous quantity of tea in a few years, but I believe that the advertising would greatly increase the consumption of tea per head per annum in the United States. The vast majority of teas sold in the United States today are poor teas, and to an amateur it seems the easiest thing in the world to convert the consumers of this poor stuff to become consumers of good teas; but Mr. Amateur has only to try it to be convinced that it is by no means an easy thing. Getting at the people of the United States is a most expensive process, and it has to be kept up for a number of years before the desired object can be achieved.

In conclusion, I can only say that I agree thoroughly with Mr. Hayter that India has had wonderful results for the amount expended. This continent consumes now close upon twenty million pounds of Indian and Ceylon black and green tea per annum, as a result of a few years' work and only a moderate amount of money expended. If it is desired to increase this five-fold, increase the amount five-fold. There is no "royal road" to it. There is only the every-day road travelled by many, who, when advertising was first suggested to them, said they could not afford it; but they soon found that they could still less afford to do without it, and that advertising made them rich, always providing they had a good article to offer the public.

I might mention that in Canada the Ceylon green tea is meeting with the most wonderful success, and in a very few years it will have driven out ten million pounds of Japan tea entirely. Now I have seen some of the most beautiful green tea, the product of Travancore; and therefore the Indian planters can supply both black and green tea to the United States. The deplorable condition of the Indian tea market, I think, calls for fresh, vigorous efforts to be made to exploit the great market of the United States.

The India planters must go whole-souledly into this matter, or else the results will be as they have been before; that is, "small expenditure and only comparatively good returns." If you were to ask a man, who has successfully exploited any article in the markets of the World, what he would do if he owned the entire tea product of India, I feel sure his answer would be.—"I would exploit the United States market by advertising."—Yours truly,

P. C. LARKIN,

FARMING AND STOCK IN TRINIDAD:
OFFSPRING OF "CINGALESE"
CATTLE,

Government Farm, Trinidad, June 13.

(The Editor "Tropical Agriculturist.")

DEAR SIR,—May I ask you again to accept my Annual Report. I cannot say whether there is any matter of importance therein: simply that last year was successful, and that the department has been removed to much larger and superior ground and the work can therefore be widely extended.

The Cingalese bull has quite recovered from his broken leg and is as pugnacious as ever. Two calves have been born to him, altogether unlike the sire. They are marked like Alderneys, and I wonder whether these Cingalese are a distinctive breed or only dwarfed by inbreeding and environment. Every one is struck by the unsimilarity between sire and progeny. The bull was put to a well-bred red-poll heifer, first time. She produced a bull calf, a strong sturdy animal, but a nondescript showing no characteristics of either parent.—I am, yours truly,

C. W. MEADEN.

[We must ask Dr. Sturgess to give an opinion on the question raised by Mr. Meaden: we know of no records available to show how far back Sinhalese cattle have had their present distinctive characteristics. Mr. Meaden's Report is a very practical and satisfactory one, such as no doubt we shall be getting from the "Gangaroova Farm" by and bye. We make a couple of extracts of local interest and application and showing the good work done:—

The chief occupation during the year has been the transfer of the Farm from St. Clair to St. Joseph. The latter place will in time become an ideal farm. There is an extensive range of first-class land for stock, well-watered and laid out for irrigation. The work of the farm can be widely extended to the evident advantage of the colony. A fine set of buildings are in the course of construction. In acquiring this property the Government will be in a position to produce the meat, as well as milk, for the Medical institutions at a great saving. I have shown above that 384 lb. of meat was produced at a cost of \$4.80. This quantity at the present contract rate would cost \$28.80. If there were sufficient stock on hand to fulfil the institutions' demand for beef, a clear saving of \$7,000 per annum might be made in their expenditure. This is a question worthy of consideration, and whether it would not be advisable to spend a sum of money in the purchase of stock so that the supplying of beef might be speedily undertaken. This would not interfere with any private enterprise as all the money for beef practically goes out of the Colony. Another advantage to the Government would be that they would have a large reserve of cattle on hand in the event of a beef famine. Twice during the year, the Colony has had to face this though fortunately without great inconvenience. Quoting from the *Port-of-Spain Gazette* the following was stated—

"At present there is very little beef to be had, and on some days during the week the sales close

as early as noon. The larger and more important proprietors can boast of having a few head of cattle in their pens, but this is not so with the smaller proprietors who have to go a scouring all over the country, with much inconvenience and with little and in some cases no success."

Although Trinidad may never be a pastoral country still she ought to be in a better position as regards her meat supply. An enterprising firm introduced a first consignment of cold storage meat with apparent success. This would fill a certain demand, but would be of little service to the poor or country districts.

Altogether the sale of stock during the year realized \$3,727 60, and stock to the value of \$1,396 was transferred to the Tobago Farm. This with the production of 132,000 quarts of milk and leaving live stock in hand to the value of \$18,500, off about 150 acres of land, is, I respectfully submit, a record of a good year's work. A profit of 9.32 per cent was made upon the capital outlay.

At a time when "poultry" are under local notice, the following is of interest:—

Sale of poultry and eggs realized during the year £12 7s 3½d. The White Minorcas were disposed of. These fowls were unsuccessful: they laid a large number of fine eggs but generally they prove unfertile and any chickens produced died. The probability is that in a tropical climate their abundant egg-laying tended to weaken their fertility. The Silver Wyandottes have proved to be suited to the climate and soil and their introduction has been a success; they grow to a good size and lay well. Silver Dorkings were imported during the year and so far promise to make a useful addition to this branch of the Farm. Dorkings are well-known for their table qualities and their introduction will be useful.
Ed. T.A.]

THE REARING OF "HELOPELTIS
ANTONII."

(To the Editor of the "Tropical Agriculturist.")

Salatiga, (Java), 7th July, 1901.

DEAR SIR,—In reading the very interesting *Helopeltis antonii* sign., published in the *Tropical Agriculturist* of June, 1901, I was struck by the mention that Mr. Green was not able to rear up this insect from the egg to the adult. One year ago I also made some observations on *Helopeltis antonii* and I found that rearing up this insect is very easy, bringing up the freshly-hatched larvæ on young cacao pods, which are often renewed (every 1 or 2 days) and kept in closed glass-boxes. In doing so I could point out that the larvæ of *H. antonii* change their skin five times. The freshly-hatched larvæ are about 1 to 1.25 millimeter long, the process of the sentellum is visible, but only 0.2 millimeter long, while nothing at all is to be seen from the wing rudiments. After the first moult the wings are indicated, the hind edges of the meso and metanotum projecting slightly behind. After the 2nd and 3rd moult these rudiments become bigger and bigger, so that, after the 4th, they extend themselves to the middle of the length of the abdomen; and with the 5th moult the insect acquires its perfect wings. As to

the duration of the different stages I noted the following data :—

Egg stage	6 days
Until to the first moult	2 "
" second "	..	1-2 "
" third "	..	2 "
" fourth "	..	2 "
" fifth "	..	2-3 "
Total	15-17 days.

Not longer than two days after the insects were full-grown, they entered into copulation; and one day after copulation the females commenced egg-laying. Each female is able to lay about 30 eggs. In captivity I could conserve alive the adult insects during 4-6 days,—Yours very truly,

L. ZEHNTNER.

Salatiga, (Java), 7th July, (Cacao Experiment Station.)

[Mr. Green, to whom we showed the manuscript, thinks this a very interesting letter. He would like to know if the *Helopeltis* is found on tea in Java; and, if so, the experiment would be an interesting one to try if the tea insect thrived on cacao and *vice versa*.—Ed. T.A.]

THE DEMAND FOR PLUMBAGO IN THE UNITED STATES.

Jersey City, N. J. (U.S.A.) June 19.

GENTLEMEN,—You will remember the writer as Vice President of the Dixon Crucible Company. We receive every week your *Ceylon Observer* paper and you have our order for your "Ceylon year book," the particular book that is to have a detailed account of all the plumbago pits.

The question was raised some time ago in one of your numbers, in the correspondence of Mr. Peto, which was followed by an editorial from you, as to the demand for plumbago ceasing in the United States, or if not ceasing, of its being very much less. The enclosed editorials, one called "Tricks in Crucible Steel Trade" and the other called "Crucible Steel's Hard Struggle" in the 'American Manufacturer and Iron World,' one of the leading trade papers in the United States, bears on this question and will speak for itself. The condition of affairs as described in these editorials is somewhat overdrawn; nevertheless, there is a good deal of truth in them. You need not return these articles as we have duplicates here, and we submit them to you as more or less evidence on a topic that is vital to the plumbago industry of Ceylon.—Yours respectfully,

JOHN A. WALKER, V.P.

[The articles are from the "American Manufacturer and Iron World" and we make a few extracts :—

A correspondent calls attention to one of the tricks in the crucible steel trade, that of substituting open-hearth steel for the product made in the crucible. . . . For many years the "American Manufacturer" with many other good publications have been calling attention to the advancement in the science of steel-making. Columns upon columns of reading matter has been offered on the subject of

the substituting of open-hearth for crucible steel. Those who have been paying fancy prices for crucible steel, if there are any such, are probably those who will not subscribe for a technical or trade paper, believing they know all that is possible for them to know about their business. . . . It can scarcely be possible that many consumers of crucible steel have been buying open-hearth steel and paying the same price they paid for crucible steel. Right here it might be well to add that the purchase of steel by brand such as has been the practice for centuries is not in keeping with modern methods. Many manufacturers are paying two prices for material which can be had for far less money and will answer the same purpose. . . . The strong invasion of the field that was formerly held exclusively by crucible steel by high carbon open-hearth is even more serious to the crucible trade than the mere fact that competition may be so easily introduced in the crucible field itself. The makers of crucible steel employed open-hearth furnaces and much of that product went into the crucible market as genuine crucible steel. The character of high carbon open-hearth steel so closely approaches that of crucible that, except for special uses mentioned, the making of the very hardest tools, that consumers accepted the substitute without question. It might be strong to assert that the Crucible Steel Company will be compelled to make a fight for existence, but in the light of the development of the manufacture of open-hearth steel and the decline of crucible, except for those special uses referred to, probably the statement is not too strong. When the consumers of crucible steel become aware of how much open-hearth steel they are buying as crucible, there cannot but be severe changes in the crucible steel trade. The higher cost of making crucible as against open-hearth, will be another important feature of the competition. Not the least, however, will be the fact that the latest crucible company will have new and modern plants with which to compete with the older and less economical plants of the crucible combination. The field for open-hearth steel is bound to expand rapidly and with the extension of its active territory will come the decline in crucible as was the case with the cruder and cheaper Bessemer product." [All this would seem to point to a lessened demand for plumbago for crucibles, ere long?—Ed. T.A.]

THE CARNAHUBA PALM OF BRAZIL.

Hatton, July 27.

DEAR SIR,—I enclose a cutting from an old "Review of Reviews" on a rather wonderful sort of palm that grows in Brazil. Have you ever heard of it? Perhaps the tree would grow in Ceylon.—Yours faithfully,

H.

A MIRACULOUS PALM TREE

which grows like a weed in Brazil, but the like of which is unknown in any other part of the world. It is the carnahuba palm. (*Copernicia ceriferá*), which grows uncultivated in the States of Parahiba, Ceara, Rio Grande do Norte, Piaui, and some of the neighbouring States. The descriptions given of it to me seem incredible. Perhaps in no other region is a tree to be found that can be employed for such varied and useful purposes. It resists intense and protracted droughts, and is always green and vigorous. Its roots produce the same medicinal effects as sarasaparilla. Its stem affords strong, light fibres which acquire a beautiful lustre, and serves also for joists, rafters, and other building materials, as well

as for stakes for fences. From parts of the tree wine and vinegar are made. It yields also a saccharine substance, as well as a starch resembling sago. In periods of famine, caused by protracted droughts, the nutritious substances obtained from it are of immense benefit to the poorer classes. Its fruit is used for feeding cattle. The pulp has an agreeable taste; and the nut, which is oleaginous and emulsive, is sometimes used as a substitute for coffee. Of the wood of the stem musical instruments, water-tubes and pumps are made. The pith is an excellent substitute for cork. From the stem a white liquid, similar to the milk of the coconut, and a flour resembling maizena may be extracted. Of the straw, hats, baskets, brooms, and mats are made. A considerable quantity of this straw is shipped to Europe; and a part of it returns to Brazil manufactured into hats. The straw is also used for thatching houses. Moreover, salt is extracted from it, and likewise an alkali used in the manufacture of common soap. But from an industrial and commercial point of view, the most valuable product of the carnahuba tree is the wax obtained from its leaves.

[We do not find the name of this palm in Trimen's Guide to the Peradeniya Gardens; but it is very probably growing there and we think we noticed the description in the magazine at the time it appeared. At the same time, this palm is no more wonderful in the multifarious purposes to which it can be put than the coconut or palmyra with the hundred or more uses found for the fruit, leaves, fibre &c.—ED. C.O.]

THE TEA CESS AND THE TEA INDUSTRY.

August 1st.

SIR,—I want to put a searching question to your readers, *i.e.*, to Ceylon tea men generally: If there is a "Cess," who pays the Cess? Mr Ross W Hayter, writing to the "Home and Colonial Mail," advises a Cess of £45,000 and says:—"It may be said that the planter is not in a position to stand this 1-16th of a penny per pound. The question just occurs to me, Who would pay it? Would not the consumer pay it in the long run instead of the grower or exporter?" How is it that such a question *can* be asked by any business man? Is it not *evident* on the face of it that any article which is successfully advertised *pays* for the advertisement. Does anyone suspect for a moment the Ceylon planters are actually out of pocket—*i.e.*, have *paid* the Cess which they imposed on themselves? Can anyone say that the Ceylon Cess, if it had *not* been imposed, would have remained in the pockets of the producers? With that money you created a demand for *your* teas in America. Your tea is not as good as Indian tea and yet it has made more headway. Can you still doubt that the Cess was not paid by yourselves but by the consumer? Mr Larkin says that he not only dares to spend large sums in advertising but does not dare *not* to advertise. The only fault about your Cess is that it is not large enough. It ought to be ten times as large, so that you could not only advertise but *purchase* tea with which you could back up your advertisements. Mr Hayter's question is ridiculous. He should have put it as a statement. He knows well enough surely that planters do not *pay* the Cess. Seeing that he put it as an interogation I am encouraged to put the same question; there may be a few tea owners who have not looked at the subject in its *obvious* light.

Let us look at what your owners promised. They promised to reduce the yield by four million pounds of tea. They knew that if they made this 4 millions they would get money for it at market rates, that is to say, 5 annas per pound—4 millions at 5 annas is equal to 1,250,000 rupees. A few of your owners promised to give 12 lakhs and fifty thousand rupees with the hope that this sacrifice would raise the prices of the remaining tea. The statement is so startling that it is worth while to work out the sum in full and leave no doubt of the figures. Four million pounds of tea would have been sold at the lowest rate at 5 annas per pound.

4,000,000 lb

5 annas

16) 20,000,000 annas

1,250,000 rupees

That is to say, these few owners promised nearly as much as the whole Cess at two pies per pound, which I advocate. Why should these owners *now* refuse to advocate the two-pie Cess? The promised reduction was about ten per cent., so we can conclude that the above owners make 40 million pounds of tea between them. 40 millions at two pies works out as follows: -

40,000,000 lb

2 pies

12) 80,000,000 pies

16) 6,666,666 annas

4,16,666 rupees

This is less than *one-third* of their former promise. In the first case they would have *paid* 12 lakhs of rupees, because the simple reduction of 10 per cent from old markets would not be sufficient to raise prices. But in the second case, whatever is paid is paid by *all* equally, and there is tea ready wherewith new markets *can* be opened, and demand increased, and, after all is said and done, no one can refute the statement that the Cess would be *paid* by the consumers. What is it then that prevents the producer from demanding a big Cess? Let each man amongst you answer this question; some may know the *real* reason. And when once the obstacle is known it can be overcome.

A pony will not face a paper screen; he has to be shoved through it backwards; when the screen is torn the rest of the competitors gallop through without fear. The obstacle between us and the Cess is a paper screen, and it is to be feared that a great number of the runners in this race have longer ears than ponies. Who will tear the screen and let all through? I have been trying to show that there is open country beyond the screen. The producer fears that he will have to pay the Cess! The pony says "*Mon Dieu*, that wall will break my head!" Our Association do not wear spurs, and when the producer jibs he is allowed to stand, and the world is amused at the spectacle of our crowd jostled around the paper screen, and no race worth looking at. In "Indian Gardening and Planting," of July 25, an expert gives his views as to what should be done and asks the question, How is this to be done? The time for questions is over, let every man answer his own questions, let him say *this* should be and *must* be done. Producers *have* an object

in view, and it is absolutely ridiculous that they should be undecided as to their course, but human nature *en masse* requires a lead. However, some of your men took the lead and promised to reduce ten millions; let them now moderate the big Cess, and *force* it on by all means in their power. Were those promises false? Were they merely blinks to deceive others? If not, if they were "pukka," honest real promises to do *whatever* was required, let them now adopt some other course.

The Tea Industry had a promise of 12 lakhs of rupees from these men, and if they are asked to subscribe four lakhs is there any good reason why they should refuse? Remember that a "Cess" means that *all* shall pay equally and without fail, there will be no possibility of subterfuge, there can be no doubt that a certain sum will be available and that it will be sufficient for the purpose, and that it will be paid by our natural enemies, the buyers. We ourselves have allowed the buyers to become our enemies—we have forced them to be so, because we had no Cess, no system, no union of any sort, no common knowledge of the rulings of supply and demand, no common sense to foresee that supply would overtake demand unless we ourselves increased the demand by advertising, and *shoving* our tea into new places. I should like you to note that those who object to my scheme do not propose any alternative; they merely doubt the possibility of this, that, and the other thing. You remember about Cleopatra's Needle in Rome and how it was got up by the suggestion of one man out of ten thousand; he only said "throw water on the ropes!" Well, then! I say to you:—Break down the paper screen. There will be long-eared ones who will shy at the broken screen, but "the Cess" will *force* them through.

A. C.

PLANTING NOTES.

THE CAOUTCHOU export from New Caledonia reached in 1900 only 24,083 kilos. No rubber was exported in January last year.—*India Rubber Trades' Journal*, July 22.

THE CAMPHOR MONOPOLY.—The Vernacular papers report that the Japanese authorities contemplate the creation of a monopoly to cover the sale of the camphor manufactured in Japan outside of Formosa. The camphor industry in Japan has made great progress in recent years, and threatens to endanger the monopoly in Formosa. Mr Gato, the chief of the Formosan Administration Bureau, has framed a scheme for the restriction of the camphor industry in Japan, and recently laid the scheme before Government. It is understood that the camphor monopoly law will be put in operation in Japan in order that sufficient protection may be given to the industry in Formosa. The construction of an additional building to the Kobé branch of the Formosan Camphor Bureau at Ono, Hyogo, and the improvement of machinery and plant having been completed, operations for refining camphor will be commenced shortly. Three oil engines of 17, 5 and 3 horsepower have been fitted. The number of operatives has been gradually increased, and there are now fifty-three men and women employed, in addition to a technical expert. About twenty thousand pounds of camphor recently refined for trial was delivered to Messrs Samuel, Samuel and Co., who shipped it to India and Australia.—*Chemist and Druggist*, July 13.

PERUVIAN COCA, COCAINE, CINCHONA, &c.—The value of the coca leaves exported from Peru in 1899 was £17,359, against £22,437 in 1898; of cocaine, £67,097, against £65,197; of cochineal, £499, against £709; of borax, £61,102, against £57,422; of cinchona bark, £7,830, against £3,046. No weights are given for Peruvian exports as a whole, but they appear in relation to various centres. Thus, Salaverry exported 335 tons of coca leaves in 1900, and 214 tons in 1899, and 284 kilos of cocaine in the former year as well, this being the beginning of the alkaloid trade at this port. Most of the leaves were sent elsewhere in Peru, probably to be re-exported. Germany received direct 16,019 kilos of coca and 110 kilos of cocaine, whilst the United Kingdom received direct only sixty kilos of the latter. Mollendo sent to Liverpool in 1900, 48,575 kilos of bark; to London, 93,051 kilos of bark, and 670 kilos of coca leaves; to Hamburg, 32,962 kilos of bark, 212,922 kilos of coca leaves, 261 kilos of cocaine; to New York 138,569 kilos, of coca leaves, and 137 kilos of cocaine. The total export of bark was 183,549 kilos; of coca leaves, 352,161 kilos; of cocaine, 398 kilos. There was no sarsaparilla exported from Mollendo in 1900, but 35 kilos were exported the previous year. From Cuzco 617,150 lb of coca leaves were exported, the average price being 16s per drum of 25 lb in Cuzco. The shipments have gone principally to Hamburg via Mollendo, but some hundreds of pounds went to New York.—*British and Colonial Druggist*, July 12.

"IMPERIAL GARDENS FOR FRUIT-TREE DISSEMINATION THROUGHOUT THE EMPIRE."—Such is the title of a pamphlet by Dr. Bonavia, F.R.H.S., sent to us with the author's compliments, the six pages of which we shall have pleasure in reproducing in our *Tropical Agriculturist*. Dr. Bonavia is well known for his horticultural writings, and his monograph on the Citrus genus in two large volumes—one of them almost entirely diagrams—we frequently refer to. In the pamphlet under notice, he discusses bananas, guavas, mangoes, mangosteens and date palms, as well as oranges. The date palm ought to do well in the drier regions of Ceylon; but not better than the useful palmyra, a grove of which ought long ago to have extended from Jaffna to Anuradhapura. One remark of Dr. Bonavia we must notice: he says "Why they have not introduced it (the mangosteen) into Ceylon and cultivated it for commercial purposes is a mystery." Well, Dr. Bonavia should know that the mangosteen is not unknown in Ceylon. Both in Kalutara and Colombo on the moist warm South-West coast it grows and bears well in some gardens; but it is a very ticklish plant to deal with. We have half-a-dozen times over got relays of healthy plants from a Kalutara friend to grow in a Colonibo garden; but without being successful in growing a single tree—they take root and look very healthy for six months or so and then wither away and die down. We have at present two plants of a larger growth (which have cost us R5 each) and they are being sheltered from the sea-breeze and coddled as well as we know, in the hope of sturdy trees resulting. But evidently the mangosteen is far less easily cultivated commercially than either the mango or orange, in Ceylon.

THE EAST INDIA AND CEYLON TEA COMPANY, LTD.

THE REPORT OF THE DIRECTORS

for the year ended 30th November, 1900, to be presented at the meeting to be held in London on 8th instant, states that the amount at credit of the profit and loss account, after crediting the balance (£8,669) carried over in last year's accounts, is £10,459. From this the preference dividend to 31st May 1899, on account of season 1898-1899, absorbed £3,000; preference dividend final on account of season ended 30th November, 1899, £3,000; interest on debentures for year ended 30th November, 1900, £100; Mahaousa Factory, amount written off, £701; deficit for the season 1899-1900, £2,911, leaving a balance at debit of profit and loss account of £152. The crop, excluding that from Madampe, amounted to 1,811,850 lb., as against 1,841,718 lb. the previous year. There was thus a small decrease from the older estates, and this reduction in yield is mainly attributable to the severe hailstorm which was mentioned at the last annual meeting. The average sale price was 5'32d per lb. and the cost of production 5'77d. The yield of the Ceylon estates was satisfactory. The chief cause of the diminished receipts of the Company is the reduction in the market price of tea. For Ceylon tea the average price fell 3d per lb. during the year and that of Sylhet 1½d per lb. This heavy drop has undoubtedly been caused by over-production; however there is reason to hope that, with the contemplated reduction of output, prices will improve. The capital cost of Madampe estate, after crediting the value of its crop, stood on 30th November last at £10,594. The Directors consider the hock account should now be closed, and have every hope that this property will now make a profit. Its yield during the past year was 123,565 lb. and the latest estimate for the current season is 175,000 lb. When the serious position of the tea market and probable result of the year's working were seen, Mr Richardson, at the Directors' request, visited the Company's Indian estates, and at his recommendation it has been thought advisable to change the management of these properties, and considerably reduce the expenditure. In order to replace tea injured by drought and hail in India, 75 acres of which have been abandoned, 70 acres of new land have been planted out, and the cost of same has been all charged to revenue. If the rate of exchange ruling for the past season had been the same as that in the first year of the Company's existence, the result would have been £3,139 more favourable. The increase of duty by 50 per cent, that is, from 4d. to 6d., has undoubtedly curtailed the expansion of consumption, and, consequently, injuriously affected the market. With reference to the Hopewell Tea Company, one-third of which belongs to this Company, calls to the amount of £5 per share have been made this year, making £9 per share paid up. Payment of this has been mainly met by withdrawing the deposit of £32,000 placed in anticipation of calls with that Company. The properties are said to be in good order and coming on well, and it is reasonable to hope that, with a better market for tea, the estates will show a substantial profit when they come into full bearing. With a view to manufacturing a better class of tea, the current season's crop estimates have been reduced by 107,400 lb. The total crop expected this season is now 866,600 lb. as compared with 529,934 lb. gathered during 1900.

EMPIRE OF INDIA AND CEYLON TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS

to be presented at the fifth annual ordinary general meeting, to be held on Thursday, the

4th July, 1901. The Directors have the pleasure to present to the shareholders their fifth annual report, with accounts made up to the 31st Dec. 1900:—

The following table shows the area of the Company's properties, and particulars of the land under tea:—

Group.	Name of Garden.	Tl. Area of Grants.	Total acres under tea.
Assam	Borjuli	... 2,518	1,985
do	Sonajuli	... 2,347	1,135
do	Namgaon	... 1,487	692
do	Daputa	} ... 3,910	461
do	Dhulapadong		791
Dooars	Good Hope	... 1,610	971
do	Hahaipatha	... 1,251	700
do	Dangua Jhar	... 260	235
do	Tasati	... 1,500	1,100
Ceylon	Lebanon	... 1,641	675
do	Knuckles	... 950	847
		-----	-----
	Total	... 17,474	9,592
		-----	-----

Capital expenditure on "Tasati" has ceased with the charge to block account in the present balance sheet, 1,100 acres have been opened out most economically in the last three years, and the work has been thoroughly well done.

CROP AND PRICES.—Alike in Assam, the Dooars and Ceylon, the gardens of the Company showed a satisfactory increase in crop in 1900 as compared with 1899, as will be seen by the foregoing tables. But the results of 1900 were unsatisfactory. This was partly due to the general fall in the price of tea, and to other causes which have injured the tea industry all round, but it was also partly the result of increased expenditure on all the gardens of the Company. Generally speaking, the local management deserved commendation for their successful efforts to improve cultivation, but the Board could have wished for a more strenuous effort to keep within the sanctioned expenditure. The average of the Bramapootra Valley of the Assam Province was 8'53 against the Company's average of 8'19 for its Assam gardens. The Dooars district secured 5'69, while the average for this Company's Dooars gardens was 6'32. In Ceylon this Company's gardens secured only 5'56 which price is below the rest of the district in which the Company's gardens lie.

DIRECTOR'S VISIT.—Mr Geo. Moore, a Director of this Company, has again spent several months in India during the past cold weather, and, while successfully promoting further measures to better the health of the labour force and improve cultivation, has done a very great deal towards introducing and enforcing economies which are of vital necessity in face of the present critical position of the Indian tea industry, owing to the heavy fall in prices. The Board, is, however, pressing for still further efforts at economy under all heads of charges except wages, a reduction of which is often the worst form of extravagance.

TROUT CULTURE IN NATAL.

Pietermaritzburg, June 18.

A meeting of gentlemen interested in angling met at the Natal Club yesterday to form an angling association. Mr Cecil Yonge took the chair, and there were present 25 anglers. The Chairman gave a sketch of the efforts made to introduce trout into the Colony, and said results showed that a penny spent in Natal in trout culture was equal to a pound spent in any other country. Mr J C Barker proposed that the objects of the association should be to obtain fishing rights on the rivers of Natal, to preserve and regulate the capture of fish. Mr R J Harrison said that land owners would see that it was to their advantage to have their rivers fished. The Chairman said that, although the Attorney-General had given the opinion that the Government and the public had no rights over the landowner, in future the Government in putting trout in should have a right over them. He questioned whether the landowners would or could decline to assist the anglers. —*Natal Mercury*

SNAKES' SKINS AND MILLINERY.

At a recent meeting of the Bombay Natural History Society a suggestion was made for the utilisation of snakes' sloughs or discarded skins. Mr. E L Barton exhibited a number of pieces of the slough cast by the large python in the Society's rooms, mounted on different materials, with a view of ascertaining what use, if any, these sloughs might be put to. The specimens mounted on bright-coloured calicoes, especially green, were by far the most successful, and the consensus of expert opinion appeared to be that, from a millinery point of view, the sloughs might be used with advantage for the purpose of trimming hats! —*Madras Mail*.

THE CONSUMPTION OF COFFEE.

One-half of the world's production of coffee berries is brought to the United States. Americans are the greatest coffee drinkers on the face of the globe now, and every year the consumption of coffee is increasing here. Last year it was more than 80,000,000 pounds for the whole country, or more than 10½ pounds a head of the population. Germany and France together only consumed half as much coffee. Germany less than 6½ pounds a head and France only 4½ pounds per capita. The United Kingdom used little more than half a pound of the berries per head of the population, but over there they made up for it by drinking more tea than any other nation. More than a million dollars is sent out of the United States every week in payment for coffee. South and Central American countries, which supply us with more than 6,000,000 pounds of coffee a year, get most of the money. Porto Rico, Java and the Philippines get almost all the rest, but a little goes to Hawaii. Last year the total value of the coffee imported into the United States was about \$60,000,000, and that was less than for several years, because the import price of coffee has fallen about one-half. —*Bradstreet's*.

RUBBER.

ACCORDING TO THE CONSULS.

The exports of rubber from Sierra Leone in 1900 amounted to £3,406 to Germany, and £22,335 to Great Britain. In Cochin China the

Government is patronising the cultivation of the gutta-percha tree, and planting is now being tried in various parts, chiefly in Laos, also in Annam and Tonkin. In Indo-China the exports of gutta-percha for 1900 amounted to 339,000 kilos, against 52,813 kilos in 1899. Gutta-percha comes chiefly from Annam and Laos. A piece of good quality is worth about £13. —*India Rubber Trades' Journal*, July 22.

COFFEE AND TEA IN THE UNITED STATES.

—Quite a number of publicists among our American cousins have gone "a wee bit daft" over the idea that coffee as well as tea can be successfully and profitably grown within the bounds of the vast western Republic. The talk about coffee-growing is the subject of amusing comment by our Brazilian contemporaries, of which the paragraph we quote today from the *Brazilian Review* is a specimen: and now we have a long article on "American Tea Growers" in the *Florida Agriculturist* from which we take an opening paragraph:—

Ere the present cycle of a hundred years is rounded out, Uncle Sam will, in all probability, be producing within his domain sufficient tea leaves for all the soothing beverage which his people can possibly drink, and mayhap will have some to spare for his brethren across the sea.

That this will be a highly desirable consummation must be appreciated even by the person who never sipped a cup of tea in his life. For one thing, it will enable the poorer classes to obtain good tea at lower prices, and for another it will keep in the coffers of the American people a fortune, amounting to many million dollars annually, which now goes to feed and clothe men and women on the other side of the globe. Under present conditions every man, woman and child in the United States consumes about twenty cents' worth of tea each twelve months, and the immense aggregate sum is divided between the tea growers in China, Japan and Ceylon, several middlemen and agents, and the vessel owners who carry the precious product to market.

The best feature of the new era which is coming, however, is found in the fact that finer tea can be grown in the United States than in the Orient. This has been conclusively proven by some interesting experiments which the United States Department of Agriculture has been conducting during the past few years at the pioneer tea plantation established in the New World.

All this "high-falutin" is based on the fact that Dr. Shepard has produced some few thousands of pounds from his tea garden in South Carolina which he can sell at a dollar per lb; while the very finest "Darjeeling" or choicest high-grown Ceylon can be imported and sold for half-a-dollar a lb. As to fineness, delicacy and flavour, it is not likely the two kinds we speak of can be excelled. With labour in India and Ceylon costing from one-sixth to one-tenth what it does in the States, it is not likely any great Tea Industry can be profitably developed in the latter. A few gardens as novelties may succeed, so long as people like to pay a fancy price from patriotic or such-like feelings.

THE VETERINARY SURGEON'S REPORT FOR 1900.

It cannot be said of many Administration Reports that the bulk of them provide reading matter of universal interest; but an exception to this general rule must be found in the Veterinary Report of Mr. Sturgess, M.R.C.V.S., presented by itself this year for the first time and which came into our hands yesterday. Considering that the writer was engaged in special work in connection with conveyance of the C.M.I. horses to South Africa and an examination of the treatment and conditions of rinderpest there—the Ceylon Government thus killing two birds (but no horses!) with one missile—we congratulate him the more on the full and clear statement he has given for 1900. As the records available have hitherto been more than meagre, it is satisfactory to find that Mr. Sturgess's systematic efforts to render these annually more complete have met with a fair measure of success during the year under review. And now that the importance of his work is coming to be officially recognised, no obstacle should be placed in the way of his thorough supervision of the scientific duties of his staff in the shape of necessitated personal attention to a quantity of clerical work which might be undertaken by less skilled hands. A mere perusal of the Government circular (given elsewhere with extracts we quote from the Report) will indicate the proportions to which this labour has attained.

Rinderpest and inoculation are, of course, the two principal topics of which Mr. Sturgess treats, the usual visits to Delft and Iranativu having nothing of exceptional interest, except the curing of Iranativu ponies of internal trouble during the October visit. Rinderpest, we learn, has been worst in the three thickest populated provinces—Western, Central and Sabaragamuwa. The cause of its spreading, when an outbreak occurs, is generally found to be the fact that the animal (the disease usually occurring in a town or some way from home) is hurried back to the estate and this infects a perfectly free place. In introducing reforms among a people where so personal a property as cattle is reared and kept under the shadow of many superstitions and popular prejudices, a trained western officer will not find his route one that facilitates unimpeded marching. So original a people as the Sinhalese will not be driven into doing what the white doctor tells him and ancient custom has to be won by persuasion, by the persuasive force of success in treatment and in their neighbours' adherence to new rules—not conquered by the overriding weight of official order or decree. In following Mr. Sturgess's remarks on native methods, we are pleased to read between the lines how appreciatively he grasps the native ways and mind and recognises what perhaps Tennyson meant when he said:—

Science moves but slowly, slowly,
Creeping on from point to point.

On the subject of inoculation Mr. Sturgess has much of interest to say and for experts

his remarks on the various methods of inoculation are of high interest. For practical purposes, however, we quote details of only the Cape Colony method, which is to be followed in Ceylon. Passing over the subjects of the staff, returns of stock imported, foot-and-mouth diseases, and classes at the School of Agriculture, we come to the Government Dairy and the Improvement of Native Cattle.

Mr. Sturgess thinks that the want of good cattle and absence of native effort to improve their stock is partly due to the fact that Ceylon does not possess a meat-eating population and partly because the native cannot (or will not, in some cases?) afford to feed his cattle better, the better the cattle the more being the food required. The plan pursued at present, of sending the best bull-calves from the Government Dairy, throughout the island, wherever applied for by the Government Agent of a province, is likely to prove a first step towards extending a desire among the natives to devote more attention to their cattle. In due time, perhaps, they will come to exercise greater care over their herds, alter the breeding methods (or want of method!) in vogue and generally raise the quality of the stock, to the increased welfare and prosperity, agricultural and otherwise, of the population generally. Next to the promotion of staple agricultural industries—in cereals, palms, vegetables, &c.—there is nothing so important in respect of native interests, as the maintenance of healthy herds of live stock and the improvement of the same. The best guarantee that such a course is being opened out with all judicious rapidity is to be found in the fact that it is under the immediate charge of a gentleman of Mr. Sturgess's experience and keenness in his work, admirable sympathy with deep-rooted custom and recognition that the pace cannot be forced where the immemorial ways of an ancient people are concerned. On the one side of the District and Provincial Revenue Officers, Mr. Sturgess has as notable work to do as have Dr. Willis and his Scientific Staff on the other.

VETERINARY WORK IN CEYLON.

(Extracts from the Report of the Government Veterinary Surgeon for 1900.)

I have the honour to present my report for the year 1900. Early in January my services were placed at the disposal of the Commandant, Ceylon Volunteers, in connection with the despatch of the Ceylon Contingent of Mounted Infantry

TO SOUTH AFRICA.

I left for South Africa on 24th February with seventy-five horses, reaching Capetown on the evening of 16th March. The horses were all safely landed on the 18th in good condition. I was on duty with the horses until 9th April, when I returned to Capetown and commenced the investigation of the methods employed in South Africa in dealing with rinderpest, as directed by His Excellency the Governor before my departure from Ceylon. After presenting my letters to the Government of Cape Colony, I was referred to

the Minister of Agriculture and the Principal Veterinary Surgeon, Mr Hutcheon, who kindly assisted me in every way he could, and whose office I attended during my stay in the Colony, collecting all the information possible, which was presented to Government on my return to Colombo on 8th July. Dr. Turner, the Principal Medical Officer, also gave me great assistance and copies of his reports upon the subject.

On my return rinderpest was prevailing in the Kegalla and Ratnapura Districts, and I visited Badalgama, Katukinda Dehiowita, Yatiyantota, and Kuanwella and surrounding villages, leaving Stock Inspectors to carry out the measures advised for the suppression of the disease. On the 25th July I left Colombo for

DELFT AND IRANATIVU

to inspect and carry out the necessary work in connection with the horses there. On Delft the mares and foals, about seventy in number, were put into the kraal and examined one by one, all being found healthy. From Delft I went on to Iranativu, where the young growing stock are kept. The ponies, forty-eight in number, were examined, and fifteen colts caught and operated upon on 30th July and 1st August, all successfully. None of them had to be caught again and were not dressed in any way after operation. In October reports reached Colombo of disease amongst the ponies on Iranativu, which I left perfectly healthy the first week in August. I again left for the Island on the 17th October in company with the Government Agent, Northern Province. I discovered after considerable trouble it was due to internal parasites in the shape of "thread worms," and all the ponies were caught and warm medicines administered. There was no further loss. Up to the time of our visit six had died, and the cause had been wrapped in obscurity, as there was no one to observe and give an intelligent account of the symptoms when a pony fell ill, and the animal was dead long before the report reached Jaffna from the island, and from Jaffna to Colombo. The disease is referred to under the name of "Helminthiasis."

THE OFFICE WORK AND GENERAL CORRESPONDENCE

has greatly increased during the year. Information relating to various cattle diseases has been given whenever applied for. Before leaving for South Africa I prepared a special paper on Rinderpest for the Planters' Association of Ceylon, which has been circulated amongst the members. During the year a circular was issued by Government making the following rules:—

- (1) That Government Agents do impress on headmen the necessity of promptly reporting every outbreak, or hold them responsible for failure to do so.
- (2) On receipt of intimation of an outbreak, Government Agents are to at once report the matter by wire to the Colonial Secretary and to the Veterinary Surgeon direct.
- (3) So long as an outbreak lasts, weekly reports are to be furnished to the Colonial Secretary by them.
- (4) The Veterinary Surgeon is, on being communicated with by the Government Agent, to take necessary steps and report to the Colonial Secretary action taken by him.
- (5) He is also to furnish a list weekly, showing all the localities in the Island where the disease prevails, and extent of the outbreak in each case.

(6) Further, he is to furnish a monthly report showing what has been done by each member of his staff during the preceding month.

These rules have been regularly observed, with great benefit. It will be seen that considerable clerical work is entailed, which principally falls upon me, as I have only the assistance of the Stock Inspectors, who are very often away from Colombo.

RINDERPEST.

During the year the Western, Central, and Sabaragamuwa Provinces have been most affected. Small outbreaks occurred in the Central, Southern, and Uva Provinces. All the outbreaks have been sporadic and not epidemic, and have principally been on the line of main roads caused by cart bulls spreading the disease from place to place.

Much is written and said about the losses due to rinderpest and other cattle disease. No doubt serious loss does occur, and is due to various causes, amongst which carelessness, prejudice, and apathy occupy a prominent place. The first few cases are not reported or isolated in the majority of cases, and infection is spread from one village to another because the cattle from adjacent villages mingle and graze together. In some cases the disease is not known, and so it goes on until a firm hold has been gained. Villagers are, as a rule, very conservative, and object to the new-fangled European interference. There is also deep-rooted superstition to deal with, as they think the disease is due to the anger of some supernatural being, and if they endeavour to check it some evil will fall upon themselves, or they fear that some measure may be ordered by Government which will give them a little trouble and so try as well as they can to conceal cases. My aim has been to meet their prejudices and objections half way, and explain what I wanted to do and the reason for it. So far we have worked smoothly, and the methods of treatment have been steadily gaining ground, slowly perhaps, but changes against deep-rooted beliefs and custom have to be gradually effected everywhere. In several villages when I first suggested inoculation the greatest fear and reluctance was shown, and only one or perhaps two cattle could I obtain for inoculation, and only these to satisfy what I am quite sure was regarded as a mad freak on my part. Afterwards, when it was found the cattle did not die or evil happen to them, owners would perhaps allow a few more to be done, and so more and more would be brought. Another thing to be considered is the

QUALITY AND STAMINA OF THE CATTLE

in the villages. Hundreds of semi-wild cattle (I am not referring to working bulls on estates in any way) are kept by village owners for apparently no purpose whatever. They are not milked or fattened for food, not fed or housed, and perhaps only seen once or twice a year. They are allowed to wander about, often in drought time, miles from their owner's home; they breed "in and in" and degenerate until they are no larger than good-sized sheep dogs. If disease appears, as it often does amongst these miserable rats of cattle, no one looks after them; half of them die, and a report comes of the alarming prevalence of murrain in a district, and the Government Veterinary Department is expected to put things straight by a few days' stay in the place, or by the enforcement, as people call it, of some imaginary regulations, but which they are

unable to frame or even suggest in practicable shape. The regulations, if I suggested, would be to compel owners to feed and take better care of their cattle or else not to keep any at all. In reading "A Naturalist on the Prowl" by "Eha," I was much interested in the following passage, which I cannot do better than quote in full, as it exactly expresses what I mean. It occurs, I think, in the description of an Indian morning:—

"Then a slow procession of spectral cattle will come upon the scene—gaunt frames of bullocks and cows and calves, with scabby hide drawn tight over sharp bones, lustrous eyes staring wantingly, and prematurely-grown, distorted horns. And they will greedily feed on what the bats have dropped. Poor things! The wide world seems to have no food to spare for them. The ground is bare of grass and the shrubs are bare of leaves as far as their fanished tongues can reach. They belong to somebody, of course; a farmer somewhere calls them his. But he does not feed them. Why should he? He does not need them just now. In due time the rain will come and the grass will grow and keep them alive until ploughing time. Then, if well beaten, they will put forth all the strength needed to pull his little crooked plough through the muddy rice ground. If the lives of some of them flicker out before that, his loss will be small and his conscience will be free. If he lifted his own hand to shorten their lives the waters of the Ganges could not purge away his sin."

There is also the question of reporting cases. The disease may exist for days and weeks in a village before the headman hears of it, and then in some cases it is not reported quite as soon as it should be. As a general rule, however, headmen do report as soon as they hear of an outbreak; one cannot put blame on a class for the negligences of a few individuals. This is the crux of the whole question. If the first few cases were reported at once, and destroyed if necessary, there would not be much difficulty in dealing with an ordinary sporadic outbreak as is usual in this country.

INOCULATION.

The great preventive measures are the methods of inoculation discovered and worked out during the South African outbreak, and which gave the very excellent results most people have heard all about. But the conditions of life under which cattle are kept in the East generally render such results almost impossible. The conditions are in every way different from those under which European and South African cattle are kept; the numbers, too, are immense, as will be seen from the returns of each Province. Almost every man endeavours to keep his trotting bull for travelling purposes, and a few semi-wild cattle running in the jungle as well; there are no good pastures; no enclosed farms; the cattle of one village mix freely with those of the adjoining village in the jungle, and are only recognizable by their brand. The effects of inoculation are temporary, and pass off in a few months. There are several methods of inoculation discovered during the epidemic in South Africa, after a great deal of research and expense, and which are of great value.

The method of inoculation advised in sporadic outbreaks by Mr. Hutcheon, Principal Veterinary Surgeon in Cape Colony, is as follows, and is the method I intend to follow as far as possible,

as I consider it most suitable and practicable in this country:—

For Infected Herds—These should be inoculated at once with either serum or glycerinated bile; every animal which indicates infection by a rise of temperature should receive a large dose of not less than 100 c c* of serum or 30 c c of glycerinated bile. The latter should by preference be injected into the jugular vein, so as to secure its immediate action. Then from eight to twelve days after all the animals in the herd which give no indication of being infected with the disease or fever temperature should receive an injection of pure bile, not less than 10 c c, and for large animals 20 c c. This will confer a lasting immunity sufficient for all practical purposes.

Clean Herds—When it is decided to inoculate a clean herd, which is in danger of becoming infected through its proximity to diseased cattle, I would recommend that the animals composing the herd should be inoculated first with 20 c of glycerinated bile, and to follow this inoculation in from eight to twelve days with an injection of from 10 to 20 c c of pure bile. This will confer a strong and lasting immunity on the animals in the herd, and will be free from risk arising from the inoculation or of introducing the disease.

When I came to the country in 1895 there were no records at all, in fact very little information of any kind available. I stood alone, and had to find all out for myself. I drew up a form in the manner in which I wanted the information, and it was not until 1897 that returns came in anything like a complete manner, and since their publication attention has been drawn to the amount of disease.

The following shows the number of cattle and the deaths in each of the Provinces for 1900 from all diseases as shown in the complete returns annexed:—

Province.	Number of Cattle.	Deaths.
Western	173,371	2,109
Central	102,214	1,514
Northern	214,213	—
North-Western	293,979	7,246
Eastern	76,499	50
North-Central	117,107	661
Uva	66,189	2,137
Sabaragamuwa	85,237	1,541
Southern	179,167	1,523
Total	1,307,976	16,781

giving a percentage of 1.28 deaths from all diseases.

STAFF.

The Assistant Veterinary Surgeon, Mr. Hoole, came to Colombo from Anuradhapura in January to assist me, as I was busy purchasing and examining horses for the Contingent. On my departure to South Africa in February he acted for me with great success and earned the thanks of Government. I took over charge again early in July, but as there were outbreaks of rinderpest frequently occurring in the Western Province, and I was likely to be away a good deal, he stayed on in Colombo until the end of the year, when I proposed to effect a fresh arrangement of staff consequent upon the appointment of additional Stock Inspectors. From 1st January he takes up his residence at Kandy, as a permanent station, for work in the Central Province.

At the time of writing this report the arrangement of the [rest of the] staff is as follows :—

STOCK INSPECTORS.—D L Dias, Anuradhapura; T Mahamooth, Jaffna; A M Fernando, M D S Wijanayaka, E W Jayatilaka, Colombo; Messrs. Fernando and Wijanayaka go out shortly—one to Kurunegala and the other to Ratnapura—for work in the North-Western and Sabaragamuwa Provinces: In this way the Central, Northern, and North-Central Provinces have been provided with assistance, and shortly the North-Western and Sabaragamuwa Provinces will be provided, and the others in turn. The inspectors work in the Provinces under the direct orders of the Government Agent, subject to my general control and advice.

RETURN OF HORSES, CATTLE, AND SHEEP IMPORTED DURING 1900.

GOVERNMENT DAIRY.

Daily visits are usually paid when in Colombo. The health of the stock has been excellent during the year. There has only been two deaths—one cow and one calf—out of a total of 114 cows and 79 calves and seven bulls, a total of 200 cattle. In November and December a disease appeared amongst the larger calves; there were fourteen cases, and all recovered. The disease is specially referred to later on in this report. When I first came out I found the yearly losses of calves was very great, and there were a number of very weak calves on hand. Thirty-four died during my first year. Since then there has been very few losses, which shows, I think, that the changes suggested in their management and the preventive measures adopted have met with some success.

IMPROVEMENT OF NATIVE CATTLE.

Some time ago the question of the improvement of the native cattle by the importation of stud bulls from India was under consideration by Government, and I drew up regulations for their management and service. On going into the question thoroughly it was found rather impracticable, and I suggested the sale of a number of calves from the Government Dairy in each Province in turn. This was not very successful, as it was found that the calves made more money in Colombo, and principally native estate owners purchased them at the dairy sales and sent them out to their estates in the country. This plan, however, did not reach the small village owner, who could not afford to buy expensive calves, and I suggested that six of the best bull-calves bred at the Government Dairy should be specially selected and retained each year for distribution to the different Provinces, being sent as applied for by the Government Agents. This was sanctioned, and is being carried out successfully, I believe, so far. Six have gone to the Northern Province and two bulls are on Irana-tivu island where the native owners have got rid of all their native bulls and are breeding from them only. During the year three have been sent to Ratnapura, two to Kegalla, and one Anuradhapura. Beyond a few European and native estate owners, there is no real attempt at breeding good cattle in Ceylon. Indeed, it would be pretty difficult to improve the breed by importing good bulls unless

good pasture is provided, and I do not yet know of any pasture lands worth the name, although I believe they could be made under good management. Under proper care and good feeding the native bull is a strong, capable little fellow, well adapted for the work which his owner requires of him, and he would be considerably bigger and stronger and better in every way if taken care of when young. There is any amount of fresh blood being brought into the Island year by year from Great Britain, India, and Australia, principally by planters, which should give to the native cattle all the fresh blood necessary for their improvement, besides the calves bred at the Government Dairy, of which an average of thirty to forty are sold every year. I once asked in a village if they would like a good stud bull sent to their district. The spokesman of the group, an old man, said "No, they did not want one, because if they bred better stock they would want more feeding, and they could not afford that, as they could hardly get rice themselves; their own cattle kept themselves mostly and required very little feeding. My advice to most cattle owners here is, Keep fewer cattle and feed them better; breed only from the best, and the cattle will improve. Take an average estate where cattle disease breaks out, and what is found? I generally find three or four hundred cattle kept solely for the purpose of manuring coconut trees; they are tied in groups round each tree in turn and manage to exist upon the poor and scanty herbage afforded; no food is given; the animals are lean and hungry; a newly-calved cow has not sufficient milk to raise her calf. What is the use of putting a good bull on the place under circumstances like this unless there is better management to follow, and unless there is some demand for good stock when reared? With a meat-eating population this would soon change and good fat stock would be produced to meet the demand for food. It must be understood that these remarks are general.

RUBBER FROM A MEXICAN PLANTATION.

The San Francisco *News Letter*, in its issue of June 15, 1901, said :—"La Zacualpa Rubber Plantation Co., on June 1, brought to this city 1050 pounds of clean, crude rubber. This is the first shipment of this year's crop, the largest single shipment received at this port, and the first from a cultivated plantation. The shipment is on exhibition this week at the plantation's general offices, Nos. 703-4, Claus Spreckel's building. This exhibit is of interest, as it enables the Zacualpa company to declare itself the only company in the United States which has produced rubber to show to its investors. The Zacualpa company is shipping to London 30,000 pounds of rubber yearly, but the Bowers Rubber Co., which bought up the present shipment, is competing strongly with other local firms for more. This rubber is so pure as to delight the hearts of dealers. The Zacualpa company now has a plantation of 725,000 rubber trees. Their plantation is situated on the Pacific coast within the department of Soconusco, Mexico. Mr. J W Butler is president and managing director, and Mr. E Noel secretary. The economical management of the company, together with its superior product, makes it a gilt-edged proposition for investors."—*India Rubber World*, July 1.

A "CORNER" IN OPIUM.

WEATHER AIDS THE SMART AMERICAN SPECULATORS.

Even opium has not evaded the commercial octopus of America. English opium-eaters are now threatened with a corner in their favourite drug,

for American speculators have bought up the available supply, and prices are already on the rise. London opium importers have received advices from Smyrna, saying that rain has hurt the Turkish crop greatly and that, before the destructive storms, American brokers bought 79,400lb. of opium, thus securing the visible supply. The highest grade of the drug is grown in Turkey, and England usually takes about half-a-million pounds. Owing to the damage to the new crop the Americans can ask their own rates, and already prices have gone up 9d. a pound in London, with every prospect of a much greater advance. A leading opium importer said recently that the Americans had acted very cleverly in cornering opium. Only a light crop was planted last year, and this fact, coupled with the weather, increased the certainty of a shortage. Usually there is too much opium for it to be cornered, but this year conditions favour the Yankees.—*Express*, July 25.

TIMBER SLEEPERS ON INDIAN RAILWAYS.

The substitution of metal for wooden sleepers in Indian Railway construction owes its origin not merely to comparative life and cost of each article, but as much to the important factor of supplies in the past not being equal to demands. In the early days India was dependent on Europe for her creosoted Pine sleepers, a trade which is, we believe, now about extinct with the general adoption of cast-iron and steel sleepers, and a more abundant supply of Indian timber sleepers, as well as Jarrah sleepers from Australia. The Bengal Timber Trading Company, Limited, Managing Agents, Messrs. Jardine, Skinner and Company, Calcutta, we would remind Railway and other Administrations, are in a position to supply first-class Sal, Jarrah and Teak sleepers, also Teak and Pine timber, in all sizes and in large quantities, at favourable rates.—*Railways*, Aug. 7.

CITRONELLA OIL,

BY ERNEST J. PARRY, B.S.C., F.I.C.

Apart from general analysis of oil of citronella, with a view to determining its purity, the great bulk of the oil on the London market is examined in order that it may be certified as passing the so-called "Schimmel's test." Pure oils of commerce give somewhat different results with this test, some being quite soluble in 80 per cent alcohol, and others, although quite soluble in 3 or 4 volumes of the alcohol, become slightly turbid on addition of 10 volumes of the solvent. Occasionally one has to decide as to what constitutes "slight turbidity" in this respect. In general I find that the citronella oils (that is the pure oils), with low sp. gr. are those which give a perfectly clear solution, whilst those with a high sp. gr. often give a slight turbidity when the full 10 volumes of alcohol are added. In cases where any possible doubt can arise as to what is the limit that this turbidity may assume, without the oil failing to pass the test, the use of alcohol of slightly higher strength will be found of service. With pure oils the turbidity almost, if not quite, disappears when the alcohol is increased to 81-83 per cent, whilst, if even very small quantities of petroleum are present, there is practically no change by using alcohol up to 85 per cent strength. It has been shown that the high gravity oils usually contain more methyl-eugenol than the low gravity samples; but this would not account for the lower solubility in alcohol. It is probable that this is due to the greater preponderance of sesquiterpene in the high-gravity oils.—*Chemist and Druggist*, July 27,

WATERPROOF PAPER.

Quite a new product into which rubber enters as an essential element is waterproof paper. This is now sold in Manchester, and is largely used in the packing of Manchester goods for abroad. It is a particularly strong brown paper, made from wood pulp, two layers of this being glued together by a solution of rubber of the ordinary type. It is expected to be a great success when it is better known, although, as it has only been on the market a short time, it is too soon to prophesy regarding its future popularity. The rubber solution used in this manufacture is not employed in the same manner as in calico-printing, for, whereas in the latter case the rubber was expected to confer very durable qualities, in the case of the paper it is not intended to be of any service after it has served its purpose as a wrapper of goods.—*India Rubber Trades' Journal*, July 22.

MR. DAVID YULE ON THE TEA INDUSTRY.

At the annual meeting of the Bank of Calcutta Mr. D. Yule, the Chairman, in his speech, referred to the tea industry as follows:—

Our tea gardens are still under a cloud, and the large capital locked up gives hardly any return on the average. I think, however, the cloud is breaking up, for we find buyers of tea willing to pay good prices for quality, although they decline to give anything like covering rates for common descriptions. It has often been pointed out that Indian gardens should endeavour to make their manufacture distinct from the coarse and badly made teas which are produced by Ceylon and China. This is far and away a better policy than throwing a percentage of the bushes out of cultivation. Nature this year has come to our assistance in reducing outturn, and our gardens are fully 20 per cent. behind last year. On the 15th of this month gardens will have made half their crop, but as we are now having September weather in August, there is not much hope of the deficit being made up and early cold weather being expected. Such being the prospects of the crop, I consider present prices too low, and unless garden proprietors bestir themselves to get some advance in values, they will find the balance of their profit and loss accounts on the wrong side at the close of the season. I am glad to say that at last there is some prospect of planters working up a demand for their produce among the millions of Indian people, who so far have not enjoyed the taste of the health-giving properties of the fragrant cup. I say fragrant cup, for recently I have made it my business to get samples of tea sent to me from the bazaars in Calcutta and other towns in India. The stuff our native friends know as tea would, I think, be called by you slow death. The majority of the samples held a visible percentage of shellac and mica sweepings, and others were doctored with some pungent scent apparently for the use of "high life." The Commission which has now been formed is the outcome of a suggestion made by His Excellency the Viceroy in the debate on the Assam Labour Bill, and as you may have noticed in the *Englishman* this morning, the practical effort now being made has his greatest sympathy. This should be sufficient to induce every well-wisher of a struggling Indian industry to say a good word for tea to the people they are in touch with. I am quite sure the Indian people will become a hardier and more

thoughtful nation, if instead of drinking the fiery juice of the palm and unboiled tank water they drink pure Indian tea direct from the gardens. The tea industry of India employs many thousand Indian people, as well as hundreds of our own countrymen; this is only one reason why it deserves the sympathy and help of every thoughtful person in the Empire.

FIBRES AND RUBBER.

We are again indebted to our Paris correspondent, M. Godefroy-Lebeuf, for a chatty letter in respect of his Rubber and Fibre experiences, given in our daily issue and *Tropical Agriculturist*. We may tell him that, while many experiments in Fibre extraction have been made in Ceylon, none has resulted profitably. At the time of coffee depression, Mr. Chas Shand improvised a machine and tried all the local fibres available, and got the best results from *Sansevieria Zeylanica* which grows freely in Colombo gardens; but the margin, even in this case, was too narrow to allow of any profit. Later experiments, by a Colombo Syndicate of practical men, were made to give a full trial of locally-grown aloes in a machine strongly recommended by a Natal patentee, and which was fitted up at the Colombo Iron Works, supplies of aloe branches being brought down free by railway; but the result was not satisfactory and there was an appreciable loss to the pockets of the gentlemen concerned. And yet Ceylon might well be said to be a paradise for the growth of fibrous plants; and Mauritius keeps up a steady export of aloe fibre as much as R700,000 worth being shipped in one year.

THE LAKE FLY NUISANCE.

REPORT OF THE ENTOMOLOGIST.

"My visit to Colombo extended from Tuesday, July 30th, to Friday, August 2nd, during which time I studied the life history of the "Lake Fly" and made the following observations. The insect proves to be a species of *Chironomus*, one of the aquatic flies, the early stages being passed in the water of the Colombo Lake." Then follows a scientific description of the insect. The concluding part of the report we quote as follows:—

SUGGESTIONS FOR REMEDIAL MEASURES.

In dealing with this pest we are fortunate in having a nearly complete knowledge of the life history of the insect, and it will be possible to attack it at each of the principal stages of its existence.

The eggs, as noticed above, are laid in the water, anchored to some solid substance which will retain them at the surface, ensuring them the amount of light and air necessary for their development. As this part of the lake is kept free from floating weeds by a system of contracts, it follows that the deposition of the eggs must be confined to the margins of the water. The removal and destruction of all floating rubbish and herbage growing in the water at the margins of the lake will ensure the destruction of an enormous number of eggs. This will not prevent the subsequent deposition of fresh hatches of eggs on the bank. But, from my observation that floating sticks form a favorite point of attachment for the egg-masses, I think it would be possible to trap the bulk of the eggs by laying down,

in the water along the margins, bamboos lightly covered with brushwood. The eggs would be deposited on these during the night. The following morning the bamboos should be lifted out and left on the bank to dry. The heat and drying action of the sun would kill any eggs deposited on these traps. The bamboos would be returned to the water each afternoon at about 5 o'clock. To reduce the available breeding places, the smaller unoccupied islets might be removed.

The larvæ, living on the surface of the mud and being independent of gaseous air, would be unaffected by any application of kerosene to the surface of the water. The restriction of the eggs to the margins of the lake fixes a limit to the feeding grounds of the larvæ. It is improbable that they would wander very far from their native spot. A zone of some ten yards from the bank, all round the lake, would practically cover the sphere of action of the larvæ. The removal of the mud, to a depth of only six inches, along this marginal zone, will effectually destroy the myriads of larvæ now breeding there. A shallow dredging, repeated twice or thrice during the year, will be much more effective than deeper dredging at longer intervals. It will be necessary to remove the oozy surface mud only. The larvæ will not thrive in the firmer gravelly or sandy mud. The insects inhabiting, as they do, merely the surface layer of the mud, it may be necessary to contrive some modification of the ordinary method of dredging to prevent the dispersal of this superficial layer during the operation. Possibly some form of hand dredging might be employed. I am confident that a judicious system of dredging, on the lines here suggested, will practically remove the nuisance or, at any rate, very greatly mitigate it.

The greater number of the pupæ would be destroyed by the same measures that have been suggested for the removal of the larvæ. But in this stage the insect is also vulnerable at a different point, namely at the time when it rises to the surface of the water preparatory to the liberation of the fly. A film of kerosene on the water at this time would kill any of the pupæ with which it came in contact, and would certainly prevent the successful emergence of any flies. If it is decided to give this plan a trial, the application should be made in the evening, shortly before dusk. The simplest and most effective way of applying the oil would be by trailing a rope, covered with rags or tow soaked in kerosene, along the surface, the ends of the rope being attached to two boats which would be rowed along the margins of the lake at a suitable distance from each other. The rope should be periodically recharged with oil.

The adult flies are notoriously attracted by light and might, perhaps, be trapped by bonfires or lighted chulahs placed along the edge of the lake. But I am of opinion that this measure would not really repay the cost. An enormous number of flies might, however, be slaughtered on Dhobies' Island and at other places where they are known to rest during the day, by spraying the grass with a mixture of kerosene and water.

I am most sanguine of profitable results from the employment of the system of dredging suggested above.

E. ERNEST GREEN,
Government Entomologist.

Royal Botanic Gardens, Peradeniya, 10th August, 1901.

THE DEAF HEAR.—No. 479 of *the Illustrated World* of 626, Chiswick High Road, London, W., England, contains a description of a Remarkable Cure for Deafness and Head Noises which may be carried out at the patient's home, and which is said to be a certain cure. This number will be sent free to any deaf persons sending their address to the Editor.

NEW PRODUCTS :

SUNFLOWER AND CASTOR OIL.

THERE is no end to the revivals of so-called "new products" in this island. It would be a great saving of time and patience if newcomers inclined to publish their views on such subjects could make themselves acquainted with what has already been written and done in the columns of the Ceylon press and even in the annals of the Planters' Association in past years. There is scarcely any possible product for local exploiting, about which much practical information, with a bearing on Ceylon conditions, cannot be found in the past volumes of the *Tropical Agriculturist*. We see that at present there is a good deal of discussion in regard to the sunflower and castor oil plants. How often, and from how many different points of view, have both products been discussed in past years! In 1889, a Colombo Firm made known its readiness to take as many as 400 gallons of castor oil a month, but without result. Possibly, inattention to this offer at the time was due to the difficulty attending the extraction of the oil; but, on the other hand, there can be little doubt that soils in Ceylon, as a rule, are too poor to yield, for long, profitable crops of oil-yielding seeds such as appertain to the sunflower and castor-oil plants. The former especially requires good soil and it is a question whether it would not, in situations suitable to it, be more profitable to grow cacao. On the other hand, there are districts in the island where the castor oil plant has been found growing like a weed. What would suit the native and even the planter best would be to gather the seed and forward it to Colombo for the extraction of the oil, if the cost of carriage were not prohibitory? A practical Engineer, writing to our contemporary, says that hydraulic plant to extract oil would cost £500 to £600. Would it not be more economical for a suitable "plant" to be established in Colombo or in some central spot upcountry—say on Katugastota estate—to which the cultivators could send and sell their crops of seed? Individual planters could scarcely face an experiment of this kind; but a Firm, with an Engineer who knows all about it, might well do so, and if a suitable Oil Mill were found successful North of Kandy, we would recommend another to be fitted up in Uva; for, it was in Walapane that "the castor-oil plant was reported to grow as a weed." Perhaps, however, the best way to make experiments in regard to oil-seed, as well as fibre extraction, would be to establish suitable machinery on the Government Farm at Gangarowa, the result being given in periodical circulars for the information of the planting and native community.

INDIAN TEA ASSOCIATION.

Royal Exchange Building, Calcutta, July 30.
Present :—Mr H S Ashton (CHAIRMAN), Mr A Tocher (VICE CHAIRMAN), Messrs H W Boyd, W Brown, D A Campbell, R H A Gresson, A C Lawrie, and R Magor. Mr R R Toynbee was absent from Calcutta.

GREEN TEA MANUFACTURE.

Letters dated 5th and 12th July, from the Secretary, Indian Tea Association, London, were brought up for final consideration and disposal. The principal question raised in these letters had reference to the bounty to be granted to Companies and Proprietors manufacturing green teas suitable for the American market. With his letter dated 23rd May, Mr. Tye had sent a statement of the views of Mr. W Mackenzie, the India and Ceylon Commissioner in America, upon this question. This statement was summarised in the proceedings of the General Committee meeting held on 18th June. In the letter dated 12th July Mr. Tye stated, in reply to enquiries made by the Committee, that the opinion had been expressed in London that "green" tea of the Ceylon type would no doubt in the long run take the place to some extent of the green tea now used in America. But the manufacture of a pure green tea resembling the Japan type, but without any mineral facing, would be more likely to find a ready market. It was also suggested by the London Committee that a Sub-Committee should be appointed in Calcutta to deal specially with the production and shipment of green teas. After discussion it was decided to appoint a Sub-Committee as suggested. The Vice-Chairman consented to serve upon it; and Mr L C Baines (Messrs, Moran & Co.) and Mr H B Yuille (Messrs Balmer, Lawrie & Co.) were to be invited to act. The Sub-Committee were to be asked to consider and to report upon the feasibility of inducing growers to manufacture green teas of similar quality; and of making arrangements whereby such teas might be bulked in Calcutta, the object being to ensure greater uniformity and to enable orders to be duplicated without difficulty.

3. Considered letters dated 16th and 24th July, from the Honorary Secretary, Central Travancore Planters' Association, respecting the proposal that steps should be taken to induce the Colonial Authorities

TO ABOLISH THE IMPORT DUTY LEVIED IN CEYLON upon Indian Tea. Reference was made to this proposal in the proceedings of the last meeting. It was there recorded that the Committee had decided to ask the Planters' Association for further information with regard to a statement made by their Honorary Secretary that there would be no objection to an *ad valorem* duty of 5 per cent being levied in Ceylon as in India. In replying to these enquiries the Honorary Secretary of the Planters' Association had stated that the members of that Association were quite agreeable to the suggestion that Government should be asked to move for the abolition of the Ceylon duty. The Committee understood that the question generally had been considered at the Annual Meeting of the Assam Branch, which was held on the 20th July. They decided to await the report of the proceedings of that meeting before addressing the Government of India.

H. S. ASHTON, Chairman.
H. M. HAYWOOD, Assistant Secretary.

COLOMBIA.—The Board of Trade have now received Decrees dealing with these matters, dated April 30th, and May 1st, 1901, respectively, that export duties are to be levied in gold as follows: India-rubber, 100lb. 0 pes. 60 cts, 2s 5d.—*India-Rubber Trades' Journal*, July 22.

THE BOMBAY BOTANICAL SURVEY.
THE EXPERIMENT WITH SISAL HEMP.

COLLECTING FOR MR. WILLIS.

The report of Mr. G A Gammie, F.L.S., officer in charge of the Botanical Survey, Bombay Presidency, for 1900-1901, includes the following:—

Mr. Bhide, the Herbarium keeper, completed a tour from Poona to Nagothna. He found many interesting plants, but his purpose was more especially to collect good material of *Podostemon hookerianus* and other species on behalf of Mr. J C Willis, the Director of the Royal Botanic Gardens, Peradeniya, Ceylon, who is making a special study of the order *Podostemonaceae*. Mr. Willis, during his visit to the Bombay Presidency in search of these plants, was good enough to give us valuable information and identifications of the materials in this herbarium. During the tours special attention was devoted to obscure plants, and many—especially Orchids—were brought back alive to Poona so that Mr. Bhide could figure them at leisure as they came into flower.

Experimental culture of Sisal Hemp.—The station at Nandgaon was fully planted out during the early part of the rains, and the plants under observation there now number 2,000. The plants were in a flourishing condition at the time of my visit, and there is a certainty of the plantation ultimately proving a success. Twenty-one thousand young plants and bulbils were distributed to various applicants and a large number have been promised for this season to the Divisional Forest Officer at Nasik. As the area at my disposal is so circumscribed and as sisal culture has become established in several parts of India, this department may now restrict itself to the growth of plants solely for distribution. During the year ten plants flowered and produced bulbils which were gathered and planted.—*Madras Mail*.

THE NEW MANURE.

Mr. John Hughes writes by last mail:—

Basic superphosphate is taking very well. At the Highland Show at Inverness I was told by the head partner of Messrs. Cunningham & Co. of Leith that they, as the Scotch representatives of the Syndicate, were doing *very well* and had sold over 400 tons already in Scotland. It will be advised *next year* when we have collected the results of numerous field experiments.

COCONUT DISTRICT. N.W.P.;

Marawila, Aug. 17th.

While the western and central parts of the island are suffering from too much rain, we are passing through rather a

SEVERE DROUGHT.

For over a month we have had no rain, and whatever moisture there happens to be on the surface soil is licked up by a dry, scorching wind that prevails. Rain is very much wanted in these parts. The two biggest

CROPS

of the year are generally harvested between May and August. This year the current crops are said

to be very short everywhere. This ought still further to raise the price of copra, for which the demand is as keen as ever it was during this year. A native estate owner is reported to have erected

A FIBRE MILL

on his estate at Kirimetiya, and to be erecting a desiccating mill. With one mill at Lunuville, one at Horrekelle, and one in prospect between the two, we cannot be said to be badly served as regards the sources of demand for our nuts. The more mills the merrier, say estate owners. In time there will be no such articles of commerce as Madampe, Marawila and estate copra. It is with extreme regret that the whole district of Chilaw has heard of

THE REMOVAL OF MR FRASER

while it cannot withhold from him congratulations on his well-deserved promotion. If he had been permitted to remain two years longer here, those who had been acquainted with the town and the district would hardly have been able to recognise it. The Civil Service has not another more gentlemanly, courteous, hard-working and whole-hearted member than Mr Fraser. His subordinates, from the highest to the lowest, affirm that they seldom worked harder and more cheerfully than with Mr Fraser. It was a pleasure to work with a superior who worked hard himself and who was the soul of courtesy. I have just seen in the papers that Chilaw is intending to give Mr Fraser a "send off." It is an honour that was not accorded his five predecessors since I have been in the district. That reminds me how badly Chilaw is being treated. It has had six Assistant Government Agents during the 5 years I have been in the district!

PLANTING NOTES.

THE OKAPI.—"Nature" records the fact that Sir Harry Johnston's okapi has now been mounted for the Natural History Museum, and will be exhibited at first in the North Hall. It is said it presents a considerable resemblance in form to a small, short-limbed and short-necked giraffe, although furnished with the large ears characteristic of all forest-dwelling animals, and with an absolutely peculiar type of coloration. No such important discovery has occurred since the giant panda (*Eluopus*) was made known to the scientific world in the sixties of the last century.—*Globe*, July 26.

AGRICULTURAL PRIZES IN ITALY.—The Federation of the Agricultural Unions of Italy, together with the Agricultural Unions of Padua and Florence, has opened an International Prize Competition for the sum of 1,000 francs in gold, to be awarded to the person who discovers and makes public the best method for obtaining exact and constant results in the determination of the fineness of the flowers of sulphur and of mixtures of sulphur and copper sulphate, to be used for combating diseases of plants. Competitors must send in their papers in a sealed envelope to the Head-office of the Federation (Ufficio direttivo della Federazione italiana dei Consorzi agrari, Piacenza, Italy), before March 1st, 1902. The papers will be examined by a special Commission to be named by the "Reale Accademia dei Lincei, Rome," whose decision will be without appeal.—*Journal of the Society of Arts*, July 5.

Correspondence.

To the Editor.

MR. COOKE'S RESERVE TEA SCHEME:
A REPLY TO "PATIENCE."

August 3rd.

DEAR SIR,—A clergyman's wife once heard her husband using very strong language; he was out of sight behind a hedge, and she called to him "Patience, dear John; Patience," and he howled back "Would you have patience with your foot in a man-trap?"

It does not remain for me to say why simple reduction would be fatal. Many Brokers and writers on tea say that any deficiency of supply from ourselves or even an excessive rise in prices of our teas would drive the Blenders to take China and Japan Tea.

In order that prices can be forced up, we have to limit the supply to our present markets to the actual requirements of our Buyers, that is to say, leaving them only a fair margin of profit between purchase and sale price, a certain addition to prices can be made to the customer without reducing consumption.

If we can manage to get a half-penny out of the consumer, and the average price of tea is 18 pence—this half-penny is 1-36th of the price of the tea; it cannot be expected that by raising the price 1-36th the same proportion of reduced consumption will necessarily be made. My idea is that by regulating supplies we shall be able to get one penny out of the buyers and dealers without reducing their profits too much, and a further half-penny or quarter-penny out of the consumers without reducing the consumption to any marked degree.

As long as we can keep within these limits no China tea will be imported to fill up the vacuum.

The reduction scheme proposed to leave the leaf on the bushes, and if this were actually done where would the supply for new markets be obtained?

My scheme permits of a supply for this purpose, but the cost of manufacture has to be considered, and this would be obtained from a Cess of two pies per pound.

The grower having paid two pies on his whole crop would be that amount out of pocket, unless his action resulted in raising prices by two pies.

Then he would have paid two and a half annas for making the reserved tea, but, as this would be paid for out of the Cess, he would be repaid out of his own money, and would still be two pies per pound out of pocket. But when the reserve tea had been sold and two and a half annas refunded to him he would be exactly in the same position as regards expenditure of money, as if he had allowed the leaf to stay on the bushes. "Patience" says that I have made no suggestion of stimulating demand. If I have not, I will now say that it stands in reason that good average tea, placed in the hands of new dealers, is more likely to create a rapid demand than are present system.

The buyers reserve all our good tea for stimulating the demand of their customers; they are continually able to give better quality for the same price; but they send only *scourings* (tea they don't want) to new markets.

I argue that average Indian tea put into circulation on the outskirts of our present demand will prove of better effect than offscourings offered at a higher price. We can if necessary put this good tea into new hands at cost price, not the total cost price, including all expenditure, but merely at the cost of making it. New markets are fed on skim milk, the cream being extracted by our buyers. I propose that we send the fresh milk (which includes the cream) direct to those who do not handle our teas.

I do not propose to "dump" our reserve tea on to new markets; that would be fatal, and it would simply return to our present buyers, but by creating a fund (a 2-pie Cess) of sufficient magnitude we shall be able to place our reserve tea with all necessary precautions that it shall not return, but stay and create a demand.

A Cess of three pies or four pies would do better, because those who refuse to supply tea would contribute more towards the general expenditure. I do not propose to reserve tea and hold it for a rise in prices. Having reserved the tea and been paid for it out of the Cess, each estate would keep the tea for the Association and send it when wanted. This would prevent the necessity of having an enormous storehouse. The agents of the "Cess Scheme" would wire for supplies to Calcutta and then whatever quantity was wanted would be collected, bulked, &c., and despatched to the agents. "Patience" says that neither growers nor Government will accept a compulsory Cess. Government will certainly agree if we can show that this course of action will allow of the expansion of the tea industry. Germany would subsidise the industry and so make all the inhabitants subscribe. We are content to force all tea owners to subscribe.

Indian and Ceylon owners offered to reduce, i.e. to wipe out 14 million pounds, which, taken at five annas per pound, comes to over 43 lakhs of rupees. Why should they refuse to pay a Cess which would cost them less than $\frac{1}{3}$ that amount? Taken at 10 per cent, 14 millions show a production of 140 millions—that is to say the makers of 140 millions offered to pay 43 lakhs without much hope of return and a two-pie Cess on 140 millions would cost them about 14 $\frac{1}{2}$ lakhs only, and I have shown that this would be repaid by the sale of the tea itself. I would point out also that the greater part of the owners, who promised to reduce quantity, were getting paying prices and they must have made the promise either because they want better prices, or fear that they may get worse. In my opinion the raising of prices is the last and lowest object in view. I myself am getting a price that pays, but I want to increase my yield so that the same prices shall pay more profit. Seeing the necessity for expansion, I have gone far beyond all other "schemers" and proposed a Cess of two pies per pound added on to the reduction scheme.

A. C.

THE PROPOSED GREEN TEA
SYNDICATE.

ITS ADVANTAGES SHOWN BY THE ORIGINAL
MAKER OF GREEN TEA IN CEYLON.

Travancore, August 9th.

SIR,—With interest I have read in your issue of 3rd inst, your leader, and also Mr. Ryan's interesting letter on the subject of the proposed "Green Tea Syndicate."

This Syndicate is undoubtedly a step in the right direction and I only wish such a scheme were as feasible in this country as it certainly is in Ceylon. In addition to other advantages as pointed out by Mr. Rosling and Mr. Ryan, such as uniformity of invoices, and ability to book repeat orders, two of the greatest difficulties this young trade has had to contend with can be by its means overcome successfully, viz:—

1. It is a matter of common notoriety that most London tea firms, if not openly, then secretly, are against the expansion of the green tea industry, which will undoubtedly deflect tea from their hands, for, however bad prices may rule for black tea in London, however bad prospects may be for proprietors or for shareholders, still a certain amount of 'sugar' in the shape of commissions on sales, return commissions on freights and often interest on Warehouse and Dock Companies' charges, will stick to the fingers of the London merchant so long as the tea enters that port. Not that this is not right and reasonable from his point of view, but the Planters' Association exists for the very purpose of upholding planting interests before any other and by its members forming a Green Tea syndicate or Guild the first difficulty, that of finance, will be overcome. At present the private proprietor in most cases finds great difficulty in drawing against green teas or in any way financing himself save and except by a forced sale in Colombo; but, Sir, I take it that a Syndicate or Guild run under the auspices of the Ceylon Planters' Association (blending its own teas in Colombo to uniform standards under the instructions of some well recognised green tea expert such as Mr. F. Street) would have no difficulty in drawing on America or Canada sufficiently to enable all members of the 'Guild' to receive at least the cost of production, say 25 cents, against the tea on its arrival in Colombo. And this facility would, I believe, give an impetus to the industry of green tea manufacture.

2. The other great drawback to the industry has been the difficulty of disposing of good fannings and clean tea dust—except at a loss—because the Canadian and American markets will have none of it in that shape, and we have not the green-tea-drinking population as in China and Japan to consume it. To suit, then, the tastes of our American and Canadian purchasers, we must eliminate all fannings and dust, which means in practice about 15 per cent and 1 per cent of our manufacture, if thoroughly done, and by this means get a good name in the above markets, where *whole leaf teas* only are of any use. (I would mention here that I have had some samples of Ceylon green teas sent me by Messrs. Moran & Co., Calcutta, which had fetched poor prices in America and that these teas, though drawing good liquor and having good flavour, were simply ruined by a proportion of fannings being mixed in with each grade, no doubt to get over the above-mentioned difficulty).

I submit, Sir, that with a "Syndicate" it will not only be feasible, but urgently advisable, to procure for the Syndicate's use the very best Hydraulic Compressing Machine that money can buy (probably it will be good policy to purchase it in America) and then deal with *this 15 per cent of tea*, moulding it into slabs of, say, 8 oz. again divided into 1 oz. divisions, easily detachable by breaking with the hand as is done with many

brands of chocolate. The slabs might be covered with silver paper and stamped "Pure Ceylon Compressed Tea" on the wrappers, the usual advertising matter stating also that the purity and good quality is guaranteed by the C. P. A., who employ an expert to pass the teas and that this method of preparation is introduced to save bulk in carriage and for the special convenience of travellers and military camps. All experts in green tea are aware that, given the teas are well-made, these neglected qualities draw a good liquor and have an excellent flavour and it is solely the appearance that is against them. Well then with a Syndicate it is at once possible to say "Vanish" fannings, "appear" "Ceylon Compressed Green Tea," which latter, if carefully made and well-advertised, will soon become a very saleable article; or I am much mistaken. The Hydraulic Press is, I know, expensive as I made enquiries years ago, but what was *prohibitive* to a private individual, with no one backing up his experiments, becomes easy of purchase and certain of success when in the hands of that powerful body the C. P. A. Apologising for the length of this letter, which I hope may be of some encouragement to the successful expansion of the Green Tea Enterprise, which was started by myself and in which, though exiled, I take a great interest, —I am, Sir, yours faithfully,

H. DRUMMOND DEANE.

THE TEA RESERVE SCHEME.

August 10th.

DEAR SIR,—Your weekly *Observer* of August 1st to hand today. I was going through it as usual without much hope of improvement in our prospects, till I suddenly came on your leader of July 29th about

THE IMPORTANT COMBINE.

My scheme proposed a sum of 20 lakhs, gathered from the entire body of Indian Owners and is five times more than proposed by the Association, but you tell us of one million pounds sterling!!! capital of 150 lakhs of rupees!! $7\frac{1}{2}$ times more than I proposed!! and it is to be gathered from a combination of Importers. There is some discrepancy in the rumour because 750,000 acres at $15 \times 5 = 20$ shillings per acre does not amount to one million pounds. Besides that the area to be brought into line *must* include half of Ceylon also. If we take 240 lb. of tea per acre for 750 thousand acres it comes to 180 million lb., about the total yield of India, and if it was intended that India *only* was to join the scheme it would have been stated definitely. The scheme seems even more complicated than mine, because the owners would have to decide the value of each class of tea separately, and then buy in any particular sort which failed to fetch their valuation. My scheme was intended to rest on the *average* price of all Indian tea and to allow Producers to find out whether they could make tea at that average price.

I do not want to run down the new scheme. It is an excellent one, and I proposed it myself some years ago, but I think that the strongest point in my scheme is "the Cess," a circumstance, a condition, which will force *all* owners to join in supporting their mutual interests. The other scheme would be apt to fall to pieces and leave us worse off than before, but a Cess would last for a definite period. When all owner,

are forced to pay the Cess they will interest themselves in the spending of it. You may not have noticed the intimate connection between private tea sales and the Importers' Combine, but when the importers refuse tea to the general buyer they will *get higher prices* at the private tea sales; we understand that some of the buyers want to pay more, and the Importers will let them have their way even at the cost of secrecy. The rumour of this Great Combine, although not absolutely correct, has probably a good foundation. Divide the figures by half—£500,000 and 500,000 acres at £1 per acre, there would be *money* and that is the prime factor to success. The 20 lakhs of my scheme is really all I want to see accomplished, but I could not go on repeating this short sentence. I had to concoct a decent scheme for the use of it. I would warn Tea owners, however, that, if they allow any combine of the sort indicated, those left out will sooner or later be left in the lurch. The combined importers will be able to crush competition amongst buyers, and our fondest hope is that we shall be able to stimulate competition for our Tea.

On July 31st, in your notes you say that Ceylon and India are still far from sufficiently united to run together in the *complicated* working of the plan I proposed in your columns. If I did advise anything complicated and objectionable I withdraw it, and shall expect your full support for the following of a 20-lakh Cess for India and a corresponding amount for Ceylon. A promise on the part of Proprietors to withdraw their surplus from London and to place it in Calcutta or Colombo, and when there is a surplus there, to place it on any terms, (the best they can procure)—on foreign markets with sufficient precautions that it shall not return to Calcutta, Colombo or London. There is certainly no use in going into further details, which can only be decided by those who will be put in charge of our affairs.

On July 29th, in the letter from your London correspondent, he refers to a recent letter for "Regulating Tea sales by a general Syndicate of Proprietors who should feed the market in exact proportion to its requirements &c., &c." I regret that I have missed that letter, unless he refers to my own scheme!! I think it is time to warn all concerned that it is *necessary* for them to join in combined action if they would save their estates. The amalgamation of a few gardens renders them stronger, and lessens the chances of those not amalgamated (excepting of course the great concerns). The amalgamation of large Companies will be infinitely more serious; they will be able to *enforce* the rule of the survival of the fittest. So that, whatever combine is contemplated, it is urgent for each Proprietor that he should insist on belonging to it.

Times are moving, Mr. Editor, and it is to be hoped that you will add all your weight to the movement. Please cease to doubt that Ceylon and India will combine; if you say they *will* do so and they do not do so, it cannot injure your reputation. If you will only pick out the slightest symptoms of mutual agreement and enlarge on it, it will do an infinity of good to the cause. At present we are ready to combine or fight if only our leaders will say which it is to be. Your Ceylon Planters come to India, and promptly "go for" Ceylon on the question of over-production. Some of the big Companies own estates in both

countries, and they would surely like to further any chance of agreement and combination. A Cess of 20 lakhs and 14 lakhs from both would do much more good than 20 from India and four from Ceylon. India has robbed Ceylon to three-fourths of the benefit of its Cess, because it had no Cess at all. Ceylon poured tea into foreign markets, but what was the use of it? India poured more into London and prevented a rise in prices. I think that I have already pointed out that there will be a struggle for the extra 2d duty when it is remitted. Our united crop is worth over two million pounds at 2d per pound; surely that is worth having, and shall we get it unless we are combined? Can you propose any scheme, other than the one I have proposed, which will enable us to prevent that two million pounds passing into the hands of the buyers and consumers?

If we put *all* our tea in the market, why should the buyers pay more than they now pay? The customer will pay what he is now paying, and when 2d duty is taken off, who will get it? It *can* be given to the consumer in order to stimulate consumption, but we ought to see that it is not given too rapidly, *i.e.*, not until consumption has increased in *proportion* to the prices reduced.

A.C.

CEYLON TEA IN AMERICA.

Colombo, Aug. 20.

DEAR SIR,—To my mind nothing can justify a continuance of the secret payments made by the Ceylon Tea Commissioner to tea firms whether in Canada or the States. Take the case of a local merchant or exporter who is also interested in estates. He is a tea producer and contributes to the Cess. He is a shipper and a seller in the States and Canada; but the money he provides in the Cess, is paid to the Commissioner who hands it to this taxpayer's competitors in America, who are thus enabled to undersell the Colombo grower-merchant there! There are many in the above position, and we object to money thus provided being paid away to local detriment.

GROWER AND EXPORTER.

[We have never seen the condemnation of the Ceylon Commissioner's policy put so neatly in a nutshell before. From the beginning though, we have held that the Cess money should have gone in advertising for the benefit of all interested in selling our teas and not in secret subsidies sure to provoke jealousy and ill-will.—ED. T.A.]

TEA EXPORTS TO AMERICA.

Colombo, Aug. 20.

DEAR SIR,—Have you statistics by you, showing the total quantity of tea imported into the U. States and Canada in each of the last five years from Ceylon, India, China and Japan, each country separately?

It would be an interesting statement.—Yours truly,

MERCATOR.

[We give the best information available at the moment, as follows:—

Tea Exports to North America in lb.

From]	1896.	1897.	1898.	1899.	1900.
INDIA	5,253,773	5,663,244	5,971,701	8,487,443	6,958,370
CEYLON	4,364,510	5,698,596	7,636,995	8,289,376	9,173,824
CHINA	30,146,000*	57,000,000†	53,000,000‡	44,367,271†	50,901,974†
JAPAN	62,061,000†	45,000,000‡	42,611,909	40,000,000‡	36,000,000‡

India and Ceylon are given for the calendar years; but the China and Japan 'seasons' end with April. The total imports into the United States for years ending June 30th are given as follows by the *American Grocer*:—

1896 ...	93,340,248 lb.	1899 ...	72,834,816 lb.
1897 ...	112,907,548 lb.	1900 ...	84,843,491 lb.
1898 ...	67,697,295 lb.		

To this must be added the imports into the Canadian Dominion and Newfoundland, about 25 million lb. a year. Altogether, it is estimated North America requires annually 28 to 30 million lb. of black teas at present and 65 to 68 millions of green and partly fermented teas. The "Commissioner" has also declared that the duty of 10 cents per ton lowered the consumption of tea in the United States by nearly 25 million lb. per annum!—*ED. T.A.J.*

THE SPENDING OF THE TEA CESS
FUND AND THE CEYLON IMPORT
DUTY ON TEA.

DEAR SIR,—I am sure all we planters are much indebted to the Ceylon press for the keen interest being taken in matters that so closely concern us in connection with the spending of the Tea Cess Funds, especially as regards America.

From 1894 to end of 1900, the total sum collected by the Cess aggregates close on one-and-a-half million rupees.

It would be interesting and instructive, if the "Thirty Committee" were to issue a pamphlet, to all who contribute to the Cess, showing roughly how and where this sum has been spent, and the results of such expenditure to end of 1900. For example, if such as the following information were put clearly before all interested, it might result in the "Thirty Committee" receiving valuable suggestions for their future guidance: such as:—

Summary of Tea Cess Expenditure with results for year:—

Country.	Salary of Commissioner, &c.	Sums spent by Do.
Proportion of General Expenditure.	Total Expenditure.	Increase during year in lbs. Ceylon tea sold.

One such schedule for each year since the commencement of the Cess, and one general schedule showing the totals for the 7 years. Another schedule for *green tea* would also be necessary.

Now that the Cess has been in existence for several years, there is something to go on, but I, like a good many other planters, am not suffi-

ciently well posted up in the Tea Fund figures to pass any opinion on future expenditure. If the "Thirty Committee" were a little more liberal in distributing concise information to all, as regards expenditure and *results*, good would I feel sure, come of it.

There need be no occasion to publish full details of subsidies made by our Commissioner and the Committee, although I, for one, doubt the necessity for "secret payments." The "Thirty Committee" must judge whether such payments have given results good enough to justify their continuance.

The Committee is composed of the best men in Ceylon, but they are likewise the busiest, and cannot spare the time to go into details. So I think they should appoint a managing Secretary, to devote his *whole* time to the collecting of information as to how and where fund money should be spent.

The salary of such a Secretary or adviser would be money well spent and so would his travelling expenses to Russia or America, or to any country, where it might be necessary for him to visit personally.

The taste for Ceylon tea is gradually becoming universal, so I think the time has now come when the efforts of the "Thirty Committee" would be greatly benefitted, if Government were to appoint an Inspector to prohibit the sale and export of all tea below a certain standard to be fixed by the Committee.

I also think the import duty on all British-grown tea into Ceylon should be abolished, and every endeavour made to make Colombo a large tea distributing centre, *the market* for foreign lands. Why force the foreigner to go to London or China! Give him a market sufficiently large and representative in a port so favourably situated as Colombo is, then we shall see foreign markets for British-grown teas increase with leaps and bounds.—Yours faithfully,

ONE OF THE NEW ORDER.

Upcountry, 19th August, 1901.

ON RUBBER, FIBRES, &C.

Paris, la 21 Juillet.

DEAR SIR,—I meant by Insuline (INSULINDE) not Insulande, the country constituted by the islands Sumatra, Borneo, Java, etc.—to answer to your demand of last C.O. June 28th.

Formol for the conservation of latex is Aldehyde formique with 60 per cent of water. You obtain Formol at 40 per cent—2 per cent of Formol is sufficient for the conservation of latex. For conservation of flowers and fruits it is preferable to alcohol; it does not change the colour of the samples nor the colour of the nose of the black bearers because these cannot drink this substance.

That the process of extraction of rubber is industrially adopted, any of your readers when in Paris can see if they call at our Co.'s office, 3 rue Scribe, near the Grand Hotel. One block of rubber weighing 105 kilos has been made entirely mechanically with barks of *Landolphia Hendelotii*, perhaps the best rubber plant for dry and almost unfertile soils.

I have received some time ago from the oriental coast of Africa a sample of a new *Sanscevera* or I believe so; and as Ceylon is the paradise for SANSEVERIA, I believe this plant will be an interesting one for you. You will see by the adjoining design that the leaf is respectable one, fully six feet long, weighing

* Excluding Formosa teas. † Including Formosa.
‡ Including Formosa. § About.

little more than 2 kilos; the circumference is about 17 centimeters. This leaf was certainly larger when fresh.

I do not know if *Sansevieria Zeylanica* is regularly grown in Ceylon, for fibre purposes, but I do not believe *S. Zeylanica* is comparable with this new sort. It is not *S. Thunbergii*, but a distinct species. It is no more *S. Perrottii* from Zanzibar but perhaps near it. A few years ago M. M. Nicholson and Watson called my attention to *Thunbergii* and I found this new sort a long way from the place where *Thunbergii* is met with. I believe this gigantic species will be easily adopted by growers, if any *Sansevieria* grower exists. How do you obtain fibre, by machinery? by hand? We are combining a little measure, but if we succeed well with all the *Sansevieria* with round leaves, such as *cylindrica*, *sulcata* and the new species; we have been unsuccessful with the species with flat leaves such as *Zeylanica*, *longiflora*, *Guiniensis* or others. I hope, in a few years, growers will think about these fibre producers and *Sansevieria* fields will be as common as Mauritius hemp or Henequin fields! *This new Sansevieria* gives fully 7 per cent of very fine and silky fibre.

I have introduced recently a new rubber producer, the *Forsteronia floribunda*. *Forsteronia* is an apocynaceous climber and more than forty are known in America, chiefly in Brazil. Two species have been regarded as producers of rubber: *F. gracilis* from Guiana and *F. floribunda* from Jamaica. *F. gracilis* is a gigantic climber, one plant sent by one of my collectors reached 4½ yards in two months, in my house. I believe *floribunda* is not a free grower but its product is as good as Para rubber. Kew regards its quality and I have been astonished when I received this same field plant from Haiti. I hope to receive fresh seeds in a few weeks. As my thermometer is always at 27 degrees Centigrade (81 to 82 degrees Fahrenheit!—ED.), allow me to present you my best compliments.

A. GODEFROY-LEBEUF.

PLANTING NOTES.

ABANDONING TEA AND COFFEE IN SUMATRA.—We learn that the British Deli and Langkat Tobacco Co., Ltd., have closed their Tea and Coffee estate, confining their attention to their staple, tobacco. A grain of comfort this for coffee and tea planters suffering from over-production.

TEA COMPANIES' CAPITAL.—From the latest *Investors' Guardian* we see that as much as £484,500 sterling was registered in new tea companies during the first six months of 1901, as against £18,000 in the same period, 1900, and £420,000, 1899. We quote as follows:—

"With the depression which has been the chief characteristic of the business of tea companies and from which not even the most soundly established have escaped, it is rather surprising to find a sum of nearly £500,000 to the credit of this year against only £18,000 in the first six months of 1900. It would appear as if some were possessed with a sublime confidence in the future of the tea industry which no depth of present depression can affect."

No capital was registered for Scotch or Irish tea companies this year or last; and only £3,000, in Irish, was invested for the period in 1900.

PINE HILL ESTATES COMPANY.—In these times of depression even 4 per cent must be regarded as a fairly good dividend on tea property, and we are pleased to notice from the report of the Pine Hill Estates Company meeting today that this amount has been declared. We congratulate all concerned.

CACAO GROWING IN SAMOA.—For Mr. Moors' long and interesting letter on this subject, see our last weekly issue and next *T.A.* We have given answers to certain questions in editorial notes to the letter. It will be observed that Mr. R. Carruthers expected to get 22 cwt. of cocoa per acre altogether in one year's crop, having got 17 from the Spring return and more looked for in October.

PEMBA RUBBER.—Various species of rubber vines grow wild all over the island, but can hardly be said to exist in paying quantity. The late Mr. Robertson, of His Highness's Agricultural Department, devoted some attention to the rubber vines during a visit which he paid to Pemba in the course of last year. He established some fifteen workmen at Ghazi, a district in the north of the island, where the vines exist in considerable number, their duty being to clear away the dense growth of useless vegetation and generally to look after the vines. There appears to be no reason why rubber should not be successfully cultivated here, and it certainly is one of the most paying of crops.—*India-Rubber Trades' Journal*, July 22.

THE FIG TRADE OF SMYRNA.—Figs form one of the most important items of export from Smyrna and a description of the trade is contained in the last report of the British Vice-Consul at that place. The chief markets for Smyrna figs are the United Kingdom and the United States, some of the Continental countries also taking small quantities. The district in which the fruit is grown lies wholly along the Smyrna-Aidan railway. There are two kinds of figs, both growing on the same tree—that for eating and that for distilling. The fruit grown on the plains is larger and richer in saccharine matter, but on the other hand the trees here suffer frequently from excess of moisture, while those on the higher ground escape the consequences of wet seasons. The fruit ripens about the middle of August, when it is picked and dried in the open air for a few days. It is then packed in sacks of about 250lb. each on camels and sent to the nearest station, whence it is conveyed by train to Caravan Bridge, Smyrna, and so to the purchasers in that town. The arrival of the first camel-load there is celebrated as a popular festival for the washing, drying and packing give employment to thousands of families. The dried figs for food are sold before the end of November, after which the sales are almost wholly those of figs for distilling; some of the latter are sent to Austria, where they are used as a substitute for chicory. Last year the crop amounted to 65,000 loads of 500lb. each, the usual price being £1 to £1 5s. per load. Another agricultural product of the Smyrna district, which forms an important item of export, is valonia, the cup of the acorn, which is of great value in tanning, as it gives weight and consistency to the leather, while the colour which results is very fast. The oaks which bear the acorns are beaten with long sticks during the autumn and the valonia dried in the sun and then sent to Smyrna, where it is graded. Last year the export from Smyrna amounted to 68,000 tons, of the value of £2 6s. to £3 6s. per ton.—*London Times*, July 2.

KOLA—to the value of 2,280*l.* was shipped from Gambia during 1900, against 2,199*l.* in 1899, and 1,345*l.* in 1898. The exports of bees' wax decreased considerably last year, being valued at 922*l.* only against 4,411*l.* in 1899.—*Chemist and Druggist*, August 10.

RICE AND CLIMATE IN THE NORTH-CENTRAL PROVINCE.—A gentleman interested in agricultural progress in the more backward divisions of Ceylon, writes from Anuradhapura:—"Why is it so little so-called 'table rice' appears to be grown in Ceylon? Up here only the 'quick' rice is grown, which is of course due to the precariousness of the water supply; even where village tanks exist, as they are usually only too small, 'heeneti' is mostly patronised. There does not seem to be much 'public' information to be had about rice. I can understand it, though, as only a few whites are directly connected with the plant. I must say so, for I am charmed with the climate as a whole, up in this district."

COLOMBO PRICE CURRENT.

Vol. XIII.]

SEPTEMBER, 1901.

[No. 3.

AGRICULTURAL BANKS.

IF there is any place where the establishment of State Agricultural Banks would prove to be of undoubted value it is Ceylon, where the condition of the small landholder is deteriorating day by day. There are several causes which have been and which are at work in reducing the prosperity of the *goyiya*. The limitation of the area of land available for his operations through the better defining of Crown titles and the division of land among a large number of inheritors, the exhaustion of the soil in patches of land which have been under cultivation for long periods without the addition of fertilizers, and the increase of individual expenses of the cultivators through the introduction of new articles of food and clothing, and through the increase in the prices of articles of daily use, have one and all contributed to the increasing poverty of the cultivator. These and other causes have driven him into the hands of the money-lender, whose exorbitant rates of interest have in many cases completed the ruin of many a prosperous cultivator. Before one can advocate the establishment of Agricultural Banks, there are two questions that will have to be satisfactorily answered :—Are the cultivators of land involved to such an extent as to make indebtedness a general rule, and are they paying rates of interest which can be classed as unreasonable and ruinous? Secondly, is this state of things causing any serious deterioration of the prosperity of the country, and will the establish-

ment of Agricultural Banks lead to an improvement in the existing state of things, and bring on such results as will justify the trouble and labour that will be required in their establishment and maintenance? Both these questions can be satisfactorily answered without entering into an elaborate system of calculation, which cannot be accurate for want of necessary statistics and particulars. There is one simple way of gauging the indebtedness of the cultivator. A return of accounts lent on mortgage deeds during a year can be obtained from the Registrar-General's Department. Such a return for a series of years will not only shew the amount of indebtedness, but will shew the proportions in which this has increased year by year. In addition to loans raised on mortgages, there is the continual secondary loan system by which a cultivator borrows from the petty trader in the village all the seed paddy he requires for sowing his rice fields, all the manure he requires for use in the fields, and the little money he takes for his urgent necessities. All these are received against the crops, and after harvesting the lender is repaid with such rates of interest as are now commonly agreed on. Both these systems of raising loans are, it may be said, becoming universal in every village, but as regards the last-mentioned method there is no way of obtaining a return or of expressing in figures the extent to which it is resorted to. The best means for obtaining anything like an idea of the extent of these temporary loans will be to select three or four villages in different districts at random and obtain returns of the temporary lo

with a view to forming an idea as to the extent to which they prevail. Then it will be found that almost every acre of paddy land under cultivation is indebted to the extent of 6 to 7 rupees each season. As to the rates of interest it will easily be found that they are most unreasonable and ruinous. The usual rates of interest in a village on a mortgage bond is from 20 to 30 per cent per annum on the capital, and on advances against crops from 50 to 100 per cent per four months on the capital advanced, working to about 150 to 300 per cent per annum. The crop loans are always given for the season, and 50 per cent is the lowest charge ever made in a village. These figures are so enormous, it is to be feared that in many quarters they may be put down as exaggerations or isolated instances; however, it may be emphatically stated here that 20 per cent on the mortgage of property and 50 per cent against crops are the minimum rates.

It must be plain to any observer, that with the depression in the productive power of land and the limitation of the area of land obtainable, and the increase in the cost of living, the margin of profits left to the cultivator must be really small, or in the most cases is a diminishing quantity. And when to all these depressing effects the rates of interest at which capital is borrowed is added, there is no reason to suppose that the average cultivator will be able to stem the current of depression unless he gets some timely aid from some new direction. There is another question which, if explained, will make our case clearer. It may be said that there must be a certain amount of prosperity in the villages to enable the cultivators to borrow to such an extent, and the sooner the weaker men succumb, the better it will be for the general state of prosperity. However, the village lender is not the villager, but the itinerant hawker, the Moorman, who has now his boutique in almost every village in the island, and who is the only man profited by this state of depression. He lends the money, he makes the advances on crops, and buys the produce at his own rates, and charges the ruinous rate of interest.

The establishment of Agricultural Banks at this juncture will be very opportune. They will just be in time to give the necessary stimulus to industry which is passing through depression.

Agricultural Banks are not new institutions, they have been established in a limited scale in the Deccan, and have worked with immense success. The latest Indian Budget statement shows that arrangements are in progress for their establishment in India on a more general scale. New Zealand has a successfully worked loan office established since 1895. The operations at this loan office were restricted to freehold mortgages upon gardens and farms, the charges for the survey of land proposed to be mortgaged was only half a guinea to two guineas, and the legal fees from 25s. to £2 according to the scale of the loan raised. The interest charged is fixed at 5 per cent, and the borrower has the option of obtaining his loan in two forms, either for a fixed period, or on an instalment system. Where the instalment system is adopted an annual charge of 1 per cent extra is made as a sinking fund; on this basis a

borrower of £100 by paying £6 per annum wipes out his debt in 37 years. This scheme has since been adopted in Victoria, South Australia, and other Australian Colonies.

The conditions prevailing in Ceylon will require the working of details to suit our circumstances, but this will not present many difficulties.

In addition to affording immediate relief to the cultivators, an Agricultural Bank, if established, will be the means of opening up a large extent of new land under our projected railway and irrigation schemes. It may also not be out of place to mention here that the benefits of a scheme of a properly-organized State Agricultural Banks will not in any sense be confined to the small agriculturist, whose claims have been advocated here. The large and more enterprising landowners, European and Native, are in a measure bound to benefit greatly by such an institution.

Total. 1.127

Greatest amount of rainfall registered in 24 hours on the 15th Aug. .9 inches:

Recorded by C. DRIEBERG.

PRACTICAL HINTS TO HORSE-OWNERS.

CHAPTER III.—SHOEING (*Continued*).

The portion of the hoof that touches the ground is called the *soler surface*, and is of very great practical interest to the horse-owner. The rim of the hoof $\frac{1}{4}$ in. or so wide that extends from one heel to the other and above up to the coronet is the wall. The heel is that portion of the wall where the latter meets the bar. The angle of the heel is formed by the heel and bars. The quarter of the wall extends from the heel to the shoulder of the wall, which is the point where the quarter and toe of the wall meet. The toe or tip is that semilunar portion situated anteriorly to the hoof. The white line on "linea alba" separates the wall from the sole. This line is the guide to the farrier

when driving nails, and when he gets inside of this he pricks the horse's foot. The sole protects the internal sensitive part of the foot from injury below and is surrounded by the bars of the wall. The bars are inflex portions of the wall which run inward from the heel and from which the frog emerges. The foot pad or what is vulgarly known as the frog, is a soft elastic lining of horny substance which occupies the space between the two bars. The parts of the frog are the toe on the point, body, heel and cleft.

I shall now briefly touch upon the function of the different parts of the horse's foot. The anatomy and physiology of the hoof of the horse are of the first importance to the Veterinary student. That part of the limb of the horse to which in ordinary language the name foot is applied is nothing but the extremity of the fingers or toes regarded from a zoological point of view, and extends from the carpal and tarsal (knee or hock) to the extremity of the limb.

The wall protects the inner structure from violence and atmospheric influences. The bars bear a certain amount of concussion and prevent the contraction of the hoof. It is the cutting away of these bars by the farrier that causes hoof contraction. The frog is the elastic cushion which prevents jar and concussion, and the cutting away of it also results in contraction. The coronary band is a soft elastic structure which unites the wall of the hoof with the main structure, and the duty of which is to prevent concussion.

A. CHINNIAH,

Veterinary Surgeon.

THE PLANTAIN.

Musa Sapientum is supposed to be what was intended by the Grapes, one bunch of which was borne upon a pole between two men, that the spies of Moses brought out of the Promised Land. It is no other than our Plantain or Banana. It prefers a rich fat soil, but it is agreed that we could and do grow it, though to a degree, in any soil; and who of us will deny it is one of the most interesting objects of cultivation for the subsistence of man? It is often the sole support of a family. Three dozen fruits will maintain a person instead of his rice and curry, or, whatever it may be, for a week. Whether used in a raw or dressed form it may be regarded rather as a necessary article of food than as a luxury. "To point out all the kinds" says a writer, "cultivated in East India alone would be as difficult to describe as the varieties of apples and pears in Europe, for the names vary according to the form, size, taste and colour of the fruit." Sixteen principal kinds are described at length by Rumphius from which all the others seem to have diverged. Of these the worst are Pisang Swangi, P. Tando and P. Gabba Gabba; and the best are the round, soft, yellowish sorts called P. Madji and P. Radja. Some cultivators at Batavia boast of having 80 sorts. Rheed distinguishes fourteen varieties by name as natives of Malabar. In Sumatra alone twenty varieties are cultivated, among which the P. Amas or small

yellow plantain is esteemed the most delicate, and next to it P. Radja, P. Dingen and P. Kalle.

Sometimes they are baked in their skins, and then they taste like the best pears of Europe. The best sorts are served up raw at the table as in the East Indies, and have been compared for flavour to an excellent reinette apple after its sweetness has been condensed by keeping through the winter. They are also the principal ingredient in a variety of dishes, particularly in one called mantegue, which is made in slices of them fried in butter and powdered over with fine sugar. Of the many cultivated sorts, that called by the French La Banana musque, is considered the best; it is smaller than the others, but has a more delicate flavour.

Coming nearer home we have our (1) Rat kehel (red), (2) Suwandel, (3) Púwálu or Kólikuttu (sweet), (4) Anañálu (elephant), (5) Horanawálu (sour), all used in their raw state; while (6) Alukehel (ash), (7) Kitala (green), (8) Soramundan (giant), (9) Newukehel (imported), and (10) Eta-kehel (wild) are made into dishes.

It is hardly known that No. 9, besides the fruit, affords a delicate vegetable in the young shoots. A peculiarity in No. 10 is that the unopened blossom is only edible. It grows wild and so nice to the palate and nutritious that it is seldom left out in the notices calling for tenders for victualling our jails and hospitals! The fruit has too many seeds and no flesh. Hence its name. I can state by experience that plantains can by cultivation be made to acquire exquisite flavours.

The Plantain takes 8 to 12 months to yield. About 100 bushes gave me a return of Rs. 20 to Rs. 25 per mensem for 5 years, and with no more attention than keeping cattle off.

Here is an opening for safe enterprize.

GEO. WEERAKOON,

Mudaliyar, Wellaboda Pattu, Matara.

FIRST STEPS IN AGRICULTURE.

First Stage—4th Lesson.

BY A. J. B.

You must not run away with the idea that everything a farmer sows in the ground will be sure to grow nicely and yield him a good crop. There are a great many enemies which the plant has to fight against, and it must conquer them all, because, once these enemies have beaten the plant, the poor thing can never rise up or gain strength to fight again. At every attack it gets weaker and weaker, and at last, if no help comes, it must droop and die. You know that a small band of soldiers has often been surrounded by such a large number of the enemy that there seemed to be danger of their all being killed. Then a strong body of their friends has appeared, and together they have attacked and beaten off the enemy, and the first little band was saved. Now, just suppose the plant to be in the place of the little band of soldiers. The enemy comes along in the shape of caterpillars and other insects, and they begin eating up the leaves or fruit or

blossoms, and some stick to the stem, others to the roots, others again to the leaves and fruit, and as fast as the poor plant is drawing in its food by the roots and leaves, the enemies are sucking it out through the stems, branches, and leaves. Then the farmer comes along to help it and kill and drive off these enemies, and he does all sorts of things, which you will understand by-and-by, to destroy them, and all the time he keeps giving the sick plants medicine, just as you get medicine when you are sick, till at last he has beaten off the enemy, and the plants are once more vigorous and strong, and yield their fruit at the proper season. You will learn all about these enemies, and their names, and how they kill the plant, and how the farmers got rid of them later on. Meanwhile, there are other enemies these unhappy plants have got. Why, if you knew all that seeds and plants and crops have to fight against, you would wonder how any green thing could possibly live to ripen its fruit. Frost is a great enemy of some plants, but it is also an enemy to insects, and kills millions of them. When a frost comes on one very early in the season, or, worse still, very late, the farmers sometimes lose their crops or a great part of them. There were two or three hard frosts in the South of Queensland in 1899 which came when all the wheat fields were looking beautiful and promised to yield a very large crop. The wheat was just in the ear, when the grain is soft and milky. Then these terrible frosts froze the ears of the wheat, and killed them, and many farmers did not get a sheaf of wheat to thresh. They cut it all down and made it into hay, and built it up in big stacks waiting for someone to come and buy it. That was what an "unseasonable" frost did.

Then there are floods. Most Queensland boys and girls know what harm floods do. Some of the best and richest lands on the east side of the Main Range are situated along the banks of rivers and creeks. After heavy rains lasting for a long time, the land cannot soak up any more water, and it pours into the creeks. These run to the rivers, which cannot carry away the water as quickly as the creeks pour it in, so it spreads over the low-lying land, and farmers have often had so much water on their farms that they have been obliged to leave their houses in boats and camp on high ground until the water had run off, and then they had nothing left of all their crops and had to begin again.

If too much water is a bad thing, too little is much worse. As you already know, plants cannot live without water, neither can animals. So when many weeks or even months or years have passed without any heavy rain, the grass and water disappear, dried up under the hot rays of the sun. Where there is no grass sheep and cattle cannot live. Where there is no rain the crops will not grow on a farm. And so all animals and plants suffer, and thousands of animals die as soon as the plants have died. Thus you see a "drought," as it is called—that is, a long period without rain—is far worse for everybody than a flood. A flood does not remain on the land more than two or three days, and there is always plenty of grass everywhere in rainy

weather. So perhaps a few cattle and sheep are drowned and all the crops are lost, but the farmer soon set to work and puts in a new crop. And this is one of the great advantages which you possess of living in Queensland. You can grow some crop all the year round. Supposing that big floods were to carry away all your corn crop in February, that is, the ripe corn that you were just going to pull and carry to the barn. In some countries you would have to wait a whole season before you could sow anything again. You would have to wait till all the snow and ice had gone before you could plough your land; and all the wheat, which, in cold countries like England, Germany, and North America, is sown just before the snow falls, so that the snow may cover it up and keep it snug and warm till the warm spring-time, having been swept away by the flood, you would have lost the wheat season and could plant nothing for at least four months.

There in Queensland, if a crop is destroyed, you at once put in another either of the same kind or something else. If you have lost all your crops in February, you can begin to plant potatoes in March, and then you can next month plant acres of onions and cabbages and other things. So that a flood is not nearly so bad as a drought.

Very often a careless farmer gets a bad crop because of his carelessness. Let us consider the question of seeds. A poor shrivelled seed, even if it has strength to grow, cannot produce a fine vigorous plant, and anyone who sows bad seeds is a bad farmer, and ought not to be pitied by anybody because his crops are pure. Did you ever see a farmer sorting out maize for seed? What did he do?

Either he spread the corn on the table and picked out all the largest and best-shaped flat grains, or he took the best-looking cobs and broke off the tops and bottoms of them where you often see single, round, small grains.

Then he threshed the grain off the rest, and so obtained the largest seeds. That is what a careful farmer would do.

But I have seen a farmer take corn for sowing out of a full sack without caring whether it was round, or flat, or broken, or withered. Such a man could not expect a good crop, and he would never make a successful farmer because, remember this, "If a thing is worth doing at all it is worth doing well." And when a man or a boy or a girl does one thing badly owing to laziness or carelessness they will in all probability be as lazy and careless about all the rest of the work, and so such people had better go and crop firewood if any one will keep their axes sharp for them, because they will never make farmers. Why, you may not think so now, but farming requires more head-work, and more careful work, and more reasoning things out than driving a locomotive engine. And farmers should learn all they can by reading plenty of books on agriculture, and they should get all the best machinery and buy the best implements and the best horses, cattle, pigs, and sheep if they mean to succeed in their business. It used to be the fashion to look down upon farmers as ignorant men, but now-a-days the farmers are looked upon as the most intelligent of men, and the greatest

men not only farm themselves, but they hold the farmers in the highest respect.

Our late beloved Queen Victoria was a most successful farmer, and so also is King Edward the Seventh. Thus no boy or girl need be ashamed to say my father is a farmer, because being a farmer means to belong to a profession which requires as much learning as age, and a great deal more than to be a soldier or a school-master or a clergyman. Well, I have gone a little off the subject, but still you have quite enough to remember in this lesson, so I shall now give you the usual questions to answer.

Questions on Lesson 4.

1. Why may the farmer not obtain a good crop from everything that he sows or plant?
2. What have plants to fight against?
3. How do they overcome their enemies?
4. State some of the enemies the farmer has to overcome?
5. What name is given to a time of long continued weather?
6. Which state of weather causes most loss to a farmer—long dry seasons or very wet ones?
7. State your reasons for thinking so?
8. Why is a Queensland farmer more fortunate to the seasons than, say, a German or Scotch farmer?
9. What happens if a farmer is careless in selecting seed?
10. How would you select maize seed?
11. Why should you be proud to be called a farmer's son or a daughter?—*Queensland Agricultural Journal.*

INTERNAL PARASITES OF POULTRY.

The internal parasites of poultry are numerous, but only two serious diseases are caused by such agents. The chief internal parasites are worms, but an often fatal complaint in fowls is due any how in part to minute single-celled animals known as Protozoa. The most important vermiceous disease is gapes. Gapes is a disease caused by a nematode or round worm which take up its abode in the bronchial tubes. It is called scientifically *Syngamus trachealis*. The gape-worm is also known as the Red-worm and Forked-worm. Not only fowls and turkeys, but pheasants, sparrows, linnets, starlings, rooks, partridges, martins, swifts, and wood-peckers are also invaded by this parasite. The disease is caused by the worms taking up their abode in the air-passages and there irritating the mucous membrane, causing inflammation. These pests, if present in large numbers, also block up the trachea and stop the passage of air to the lungs. In both ways the birds may succumb. The gape-worm is nearly always found in copula inside the host, the small male-worm being permanently attached to the female towards her head end, the two worms making a fork, hence its name the Forked-worm. In colour the gape-worm is red, often bright red; in length the female may reach four-fifths of an inch, the male seldom more than one-fifth. There is great variation in size, some females being only one-fourth of an inch long. As a rule, a number of worms may be found

together in a fowl's trachea, often as many as twenty crowding in particular parts of the tube.

The symptoms of gapes are a curious listless gaping of the mouth, a whizzing cough, a stretching forward of the neck and the frequent appearance of frothy saliva in the mouth and sometimes in the nostrils. When the female worm becomes mature and full of eggs, she and the attached male are expectorated by the bird. These worms lie about the ground, and sooner or later burst by cadaveric decay, when the minute eggs not 1-25th of an inch in length are spread over the ground or in the water. Each worm contains a great number of eggs. It will be thus seen that land may soon be contaminated by a few birds suffering from the disease.

The eggs hatch in damp places and in water into small white embryos. Both eggs and embryos on entering a chick develop direct into the gape-worm.

Experiments have shown that birds fed with ova and embryos of *S. trachealis* will develop gapes, and thus no second host, such as we find in the tapeworms, is necessary. Although a second host is not necessary, numbers of the eggs and embryos are swallowed by earthworms, and doubtless fowls very often contract gapes when eating these useful annelida, which thus act as carriers.

It is chiefly in chicks and turkey poults that gapes causes the greatest mortality, although old birds are sometimes attacked. The birds obtain the embryos especially from polluted water and from damp ground, but also through the agency of earthworms. That wild birds play some part in its dissemination is also extremely probable,

Prevention and Remedies.

Any bird showing signs of the disease should be isolated. Chicks should not be kept with the stock birds. Fresh breeding ground should be used if possible every year. The worst outbreaks are always on overstocked land. Water vessels should be kept scrupulously clean, and only pure water given to the birds. The drinking troughs are best cleansed by being put in boiling water and well scalded. The worms may be partly removed from the trachea by means of a feather dipped in oil of cloves or eucalyptus oil pushed down the windpipe and turned round and round, but not those lower down the bronchi. A fumigating box, in which several birds can be placed at once, is useful; either Camlin powder or finely-ground chalk and camphor blown into the box will loosen the worms, which the birds expectorate during the violent fits of coughing the powder produces.

It is most essential that all chicks which die from gapes should be burnt or otherwise destroyed. If the birds are kept in small runs, the run should be purified, after an outbreak, either with gas-lime or watered with a 1-per cent. solution of sulphuric acid.

White Intestinal Worms.

Although death is not frequent from intestinal worms, of which both round worms (Nematodes) and flat worms (Cestodes) are present, yet debility is very often caused by two species of Nematodes—the White Intestinal Worms (*Heterakis papillosa*

and *inflexa*). These small white or creamy-coloured worms are chiefly found in the duodenum, and generally in groups of from ten to fifteen. Sometimes they form a plug which blocks up the alimentary canal. Birds infected with them are usually ravenous and yet keep losing condition. In length these white worms vary from one-third to the three-fifths of an inch in the case of *H. papillosa* and from 1 to 4 inches in *H. inflexa*. The eggs or embryos are probably obtained from dirty water but also off the ground. Diseased birds should be isolated. The worm can easily be expelled by a dose of thymol; one grain made up in a dough pill and administered morning and night. Similar good results have sometimes been obtained by the use of three grains of santonine given in the same way.

Diphtheritic Roup is one of the most contagious diseases from which fowls suffer. It is due at least in part to certain very lowly organised single-celled animals called Protozoa which invade the mucous membrane of the mouth, pharynx, and even the drop and windpipe. This virulent disease manifests itself either as loose yellow cheesy patches or as small firmly-fixed nodules in the mouth, the latter especially around the tongue and beak. In these false membranes and the tissues beneath them may be found the minute parasites which either directly or indirectly cause the false growths. Certain authorities state that bacteria are the active agents, but the probability is that these Protozoa are entirely accountable for the disease. If left alone a diseased bird is almost sure to die.

It is most important that any bird showing any symptoms of this complaint should at once be isolated, and the drinking vessels in the run well disinfected by boiling and strong carbolic acid.

The loose growths should be very carefully removed with a blunt knife or two blunt needles, and the mouth well washed out with a 10 per cent. solution of salicylate of soda or boracic acid. Probably several operations will be necessary, as some small diseased areas may escape notice. In any case the mouth is best treated several times with the disinfectant. The hard patches may be burnt away with lunar caustic. Every dead bird should be carefully destroyed and the run or yard disinfected either by sulphuric acid or by a dressing of fresh gas-lime after an outbreak. The best results in treatment have been obtained with salicylic acid or salicylate soda, and it is advisable to place a one per cent. solution for the fowls to drink for a week after any signs of the disease have been noticed in the run. In no case should a bird be allowed freedom until it has been completely cured. When the disease is very advanced it is best to kill the bird and destroy it, but if taken in time a cure can be easily effected. Another disease closely related in origin to this form of Roup and often found with it is a comb and wattle disease called *Epithelioma contagiosum*. It appears as yellowish brown nodules varying in size from a pin's head to that of a bean. A hollow from which a yellow exudate oozes and forms a brownish crust or scab appears in the nodules. The parasites

are minute protozoa which invade the epithelial cells. The best treatment seems to be painting the diseased areas with oil of turpentine and isolating the bird.

To avoid all parasitic diseases of poultry it is very important that fresh stock birds should be well examined before being turned out, as a single diseased bird, especially if it be a cock, may soon contaminate a whole run.—*N.S.W. Agricultural Gazette.*

THE FIG.

In view of the fact that a number of people are trying to grow figs and grapes, we insert the following notes—with reference to the fig industry near Smyrna, one of the chief fig-growing districts—which, we believe, will prove of interest to local growers of the fruit. The notes are extracted from a report by Mr. W. Finacure after a visit to the country:—

The soil in the Meander Valley, where the fig of commerce grows, is, owing to its position, very loose, and very deep, and has the advantage of retaining moisture. Many opinions have been advanced to me why this valley is so adapted for this peculiar kind of fig, one being that the tree requires moisture, and the character of the soil is such that it retains it. Another, that the valley is sheltered, which is the case; it is surrounded by mountains. Another, that the soil contains a certain amount of sweetness, a proof of which is instanced the immense quantity of Liquorice it produces. It is impossible, to my mind, to arrive at any correct conclusion, because cultivation is carried on so recklessly and stupidly that it is difficult to say what are the precise advantages from which the tree profits.

The cultivation as conducted by the natives is bad. The soil is badly tilled, the trees badly grown, they are untrained, and the suckers which grow off the parent tree, under the delusion that they add to the producing power, are fastened on to the tree. No doubt this gives a greater bulk, but it is not agriculture. Rules as to drainage are utterly disregarded; the fig may require much moisture, but a certain amount of drainage is also necessary. I have seen a whole plantation flooded with rain water for want of escape, simply because the natives are too lazy to form the ground properly. All Englishmen to whom I have spoken agree with me that the impressions which I formed as to the slovenliness of the peasants are quite correct, and I am certain that as a consequence of bad cultivation the fig has deteriorated. The skin is leathery, and the flavour poor. The fact is, Nature has done so much in Asia Minor that man is not inclined to exert himself.

Fertilisation takes place when the fruit is one-third the size; it will attain when ripe and to prevent the fruit dropping prematurely, and to hasten its ripening, caprification is resorted to. It consists of placing the wild fig among the branches of the domestic one. Wreaths are made by stringing loosely on pieces of rushes from two to twelve wild figs, according to the size of the tree upon which it is to be placed. The peasant takes a basketful of these wreaths and flings

them into the branches where they remain. The insect which infects the wild tree leaves it and enters the domestic fruit by the orifice. This is the process which is called caprificatio, and it is undoubtedly this action which prevents the domestic fig from dropping before maturity and makes it grow large. There are, of course, many proofs in support of this theory, but the most recent and authentic one which I have heard is from the lips of Sir Edwin Egerton, the British Minister at Athens, a gentleman who takes a considerable amount of interest in matters of this kind. Sir Edwin told me that there is a fig tree in the Embassy garden, the fruit from which always dropped prematurely. He procured a wild tree and planted it in the garden, and when it bore fruit he followed the caprificatio practice. Since then the fruit remains on the tree, not only until quite mature but actually until half dry.

The rainfall at Aidin* for the twelve months from July, 1895, to June, 1896, was 21.71, and from July, 1896, to June, 1897, was 26.45. In ordinary regime July and August are rainless in all the country from Smyrna to Ortakchi. If there is rain, as I am informed, there was this year, it is not seasonable for the fig, and if there is rain early in September it is damaging, inasmuch as it prevents the completion of the drying and interferes with the despatch of the fruit in its best condition.

The temperature in the shade runs freely to 90 degrees Fahr., any time in June to August, and with north-easterly winds to 95 degrees to 100 degrees occasionally. In winter it runs as low as 45 degrees to 50 degrees. I have not been able to obtain complete data as to the temperature, because no record is kept, but I am informed by the British Vice-Consul at Aidin that the above is a correct estimate.

I have been informed by the Director of the Railways that his lines have carried this year to port (Smyrna) over 30,000 tons of figs; this, of course, does not represent the whole production, which this year was below the average owing to unseasonable rains, for immense quantities are carried by the caravans, besides the enormous consumption in the country. Apart from the fig, which is the staple product of the country, corn, maize, barley, oats, millet, and all cereals are grown. All fruit, excepting tropical fruit, grow; the date palm is grown but does not bear fruit owing to too much cold in winter.

Enormous quantities of the liquorice root are dug out of the ground in the Aidin district. Messrs. McAndrews and Forbes, of London, have an establishment where they collect the root, pack it in bales, and export it chiefly to the United States, where the juice is used in the preparation of tobacco. I see no reason why the production of liquorice should not be made an industry in Queensland. All that it requires is, after digging up the roots, to cut them in suitable lengths, pack them in a kind of wool-press, and they are ready for export.

The importance of the colony entering into the fig cultivation cannot be over-estimated, when it

* 81 miles from Smyrna and in the heart of the fig-growing district.

is remembered that the cost of experimenting is not very great. Any farmer can grow a row of trees on the margin of his allotment in much the same way as that in Italy. Trees are grown along the border of land carrying cereals, adding very much to the effect of that beautiful country.

There are parts of the country in which I am sure the fig will succeed, and if once we are successful it will be a source of great wealth to the colony. The Smyrna fig is deteriorating, as I have already said, owing, I suppose, to cultivation; and if the colony obtains a footing in the markets of Europe, Asia Minor will have reason to regret its lethargy. The countries which mostly draw the best quality of figs, those called *Elmes*, are the United States and Germany.

INFLUENCE OF FORESTS ON THE CLIMATIC CONDITIONS OF A COUNTRY.

Though it has been admitted in the first part of this introduction that the climate of each country and of each district is *prima facie* dependent upon its geographical position, its elevation, the configuration of the ground, and other cosmic causes which are independent of local circumstances it can hardly be denied that the existence or non-existence of large well-wooded areas in a country naturally capable of growing forests affects its climate in a very marked degree. History proves this to us in numerous instances where the deterioration of the climate of whole districts, and even of whole countries, has followed the destruction.

The once well-wooded Dalmatia is a stony desert; Persia once one of the granaries of the East is barren and desolate over a large extent of the country. North Africa, formerly one of the main corn markets of Rome, is subject to the severest droughts. Spain, Italy, Sicily, Greece and Asia Minor have suffered greatly from deforestation, and finally, but not least, India especially in the intermediate and dry zones in the Deccan, and in the north-west of the country has been injured by the destruction of her forests.

Even Oskar Peschel, who questions the importance of the influence of forest growth on the climate of a whole country perhaps more than any other writer of note, throws no doubt on the observations made by Boussingault, Humboldt, and Bompland, and acknowledges the local influence of forests on the precipitation of moisture. He says, however, and he has numerous followers even within the ranks of the Forest Department, that the amount of rain which falls year by year on the Continent would be exactly the same if there were no forests at all.

"The amount of rain," he states, "depends on the extent of oceans and seas, on the degree of heat, and on the rapidity with which the air moves over the surface of the waters. None of these conditions are changed," he writes, "by the extent or absence of forests. All air currents blowing from the sea are year by year charged with the same amount of moisture, which precipitates as soon as the air is cooled below the point of saturation. If such precipitation be caused by forests, the air currents reach the

regions behind these forests drier and unable to yield a further supply of water."

It is thus Oskar Peschel teaches in his well-known work "Neue Probleme der vergleichenden Erdkunde," but he entirely omits from his calculation re-evaporation of moisture precipitated on the land, and his conclusions cannot consequently be accepted. A well-wooded forest area may best be compared to a landlord who spends his income derived from the country within it and for the benefit of his neighbours where as cleared areas resemble absentee proprietors who scatter their revenues in foreign parts. It rains; the drops are scattered on the leaves and fall in a soft gentle spray or in slow falling big drops, which have collected on the foliage on to the spongy forest ground. The water has thus time to percolate slowly into the soil below, whence a large quantity is gradually pumped up again through the roots of the forest trees exhaled by their leaves and again assists in forming rain clouds. Wooded areas, no doubt, extract under the same circumstances more moisture out of the air than for disforested regions, but they serve as a store-house and yield again what they take, whereas a great portion of the water precipitated on barren soil is only recovered by evaporation from rivers, lakes, and oceans. Forests use, therefore, much less moisture than barren areas in the same position and under similar conditions and augment the atmospheric moisture in regard to regions which are separated by such forests from the sea instead of diminishing it. Their action in this respect is not the same time as that of an intervening mountain range.

In Assam, which is a broad, isolated, well-wooded valley, rain clouds form in the winter and it rains when no air currents reach it from the sea. The clouds are home-born and are to some extent, at least, due to re-evaporation from the vast forest areas still in existence. The same laws naturally apply to any locality, though they may not be so strikingly exemplified. It may be argued that evaporation from open ground is much more intense than from soil covered by forests. No doubt this is the case, and Ebermayer in his "die Physikalischen Einwirkungen des Waldes auf Luft und Boden" gives the following data:—"The forest alone, without the cover or dead leaves diminishes the evaporations by 62 per cent. as compared with that in the open. Evaporation is consequently 2.6 times less in the forests. A covering of dead leaves and vegetable mould diminishes evaporation by a further 22 per cent. Forests with an undisturbed covering of dead leaves and vegetable mould lessen the evaporation as compared with that in the open by 84 per cent.

These data are based on observations made in Bavaria during the summer months. In the Indian climate the difference, which increases in proportion to the heat and dryness of the atmosphere would be even more considerable.

The above data refer to the evaporation from the soil, which, of course, can only take place as long as there is water on the surface which in the open is not the case for long, as it either flows off or gravitates out of reach of the influence

of evaporation. In a forest the water does not flow off with the same rapidity, and much of that which gravitates into the soil is pumped back by the long roots of the forest trees, and especially during the period of vegetation is exhaled by the leaves in quantities which represent far more than the moisture evaporated from the open ground. There can be no doubt, whatever may be said to the contrary, that the widely-spread notion that forests tend to increase the rainfall, and that in a warm country, diminishes its moisture, and consequently its fertility is correct. As already pointed out the theory is proved by history and ruins, and the rapidity with which changes in the climate of different countries have taken place entirely forbids that such sudden modifications should be ascribed to cosmic causes. We accept other scientific problems on such more flimsy evidence, but in this instance a large number of us suddenly swerve aside and follow a school which starts new theories on partial observations and leaves re-evaporation out of consideration. Ebermayer found from experiments made that during July, the hottest month in Bavaria, only 6 per cent which filtered down to the depth in a forest, the ground of which was covered with complete and undisturbed vegetable mould.

In the one case the water rapidly runs off into streams and seas by sudden floods and freshets, and this too when the whole atmosphere is surcharged with moisture. In the other instance the water is stored for re-evaporation through the foliage of the forests, and is given forth at the time when the air is drier and the winds do not blow from the sea. It may be safely stated that more than the rain which is thus stored in the ground is re-evaporated by the trees in time of need, and even at this low computation a well-stocked, a well-protected forest area, the vegetable mould of which is undisturbed by either fire or the axe or rake of the "rab" or "sir" collector would re-supply to the atmosphere at least one-third of the moisture which is precipitated on it. This would be available for the open country. If therefore 30 per cent of the country was under complete forest, the rainfall should increase by 10 per cent under conditions similar to those which exist in Bavaria in July.

In India, or any other country with such a fierce climate as ours, the influence should be more marked.

The monsoons in India, it is argued, must be quite independent of forest growth. Quite so. Forests can have no influence whatever on the amount of moisture drawn from the ocean, and the general direction of the winds is unquestionably governed by greater causes, but, apart from this, periodical rains are subject to the same general laws as all other rains, and must, therefore, be affected by the same causes, and amongst them by extensive forest growth, in exactly the same way and degree. The air may be charged with moisture which need not, however, be precipitated. If an extensive snowfall in the outer Himalayas can affect the monsoon rainfall, it seems certain that forests can do the same, though probably not to the same degree.

No. 4.

TROPICAL TIMBERS AND THEIR RINGS OF GROWTH.

BY HERBERT WRIGHT, A.R.C.S.

[Especially written for *Indian Gardening and Planting*.]

HERE is probably no more interesting study in timbers than that of the seasonal elements which a transverse section of the stem exhibits. The majority of persons are familiar with the historical tables usually attached to, or painted upon, the successive annular rings of stem sections in the museums and gardens of Europe. The validity of the idea that each ring counts for a definite period of time in the life of the plant is accepted as sound, though in past times much controversy was waged on the nature of the causes producing these time-checking arrangements of the timber elements. The bark pressure theories of Sachs and T. Hartig, the theory of osmotic variation waged by Russow, and the ideas of Weiler and Robert Hartig, respecting nutritive supplies to the tree, were all found insufficient to explain the nature of the causes which determined the formation of rings of growth. It was left to the genius of Strassburger and his contemporaries to explain the formation of the rings in terms of the varying physiological needs of the plant.

In temperate zones the deciduous trees burst into new foliage during spring, and the main function which the wood has to perform is that of supplying copious quantities of water to the growing leaves. This is accomplished by the production of large lumined, thin walled elements, which form connected systems from roots to leaves. During autumn the demand for water is not as great, but there is an

increased weight of plant tissue, and the necessary elements to give support and rigidity are added in the form of narrow elements possessing very thick walls.

The thick walled narrow elements of autumn abut directly on the large elements of the next spring, and hence the line of demarcation showing the limit of growth for any particular year is often very conspicuous. The idea that each ring represent one year of time is therefore correct for those trees in temperate zones which exhibit such periodicities in leaf production. In the tropics, however, where as many as four seasons have each a recognised power, and the arborescent vegetation is often characterised by more than one periodicity in leaf production per year, the time represented by each ring of growth is not necessarily one year.

It is obvious to a casual observer that the very great differences between the periodicities in leaf production of the Flamboyant and Cotton trees, or those between the Candle, Almond and Para rubber trees, or better still between an evergreen having no fixed periodicity and a deciduous tree having the annual regularity of *Schizolobum excelsium*—such differences must result in the production of very dissimilar tissue arrangements in the wood of the respective trees. We therefore see that in order to correctly interpret the "seasonal" rings of growth we must know exactly the characteristic periodicity and, since the climate and vegetation in the tropics are as widely different from those of temperate zones, we may expect the problem to assume some degree of complicity.

In tropical countries such as Ceylon, where the air is hot and damp throughout the year, the majority of trees are usually considered to be of an evergreen nature. Many of these ever-greens, such as species of *Cinnamomum* and *Eugenia*, Mangoe

and Jak, etc., have no fixed periodicity, and new leaves may occur any month in the year; others produce leaves at a definite time each year, and of this class the most conspicuous are the ebony trees. Further, it is worthy of note that those trees of *Diospyros embryopteris* and *Diospyros Gardneri*, which as yet have not produced sexual organs, are invariably characterised by a biannual foliar periodicity. A comparison between the rings of growth of a young ebony—not flowering—and one regularly producing flowers, should therefore prove highly interesting. Next to the evergreens we may for comparison place those trees which drop their old leaves simultaneously, but which have produced leaf buds prior to the fall of the old ones, as in *Dillenia indica*, *Rhopalocarpus lucidus*, etc. Many others however, have gone a step further, and the production of new leaves is delayed until the greater part of the old leaves have dropped and the tree assumes a semi-bare condition, as in *Ficus Trimeni*. Continuing in this direction we come next to those trees which, like the *Inga saman* and *Caudle*, are bare for a few days, and finally to those like *Erythrina umbrosa*, *Careya arborea*, *Bombax*, *Hevea brasiliensis*, *Dalbergia frondosa*, *Plumieria acutifolia* and a host of less familiar trees which remain leafless for several weeks or months during every year.

There are very few species in Ceylon which drop their old leaves and produce new foliage more than once per year, a notable exception being the almond—*Terminalia catappa*.

Not only does the foliar periodicity vary with the species, but trees of the same species exhibit great variability, and it is even doubtful whether the same tree produces new leaves at exactly the same time from year to year. These differences must be due either to the varying personal requirements of the plants or the environment under which they exist.

In studying the personal equation of the plant one cannot but conclude that one of the foremost objects in dropping the leaves is to check excessive transpiration. In the Peradeniya districts and in all those parts of the island which feel the dry heat of the N.-E. Monsoon, many of the deciduous trees drop their leaves before or during the hottest months—February to April and thereby avoid a condition of transpiration which might otherwise prove fatal. The noteworthy examples are *Crataeva Roxburghi*, *Erythrina indica*, *Ficus Amottiana*, *Sterculia halanchos*, *Schizolobium excelsum*, *Oroxylum indicum*, *Cupania edulis*, *Antiaris innoxia*, the Cotton and Para and Ceara rubber trees and many others familiar to the tropical tourist. That this is one of the prime objects is further indicated by the behaviour of *Careya arborea*, *Eriodendron afracuosum*, and others in the Bibile and Batticaloa districts, since in these places the production of new leaf is delayed considerably—an obvious advantage where the S.W. Monsoon is replaced by hot dry weather. If it were necessary to bring proof in support of this idea, one need only point out the behaviour in desert areas where those plants, the tissues of which are neither fleshy nor protected by hairs or other contrivances, drop their leaves prior to a period of drought. The zerophytic plants having leaves which either in virtue of their succulence retain for a long time the greater part of the water they have obtained, or are so protected by hairs, wax, cuticle, sunken stomata, etc., that loss of water by transpiration is at a minimum, such plants remain ever green throughout the hottest months. The plants not so adapted must necessarily drop their leaves in order to prevent excessive loss of water. In temperate zones a reversion is seen, since it is during the cool months that the trees become bare, and only when heat and sunshine present their maximum strength that the arborescent vegetation puts on the best show of leaf.

One of the reasons why, in temperate zones, the trees drop their leaf in winter is probably to be found in the fact that the soil is so cold that absorption cannot take place through the roots, and hence no supply being guaranteed, the plants lose their foliage until the warmer weather arrives.

Though the checking of transpiration seems to be one object, it is rather surprising to notice the comparative zerophytic nature of the leaves of *Ficus Arnottiana*, *Ficus Trimeui*, and others where the transpiration is probably much less than that from the tender leaves of *Brownea grandiceps*, and yet the former are deciduous and the latter is evergreen. Further, we have to face the difficulty that the hottest part of the year is not that chosen by all the deciduous trees, as is instanced by the behaviour of *Albizia procera* and *Dalbergia frondosa*, which become bare in the Peradeniya districts during the dull wet month of July when transpiration cannot be at all excessive. But what is still more difficult to bring into conformity with the theory of checking transpiration is the production of abundance of fresh foliage when the dry heat of the N.-E. Monsoon is asserting its maximum power. This occurs with trees of *Sclerocarya caffra* and *Terminalia melanocarpum* during the hot month of March, and similarly *Sterculia balauchos* and *Chlorocylon Swietinia* in April. It is highly probable that many of these trees have, in the migration of species, found their way into districts where the climate is not in agreement with their old periodicities. They may, or may not, acquire a new periodicity, and it would be important if we could determine whether the periodicity of imported species grown from seed remains the same as in the native districts. One might also notice whether a species, native of our country, shows the same periodicity as locally grown trees when introduced again from abroad.

Many of the peculiarities will probably have to be explained on purely personal grounds, since they do not lend themselves to correlation with known environments. The power of the personal equation can be better studied in the tropics than in temperate zones, since the variation of season has such a preponderant influence in the latter areas.

Many instances are known which point to the operation of purely individual forces within the plant. In *Java et ses Habitants*, by I. Ohailey-Bert, mention is made of the fact that trees of the same species of *Paladium* are growing side by side and under conditions almost identical, and yet one may be bare at a time when the others retain full possession of their foliage.

Mr. Nock also informs me that the English oaks grown at Hakgala under a comparatively temperate climate behave in the same irregular manner. This individual variation cannot be better studied than at Peradeniya, where *Lagerstroemia flos-regina*, a native of the moist lowcountry of Ceylon, grows in abundance. Here, in the month of February, one tree was perfectly bare and yet others only a few yards distant were in full foliage; others were about to drop their leaves, and during the same month one had not only dropped its foliage, but burst into new leaf and followed this by production of flowers. Similarly with trees of *Bridelia retusa*, also a native of the moist lowcountry. So much then to indicate that internal factors may be at work in determining periodicity of leaf production.

On the other hand, there is considerable evidence in the acclimatisation of trees that the power of environment is very great. A moment's consideration of the powerful influence of a temperate climate on the phases of vegetation is alone sufficient. There are instances which seem to point to the possibility of a new periodicity, without the loss of the old one, being produced by a change of climate. Here we must content ourselves with a few examples which indicate the power of climate. One case of

more than usual interest is given by Dr. Watt, Vol. I., p. 46, where the behaviour of *Acacia dealbata*, Link, indigenous to New South Wales, Victoria and Tasmania, has been entirely changed by the climate in the Nilgiris. The facts are, that in 1845 and up to about 1850, the trees in the Nilgiris flowered in October, which corresponded with the Australian time, but about 1860 they were observed to flower in September; in 1870 they flowered in August; in 1878 in July; and in 1882 they began to flower in June, this being the spring month in the Nilgiris corresponding with October in Australia. It therefore takes nearly 40 years to regain its habit of flowering in the spring, i.e., to become perfectly acclimatised (*Ind. For.*, VIII., 26).

I am also informed that the English oaks now growing at Johannesburg further illustrate this point, since they begin to drop their leaves towards the end of May, remain here until near the end of August, when new leaf appears, to be followed by flowers which ripen into fruit by Christmas.

These are very striking examples, and what we are particularly anxious to obtain is a satisfactory table of comparison showing the behaviour of the deciduous trees under different climates. The importance cannot be overestimated, as we shall obtain one string of facts which, together with some knowledge of the rates of growth of the plants in question, will materially assist us in our attempt to interpret the seasonal peculiarities of tropical woods. Having in view the innumerable side-issues to which such a problem may lend itself, we confine ourselves to the following points:—

I.—When the plant drops its leaves.

II.—When the new leaves appear.

III.—When the flowers appear.

A list of those plants which are deciduous in Ceylon is now appended in the hope that all interested will forward as much knowledge as they possess respecting the behaviour of any or all of these plants; *Albizia stipulata*, Boer; *Albizia Lebbeck*, Benth; *Albizia procera*, Benth.; *Antiaris toxicaria*, Lesch.; *Anogeisum latifolia*; *Acacia suma*, Kurz; *Aleurites triloba*, Forst.; *Alstonia scholaris*, Br.; *Adenanthera bicolor*, Moon; *Bombax malabaricum*, D. C.; *Bassia longifolia*, L.; *Bauhinia*; *Bridelia retusa*, Spreng; *Cratæra Roxburghii*, Br.; *Cochlospermum gossypium*, D. C.; *Cassia multijuga*, Rich.; *Cassia grandis*, Lf.; *Cassia nodosa*, Ham.; *Cassia fistula*, L.; *Clerodendron Thomsonae*, Balf.; *Cedrela serrulata*, Mig.; *Cedrela odorata*, L.; *Careya arborea* Gaertn.; *Chickrassia tabularis*, A. Juss.; *Chloroxylon swietenia*, D. C.; *Canthium macrocarpum*; *Cupania edulis*; *Citherexylum cinereum*, L.; *Couroupea guianensis*, Aubl.; *Derris robusta*, Benth.; *Derris dalbergioides*, Baker.; *Diglossostyles axillaris*; *Dipterocarpaceae*, *zeylanicus*, Thw.; *Dipterocarpus hispidus*, Thw.; *Dalbergia melanoxylon*, G. and P.; *Dalbergia frondosa*, Roxb.; *Dilena indica*, L.; *Eriodendron aufractuosum*, D. C.; *Enterlobium cyclocarpum*, Grisib; *Erythrina indica*, L.; *Erythrina verticillata*, Willd.; *Erythrina umbrosa*, H.B.K.; *Engenia jambana*; *Ficus religiosa*, L.; *Ficus Trimeni*, King; *Ficus Arnottiana*, Mig.; *Ficus Wightiana*, Wall; *Ficus infectorea*, Roxb.; *Ficus semicordata*, Mig.; *Ficus elastica*, L.; *Ficus altissima*, Bl.; *Flacourtia Ramontchi*, L. Herit; *Gmelina arborea*, Roxb.; *Hevea brasiliensis*, Muell Arg.; *Heterophragma adenophylla*, Seem.; *Litsea sebifera*; *Lagerstromia flos-reginae*, Retz.; *Lagerstromia tomentosa*; *Manihot Glaziovii*, Mull.; *Michelia champaca*, L.; *Oroxylon indicum*, Vent.; *Odina Woodier*, Roxb.; *Pithecolobium saman*, Benth.; *Pericopsis Mooniana*, Thw.; *Poinciana regia*, Boj.; *Plumieria acutifolia*, Poir.; *Pterospermum semisgittatum*, Ham.; *Phyllanthus emblica*, L.; *Pahudia Javanica*, Mig.; *Peltophorum Leunei*, Benth.; *Peltophorum ferruginum*, Benth.; *Pterocarpus echinatus* Pers.; *Pterocarpus marsupium*, Roxb.; *Pterocarpus indicus*, Willd.; *Parmentiera cereifera*, Seem.; *Pityran the verrucosa*, Thw.; *Parkia biglandulosa*, W. and A.; *Phalocarpus lucidus*, Boj;

Spondias mangifera, Willd.; *Sapindus laurifolia*, Vahl.; *Sclerocarya caffra*, Sond.; *Sterculia Balangas* *Schizolobium excelsum*, Vog.; *Sterospermum Xylocarpum*, B. and Hkf.; *Sterospermum cheleniodes*, D. C.; *Sterospermum suaveolens*, D. C.; *Schleichera trijuga*, Willd.; *Stephegne tuberosa*; *Saccocephalus esculemus*, Afz.; *Sapium biglandulosum*; *Swietenia Mahogany*, L.; *Styrax Benzoin*, Dryand; *Terminalia catappa*, L.; *Terminalia bellerica* Roxb.; *Terminalia melanocarpum*, F. M.; *Terminalia parviflora*, Thw.; *Terminalia chebula*; *Tectona grandis*, L.; *Tabebuia Pallida* Lindl.; *Tamarindus indicus*, L.; *Vitex Leucoxylon*, L. F.; *Vitex altissima*, L. F.; *Xanthoxylon Rhetse Yizyphns glabrata*, Heyue.

QUESTIONS FOR CACAO PLANTERS.

(To the Editor, "Tropical Agriculturist.")

SIR,—I heard some time ago that Mr. Carruthers and Mr. Huxley were compiling a set of questions which it might be hoped cacao planters would find it in their interest to answer for the purpose of enabling Mr. Carruthers in particular, and everyone in general, to obtain some reliable information, or at least to enable such to be deduced from replies which would be elicited. This was some time ago, and I personally have received nothing up to date of the kind. In view of this I venture to send you a list of questions, for publication if you think fit. By the medium of your paper, in which—for the discussion of planters' interests you have given already, from time to time, considerable space—a publicity would be obtained for a subject, that needs considerably more light on it than we have at present.—Yours, &c.,
P. O. D.

Moneragalla, August 24th.

(Questions for circulation among Cacao Planters.)

District

Aspect (N., S., E., W., &c.)

Date (year)

Maximum and minimum elevation

Heavy rainfall per annum

Wettest monsoon (quote months)

Principal cropping season (quote months)

I.—*Varieties*.—1. Is Forastero or Caracas in your opinion the more remunerative?

2. Quote any particular variety or hybrid doing especially well with you?

3. At about what elevation is your best cacao?

4. What coloured flowers in your opinion mature best?

II. *Canker*.—1. How do you treat for canker (a) by light shaving, (b) deep cutting, or (c) any other methods.

2. Do you destroy diseased shavings and pods: if so how?

3. Do you treat systematically? if so, state length of round?

4. In what months is canker most prevalent with you?

5. What was the original environment of your worst cankered fields?

III. *Suckers*.—1. Do you grow suckers from the base or lateral branches, or both? and what are their respective effects on the tree?

2. Do you encourage suckers with any idea of immunity to canker?

3. Are you satisfied with them on this or on any other count; if so, what?

IV. *Manure*.—1. With what do you manure, if anything?

2. How do you apply it?

How much per tree?

4. Any improvement in appearance, or what increase of crop?

V. *Pruning*.—1.—Do you prune either old or young cacao?

2. Lightly or heavily?—for crop, ventilation, &c,?—for spread or shape?

VI. *Helopeltis*.—1. State your method of treatment.

2. Length of round.
 3. Length of time under treatment.
 4. When most prevalent.
 5. With what result, satisfactory or otherwise?
- VII. *Shade*.—1. What shade do you prefer if any?
2. At what distance for new clearings?
 3. At what age would you thin out, and how, if at all?
- VIII. *Crop*.—1. What is the annual average yield of pods per tree on your cacao in full bearing? State Caraccas or Forastero (hybrid mixed, &c.) and approximate age.
2. What proportions of good and black cacao do you get?
 3. To what do you attribute any variation of these proportions throughout the year?

INSECT PESTS.

CIRCULAR TO FRUIT GROWERS.

The Secretary of the Department of Agriculture has caused a circular letter to be sent to all the Societies in the State, of which the following is a copy:—

"I beg to draw the attention of your Society to the recently amended regulations under 'The Insect Pests Amendment Act, 1898,' and more particularly to the new Regulation 20, governing the use of second hand fruit cases, which reads as follows:

"The use within the State of second-hand fruit cases or packages that may reasonably be supposed to have contained fruit is prohibited, and the Chief Inspector or Local Inspector may order the disinfection of same, as provided in Order 11, or by any other means that may be directed by the Secretary of the Department of Agriculture, and failing such disinfection shall seize and destroy same.

"Experts are agreed that the use of second-hand fruit cases, without being disinfected, is one of the surest methods of disseminating disease. This being so, it behoves everyone interested in the horticultural advancement of the State to prevent the use of second-hand cases as far as possible, unless they have been previously disinfected.

"In accordance with the expressed desire of recent Producers' Conference, the Department has, in order to discourage the use of second-hand cases, obtained the co-operation of the Railway Department in the matter of differential rates being levied on new cases imported or locally made, and second-hand cases.

"The material for cases in shooks can be obtained in Perth, subject to slight market fluctuations, at the average price of 8s. 6d. per dozen.

"Not only is it in the interests of growers to discourage the use of second-hand cases, but also to encourage the use of an uniform case, and it stands to reason that, the contents being good, the more attractive the manner in which fruit is marketed the higher will be the returns.

"A new and uniform case, the distinctive individual brand of the shipper, an attractive address-label, and careful grading and packing, will secure a maximum return and drive the worthless fruit out of the market—it is carelessness and rubbishy fruit that brings down the average—and, while ensuring to the grower a better profit, will also ensure to the consumer a cheaper, because a better, and a more regular supply of the best fruit.

"Now local growers have to compete against the Eastern States, it is imperative they should attend carefully to details.

"No matter how careful the inspection at the port of entry, experts are of opinion that the danger of introducing diseases new to this State will always be present, and this knowledge should stimulate the local growers to exercise the greatest vigilance in preventing the possible introduction of diseases into their orchards.

"The saving of a penny or so per case, by using second-hand cases, may be the means of introducing into an orchard a disease that may cost hundreds of pounds to eradicate, if it does not finally render the orchard worthless.

"This Department, as you are doubtless aware, has only four Inspectors to supervise over four thousand widely-scattered orchards and vineyards, and I am appealing to your Society now to appoint from its membership, one or two, or three or more—as you may think fit—honorary inspectors, who will assist this Department in administering the Insect Pests Act. It is in your own interests I ask you to assist the Department. You have now to face the competition of the Eastern States in fruit and diseases, and you can only successfully do this by exercising eternal vigilance in keeping your orchards and vineyards free from disease, and the best way to do this is to follow the lines indicated;—

"1. Plant vigorously, but only the best varieties, having an eye always on the export trade of the future.

"2. Cultivate thoroughly and prune properly, and do not starve the trees if a little fertilizer will help them.

"3. Spray carefully and often, remembering that a single spraying is seldom of much use.

"4. Allow no second-hand cases to come on to your place. If they do disinfect at once.

"5. In the interests of your neighbours send no second-hand cases away unless disinfected.

"6. Ship only the primest fruit turning the rest into jam or pork. Either will pay you better than spoiling your own market by supplying rubbish. "It is an ill bird that fouls its own nest."

"7. Pick grade, and pack as if you were handling eggs, and use only new cases, branded with the name of the orchard, and legibly addressed on an attractive label, to your agent.

"If you decide to appoint honorary inspectors, in the different centres of your district, as I hope you will, I will endeavour to secure them any actual out of pocket expenses they may incur in the execution of their duties.

"Remember 'Eternal vigilance is the price of success.'"

"I have the honour to be, Sir

"Yours obedient servant,

L. LINDLEY-COWEN,

"Secretary."

—Journal of the Department of Agriculture Western Australia.

GOOD AND BAD CASTILLOA.

(Translation of an Article in the *Journal de Agriculture Tropicale*, July 1901.)

Castilloa is the rubber-tree par excellence of Mexico and Central America. The innumerable companies for rubber-growing formed lately with North-American capital have the *Castilloa* always in view. From this we may conceive the very strong interest which attaches to the communication translated herein. It is extracted from a German pamphlet* appearing early this month, and from which we shall have occasion to borrow still further. The author, Mr. Th. F. Koschny, has been a settler on the Rio de S. Carlos (Republic of Costa Rica) for nearly twenty-five years. He is certainly a most observant man; Professor Warburg, in his book on *Castilloa* and its culture, quotes him on every page; Mr. Koschny is in fact a most devoted correspondent of the *Tropenpflanzer*.

* Th. F. Koschny:—Die culture des *Castilloa-Kautschuks*. In 8d.; 50; published as a Supplement (Beiheft) of the *Tropenpflanzer*, that admirable review of Tropical Agriculture, of Berlin.

zer, the review directed by Mr. Warburg. Nevertheless, Koschny does not seem to be a botanist; on this side matters seem to require some controlling by some one in this line of business. Mr. Koschny moreover mentions that he sent to the Botanic Gardens of Berlin samples of all the parts of the species and varieties he refers to; so that we shall not be long without attaining a fixed idea of the distinctions and assimilations he establishes.

Several authors have already distinguished species and varieties in the genus *Castilloa*; all the information on this point will be found in the French edition of the *Plantes a Caoutchouc* of Warburg now being brought out in serial form by Challamel (that excellent colonial publisher, 17 rue Jacob, Paris.)

This edition has been executed under our supervision; we have provided it with a great number of annotations completing the original text and putting the facts in their true light. In particular, on what concerns the species and varieties of *Castilloa*, we have made a resume of all that is known up to date of Koschny's new monograph; even the facts set forth below will be found indicated in our book, as the outcome of anterior communication with Koschny, but less precisely.

All this goes to say that the reader with a real interest in getting accurate information as to the *Castilloas* to cultivate and the *Castilloas* to avoid would do well not to rest content with the statements he will find below, but to re-peruse also the corresponding paragraph of our edition of Warburg. It would be a waste of available space were we to reprint that paragraph here; and there is no necessity for doing so, for the book will be on sale in a few days.

In the text which follows, we shall see that we have four sorts of *Castilloa* to deal with. The catalogues of dealers in seeds and tropical plants only comprise two:—

1. *Castilloa elastica*, without distinction of varieties;
2. *Castilloa Tanu*, this last *Castilloa* being of quite recent appearance.

The last list of seeds and plants distributed in the German colonies by the agency of the "Kolonial-Wirtschaftliches Komitee" of Berlin, mentions the *Castilloa alba*; this is probably seeds coming from Koschny.

After this preamble, here is what Koschny says:—
"I know here four sorts of *Castilloa*; three seem to belong to the "species *elastica*, the fourth to the species *tanu*." Here are the native names of these four sorts of *Castilloa*:—

HULE (pronounced OULE) BLANCO; translation: white rubber-tree; as a scientific name I propose for this variety, that of *Castilloa alba*.

HULE NEGRO; black rubber-tree; I propose to call it *Castilloa nigra*.

HULE COLORADO; red rubber-tree; I propose to call it *Castilloa rubra*.

HULE TANU; the people of the country call it also gutta percha; its scientific name is *Castilloa tanu*.

"The four sorts of *Castilloa* I have just enumerated are identical or nearly so as regards the exterior aspect of the branches, pseudo-branches" (for the explanation of this term, see the Chapter *Castilloa* in our edition of Warburg.—Editor's Notes), leaves, &c.

"The base of the trunk of the *Castilloa* presents folds or tabs of which the height varies from thirty centimetres to two metres according to the age of the tree. We call these prolongations of the trunk here *Gambas* (limbs); they correspond to the thick roots which run along the surface of the soil or immediately under the surface. The three varieties of *Castilloa elastica* have these *gambas* thick, with the upper edge slightly rounded; with the *Tanu*, on

the contrary, the *gambas* are thin and their upper edge more acute.

"1. **HULE BLANCO** (*Castilloa elastica* var. *alba*.) Seen from a distance the trunk shews glimmers of white and red. The white colour is due to a white lichen, very delicate, which causes no injury to the tree.

"The very old trees have the bark covered with heavier mosses and lichens of a dull colour; and then it becomes almost impossible to distinguish them from the other forest trees: the underwood prevent one from seeing the crown of the *Castilloa*, and the **HULERO** (rubber-gatherer) as likely as not goes by without suspecting the presence of a rubber-tree, unless by chance he finds some of its leaves on the ground; these are as a fact bigger than those of most of the forest trees, and moreover may be recognised by their rolling themselves up into tubes as they dry.

"The latex of the **HULE BLANCO** is thick. When we tap the tree, only a part of the latex follows the track of the gutter and reaches the receiver, unless one guides it with the finger to make it take the exact direction desired; under natural conditions, nearly half of it sticks in the incisions themselves.

"The **HULE BLANCO** is, of the three varieties of the *Castilloa elastica*, that most frequently met with in the mixed forests; it is the only one worth the trouble of cultivation. Its bark and its bast are thicker and at the same time softer than those of the other varieties. The **HULE BLANCO** is never met with in the high forests; it prefers the places rather thinly grown, where its crown can be sufficiently exposed to the air, while at the same time its stem is shaded by the undergrowth. It is the **HULE BLANCO** which stands wounding best; it is the tree which gives the most caoutchouc with the least risk of premature exhaustion; this thanks to the property in its latex of coagulating within a short time. By sticking in the furrow and cracks of the bark the latex of the **HULE BLANCO** begins by giving a mass quite soft, like thick cream, which would at once be washed off were it to rain at that moment; but should a dry wind be blowing at the time of tapping, the solidification of the latex would be produced so quickly that next morning its condition would quite defy the rain. At the end of from six to eight days, according to weather, the transformation into caoutchouc is complete.

"**HULE NEGRO**. The bark of this variety is dull in colour and very much furrowed. It is rich in latex; but as the latter is very watery, its flow easily becomes excessive and the tree dies of exhaustion. The bark of the **HULE NEGRO** is a little thinner than that of the **HULE BLANCO**, but it is very fibrous and resistant. This variety is certainly shade-loving and only to be found in high forest. Its bark resembles in every respect that of the common trees of the forest; for this reason **HULE NEGRO** is very difficult of detection when one is traversing the forest. The cultivation of the **HULE NEGRO** cannot be recommended, on account of its tendency to die when wounded. This tree is generally to be found mixed with other *Castilloas*. All the same, it is perhaps the least common variety; most likely because being particularly sensitive to wounds it must have succumbed before the other kinds to the brutal methods of exploitation of the hulero.

"3. **HULE COLORADO**, 'red-rubber-trees.' It is the bark which shews the reddish tinge, especially that of the branches. It is smooth, thin, and brittle; its fracture is conchoid; the edges of the channel made for its bleeding have a tendency to open out and burst. The yield of latex is scanty; still the caoutchouc is of good quality.

"The bark of this variety has so little resemblance to that of the others that one would hardly recognise the tree as a rubber-tree were it not for the identity of its general form, the shape of its crown

* Editor's Note, Botany only knows *C. Tanu*; this difference of spelling is unimportant; but what is strange is the discrepancy as to the quality of caoutchouc furnished by the tree in question,

of its ramification, foliage, &c. As a matter of fact, while the bark of the HULE BLANCO and HULE NEGRO splits in the longitudinal (vertical) direction, that of the HULE COLORADO is smooth but presents quite a curious aspect by virtue of the light furrows running over it in a very oblique direction. By these furrows the bark of the HULE COLORADO appears as it were garlanded. These garlands or ribbons have yet another peculiarity: they are ornamented with little round knobs, disposed in vertical and horizontal series. At a given moment, these knobs break up; they then contribute towards making the bark take on that general reddish discoloration characteristic of the HULE COLORADO. Apart from these oblique furrows, this be-ribboned arrangement, and these knobs, the bark of the HULE COLORADO is absolutely smooth, without the least fissure, if we except the twigs and young branches of which the bark has not yet taken on its final form. The bark of the HULE COLORADO is much thinner than that of the two preceding varieties; the bast is scarcely developed at all.

This variety is found everywhere mixed with the others, both in the high forests and in the mixed; as a rule it is rarer than the HULE BLANCO; still there are places where it predominates. I should not be surprised if the poor results of *Castilloa* cultivation in Java and Ceylon were due to their having unsuspectingly planted this worthless variety. Should it turn out that the Java and Ceylon cultivation has been of the HULE COLORADO, the relative check to this culture would be explainable by the fact that this variety is much more shade-loving than the HULE BLANCO; now it is very likely that in those islands the *Castilloa* may have been grown without any shade."*

*4. CASTILLOA TANU. This tree is called TANU by the Mosquito Indians; the huleros call it *gutta percha*. The bark is very like that of the HULE BLANCO, but rather greyer in colour; to distinguish this *Castilloa* from its three fore-runners, the easiest feature is that offered by the prolongations of the base of the trunk (*gambas*), which are more salient, much slenderer and with the upper edge more acute. This *Castilloa* does not exist in the valley of San Carlos; † it is only to be met with starting from the outskirts of Blewfields (on the Mosquito Coast) and further to the north; on the Pacific slope there are certain places where the TANU is very frequent.

"The leaf and all the bearing of the tree suggest the HULE BLANCO; the latex is very abundant, but in drying it resinifies and hardens; as for elasticity, this so called caoutchouc is no-where."

ABOUT CASTILLOA TANU, HEMSLEY.

Just as we are going to press we receive from Mr. Godefroy-Lebeuf to whom we had communicated Mr. Koschny's study, a note in favour of the *Castilloa Tunu*, Hemsley. Mr. Godefroy-Lebeuf works out in a more circumstantial fashion the idea expressed by us in our annotations on the account of observations published by Mr. Koschny under the title "Good and Bad *Castilloa*." We cannot do better than reproduce just as it stands the letter of Mr. Godefroy-Lebeuf.

"We must not scatter discredit on the *Castilloa Tunu*, Hemsley. Should all the TANU's or TUNU's of Costa Rica be deemed unfit for any purpose, the *Castilloa Tunu*, Hemsley, will still stand out as a most excellent caoutchouc, equal to the best *Castilloa* rubbers.

* *Editor's Note.*—The discussion as to whether *Castilloa* should be grown in the sun or in the shade will be found fully set forth in Mr. Waburg's book; but besides that we shall give, in a coming number, some more extracts from Koschny's pamphlet. He is a decided advocate of shade.

† *Editor's Note.*—Where the author has his property.

"This species has been determined by Hemsley chiefly on the specimens of my collaborateur, Eugene Poisson, who has brought back from Costa Rica not only herbarium specimens but samples of latex and of caoutchouc drawn from this species.

"That the tree known in Mr. Koschny's country as 'Tann' or 'Tunn' gives bad caoutchouc is quite possible, but the plant is undetermined botanically. Is it alone a *Castilloa*?

"There is another proof of the good quality of Hemsley's *Castilloa Tunu*, in the care taken by planters to use this kind alone. Mr. Eugene Poisson, now actually in France, can give us more definite information.* It is unfortunate that Koschny did not accompany his particulars with botanical specimens; one cannot trust to simple descriptions. The genus *Castilloa*, notwithstanding the small number of species described, is terribly mixed. Where does *Castilloa elastica* begin? Is *Castilloa Markhamiana* a true species? Is *Castilloa australis* distinct from the Costa Rica species?

"I only know one thing, and that is that the *Castilloa Tunu* of Hemsley gives an excellent gum."

A. GODEFROY LEBEUF.

PINE CULTIVATION.

THERE has been a very great interest taken of late in Pine Cultivation. Pines have always been grown more or less in Jamaica, but given very scant attention, and comparatively few have been shipped abroad. Since good hopes of a direct line of fast steamers, especially fitted to carry fresh fruit between Great Britain and Jamaica, were first held out, there has been a considerable planting of pines, and since the "Direct Line" became a certainty, still greater attention has been directed to pine cultivation as a probable source of profit. There have come to Jamaica men from Florida who were engaged in the growing of pines there, and who have taught us a great deal in better ways to deal with the plants; at the same time they have also learned that they had to adapt their ideas to Jamaica conditions as these are in many ways different to Florida. These Floridians also brought with them suckers of pine-apples new to Jamaica, some of which may be very useful to us. Oh, it is easy to plant pines! says somebody. Of course it is; it is also just as easy to plant bananas, cocoa, or oranges, that is, by just sticking them in holes in the earth: but there are also ways of dealing with all plants that are expected to produce as high a return of a marketable product as possible, that will tend to this end, while the merely sticking in process will always give only a precarious change of producing something. Now in dealing with Pines we have first to choose the land. Pines will grow almost anywhere, but if the land is not naturally dry such as around Kingston, and on the plains on the south side, it is best to have a natural drainage and so the best plan is to choose sloping land; the freer the soil is naturally, the better, although some varieties of

* *Editor's Note.* Our mutual friend, Mr. Poisson Junr., has just returned to Paris after a long and difficult journey of exploration; agricultural and commercial, through Dahomey. We would ask him to spare a few moments from his well-earned rest to give the readers of the *Journal d'Agriculture Tropical* an account of how he collected the specimens of leaves, fruits, and caoutchouc which have served Mr. Hemsley in his description of *Castilloa Tunu* in the 'Icones Plantarum' of Hooker, 2. Unless we have mis-read the German text, which by the way is none of the clearest, Mr. Koschny has sent botanical specimens of his *Tunu* to the Botanic Gardens of Berlin. The 'Tropenpflanzer' will no doubt let us have the result of their study, which we will duly notice.

Pine-apples seem to delight in stiff soil, for on such land are they found growing naturally wild. The land must always be well drained, if not naturally, then artificially. You would, of course, fork or plough your land first: digging little holes and sticking the plants in, is no good at all, for remember, that it is not simply a fruit that is to be produced; it is a good sized fruit that will stand a Journey, be attractive and have a good chance of fetching a fair price. The soil must be made loose, but not necessarily to any great depth as the pine is a surface feeder; still the soil must not be only scratched loose for an inch or two; the ordinary depth of a foot fork is a suitable depth to dig. Having forked the land, it will be all lumpy and rough; the sun and breeze will dry it up, and then the rains will partially crumble it down: it is therefore well to commence on your land a month or two before you mean to plant; you can assist this fining process by going over the land with an Assam fork, and smashing the clods, thereby making the soil smoother and more level. Of course if a plough and cultivator and harrow can be used, the land will be ready so much the quicker. These implements for saving labour are exceedingly handy and are now sold so very cheap as to be within the reach of nearly everybody. Neighbours can cooperate and one get a plough, the next a cultivator, and the next a harrow, and arrange to use them consecutively: that is, when one man has had the plough a week, he passes it on, and starts out with the cultivator for a week to stir up and break the land more thoroughly after the plough has broken the soil up into clods; then he passes on the cultivator, and starts with the harrow to crumble the surface still finer, and smooth it down level. Of course the co-operators must not be of quarrelsome and jealous dispositions, else there will be disagreement. But with suitable people, the plan works well and saves outlay and waste, for few of the smaller cultivators require all three implements like a plough, a cultivator and a harrow constantly. Now when your land is prepared, in wet districts it is good, though not an absolute necessity, to put the pines in raised beds with small drains between, which also do as foot paths. This is for more complete drainage. It suits well to put pines in beds between young orange trees and thus utilise the land, while the cultivation given to the pines will leave the land in good condition for the roots of the orange trees when they extend in the course of a few years, and fill up the space between; the soil will then be in fine tilth. The beds should be of a breadth to be reached at all parts between by a rake or hoe, from the walks, so 6, 7, or 8 rows will be quite enough.

The next great question is the kind of pines you will plant. There are far more varieties of what we call native pines than are generally known. There are the Ripley, (Red and Green,) Sugar Loaf, Bull-head, Black and Cowboy which are more or less commonly known, though the Bull head and Cowboy are often mixed; but they are not the same. There are other native pines, which are not so well distributed throughout the island, and yet are distinct from any of those I have named. The same pines, however, often receive different names in some parts of the island: thus the Cowboy, is the Man o' Wa Pine in Hanover, and the Mammee Pine in St. James and in other districts the "Crab Pine." About Porus there is a Pine called the Cheese Pine which bears a fairly good fruit, and in the St. Thomas-ye-Vale district of St. Catherine, there is a Pine of very fine appearance, called the "Sam Clark"; it grows absolutely wild in the bush, and seems to delight to make head-way among the long rank, wet grass, for the district is rather a wet one. There is also a curious pine called—the "Jerusalem," which bears miniature pines—complete little pines, tops and all, round the base. Of the im-

ported pines, there are the Rothschild, the Abbaka, the Enville, the Golden Queen, the Porto Rico, the Smooth Cayenne, the last of which is proving the best grower and most marketable pine of all these. It has smooth leaves, no thorns, and grows to a large size, and is a quick, strong grower, and sure fruiter, the suckers are at present rather expensive, being from 9d. to 1s. each, as they are in great demand both here and in Florida. Imported suckers take a year and a-half to fruit, and then bear at any time of the year, but the suckers from these bear fruit at 10 and 14 months from planting the same as native suckers, depending upon the season when they are planted. The Smooth Cayenne weighs from 6 to 12 lbs.—often more. If any one can afford to plant out such expensive pines, and has favourable land, I am sure it would be a profitable speculation, as hardly less than 2s. a piece would be the return in the London market and if grown with some judgment and care, and brought in out of the usual season in Jamaica, (for our usual season is exactly the worst season for foreign markets,) would fetch not less than 3s. 6d. each, if of good size. The only other imported pine that has been in any way freely planted is the Abbaka; it grows to a good size, hardly so large as the Smooth Cayenne, and is screw shaped, large at the base and tapering up much like the Ripley. The Ripley stands easily at the head of all Pines for flavour; not one of the imported can compare with it in this respect, nor indeed with the Black and Sngar Loaf Pines. Unfortunately for us, pines sell almost entirely by their appearance; if they are big, well shaped, with good tops and with an attractive colour as they ripen, they will sell well. The Ripley is not more than 4 or 5 lb. weight at the very best, generally 2 or 3 lb., though I quite believe that good cultivation and selection of the sucker from plants that have made the largest fruits would result in bigger fruits ultimately. Nor is the Ripley, as usually grown, a very nicely shaped fruit, and its top is generally small and often twisted. These defects, I believe, can be remedied. Otherwise the Ripley is an excellent pine, it packs easily, and stands transport very well. Perhaps the next best pine in flavour is the Black Pine; and as it grows to a large size without much cultivation, is a very shapely and nice coloured pine when ripe, and stands transport exceedingly well, it is one of the best to plant; its one weak point is that until it is very nearly full-ripe it does not colour-up, so that markets not used to it think that its dark colour means unripeness. Then there is the Bull-head, which is known by the smooth leaves of its suckers, which have only a few little prickles at the top or here and there on the leaves. I think that the smooth Cayenne may be a highly improved type of the same pine, or the Bull-head and uncultivated or degenerate Smooth Cayenne, at any rate they are like each other. The fruit of the Bull-head Pine under cultivation grows to a very large size, is shapely and stands transport exceedingly well, but is not, as yet, palatable fruit. The "Sam Clark" has hardly more than been tried as a marketable fruit, and so I will not speak much of it, only to say that it has a very pretty appearance. By this time next year I hope to speak with authority on it. The Cheese pine, too, I have not yet had personal experience of as a shipper. The Sugar Loaf, perhaps the most common pine in Jamaica, one which grows equally well from sea level to the hill tops, and a fruit which grows to a very large size, and which is very agreeable to eat, is unfortunately a very poor shipper. I have noticed in the market reports of the United States this year, enormous—that is the word—receipts of pines from Havana in Cuba, whole steamer loads, as many as 2,000 barrels in one cargo, and that often twice a week these were Sugar Loaf Pines, and the prices were often as

low as $2\frac{1}{2}$ to $3\frac{1}{2}$ cents., that is less than a "quatte" each. Of course, these pines would not be in very good condition, and were roughly packed probably, and the fruit goes soft very easily.

Having fixed on the kinds of pines you will plant, you must see that you get good suckers. A ratoon sucker is the young plant that springs from the root of the old one, other suckers start out from the base of the fruit stem. The little plants starting out from the base of the fruit itself are called "slips," and the tops are the "crowns." A good sucker should not be less than 9 inches in length or more than 18 inches to be at the best for planting. If the suckers are very young and small, the eyes from which the roots are to start will not be sufficiently developed, and so will be likely to rot out if the soil is wet or in a dry spell to dry up and wither, before the eyes can swell out sufficiently to start roots, which development ought to take place while the sucker is growing with its parent's support. Larger suckers than 18 inches do well enough, but are too top heavy, so that they have to be deeply planted to prevent the wind blowing them over; deep planting is, however, one of the things to be avoided. To get over this difficulty, it is quite correct to chop off the ends of the long leaves, and plant a stump as it were, leaving all the heart of the sucker; the leaves will grow up again and the plant produce a very good fruit; but if the sucker is too advanced, and is thus cut and planted, it will probably send out a young sucker instead of growing itself, which is just as good. The base of the root-stalk of the suckers should always be cut smoothly across before planting, and the lowest leaves around the stem and which cover the eyes, peeled off; this will allow the roots to start out into the soil at once; if these lower leaves are left on, the young roots often cannot pierce through, and simply curl themselves round and round; the plant is then spoken of as root-bound. It does not kill the plant, but retards its progress. The sucker is now ready for planting. Close planting has been found most suitable, for not only is there less ground to prepare and keep clean for a greater number of plants, but the grown plants leaning against each other support the fruits erect, as they have a tendency, through being top heavy, to fall over, and either break or get sun-scalded. Not more than three feet wide between the rows for all Jamaica pines, and two feet between the plants are now considered the regulation distances, and I think Bull-heads could be closer, such as two feet by $1\frac{1}{2}$ feet, with advantage, as not having thorny leaves, workers can go through them easily. When you plant, you scoop out some of the soil, and put in your suckers, sufficiently only to cover the eyes, and press the earth tightly around it. Keep your ground clean; you will find a common garden rake a handy implement for stirring the surface soil, and there are small hand cultivators, one-wheeled and two-wheeled, with a variety of implements that can be fixed on at pleasure, such as little ploughshares, weed scrapers, cultivator teeth, rakes—which are most expeditious and effective workers. For cutting out weeds in pines when they are grown thick and for loosening the top soil, there is an implement called a Scuffle Hoe which is very well adapted to its purpose.

About manuring,—if you can cover your ground with pen manure of any kind before cultivating, it will stimulate the growth of the plants greatly, and if you are able to find enough wood-ashes, these will be most beneficial to the pines as fertilizers used as a top dressing lightly raked in. If you have not manures of any kind, and you wish to push your pines on faster, you can always buy artificial fertilizers in Kingston, specially made up for the needs of Pineapples. Your plants, if Jamaica suckers, will fruit in from 9 to 12 months from

planting if planted from June to August—if planted from November to January they will take over 12 months, even to 15 and 18 months; this is because the plant will ever make an effort to come in at its natural season no matter when planted, and will try to delay blossoming until the hot dry months from January to March—with irrigation and some control of the elements it is likely this would not matter. If imported suckers, as I have already said, they will take longer, the Puerto Rico taking likely enough two years from planting, but although exceedingly large it is not a desirable pine to plant. The natural season for the fruiting of Pineapples in Jamaica is from May to August, and there is also nature's season for planting, as it is then the young plants are produced, but as it happens, late June, July and August, are just the times when our fruit is least wanted in northern countries as the fresh, home-grown fruits, cherries, strawberries, plums, tomatoes, gooseberries, etc., are just coming in then. The best time of the year to get our pines in is from November on to May; before Christmas, pines are in best demand. It is quite possible for large plantations to get them in then, but not for the small man, and this is how. You must plant from September to December; at that time you cannot find medium sized suckers, unless you have been planting out earlier simply to get suckers, for as we have said the natural season is midsummer, so that the suckers have been growing since then; if you break these large suckers of six months' growth towards making a fruit, from the old stem and plant, it may cast them back enough for them to take about a year to fruit, but many will shoot their blossoms and fruit in their usual seasons all the same, and the fruits will be small, so that you may not have any gain at all, although the prices abroad may be better at the end than in the middle of the year. If persisted in, I think it sure that good young plants could be got in from October to December quite regularly, and the fruit brought in at the desired season, a year to 15 months later, and by replanting small suckers every year in August and September, the fruits will mostly come from November to March. Slips take 18 months from planting to produce fruit, but they give fine fruits even better than from suckers. Crowns take 20 months to two years, to produce fruit. It looks as if there would be a good market in Great Britain, and after that the Continent of Europe, for all the pines we can produce, and I deem it very probable that the new Direct Line of fast fruit steamers will enable us to supply the whole of Europe with pines, from Gibraltar to St. Petersburg, the only query left, but an important one, being the net profits to the growers. This remains to be tested. J. B.

—*Journal of the Jamaica Agricultural Society.*

MANGO.—It may not be generally known that wheat is not the largest grain crop produced. Maize stands first with 2,778,108,000 bushels to its credit in 1900, against 2,468,799,000 bushels of wheat. Nearly the whole of the maize was grown in the American continent.—*Journal of the Department of Agriculture.*

How to PLANT CUTTINGS.—Many amateurs make great mistakes, in planting cuttings. They leave three-fourths of the lengths of the cutting above ground, and very often push the cutting down by main force into the soil. The most successful way is to make cuttings from 6 to 12 inches long. Make a narrow trench, and put 1 inch of sand at the bottom, and place the cuttings at such a depth that only about two eyes or buds are exposed above ground. Throw a little more sand against the base of the cutting, fill in the soil a little at a time, and tread it very firmly against the base of the cutting. Leave the surface loose.—*Queensland Agricultural Journal.*

TEA SEED OIL, AND OIL CAKE.

MEMO :—The subjoined report by Mr. H. H. Mann, R.S.C., F.I.C., upon these products is published for information, by the Indian Tea Association:—

On the 27th June I received from the Secretary of the Indian Tea Association samples of Tea seed Oil and Tea Seed Oil Cake which had been sent, through Mr. H. St. J. Jackson, by Mr. H. Drummond Deane of the Stagbrook Estate, South India, with a request that I should make an analysis of them and report to the Committee. This I have now done so far as is necessary for our purpose—and it is perhaps a convenient opportunity to lay before you my views as to the possible value and usefulness of both products, especially as a large amount of seed is now produced, and must be utilised, if utilised at all, in some other way than for sowing.

The value of seed of this character almost entirely depends on the usefulness of the oil and on the possibility of getting good feeding or manurial material from the residual cake. It was attempted in 1885 to put tea seed, as such, on the London market under the name 'taune.' Great interest, I understand, was manifested, but the seeds found no buyer, and the price asked sank quickly to a level far below the cost of importation. At the present day the seed does not come into commerce at all except for the production of new bushes.

The following analysis by Mr. D. Hooper. ("South of India Observer," 1894) of Tea Seed from the Nilgiris previously dried, shows the composition of the material:—

Fixed Oil	22.9	per cent.
Albuminoids	8.5	"
Saponin	9.1	"
Carbohydrates	19.9	"
Starch	32.5	"
Fibre	3.8	"
Mineral Matter	3.3	"
				100.0	

Of these constituents, those of interest for our purpose are the fixed oil, the saponin, the albuminoids i.e., the nitrogen and the mineral matter. Let us take these *seriatim*.

THE FIXED OIL

Is present in small amount compared with that in most other oil seeds, such as linseed, cotton, or castor. I am bound to say, however, that many samples appeared to contain much more oil than the seeds quoted above, but I should consider Mr. Deane's figure of 25 per cent. obtainable by hot pressure as an extreme one for practical working. If high quality oil is wished, the seeds will have to be pressed cold, and not more than 20 per cent. may be anticipated. Even this, I fear, may be taken as higher than would on the average be obtained under commercial conditions.

The oil itself is a clear, light yellow, liquid, non-drying oil, approaching olive oil in character, but which always has a more or less acrid taste. The samples sent by Mr. Deane appears to be free from saponin—a poisonous substance (see below) which nearly always occurs in it, but in order to get this freedom great care has to be taken in pressing. Though when heated the poisonous properties of the saponin are destroyed yet the small quantity which may be present would condemn it as an edible oil for use in western countries. The Chinese, it appears, have long used it for cooking purposes and it might possibly be employed by the people of the tea districts in a similar manner if it were easily obtainable.

As a lamp oil it answers very well, and would seem to be quite capable of local introduction for this purpose. I say local introduction because burning oils are at present rather at a discount

in the markets of the world compared with their former position—kerosine and petroleum products having largely taken the market in the great centres which was formerly theirs. At the same time the fact that it is satisfactory for this purpose should not be forgotten.

The oil produces an excellent soap hard and white. For this purpose the presence of saponin would be no disadvantage but would rather add to the lathering power of the soap. If the oil could be produced in quantity and a supply guaranteed at a rate which would compete with the other vegetable oils, there is no doubt an opening for it in this direction.

THE SAPONIN,

This poisonous constituents of the Tea Seed is all but entirely contained in the cake, after expression of the oil. It is a white solid sweetish to the taste at first but rapidly becoming bitter and acrid in the mouth and it leaves a biting sensation in the throat for some time. It is exceedingly poisonous and its presence at once destroys any chance of using the cake or the seeds as a feeding stuff for animals.

THE ALBUMINOIDS AND NITROGEN.

To the nitrogen contained in the albuminoids the cake would owe the greatest part of its manurial value. In this respect, however, it does not for our moment compare with most other oil cakes. Compare, for instance, the following figures representing the average amount of nitrogen in other manure cakes compared with that given by Tea Seed Oil Cake:—

	Nitrogen
	per cent.
Mustard Cake 4 to 5
Linseed Cake 4 to 5.5
Castor Cake 5.5 to 6.5
Decorticated Cotton Cake 6.5 to 8
Undecorticated Cotton Cake 3.5 to 4.5
Tea Seed Cake 1.92

Thus, if castor cake were worth 2 rupees per maund in Calcutta, calculating on the basis of the nitrogen alone, the tea seed cake would only be worth about 12 annas per maund.

THE MINERAL MATTER.

In other points the Tea Seed Cake is likewise inferior for manurial purposes. Comparing again the following figures for mineral matter and phosphoric acid in several manure Cakes, this will be clearly seen:—

	Mineral Matter		Phosphoric Acid	
	per cent.		per cent.	
Mustard Cake	.. 8 to 10 2 to 3	
Linseed Cake	.. 4 to 6 1.5 to 3	
Castor Cake	.. 9 to 10 2 to 3	
Cotton Cake	.. 7 to 8 3 to 4	
Tea Seed Cake	.. 3.3 to 4.07 0.58	

Taking these various points into consideration, it will at once be seen that as a manure the cake produced by pressing tea seed is of very inferior character, and would hardly pay for carriage over very long distances for this purpose,—nor can it compete in any market with cakes produced from other oil seeds. On the other hand it is quite good enough to use locally, provided the net cost does not exceed 8 to 12 annas per maund on the garden.

It (the cake) is however supposed to have insecticidal properties; and might be useful for this purpose. In the paper above quoted, Mr. Hooper suggests spraying the bushes with a decoction of the seeds, or dusting the plants with a powder made by grinding them up. Such a decoction is likely to be serviceable against red spider, but exactly of what value it is can only be determined by trial. Spread on the ground round the bushes

the cake would be likely to keep away some types of caterpillar, and other pests which spread by creeping from bush to bush, or which make their home in the ground during the day. A strip covered with the cake between the tea and the jungle would probably keep out many of the pests which creep the surrounding land into the tea.

The utility of the cake itself as an efficient substitute for soap is very doubtful. Though it lathers well, on account of its saponin content, yet this does not necessarily mean that it has great cleansing properties. Nevertheless it has been used for many years in China instead of soap, and it would probably be of some value for this purpose. One more use is made of the cake in China. It is there stated to be very effective as a poison for fish.

On the whole, therefore, while I think there would be a market for the oil if it could be obtained in quantity and fairly cheaply it must, for the present, be a local one, and the material could hardly compete with oils already in general commerce, unless it be for the production of superior soaps. As a lamp oil it has distinct advantages which should recommend it for local consumption. The press cake is useless for feeding, and forms an inferior manure, though one quite good enough to apply to the land and also to cart for some distance, provided the cost on the garden does not exceed 8 to 12 annas per maund. It would probably be useful as an insecticide—both as cake against certain caterpillars, and as decoction which might replace that of a wild fern now used in Dibrugarh against Red Spider. The analysis of the cake supplied by Mr. Deane was as follows:—

Moisture	11.99
Oil	10.48
*Albuminoids	12.00
Carbohydrates, &c.	58.80
Woody Fibre	2.66
†Phosphoric Acid58
Lime11
Alkaline Salts, &c.	2.78
Sand60
			100.00

*Containing nitrogen 1.92
 †Phosphate of Lime 1.26

HAROLD H. MANN

CALCUTTA, August 12th, 1901.

CULTIVATION OF SWEET POTATOES.

BY PERCY G. WICKEN.

The Sweet Potato (*Batatas edulis*) is a native of tropical South America. It was first introduced into Europe from Brazil, and has since proved to be well adapted for cultivation in the Australian States. It is a robust and hardy growing plant, and, given suitable soil and locality, is a prolific bearer; it is valuable both as food for man and cattle and should take a much higher position in our rotation of crops than it has done in the past.

SOIL AND LOCATION

A soil free from stones seems essential, and a sandy loam is the best for this crop. A stiff clayey soil causes the tubers to split when the weather becomes dry and hot.

The ground requires to be well drained, and in a district that will be free from frost during the growing months, viz: October to April. In many localities the cuttings cannot be planted out until November, owing to the weather not being sufficiently warm to start the cuttings in time to plant out earlier.

SEED BED.

Many settlers fail in growing this crop from want of knowledge as to how to produce the cuttings

to plant out. The following is the method I have found most successful. Mark out a piece of land, in a sandy soil if possible, sufficiently large to allow the potatoes to be spread over. An area of 6 ft. by 6 ft. will be sufficient for 2 cwt. of potatoes. Then remove the top four inches of soil from the space and place on each side of the bed, now take your potatoes and lay on the bottom of the bed, taking care that they do not touch each other, and throwing out any that have started to go bad then put back the soil previously removed on the top of the potatoes, levelling the bed and lightly packing down with the back of the spade. If the ground is very dry give a good watering. In a few weeks' time, according to the weather, the young shoots will appear above ground, when about three inches high they are ready for planting out. Start in one corner of the bed and remove the soil and lift out the potato, and it will be found to be covered with young shoots, some potatoes having a few dozen, others up to a hundred shoots, according to the size of the potato. These shoots are now broken off from the tuber and are ready for planting out. The tubers can be replaced in the ground the same as before, and in a very short time a fresh crop of shoots will appear which can be removed in the same way, and if not too late in the season, a third crop may also be obtained.

In localities where the season is late the following method may be adopted. Make a frame of same old boards, sink about 1 ft. in the ground and about 1 ft. above it. Throw out the first foot of soil and then place in the space about 18 inches of good stable manure and tread well down and cover with about 4 inches of soil, leave for a couple of days, and then lay the potatoes on top of the soil the same as in the other seed bed and cover with 3 or 4 inches of fine soil. The shoots will come very quickly. If there is still any danger of frost, the beds must be covered at night with a light brush or calico screen, and the cuttings must not be planted in the field until all danger of frost is over. If the shoots appear in the bed in an irregular manner, it is better to pull them out by hand when required, than to disturb the whole tuber, which will be covered with small sprouts. The shoots will come away easily, and if pulled carefully very few will be broken. The shoots should be kept in a box or wrapped up in a wet sack while being taken from the seed-bed to the field, and should not be left lying about exposed to the sun.

MANURE

The Sweet Potato feeds largely on Nitrogen and Potash with a smaller amount of Phosphoric Acid, and a manure containing these ingredients should be used. A mixture composed as follows;—

- 3 cwt. Nitrate of Soda
- 4 cwt. Kainit
- 3 cwt. Superphosphate

per half ton would probably give good results. It should be applied in the ridges at the rate of 3 or 4 cwt. per acre at the time of ridging up the ground preparatory to transplanting the cuttings.

PREPARATION OF LAND.

The land requires to be well and deeply worked, and the crop responds well to deep cultivation; being a summer crop it requires to obtain its moisture during the dry weather and for this purpose sends its roots deep down into the soil. For this reason subsoiling is of great advantage to the plant as it is to most other plants. After the soil is well broken up it requires to be brought to a fine tilth by discing, harrowing, etc. As soon as the plants are nearly ready for transplanting the land should be drilled out into ridges, 3 feet 6 inches apart, by a drill plough, or a corn hilling disc is very useful for this purpose. The system I carried out for planting was as follows:—A small hill was made by running the cornhilling disc along the rows with

the discs set at a slight angle, the manure was then spread along this drill by hand, the machine again run over the hill with the discs set at a greater angle which hilled it up to a good height and covered the manure, and the land is then ready for planting the cuttings or slips.

PLANTING.

The slips should be planted in rows about 18 inches apart, and with the rows 3 feet 6 inches apart it will take 8.556 to the acre. If the rows are 4 feet apart 6.136 to the acre. The best method for planting is for one man to go along the row with a marker and mark out where the slip is to go and to make a hole in the ground, the planter following and putting the slip in the hole previously made, care being taken to press the earth well round the slip. If planted on a dull day and the ground is fairly moist the percentage of misses will be very small. Any slips that fail to take root can be replaced later on. Later in the season if it is desirable to put out a larger area, or a large number of misses require to be replaced, slips can be cut from any of the growing vines and planted out in exactly the same manner as those taken from the seed bed as previously described. From observations made by the writer it does not appear to have any effect on the crop whether the slips are taken from large or small tubers, so long as they are healthy and vigorous. It would therefore be more profitable to use the smaller size potatoes for this purpose, which are not so ready of sale as the larger ones.

CULTIVATION.

When the young plants are once established very little more requires to be done, except to run the Planet Junr. cultivator between the rows at frequent intervals so as to keep the ground free from weeds and well stirred. If there are many weeds come up, it will be advisable to give the hills a good hoeing to prevent the weeds from growing and depriving the potatoes of their food and moisture. In running the cultivator between the hills care must be taken not to set the implement too wide so as to tear down the side of the hills and expose the young roots to the sun.

HARVESTING.

This operation must be performed by hand, as the tubers grow to a large size, and if dug by a plough large numbers are cut to pieces, and otherwise damaged. They should be dug during dry weather and as soon as the tubers have reached maturity and before they have time to make a second growth. The maturity of the sweet potato may be ascertained by breaking it. If the sap oozes freely it is of course immature, if little sap exudes it is nearly mature. Experience will soon be gained in this matter. As a rule the tubers are ready to dig about the end of March or the beginning of April. Care must be taken in digging and handling not to bruise the potatoes, as a small bruise when freshly dug is likely to cause the potato to rot. It is also beneficial to leave the potato in the sun for a short time after being dug before bagging or putting into a shed, and when bagging all damaged, cut or bruised potatoes must be excluded. These damaged potatoes will only keep for a short time, and can be used on the farm for feeding pigs or other stock.

PRESERVATION.

One of the most difficult points about Sweet Potato growing is difficulty of keeping them so as to market at times of the year when they will fetch a good price, and also during the winter months so as to have a supply for the seed beds in the spring. The best way on a large scale is the method of "hilling or banking." This should be carried out under a shed or open roof so that the bank is not exposed to the weather. The best method to proceed is—lay on the ground, which must be dry, a good layer of saw; on top of this pack the potatoes in the form

of a mound and cover the whole heap with a quantity of straw, and then put sufficient earth on top to cover the whole. In many instances where large stacks are built a zinc pipe perforated with 1 inch holes is placed through the centre of the stack, which allows all surplus moisture to escape while the potatoes are going through the sweating process. Another method which is only applicable on a smaller scale, but which I have always found very successful, is to obtain a number of old empty cement barrels, which can generally be picked up very cheap, place in the bottom of the barrel a layer of dry sand about 3 inches deep, then a layer of potatoes, then another layer of sand and so on until full, placing about 4 inches of sand on top of the barrel; this will keep the tubers quite sound all through the winter, and only one barrel need be opened at a time as required for use.

VARIETIES

There are a large number of varieties of sweet potatoes. At the Georgia Experimental Station, U.S.A., thirty-four varieties were grown last season and reported on, the heaviest yield being the White St. Domingo. In the Australian States, however, only two varieties are at the present time obtainable, and they are generally known as the White Sweet Potato and the Red Sweet Potato. Both are good varieties and grow and yield well; the white will grow in cooler districts than the red.

DISEASES.

The Sweet Potato is attacked by several fungus diseases. The most important of these is the Black Rot Fungus *Ceratocystis Fimbrata*. The accompanying illustrations show a tuber attacked by this disease. It attacks the plant at any time of its existence even after being stored. The black spot is at first very small, gradually increasing in size until the whole tuber is destroyed. Owing to the nature of this disease, it is important that every precaution should be used to prevent it obtaining a footing. For this reason no diseased tubers should be used in obtaining shoots, young plants should be selected with great caution and diseased or suspicious tubers destroyed. Should any signs of the disease appear the plant should be immediately sprayed with Bordeaux mixture, which will prevent the development of the spores. All diseased plants should be burned, so that the spores of the disease do not remain in the soil. Do not plant in the same ground as a previous crop has been in, but carry out a system of rotation of crops and thereby prevent the spread of disease.—*Journal of the Department of Agriculture of Western Australia.*

PLANTING AND NEW PRODUCTS IN ZANZIBAR.

COFFEE—TEA—CACAO—RUBBER AS WELL AS COCONUTS AND GLOVES.

Guly in April 1901 does the report dated February 24th, 1900, of Mr. R. N. Lyne, Director of Agriculture, reaches us:—

He says:—Mr. W. J. Robertson (who must be an old Ceylon planter) has briefly explained the progress that has been made at Dnnga with Coffee, Tea and Cocoa. You will observe that in each case the condition of the young plantation is satisfactory and the prospects encouraging. Mr. H. Lister's report on the Tundaua plantation is included. This has been a very bad year for cloves, coconuts and fruit, and the natives at one time suffered much from the failure of their first crops. Growth has, however, revived under the timely rains of December and January.

(From Mr. W. J. Robertson's Report on New Products.)

Coffee.—A Liberian coffee clearing of $4\frac{1}{2}$ acres was planted early in April. The distance of the rows were 9 ft. apart and the plants in the rows 9 ft. from one another. These distance, 9 ft. x 9 ft., when planted, give 537 plants to an acre. Holes 18" x 18" were cut for each plant, and left open for some days and filled in with top soil. The plants were only about 6 inches in height and were most carefully planted, each one being shaded with bracken fern at the same time. The plants in the clearing are now nearly all 3 ft. high, a most vigorous growth for 8 months, and the clearing has a good even cover. This I also attribute to the judicious shading. The only vacancies in the clearing have been caused by snails (*kono-kono*) eating the young plants, and reattacking them after shooting out new young leaves, until they eventually die. We put on women every morning going over the clearing collecting the snails which had a slight effect in reducing the number. They do their work of destruction at night and early in the morning wend their way back to cover such as bananas, aloes, etc., and this is the time to catch them. We have since found the best remedy is to put a little lime or ashes round each plant. Snails will not go over this. They do not attack tea or cocoa but seem to have a particular liking for coffee, fruit, kola and shade tree plants, which latter we have to protect by fencing with sticks put close together round each tree. They will always be a source of destruction to young plants and a means must be found of exterminating them. The growth of the Liberian coffee plants equals anything I have seen in Ceylon, where it is chiefly grown in the low country, and the clearing is quite a little picture. A nursery of young L. coffee plants is coming on well at Mpapa and the few vacancies there are will be filled up when the planting season comes.

I would not recommend the further planting of Liberian coffee as I am of opinion that Arabian would grow well at Dunga, and it is a far more satisfactory variety to grow and deal with in every way. Liberian has a rough coarse berry and is hard to pulp and fetches a low price compared with Arabian. I think that Dunga is adapted in every way for a Coffee estate, the lay of the land is good, the soil a dark sandy loam with sandy clay bottom, and the rainfall considerable. Dr. Voelker's report showed the soil at Dunga fairly rich in phosphoric acid which, with lime, is the most important mineral constituent in a coffee soil. A few (about 20) Arabian coffee plants were planted at Dunga about 3 years ago and lived and grew all through the drought of 1898. I topped these a few months ago and they are now forming into good bushes, equal to any of the same age that I have seen in Ceylon. About $3\frac{1}{2}$ acres of land has been cleared, lined 6 ft. x 6 ft., holed and filled in. The holes were cut 18" deep, 18" wide at the top and at the bottom. This clearing will be planted with Arabian coffee when the season comes round. The seed was procured from Nyassaland and as the plants are coming on well at Mpapa nursery they will be fully 1 ft. high when planted out. We have also ordered $\frac{1}{2}$ bushel of seed from Nyassaland, which will give enough plants for supplies in 1901 and to open up a further 25 acres. There are also a few plants of *Coffea stenophylla* in the Mpapa Nursery, the seed of which was sent us from Sierra Leone. These will also be planted out in the rainy season."

Tea.—An experimental clearing of about $4\frac{1}{2}$ acres was planted in April at the N. end of Dunga near the labour houses at the end of the avenue. The plants were set 5 ft. by 5 ft., giving 1,742 plants to an acre. Holes 18" deep x 12" wide were cut and, like the coffee, left open for some days to take all sourness out of the soil and, previous to planting, were filled in with good top loam. The holes in this way contain good free soil and the young roots of the plants can find their way down without any obstruction. The seed of the plants, an Assam Hybrid,

the most suitable variety for low elevation was obtained from Horagalla Estate, Ceylon. It was packed in charcoal and, considering the long voyage it had to undergo, reached here in first rate condition, quite 50% of the seed giving plants, often a very good percentage for seed sown in local nurseries in Ceylon. The seed arrived here rather late in December 1898 and the plants were only about 4 months old from seed when put out in the clearing. Plants should be at least 6 months in the nursery before being moved, but as the monsoon was on and showed every sign of being a good one we decided to plant up the $4\frac{1}{2}$ acres rather than lose a year. There are some vacancies, the smallest plants having died out, but on the whole the clearing is a success and has a fair cover, most of the plants being now over 2 ft. high and looking vigorous. The growth of these plants has been as good as I have seen in the low country of Ceylon, for the 8 months they have been planted out. The plants were all shaded lightly with bracken fern when planted and to this I attribute the success of the clearing. In a country like Zanzibar where the weather is so uncertain and the sun so fierce all plants should, in my opinion, be lightly shaded immediately after planting, even in wet and cloudy weather, and after they show signs of having set the shading can be cautiously and by degrees taken off and so harden the plants. A half maund (40 lb.) of the same seed arrived from Ceylon in September 1899. This was put out at the Mpapa nursery, and has come up well. The vacancies in the clearing will be planted with these plants in April next when they will be nearly 7 months old and should thrive well. It is most important to always have a nursery of young plants coming on to supply what vacancies have occurred during the year, whatever size the clearing may be, as in this way alone can an even cover be obtained. After the tea is three years old supplies do not thrive, so during the 3 years special attention should be given to supplying each planting season. This holds good for all clearings of coffee, cocoa, etc. After supplying the vacancies in the old clearing there will be sufficient plants to extend the area 2 or 3 acres. Two acres have already been lined and holed ready for the planting season and as all the plants will be 7 months old from seed, with a favourable season this clearing should do well. The first planted tea will be ready for its first topping about July 1900 when it will be 15 months old. The plants will be cut down on red wood to 18" leaving the young laterals around untouched, which will soon reach the level to which the plant has been topped and increase the surface of the forming bush. From this topping a little leaf can be collected and a few lb. of tea made. The bushes will then be left alone till about the end of the second year, viz., about January 1901, when they will get their 2nd topping. Should the growth be very vigorous a little leaf could be plucked a month or so before this topping. The bushes will then be cut down to 22 inches on red wood, or 4 inches above the 1st topping, leaving all lateral branches as in the first topping and when they reach the level the bushes will have a good surface. When the shoots from the 2nd topping have reached over 6 inches (or 28 inches in all) they will be plucked off to this height and this will be the plucking surface of the bushes for the year, and anything below this must be left until it reaches above the surface. After this the bushes will be gone round regularly every 9 days and what leaf is ready over the plucking surface, plucked off. The bushes should be in full bearing by the end of 1901; but great care must be taken to see they are not over plucked by the labour when going round them. Judging from the growth of the plants that are coming on now and from the forcing nature of the climate as well as by the continuous heavy dews all the year round I

am of opinion that tea will grow and flush well in Zanzibar, wherever there is a fair depth of soil. There is a great similarity of climate between Zanzibar and low country, Ceylon, where tea gives a yield of from 600 to 800 lb. an acre. There is also a good proportion of iron in the soil about here, a most important mineral constituent of tea. Tea can never be a large industry in Zanzibar as there is not sufficient suitable land, but there is enough to grow what is required for local consumption and this I believe would pay handsomely. But in any case our experimental clearing will be able to test this in a year or so. A maund (80 lb.) of seed is on order from Horagalla Estate, Ceylon, and this should give enough plants, when put out in the nursery, to supply vacancies in season 1901, and extend the area 6 acres. This will give a total area of nearly 13 acres and be sufficient to thoroughly determine if tea will grow and pay to grow here. A careful account of all expenditure under tea will be kept.

Cocoa.—An acre of *Cocoa* was planted in November, 1898, but as the N. E., mousoon was a failure, hot dry weather set in, and we lost about 40 o/o of the plants. These were supplied in April last and the clearing has now a good cover. Another 7 acres of land was opened and planted up last April. The distances of the plants were 14 ft. x 14 ft., which give 222 to the acre. Holes 18 in. x 18 in. were dug for these. The plants were brought up from seed in bamboo pots and were all fine sturdy plants over a foot high when planted out. The pot being planted out in the hole the roots were in no way disturbed, a most essential point with *cocoa*, as the slightest damage to the root would cause the death of a plant. The clearing has a good cover and the plants are looking most promising. *Cocoa* is a most disheartening product to grow. It is the most delicate of all the common economics and has to be carefully dealt with from seed to planting. Nearly every insect attacks it and the plants are from time to time bared of their leaves and hang, many of them dying out in consequence. They must be kept supplied yearly. After a plant is 3 years old it may be called set. *Cocoa* does well down to sea level in Ceylon and should do well here. It is a struggling plant and will eventually make a soil for itself. It is very hard to get good fresh seed into Zanzibar as it does not keep any time and would arrive here in a perished condition if subjected to a long sea voyage. The last lot from Seychelles did well and we are getting 100 pods more from here. This will give enough plants to supply the old clearing and extend the area another 5 acres n season 1901.

Cocoa is a product that must have permanent shade to thrive well, while young bananas and mahogo act as good temporary shade. These we have planted in our clearing and in April will plant more permanent shade trees. For this purpose we have some plants of *Pithecolobium saman* coming on well at Mpapa nursery. This tree is a rapid grower as well as a deep feeder and the particular property which it possesses, and which makes it so valuable as a shade tree, is that of closing its leaves at night and thereby not interfering in any degree with the deposition of dew, whilst in the day time the foliage is not so thick as to exclude too much light. The jak tree, though it does not grow very rapidly, is also a deep feeder and its timber is valuable. We have plants of this tree coming on which will be planted out in the S. W. monsoon and we also intend to try *castilloa elastica* for shade. The bois immortelle has been already planted in the 7-acre clearing and the trees are nearly 3 years old. It is the chief and favourite shade tree in Ceylon and Trinidad on account of its rapid growth but does not seem to thrive well in Zanzibar, many of them dying out after they are 2 years old and the growth is very backwards. While on the subject of shade trees I may men-

tion that I am of opinion that in a hot country like Zanzibar where the sun is so fierce and droughts are apt to occur, shade trees should be planted through all clearings at the time the product plants are planted, as in this way they will not impede the root growth of the young plants. Good deep feeding timber trees should be selected as in the event of the clearing proving a failure, value can be got out of them afterwards.

W. J. ROBERTSON.

Rubber.—We have not been fortunate with our rubber plantations, principally because we were tempted to put out most of our young *Para* and *castilloa* trees in November 1898 in anticipation of the small rains, which, however, failed. During the subsequent hot weather many of the trees died. Those that survived are doing well, especially the *castilloa*, the few remaining trees of which look extremely healthy. Two of the *Para* rubber trees that were planted at Dunga in 1897 have shot up to over 15 ft., but others, contemporary with these two, seem to hang. The *Para* rubber trees that were planted at Pemba in one of the rice flats of Tundana, and which I spoke of last year as having surpassed our Dunga trees, have received a check which I attribute to stagnant water at the roots remaining over from the rains. It was after the rains that they began to fail. These trees may recover though some of them have been killed, but in any case it is instructive to note that the young *Para* trees which were planted in a fairly typical Pemba rice flat—a low moist forcing valley, swampy as all Pemba valleys are—in the wet season, have not up to now been a success. We have not proceeded with the planting of *Ceara* on the coral. The trees do not thrive there and their stunted growth makes them an easy prey to parasitic attacks. There is not a good vigorous tree from the one thousand we put out two years ago. By contrast there are a few *Ceara* trees in the deep soil round the house which have grown to fifteen feet in the same number of months and are now bearing seed. The soil of the coral is too shallow for the proper support of this plant. We may sum up our experience in rubber planting as being on the whole so far unfavourable both in Zanzibar and Pemba. We still intend, however, to continue the experiments as individual trees of all the species represented grow well. These are *Iveea braziliensis*, *Castilloa elastica*, *Mangifera glaziovii* and *Ficus elastica*. We purpose, however, to confine our attention principally to improving the natural forests of Pemba, work in which is now proceeding.

Vanilla.—We have increased the cultivation of vanilla to 3,000 vines. All the new plantations were set out in small patches of natural forest dotted about the estate. Lines of mbono were laid out inside as live supports and the vanilla trained along these. The first plantation in 1897 was planted with mbono as the only shade, and we have had much trouble in keeping the vanilla protected from the sun's rays during the cold season when the mbono sheds its leaves, as well as during the hot months. Planting in forest shade relieves all anxiety upon this point, though it remains to be seen whether the vines bear so well, as the cover may prove too thick. The plantations look well. This year we may expect the old plantation to flower and fruit.

China Grass (Bahmeria nivea).—Two cuttings have been made from the small plot of China grass, the first on April 7th. Seven roots yielded 70 stalks, $\frac{1}{2}$ inch thick and 5 to 6 feet long, the total gross weight, including leaves, being 25 $\frac{1}{2}$ lbs. The ribands had a good length but were not considered good enough to send home. The canes had 2 feet of young growth at the top, the ribands from which had not matured and easily broke. The canes have always this young growth at the top which materially diminishes the fibre-bearing length. The plants have been allowed to grow without watering in order that their growth might be observed.

under conditions corresponding to those they would encounter in a plantation here. Another small patch has been planted with stolons from the original plants and is growing well.

Machni Plantation.—Clove picking began in July. Our yield of cloves this season has been under 100 fraslas as compared with 1,537 last season, so we have practically nothing to report about the crop except to say that it has been a failure. The trees however look well and I hope next year we shall see some return from the extra weeding we have given this plantation since we took it over. The yield of coconuts has also fallen off. We gathered 93,489 nuts from about 3,106 trees, an average of about 30 nuts per tree. 75,000 of these were gathered during the first 7 months of the year. Trees always yield poorly after July, but the contrast this year has been striking; moreover the nuts have been small. The net profit shown on this shamba for 1898 was Rs. 3,711; and for 1899 Rs. 2,384. The profit on the season, August 1898—July 1899, was Rs. 5,917. This is after paying all expenses—weeding contracts, overseer's wages, the planting of 5,000 coconut trees and 12,000 seed nuts, from which we have 9,000 young plants ready to put out in April. The monthly expenditure averaged about Rs. 200 including overseer's wages. We intend this year to replant all the vacant places, amounting to several thousands, both in the Machni and Dunga clove plantations.

Dunga Plantation.—Clove picking began at Dunga on July 24th. The yield up to the end of December has been about 190 fraslas with very little more indeed to come in. The 1898-99 crop amounted to 381 fraslas. The shipment of 35 bales (140 fraslas) of cloves we sent home last year to Messrs. Gray, Dawes & Co., sold very well. The following correspondence was received from Messrs. Gray, Dawes & Co., on the subject of these cloves:—"March 22nd, 1899. We have received your small shipment of thirty five bales cloves and are pleased to be able to report most favourably on the condition and quality. We class them as very fine picked Zanzibar cloves, bright heads and stems. Up to the present we have succeeded in selling twenty five bales at 5½d. per lb. and we hope soon to be able to sell the remaining ten bales at the same price. This rate is fully 2d. above the market quotation, and we think we are right in saying that a difference to this extent between fair and fine cloves has never been realized before."

"June 5th, 1899. As already explained there is only a very limited demand for fine cloves at such a high price, and should a shipment of say 500 bales come forward they would only realize about ½d. per lb. over the market price for fair cloves. For shipments of say twenty to thirty bales at a time we think the high price could be kept up provided sales were not forced." The remaining 10 bales were sold at 5d. As explained in my report for 1898 very simple measures were adopted in the preparation of these cloves. They included picking, as far as possible, only ripe cloves (when picking is kept well in hand the difficulty is to prevent the people gathering green cloves to make up their measure, green cloves shrivel); separating the burst from the sound buds in the stalking; spreading out in the godown at night and never allowing any fermentation to set up; turning over the dried heap every day; passing the dried cloves through a screen to separate out the light heads and dirt. A portion of the cloves were dried in the glass house, but I think this had not much to do with the improvement in quality, though perhaps a little. The net proceeds of this small consignment, after paying all expenses of freight, commission, etc., was Rs. 1,332 equal to Rs. 9½ per frasla. Messrs. Gray, Dawes & Co. state that this high price could not probably be obtained for more than 20 or 30 bales, but they also say

that for large quantities of, say, 500 bales, ½d. per lb. over the market price for "fair" might be expected, which is equal to over a rupee a frasla, well worth the small extra expense and trouble incurred. His Highness the Sultan directed me to construct some clove drying stages at Machni. They consisted of a number of square wooden frames 5ft. by 5ft., into each of which 4 sliding trays closed, one on the top of the other. The square frame or box was supported on 4 short posts and roofed over with makuti. The cloves are spread out on the shelves and remain there till dry. At night or in a shower of rain the four shelves can be at once closed, thus saving a great amount of labour, besides allowing the cloves free circulation of air. The trays are of the size of the ordinary drying mats and can be made either of canvas or of perforated zinc. They can be constructed by the plantation carpenter at little expense. We had not sufficient cloves at Machni to judge of their efficacy, but we erected two of the stages at Dunga for the sake of experiment and sent a sample of the cloves home to Messrs. Gray, Dawes & Co. who reported on them as follows:—"In the present state of the market (Dec. 1899) they would we think realize 5½d. per lb. in small quantities. The cloves are nice and clean and heads particularly bright. A comparison of these with the shipment of 35 bales shows them to be of much finer appearance, although this is no doubt partly caused by the previous lot having gone off considerably through keeping." We continue to plough between the rows, to dig round the trees and to scatter a little manure, already with marked effect upon the appearance of the plantation, and we are now topping all except the largest trees. The tops of the trees can never be properly picked and are therefore better cut away. This, besides, develops lateral growth in the tree, keeping the buds within access of the pickers. Topping should also induce a more vigorous growth of leaf and bud. I believe that in the old days when labour was plentiful Arabs systematically topped their clove trees.

The coconut trees at Dunga have not yielded well, the average being 31 nuts per tree. The decline occurred during the latter half of the year. The number of trees bearing ripe nuts also showed a falling off as the year advanced, only 50 per cent. of the trees being climbed during the August gathering. The price has varied between Rs. 18 and Rs. 25. A new plantation of 1,579 trees was laid out in April and May, the young palms being placed 35 feet apart. The gaps in the old plantations were also supplied. The receipts from the sale of fruit and from the rent of cultivating tenants amounted to Rs. 187.14-0 which just covers the cost of collection. This has been an extremely bad year for fruit of all kinds, with the exception of pineapples.

During the 5 years, 1895-9, Pemba has yielded 73 per cent., and Zanzibar 27 per cent., of the total crop.

—Zanzibar Annual Report.

ZEBU CATTLE IN TRINIDAD.

BY C. W. MEADEN.

Manager of the Government Farm, Trinidad.

AND J. H. HART, F.L.S.,

Superintendent, Royal Botanic Gardens, Trinidad.

The introduction of Zebu cattle into Trinidad dates from the year 1879, when three bulls and three cows were imported. Others were introduced about the same time or a little later, by enterprising planters, and the resulting influence on the herds on their estates was markedly apparent. The notes in this paper, however, refer in the main to the work of the Government Farm. The bulls originally introduced were obtained from the East Indian Government Hissar, an establishment maintained by that Government for the production of gnu bullocks. This institution does not part with female stock and Trinidad is under an obligation to General Angel of Hissar, farm for the purchase of its cows, which were described as pure bred Hurnahs. From this beginning the Trinidad herd has been formed. It has been kept pure, and, by the introduction of a new bull every fourth year, deterioration has been prevented. Photographs and measurements have been exchanged with the Indian Department which show that Trinidad is not only on equal terms with, but, in some instances, even in advance of them.

The Zebu or Brahmin is of great antiquity, and the continuity of special characters and form is specially remarkable, naturalists classing it as a distinct species under the name of *Bos indicus*, a name which indicates its native country. The points of a true Zebu are not difficult to describe, but their crosses are scarcely distinguishable from a pure bred animal and it is only when an authentic herd-book is available that any positive pronouncement can be made; a state of affairs which obtains in almost any breed of cattle. The distinguishing points of this magnificent breed may be described as follows:—Prominent hump on the forequarter of the male and female—smaller in the latter; long pendulous ears, silky to the touch; heavy dewlap extending to the lower jaw; short crescent horns; drooping hind quarters; fineness of skin; slender limbs; and tail terminating with a fine trace of black hairs. The appearance of the animal should be calm and dignified, the eye full and prominent, with a look of latent power than can at times be well displayed. A pure bred bull on his own domain is one of the most stately animals in existence. The Zebu ox is a splendid draft animal well adapted for tropical agricultural work, extremely active, and possessed of great powers of endurance. His fine limbs, sound hard feet and good action are all in his favour as a working animal. With a minimum amount of feeding and care he is capable of doing more heavy and exhausting work than any other beast of burden in the tropics. Well bred oxen are however somewhat difficult to break in, but once broken, they are very docile and obedient, as can be seen by the way in which little coolie boys are able to control them. The Negro is, as a rule, unable to exercise the same control over this class of cattle as the East Indian driver. Good working oxen are always saleable and the prices realized at the Government sales have invariably been satisfactory, although of late years they have decreased somewhat owing to the uncertain state of the sugar industry.

As milkers, the pure breed fails in some respects. Most of them resist the restraint which necessarily accompanies the act of milking and in consequence their yield is deficient. Their milk is somewhat weaker than that of ordinary milch cows under the same treatment, the analysis showing as follows:—

	Specific gravity.	Solids (not fat).	Fat.	Ash.	Cream
Zebu Cow	1031.0	8.9	3.72	.72	4.5
Ordinary Cow	1027.7	9.09	4.55	.75	7.0

The above analysis was made with the afternoon milkings. It would not be fair to the Zebu, however, to condemn them entirely on the trial of their milking qualities in Trinidad. It is certain that for long years in India the milking qualities have not been at first consideration, other points have been considered as of more importance in selection. It is clearly possible that, by proper selection, a strain of Zebu milkers might be obtained little, if at all, inferior to any other class of cattle. This view is strengthened by the fact that individual cows have been found among the herd which have proved themselves excellent milkers. The practice in Trinidad is to allow the calves to run with the dams as soon as they are strong enough, with the object of bringing them forward as fast as possible, and giving them every advantage at the annual sales.

Crossing milch cows with a pure bred bull has often resulted in the production of first class milkers, but the milking qualities appear to suffer if bred too close. A first or second cross produces animals eminently suited to the tropics, inured alike to heat or moisture, invariably thrifty, and giving milk which compares favourably both in quantity and quality with that of any country. What knowledge we have of the crossing of this breed for the production of beef is distinctly favourable, the quality is good, and from the butcher's point of view, they scale well. The waste in offal in animals killed in the tropics is generally greater than in temperate climates, on account of certain local conditions.

Our bullocks from the time they are weaned until reaching four years old are entirely grass fed, except for a short preparation previous to selling. At this age they scale some 1,000 to 1,200 pounds, and are generally sleek and in prime condition for the butcher. Having been fed in clean pastures the meat is tender and entirely free from the large amount of "muscle" which renders the flesh of the imported Venezuelan cattle so tough and tasteless.

Well bred Zebu cattle cannot be termed tractable in the same way as the Hereford, the Polled or the Jersey, but on their own ground they are not difficult to deal with. Trouble arises, however, on their transference from one place to another, or on any alteration in the handling to which they have become accustomed. In such cases they show extreme excitement and are prepared to go over, or through, anything. Another disagreeable feature is their lying down and offering passive resistance when overcome. The best treatment in such a case is, not to beat them or to permit the too common practice of tail twisting, but to fill their nostrils and ears with cold water by throwing it smartly in their faces. Nothing brings them to their feet quicker than this simple and harmless treatment. The plan of dealing with cattle in the Trinidad herd is not to drive them but to call them, rattling the feeding bucket at the same time. Zebus can be easily led, but they cannot be driven. To effect this, one or two of the herd are trained to hand-feeding. They soon recognize the rattling of the bucket, so that when the herd is wanted, the cry of the herdsman and the rattling of the bucket brings them home at a gallop.

Before being sold oxen are put into a reserve pasture which has been shut down in preparation for them, where they remain for some three months, and are hand-fed during this time with a mixture containing coco-nut meal, Indian cornmeal, and "middlings" with a small addition of salt and linseed meal, which binds the whole and prevents waste in feeding. The ingredients are made into a mess with water and hand-fed in about half-pound lumps, each animal receiving about three pounds at a time. The mixture is carried to the field in buckets, one man stands guard, while the remainder, taking each a certain number, see that

every animal receives its share. This feed costs about five cents a day or 6s. 3d. per month, and has the effect of putting on a nice clean finish to the animal previous to sale.

For crossing with other breeds there is no better animal than the pure bred Zebu, the cross with native stock giving excellent results. The half or three part Zebu, heifers crossed with Devou, Hereford, or Polled bulls, give rise to a very profitable class of stock.

Jamaica has for years been a good customer at the Trinidad sales of pure bred stock, and is probably largely indebted to Trinidad importations for the improvement in her herds. British Guiana, Antigua, Grenada, Honduras, and Venezuela have also been purchasers, and as the export has been in no way restricted, the neighbouring Colonies have been able to take advantage of and to benefit by the Trinidad importations, a privilege of which they have not been slow to avail themselves. It is understood that in Jamaica half-breeds from the Zebu are in great demand and sell at considerable advantage as compared with the native cattle. The value of pure bred two-year-old bulls has ranged from £50 to over £100 in accordance with the size and points of each animal, the number offered and the number of buyers present. Pure bred heifers are now worth about 75 to 150 dollars, while bulls will probably range from 150 to 300 dollars. As, however, all cattle are sold by auction, this must be taken as only an approximate estimate of the price they are likely to realize.

The Government Stock Farm in Trinidad is now entering on a wider phase of existence, and it is hoped that the management will be able to handle a certain number at least of all the most useful class of stock. In a short time additions will be made to the Zebu, Guernsey, Red Polled, and Hereford herds, from which it is hoped to secure acclimatized progeny possessing the best characters of the various breeds, and that the support afforded will enable the Trinidad Farm to maintain its position of being one of the best institutions of its kind and to become the stud farm of the West Indies.—*West Indian Bulletin.*

THE FODDER FOR INDIA.

Mr B. F. CAVANAGH, Superintendent of the Agricultural Gardens, Madras, writes to us with reference to "Paspalum dilatatum."—Its native habitat is doubtful. Some authorities affirm that it is a native of South America while others claim Ceylon as its origin. The grass was first brought to the notice of Australians by the late Baron von Muller, who recommended it on account of its high nutritious qualities and its drought-resisting properties. A very interesting account of Mr. Williams' experiments with this grass is given in the "Agricultural Ledger" Series No. 33 (1901) No. 1, Page 3. But the climate of New South Wales, where those experiments have been carried out, and the climate of the Indian plains cannot be compared. The most northern point of New South Wales is 32 degrees south of the equator, and again, their experiments were carried out not at sea level but at an altitude of from 400 to 500 ft. We have a small plot here, which we have to water regularly; otherwise, it would shrivel up. It flowers freely, but the seeds are barren. There is no doubt that at any elevation above 1,000 ft. and on any poor soil it will be worth cultivating and will pay, provided it has water. I received a letter from an Ootacamund correspondent in which he says "P. dilatatum is a valuable grass, slow of growth at first, but when once established it forms dense tufts 4 feet high, and seeds freely, "no doubt seeds collected at this elevation would be good." I have not heard of a single success on the plains. There is a small place just outside Bangalore, viz. Whitefield, where I believe if it was tried it would prove a success. There, I am told

water can be obtained at 7 feet from the surface, which means that the ground would hardly ever get into the hard, dry state it does on the plains.

Re cultivation to form a good pasture at once. It requires from 6 to 8 lbs. of seed per acre. This allows for barren seeds, as there is always a percentage of failures. The ground may be prepared the same as for ordinary pasture and seeds sown broadcast. Again, 2 and 3 lb. may be sown to an acre, and left until it ripens its seeds; these will fall to the ground and germinate, with the result, a good thick pasture. When once established it will choke all other weeds. Another way is to sow in nursery beds and transplant into drills 18 inches apart and the plants 6 inches apart. An acre of ground treated in this way reached a height of 5ft. and a test cutting produced 13 tons 3 cwt. Never sow in the dry season; either sow in showery weather or just before the rains. Seeds are obtainable from Messrs. Law, Summer and Co., Swanston Street, Melbourne, Victoria, at 5s. 6d. per lb.

Re your correspondent's question:—

(1) I would advise sowing in nursery beds and transplanting when large enough to handle. If he is on the plains he will certainly have to water them; it does not require a rich soil. (2) To my knowledge, no experiments on a large scale have been carried out on the plains. The chief authorities for this grass are the farmers of New South Wales and Victoria. The Calcutta Horticultural Gardens were the first to carry out experiments, but these would count for nothing, as the climate there is more genial, and they have always a supply of good fodder from Indian grasses. (3) It may be grazed green; none of it being wiry, cattle will eat any part of it, even from the crown to the seed head. There is no reason why it should not make good silage.

To sum up *P. dilatatum* will thrive on almost any soil, sandy or otherwise, provided it can obtain sufficient moisture. Salt water will not effect its growth, and it will stand the two extremes, heat and cold.

"NATURE TEACHING."—This mail brings us "with the compliments of the Commissioner Imperial Department of Agriculture for the West Indies," a copy of a clearly printed, compact little manual of some 200 pages including glossary, appendix and index, which should at once be revised, adapted and published by the Government of Ceylon for use in nearly all schools in this island. The full title of the book is:—

Nature Teaching based upon the general principles of agriculture, for the use of schools by Francis Watts, F.I.C., F.C.S., Assoc. Mason. Coll. Birmingham, Government Analytical and Agricultural Chemist, Leeward Islands.

The following extracts from the introduction indicate the purpose and use of the little manual:—

In the pages of *Nature Teaching* prepared by Mr. Francis Watts, F.I.C., F.C.S., and now issued as a Text book by the Imperial Department of Agriculture, an attempt is made to place in the hands of Teachers both in Elementary and Secondary schools a well selected, but co-ordinate body of information suitable to West Indian conditions, to be supplemented in each case by numerous illustrations and experiments in which the pupils themselves take an active part.

By a judicious combination of work in boxes and pots, and work in the open garden, a teacher should succeed in keeping a class well in hand without confusion or loss of time. In the absence of a school garden a considerable amount of instruction may be given by means of boxes and pots alone.

LION HUNTING IN ZULULAND.

AN EXCITING EXPEDITION.

WITHIN THREE YARDS OF A LION: A FAMILY
OF SEVEN APPEAR: WILDEBEESTE,
ZEBRA, AND HYENA: A BIG BAG.

We have received permission to publish the following letter written by Mr. C. Manning, of Mt. Edgecombe, describing a lion-hunting expedition in Zululand, in which he and a friend had a most exciting experience:—

Almost immediately on our arrival at the Ubombo, Leslie and I (Mr. Miller had not turned up), obtained the best information procurable from native sources, as to the usual lair and hunting grounds of the lions, which obviously lay up in the thick bushes near to where the herds of wildebeeste roam about on the open plains. These and the zebras (Burchell's) form the lion's ordinary bill of fare. We, primed with the above information,

ERECTED A SMALL SCHERM OF UKMINZA
THORNS,

and a few strands of wire, in a very likely-looking donga, fringed on all sides with fairly heavy timber. Our scherm was about three yards square, and we made ourselves fairly comfortable for the nights to follow, by means of a waterproof sheet, air pillow, and a couple of blankets each. We arranged the bait we had brought from Nongoma, 12 yards from the scherm, and awaited developments. I should have mentioned that, most unfortunately, the blue lights we had ordered through Mr. Miller had not come to hand, owing to his delay *en route*, and we had, therefore, to depend on the use of E. C. powder to light up the scene when the lions should arrive. As the flash of the powder would be only momentary, and there was no moon until about 2 a.m., we, after some discussion, decided to use S.S.C. in our shot guns, and keep our .303 rifles as an emergency.

The first night passed off without any event. Our living bait, to our consternation, remained absolutely silent, and we heard only the cough-like bellow of the wildebeeste all round us, varied occasionally by the weird cry of a prowling impisi (hyena). We had reckoned on our bait giving the lions some evidence of his presence, but no doubt instinct warned him from giving himself away, and he remained as silent as the Sphinx, and quite impervious to our occasional attempts to rouse him up. We put in time next day by shooting a wildebeeste hull each, and sent the meat to our main camp. The night following

THE DENOUEMENT

came off. We were aroused at 10 o'clock, and realised that the opportunity of our lives had come. I had only just raised myself on my elbow, and had not got hold of my gun, when above me, not three yards off distinct against the skyline, loomed the body and large round head of a lion, who had evidently walked up to reconnoitre our scherm. It was only for an instant, however, for, satisfied, or the reverse, as to our vicinity, the lion glided off like a ghost into the darkness. I confess that, for those few seconds, my heart

appeared likely to knock my ribs in. We could hear the savage, hoarse grunt of the lions, but the intense darkness veiled the scene only 12 yards from us, except for the occasional glow of a huge feline's eyes, which resembled the phosphorescent flash of the glow-worm. We had spread a quantity of powder on a box, and matches being handy, Leslie struck one, applied it to the former and night became day. Never shall I forget the scene which for a few seconds presented itself. The bait was still there, and at the first flash of the powder, from the carcass, on all sides, sprang lions, their tawny hides looking white as polar bears in the bright light. I fired at one huge brute, which was lying right across the carcass, and Leslie fired a bullet at one which bounded away to the right. Then darkness again—darkness made more intense by the bright glare of the preceding few seconds. What was happening? Were the startled lions rushing away to the deep and wooded hollow below us, or were we to feel the crash and impact on our slightly-built scherm, of some charging and wounded monster? It was impossible to say, and we sat tight, clutching our guns in hand, and awaiting events. Leslie had been handicapped by lighting up the powder, and did not therefore feel sure of the result of his shot, but I knew I had been on the mark, and a

LOW GRUNTING, AND ALMOST HUMAN-LIKE
MOANING

near us told me that I had made no mistake. We expected no re-appearance of the lions that night, but, to our amazement, in less than 15 minutes from our shots, deep hoarse grunts, the rending of flesh and the cracking of bones, made it evident that the enemy entertained no idea of relinquishing the "spoils of war." It was now my turn to light up, but the powder had been too heaped up, and the flesh which resulted on my applying the match was barely momentary and so vivid that, for a few minutes, I was absolutely blinded and feared my eyesight had gone. Fortunately this was not the case; but I was effectually prevented from seeing anything of the lions. Leslie had fired, but apparently without any effect, for no welcome response answered to the shot. Darkness—Egyptian—and again the terrible uncertainty of what was happening, or what would happen. As seven lions were around (one brushed our scherm, as we found by the spoor next day), developments might be expected at any moment, but again we sat tight as wax and as silent and motionless as mummies, hoping that thereby we might yet get another chance if fortune were so kind. This proved to be the case and once more during this eventful night were we to hear the low murderous grunts and savage snarls of the fierce beasts as they assembled and squabbled over the dead animal. We had an old Zulu kehla with us in the scherm and we decided in low, whispered undertones that, to give us an equal chance at the lions, Umgeschow should light up the powder. He did so, and the nitro being now more evenly distributed than before, the flash which resulted was the best of the three attempts,

ONLY FOUR LIONS

had returned, but I was able to put in a quick right-and-left at one of them as it sprang to the right of the carcass. Leslie also hit a big chap hard, as he broke away to the left, and we heard him grunting furiously down in the donga, and he had evidently, in his rage, turned upon one of his companions who had approached the wounded beast. My lioness, stricken to death, was meanwhile grunting hoarsely, and moaning *in extremis* hard by our scherm. Soon these sounds ceased, and the silence of the night was broken only by the weird and mournful cries of an owl, or the "kwawk" of some distant wildebeeste. Almost breathless we lay and hoped, but hoped in vain, for a further visit from the giant feline. Slowly the crescent moon rose over the tree-tops, about half past one, and just as its faint rays pierced the dark shadows around we heard the savage growling of a lion by the carcass, and felt sure that luck was once more with us. Not so, however, for silence soon reigned unbroken, and it was evident that one of the party of lions had come up, had winded us, and had then followed his companions down the valley to the Umkusi River. It seemed ages before this never-to-be forgotten night passed, and we were enabled by the wan light of the coming dawn to crawl out of our scherm, and find out what result had been achieved during those, the most exciting hours of our lives. This was soon seen, for there, within, respectively, 20 and 30 yards from the carcass,

LAY THE GRIM AND TAWNY FORMS OF TWO FINE LIONESSES.

They were both in perfect condition and looked the personification of brute strength with their massive limbs, as we shook hands warmly by them, and drained a flask of mountain dew to the goddess of sport.

Natives from our camp soon arrived, and we endeavoured, but in vain, to track Leslie's wounded lion, through the thick thorn bushes along the donga. Poor Leslie was naturally terribly disappointed at losing his lion in this way, and I think you will understand my feelings as a sportsman when I say I fully sympathised with him in his hard and cruel luck. I have now little more to add re lions. Naturally we were exultant in the success of our plans, and I may add, by the way, that, had the blue lights come to hand, I am firmly of opinion that we

SHOULD HAVE BAGGED THE WHOLE

FAMILY PARTY

of lions. We laid bait, and changed our scherm to other places, when we found that the surviving lions did not return to the carcass the following night. All in vain, however, and I may say, briefly, that we had no more luck, the remainder of the lions having apparently had their nerves so badly shattered that they cleared right away from that district. We slept in scherns for nearly a fortnight after the big event, and did all that the wit of man and native cunning could do to bring us to terms with more lions, but it was not to be, and Leslie

had to return to Nongoma without retrieving his ill fortune. I am now also forced to throw up the sponge, and am of opinion, in the light of past experience, that lions in the Ubombo district are restricted to those mentioned, and that, had other and undisturbed packs, or even single lions, been about, we must inevitably have come across them, or at least seen their spoor about the neighbourhood. Fever is worse there than in any other part of Zululand, and poor Gold, clerk to the Ubombo Magistracy, contracted fever, and died after a few days of hut-tax collecting in the vicinity of our lion-shoot. So we shall be lucky indeed if we get off scot free. I have shot altogether about 200 head of game, buck, and bird, but my

BAG HAS BEEN GREATLY LESSENED BY

DANGER OF BOER RAIDS,

and on account of our not firing shots while hunting, to avoid disturbing the ground.

—Natal Mercury.

C. M.

PRODUCE, PLANTING, AND COMMERCIAL NOTES.

The wisdom of the policy of selling tea by means of

SECRET AUCTIONS

has been keenly debated from the first, and the controversy still goes on. We notice that the *Grocer* of last Saturday publishes a list occupying several pages of the marks of teas disposed of in secret, so that the retailer may, if he choose, trace these packages. Those who favour the new departure claim that, apart from the right of the producer to sell his teas in any way he may think fit, the publication of the sales has long been a sore point with many wholesale dealers, and has been one of the factors operating against higher prices. Some of those who believe that these secret sales are a mistake claim that a false impression as to the extent of the dealers' profits is thereby created, and that the wholesale trade will suffer in consequence. There is a letter in the *Grocer* of last week signed "Kandpore Tea Company," in which the writer takes exception to these secret sales on other grounds. They say: "This, we think, is one of the greatest blunders ever made by the wholesale tea dealers, *i.e.*, by a few of the leading houses who have prevailed upon the importers to try the system. It is a blunder because this step is open to misunderstanding and misrepresentation: misunderstanding on the part of the misinformed daily press, which is publishing absurd and misleading articles; misrepresentation by some blenders, brokers, travellers, and others interested in doing wholesalers an injury. It is monstrous to represent wholesale tea dealers, as a class, as bloodsuckers, and secret sales as a scheme for adding to their already exorbitant gains. Nothing could be much further from the truth. Whose trade is suffering from inadequate profits more than the wholesale tea dealer's and who has been so much the grocer's friend in the way of credit-giving and otherwise as he has been? Not a few grocers finance their business mainly on the credit they take on tea and duty. This system of small profits and slow returns is, though a boon to the retailer, the reason for the hard times amongst the wholesalers, who in looking out for some means of bettering their terribly cut profits have hit upon this expedient of secret sales, an expedient, however, which will not help them, because it will not lessen competition. The whole trouble is due to the prevalent Yankee system of trading, which makes not only some dealers, but also some blenders, brokers, travellers, and grocers utterly selfish, untruthful, vindictive, and morally dishonest. The golden rule is in sad disuse nowadays; indeed, some men

devote half their thoughts to devising schemes for injuring their competitors. Unfair competition (including printed and verbal bunkum, weight with package, and charlatanism) is the root of all evil in trade, and is more rampant in tea than in most businesses. We can write on this subject of secret sales without bias, as our trade is not in originals."

The "Daily Express," in commenting on these sales, is rough on the

TEA BROKER,

without regard to the question that some brokers are opposed to these secret methods. It says:—Failure appears to have attended the efforts of the London tea brokers to withhold the market price of tea from country grocers. Some of the inner reasons for the bad 'secret sales' system were given to an 'Express' representative yesterday by a member of the trade. 'The attempt to conceal prices,' he said, 'marks another stage in the downfall of the middleman, the broker who has stood so long between the importer and the retailer. The first step was the assault made upon the market by big firms like Lipton's, the Home and Colonial Stores, and the International Tea Stores, who are now represented at the public sales by their own buyers. After these came the man who gives you a teapot with your pound of tea, or a pension for your widow, or a quarter of a pound overweight. All these people are taking lots of tea off the market without troubling the dealers. As a natural consequence the latter have endeavoured to make up their losses by extra profit out of their sales to country grocers. But the country grocer is too wide awake to pay more than a fair percentage on the market price, and, with the help of his trade journals, and a list supplied by the Market Prices Company, has managed to hold his own. To demonstrate the possibility of doing business on a fair and equitable basis, the Market Prices Company has now offered to supply grocers with teas bought at public sale, the only charge being a 5 per cent commission, the company always handing over the original weight notes, invoices, or contracts to verify the actual prices paid.'

With reference to the letter of "Kar Guzar" to the *Financial Times*, on the question of

TEA COMPANIES,

which we printed last week, Mr. George Seton, writing to our contemporary, says: "The letter of your correspondent, 'Kar Guzar,' on Indian tea companies comes at an opportune moment, and his suggestions are well worthy of consideration. Your own editorial remarks also are very much to the point. I would only add to them that shareholders in tea companies would gain much by keeping a close eye on your editorial columns. There is no doubt that the issue of a half-yearly interim report, or, even better still, the holding of a half-yearly meeting of shareholders, would be a great gain to shareholders both in the case of tea companies and, indeed, if any similar industrial undertakings which, like tea, are subject to sudden and great change in the degree of their prosperity. Your suggestion for an association of shareholders is one that has occurred to me, and I think the present moment would be a favourable opportunity for creating such a body. Such an association would, of course, be of little use unless it embraced a large majority of the shareholders in these companies, and it would also be necessary that it should have some official or representative as a centre round which shareholders might gather for mutual protection, and if you, Mr. Editor, could in any way assist in bringing about the formation of such an association you would do a great benefit to the industry. The difficulty would be in drawing in all the scattered shareholders, both large and small, throughout the country. In advocating the idea, I wish it to be clearly understood that it is not desired to interfere in any way with the

ordinary administrative duties and obligations of directors and managing agents. The chief object of the association should be to control the general policy of the companies whenever, in the minds of the majority of the chief shareholders, it appeared to be drifting into a wrong channel. As a case in point, I would merely instance the recent excessive garden extensions, which, by causing an abnormal increase of production, has brought about the great fall in the price of tea that has occasioned the present unfortunate and disastrous state of the tea industry."

Another correspondent, who signs himself "An Importer," says: "In reference to a letter signed 'Kar Guzar,' as I have considerable experience of

LIMITED COMPANIES,

I trust that a few remarks may not be out of place. I quite agree that reports should be issued within three months of closing of accounts, and in many cases it would be desirable to publish interim half-yearly reports. I question, however, the expediency of publishing or sending to shareholders the confidential reports made to the directors by managers or visiting agents. If such a custom were to obtain, there is a danger of reports being made merely with a view to publication. With all defence to the shareholders generally, I venture to state that comparatively few understand the business of tea planting, and it is highly probable that, if they were fed with continual reports as suggested, they would be misled, simply because they are not experienced in the matter. Moreover, I think such a system would lead to much more speculation in tea companies' shares, and that is most undesirable. Of course, any enterprise depending on crops is largely speculative, but I hold that those who are interested in tea companies' shares should do so with the idea of holding, and not of selling when there is a rise. We must expect occasionally to have depression in the tea trade as in every other trade, but, if investors are judicious in their selections, they ought not to lose their heads because of the present crisis, but 'wait till the clouds roll by.'"

"A feature of the tea trade in Toronto," says the *Canadian Grocer*, "is the samples of

INDIAN GREEN TEAS

that are being submitted to the trade this week. They are from the Dooars and Sylhet districts, and they are being offered at a most favourable price. But their chief recommendation is their quality. Those who have tested them say they are beautiful in style, and in cup quality exceptionally good. One dealer declares they are the finest he ever saw. Hitherto green teas of India shown here have not been properly made. But, however excellent the quality of the Indian teas may be, the attention of the public must be drawn to them if they are to become an important factor in the market, either in Canada or the United States."

It is but a poor consolation to tea planters to hear of the troubles of those who grow other products, but just at present it is difficult to discover anything very inspiring about the position of either

TEA, COFFEE,

or sugar. The latter we know has been under a cloud for years, and so far as the West Indies is concerned, the planter of cane sugar, or what there is left of him, is endeavouring to imagine that the silver lining is somewhere about, even though he cannot see it. Coffee planting in India is not a pursuit which recruits the ranks of millionaires, nor does it satisfy the aspiration of those who engage in it elsewhere. In Brazil coffee planters are suffering from depression, while in less favoured climes there are various causes operating against the grower of coffee. The latest Consular report from Costa Rica shows that planters are making grievous complaint, notwithstanding the prices which prevailed here last year. Coffee

is still Costa Rica's staple product and most important article of export. The year was a good one for exporters, the average price paid by them to the growers for the berry in fruit being only £1 10 per fanega (400 lbs), as against £1 11s per fanega in 1899, while the prices realised abroad were higher by 1½ per lb, the actual figures being—1899, net average value, 4½d per lb; 1900, net average value, 5½d per lb. Growers complain, however, that at these prices coffee barely pays expenses, and it is possible that, if there is no improvement in the near future, many of the older farms and also those in inferior soil will be abandoned. The Consul remarks that, so far from any prospect of an advance in price, appearances all point the other way. The improvement in the coffee markets abroad was only temporary, and the prices obtained for the first part of the 1901 crop are, in many instances, as much as £1 per cwt less than those of the preceding year.

The attempt to cultivate

COTTON

in West Africa will be watched with interest. Experts are of opinion that the soil in some districts is congenial to the plant, and the similar attempt made many years ago failed more through lack of encouragement than anything else. The firm of Messrs. Elder, Dempster are said to be promoting experiments in British West African Colonies.—*E. and C. Mail* August 2.

AGAVE (ALOE) FIBRE INDUSTRIES IN INDIA.

We are greatly interested to learn from the *Madras Mail* of textile industries (extraction of fibre from Aloes) being started in both the Bombay and Madras Presidencies:—

"We read and hear so much from time to time of new textile industries being introduced or recommended for introduction into this country, and see, as a rule, proportionately so little being really and practically done, that it is positively refreshing to learn that alone planting and the extracting of fibre therefrom on a commercial scale has actually been set on foot in the little District of Anantapur. Two years ago, an Agave Fibre Company was formed at Pawai, in the Bombay Presidency, and an area of 459 acres, 356 of which were occupied by a lake, were acquired for the purpose of carrying on the industry. Work was started with a swing, and now that a similar industry has been launched here, it will be of much interest to know how the Bombay experiment is getting on. It may be noted that this is not the first time that the Bombay Presidency has considered in a practical way the utilisation of Agave fibre, for in 1875, under the auspices of the Government of Bombay, an experiment was undertaken for the manufacture of paper at the Girgaum Paper Mill, but the experiment was most awkwardly and carelessly put through, and the result was, of course, a failure."

We shall watch very closely for the results of the experiments at Pawai and Anantapur, and even now to learn what machinery is employed and whether existing Agaves are being utilised, or the results of planting are to be waited for, would be useful.

A TEA DISEASE IN SOUTH INDIA.

Mr. C A Barber, Government Botanist, Madras, has written an interesting report on "A Tea Helmin Disease in South India." The disease

was first brought to notice in Madras by Mr. A Brown, of Glenfruen Estate, Devala. The virulence of the outbreak at "Glenfruen," says Mr. Barber, fully justified the fears expressed by the manager of the estate; but it was strictly localised, and there does not appear to be any great fear of the pest spreading. But Mr. Barber does not disguise the fact that, if the pest "once got a fair hold of a perennial like tea, it might spell disaster." The parasite is known as *Heterodera radicicola*, and is frequently the result of careless or inefficient cultivation, especially on old garden lands which have been allowed to run to waste. It was discovered in five different localities in the Wynnad and is said to be probably widespread. The disease causes an immense amount of damage all over the world, and Mr. Barber says there is little doubt that it has been a root parasite for centuries.—*Madras Mail*, Aug. 20.

SISAL HEMP AND OTHER FIBRE PLANT CULTIVATION IN TRINIDAD.

BY MR. QUESNEL, 11TH JUNE, 1901.

I have seen, with a deep regret, some persons rejecting at first the idea of cultivating fibre plants in Trinidad as requiring too much capital and too costly machinery.

This is a great mistake. Yukatan is there as a proof of it, because the Indians of that country export now more than 100,000 tons, prepared with a very rough machine called "Raspador," a wheel of four feet diameter, working at 160 revolutions a minute. The cost of it cannot be, with horse gear, above \$150. That machine is easy to move from one place to another. It wastes a certain amount of material, and is slow at work; but it is not the first time that the primitive appliance of the peasantry has succeeded better than costly machines and big capital, with their heavy interests and annuities. The Raspador gives net 333 lb. in ten hours. A machine for working three quarters of a ton would cost, with steam engine and the buildings to correspond, £1,200 at least, when five Raspadores would not cost more than £150.

A steam engine would not be movable and could not be economically established where the area under cultivation would be less than 1,000 acres.

I take my data from various reports from Dr Morris, Imperial Commissioner of Agriculture, Barbados, and from Mr Richard Dodge, of the Washington Fibre Investigation Committee on account of the Government of the United States.

From them I come to the conclusion that the fibre plant gives a hemp of a value of £30 a ton in London, which I reduce to £14 a ton after all wing for discount, commission and freight, and also for cultivation and packing. This is less than the amount given in the reports referred to.

I take for planting five rows in 36 feet, that is to say, four at six feet distance and the fifth at twelve. I put the plants six feet apart in the rows. This gives me more than 1,000 plants to an acre. Each plant at four years gives forty leaves a year of a weight of 50 lb. of which four per cent turns into fibre, dried and white, or two lb. of fibre to a plant, or 2,000 lb an acre. £4 a ton is more than three cents a pound. I allow only 2½ cents a pound to make \$50 an acre. Thus an acre producing net \$50 yields double the results of 200 cacao trees on an acre, at ten bags per 1000 trees at \$12 net (when 6s is the London market quotation) or two bags, \$12=\$24. It is a great deal more than 20 tons of sugar canes to an acre at 9s a ton, leaving probably not more than 1s a ton to the cane farmer, or £1 an acre.

If an acre gives 2,000 lb a year, and a Raspador prepares some 333 lb a day—100,000 lb a year of 300

days—it will require 50 acres to produce sufficient fibre for one Raspador's work in one year, five Raspadores for 250 acres, 20 for 1,000 acres.

But what strikes me more is that I noticed that on all the sugar plantations, all the cacao estates, everywhere on Crown lands, there is a large extent of useless land, when not first class. Well, the fibre plants grow nearly everywhere except on absolutely barren lands. And immediately every one can foresee what is the future of Trinidad when all lands, unless barren, will be cultivated with plants yielding double what cacao gives: 1,000 acres of land for sugar canes giving 1,500 tons of sugar, will require (if I do not make a mistake) £37,000 worth of machinery, at least; and 1,000 acres of land for fibre plants will require only 20 Raspadores costing £600, and will give yearly, at \$50 or £10 per acre, £10,000 sterling to repay cost of land and of contracts.

But no industry can be established with safety if it is not started with economy and perseverance or if any one is discouraged because purchasers do not come from abroad to buy the first pound before it is ready. I believe that this, and five or six years' gambling in the London Exchange, have stopped the first attempt made in Tobago and in the Bahamas some ten years ago. But the machines have been greatly improved during the last four years, the prices after fluctuating during the time of speculation between £13 and £75 have become steady at £50, and the plants, ten years old now, are everywhere giving sprouts from their roots, and seeds from their poles.

The Agricultural Society is being called upon to decide regarding the introduction of hard-working immigrants from Teneriffe. Can we find a better basis for settlement by free companies of these free people, in a free country? Profitable contracts could be offered to them on landing at the Quay at a rate of \$25 an acre, five after brushing, \$5 after planting, \$15 on delivery on fourth year. Each contractor would not receive more than 12 acres to be planted in three years—four acres a year. As there is very little trouble in cultivating the fibre plant when it is a year and a half old, every year each contractor could receive some four acres more. In five years he would have planted 20 acres and from the fourth to the ninth year he would receive \$500, whereas 12 acres in cacao, or 2,400 trees, would give him only \$480 in the same time.

Port-of Spain, 11th July 1901.

—*Journal of the Jamaica Agricultural Society.*

“NEGRO NILELAND AND UGANDA”

Form the subject of an instructive paper (with map) in the latest *Quarterly Review*, and the strong hope is expressed that, by the wealth of its products and the mart offered for trade, this land of the greatest lake and the greatest river in Africa will soon justify its being brought under the British sphere of influence. Reference is made to the recent discovery by the head of the Scientific Department of the Uganda Protectorate (Mr. Alex. Whyte, so well-known in Ceylon, and who has surely taken a new lease of life since he went to East Africa) of the “potto lemur,” and although “the plagues of Egypt,” indeed of the tropical world, seem to be concentrated in one part of the land, yet there are most glowing accounts of beauties and advantages as may be judged from the following extracts:—

The Uganda Protectorate is the crown of tropical Africa; it contains all the wealth, all the wonders, all the beauties which are elsewhere widely scattered or are found in incomplete assemblage. Here we have the mightiest of African rivers and the largest of African lakes, a Lake, moreover

whose shores—in its northern part, at any rate—exhibit many an earthly paradise. Here we have cat-racts like the Ripon and Murchison Falls, only surpassed in beauty by the Victoria Falls on the Zambezi, and in size by some of the Congo falls; a mountain-range—Ruvenzori—whose perpetual snows extend for twenty miles; an extinct volcano of extraordinary grandeur—Mount Egon; forests in Uganda, in Unyoro, and in Toro, which in tropical luxuriance rival those of the Amazons, woods of conifers (on the Mau Plateau), recalling the scenery, temperature, and aroma of the Black Forest. Over the western part of the Protectorate coffee grows wild. Indiarubber, incense, acacia gum, and most other vegetable products characteristic of Africa are found in abundance. The rivers—even the small mountain streams—and the lakes abound with fish of excellent quality. This land of Beulah, with a climate often delicious and scarcely anywhere disagreeable, would be an earthly paradise if it were not for the fever—malarial or hæmaturic—which is prevalent in most parts below an altitude of 6,000 feet. Fortunately, the greater part of the eastern third of the Protectorate actually lies above an average of 6,000 feet, ranging between that altitude and 10,000 feet on its plateaux, with here and there a peak ascending to still greater heights. A not inconsiderable proportion of the western area of the Uganda Protectorate also rises to plateaux fairly free from malarial fever. Whole districts of this description have been found so absolutely healthy by those Europeans who have resided there for any length of time that there is good reason to hope that we have discovered here a portion of Equatorial Africa which may be colonised by the European races; the more so because inter-tribal warfare and other causes have depopulated this temperate region to a considerable extent, leaving large tracts of it without a single human inhabitant.

All Negro Nileland, with the exception perhaps of the forests near the Congo watershed, is suited for the breeding of cattle, horses, goats and sheep. There is apparently no tsetse fly, and as yet no dreaded horsesickness has arisen to prevent the keeping and breeding of horses, mules and donkeys. Donkeys indeed are native to the land, the wild ass from which our domestic animal is derived being found in the eastern territories of the Uganda Protectorate and in the eastern parts of the Nile basin. Camels are likewise kept in the regions round Lake Rudolf and the south west of Abyssinia. It is in fact a stock rearing country of the very best. A steamer placed on the Victoria Nyanza could convey goods round two thousand miles of coast to the railway terminus on Kavirondo Bay, where, before many months are over, the British Government railway from the Indian Ocean will have attained its first objective in placing the Victoria Nyanza within thirty-six hours' journey from Mombassa and three weeks' from London.

Ivory is the present wealth of all this land—ivory in quantities unknown, unheard of, in any other part of Africa; and elephants are still living in such enormous herds as to stand in no danger of extinction from past excesses on the part of ivory-hunters, while it is now made a misdemeanour to shoot a female elephant, or a male elephant carrying tusks less than ten pounds in weight. In the marshy districts, which are uninhabitable by man and which are spotted all over Negro Nileland (as though on a map one had dropped a little wet sponge at intervals), the elephant will find pre-

serves where he will not be in rivalry with human cultivation, and yet will be within reach of the authorised sportsman and the *keddah* manager—for there is no reason why attempts should not be made after a time to drive the young wild elephants into domesticity, as is done in Siam, Ceylon, and India. Grain will be another staple of Negro Nileland—dhurra, maize, millet on the Nile flats and in the lowlands; wheat, barley, and oats, on the plateaux and on the mountains. Already wheat has penetrated southward from the Arab Nile and is cultivated on the highlands north of Lake Rudolf. Enormous quantities of other grains already familiar to African cultivation are produced in these lands. Bananas grow by millions in Uganda and Unyoro. In all the upland countries such as those of the Bahr-el-Gazal watershed, Uganda, and the mountainous region between Uganda and Lake Rudolf, the coffee shrub grows wild, and wild coffee is chewed by natives as an agreeable bitter. The lakes and river swarm with fish of excellent quality. Nor is salt wanting to season these food-stuffs; for within British territory there is a salt appanage of Lake Albert Edward, and there are salt deposits along the eastern shore of Lake Albert, and on the shores of Lake Rudolf. In many districts ground-nuts grow so abundantly that quantities of vegetable oil of fine quality are produced. In the forests of Mount Ruwenzori, and on the plateaux and mountains to the north of the Victoria Nyanza there are conifers growing which produce timber of the finest quality for building purposes. In the forests of Uganda and the Bahr-el-Ghazal watershed, indiarubber, dye woods, ebony, and building timber are abundant.

RUBBER IN UGANDA.

We are glad to see that Sir Harry Johnston is opposed to the granting of exclusive concessions of rubber forests in Uganda to individuals or associations, and advocates the plan of allowing the natives under proper supervision to gather the rubber and sell it to whom they will.—*Westminster Budget*, Aug. 2.

COFFEE PLANTATIONS IN THE CONGO

A Belgian correspondent, who has served in the agriculture and forestry department in the Congo Free State, writes to explain the means by which the Congo authorities have created the shadow rather than the reality of a great industry in coffee. In their haste to fill the country with extensive plantations they gave rewards for every area planted with more than a certain number of trees, the trees to be no less than 75 centimètres in height. The sum of money awarded was to be shared between the magistrate and the planters of the district. The result has been that trees have been planted everywhere and anywhere, in all kinds of soil and without any kind of care. Enormous numbers of trees have reached the requisite height for the reward, but either from subsequent neglect or conditions unfavourable to further development they have stopped short of fruitful maturity. Our correspondent alleges that the planting of cocoa has not been in any degree more careful, and that the whole policy of the Congo authorities towards cultivation is compounded of a foolish lavishness—as in the case of these rewards—and a very short-sighted economy.—*London Times*, Aug. 1.

PARA RUBBER FOR RATNAPURA.

LEASE OF 1,000 ACRES.

Mr. Margetson, a gentleman who arrived in the Island from South Africa about two months ago and has had extensive experience of Para Rubber cultivation in South Africa, and is confident of being able to grow it easily in Ceylon, has leased a thousand acres of land in the Ratnapura district for a period of forty-nine years, and means to plant it fully with Para Rubber. The land in question is known as "Nimitigala Nindagama," belongs to Idunalgoda Kumarihami, and is situated about twelve miles from the town of Ratnapura. Mr. Margetson means to import the best seeds from South Africa, and will proceed on the most approved lines.—Ceylon "Standard." [In view of the above announcement we quote as follows from our work, "All about Rubber and Gutta Percha":—

AFRICAN SOURCES OF SUPPLY.

At the Cape of Good Hope there are many species of Euphorbias which are said to yield a substance very similar to Cattimandoo, but hitherto I have only been able to see fragments, and thus have been precluded from making any experiments. Like the *Euphorbia officinalis* the juice is so acrid as to give intense pain and irritation to any part of the body with which it may come in contact, especially the eyes and nostrils. Dr J. Cormbie Brown, whilst holding the post of Government Botanist at the Cape, paid much attention to the subject, and favoured me with much correspondence upon it. Our united efforts bore no fruit. The substance has been well spoken of as an anti-fouling dressing for ship's bottoms. Mr Baxter, whilst on the Niger Expedition, collected a specimen of *Chrysophyllum* (Sapotaceæ) yielding a substance like gutta-percha, but no specimen seems to exist. Tropical Africa should indeed be rich in such substances, and doubtless such will prove to be the case when careful search and enquiry is made. With regard to the whole question of the Pseudo Guttas, Balata should most certainly receive attention, and efforts should be made by the Government to introduce it into Ceylon and elsewhere. Pauchontee, &c. should receive attention, and the possibility of the utilisation of the rest of the group not denied till further trial has been made.—*J. C.—Indiarubber and Guttapercha Journal*.—Ed. T.A.

COCONUTS IN THE WEST INDIES.

In Trinidad coconut trees thrive particularly well, and especially so in the district of Mayaro, where the finest coconuts, or coconut walk, has curiously planted itself from nuts originally cast ashore from a wrecked vessel. These trees bring forth a bunch of nuts every month, and the bunches average nine nuts each. Sixty good nuts go to a gallon of oil, and this gallon averages \$1 or 4s 2d. The yearly value of a coconut tree is therefore roughly set down at \$1, from which it will be seen that nine thousand six hundred coconut trees are sufficient of themselves to pay £2,000 interest, at eight per cent on £25,000. In Jamaica eight and nine inland-grown coconuts go to a quart of oil, coast nuts six to eight; thus, it seems as if a gallon of oil could be produced from half the quantity of nuts here than in Trinidad.—*From The Journal of the Jamaica Agricultural Society*, for July 1901.

TEA SEED OIL AND CAKE.

MR. MANN'S REPORT TO THE I.T.A.
Calcutta, Aug. 22.—Mr. Harold Mann, a chemical expert, has submitted to the Indian

Tea Association a report on tea seed oil and oil cake, which concludes as follows:—“While I think there would be a market for oil, if it could be obtained in quantity, and fairly cheaply, it must for the present be a local one, and the material could hardly compete with oils already in general commerce unless it be for the production of superior soaps. As a lamp oil it has distinct advantages, which should recommend it for local consumption. The pressed cake is useless for feeding, and forms an inferior manure, though one quite good enough to apply to land and also to cart for some distance provided the cost on the garden does not exceed 8 to 12 annas per maund. It would probably be useless as an insecticide, both as cake against certain caterpillars, and as a decoction which might replace that of wild fern now used in Dibrugarh against red spider.”—*Madras Mail*, Aug. 22.

TWO QUEENSLAND PLANTS (PESTS!) REFUSE TO APPLICANTS FOR INDIA.

The Agricultural Adviser in Queensland (Mr. P. M'Lean) has received two applications from India, which in view of the experiences in Queensland, appear peculiar. In one case some specimens of the water hyacinth are required for ornamental ponds near Madras, and the application points out that all precautions will be taken to prevent it spreading. In another case some seed of the weed, *sida ritusa*, are asked for. Mr. M'Lean has declined to be the medium for probably affecting India with such pests, (says the *Queenslander*). Those who saw the water hyacinth in the Brisbane River after the recent fresh, and who can realise what a pest it has become in the upper reaches of the stream, and those also who know the tenacious and prolific nature of the weed of which seed is asked, will commend Mr. M'Lean's decision.—*Metbourne Leader*, Aug. 3.

BOLIVIA AND AMERICA.

(Special to the “*India Rubber Journal*.”)

We are in receipt of information of such an astonishing character that were the source of information not so good, we would be compelled to hold it back for further investigation. We are assured, however, from indisputable evidence, that this great deal is in progress, if not already finished.

The abundant resources of Bolivia are not likely long to remain unexplored. By a recent agreement between the Brazilian and Bolivian Governments, an immense territory covering over 75,000 square miles in the northern province of Accra is now in the undisputed possession of the latter Government. The boundaries of the territory are these: On the N.E. the frontier line between Bolivia and Brazil; N.W., W., and S.W., the frontier line of Bolivia and Peru; S.E., the river Abuna, and a line from its fountain head to the junction of the Inambari and the Madre de Dios rivers. The area covers one of the richest rubber-producing countries of the world.

This concession has been acquired by one of the most powerful financial groups in America, who will practically stand possessed of all rights, with the Bolivian Government as partners. Custom-houses, stores, steamers, etc. will be established throughout the territory.

The possibilities of the territory are best illustrated by the fact that in January and February, 1899, with one Custom House, something like £80,000 was collected in duties, and at present the practically undeveloped territory is producing rubber to the extent of 2,000 tons a year.

Not only are the trees in this district very numerous, but it is common knowledge among the rubber gatherers that the yield given is immensely greater than on the Amazon. The rubber estates of Para knew this to their cost when the difficulty of obtaining labour began, for the gatherers would far sooner travel up and obtain the rubber with less than 50 per cent of the export.

And now, having given the facts which time will substantiate, it may be interesting to wander into the realms of conjecture and try to discover the leading motive in this agreement. Is this group of financiers, whose strength is absolutely beyond cavil, entering into this agreement for philanthropy, or to create free market in raw rubber for the benefit of the whole community of rubber manufacturers? Or is there any connection between them and the Rubber Trust of America?

It is impossible for us at the moment to substantiate the statement that the Rubber Trust is the controlling power in this group of financiers, but, like the Scotsman, we “hae oor doots,” and we fancy that our view will be shared by many who know something of the inside working of the organisation.

Sir Martin Conway, in his book which was published last week, “*The Bolivian Andes*,” has a chapter upon the rubber industry. It may be worth mentioning here that if we were told Sir Martin Conway had an interest in this enterprise, we should not feel greatly surprised, and should be rather glad of the fact that an Englishman had a finger in the pie.

This is what Sir Martin Conway says: “My position in Bolivia as a scientific explorer commended to the consideration of the Government, placed me in an exceptionally good position for obtaining information about the undeveloped resources of the country, and the attitude of the leading men towards foreigners and foreign enterprise. I soon learned that it was the desire of men of all political parties to attract foreign and particularly English and United States capital, in order to open up the great mineral and other wealth of the country, which local capital does not avail to exploit.” “Land or claims in old occupation, but now unworked or little worked, are liable to have doubtful titles, which, however, it is no one's interest to dispute till some wealthy individual or corporation buys them from the apparent owner and spends money on their development. But lands such as the rubber forests, to which I shall presently refer at length, which have never passed out of the public domain into private ownership at all till quite recently, and under the provisions of Acts of the Legislature, are now owned by an indefeasible title which no one attempts to dispute. “Up to the present time, however, none of the titles have been contested and it does not appear to be the interest of any individual to contest them; while the chief interest of the Government is to induce men of capital to work the forests, introduce immigrants, develop lines of communication, and so increase the general trade and prosperity of the country. It is not likely, therefore, that the Government will attempt to upset titles, even if they are not absolutely satisfactory, provided that the forests in question are properly worked. “It must be borne in mind that the area under discussion does not include the whole Rio Beni and the region of the plains about it, but only the upper part of that region and about the foothills of the Cordillera. The rubber that comes from the lower Beni is carried away to the eastward, and emerges into the light of commerce as Para rubber. It is only the forests of the lowest eastward Cordillera slopes and the plains immediately at their foot that are comprised in the Mollendo district. The rubber trees there are *Hevea*

Lutea, a large forest tree, approximately as big as an average English elm. These trees are self-planted. They grow in clumps, or estradas, of from 100 to 150 together, and these clumps rise well above the other forest trees, and can be seen from afar, so that the richness of any area can be judged by a general oversight from a commanding position.

"The cost of production, in Bolivian dollars, of 100 lb of Mollendo rubber in the Mapiri forest is as follows:

Paid to contractor, per 100 lb	73.00
Loss in weight, 10 per cent	7.30
Freight from the forest to Sorato Town	5.91
Commissions and road tolls60
Cost of administration	10.00
Sacking, packing, commission, and freight to Chililaya, on Lake Titicaca	2.20
Freight, insurance, and all incidental expenses to London	12.00
			110.10

"Or, reckoning the Bolivian dol. equal to 181, the cost of a pound of Mapiri rubber put down in London is 19 82d.

"From the books of two other forest owners in the same neighbourhood, I find a slightly higher cost, 20.16d per lb. The present price of this rubber in London is about 4s per lb.

"Coming now to a consideration of the possible supply of rubber to be drawn from the Mollendo forests, we enter a region of conjecture, for, of course, the trees have not been counted, not even the number of estradas. A part of one estate has been recently proven to contain 6,410 estradas (961,500 trees), when, according to the original estimate, the whole estate contained only 500,000 trees. Twenty million trees may be taken as the lowest probable limit of the number of trees, while they may not improbably turn out to reach 50,000,000, or even more. Now, in the season 1897-8, the amount of Mollendo rubber exported was 491,037 lb, which, at 3 lb per tree, represents the yield of only 163,695 trees, and the same number of days' labour at 3 lb per man per day. If one Indian is taken as working for three weeks, it represents the labour of only 7,795 Indians out of a population of 300,000 in the Department of La Paz. The possible increase of output is thus clearly enormous. How is it to be brought about?

Sir Martin's answer to this query is that the forest proprietors must make roads for themselves, for the Government is too poor yet; the rubber-producing provinces must be governed wisely and well, with scientific foresight. The query, we imagine, was half answered before it was asked.—*India-Rubber Trades' Journal*, July 22.

COFFEE IMPORTS AND EXPORTS.

We recently showed that, according to the Customs Accounts for 1900, about a million lb. of coffee approximately, was imported into, and exported from, Ceylon last year. But we learn from a Colombo merchant that a certain quantity of coffee from Southern India is brought over in "parchment," to be "cured" and re-exported home from Colombo, there being no import duty (as in the case of tea) to interfere with this trade coming to our port for the benefit of the men, women and children employed in local mills.

Now, what we want to point out to the Chamber of Commerce and Planters' Association is that no notice is taken of the coffee referred to as "re-exported" in the Customs Accounts. On the contrary, all the imports are put down as for "home (local) consumption," and all the exports as the

"produce of Ceylon"! But it is evident that, by whatever quantity came here from Southern India to be "cured," the figures for local consumption and production are wrong for 1900. This is a matter of some importance and should be looked into; for both the Chamber and Association publish the coffee exports as indicating the local crop. The fault may not be with the "Customs," but rather with the owners or agents of the coffee brought here to cure, in that they have failed to declare to the Customs that the same was not for local consumption, and again, in exporting, that it was not the produce of Ceylon.

PLANTING NOTES.

COFFEE.—Dr. David B. Reeder, of Chicago, condemns the habitual use of coffee as harmful, and his opinion is supported by the *Journal of the American Medical Association*. Coffee is said to produce serious nervous disorders, and is considered by some physicians to have a worse effect than alcohol. It is urged that Americans consume too much coffee.—*Rio News*.

CUSTOMS INSPECTION OF TEA.—We remarked yesterday that what Ceylon chiefly wanted was a "standard" below which no tea should be allowed to be exported; but the same standard could, of course, be applied to imports when Ceylon is made a "free port" in respect of tea, and then rapidly becomes the greatest Tea Port in Asia.

TEA COMPANY MEETINGS.—Two important Tea Company meetings were held in Colombo today, the Hapughalande Company (of which Messrs. Lewis Brown & Co. are agents) declaring a dividend of 5 per cent, and the Wanarajah Company (Messrs. Baker & Hall, agents,) paying 12 per cent for the half year or 17 per cent for the full period. This we consider a very splendid result indeed in these depressed times and reflecting the greatest credit upon Mr. Keith Rollo and the other members of the staff, as was duly recognised by the shareholders today.

COCONUT OIL.—It is curious how reports seem to get about, that are so utterly unfounded, that the people concerned are often the most astonished at the news. The Secretary of Central Trelawny Branch reports an interview with the manager of the Kokal Company at Rio Bueno (See Branch Notes.) It was curiously reported and mentioned at one of the meetings of the Board of Management of this Society that the Kokal Company were going to shut down; that they could not get nuts enough, or that they could not get them cheap enough, or make enough oil from them to make them pay. But Mr. Scott reports that the manager has said to him that anyone saying the Company was going to stop business is very far wrong, that they have contracts for two to three millions of nuts, that they do not buy less than one thousand at a time, (which shows that they can get plenty,) and that they pay thirty shillings per one thousand for nuts, and for husked nuts forty shillings per one thousand. We are glad that the enterprise is prospering.—*The Journal of the Jamaica Agricultural Society*, July 1901.

INSPECTION OF PEARL BANKS.

CAPTAIN J. DONNAN TO THE HON. THE COLONIAL SECRETARY,

Master Attendant's Office,

No. 62. Colombo, April 15, 1901.

SIR,—I have the honour to report on my recent inspection of the Pearl Banks, during which I examined the following banks:—

BANKS IN THE NEIGHBOURHOOD OF ARIPPU.

2. Cheval Paar, Modragam Paars North and South, Periya Paar, Periya Paar Karral, Outer Vankalai Paar, Kallatidel Paar, Jaggerboom Paar, and Kondatchi Paar.

BANKS IN THE NEIGHBOURHOOD OF KARAITIVU ISLAND AND DUTCH BAY.

3. Dutch Modragam Paar, Karaitivu Paar, Alantra Paar, Muttuvaratu Paar, Moodelicoolie Paar, Hamilton's Muttuvaratu Paar, and Steuart's Paar fished in 1832.

BANKS IN THE NEIGHBOURHOOD OF CHILAW.

4. Udupankare Paar, Muttubundi Paar, Jokenpidi Paar, Nagil Paar, Wanatty Paar, Karakupane Paar, and Chilaw Paar.

BANKS IN THE NEIGHBOURHOOD OF MARAWILA.

5. Marawila Paar South and Ooiowette Paar.

BANKS IN THE NEIGHBOURHOOD OF NEGOMBO.

6. Negombo Paar, Muttooparawatte Paar, Haly's Paar; and prospecting on a new spot where I found a fine rocky bank very suitable as regards position and depth of water for pearl oysters to settle upon, but unfortunately no oysters were found in it. This rocky bank is a new discovery.

7. I found pearl oysters on the Cheval Paar, Periya Paar, Periya Paar Karral, Outer Vankalai Paar, Modragam Paars North and South, Kondatchi Paar, Dutch Modragam Paar, Karaitivu Paar, Alantra Paar, and Muttuvaratu Paar. No oysters were found on the other banks.

CHEVAL PAAR.

8. On the west side of this bank three detached beds of pearl oysters were found, one on the south part, one on the centre part, and one on the north part. The bed on the south has an area of about 151 acres, estimated to average 23 oysters to a dive, and to contain about six millions of oysters; the bed on the centre part has an area of about 1,000 acres, estimated to average 30 oysters to a dive, and to contain about 54 millions of oysters; and the bed on the north part has an area of about 534 acres, estimated to average 21 oysters to a dive, and to contain about 20 millions of oysters.

(a) These three beds total up for the west side of the Cheval an area of about 1,685 acres, estimated to contain about 80 millions of oysters.

(b) On the east side of this bank two detached beds of pearl oysters were found, one on the south side and one on the north side. The one on the south side has an area of about 2,523 acres estimated to average 34 oysters to a dive, and to contain about 155 millions of oysters; and the bed on the north side as an area of about 636 acres, estimated to average 37 oysters to a dive, and to contain about 42 millions of oysters.

(c) These two beds total up for the east side of the Cheval an area of about 3,159 acres, estimated to contain about 197 millions of oysters.

The total for the whole Cheval Paar is an area of 4,844 acres, containing 277 millions of oysters.

(d) The area of oysters in March, 1900, was about 5200 acres, so that the present area is less by 16½ per

cent. No estimate was then made of the number of oysters on the bank, as they were too young to be estimated.

(e) The age of the oysters now on both sides of the Cheval are similar, 1½ to 2 years. The oysters on the east side are somewhat larger than those on the west side, and therefore look older. I have noticed however on previous occasions that oysters on the east side Cheval grow larger in size and more rapidly than those on the west. I have no doubt that the oysters now on both sides of the Cheval are the same oysters that were found on it in March, 1900. They were then all on the west side of the bank, only two small insignificant patches being on the east side. It therefore seems that many of the young oysters must have migrated from the west side to the east, or were probably drifted over by the effect of the last south-west monsoon, thus accounting for there being now fewer oysters on the west side, and so many more on the east side of the bank, than there were in March 1900.

PERIYA PAAR.

9. On this bank a bed of young oysters from 12 to 18 months old was found, having an area of about 557 acres, estimated to average 18 oysters to a dive, and to contain about 20 millions of oysters. In March, 1900, the area of the bed of oysters on his bank was about 2,000 acres, and therefore it is now diminished by 72 per cent., with a corresponding loss of oysters. There seems to be therefore very little hope of the oysters now on this bank being found on it next March.

PERIYA PAAR KARRAI.

10. On the south-west side of this bank a bed of oysters from one to two years old was found, having an area of about 248 acres, estimated to average 20 oysters to a dive, and to contain about seven millions of oysters. This bank has not been fished since the years 1835 to 1836. Oysters are very seldom found on it, but the present stock of oysters may possibly come to maturity.

OUTER VANKALI PAAR:

11. On this bank two detached beds of oysters from one to two years old were found. The beds lie close to each other and, combined, have an area of about 273 acres, estimated to average 26 oysters to a dive, and to contain about 12 millions of oysters. In March, 1900, this bank had a bed of young oysters in abundance from three to six months old, of an area of 564 acres. Now the two beds of oysters on it are only half that area, showing a loss of 50 per cent. in one year. This bank seems to be quite as unreliable as the Periya Paar.

NORTH AND SOUTH MODRAGAM PAARS.

12. On the north bank a very small patch of oysters about two years old was found; and on the south bank a small scattered patch of pinna shells with oysters of two years old attached to them were found. These two patches of oysters are quite insignificant.

KONDATCHI PAAR.

13. On this bank two detached beds of pearl oysters from 1½ to 2 years old were found, having a combined area of about 196 acres, estimated to average 39 oysters to a dive, and to contain about 12 millions of oysters. It is said that oysters on this bank are deficient in pearls, and therefore never become worth fishing, but I presume that character applied to the old Kondatchi Paar, which lies much nearer to the shore, and has less water on it than the present bank, which is not far from the east side of Cheval Paar, and I see no reason why the oysters on it should not become as valuable as on other banks, if they remain on it.

DUTCH MODRAGAM PAAR.

14. On this bank two small detached beds of pearl oysters from 1½ to 2 years old were found, having a combined area of about 51 acres, estimated to average 21 oysters to a dive, and to contain about 1¼ million of

oysters. The bed of oysters on this bank in March 1900, was about 386 acres in area covered with young oysters. Since that time the oysters have rapidly disappeared from the bank, and therefore there is little chance of any oysters being found on it a year hence.

KARAITIVU PAAR.

15. On this bank a fairly large bed of pearl oysters six to twelve months old was found, having an area of about 234 acres, estimated to average 40 oysters to the dive, and to contain about 30 millions of oysters. This bank has produced mature oysters before, some having been fished from it in December, 1889, and in April, 1890, and therefore there is no reason against a due proportion of the young oysters now on it coming to maturity.

ALANTURA PAAR.

16. On this bank a small bed of pearl oysters 12 to 18 months old was found, having an area of about 46 acres, estimated to average 33 oysters to a dive, and to contain about five millions of oysters. A very small bed of mature oysters was found on this bank in February, 1892, and therefore there is a likelihood of a due proportion of the oysters now on it coming to maturity.

MUTTUVARATU PAAR.

17. There is an extensive bed of pearl oysters on this bank from 1, 1½, to 2 years old, having an area of about 1889 acres, estimated to average 51 oysters to a dive on the northern portion of it, and 31 oysters to a dive on the southern portion, and to contain about 178 millions of oysters. The area of this bed of oysters in March 1900, was about 2,020 acres. The present configuration of the bed shows that a large area on the north-west side of the southern portion of the bank has been completely cleared of oysters since March, 1900, and this accounts for the present deficiency in area as compared with that of March, 1900. On the other hand, the oysters on the north part of this bank have spread a little more to the north-east than they were before.

(No. 18 appeared in last night's issue)

19. On several occasions during the inspection when at anchor on pearl banks the crew of the vessel caught some rock fish from about 5 to 15 lb. in weight. The stomachs of these fish were found to contain nothing but fragments of pearl oyster shells and other shells, some of which must have required considerable pressure to crush them, and on some occasions I saw from the deck of the vessel swarms of fish moving about near the bottom. I have no doubt that rock fish are chiefly responsible for the destruction of young pearl oyster beds, and I firmly believe that all that is necessary to preserve the oyster beds and to increase the number of pearl fisheries is to devise some practicable means of protecting young oysters up to the age of two years or more from the attacks of such fish.

20. There is no lack of pearl oyster spat in the neighbourhood of our Northern Pearl Banks, as young oysters have been frequently found on some of the banks, but none left when the same bank has been examined the following year. Such disappearance has generally been attributed to migration of the oysters, but I am however convinced that the chief cause of it rests with the rock fish.

No. 21. (Appeared in last night's issue.)

22. I annex for facility of reference a tabulated statement of the pearl banks on which beds of oysters have been found, and of their area and estimated number of oysters, also an explanatory note of how the estimates have been framed.—I am, &c.,

J. DONNAN, Inspector of Pearl Banks.

Tabulated Statement referred to, showing the Name of the Banks on which Pearl Oysters were found during the Inspection of March, 1901, the Area of

the beds of Oysters, and the number of Oysters estimated to be on them.

Name of Bank.	Area of Bed of Oysters in Acres.	Total estimated Numbers of Oysters on the Bank.	Age of the Oysters.	Remarks as to future Prospects.
Cheval Paar	4,844	277,000,000	1½ to 2 yrs	Prospects of fishery good
Periya Paar	557	20,000,000	12 to 18 ms	Bank unreliable
Periya Paar Karrai	248	7,000,000	1 to 2 yrs	Oysters likely to mature
Outer Vankalai Paar	273	12,000,000	1 to 2 yrs	Bank unreliable
Kondatchi Paar	196	12,000,000	1½ to 2 yrs	Bank has not produced a previous fishery
Dutch Modiragam Paar	51	1,750,000	1½ to 2 yrs	Bank unreliable
Karaitivu Paar	234	30,000,000	6 to 12 ms	Oysters likely to mature
Alantura Paar	46	5,000,000	12 to 18 ms	Oysters likely to mature
Muttuvaratu Paar	1,889	178,000,000	1, 1½ to 2 yrs	Prospects of fishery good

Total 8,338 542,750,000

NOTE EXPLANATORY OF HOW THE ESTIMATE IS FRAMED.

The inspection vessel is anchored on the centre of the bank, and from it three buoys are laid out north east, south and west at ¼ mile, ½ mile and ¾ mile from the vessel, by a steam launch towing a patent log to give the distances. Four inspecting boats with crew and divers and coxwain in charge range themselves between the vessel and the quarter-mile buoy on north side, at equal distances apart, the outer or fourth boat being close to the buoy. They start on a circuit round by east keeping their respective places until they return to the starting point. The coxwains are supplied with diagrams of the three circular lines they have to make.* They mark on these lines the position of each dive that is made, and note down the nature of the dive, whether on sandy bottom, rocky bottom or oysters, each of these having a separate distinguishing mark, and at each dive on oysters the number of oysters obtainable to a dive and the number of square yards of bottom surface required to give that number of oysters are also noted. These particulars the coxwains obtain from the divers. When the first set of rounds has been made the boats range themselves between the quarter and half mile buoys and complete the second round in a similar to the first; and then a third similar round is made between the half mile and three-quarter mile buoys, so that when the third round is finished twelve equidistant circular lines have been dived upon over a circular space of 1½ mile in diameter, which is considered a fairly good day's work for the boats and divers.

When the boats come in I transfer the dives marked on each coxwain's diagram to mine, which has a circular line for all the tracks of each boat, and when that is done all the dives that have been made on

oysters, which have a special mark, show up most plainly. Then by running a pencil line round the outer edge of the dives on oysters the configuration of the whole bed of oysters is made clear, and as the circular lines are drawn to scale the area of the bed of oysters is easily calculated. Of course the area obtained in this way is only approximate, but it is sufficiently so for the purpose required.

Then as regards estimating the number of oysters on the bed. The percentage of blank dives, that is, dives without oysters, to dives on oysters, within the lines defining the bed of oysters, is ascertained, and a corresponding percentage of the whole area of the bed is deducted from the area, and the remainder represents the area for oysters; which area divided by the area to an average dive given by the divers produces the number of dives required to clear the whole bed of oysters; and that number of dives multiplied by the average number of oysters to a dive for the whole bed, as also given by the divers, gives the total number of oysters on the whole bed. Of course the accuracy of such an estimate depends upon the accuracy of the estimates given by the divers of the number of oysters obtainable to a dive and of the space cleared by a dive. Hitherto, however, my estimates framed in this manner have been less than the actual number of oysters taken up at a fishery.

J. DONNAN, Inspector of Pearl Banks.

THE BAMBOO AND ITS USES.

Small coppices of bamboo form one of the most striking features of the farm, or estate—as fruit orchard in Natal—to use the more common coast designation. The bamboo serves many purposes. Primarily, as a shelter to the fruit crops from wind, it is of great value. Then it has very material and direct uses, and on this account Mr James urges general cultivation throughout the colony. On the coast, the growth, of course, is more luxuriant than can be expected in the upper and colder parts of the colony, but, as there are immense varieties—many excellent kinds growing in parts of Japan and China, where the winters are of intense severity—he believes that ever for the coldest parts of South Africa suitable varieties might be found. When he first planted a few clumps, some twenty years ago, he did so with two objects in view: first, to give shelter; and, secondly, for selling to Indians as poles for their house construction. A ready sale for the poles is found from 3d to 1s each. The top height of his bamboos is about seventy feet, but there are kinds which reach in India 120 feet, the diameter at the base being one foot, and from sections of this thick part the Indians make barrels for oil.

The bamboo fruit box often seen in Durban, and sometimes in Maritzburg and beyond, was, so to say, invented by Mr James. He now has imitators, and he would be glad to see more. The boxes are of great strength, and, for permitting the free circulation of air among the fruit, they are perfect. The only sawn wood required is for the ends. The ends for the small boxes—weighing, with contents about one hundred pounds—are solid, while for larger boxes the ends are square frames, and are filled in with small bamboo slats. These boxes can be made of any size, and, as they cost less than half what boxes cost made of ceiling boards, they would serve admirably for sending certain kinds of farm or garden produce from a distance to market. The manufacture is simple, and, moreover, it is easily learnt by Indians,

or by intelligent natives. The poles, which are taken from plants at least ten years old, are first allowed to dry. They are sawn to the required length, rather a small-tooth hand-saw being used. The lengths are then split; a bamboo of four-inch girth gives about five slats. For this work, the man I saw at work was using a plough coulter, which had had the upper end shaped into a handle by the village blacksmith. The trimming follows. This was done by an Indian, squatting on his haunches. His tools were a side axe and a bush knife. The latter was the implement most used, and the rate at which he trimmed the length was astonishing. The nailing of the boxes together was done with a sort of automatic ease and regularity. Mr James has always in training several of the hands, so as to avoid ever being in a fix for want of capable workers. Here are the prices:—

	s. d.
The sawn timber ends	.. 0 6
Hoop iron 0 1
Wire nails 0 1½
Labour and bamboo..	.. 0 6½

Total 1 3

Such is the cost of a bamboo box two feet two inch by one foot six inch, and nine-inch deep, which, filled with citrus fruit, weighs almost exactly one hundred pounds. The increase of cost is comparatively small, owing to the fact that the timber required for the ends is not solid, but, as explained, is made into a square frame. Mr James is convinced that a factory for the making of these boxes and other articles from bamboo would do a profitable business. The difficulty lies in the want of bamboo. It is not commonly enough grown to justify the manufacture being undertaken as an independent business. Ten years would have to go by before purposely-planted bamboos on a large scale would be fit for manufacture.

The bamboo is impressed into many more services by Mr James. The walls and doors of his sheds and stable are bamboo, the ladders for gathering fruit are bamboo, the water troughs for the poultry are bamboo, and even the handles for hammers and the kitchen Kaffir's axe are of bamboo. Most Colonists know how soon the handle of the last-named implement comes to grief, and when they learn that a bamboo handle successfully resists the bad treatment it gets from average kitchen boys, they will realise how tough must be the fibre of the bamboo. In some parts of the shed walls I noticed the "borer" was busy, while other sections were untouched. Mr James is of opinion that, if bamboo is cut at a certain time of the year, the "borer" makes no entrance, but that that time is he has not yet concerned himself to determine.

"Some people," said Mr James, "find the propagation of the bamboo difficult. I cannot say I have found any difficulty. It should be planted as sugar-cane, the holes being a little deeper, and about thirty feet apart. The lengths planted should be about four feet or five feet, and great care should be taken not to injure the shoots. In damp rich soil they grow big and strong, and on dry poor soil, thinner and harder. Very poor, dry soil gives the best whip sticks?—*Natal Mercury*, July 13.

NILGIRIS AND BURLIYAR
GARDENS:

ECONOMIC AND OTHER NOTES:
TAPIOCA—PLANTAIN FIBRE—CAMPHOR PLANT
—RUBBER—CINCHONA.

(From Mr. Proudlock's Administration
Report.)

In July 1900, cuttings and plants of four varieties of the Tapioca plant, which is largely grown in Travancore, were obtained by exchange from Mr M Labouchardiere of Trivandrum. One variety has not been established, but the remaining three varieties are now doing well at Burliyar. Mr Labouchardiere very kindly sent samples of the prepared Tapioca, together with an interesting note on the methods employed in Travancore in cultivating the plant and in preparing the flour from the tuberos roots,

Thirty-six plants of *Musa textilis*, Née, the species of plantain which is so largely grown in the Philippines for the production of the valuable fibre known in commerce as "Manilla hemp," were presented by Charles Gray, Esq., of Coonoor. They are growing vigorously at Burliyar, and also fairly well in Sim's Park, Coonoor. From the accounts of "Manilla hemp" given in the Kew Bulletin, Additional series II., I.—Vegetable fibres, and also in Volume IX. Part I, new series, in 1891, pages 57—62, of the journal of the Agri-Horticultural Society of India, the Curator had several of the two patterns of fibre-cleaners made, that are in general use by the natives of the Philippine Islands for cleaning Manilla hemp. The essential parts of these fibre-cleaners can be made at a cost not exceeding R3. The fibre can also be extracted by scraping the $1\frac{3}{4}$ "—wide strips, with a blunt knife or piece of bamboo, on a hard, smooth board or plank, with some arrangement for a dribbling supply of water to fall on the fibre while it is being cleaned.

It may be appropriately mentioned here that one of these fibre-cleaners was supplied, gratis, in July 1900, to the Superintendent of Coimbatore Jail, at the request of Lieutenant-Colonel O'Hara, I. M. S., Inspector-General of Prisons, who had one of the Coimbatore Jail wardens sent to Ootacamund to be shown the method of extracting fibre by means of one of these simple machines. It is understood that the Inspector-General of Prisons has directed experiments in cleaning plantain-fibre to be carried out in his department.

It, however, requires a considerable amount of practice before a man becomes expert at the work of cleaning plantain-fibre with one of these simple machines. Besides this, it is well understood that the conservative traditions, suspicions and prejudices of the people are by no means easy to overcome when any attempt is made to introduce among them (although it may be intended for their ultimate benefit) the knowledge of any useful art from another part of the world

Demonstrations in cleaning both the *Musa textilis*, and the common plantain-fibre with these primitive, but very effective, machines were given to natives at Ootacamund, at Sim's Park, Coonoor, at Burliyar, and also at Kullyar, with a view to making them practically acquainted with the fibre, which they, one and all, confessed they were previously unaware of. Among them were persons from such places as Mettupalaiyam, Coimbatore, Palghat, Nilambar, Trichinopoly, Krishnagiri and Mysore province

When an ordinary plantain stem* has borne a

*The word "stem" is used here for the sake of simplicity. Botanically, the so-called stem of the plantain is not a stem at all, but is really composed of the broad laterally-curved leaf stalks compactly folded over each other to form a support (which serves the purposes of a stem) for the blades of the leaves.

bunch of fruit, it is cut down and usually thrown away by the owner or by his servant. Taking the aggregate of the plantain stems in this Presidency alone that are cut down annually and thrown away, the waste of fibre, which might be put to some use, must be enormous. If therefore, the ryots could be induced to clean and to make use of the fibre locally, perhaps an export trade in it, and also in Manilla hemp, might be created in course of time.

In the Dictionary of Economic Products of India, volume V, pages 296—307, will be found a great deal of valuable information regarding "Manilla hemp" and other plantain-fibres, and of the many, mostly unsuccessful, efforts that have already been made to establish an industry in them in India.

The best camphor plant among those that were planted on the 1st December 1899 was 7ft. 9in in height on the 22nd March 1901. The species (*Cinnamomum Couplera*, Nees and Eberm.) which furnishes the Formosan Camphor of commerce and which is now fetching very high prices, will grow in India at sea level e.g., the short avenue in the Royal Botanic Gardens, Sibpur, near Calcutta, as well as at high elevations in Southern India, e.g., the trees in the Botanic Gardens, Ootacamund, 7,400 feet elevation. It will, therefore, be seen that the tree will grow successfully under a very wide range of conditions as to temperature.

The Para rubber trees (*Hevea brasiliensis*, Mnell. Arg.) which were planted in November 1898, are growing rapidly. The tallest tree was measured on the 22nd March 1901; it was 18'-8" in height and had a girth of $7\frac{1}{2}$ inches at one foot above the ground. This species yields the most valuable kind of rubber hitherto discovered.

The Central American rubber trees (*Castilloa elastica* ?), which were planted in September 1898, are doing well. The tallest tree, measured on the 22nd March 1901, was found to be 12 feet in height, and the stem was 14 inches in circumference at one foot from the ground.

Of the plants of *Kickxia Africana* ? (one of the most valuable species of West African rubber trees) that were planted in December 1899, the best tree was found to be 3'-10" in height on the 22nd March 1901. This may be considered as very satisfactory growth.

The Ceara Rubber—*Manihot Glaziovii*, Muell. Arg. —Much attention was given to this species during the year at Kullyar, at Burliyar, and also at Nella-cotta and at Pandalur in the Wynaad. It may be mentioned here that the practical study of this rubber tree has been carried on by the Curator for several years now as opportunities occurred, but chiefly in the intervals between his official duties.

One of the main outcomes of these observations is that trees of the same age and size have been found to differ from one another remarkably in their yield of rubber. A large tree, girthing 3'-10" at four feet from the ground, was tapped at Pandalur in February 1901, and it yielded only about a tea-spoonful of latex. This tree was cut down and brought to Ootacamund as a specimen of a perfectly useless Ceara rubber-yielding tree. On the other hand, a few good rubber-yielding trees have been met with and noted at Kullyar, at Nella-cotta and at Pandalur. Cuttings of one of the best rubber-yielding trees at Kullyar were taken and planted in Burliyar in January 1900; and a few of the plants raised from them are now over 14 feet in height.

In February 1901 cuttings were taken from the best latex-yielding tree at Nella-cotta, and also from the best tree at Pandalur, and have been placed in one of the glass houses in the Ootacamund garden in order to get them to grow. Later on, it is intended to plant them out at Burliyar or elsewhere, with the object of testing them, and to propagate them if they are found to be as good rubber-yielders as the parent trees.

What has been accomplished by the Dutch in Java in connection with the selection, propagation and

improvement of cinchona trees, which now yield surprisingly high percentages of alkaloids, and also by the Vilmorins of Paris in connection with the production of new varieties of the sugar beet-root which yield high percentages of sugar, might also be done in connection with rubber trees with probably equally encouraging results in course of time.

It will be observed that only a small beginning has been made to discover the best rubber-yielding tree or trees in each of the plantations named, and to propagate them by cuttings. This should, however, also be done in the case of all plantations or groups of the trees in the district or even beyond it. The yield of latex by the progeny of the best trees, planted in order in one garden, would, in turn, have to be compared; and by working on the lines of tentative selection, propagation and cultivation of only the very best latex-yielding trees it is reasonable to hope that, in course of time, a variety of the tree yielding a really paying percentage of rubber may be evolved.

These principles will no doubt also apply to all other species of rubber-yielding trees.

51. For the sake of convenience it may here be mentioned that, in February 1901, the Curator tapped a tree of *Plumeria acutifolia*, Poiret, at Gadbrook, Nellacotta, Wynaad, and obtained a small cake of rubber from it. A report on the quality and value of this rubber will be obtained in due course.

CEYLON EXHIBITS IN THE BREMEN MUSEUM.

The *Weser Zeitung* has a full notice of the additions recently introduced into the Museum of the great trading centre, Bremen, from Ceylon. This journal writes: "The products from this pearl of the British Colonial possessions are almost all beautiful samples, well laid out; especially noteworthy are the tea, spices, cinnamon, pepper, vanilla, cardamoms and the products of the coconut; there is also a fine collection of specimens of graphite and mica. The trade of Ceylon with Germany, though small, is increasing. In shipping intercourse Germany stands second. In the year 1899 only 132 German ships entered the Colombo harbour with a tonnage of 336,530 tons; but with the duplicating of the East Asian Postal line and further extensions of freight lines to Hamburg the rate must have been greatly increased. Germany's export to Ceylon was in 1898 1.7 million rupees, in 1899 2 million rupees, while the imports from Ceylon rose in the same time from 3.8 million to 4.75 million. Tea occupies the first place among the exports of Ceylon... [Then follow figures to show how tea has taken the place of coffee... Tea production has increased so rapidly that just now over-production is feared, especially of the lower grades. Already many methods have been tried to bring down excessive production... the 10 p.c. limit, &c. Tea cultivation is carried on, increasingly, on scientific principles, with the assistance of English and other European chemists. Manures scientifically selected are largely imported into the island.

"But the cultivation of cacao, bark (cinchona) and cinnamon have all gone back, of the latter large quantities still go to Germany. If we include the chips used for the extract of oil, a larger quantity goes to Germany than even to England... The products of the coconut palm have greatly risen in importance for exports, i.e. coir fibre,

oil, poonac, copra, &c... In the year 1900 443,959 cwt. coconut oil were exported and 362,467 copra, the latter mostly to Russia. Poonac is largely sent to Germany where it is used as fodder.".....[Fibres and kitul fibre are then enlarged on]... Also precious stones and talc, from which latter lamp glasses, cylinders and shields are now made.

VENEZUELA PEARL FISHERIES.

The United States Consul at Maracaibo, in a recent report, says the principal pearl beds are at El Tirana, north-east, and Macanao, north-west, of Margarita. About 2,000 men find constant employment in this trade. The fishers use meal scoops which are dragged over the cyster beds, and when filled are brought to the surface, where the shells are opened and carefully examined. The pearls are very fine in quality, beautiful in lustre, and run from white to yellow; occasionally a black one, priceless in value, is brought to the surface. One white pearl of large size and good quality was recently sold in Margarita for £354. The value of pearls found near Margarita is estimated at about £180,000 per year. Most of these pearls go to the Paris market, which sellers claim to be best.—*Globe*, Aug. 9.

QUALITY OF CARDAMOMS.

Messrs. R C Cowley and J P Calford have made investigations into the quality of cardamoms and have aimed at the following results:—

	Malabar.	Mysore.	Mangalore.
Number of fruits in 10 gmes	80	55	45
Percentage proportion of pericarp	30	25	20
Percentage proportion of seed	70 { dark 57 } { light 13 }		80
Percentage of ash from dark seed	5	3.3	2.9
Percentage of ash from light seed	8.5 to 9	4.5	—
Percentage of ash from pericarp	13	7.1	7.6

They say that lime predominated in the pericarps of all varieties to such an extent that an admixture of twenty per cent of pericarp with seed would be readily distinguished by precipitation as oxalate from acetic acid solution of ash. Two-thirds the ash of Malabar pericarps is soluble in acetic acid, but of the seed ash less than one-half is soluble, and this portion is mainly potassium salts. Manganese and iron are present in all varieties, but in Mysore the proportion is very small. Cobalt was not found. It is suggested that the yield of volatile oil might be a useful test. (1) They conclude that an ash determination of the seed is *per se* of questionable value as an index of quality. (2) The mineral constituents are not constant. (3) The large proportion of lime in pericarps is characteristic of all varieties. (4) The ash percentage of light-coloured seed is always higher than that of dark because of the imperfect development of matter. The reference to lime is somewhat astonishing in the face of the general deficiency of this ingredient in South Indian soils.—*Planting Opinion*, August 24.

PRODUCE, PLANTING AND COMMERCIAL NOTES.

A paragraph has appeared in some of the papers here to the effect that Mr. Wilson, United States Secretary of Agriculture, has stated that the United States "will soon be able to produce all the tea she needs. Last year the department sent tea plants to every Gulf State for experimental purposes. At Summerville, South Carolina, the two tons grown there last year so satisfied the New York investors that they immediately formed a syndicate and bought 6,000 acres to devote to tea cultivation." Those tea experts who know the flavour of this home-grown tea are less sanguine than Mr. Wilson about the success of American tea—at any rate, this side of eight or ten years. No doubt if the duty on tea is maintained the American tea industry, thus protected, will some day assume proportion, but this is all the more reason why Indian and Ceylon planters should capture as much of the American market as they can, and endeavour to stick to and develop it as promptly as possible. It is well worth a strong effort.—*Home and Colonial Mail*, Aug. 9.

THE TEAPOT IN INDIA.

BY SIR EDWIN ARNOLD.

(*Daily Telegraph*, Aug. 3rd.)

In a recent speech upon the Assam labour question Lord Curzon made a suggestion which may prove to be the beginning of a new social era in India. Full of ideas as is the accomplished Viceroy, I am inclined to think that the most brilliant and fruitful of them all was set on foot when his Excellency asked why India could not be induced to drink her own tea. Why not, indeed? we may well inquire. It is known that she grows the best tea in the world, and Assam, indeed, is the original mother-country of the little bush which has become so famous and necessary. Yet, as a matter of fact, hardly an ounce of tea, black or green, is consumed by Indian natives; it is still as strange and foreign to them as it was to Mr Pepys when, on Sept. 28, 1660, he wrote in his diary: "I did send for a cup of tea, a China drink, of which I had never drank before." That was the beginning of the "cup that cheers" in England, and it was about the same time when the chairman of the East India Company, writing to Calcutta, added the famous postscript to his letter, "Tell our agent to buy and send hither six pounds of the best tay he can gette." And now what a business it is! India and Ceylon between them do an enormous trade, which has quite outpaced the tea-gardens of China, and could and will be greatly extended. Japan and the Celestial Empire are her principal rivals; but Japan drinks a great deal of her own and sends all the surplus to the United States, the world in general, which in this case really means Russia, America and England, being supplied, the first-named entirely from China and the others from the general market. Now it would be an excellent thing if India would take to the drinking of tea. That it may become

A UNIVERSAL AND POPULAR BEVERAGE

is proved by Japan, where, taken without milk or sugar, its use is constant and pervading. Many other nations have similar drinks. The South American takes his "maté"; the African his "pombé"; the Polynesian "kava," and so on. But the Hindoo has always been contented with

simpler water. I hardly know of any other potable among them except the liquid in which rice has been boiled, which they call "conjee," and sometimes, perhaps, milk and water, with a little spice in it. The Hindoo housewife does not make stews nor soups—fornbidden these things by her creed—and very rarely does she provide anything like a vegetable broth. Most of the household food, such as chupattis, grain, &c., is cooked on sheets of iron, the sancepan coming very little into the domestic cuisine. The Hindoo housewife knows nothing of cocoa or chocolate, and has never even tasted that coffee of which her Mohammedan sister partakes. But what an excellent thing it would be if Lord Curzon's idea should make her a tea-drinker! Taken as the Japanese take it, pure and simple, without cumbrous paraphernalia, tea-drinking would well suit the population. First of all it would, as in Japan and China, lead to the general habit of boiling all the drinking-water. That one custom would save lives by hundreds of thousands, for the peasants, once habituated, would take cold tea with them to the fields, and avoid for themselves and their children the terrible evils of the village tank. Next, tea, though only slightly nourishing, prevents waste of tissue, and helps food to assimilate; so that the trifle spent in a cheap but good leaf would be well repaid. Thirdly, it is a social cup, conducing to conversation and family peace, and would be a great boon to the patient, gentle womanfolk who have such few pleasures.

Of course, there must be no question of five o'clock fashions and elaborate tea equipages. A kettle, a teapot, and some cups should comprise all the machinery necessary. Milk and sugar are innovations introduced by the West; and spoons, plates, and cream-jugs are not in popular knowledge. Every morning the Hindoo household sends forth a mother, an aunt, or a sister to the village-well, where the chatty of copper, brass, or baked clay is filled to the brim, corked with a tuft of convolvulus or lemon-grass, and carried back to the hut for the day's consumption. The cooking stove is a hole in the ground with a few stones, the fuel charcoal or cow-dung cakes. Everything is primitive, and will remain so. Yet, if once Lord Curzon's good idea should strike root into the soil, I hardly know what boon could prove greater than tea-drinking established as

A HABIT AMONG THE HINDOOS.

Beside the countless lives saved by boiling the water, the homes made pleasant by the little social graces which cluster round the tea-pot, and the pride and comfort of a little luxury embellishing daily life, it would be a stupendous lift for the tea industry of the land. Accordingly the Viceroy's suggestion has been intelligently taken up. An official crusade for the propagation of the tea-kettle has actually been started. We learn from a high Indian authority: 'A tea distributing agency has been formed, and Messrs. Andrew Yule & Co., have undertaken the work of distribution for three years without remuneration except out-of-pocket expenses. The Tea Association has given, a grant of 40,000 rupees. The large agency houses headed by Messrs. Finlay, Messrs. Muir, Messrs. Yule, Messrs. MacNeill, Messrs. Octavius Steel and others, have agreed to contribute three-quarters of a million pounds of tea annually. With the present low prices, the native consumption is expected to reach 15,000,000 or 20,000,000 pounds. If this is achieved, nothing more is likely to be heard of over-

production. Special efforts will be made to cultivate a taste for tea-drinking among the native passengers on the railways, who exceed 160,000,000 annually. An average consumption of one ounce would give 10,000,000 pounds consumed in a year on the railways alone, without counting the consumption of the general population."

Mark how splendid is the outlook of all this! Talk of storms in a teacup; here is promise and potency of golden profits for the planters, enhanced revenue for the Government, and health and pleasure for a population of 250,000,000,

ALL ENSHRINED IN A TEA-CHEST

If the notion took root, Assam and Cachar might safely double their tea-gardens; the Indian potters might make a little fortune in each district by turning out such utensils as native taste would demand, and although sobriety is a virtue which few Hindoos have to learn, the use of tea is everywhere seen, and above all in Japan, to be the greatest friend of temperance and gentle manners. There is a whole gold-mine in the idea of supplying Indian railway travellers with hot and cold tea in place of the untempting and rather perilous water-jars now on offer at all stopping stations. Cold weak tea is probably the best and safest beverage for thirsty throats; and if Lord Curzon's suggestion led to nothing more than a growing habit of boiling drinking-water, it would be a result worth any efforts. Only too much must not be hoped for. The Hindoo is beyond all men cautious, conservative, and caste-ridden. The tea he uses would have to be specially grown, prepared, and guaranteed, and the Brahmans and higher classes must first be won to the teapot. Perhaps something classical might be found in the scrolls of Hindoo mythology which would sanctify and recommend the tea-leaf, as has happened in the case of the sweet basil. In front of almost every Hindoo door will be seen a square earthenware pot marked with rude figures in coloured chalk, and containing a dwarf shrub. This is the holy Tulsi—the plant consecrated to the protecting deity; and the Indian housewife would as soon forget to grind the day's grain in the little stone-mill as to pour the morning water over the Tulsi-plant on her doorstep. My good friend,

SIR MOUNTSTUART GRANT-DUFF,

who, like King Solomon, knows the Eastern flora from the cedar to the hyssop, could find, I am sure, something charming and authoritative about that plant which, indigenous in Assam, has borrowed its name of "Teha" from China, and is least of all known in the land where it grows best and most naturally. If, then, Lord Curzon can teach India to drink tea he would, in my judgment, deserve for ever to rank among her greatest benefactors, and it is a policy which I am sure all Englishwomen will appreciate and support.

TOBACCO AND COFFEE PLANTING IN DELI, SUMATRA.

From an old Ceylon planter.)

O. K. Sumatra Aug. 11.

For two years it has been a hard struggle; beef \$1 per lb. and heavy Dutch import duties on all goods. It has been all I can do to cover current expenditure. There is a cruel inequality in this world. Here am I slaving away on what might almost be called sweating wages, in

coffee; and about four hours' distance is a man, in tobacco, whose commission last year is stated to be 240,000 guilders. Don't mistake it: *Two hundred and forty thousand guilders* at 1s 8d = £20,000, twenty thousand golden sovereigns as one man's commission on profits for one year's working. This may be exaggerated; but not by very much, I believe. At any rate, though this be the highest perhaps ever won, £10,000, ten thousand pounds, is not an uncommon sum for a tobacco manager to pocket as his commission on a year's working.

I know very little of

TOBACCO;

and just now, my chief being in Europe, I am tied hand and foot. Next year I shall have more freedom and will try and move about and get some tobacco figures for you.

As for

CACAO,

with ideal soil and ideal climate, nobody will look at it here.

Last year Von Roll, managing Director of the premier coffee Company in this district, went home and I gave him a letter to you—but homeward his ship called on Sunday, and outward at night, so he had no chance of seeing you. To Baumann also I gave a letter. His steamer also called on a Sunday!

We are just now picking two crops here,

COFFEE AND CATERPILLARS.

We have the same pest that Selangor suffered from two or three years ago, but I am not nervous about it, as I think we have taken it in time. One estate was eaten to besoms before any one knew that caterpillars were in the district; but this gave the alarm, and no ragged bushes are to be seen.

'A NEW FODDER GRASS FOR INDIA.'

is the title of a paper filling the first number for 1901 of Dr. Watt's "Agricultural Ledger," dealing with "*Paspalum dilatatum*." Much of the information given refers to Australian reports and very little experience so far has been got in India. Knowing the great interest Mr. Nock of Hakgalla takes in "fodder grasses," we sent him the paper in the "Ledger" for his opinion and he has been good enough to write as follows:—

"I notice Dr. Watt states on page 3 that 'this grass is indigenous to Ceylon,' which, I think, is a mistake, as I never met with it wild and it is not mentioned under *Paspalum* in Trimen's 'Flora of Ceylon.' Baron Ferd. von Mueller (p. 1) gives 'Extra Tropical South America' as its native habitat. I am afraid I cannot say very much about it yet. I have it growing here, also in Nuwara Eliya and Badulla. In Nuwara Eliya in good soil it is growing very well and is particularly robust, but its habit is nothing like what is described in Dr. Watt's paper, the longest blades in Nuwara Eliya being not more than 12-14 inches, instead of 5 feet. Probably this is on account of the cold. It has, however, taken firm hold of the soil and bids fair to become a valuable addition to the few good fodder plants of the locality. A small bed of it at Hakgalla is looking very healthy and promises to do well, although it is too young (6

months old) to be sure about it. Another small bed in the Badulla gardens has made a very good start, but was only about 3 months old when I saw it last and it was then 9 inches high."

COCONUTS IN DEMAND.

Coconut cultivation has been rapidly extending in these parts through European and native enterprise during the last fifty years; but instead of the apprehension of over-production which, like a hobgoblin, now haunts the pillows and disturbs the slumbers of the Tea-planter, the local coconut planter is cheered by the bright prospect of steadily increasing prices for his produce for which the demand is in excess of the supply. Coconut timber, nuts, oil, copperah, fibre, in fact, the various produce of the palm, fetch very good prices. Coconuts are at present very dear and the demand for them will be greater when the railway begins to run.—*Cor. Jaffna, Catholic Guardian, Aug. 31.*

TOBACCO AND OTHER CULTIVATION IN NORTH-CENTRAL CEYLON—AND IN BORNEO.

Mr. W. D. Gibbon writes:—

"I note your footnote to my news from Borneo. 'God help the man' who tries to plant tobacco of the sort that Borneo and Sumatra supply, in the North-Central Province. You seem to forget the melancholy failure made by the Sumatra planters who certainly knew how to grow in Kurunegala the sort of leaf wanted; but whose undertaking was such a ghastly failure.

A JAPANESE TEA COMMISSIONER STARTING FOR FRANCE.

The late Paris Exposition of 1901 has unexpectedly had a good effect upon our tea trade. Since the close of the exposition, during which display our tea house opened there enjoyed universal favour, the Central Tea Guild in the Capital, by which corporation the above tea house was opened in the Exposition grounds, has received many orders either officially or privately from various establishments and individuals in France for the shipment of the Japanese leaves; our honorary Consul in Marseilles having likewise been asked by some French merchants for recommendation to a respectable Japanese establishment for the opening of transactions in the tea business. Such being the case, the Tea Guild will despatch Mr. Kisaburo Sano to France for the purpose of arranging contracts with the French establishments in connection with orders received and the gentleman is expected to set out on his mission on the 10th instant, taking with him a variety of samples consisting of 500 kilo. of leaves from the Kobe Seicha Kaisha, 300 kilo. from the Yokohama Seicha Kaisha, 100 kilo. each from the Chuo Kaigisho, the Formosa, Chasho Kokai, etc. It is said that, in case the contracts will be arranged between the French establishments and the commissioner above referred to our tea shall hereafter be shipped directly to France from various tea establishments both in Formosa and Japan proper.—*Japan Weekly Times, Aug. 10.*

TEA IN AUSTRALIA.

"THE STORY OF THE TEA TRADE" is the title of an attractively written and illustrated pamphlet issued by the well-known Indo-Ceylon Tea Firm, James Inglis & Co. of Sydney, the founder of which has done so much to popularise British-grown teas in the Australian Colonies. Charming pictures are given of both Indian and Ceylon tea plantations and of all the processes from the clearing of land to the shipping of tea boxes. The following page is worth reproducing:—

The Melbourne International Exhibition of 1880-81 was inaugurated with much pomp and ceremony in the Victorian capital. Mr. Inglis, under Sir Edward Buck, K.C.S.I., Chief Commissioner for the Indian Empire, was again put in charge of the Indian Court and Exhibits, as Executive Commissioner. Special attention was, of course, paid to the exploitation of the Indian Tea industry. A dear old colleague of the writer—the late A. M. Ferguson, C.M.G., proprietor of *The Ceylon Observer*, and Executive Commissioner for Ceylon—proved a willing and able co-worker with Mr. Inglis, in the effort to exclude impure and objectionable China Teas from the Australian market, and substitute therefor, the pure, strong, and flavoury growths of India and Ceylon. It was a "hard row to hoe." Vested interests were strong. The China traders and importers had long "ruled the roost," but the twin colonies in Her Majesty's Indian Empire, had a "good cock to fight," and they fought it for all it was worth. In the Press and on the platform, white-heated controversy raged. Mr. Inglis was in the thick of the fight. He wrote pamphlets; he lectured; he wrote to the Press, and in both the Indian and Ceylon Courts, beautifully furnished Tea kiosks or lounge rooms were fitted up, wherein Tea was dispensed; and so by "here a little and there a little," the undoubted merits of the Indo-British-grown Teas forced their acceptance far and wide, and the following table, kindly compiled for us by Mr. Dyer, of Alfred Harvey and Co., shows at a glance how the fortunes of the fight have gone. In 1880-1, the total recorded imports of Indian and Ceylon Teas to all Australia, were less than 100 lb. of either. Leaving the intermediate early years out of the record, a glance at this table will, we think, somewhat astonish you.

SHIPMENTS OF TEA TO AUSTRALIA SINCE 1888.

Year.	China,	Indian,	Ceylon.
1st May to 30th April.	lb.	lb.	lb.
1888-89 ..	24,118,451	2,880,596	846,104
1889-90 ..	21,050,332	3,600,000	1,533,440
1890-91 ..	15,378,142	4,716,827	2,814,713
1891-92 ..	13,875,993	5,139,523	3,541,618
1892-93 ..	14,898,258	3,845,328	5,694,729
1893-94 ..	13,986,445	6,514,356	7,650,000
1894-95 ..	10,463,585	8,000,000	4,452,214
1895-96 ..	11,262,500	11,102,506	6,818,503
1896-97 ..	6,756,656	12,862,701	6,267,000
1897-98 ..	4,593,000	6,596,728	13,337,604
1898-99 ..	5,737,063	6,248,811	15,899,389
1899-1900..	6,517,406	8,301,839	15,349,144

See the enormous shrinkage in China Teas. Even now Indian imports exceed those from China, and the Ceylon shipments about equal both combined.

☞ QUININE IN COREA.—Our Consul at Corea says that the importation of quinine, to which reference was made in the trade Report for 1898, continues to be an item of some importance in the import trade. During 1900 the quantity imported was 120 cases of 100 1-oz. bottles each, representing a value of about £8,000. The business is in the hands of a German firm.—*British and Colonial Druggist, Aug. 23.*

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop, August-September delivery 1901; booking necessary before the end of April; quantities of 100,000 and over at special low rates. Plants available all the year round. 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year."

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery, 1901, booking necessary before the end of March; large quantities on special terms; Plants in Wardian cases.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter, in sending an order for this seed, wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Kickxia Elastica.—(*Puntumia Elastica*).—Seeds and Plants, orders booked. (Lagos rubber.)

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Urceola Esculentia and U. Elastica.—Same as above. (Burma rubber.)

Parameria Glandulifera.—Orders booked for seeds for January-February delivery; also plants; immediate booking necessary. (A good rubber creeper of Malacca.)

Landolphia Kirkii.—Seeds in July-August, early booking necessary. Plants can be supplied all the year round. (A highly-recommended species.)

Chonemorpha Macrophylla.—Seeds and Plants; orders booked. (A very valuable rubber-yielding creeper.)

Memisops Globosa and Payena Leerii.—Seeds and plants in July-August, booking necessary before April.

Achras Sapota, Willughbeia Firma, W. Edulis and other Rubber and Gutta Percha yielding Trees and Creepers, Seeds and Plants.

Cinnamomum Zeylanicum (Cinnamon superior variety). New crop of seed in April to June, booking necessary before the end of February; also plants.

Coffea Arabica, Liberian Hybrid and Maragogipe Hybrid.—New crop March-April; immediate booking necessary.

Cinchona Ledgeriana.—Seeds now ready, also other varieties.

Seeds and Plants of Nutmeg, Clove, Sandalwood (white and red), Pepper, Cardamom, Vanilla, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products of Foreign countries for 1901-1902, now being prepared, and will be ready in a few months.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Price List of Seeds and Plants for CEYLON use, post free, on application.

Our new Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms &c., Timber Trees, Trees for Avenues, Hedges, Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palm, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Orchids, Bulbs, Dracænas, now being prepared, and will be ready shortly.

Special Arrangements made with British Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

To the Editor.

CACAO-GROWING IN THE SOUTH
PACIFIC ISLANDS.

22 CWT. CACAO PER ACRE IN SAMOA !

Apia, Samoa, May 21st, 1901.

SIR—In your issue of March 1st this year and on page, 615 is an article styled "Cacao: Pollination and 10 cwt. to the acre."

I regret to say that none of us in Samoa have sufficiently followed your valuable Journal to understand properly what the term "Pollination" means. We suppose it means that the pollen

from the male flowers is to be introduced into the female flowers by hand, in a manner somewhat similar to that employed in fertilising Vanilla. Would you be so kind as to explain the term to us? [Yes: to apply pollen to a stigma.—Ed. T.A.]

The culture of cacao has but begun in these islands and less than 500 acres are now planted. Within the next six months we look to get in an additional 200 acres and such arrangements are being made that we believe a very large area will be set out in 1902, probably over 1,000 acres for that year.

Next year about 150 acres will be in full bearing—that is lands cultivated by foreigners. It is also likely that an additional 100 acres of native cultivation may also be in good bearing as well. As we are cultivating cacao quite differently from the manner stated in "Pods" article, I have thought it might be of some interest to recount for you our experiences, and the results so far obtained.

Mr "Pod" speaks of cultivating trees so close that 300 may be set out on a single acre. And he fears that the Ceylon soil will not stand such a drain as 5 cwt. of cacao per acre per annum. And he calculates that 15,000 pods will produce about 5 cwt. of cacao—about 30 pods to the lb. In Samoa we are planting our trees spaced so that we get from 120 to 150 trees to the acre, and some people think this too close. Last year they averaged 6 lb per tree of cured merchantable cacao of the highest quality, and this year's first crop has already averaged close upon 6 lb per tree, so that, with the October crop yet to come, it is pretty safe to say we will get from 8 to 10 lb cacao per tree. Mr. "Pod" seems to be well satisfied with a yield of from 2½ to 3 cwt per acre, per annum, but thinks that pollination may double this yield. We are not resorting to this expedient here to get still more favourable results.

We have both the Criollo and the Forastero varieties, and their crosses, in all our fields and all thrive equally well. So far we have had no disease or pest to fight, and we hope we may escape such difficulties. Manuring is not thought of yet, but in time we may have to resort to it, though we see no present signs of so doing.

As this enterprise is of a comparatively recent date in Samoa—the life of the cacao tree in these islands is as yet undetermined; but with our trees spaced 18 feet apart, we think they should last reasonably well. When the seasons have been particularly dry, we have noticed that a good few pods turn black just before maturing. No

one here has been able to account for this. This year we have had showers quite constantly and the percentage of black pods is very low. Some have said that our trees were not able to mature so many pods as were being produced, and nature, in order to relieve the tree, destroyed in this way a part of the produce. Possibly in Ceylon the same phenomenon has been observed and most likely you can tell us its cause; maybe you can also name its cure. [Is it not evident that drought in Samoa is to blame?—Ed. T.A.]

I have seen very many trees this year with from 150 to 200 well-matured cacao pods on them for the April crop—and it is to be noted that the tree will keep right along, bearing slowly till October—when another sizable crop will be harvested, probably about one half as large as that produced in April.

On a tree just four years old, within a mile and a half of Apia, I have this April personally counted 270 fine well-matured cacao pods, and the cacao from this orchard, being cured, distinctly showed that 16 pods were sufficient to make a pound of merchantable cocoa.

We have here cacao trees but two years and five months old which are now full of young cacao pods, but it is my belief that, although many cacao trees will bear soon after they are three years old, a paying crop cannot be counted on until the fourth year.

As to the price we have had for our cocoa I may say that, though the buyers have found some fault with our methods of curing it, still what we have sent away has brought, in San Francisco, from 16 to 18 cts. per lb. and the bulk of it, which has gone to Hamburg, has realized of late 93/6 per cwt., with the promise of a better price as soon as we could deliver in quantities sufficiently large to induce the manufacturer to make up our variety of cacao by itself. Mixed with other cocoas it loses its identity.

We see no reason to apprehend that the price will fall—in fact all of our information leads us to believe we may even get more before long. We cultivate either variety indifferently. If one raises the Forastero cacao he gets larger pods, but not so many as if he attempted the Criollo. There is no difference in the cost of cultivation and little in the gathering and curing.

If we are raising from 8 to 11 cwt. here in Samoa per acre against your 2½ and 3 cwt. in Ceylon, the conditions here must be infinitely better than with you.

I may say that very many people believe we have here the most perfect cacao conditions in the whole world. Others say that "Mr Pod" is surely underestimating the usual yield in Ceylon. Will you, Mr Editor, kindly inform us which opinion is right? [Samoa has undoubtedly far richer soil than Ceylon.—Ed. T.A.]

The Cacao outlook has been such as to attract a great deal of notice here in Samoa, and nearly every storekeeper, and trader, is getting into it for all he is worth.

Previous to the discovery of our capacity for production, lands back from the sea—no matter how good—were almost unsaleable.

Four years ago, 3000 acres, almost adjoining Apia, were sold to the French Catholic Mission for \$2 per acre U. S. gold.

Similar land farther away was sold during the early part of this year for from \$2.50 to \$4 per acre. Just now this land could be easily resold at

from \$6 to \$20, and to my mind is still remarkably low. We have here to pay our labourers much more than you pay to your coolies, but we expect, I think, more work out of them.

Just now we are paying \$8 per month and feeding the people at a cost of \$4 more per man:—\$12 in all. You will please understand that we are up till now using English money, and that we reckon 4 shillings to the dollar, and therefore our dollars are about twice as expensive as those mostly in the East Indies. [Rupees in East Indies at 1s 4d each, and 10 rupees a month is high for a working coolie.—ED. T.A.]

Still with the high rate we are paying we expect to make profits up to, and in fact much past, 20 pounds sterling per acre, per annum, after our Cacao trees are past their fourth year.

All of our land is covered with dense forest which has to be cleared out, and this expense runs into about 8 or 10 pounds per acre, including seed and planting. Some retain part of the forest for shade and so get their land in cheaper. I am using both methods myself and cannot yet say which I prefer. All readers of your esteemed Journal who reside here will be glad if you will kindly comment upon these statements and if you will answer the few questions propounded.

The British Consul at Apia is well versed in the culture of Cacao as practised here—and he will cheerfully corroborate any of the above statements I have made.

H. J. MOORS.

Apia, July 6th 1901.—Somehow the above letter, dated away back in May, has remained here unsent. Since it was written we have got our April cacao cured and away before this. On the 4th inst. at the usual jollification held at the U S Consulate, Mr R H Carruthers of this place announced that his cacao for the earlier part of the year had turned out 17 cwt. to the acre. Now there is no more reliable man in the world that this gentleman, an accomplished British Barrister.

The October crop is yet to come and I make no sort of doubt but that Mr Carruthers will be able to harvest, at the very least 5 cwt. more per acre, thus making 22 cwt. for the year for each acre. The trees are seven years old, planted 15 feet apart at an elevation of 450 feet and just two miles from the sea shore. A little breadfruit shade has been left. No disease has so far attacked any trees here: a little trouble we have had with white ants, and with a sort of fungus. Borers also in rare cases attack the tree, but do not seem to be able to kill it.

The only difficulty so far as I can see is that we have at times a number of black pods, and we do not rightly know why they get so.

The bees probably assist at the pollination in some way.

Land seems every month to enhance upon older values. Shortly, I expect, when we begin handling easy cacao moneys, there will be a little excitement over our prospects.—Very truly yours,

H. J. MOORS.

THE AMERICAN TEA CAMPAIGN:
QUESTIONS FOR THE "THIRTY COMMITTEE"
AND MR. WM. MACKENZIE TO CONSIDER
AND ANSWER.

Honolulu, July 17.

DEAR SIR,—Mr. Mackenzie in his report to the "Thirty Committee" dated New York March 20th, 1901 writes:—"I did not go to

Chicago this time, because I met down here all the men I wished to see." What more proof can be required to show the absurdity of continuing the tea campaign in America on present lines, That the funds from the Tea Cess, spent in America, have been devoted to our Advertising Agent's chosen disciples, to the detriment of the unfortunate cess-payer, (who is anxious to see Ceylon tea throughout the length and breadth of the land, not merely confined to the few stores controlled by our Advertising Agent's chosen disciples), must be clear to those who have the privilege of reading our Advertising Agent's private reports. It is little wonder that nine-tenths of the tea merchants in the United States of America have a bitter feeling against the Ceylon Tea Planters in general, and take no interest in the sale of the teas they grow; and so long as our advertising funds are restricted to the chosen friends of our Advertising Agent they are not likely to change. No doubt our Advertising Agent will cry poverty, but then why does he continue to pay a third of the advertising? If funds are limited, and over applied for in the United States on the one-third basis, why not offer to pay a fourth, and so on from time to time, reducing the assistance as firms come forward.

Mr. Mackenzie has been working the tea campaign in America for about seven years; it would be very interesting to those who perforce have to contribute to the Cess fund to know how many cities in the United States and Canada Mr. Mackenzie has visited during the seven years? If, during the seven years, he has ever visited the Western States, or any cities in the West of Canada?—which I have been informed he has not. How many firms he has honored with a call, (I don't think that would be a difficult matter), and last but not the least important, how many months—during the seven years he has been our paid Advertising Agent for America—has he resided in that country?

R. V. WEBSTER.

A NEW SCHEME FOR REDUCING THE OUTPUT AND OVERPRODUCTION OF TEA:

AN INCREASED CESS TO BUY UP, AND ABANDON
50,000 ACRES OF TEA.

Central Province, Ceylon, August 26th, 1901.

SIR,—Four schemes have now been put before tea producers which the authors believed would save the large number of growers of low quality teas from ruin and make the more fortunate owners of estates which produce the better quality teas more certain of being able to continue to secure the handsome profits they have secured till lately. Two of these schemes (Mr A Cooke's, and Mr A Thomson's brought forward in London) are based on the regulation of the sale of the tea produced in India and Ceylon and do not depend on the reduction of the output. The regulation of the sale of tea would no doubt benefit producers; but considering the large over-production of last year and the heavy stocks of Indian and Ceylon Tea at the beginning of this year it seems to me that the reduction of the output is of far greater importance than the regulation of the sale. One

of the schemes for reducing the output, the Rutherford-Rosling, has fallen through. It would have done good if it could have been carried out; but it was impracticable. The other, Mr James Sinclairs would be a sure way of reducing the output, but it will probably come to nothing from the same course (want of unanimity) as the Rutherford-Rosling scheme, produced to some extent by the difficulty of finding work for the coolies during the month, the tea bushes are to be left unplucked and from a considerable minority of producers not being willing to adopt it because they think it unnecessary.

I venture to put forward a scheme, which, if brought into operation will reduce the output and can afterwards be made to regulate it. I propose that Government be asked to raise the Tea Cess to 2 or 2½ cents per lb. and to advance, if required, any reasonable amount on the security of the Tea Cess. The excess of the increased Tea Cess over the present Cess to form a Fund to be used by a Sub-Committee of the "Thirty Committee" to buy estates which may be in the market or offered at a low rate per acre, to the extent of 50,000 acres of tea in cultivation. These estates to be abandoned with the exception of a small part of each sufficient to give employment to a small gang of coolies to be kept to guard the buildings, machinery, furniture, &c. A large staff consisting of an experienced Inspector and Valuator, a number of itinerating superintendents and a native overseer (Conductor or Kanakapulle) on each estate will be required. If 50,000 acres of tea could be bought at once and 45,000 be left unplucked, there can be no doubt whatever that the price of tea would go up. It would not be desirable that the price should be forced up too much, that could be prevented by taking a larger part of some of the better of the purchased estates into plucking again and if deemed desirable some of the poorer estates could be totally abandoned and the moveables sold. The Cess would be levied from the producers, but consumers would actually pay it, by being obliged to pay higher prices for the teas put on the market.

This, Sir, is my scheme. It is a large, daring and elaborate one. There are, I am aware, many difficulties to be overcome, but I feel confident that if it can be brought into operation it will effect all that I claim for it.

B. C. C.

[There can be no harm in such a scheme as this being put on record and advanced for consideration but we fear it will be labelled "not feasible" for the present time at least.—ED. T.A.]

TEA IN THE UNITED STATES AND CANADA.

To the Editor of "The Home and Colonial Mail.")

SIR,—We have been much interested in the correspondence that has appeared in your journal on the subject of the development in the United States and Canada of a market for Indian teas, and more particularly with reference to the introduction of Indian green teas in this country, with a view to the displacement of Japan and China green teas, which form such a large part of the teas consumed in North America.

We, as brokers, handling chiefly Indian and Ceylon teas, have a personal interest in the development of this business, and it occurs to us that

we might add a few remarks to what has been already said, without presumption.

We believe that it is a possibility to capture the tea-drinking population of the United States for Indian and Ceylon tea.

We believe it is also possible to increase the per capital consumption of tea in the United States by, in some measure, increasing the relative consumption of tea as against coffee, which is now the great beverage of the people of the United States. These are objects which, we understand, are ardently desired to be obtained by the tea growers of India and Ceylon.

There is, therefore, the only question of how, and how best, to obtain these ends.

We doubt not that, if the planters give the matter serious consideration, and, we are informed, they have been seriously considering it, that they will be able to collect such information as will enable them to enter on a campaign along the right lines.

We believe that all will be agreed that the plan of operation must be advertising in some form or other, and we think that the most effective form can be arrived at by conferring with those who have had most experience, as we can quite conceive of a very large amount of money being expended judiciously in advertising without realising in any adequate or compensating degree the end desired.

Happily the Indian planters can have the benefit of the experience of those who may be said to have gone before them in the struggle.

The Ceylon Association has done some excellent work, and we would suppose that community of interests between Indian and Ceylon producers is such that the knowledge and experience gained by Mr. Mackenzie, the Ceylon Commissioner, would be gladly placed at the disposal of the Indian Association. Certainly we do not look on India and Ceylon so much as competitive, as of co-operative forces in the campaign.

We think the growth of Indian and Ceylon tea business in Canada, and the means that brought this about give an experience that the planters might well consider as a proper guide in their efforts to capture the United States, and to further extend their business in Canada by the development here of a market for green tea, for in Canada we consider the work practically done as regards black tea, the importation of China black being now comparatively trifling.

There can be no doubt whatever that the advertising persistently, extensively, and continuously of some private parties here of packet teas, and the sale resulting therefrom which compelled all dealers to follow (some less willingly than others, but all of necessity), and to stock and offer for sale Indian and Ceylon tea accounts for the very general use in Canada today of Indian and Ceylon, and the relatively small use of China, and we look for the displacement of Japan tea in this country in exactly the same way by the advertising of Ceylon and Indian green teas.

We might mention this fact (which is not questioned by any well informed person here) for the encouragement of your planters, that no consumer of Japan tea, who has once got accustomed to the use of Indian and Ceylon tea, ever goes back to drinking Japan, so all progress made and every advantage gained becomes permanent.

We think the present season presents an exceptional opportunity for the activities of your planters, as Japan teas are even higher in price than last year,

while Indian and Ceylon are on a very low level, so that the natural tendency of the curtailment of consumption of a high-priced article, and the natural increase of the consumption of a low-priced article, will have a tendency to assist the efforts of the Indian Association.—We are, yours respectfully,

J. L. WATT AND SCOTT.

Toronto, Canada, July 17.

—*H. and C. Mail*, August 23.

THE INDIAN TEA CESS.

August 26th.

DEAR SIR,—For many months the possibility that India would consent to a Cess has appeared almost hopeless, but in spite of the difficulties in the way, it was evident to me that Tea owners would take steps to protect their interests if sufficient endeavours were made to influence them. At the present moment the idea of a Cess on the same lines as that of Ceylon is openly discussed, and appears almost certain. I do not know how much my own endeavours have had any influence on public opinion, and at present the small Cess only is advocated, while I have persistently advocated a Cess of two pies per pound without receiving much support in "the Press."

A prominent Southern India planter advised me to draft a circular and have it printed in pamphlet form so that all the Associations could be appealed to directly. He offered R50 towards expenses, and I am arranging to carry out his advice. But I am strongly impressed with the idea that the way to get at India is through Ceylon. Ceylon men were the first to have a "Cess," and this is an Industrial departure which may have great results. Ceylon is almost certain to have a Green Tea Association before we have it in India. And if by any means Ceylon can be impressed with the necessity of a 2-pie Cess it will be passed and become a fact. Ceylon made a grand effort, and the Indian Tea owner will shortly follow in the same course. This would be within the reach of my poor comprehension if Ceylon had not passed through a crisis, and the only hope for better things seems to be that Ceylon will lead the way.

What has your Cess done for you? It has enabled you to keep pace with India, but it has not averted the crisis. Your markets are still too restricted, and do not absorb your yield at a fair price. I cannot understand why Tea owners will not face the situation and take measures to insure prosperity and expansion. I will put the matter before you in a nutshell:—3½ lakhs for foreign markets have failed to avert a crisis. Is it reasonable to hope that six lakhs will have any appreciable effect? Is there any reason to expect that 2½ lakhs more will enable our dearly beloved Associations to increase the demand even to the extent of our natural increase from extensions already growing into maturity? Are we to be left for ever with a mere permission to make tea and reap no benefit from it? The six lakhs of the Combined Cesses will enable most of us to continue making tea, but cannot possibly enable us to make more profit. I am ready to retire from the lists, if anyone can give even a glimmer of hope that the strain will be removed if India consents to a Cess "like that of Ceylon." Everyone admits that a very large sum of money is required, that tea supply must be regulated; that new markets must be fed; in fact everyone knows exactly what is wanted, but will not propose a

sufficient remedy. If we had to pay a Cess of two pies, it would be madness to speak of it to Tea owners. If we do actually have to pay that Cess it will mean that those who make a profit now will get Rs33 per thousand maunds of tea less profit. And those who lose will lose more to that extent. Certainly this state of affairs would end the discussion by the Parliamentary method of "Closure."

I do not, for one moment, advocate paying a Cess of two pies a pound. What I do advocate is imposing a tax which shall be paid by the buyers and consumers, and that the amount imposed on them shall be of sufficient magnitude to enable us to place good average tea on new markets, so that the increased demand shall keep pace with our certain increase in yield. It puts my scheme in a pleasanter light, rose-coloured if you will, but to my mind the dawnlight of a new era in tea. We will force the buyers for our present markets to pay enough money to open out new markets. If any of your Ceylon men will see it in this light let them say so, and let them try and influence others. My own dreams may be too bright because of the contrast with the black darkness of the past, but your men have clear heads and the above idea should settle the matter. If they decide that the Cess has to be paid by the grower, no one would be such an idiot as to advocate a continuance of it. But if you decide that it is paid by others, the only question remaining is how much is it advisable to take from them. I propose 2 pies per pound because this sum would make practically no difference to the Buyers and Consumers, and it would be sufficient to lighten our markets of seventeen million pounds of tea. Mr Rosling ought to back up the scheme, because it is the outcome of his reduction scheme. His proposal was jumped at by Indian growers, but Mr Rosling forgot to make provision for the "space" which would feel the want of the reduced Tea, and he forgot the new tea growing so gaily in the sun and rain, and the jolly little estimates for extensions which we have since then seen mentioned in Company reports. He forgot that, by shutting off steam, a train going up-hill will retire backwards until it comes to its natural level. Recent proposals for a small Cess are not much better: they simply put on the breaks and keep us where we are. Had Mr Rosling known that owners would promise to reduce he might have extended his scheme, I began where he left off, and with the certain and stupendous fact that Indian owners had promised to give 31 lakhs of rupees to control the market. They say that straws show which way the wind blows, but the above was no "straw"; it was the "set" of a strong current. If we can guide that current, our difficulties will vanish.

Let us examine the hidden meaning of "the Cess." Germany pays a bounty to its sugar producers, that is to say it pays a Cess on every pound of sugar exported; but it forces every soul in the country to pay its share in that Cess. Is Germany poorer by the amount paid as bonus? If not, then nothing has been paid by Germany. Have Ceylon owners paid their Cess? If not, who has paid it? Of course, new consumers of tea have paid it; had there been no new consumers, the growers would have been heavier losers than they are now; their only fault was that they did not go far enough. Your Cess is a 100 horse-power engine. You have so far used only one

horse-power and have failed to move your industry, I advocate the use of 10 horse-power by India and Ceylon combined. Will you forgive me for pointing out that your writers are more ready to advance objections to any scheme than to forward any ideas of their own.

Your recent Green Tea Syndicate scheme is a case in point, and the balance is on the side of objections. Mr Fraser shows that the scheme is practicable, but doubts whether money can be obtained. He says that the Cess should be doubled, and this is quite right, and if we want a Black Tea fund, the Cess must be quintupled.

Mr Ryan recommends you to be slim, wily, and up-to-date; India has been so "slim" that it refused to take money from the buyers and customers, and Ceylon was so "wily" that it restricted the amount taken to an insufficient sum. It is "economy" to refrain from spending money on Foreign Markets, but it is real political economy to get enough for the purpose out of the buyers and consumers; anyhow it is the best policy.

For the future I recommend that everyone who enters the discussion shall give his name. We know the names of the men who speak at Association meetings, and by giving names to the press we can form an informal Association. The weakness of newspaper discussion lies in the fact that the whole discussion is not placed before the readers. I collected all the "crisis" letters to the *Indian Gardening and Planting*, and made a book of them; it would cost about 400/ to 500/ to print all this as a pamphlet but the result would be great. I have seen all the "pros and cons" and I am convinced that the scheme I advocate is feasible. The "Pros" are so decided and sensible, and the "Cons" so weak and futile, that I have no doubt of success if the matter could be placed before Tea men in a condensed form. I interviewed a few heads of Tea firms in Calcutta and found that they had not had time to study the question in full, and it seemed to me that with time and opportunity I could convert them to favour the Cess.

We have absolute indications that the British Tea producer is willing to adopt measures for reform when he considers them sufficient. They know that a small Cess is not sufficient and that is the reason why they have not spoken of it sooner. They imagined that "reduction" was a *sufficient* measure and promptly promised to reduce 14 millions. It was the insufficiency of the measure that stopped your Ceylon growers from promising their proportionate amount. Now I have put before them measures which will be *sufficient*, and I have no doubt of success, because I do not judge by castles in the air, but by past *solid facts*, and by experience.

If Messrs. Rosling, Ryan, and Fraser, &c., &c., will place any other scheme which has even the look of being *sufficient*, they need not doubt of success. You take it for granted that opposition comes from men with their eyes open; try the method of discovering whether these men really *do* know all sides of the question to the same extent as you yourself know it.

The fate of the Private Tea Sales should show that growers are tired of being fed on chaff, and that they intend to get "wheat" somehow. I believe in your Ceylon men because they *have*

done things to secure unity and strength amongst Tea growers. I have that sure ground to stand on when I appeal to them to go further, and to go far enough.

A. COOKE.

PLANTING IN BRITISH NORTH BORNEO:

TOBACCO—CARDAMOMS—COTTON.

Kandy, Aug. 30.

DEAR SIR,—The following news I have today received from British North Borneo may be interesting to your readers:—"Our tobacco industry is holding its own. I should like to see some one try cardamom planting which is such a success in Ceylon.

"Enquiries are being made regarding land for cotton which grows here like a weed. Ceylon men might find a good opening here as cotton planters.

"The railway is nearly finished and we will soon have many Chinese settled between Jesselton and Beaufort."—Yours truly,

W. D. GIBBON,

Agent, British North Borneo Government.

[Ceylon men had better first see what land the Northern Railway is to make available in Ceylon, with cheap labour, for Cotton and Tobacco.—Ed. T.A.]

TOBACCO-GROWING IN NORTH BORNEO AND CEYLON.

Kandy, Sept. 5.

DEAR SIR,—Our correspondence regarding the merits of British North Borneo and Ceylon is of service to both countries. What I contend is that tobacco wrapper leaf is acknowledged to be a profitable cultivation in Sumatra and British North Borneo where they have undoubtedly now a suitable soil, rainfall and transport facilities.

I know nothing about rice or cotton cultivation either in Ceylon or British North Borneo, but I do know that tobacco wrapper leaf cultivation was a ghastly failure in Ceylon, though we had Sumatra experts and capitalists on the spot to watch its cultivation.—Yours truly,

W. D. G.

[Tobacco-growing by Europeans in the tropics is surely the most uncertain of pursuits—one year giving large fortunes and another yielding little or no profit. We were in Amsterdam in 1891 when Java and Sumatra Tobacco companies were so depressed that Dutch friends of our acquaintance were ready to sell out at a fraction of what they had paid in. Since then, there has been a great recovery, and Mr. Turing Mackenzie now reports "£10,000" or "£20,000" as a Sumatra Company's Manager's Commission in one year! In Ceylon even, we know of the grand return Mr. Vollar got from one Dumbara crop of tobacco (all used as "wrapper leaf") but such a handsome return was, we believe, never afterwards repeated. We do not, for a moment, deny the advantages of North Borneo as a tobacco-growing country; but seeing the risks attending the transfer of

men with limited capital to a new country, we have said that there should be room ere long in Ceylon for new ventures in cultivation, in connection with the public works now under construction.—*Ed. T.A.*]

PLANTING NOTES.

THE CONSUMPTION OF QUININE—in the United States, is rapidly increasing. For the year ended 30th June last, there was an increase of one million ounces in the consumption as compared with the previous year, and nearly three-fourths of the world's supply are now required for America. There is every prospect of a keen demand and good prices for bark and the febrifuge.

MR. COOKE'S TEA SCHEME.—Mr. Cooke deserves a better reward than we fear he is likely to obtain. His latest reply (see page 255) to an objector who has not grasped his full proposals is lucid and satisfactory, except that we are now told the reserved tea will be kept by the producers until wired for. Hitherto we understood the tea was to be ready on the spot to meet the demand, whenever created.

THE TEAPOT IN INDIA.—Fanciful in much of his imagination, perhaps, but practical in at least two or three suggestions he makes, is Sir Edwin Arnold in his useful contribution to the literature of tea expansion, which we quote on page 248 from the *Daily Telegraph* of Aug. 3. He points out carefully what an improving effect tea is likely to have on the native health, habit and character. It will obviate the dire drinking of unboiled water; it will be nourishing, and (but we query this) act as a digestive, and it will promote peace, socially! There are minor slips, e.g., in speaking of the agency houses of Messrs. Finlay and Messrs. Muir; but the article is well worth reading.

COFFEE-TEA.—A correspondent writes to the editor of the *Queensland Agricultural Journal*—As you invited experiences re coffee-tea in the *Queensland Agricultural Journal* of March last, I am very pleased to send you mine. I acquired it when on a selection, on the road to Emu Park from Rockhampton. Having then an experimental plot of about twenty coffee trees growing, and reading that tea made from coffee leaves dried was very highly esteemed in some coffee countries, I determined trying it for myself. First, I dried leaves in the sun, but the product was disagreeably tasted when tried. Finally, I dried some leaves in a camp-oven, slung so as to swing over a fire, keeping them constantly stirred until they were dry and fairly crisp. Tea made from them was much enjoyed by all who tasted it; and one who did was the editor of the *Rockhampton Bulletin* at that time, but dead now for years past. He greatly enjoyed it, and my wife and I liked it better than any tea we could purchase. I intend growing a few coffee-trees for the leaves only, where I am now, as I am sure, if it be only dried properly, we could dispense with tea, provided we had sufficient coffee leaves to make our own tea from. To dry it properly is everything. It must be done quickly, and done to a turn; it has an aroma and flavour that any lover of tea would enjoy.—*Planting Opinion*, Aug. 23.

THE WEST INDIAN BULLETIN—No. 11, VOL. II, last received, is an unusually interesting number, and includes a variety of useful papers, such as "The treatment of soils in Orchard cultivation in the tropics" by the Hon. F. Watts, F.I.C., F.C.S., Government Analytical and Agricultural Chemist to the Leeward Islands; the Marine Resources of the B. W. Indies, by Dr. Duerden, A.R.C.S.; the cultivation of Onions at Antigua by W. N. Sands, Curator of Botanic Station; Artificial Drying of Cacao by G. W. Smith; Zebu Cattle and Breeding for Beef in Trinidad by C. W. Meaden of the Government Farm; but, above all, an illustrated paper on "Rubber Planting in the West Indies" by J. H. Hart, F.L.S., Superintendent, R. B. Gardens, Trinidad, with the result in girth discussion. Mr. Hart quotes from our *T.A.*—Dr. Morris mentioned that the Mexican rubber, *Castilloa*, had answered admirably in Honduras as a shade for cacao. The largest tree in Trinidad is over 75 feet high with a girth of 6 feet at 3 feet from the ground; others planted in 1886 are 58 feet high and 60 inches in girth. One of these on being tapped gave 214 lb. of rubber fluids and 69, or 32 per cent of clean rubber. We must quote at length in our monthly periodical.

THE PROSPECTS OF COFFEE IN BRAZIL.—The accounts of the Dumont Company for the past year, says the *Brazilian Review*, conclusively prove two points—that, when properly managed, coffee estates can yet be made to yield handsome profits, and the advantage of efficient over the careless and unscientific methods that have generally prevailed. By strict attention to economy and the introduction of the most modern machinery the quality of the output of the Dumont has been so improved as to command an average price of 40s 2d per cwt, more than 12½ per cent. better than the average quotation for "Santos, good average" for the same period. However planters may grumble, the future of coffee is all right. If the present owners cannot work at a profit there will not be wanting others with more energy and more capital to put the industry into shape and make it pay once more. The future of coffee lies in co-operation and the introduction of more economical methods, the improvement of quality and more attention to grading. By the concentration of a dozen or so small plantations into one property, the present wasteful and inefficient administration must be economised and replaced by scientific treatment and every advantage taken of the hydraulic power so abundantly provided in many districts by Nature, by which the cost of handling and transport on the estate might be reduced at least to half. The slow and costly "terreiro" process will have to be given up and the coffee be dried mechanically, probably also by electricity. In fact coffee planting is yet in an almost primitive state. The creaking wooden-axled bullock cart is still the common means of conveyance, and drying as primitive as in the year 1. Something has been done in the way of pulping and hulling machinery, but as far as cultivation itself is concerned everything is primitive. At present plantations are going almost for the asking in some districts and offer a splendid opportunity to men of energy, imbued with modern notions of the superiority of machinery and science to brute force and rule of thumb, for lucrative investment of capital.

GREEN TEA SYNDICATE.—We direct attention to a letter from Mr. Drummond Deane (see page 203) with a good deal of interesting information in respect of Green Tea. In regard to the Syndicate, our correspondent should know that scarcity of capital, and the difficulty of reconciling contending mercantile interests stand in the way of its local formation, however desirable in theory it may appear to be.

SAILING THROUGH A SEA OF BANANAS.—Captain Farrant, of the London-owned steamer Aldborough, on his arrival at New Orleans told a remarkable incident of the passage. He thought he had lost his reckoning in Crooked Island Passage, and had steered into a banana plantation. The blue waters of the passage threw a shade of green over them ahead of the vessel, when the Aldborough, which was going at about nine knots speed, began to throw bunches of bananas from each bow. It was then seen that what appeared to be an emerald sea was a perfect sea of bananas surrounding the vessel. The crew tried to hook them with anything at hand, the coal-heavers bringing coal-baskets into requisition but with all their efforts none were captured. Captain Farrant could not account for the bananas in the sea until it was known that the Norwegian steamer "Uller" had been ashore and had jettisoned about two-thirds of her cargo of bananas before she could be floated.—*Perth Herald*, Aug. 23.

GLASGOW EXHIBITION, BLACKMAN EXPORT COMPANY, LTD.—The Blackman Company's Exhibit covering 700 sq. feet is an interesting one. Seventeen of their well-known Blackman Fans are shown in motion, the largest of which, 96 inches in diameter, is driven from the shafting overhead by means of a belt; others varying from 72" to 12" in diameter are driven direct by electric current, these Fans being combined with Electric Motors of the Company's own manufacture, especially designed for this class of work. Four of the Fans deliver air, warm or cold at pleasure, from the four sides of the upper part of a central column or Kiosk, which is a prominent feature of the Stand. On this Stand there is also a Model Drying Installation consisting of a drying compartment arranged in conjunction with a Blackman Electric Fan 24" in diameter and suitable Radiators for heating the air. The main advantages gained by the Blackman System of drying is that almost every class of material and produce is effectively and rapidly treated with the greatest economy both in cost of drying and in the space occupied by the drying chambers, whilst the quality of the material so dried is much superior to that baked or stewed in closed stoves. Twenty-four Blackman Electric Fans are used for ventilating the restaurants in different parts of the Exhibition. Messrs. McKillip and McKenzie have 14 of them, from 24" to 42" in diameter, in Restaurants Nos. 1, 2 and 3, where their cooling and ventilating effect is highly appreciated. Four others of similar sizes are used by Mr. Jenkins in Restaurant No. 5; two more in the Indian Theatre, and two in the Bermaline Model Bakery. An imposing addition to the Exhibit is a large assortment of Keith's patent Hydraulic Rams and Pumps, Heating Apparatus, and High Pressure Gas Lamps of great brilliancy, for which the Blackman Export Company, Ltd., of 70, Finsbury Pavement, London, E.C. are the Exporting Agents.

"DR. KOCH'S MODE OF TREATING MALARIA"—says a local medical authority—"should be given a trial. We have not yet learnt whence the organisms come, when the ground is turned up. This is not satisfactorily discovered. We hope to arrive at it soon."

VANILLA.—Although only a small supply offered at auction the demand was poor, and only part sold, at about 1s decline, as follows:—Seychelles: 7 to 8 inches, 15s to 18s; 3 to 7 inches, 11s to 15s 6d; and common splits, 3s 6d to 10s 6d per lb. Mauritius: good, 7½ to 8½ inches, 20s; 6½ to 7 inches, 18s 6d to 19s; 6 to 6½ inches, 15s to 17s 6d; and common splits, 10s to 15s 6d. Bourbon: fair, 5½ to 7 inches, 15s to 15s 6d. The export of vanilla from Mexico decreased considerably both in quantity and value during 1900, as the frosts and rains in the early part of the year and the want of the latter at the proper season spoilt the plants, and the crop was subsequently lost. The quantity exported was 60,921 lb, as against 133,675 lb in 1899, and the values were respectively 62,565l and 181,547l. Vanilla is now receiving the attention of many of the American agricultural companies whose properties are in the State of Vera Cruz, and it is quite probable that the exports during 1901 will, under normal conditions, be greater than in 1900—*Chemist and Druggist*, Ang. 24.

PLANTS AND ELECTRICITY.—M. Berthelot announces he has proved that the development of plants is affected by electricity. He has been carrying out the experiments at his country seat at Meudon, near Paris. A tower nearly 90 feet high is erected in the grounds, which M Berthelot has been using for experimenting on the influence of natural electricity in transferring to plants free nitrogen from the atmosphere, and also for studying the variations produced on plants by altitude. One of M Berthelot's experiments was directed to proving that a plant submitted to the influence of electric waves absorbs more nitrogen than another plant placed under the same conditions, but not influenced by electricity. M Berthelot considers he is justified in supposing that he has fully demonstrated that free nitrogen in the atmosphere plays an important part in the life of plants, on the ground that crops of vegetables are obtained in high altitudes without the use of artificial manure, owing to the greater tension of the electricity.—*Chemist and Druggist*, Aug. 10.

MR. R. V. WEBSTER'S LETTER FROM HONOLULU—on page 253—offers a wonderful comment on the speeches in favour of the Tea Commissioner at the recent meeting. To our evening contemporary, with whom Mr. Webster used to be a far greater favorite than Mr. Mackenzie, this contribution ought to prove perfectly delightful reading. The "Thirty Committee" will now see what one of their Agents thinks of the other's work. We verily believe Mr. Webster is perfectly right as to secret partial payments to certain favorites, *enraging 9-10ths of the American tea dealers against the very name of "Ceylon tea."* We said this would be the result of the secret policy, at the beginning, and have repeated our opinion at intervals ever since. Ceylon tea, in fact, would have been in a far better position in the United States, if not a single secret or partial payment had ever been made: a million of rupees have, probably, gone for worse than nothing.

THE HAPUGAHALANDE TEA COMPANY, LIMITED

REPORT OF THE DIRECTORS.

The seventh annual general meeting of the shareholders was held at the Company's Registered Office, 22 Baillie Street, Fort, Colombo, today at 11:30 a. m., there were present:—Messrs A Cantlay in the Chair, Keith Rollo, R Davidson, Wm. Taylor, Wm. Milne, (by Attorney R Davidson); Mrs Grace Stanton (by her Attorney A Cantlay), and Tudor Stanton for Agents and Secretaries.

The Secretaries read the notice convening the meeting as it appeared in the Government *Gazette* of 2nd August 1901 and then the minutes of general meeting of shareholders held on 18th August 1900 which were confirmed.

The report and accounts having been taken as read, the Chairman favourably moved the adoption of same. This was duly seconded and unanimously adopted. A dividend at the rate of 5 per cent for season 1900-1901 payable forthwith was then declared.

Mr A Cantlay was re-elected a Director and Mr John Guthrie appointed auditor for the current season on the usual fee.

With a vote of thanks to the Chairman the proceedings terminated. Appended is the report: **ACREAGE.**

	A. R. P.
Tea in full and partial bearing ...	385 0 0
Jungle, &c. ...	369 1 3
Total Acreage ...	754 1 3

Your Directors beg to submit their annual report and accounts for the twelve months ending 30th June, 1901.

The quantity of tea manufactured for the season (including estate and bought leaf, but exclusive of that manufactured for other estates) was 181,020 lb.

Estimating the unsold tea at a safe valuation, the nett amount realised for this product has been R49,050.27, equal to an average of R27.09 per lb.

After setting aside R3,293.58 for depreciation on buildings and machinery, the sum available for distribution (including R1,861.14 brought forward from last account) is R13,992.13. From this sum the Directors recommend payment of a dividend of 5 per cent absorbing R8,500, and leaving R5,492.13 to be carried forward.

In terms of the articles of association Mr Alex. Cantlay retires from the Board of Directors and is eligible for re-election.

The appointment of an Auditor for the current season will rest with the meeting.

THE WANARAJAH TEA COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

ACREAGE:	
Tea in bearing ..	1,028 acres
1896 12 ..	"
1898 20 ..	"
	Acres
Timber Trees	20
Forest	27
Grass not available	27
Total ..	1,134 acres

The Directors have the pleasure of presenting to the Shareholders the Report, Balance Sheet, and Profit and Loss account for the year ending 30th June, 1901.

The crop harvested amounted to 436,945 lb., against an estimate of 420,000 lb. The crop for 1900 was

lb. 447,255. This result may be considered satisfactory in view of the slightly finer plucking considered necessary to meet the altered conditions of the market.

Lb. 279,529 have been sold in London at an average of 51.55 cents, but it is not anticipated that the balance will realise so high a figure.

MANURE.—The estimate provided for 311 acres. The acreage completed was 333, at a cost of R13,187, or R39.66 per acre.

The amount at the credit of Profit and Loss account is ...	R107,820.00
Including the balance brought forward of ...	R 42,376.56

in which is incorporated a sum of R7,372.32, being the amount underestimated in last year's account for Tea in store or afloat. After payment of an Interim Dividend of 5 per cent there remains a sum of R86,975 available, which the Directors recommend to be applied as follows:—

To a final dividend of 12 per cent, making a total of 17 per cent. for the year	R45,360
To be carried forward	... R41,615
	<u>R86,975</u>

The estimated crop for the season 1901/1902 is 440,000 lb. of made Tea.

The Visiting Agent's reports can be seen by Shareholders at the Company's Offices.

Mr. J C Dunbar retires from the Board by rotation, but is eligible for re-election. The election of an Auditor for the ensuing year rests with the Shareholders.

By Order of the Board
PAKER & HALL,
Agents and Secretaries.

CLUNES ESTATES COMPANY OF CEYLON, LIMITED.

REPORT OF DIRECTORS, CLUNES DIVISION.

Superintendent :—R. O. DE SARAM, Esq.

Tea in bearing	340 Acres.
Tea in partial bearing	50 "
Forest	174 "
Total	564 Acres.

ERRCHT DIVISION.

Superintendent :—S. LAYARD, Esq.

Tea in bearing	361 Acres.
Tea in partial bearing	142 , "
Forest and Waste Land	244 , "

Total 747 Acres.

GRAND TOTAL ... 1,311 Acres.

The Directors now submit to the Shareholders Accounts and Balance Sheet of the Company for the year ending 30th June, 1901.

The amount of crop secured was very disappointing—i.e.: 392,880 lb. against an estimate of 468,000. The shortfall of 75,120 lb. being due partly to unfavourable weather and partly to the adoption of a fine system of plucking necessitated by the serious drop in prices in common teas experienced for the last eight months. The nett average price realized was 25.60—whilst the cost of production was 21.67 cents per lb. which included the cost of manuring 140 acres.

After providing the usual sums for Depreciation of Buildings and Machinery, the result of the year's working shews a nett profit of R3,203.78, equal to about 1 per cent on the paid up Capital of the Company. To this must be added the balance of R3,667.23 brought forward from last year, bringing the total at credit of Profit and Loss Account to R6,871.01.

The Directors recommend that a sum of R2,500 be transferred to the Extension Fund and that the balance of R4,371.01 be carried forward to next year's account.

It will be noticed that the loans have been further reduced during the past year—and that Government has acquired rather over 6 acres of land for Railway purposes.

The estimate for the season 1901-1902 is 453,000 lb of Tea against an expenditure on Working Account of R83,553.20.

The estimated expenditure on Capital Account is R5,600 for extension to Erracht Factory, not undertaken last year.

In terms of the Articles of Association Hon. Mr. W H Figg now retires from the Board but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

ST. HELIER'S TEA COMPANY.

The Ninth Annual Ordinary General Meeting of this Company was to have been held on the 7th ult. at the office of Messrs. Bois Bros. and Co., but did not take place on account of the want of a quorum. The following is the directors' report:—

ACREAGE.	
250 acres	in bearing
29 do	planted in 1896
34 do	do 1898
<hr/>	
313 acres	
114 do	Jungle, &c.

Total 427 acres

The Directors have now the pleasure to submit their Ninth Annual Report to the 30th June last.

The crop, which was originally estimated at 105,000 lb. of made tea to the 30th June, has turned out only 88,181 lb., realizing an average price of 33.03 cents per lb. as against 36.29 last year.

The cost of the tea in Colombo, exclusive of the sum of R885.61 expended on Capital Account, works out at 28.05 cents per lb., as against 24.65 cents per lb. last season.

The Visiting Agent's report, dated 4th August, 1901, can be seen by the Shareholders at the Company's office.

The Directors much regret having to record the death of Mr. W Sandys Thomas, who had been connected with the Company since its inception. Mr. H G Bois was appointed to the seat thereby rendered vacant, and retires in accordance with the Articles of Association, but, being eligible, offers for re-election.

Mr. Stanley Bois retires from the board by rotation, but, being eligible, also offers himself for re-election.

The Shareholders will have to elect an Auditor for the season for 1901-02.

KANAN DEVAN HILLS PRODUCE COMPANY, LIMITED,

REPORT OF THE DIRECTORS

for the year ending 30th November, 1900, to be submitted to the fourth annual ordinary general meeting of shareholders of the Kanan Devan Hill Produce Company, Limited, to be held in the registered office of the Company, 22, West Nile Street, Glasgow, on Monday, the 26th day of August, 1901, at two o'clock p.m.

The Directors have now to submit their report for the year ending 30th November, 1900. The crop gathered during the season from the tea estates amounted to 1,444,695 lb. and realized an average of

7.27d per lb. The coffee amounted to 1,400 cwts, and cinchona to 555,089 lb. The amount at credit of profit and loss account, after providing for commission on profits to tea estate Managers, Agents in Calcutta, and Secretaries, interest and discount on bills &c., and dividend on preference shares, is £10,037 7s 8d. Out of this the Directors propose to pay a dividend at the rate of 3½ per cent. on the ordinary shares, payable on 30th August, 1901. This will absorb £9,100, leaving a balance of £937 7s 8d to be carried forward to the following year. Considering the unprecedented crisis which has prevailed in the tea market during the past six months, the result is satisfactory. In Assam the properties are all in good order. In Travancore the progress in the important works in hand has not been so rapid as was anticipated. Communications have been much improved by the completion of the wire ropeway, which is now working satisfactorily. The cart road of 10 miles from Bodinayakanur to the foot of the hills, constructed by the Company's officers, has been inspected, approved, and taken over by Government, and it is believed that a Steam Tramway will be laid down on this road, and on to Annamayakanur, the station of the South Indian Railway where the Company's produce is despatched. The cart road from the top of the ropeway to the Company's headquarters at Munaar is now being metalled, and it is hoped this work will be finished by the end of the year, when permanent cart traffic will be established. Meantime, the one line tramway is working fairly well. Three new factories for the manufacture of the Company's tea were under construction during the year under review. These have been opened for manufacture during 1901 and are now fully equipped. Another factory is being erected, and three more are on order. Owing to want of accommodation and a defective water-course, full justice could not be done to the tea in 1900, but it is hoped, with the new factories mentioned above, a marked improvement in the quality will be effected during the year. Some of the 1901 invoices have been sold in the London market at a considerable improvement in price, and samples recently to hand show good valuations. An area of 2,763 acres new tea was added to the cultivation during the past year. The result of this planting was generally satisfactory, but the vacancies are being carefully supplied.

As the shareholders are aware, the Company's Concession in Travancore is considered one of the finest fields for cinchona in the East, and the Directors, finding the product to be profitable, are doing all they can to judiciously develop it. The cinchona tree yields the bark from which quinine, so much valued in medicine, is obtained. It has been arranged that 2½ millions cinchona seedlings, reared from specially selected seed, will be planted during 1901, and a similar quantity will be planted in 1902. These seedlings will be planted throughout the existing tea cultivation; and, as the growing and putting out of the plants will be practically the only expense incurred, the outlay will be small. The up-keep will cost little extra; and it is anticipated that a valuable crop of bark will thus be secured cheaply. With a view of obtaining the fullest information in regard to cinchona, the Directors recently sent one of their managers on a visit to the cinchona plantations of Java, and his report is both useful and encouraging. The Directors feel that, with its large holding in cinchona, the prospects of this Company are more assured than if they rested on tea and coffee alone. The greatest care will be taken to make the cinchona-planting a thorough success. The season in Assam, although a bad one generally, did not materially affect the Noakacharee Group of estates, the yield both in quantity and quality being fairly satisfactory, namely—898,123 lb against an estimate of 827,600 lb, while the average price realized was 7.88d per pound.

During the year under review the following extensions, arranged for shortly after the formation of the Company, have been made:—19 acres tea in Assam, 2,744 acres tea and sixty acres cinchona in Travancore,

The total area under cultivation at 30th November last was 16,086 acres, namely, 14,441 acres tea, 944 acres coffee, 701 acres cinchona. The estimated crops for the current year are 2,217,225 lb of tea, 942 cwt of coffee, and 248,500 lb of cinchona bark. As explained in the circular letter of 7th August, addressed to the shareholders, Mr P E Buchanan, the special adviser to and visitor for the Board proceeded to India by the mail of January last and he, along with the managing agents in Calcutta and Colombo, and the Company's visiting superintendents, has been able to effect considerable economies in working without impairing the efficient up-keep of the estates, which should help the results of 1901 and subsequent years. In the circular of 7th August, above referred to, and in the circular of 9th ultimo, the Directors gave information regarding the position of the tea industry and the prospects of the Company.

In terms of the articles of association one of the Directors, Sir Robert D Moncreiffe, Bart., retires at this time and is eligible for re-election.

The auditors, Messrs Alexander Sloan & Co., C. A., retire, and offer themselves for re-election.

POSITION OF TEA AND ADMINISTRATION OF TEA COMPANIES.

The *Financial Times* has published several letters of late on the position of tea from a shareholder's point of view. The main object most of the correspondents have in view is the necessity for accelerating the production of annual reports and bringing pressure to bear on directors, so that there shall be no keeping back of information.

Mr. George S-ton, writing to our contemporary on the position of tea and the administration of tea companies, says:—"It is now, I think, generally admitted that the chief cause of the present disastrous position of the tea industry is to be found in the undue additions to the planted area, which have been made during the past ten years or more. The earlier large extensions were made by new companies, which were formed avowedly with the object of planting out entirely new gardens. These were, of course, the original and chief sinners in the race of competition and over-production, but they had this excuse that, to all appearances, the Indian exchange was progressively falling, and there seemed every reason to believe that this favourable influence would continue. Since 1894 or 1895, however, the principal extensions have been made, as additions to their areas, in all the different districts by the older companies, which already possessed large productive properties, and they have been made with a full knowledge of impending unfavourable conditions—a high rupee and dropping prices for tea. It has been contended, however, by the administrations of these companies that this course was prudent, and was forced upon them by the necessity of providing against a known depreciation of their older gardens. Granted that this contention was right, it was to be expected that the entire cost of such improvements would be charged to revenue. But what do we find to be the case? Of all the leading companies only a few—notably the Assam, the Jorehaut, Bramapootra, Chubwa, and (in a measure) the Assam Frontier—followed this course, and their additions to area were of modest extent. Nearly all the other large companies carried the cost of these additions wholly, or in very large part, to block account. Some of them—wise in their generation—made fresh capital provision at a favourable time. Doom Dooma, owing to the exceptional soundness of its finance, could always raise fresh capital when required; Jhanzie issued capital at the top of the tea boom at almost Consol rate of interest; Jokai issued preference capital, and also accumulated a real invested reserve. But what of others whom we shall allude to alphabetically to avoid invidious distinction? The Dooars Company has more than out-

spent its entire reserve; the Empire Company has done the same, and now suspends preference dividends; the Imperial Company, the Lungla Company, the Makum, the Nedeem and Singlo Companies all developed their gardens on borrowed money, and either have had, or will have, to raise heavy prior charges, which practically cut off shareholders for a series of years from any hope of dividends. Possibly those responsible for these laches will point to English railway administrations, and say they have 'sinned in good company' but this like folly of our railway kings is now, I think, generally condemned both by the financial Press and by public opinion. Railway companies moreover had the excuse that these heavy betterments were forced on them by the public demand for increased facilities and by Government pressure. Tea men had no such excuse, and in any case two blacks do not make a white. The prevention of such errors of the past, with a due control of the policy to be followed in the future, is a work well suited for the Tea Shareholders' Association, the formation of which has been advocated so ably in your columns; this question, moreover, touches very closely on the matter of the appointment of auditors, so ably treated of by one of your correspondents only a few days since, as depreciation and additions to block are essentially an auditor's matter."—*Home and Colonial Mail*, Aug. 9.

THE NYASSALAND COFFEE COMPANY'S ESTATE.

SALE WITHDRAWN AFTER A BID OF £300.

The auction sale of the Nyassaland Coffee Company's estate was held on the 7th ult. but the highest bid was £200, and the estate was withdrawn. The plant on the estate was also withdrawn on account of the low figures offered.—*Central African Times*, July 13.

TEA GROWING IN LOUISIANA.—From the thirteenth annual report of the Agricultural Experiment Stations of the Louisiana State University and A and M College, for 1900, just received we learn:—

Tea Plants.—In co-operation with the United States Department of Agriculture, this Station is growing over six hundred tea plants, with a view of testing practically the raising and curing of tea leaves. The success of the industry in South Carolina has stimulated the Department of Agriculture to try it elsewhere in the South.

It will take some time yet before six hundred plants develop into plantations of thousands of acres required to enable America to do without foreign tea!

TEST FOR EXHAUSTED TEA.—Dr. Nestler in the *Journal de Pharmacie d'Alsace-Lorraine*, puts forward a test to determine whether tea leaf has been previously used or not. Professor Tichominow's test is said to be untrustworthy. This depends on the production of a greenish tint by unused tea after two days' standing in a solution of acetate of copper. Tea which has been twice infused, however, will sometimes give this colour. Dr. Nestler's test is as follows: A little of the tea is crushed between the fingers and placed on a watch-glass. This is covered with another watch-glass, and heated gently. On the upper glass there is soon an appearance of small drops, and after ten minutes' heating crystals of theine are visible to the naked eye. The identity of these crystals can be shown by hydrochloric acid and a solution of chloride of gold, which gives a more or less yellowish prisms of a silky, long, slender character.

PRODUCE PLANTING AND COMMERCIAL NOTES.

THE RUSSIAN EXPERIMENTS IN TEA GROWING,

like those in the Southern States of America, do not suffer for lack of advertisement. The news of the success of these experiments in both countries is noise abroad at intervals, and expectations are raised which, if fulfilled, may at some future date have an effect on the tea markets of the world; but this will not be just yet. Referring to the Russian experiments, the Vienna correspondent of *The Times* says (Aug. 21st):—"According to Austro-Hungarian official reports the efforts that are being made to introduce the cultivation of the tea plant in the eastern districts of the Trans-Caucasian territory are proving successful. The plantations in the neighbourhood of Batoum are flourishing and the two crops already gathered were very satisfactory. The series of experimental plantations established last year on the Caucasian coast of the Black Sea are to be greatly extended. Further plantations are to be started this year in Mingrelia and the Sukham district. Up to the present the plants have chiefly consisted of slips grown from Chinese seed. This year it is decided to try the species known as kangru, which has yielded excellent results on an estate at Tchakva belonging to the Imperial family."

OPPOSITION TO SECRET TEA AUCTIONS.

Active opposition to the secret tea auctions is shown wherever grocers congregate. The Metropolitan Grocers, Provision Dealers, and Oilmen's Association passed a resolution last week appealing to the Grocers' Federation to issue a circular on the subject, and the Bradford Grocers' Association made a formal protest also. The *Grocer* last week again publishes a list of marks of tea sold at the private sales. It also publishes a letter on the subject in which the writers say: "It is evident that an organised attempt is being made by the brokers, wholesalers, and big retailers to get the conditions of tea sales back to a level of the old times which were so good for the wholesale teaman. The retail grocer (what is left of him) has, however, had quite as keen a time as his friend above, and having been brought to the grindstone by Government-fed competition, combinations of every kind, 'presents' humbug, bonus delusions, pension weeds stamp trick, and war tax oppression, he is of necessity no longer the easy-going tradesman of those 'good old times,' but has perforce to keep himself posted with all the means at his command, and will accordingly kick against this attempt to put on the extinguisher and bid him shut his eyes, open his cheque-book, and take what 'plums' the 'secret' dealer has to send. Probably the country grocers have been waiting for the trade associations to give the ball a start, and, unless the Federation does vigorously take up the matter, it should put up the shutters." The *Grocer*, commenting on this, says: "We strongly sympathise with the writers of the above excellent letter, but have not much faith in the black-list idea. Most firms buy at the secret sales in order to pick up bargains thereat. The exposure should rather be of those who, to make the secret auctions a success, agreed to boycott the public sales and so damage the legitimate and proper method of conducting the wholesale tea business.—*H and C Mail*, Aug. 23.

ST. HELIER'S TEA COMPANY.—We publish on page 260 the annual report of the directors which shows a shortage in crop of 16,819 lb., as compared with the estimate, while the average price realised was only 33.03 cents per lb as against 36.29 in the previous year. The cost of the tea in Colombo had also been greater.

UGANDA AS A RUBBER-PRODUCING DISTRICT.

SIR H JOHNSTON'S REPORT.

About one-fifth of the area of the Uganda Protectorate is covered more or less densely with rubber-producing trees and vines, principally belonging to the Apocynaceae order (*Taberna montana*, *Landolphia*). There is said also to be a species of real gutta-percha tree, but of this I have no certain proof. The rubber derived from the above-mentioned sources is of very good quality, and the samples which we have submitted to examination on the east coast of Africa, and at Kew, though not quite properly prepared, have fetched from 2s to 3s per lb. A much larger consignment of various kinds of rubber is now on its way to England for examination. I regret that it should not have arrived in time for me to add to this report more definite particulars, but the matter must be treated of in a subsequent despatch, when Sir W Thiselton Dyer has examined the specimens. I can, however, speak confidently, both in regard to the extent of the country with rubber-producing trees and vines and to the average value of the rubber. When I first arrived in Uganda, I found the natives totally ignorant of the resources of their forests. They valued the rubber vines chiefly for their edible fruit, and the sap, if used at all in any local industries, was not known to have any commercial value. Mr Whyte, the director of the Scientific and Agricultural Department, assisted me to take the matter up, and the Uganda chiefs, once informed of the value of this industry, co-operated in sending young men to be instructed by Mr Whyte in the methods of procuring the rubber from the tree or vine without injury to the source of supply. We endeavoured to impress on the natives that they must "milk" the trees, but not kill them, and that the trees or vines, dealt with properly in this fashion, furnish a continual revenue. Prior to this course of instruction, an agreement was concluded with the native chiefs, which brought all the forests of the Uganda Protectorate directly under the Crown. It has become, therefore, illegal for anyone to gather rubber in those forests without permission. But in order to encourage the nascent industry, I informed all the chiefs that until further notice, we would permit their people, without restriction, to obtain rubber from the Government forests on the understanding that they only did so after the manner prescribed by the Scientific Department. They would then be permitted to sell the rubber thus obtained at a reasonable price to the merchants, retaining the price received for their own benefit. The Government profit comes in through the establishment of a 15 per cent ad valorem duty on rubber exported from the Protectorate. The buying price, duty, and other expenses combined, should bring up the local cost of the rubber to the merchant to 1s per lb. Another 3d per lb would probably meet the entire cost of transport by the Uganda Railway and ocean steamer to a European market, where the eventual selling price might range between 2s and 2s 6d per lb, so that something like 100 per cent profit ought to be made on the transaction. I have not up to the present time taken any steps to regulate the native price of the rubber; but, in consideration of the facilities we afford the natives, I think it would be as well, later on, to limit their selling price to the merchants to a maximum of 9d per lb. I am not in favour, personally, of granting at present any exclusive concessions of rubber forests to individuals or associations. I think it would be far better to adopt, experimentally, the plan I have sketched forth of allowing the native, under proper supervision, to gather the rubber and to sell it to all and sundry at his own price up to a reasonable maximum. The Government profit would, as I have pointed out, be represented by the export duty, which I found already established in the Protectorate before my arrival. I

consider, therefore, that all parts of the Protectorate, bearing in any profusion rubber trees or vines, should be kept under Government control. Of course, if the native does not spring to the advantages offered him, and remains too lazy to gather the rubber, we must consider some other method of producing it for sale. Considering how deeply the various missionary societies are interested in the welfare of the natives, it might not be out of place to suggest that they should in their schools give technical instruction on the subject of rubber-collecting, and urge on the natives the importance of taking a leading share in this industry. —*India-Rubber and Gutta-Percha Journal*, Aug. 5.

MANUFACTURE OF COCONUT BUTTER

We have had our attention drawn to an article that appeared in your *Journal* in May last (see ante p. 535), with reference to the manufacture of coconut butter in Germany, but we fear that the prominence given to a foreign manufacture (while the fact that the same article was originally invented and manufactured in this country is entirely ignored) may mislead some of your readers. It is no doubt most interesting to your readers to learn that coconut butter is made in Mannheim, and we trust that it is of equal interest to them to know that the same article is made in this country. Our factory at Silvertown was the first to produce coconut butter; and so large has the trade become that we have started a second factory at Liverpool. We believe that in this particular industry our foreign rivals have failed to secure the lead, as they have in many others, for the output of our two factories is believed to be greater than that of all other makers put together.

Our coconut butter and coconut suet, to which we give the registered trade names of "Nucoline" and "Veju," are sold in very considerable quantities by the leading stores in London and provincial towns, and are fairly well-known in the colonies and abroad, and most popular amongst Vegetarians, Jews, Mahomedans, and others who prefer vegetable to animal fats, on account of the guaranteed purity and economy. The sales to tropical climates, where the good keeping qualities of nucoline are much appreciated, increase rapidly. For retail trade, nucoline is packed in tins of various sizes, from 1 lb upwards, and the price compares favourably with the foreign makes.

We also make several harder fats from the same source, specially for manufacturing confectioners; in fact the predecessors of this company were the original makers of "Cocos Butter," which is now so extensively used in the manufacture of chocolates and other sweets.

We trust that, with this information before you, you will correct any possible misunderstanding on the part of your readers that the centre of the coconut butter industry is situated abroad.

FRANCIS T LODER, Managing Director.

Loders & Nucoline, Ltd.,
Cairn Mills, Silvertown, London,
31st July 1901.

**" JOURNAL D'AGRICULTURE
TROPICAL "**

Such is the title of a new French Magazine, commenced last month in Paris (10 Rue Delambre) and published by M. J. Vilbouchevitch. It aims at supplying information not only for planters and scientific men, but also for investors, those engaged in com-

merce with colonial products or in supplying material for the colonies; in fact it aims at serving a commercial as well as planting community. In Paris, four years ago, M. Henri Lecomte started a similar brochure, called "La Revue des Cultures Coloniales," but we learn that this does not meet the wants of the Colonial public, edited as it is now by a Doctor of Law. Then, there is "L'Agriculture Pratique des Pays Chauds," but this is a bulletin of the *Jardin Colonial*, an official publication appearing every two months, and is likely to be too bulky and documentary, to embrace matter culled from various tropical countries outside the limit of the French colonies.

There are excellent publications in the French Colonies in Réunion, Mauritius, New Caledonia, Indo-China and Madagascar, from which the editors hope to quote and they refer to the *Bulletin Agricole de la Martinique*, edited by Messieurs Landes, Saussière and Thierry as having been a remarkable paper. But this new venture is not intended as a rival to all these but rather will work together with them. The publisher writes:—"We hope to bring forward products such as the Ramie which are not yet profitable for Europeans but offer problems that interest hundreds of investors and planters. We shall avoid dwelling on products that are almost monopolised by countries to which the French language does not penetrate. We shall reserve a little corner for European vegetables and fruit trees which, while not calling for any big outlay, add a pleasure to life in the tropics. To the tropical fruits, among which some are so delicious, we shall steadily revert as they are increasingly exported to Europe. Cattle and poultry, bees and silk-worms will also engage our attention, and, as we become rich, we hope further to enlarge our scope." In the present number the following are the subjects of the chief articles: Sisal Hemp and the other fibre-yielding aloes; Machines for the preparation of Hemp fibre; The Ground nut and its enemies; Good and bad Castilla; The Mulberry of Tonkin; Coffee in the Transvaal; Plantains, sweet and cooking ones, and methods of drying; Reviews of books; Commercial aspects.

**INDIAN TEA MANUFACTURE,
1901 SEASON.**

**ESTIMATE FOR THE REST OF THE
SEASON.**

184 MILLION POUNDS FOR THE YEAR.

CALCUTTA, Aug. 29.

The following has been issued by the Indian Tea Association:—

"The tea manufactured to August 15th is

Assam	...	29,549,019 lb.
Cachar	...	9,996,256 lb.
Sylhet	...	11,581,497 lb.
Darjeeling	...	4,330,034 lb.
Terai	...	1,525,254 lb.
Dooars	...	11,430,509 lb.
Chota Nagpore	...	80,600 lb.
Chittagong	...	319,562 lb.
Kangra Valley	...	2,200,000 lb.
Dehra Dun,	...	1,153,794 lb.

Total **72,166,525 lb.**

CALCUTTA, Aug. 29, 4-8 p.m.

The continuation of the Indian Tea Association's statement reads:—

"The balance of tea to be made is:—

Assam	...	40,775,333 lb.
Cachar	...	14,232,421 lb.
Sylhet	...	19,831,723 lb.
Darjeeling	...	3,178,390 lb.
Terai	...	1,605,040 lb.
Dooars	...	18,524,426 lb.
Chota Nagpore	...	73,000 lb.
Chittagong	...	551,837 lb.
Kangra Valley	...	870,000 lb.
Dehra Dun	...	670,000 lb.

Total	...	100,380,170 lb.
[Total manufactured	...	72,166,525 lb.

Total for 1901 season	...	172,546,695 lb.]*
-----------------------	-----	-------------------

To this there must be added:—

Kumacn	...	300,000 lb.
Outside Gardens	...	11,500,000 lb.

[Grand total]	...	184,346,695 lb.]
---------------	-----	------------------

The shipments to America and the Colonies and other ports are estimated at 25,000,000 lb. and, to meet local and trans-frontier demand 9,000,000 lb. which leaves 150,000,000 lb. for Great Britain."

[We give the totals we have arrived at, but our correspondent telegraphs 172,496,695 lb. as the total, for 1901 season,* showing a difference of 50,000 lb. unaccounted for.—ED. T.A.]

"VEGETALINE": A PRODUCT FROM REFINING THE COCONUT.

Anxious housewives will be glad to know that "Vegetaline," made by a Marseilles firm by refining the oil extracted from the copra (dried coconut), and now placed on the English market, is not, as was feared, an imitation butter, or even a substitute for butter in its domestic uses. According to Messrs. McAulay Brothers, the maker's agents, "vegetaline" is almost entirely a manufacturer's article, although it can be used in the kitchen for making pastry, and will be supplied in retail if there is any demand for it. But the value of the process by which "vegetaline" is made, will, it is claimed, be in providing bakers and biscuit manufacturers with a substitute for butter which is not only pure and cheap, but which, for biscuits in particular, is better than butter. "Vegetaline" only resembles butter in its fatty nature; it is white, and much harder than the dairy product.—*Daily Express*, August 15.

UNIQUE USE FOR THE PLANTAIN.

Amongst the multifarious purposes to which the indispensable plantain is put, surely the most unique is to make it yield a substitute for salt in cooking! Mr B C Basu, in a bulletin recently issued by the Assam Agricultural Department, asserts that the alkaline water, made from the plantain, is used to an amazing extent by the natives of the Province in this way. The sheaths of the fruit and the thick corn are dried and reduced to ashes, which are kept till required for use. To extract the alkali the ash is put in a pot, which has a few holes in the bottom lightly plugged with straw. Water is added and the filtrate which runs off is caught in another pot, and is ready for use. When the sheaths alone are used the process

is even simpler. The ashes are placed in a cup of water and in a few minutes the solution is prepared. The practice seems to have grown up in Assam when common salt was scarce and could only be drawn from Bhutan and the Naga Hill. That it should be persisted in now, when fine Liverpool salt can be purchased in every country shop and the custom of bartering paddy for salt prevails in the country at the foot of the Bhutan Hills, is a remarkable instance of the tenacity with which the native clings to his ancient customs.—*Times of India*, Aug. 29.

THE MOSQUITO THEORY.

RIDDEN TO DEATH: ANOTHER PHASE:

THE LAGOS VIEW.

There seems to be an impression in Lagos that the great new mosquito theory is being ridden to death. The *Lagos Standard* characterises it as "a craze which threatens to cause as much annoyance and inconvenience as the ravages of the much-maligned insect itself." The latest development is that, owing to water in the houses being likely to breed mosquitoes, the Sanitary Inspectors have been commissioned to enter into private dwellings and overturn and destroy utensils used for storing water. The wisdom of this edict is, in the opinion of our contemporary, more than questionable. "How our Sanitary Inspectors, who have had no particular training in that respect, can tell the larvae of the mosquito is not very clear. Besides, it is very hard lines that the Government will not provide the town with pure drinking water, and after people have been to the trouble of getting good water from Apapa and other distant places, they should lose not only the water, but their utensils as well. When the authorities have filled up the many swamps that abound in the island town of Lagos, and looked after the drains, so that there will not be so many stagnant pools and muddy puddles in the most prominent streets after every heavy downpour of rain, it will be time enough to interfere with the domestic arrangements of peaceable householders."

The *Lagos Weekly Record* takes the same tone, saying that the new regulation implies a very serious interference with the domestic concerns of individuals and will doubtless lead to much vexation and trouble. The mosquito will breed everywhere and anywhere, and putting people under privation in this way is not likely to retard or prevent the process of breeding, as experience has shown.—*Central African Times*, July 27.

ZANZIBAR NOTES.

(From the *Zanzibar Gazette*, Aug. 14.)

PEARL DISCOVERIES.

Captain Oldfield has found a shell which, besides containing two very large pearls, is covered all over its inside with knotty pearly excrescences. Unfortunately the pearls, which are of a very good colour, are not regular in shape and are not therefore of much value, but this find shows that our pearl-oysters are really good ones and that the reputation enjoyed by Zanzibar and Pemba as pearl-producing Islands is quite justified.

EUCALYPTUS AND MOSQUITOES:

Sir,—In a recent issue a suggestion was made recommending the use of eucalyptus oil as a preventive against the bite of the mosquito. An

experience of mine proves the exact contrary. Staying some years ago with a friend in Venice, conversation after dinner turned upon this subject. Having noticed the large quantities of mosquitoes, and my friend suggesting the possibility of being bitten, recommended me to rub my face with the oil upon going to bed and also to sprinkle a few drops upon my pillow. The next day on rising my face was bitten in many places, and very painful, thereby proving, to me at least, in the most satisfactory or unsatisfactory manner that the oil of eucalyptus has no virtue whatever in keeping the dreaded insects away.—Yours, &c.,

C. TATTERSHALL DODD.

Tunbridge Wells.
—*Morning Leader*, Aug. 12.

CENTRAL AFRICAN NEWS.

(*Central African Times*, July 13th.)

Mr Brown, formerly at Mount Zion Plantation, Mlanje, has become connected with the Church of Scotland Mission, and has gone to Domasi.

The rubber-collecting in most of the Luapula district is said to be getting pretty precarious at present, on account of the plants being used up. There is every likelihood that in the course of a year or two when other plants come away there will be plenty to be had.

We learn from the Secretary to the Chamber of Agriculture & Commerce that at a special meeting of the Committee of that body, held on the Thursday, the business was of an interesting nature. The subject of cotton growing was discussed at great length, and various opinions from gentlemen and firms interested in the question were put before the meeting. It was felt that the great drawback to an industry in cotton is the high rates of freight. The Secretary has had some correspondence with the Administration on the subject of the new coffee seed, but we regret to hear the seed may not be available for this year's nurseries. This is a great misfortune, but we hope that some of it may yet be in time for this season.

July 27th.—Mr Blenkiron and Mr Casson, of the B.C.A. Administration, left for home on Sunday morning on furlough.

Mr Theo. Cox has been very successful in raising a most excellent crop of tobacco grown from American and other seeds at Nyamitete Estate, Cholo. The crop is now being harvested, and should give a very fair return.

CHRISTMAS ISLAND PHOSPHATES.

In the course of his report on his recent visit to Christmas Island, Mr. L.H. Clayton states:—

"That two kinds of phosphates are found on the island—lump and granulated. The latter has the appearance of coarse white sand. A large number of narrow pits have been dug, and the quantity of phosphate discovered has been enormous. Mr Clayton says the latest estimates of the amount of phosphates on Phosphate Hill is 12,000,000 tons. He expects that 75,000 tons will be shipped this year, against 37,000 tons in 1900."—*Chemist and Druggist*, Aug. 10.

VENEZUELAN PEARLS.

One of the principal sources of the wealth of the Venezuelan Island of Margarita lies in its pearl fisheries. The pearls of Margarita have been known since the discovery of the island by Columbus and his followers. It was on this island and on the mainland

adjoining that the Spaniards found the natives decked with pearls. History claims that these pearls were one of the prime causes of trouble among the adventurers who first visited and settled on those shores. Pearls having lately risen in value, there has been extraordinary activity on the island. Buyers from different parts of the world reside there, and purchase from the native fishermen the products of their industry. About four hundred sailing boats are used by the natives in the fisheries of Margarita and its neighbouring islands of Moche and Mubagua. The principal beds are at El Tirano, north-east, and Macanao, North-west of Margarita. About two thousand men find constant employment in this trade. The fishermen use metal scoops which are dragged over the oyster beds, and when filled brought to the surface where the shells are opened and carefully examined. The boats in use are from 3 to 15 tons, and pay to the Venezuelan authorities about 12s each for permits to fish. According to Consul Goldschmidt, the pearls are very fine in quality, beautiful in lustre, and run from white to yellow in colour; occasionally a black one, priceless in value, is brought to the surface. One white pearl of large size and good quality was sold in Margarita and not long since for £349. The shell of the oyster is not of much commercial value being too thin for the manufacture of buttons and other fancy articles such as are made from the Oriental pearl shell; this, it is stated, is due to the short life of the Margaritan pearl oyster, eight years being about the average age. Pearls from dead oysters have very little value, as they lose their lustre. A French company has recently started fishing for pearls by means of divers and diving apparatus, and expect great results from their enterprise. The divers claim that they can select the larger oysters and leave the smaller undisturbed giving them time to grow and increase in value. This company, at the head of which is a prominent jewel merchant, purchased the concession from a Venezuelan, and must pay the Venezuelan Government 10 per cent royalty on the profits of the enterprise. The value of pearls found near Margarita is estimated at about £120,000 a year. Most of these pearls go to the Paris market, which, sellers claim, gives the best results. If the new method adopted by the French company is successful, the output of pearls will, it is stated, be considerably increased in quality and value in the future.—*Journal of the Society of Arts*, August 9.

A GIGANTIC SUNFLOWER.

An enormous Russian sunflower has been grown at Manly by Mr. J.A. Beal, of the Lands Department. The plant only bore one flower, which was 14 inches in diameter when cut. It is not often that such large flowers are seen, although we believe that in England specimens of Sutton's giant sunflower have attained a diameter of 16 inches, the plants being 10 feet in height.—*Queensland Agricultural Journal*, August 1.

PEARLS IN THE PHILIPPINES.

Colonel Clarence R. Edwards, chief of insular division, War Department, is preparing a gazetteer of the Philippine Islands which will contain much valuable information from official and other sources. He has just completed a comprehensive account of the pearl and shell fisheries of the Sulu archipelago. During the year 1899 the value of shells, not sawed, cut, polished or otherwise manufactured, imported into the United States for home consumption was \$969,319, and in 1900 \$1,016,723. The manufactures of shells, mother-of-pearl, etc., are now almost entirely confined to the United States. In the years above mentioned but \$82,610.40 and \$38,362.32 respectively of shell and mother-of-pearl manufactures of all kinds were entered for consumption. In regard to pearls, the best English expert says that the Sulu archipelago produces

the finest round pearls in the world. The known pearling area in the Sulu and Celebes seas possessions of the United States is 15,220 square miles. More than double that area possesses the physical conditions necessary to the best form of pearl oyster life and the nacreous shell which contains it. Siassi, in the Tapul group of the Sulu archipelago, is the strategic centre of the most active pearling industry in United States territory, and should be made the station. There are a number of fishing villages and several thousand fishers in the vicinity. The value of pearls, in their natural state or split, imported into the United States for home consumption during nine months ending March 31st 1901 was \$1,036,480, ranking next in value to diamonds.—*Chicago Record-Herald*, July 22nd.

MOSQUITOES AND DRAUGHTS.

Mr F G Afalo writes in the *Morning Leader* of August 19th :—The mosquito, malarial or otherwise, appears to have a dread of draughts and air-currents generally, and small punkahs, worked by electric motors of one-sixth horse-power, are being used with excellent results in hotels and private houses in the States. The insect pests are found to avoid the rooms thus ventilated, and there is no reason why every bedroom in mosquito country should not be thus rendered innocuous.

THE WORK OF LEAVES.

Under the belief that the sun has a great deal to do with ripening fruit, many people remove the leaves of grape-vines and tomatoes to allow the sunlight to reach the fruit. *Meehan's Monthly* says—Sunlight does usually add to the sweetness and general good character of the fruit; but ripening is a vital process, in which an abundance of good, healthy foliage is the prominent agent in the work. In short, a bunch of grapes ripening in comparative darkness would be far preferable to one grown in the full light with most of the vine leaves taken off. But the leaves themselves must be vigorous and healthy. They are not healthy when crowded. For this reason, the good gardener thins out the weak branches in the early stage, so as to have plenty of room for the development of larger ones later on.—*Queensland Agricultural Journal*, August 1.

NILGIRIS BOTANIC GARDENS.

We are in receipt of Mr. Proudlock's Administration Report for 1900-01 which is as full, varied and interesting as usual. The following refers to his recent visit to Ceylon :—

The Curator visited the Royal Botanic Gardens Peradeniya, and the Botanic gardens at Hakgala and at Heneratgoda, Ceylon, in January 1901, in accordance with the orders of Government, for the purpose of seeing these gardens, of gaining information about rubber trees in Ceylon and of obtaining such species of plants as were unrepresented here. A list of desiderata was made and submitted to the Director of the Royal Botanic Gardens, Peradeniya. The seeds and plants asked for will be forwarded by him to Ootacamund from time to time as they can be spared in due course. Mr. Willis, the Director, very kindly showed the Curator, in the gardens and in the excellently-equipped laboratory at Peradeniya, the methods employed at Peradeniya and at Heneratgoda in tapping the Para rubber tree *Hevea (brasiliensis)*, and in preparing the rubber for export.

Judging from the rapid growth made by the Para rubber trees at Heneratgoda (about 33 feet above sea level), it is a tree of considerable value

that is eminently suitable for extensive cultivation in suitable situations in Southern India; while this opinion is amply confirmed by the growth made by trees of the same species at Burliyar (2,400 feet) on the Nilgiris.

The Curator desires to acknowledge the kind help and courtesy which he received at Peradeniya from Mr John C Willis, M.A., the Director, from Mr Herbert Wright, Scientific Assistant, and from Mr Hugh Macmillan, the Curator; and at Hakgala Botanic gardens from Mr W Nock, the Superintendent. From the notes on the Experimental Garden at Burliyar (we should like to know its situation, elevation, etc.) we quote some interesting paragraphs, which will be found on page 246.

THE INDIAN TEA CROP AND ESTIMATE:

FOR THE SEASON, 1901-2.

We direct special attention to the remainder of the important statement issued by the Indian Tea Association, estimating the total crop for the current Season, the first portion of which we give on page 263 and in which we have only to make one slight correction—that the figure telegraphed for Doovars was, we find, 11,430,509 (not 11,435,109) lb.; this will give the total of tea already manufactured (up to August 15th) as 72,166,525, (not 72,171,125 lb.) On page 177 of our Directory it is shown that no estimate of the current crop had been issued up to June 5th and the figures elsewhere are therefore the first of their kind for the 1901-2 season. Seeing how the market is rising week by week, thanks to smaller outturn and finer plucking, we trust that the Indian difference of nearly 5½ million lb between Revised Estimate and Actual Outturn, for 1900, will not be realised again this year. The figures in question read :—

Actual outturn for 1900	...	187,527,435 lb.
Revised estimate of crop of 1900		182,144,874 lb.

Difference : 5,382,561 lb.

Now the current estimate is, to begin with, 2,201,821 lb. ahead of the estimate last year, but with the considerable reduction of output that is taking place in India, we should hope that the actual outturn will prove quite within the estimate of 184,346,605—or a decrease of 3,180,830 lb. on the actual crop of 1900-01.—So may it prove.

THE INDIAN TEA CROP FOR 1901-2 (season ending 31st March) being now estimated at 184,296,695 lb. is expected to be 3¼ million lb. behind the actual crop of 1900-01; but for Great Britain, only 150 million lb. are estimated to be shipped this season or 10,753,157 lb. less than were sent to London in the past season, according to the statement of the Indian Association, although another statement shews the deficiency at less than two millions. With some million lb. less from China as well as Ceylon, there ought to be a considerable difference in London stocks by the end of the year.

RUBBER IN THE PEMBA ZANZIBAR FORESTS.

The chief interest in the forests centres about the rubber creeper, *Landphia Kirkii* (M'pyo). In some places the rubber creepers grow thickly, and in the others large areas are without any rubber. The *L. Kirkii* as it grows in Pemba is not a large creeper, rarely exceeding the thickness of a man's wrist. But it attains considerable length in creeping along the ground, or in linking itself over the boughs of the trees. The bark is red and rough and when sliced off liberates a snow-white latex which almost immediately coagulates into india-rubber. The process of collection requires some skill and experience to be profitably conducted. Where the vines are plentiful and rich, an experienced and industrious man will bring in as much 3 lbs. a day while an unskilled workman will scarcely gather a quarter of a pound. The general mode of collection consists in slicing off the bark in the form of scarfs at intervals of a few inches or a foot. When three or four scarfs have been made the collector dabs the wounds with salt water, which he carries in a calabash by his side for the purpose. The salt water causes the juice to coagulate as it exudes, preventing it from dripping to the ground and being wasted. He now leaves these scarfs and proceeds to make and treat others on the same vine or an adjacent one, after which he returns to his original group. This interval gives the rubber time to collect. The latex is now pure rubber and pulls off clean and white. With the ball he may have already gathered, the collector goes over each scarf in succession, merely rolling it along. The fresh rubber clings to the ball which grows in size, but does not clog to the fingers. If the collector has no salt water he smears the juice at once upon his arm when it coagulates rapidly. Probably the saline exudations of the skin assist the process.

A good deal of waste in the collection takes place if the men are left to themselves. They will, for instance, only operate upon those parts of the vines which are within easy reach, leaving the upper regions among the trees untapped. Again there is always an "aftermath" upon the creepers, which collects a quarter of an hour or so after it has apparently been done with. The "aftermath" consists of only a small quantity of rubber scarcely worth the collector's while to return and gather, but the accumulations from hundreds of vines amount to a good deal in a day and in time would sensibly affect the quantity gathered.

Growing side by side with *L. Kirkii* is another creeper known to the natives as *Mbungo*. It exudes a sticky juice if tapped. The juice, however, will not coagulate but clings tenaciously to the fingers like treacle. Upon the application of heat it is converted into a semi-solid mass like putty.—*Zanzibar Gazette*, Aug. 14.

MANY RUBBER SPECIES IN BOLIVIA

Sir Martin Conway, in his latest work, "In the Bolivian Andes," ascribed the rubber of south-western Bolivia—known commercially as Mollendo rubber—to the tree *Hevea lutea*. Sir Martin having previously stated, in a lecture before the Society of Arts in London, his impression that the rubber tree of this region was the *Hevea Brasiliensis*, some interest has been felt as to the cause of the change in his conclusion. On this point he has written to us as follows:

To the Editor of the *India Rubber World*: *Hevea lutea* is, I believe, the chief form of *Hevea* on the eastern slope of the Andes. My authority is the collection in the Kew herbarium, which has specimens of *Hevea lutea* from that district, but none of *H. Brasiliensis* except from regions farther east and lower down. My own specimens were only leaves, and insufficient to determine the species.

My information is to the effect that rubber is extracted, along the eastern slope and foothills of the Cordillera Real, in Bolivia, from some twelve different kinds of trees. What are they? No one knows. I have just sent a properly-equipped botanist to spend a year investigating the matter from a purely scientific point of view, and I shall present a complete set of his collected specimens to the New York herbarium. We shall then know something definite.

I have received specimens of yet another kind of *Hevea* from the southeast of Bolivia, but the specimens are not good enough for complete description. There doubtless exist heaps of kinds of rubbers in the Amazon basin about which we know nothing.

MARTIN CONWAY.

Red House, Hornton Street, London, W., July 3, 1901.

The exploration work begun by Sir Martin Conway in Bolivia, referred to already in the *India Rubber World*, is to be continued by a party organised and equipped by this gentleman, and which left London on June 26, to be absent a year. At New Year the party were joined by the botanist mentioned in Sir Martin's letter, Mr. Robert S Williams, one of the senior aids of the New York Botanical Garden. It is to this institution, by the way, that the specimens collected are to be sent. The New York Botanical Garden of late has developed into an establishment of much importance, and its herbarium bids fair soon to rank with those at Kew and Berlin. There is now being arranged a collection of over 3,000 fine specimens obtained for the garden in Colombia, and which is described as one of the most important collections of herbarium material that ever came out of tropical America. The scientific directors are much interested in whatever pertains to a fuller knowledge of rubber-producing species. By the way, there is now at the garden a rubber plant grown from a seed of an undetermined species obtained from Colombia in the collection mentioned above.

The rate of increase in the exports of Bolivian rubber via Mollendo, on the Pacific coast, recorded from time to time in the *India Rubber World*, seems not to have been maintained latterly. Our last return published was for the fiscal year 1898-99—1,037,127 pounds, of which 793,418 pounds appear to have been shipped in the first half of the period. There is now at hand a return for the calendar year 1900, as follows: Shipped to Liverpool, 314,162 pounds; to London, 22,752; to Hamburg, 240,033; to Havre 37,816; to New York, 1751; total, 616,514 pounds.—*India Rubber World*, Aug. 1.

ASSAM AND CEYLON COOLIES'

WAGES COMPARED.

On the topic of wages, Mr Cotton says in his report, just issued, on Labour Immigration in Assam;—

The most remarkable feature of the figures for 1900 is that they show a lower rate of wages than the average of any year since 1895. The amount is considerably below the statutory so-called minimum wage, and when the average is below the minimum of Rs 5 and Rs 4, it follows that in the majority of cases the minimum was not earned. Converted to a daily rate, the average wage paid to men has been a little over two annas and nine pies, and the average wage paid to women has been a little over two annas a day. This is a miserable average pittance, and leaves no room for doubt that employers have been endeavouring to effect economy in working at the expense of the labour force. Figures, and facts, when they are considered in connection with the annual expenditure of some 30 lakhs of rupees in acquiring coolies—an outlay which

would have been unnecessary if the wages offered were sufficient to attract labour—leave the Chief Commissioner more and more convinced that the insufficiency of wages is the most serious of the troubles from which the industry in Assam is suffering. He is no longer prepared to advocate half measures, and it is, in his opinion, a serious consideration whether the Legislature ought not now to accept the situation which the Secretary of State has always pointed out would be inevitable when the means of communication were improved and abolish a penal contract altogether and leave Assam planters to get their labour in the same manner that the Duars and Chittagong and Ceylon Planters obtain their supply. The case of Ceylon is particularly in point. The Chief Commissioner finds, from information published by a special correspondent in the *Englishman*, who wrote after making local enquiries on the island, that labour there is free and unfettered by indenture, or anything in the nature of agreement that either party cannot terminate with a month's notice; that the coolies are imported by sea from the Madras Presidency, and that the average cost of importing labour is only R10 per head; that men are paid a daily wage of 33 cents, or about 5½ annas, and women 25 cents, or exactly 4 annas; and that they receive, as they do in Assam, free quarters and medical attendance, etc. There is no labour difficulty in Ceylon, because the labourers are paid a fair market wage: but in Assam the difficulty is always present, and Mr Cotton's recent experience has led him to the conclusion that it will never cease until it is allowed to solve itself, without the assistance of Government, and without any kind of penal legislation, by the ordinary laws of supply and demand.

It appears to the *Englishman* that Mr Cotton here falls into the error of comparing the Tamil coolie with the Kol, with whom he has no analogy. The crux of the question is—are the coolies better off in Assam, or are they not, than they would have been if they had remained in their own country? Without analysing the figures supplied by the Assam Administration, we maintain that they are—or why do they emigrate with their families?—*Madras Mail*, August 23.

A NEW NATAL ORANGE.

In his district report to the *Agricultural Journal*, Mr. J L Knight, magistrate, Inanda, writes: It may not be generally known that a gentleman in this county, who is a scientific horticulturist by profession, has raised a new and very fine species or variety of orange, which he has decided to call the "Natal Victoria," the latter after our late Queen, with Natal prefixed to denote the country of its origin. I think the "Natal Mammoth" would have been a more appropriate name, as it is certainly a mammoth orange. It is without exception the most delicious orange I have ever eaten, with a flavour which is new and entirely its own. Some of the fruits have reached 25 oz. in weight, and measured 15½ in. in circumference. A little time since, one twig was picked with four oranges on it, which turned the scales at 5½ lb the four and this notwithstanding that the tree had suffered severely from the drought last year, and has not yet quite recovered, and the size of the fruit, therefore, this season, not up to the usual average. The "discoverer" informs me

that, given suitable soil, and a favourable season, the oranges will average at least 20 oz. The tree is quite distinct from all other oranges, very large, with curly leaves, and the seedlings partake of the parent tree, proving it to be a really distinct orange from all others. It is a most robust and vigorous grower; a few grafted four years ago are now in full bearing. The grower has at present some 200 young grafted trees for disposal, and hopes to have 600 more by this time next year. Any person, being desirous of obtaining young plants, could do so by applying to me for the address. In the meantime I may say that I have seen and tasted the oranges, and can vouch for the abovefacts. I have written entirely on my own initiative, and for that reason am unable to give the name of the grower.—*Natal Mercury*, August 5.

LADYBIRDS: A PENNY EACH:

An agent of Professor Lonsbury, of Cape Colony, is collecting 20,000 ladybirds in Massachusetts. One hundred children gather them in, and receive one penny each for them. The farmers, who never before appreciated their ladybirds, want the exportation stopped. They suggest a close season for the insects.—*Daily Express*, Aug. 6.

PROFESSOR KOCH ON MALARIA.

"When I was a student of medicine, we were taught that malaria was not an infection disease, i.e., not transmissible from person to person, and that it was originated by inhaling bad air. It was regarded as the type of the miasmatic as contrasted with the contagious diseases. What a change has taken place since then! Now we know that malaria can be transmitted when one injects the blood of a malaria patient into the body of a healthy person,—a case, indeed, which does not occur under natural circumstances. We know also that malaria is not caused by gaseous substances but by micro-organisms, which belong to the category of the animal parasites, are imbibed by gnats with the blood they suck, further developed in the bodies of the gnats, and finally inoculated into healthy human beings again. So, according to the views now prevalent, malaria cannot possibly be produced without the co-operation of two factors, namely the malaria parasites and the gnats. * * *

PREVENTIVE MEASURES.

"Now a number of other measures, based on better knowledge of the etiology of malaria, have been proposed, of which the following are the most important. Firstly, people are advised to avoid the neighbourhood of malaria patients, and to fix their abode at least one mile away from places where malaria prevails. Secondly, it is proposed to exterminate the malaria-transmitting gnats by destroying their larvæ at the easily-accessible breeding places. Thirdly, human beings are to be protected against the gnats by wire-nets for their dwellings and by gloves and veils for their hands and faces. Fourthly, efforts are to be made to exterminate the malaria parasites by the rational use of quinine.

"It is obvious that these four proposals are theoretically of equal value. If one never has occasion to go near people suffering from malaria,

or if one is never stung by gnats one cannot get malaria: and if either the gnats or the malaria parasites are exterminated malaria must vanish for ever, because one of the factors absolutely necessary for its production has ceased to exist. How these proposals will stand the test of practice however, whether it is possible to carry them out to so general an extent as we had to suppose in estimating their theoretical value, is quite another question. The discussion of this question is of special interest at present, because experiments are now being made everywhere with a view to proving the practicability of the measures I have mentioned. I believe, therefore, that I may count on your assent, if I choose the said measures for the theme of this lecture, and take the liberty to discuss the measure proposed by myself in somewhat fuller detail.

THE DRYING-UP OF SWAMPS.

"If we begin with the drying-up of swamps, a measure which has been known from of old, we must regard its efficacy as confirmed by manifold experience and consequently as proved. Now, indeed, we know that the effect is not due, as was formerly supposed, to the prevention of the rotting of vegetable matter which was supposed to emit the gases that caused the disease, but to the destruction of the breeding-places for the gnats. So, strictly speaking, this measure coincides with that aimed directly against the larvæ of the gnats, of which I shall speak later on. Formerly attention was paid almost exclusively to extensive swamps, which could be dried up by regulating rivers and by means of deep drains through which the water could flow off. In this way districts have not infrequently been freed of malaria. In those cases, however, the purpose was always gained by very expensive works, of which it cannot even always be said that they were necessary, for it has been discovered that the anopheles gnats, which are the chief transmitters of malaria, have their breeding-places much more frequently in little puddles and pools than in great swamps. Several times in New Guinea I saw many larvæ of anopheles gnats in quite small gatherings of water, in wheel-marks and even in water-butts. In Italy I repeatedly found them in water-vessels which were placed in gardens for the purpose of watering the plants. In future, then, it will be necessary to pay attention to the small and even smallest gatherings of water—which can generally be rendered harmless by filling up or by frequent emptying—rather than to large swamp which cannot, as a rule, be easily got rid of. * * *

LARVICIDE.

"Of the direct extermination of the larvæ of the gnats by destroying the breeding-places, pouring petroleum into the water, or other larvicidal means the same may be said. * * *

SEGREGATION.

"The proposal to run away from malaria, so to speak, by living at least one mile away from all native settlements where malaria prevails, is one with which I have very little sympathy. * * *

NETS, VEILS AND GLOVES.

"The proposal to protect the inhabitants of malarial districts at night against the gnats' stings by nets, veils, and gloves sounds very plausible at first. It has been received with great enthusiasm, and has been acted upon in Italy at many places, and, to all appearance, with good success.

But in the case of this measure, too, reasonable as it looks from the theoretical point of view, it was soon found that it admits of but very limited application in practice. In Italy at least the arrangements for securing houses against malaria seem not to have been resorted to yet, except in the case of the railway signalmen's cottages and some small railway stations; and as to the wearing of veils and gloves, it may perhaps be practicable in the Italian climate, but in the tropics the number of people that will willingly adopt this measure is not likely to be great.

QUININISING THE POPULATION.

"I come now to the measure proposed by myself, which aims at exterminating the malaria parasites in man by means of quinine. In making this proposal I presuppose two things, firstly, that the malaria parasites are restricted to man, and secondly, that we can destroy them, or at least render them harmless, by means of quinine. As to the first of these two presuppositions, I regard it as adequately proved by the fact that nobody has yet succeeded in finding parasites identical with the human malaria parasite in the blood of any animal. Just as little has anyone succeeded in artificially transmitting human malaria parasites to animals. The second presupposition is proved by the observation that may be made in medical practice every day that, when quinine is properly used, the malaria parasites disappear from the blood of the patient. The fact, it is true, does not afford certainty that they really are destroyed; they may have only disappeared from the circulating blood, but remained in the internal organs, especially in the spleen and in the bone-marrow. And in fact this is mostly the case after a single treatment with quinine, as the extreme frequency of relapses proves; the malaria parasites are not got rid of till after the treatment with quinine has been continued for a length of time.

"But as soon as one knows this effect of quinine on malaria parasites, one will of course not restrict one self to a single application of quinine, but will continue to give it in suitable doses till the parasites have really died. * * *

MICROSCOPIC EXAMINATION.

"If, therefore, we wish to render all, or as nearly as possible all, parasites innocuous by quinine, we must take chronic sufferers from malaria and also the children into account. But the only way to gain this end is to examine the blood of all persons suspected of malaria with the microscope. In all the attempts I have hitherto made to exterminate the malaria parasites I have acted on this principle, and have been able to convince myself that the execution of this measure is not so difficult as it may at first sight appear. * * *

MOSQUITOES' PREDILECTIONS.

"A very interesting and also practically important fact strikingly observable at Fasana and partly at Stignano, too; the malarial cases were specially numerous in certain houses and groups of houses, and these were in the periphery of the place, whereas the centre was almost free. I had occasion to make the same observation before at the town of Grosseto in Italy. From this we may conclude that the infecting mosquitoes do not fly anywhere and everywhere, or disperse equally over a place but have predilections for certain places. Now, in

combating malaria, it will be very advantageous to find out what places they prefer, and to pay special attention to such. From this focal behaviour of malaria I drew the practical conclusion that it is not necessary at the outset to free whole places or extensive regions of the malaria-parasites. It will be perfectly practicable to advance step by step, in exact accordance with the number of assistants at disposal, without having to fear that the ground just freed of malaria will be at once reinundated by infected mosquitoes from the still malarial neighbouring districts.

THE EFFECTIVE QUININE DOSE.

"I now come to the question as to the best method of removing the parasites permanently from the blood of malaria-patients by treatment with quinine. With a view to deciding this question I have made very many experiments, and have arrived at the following results, which, for the rest, every observing physician who has frequent opportunities of treating malarial patients will find confirmed by his own experience. Doses of quinine of less than one gram (15.432 grains) are insufficient for adults. The effect of the quinine is very greatly strengthened by giving full doses several days running. Considering these two facts, and in order to minimise the use of quinine, I order one gram of quinine to be given two mornings running, which is repeated after an interval of nine days. This treatment must be continued for at least two months, or better three, because one is not safe till then against relapses. In obstinate cases one gives one gram of quinine three days running, and reduces the interval, if necessary, to seven days. In quartan-fever, which is well known to be the most obstinate form of malaria, quinine must be given three days running from the first. There are people with whom quinine does not agree if taken through the mouth; in such cases it must be given under the skin. The patient must be observed for a length of time after the treatment, and his blood must be examined from time to time, in order that one may be quite sure that he is permanently cured and free of malaria parasites. In malarial districts proper the combating of malaria will restrict itself in the main to the treatment of the children and of the persons who have immigrated in the immediately preceding years. To children under six months one generally gives one-tenth of a gram, to older ones more, according to their age. They generally stand quinine very well even in comparatively larger doses than adults, so that one need not hesitate to give children of five to six half a gram. They do not dislike it either, if given as a powder mixed with raspberry syrup, or if sweet tea or the like is given after it. If necessary, one can give enquinine, which, however, unfortunately cannot be used much, owing to its high price. For the rest, the treatment of children suffering from malaria is one of the most grateful tasks for a physician. When I arrived at Stephansort in New Guinea there were no children there. They had always died of malaria. I took special pains to protect the children that were born during my stay there, and those that came to the place with their parents against the pernicious influence of malaria. They were all examined from time to time for malaria parasites, and treated with quinine, if any were found. Under such treatment those children, whose number amounted at last to about a dozen, thrived splendidly; not one of them died.

"The practicability of my method was proved by an experiment I made at Stephansort in New Guinea. It is a settlement of the New Guinea Company with 734 inhabitants. Of these 157, *i.e.*, 21.4 per cent, were suffering from malaria. This figure was soon reduced to a small remainder, consisting exclusively of quartan cases, and this favourable result was not a merely temporary one, but lasted till the date of the last news I received.

PRACTICAL TESTS OF DR. KOCH'S METHOD.

"Further experiments, testing the practical efficiency of my method, are going on at this moment in German South-West Africa and in the Brioni Islands, and experiments are to be begun soon in East Africa, and the former ones continued in New Guinea. At bottom, however, no further proofs of the value of my method are at all necessary, for the results of the extensive and successful attempts to stamp out malaria are already at our disposal. You are well aware that malaria was very prevalent in most European countries only thirty to forty years ago. Since then it has very rapidly diminished, and now it has nearly everywhere wholly or almost wholly disappeared. What I have just said is especially true of England, France, Belgium, Holland, and Germany. Attempts have been made to explain this very striking decrease of malaria by the drying up of the swamps, but this explanation is by no means admissible. There still are swamps enough everywhere, and the transmitters of malaria, the anopheles gnats, are still to be found in large numbers wherever malaria used to be. So there must be other reason, and the only other reason discoverable is the much more general use of quinine, which is the only deadly weapon we have against the malaria parasites. Quinine used to be so dear that only well-to-do people could get it. Moreover, since its use became more frequent, the doctors have learned to use it more rationally. So the number of malaria cases that were properly treated and permanently cured became greater and greater, whereas formerly every case was followed by endless relapses. Consequently the infectious matter has become rarer and rarer, and the anopheles gnats, which are probably just as numerous as they used to be, no longer transmit any malaria parasites to transmit.

The prevalence of malaria in Germany only thirty years ago, and the extent to which it has diminished since then, is best shown by the statistics of the German army. In 1869 the number of cases still amounted to 54.5 per thousand; now it is 0.45 per thousand; that is, it is more than a hundred times rarer now than then. In 1874 the garrison of Spaudau, a fortress near Berlin, surrounded by swampy meadows, had 664 cases of malaria per thousand men; now, though the swamps are just as they were, the figure is one half to one per thousand. In Batavia and other towns in Dutch India, which used to be notorious for their malaria death rate, and were called "the European's Grave," a considerable improvement has taken place since the gratuitous dispensing of quinine was introduced.

THE CASE OF POLA.

"A very interesting illustration of what I am now saying came to my knowledge lately at Pola, the principal seaport of Istria. Being also a warport, it has a large garrison, and it has from of old had the reputation of being severely infected with malaria. In 1864 the naval garrison there had 887

cases of malaria per thousand men. But the state of things gradually improved, and malaria has considerably diminished since then. In the last few years the number of malaria cases in the same part of the garrison has been only about 30 per thousand that is only one-thirtieth of what it used to be. In this case also people were disposed to ascribe the improvement to the drying up of two swampy meadows near the town, which was effected in the years 1868 to 1870. But apart from the fact that the decrease of the malaria was not simultaneous with the draining of the swampy meadows, but took place quite gradually and equably in the course of the last thirty years, at about the same rate as in the German army, there is another circumstance which speaks very decidedly against the causal connection between the decrease of the malaria and the draining of the meadows, namely the following: while malaria has been diminishing in the garrison it has been increasing among the civil population, which is no more and no less exposed to the influences of the climate and the soil, including the swamps near the town, than the garrison. In 1890 the number of malaria cases in Pola and its suburbs was 24.8 per thousand; since then it has risen to 132.5 in the year 1900, that is more than five-fold, and that not suddenly, but quite gradually. In the same period the number of cases in the garrison has gone down to one third. So here we have the striking phenomenon of an increase of the number of cases in one part of the population and a decrease in another in one and the same place. This can be due only to some difference in the circumstances of these two parts of the population, and the difference is that the garrison is under continual medical supervision, so that every case of malaria is at once properly treated, whereas among the civil population, for which medical assistance and quinine are too expensive, this is not the case.

"Of reasons, then that speak for the practicability of the measure proposed by me in different climates under different social circumstances, and on whatever scale one likes, there is certainly no lack. Nevertheless I do not ask you to come to a decision on this question just at this moment, when, as already stated, experiments testing the value of the various methods proposed are everywhere being made. In a few years the practical results of these experiments will be known to us, and then you may act on the good old saying "Prove all things; hold fast that which is good."—*Pioneer*.

STRANGE CIRCULAR TO THE "MUIR" SHAREHOLDERS.

INADEQUATE REASONS GIVEN FOR DELAYING REPORTS AND ACCOUNTS.

On the top of the discussions that have recently taken place as to the position of Indian Tea Companies, the circular just issued by the Muir concerns comes with peculiar force and serves to illustrate in a sufficiently startling way the critical state of the industry. We believe this is the second communication of the kind the shareholders of these companies have received this summer, and therefore more interest attaches to the present document than at first sight appears. We reproduce the circular practically at length in

order that our readers may fully appreciate the arguments set forth:—

Registered Offices—22, West Nile-street, Glasgow, 7th August, 1901.

Dear Sir,—

The Consolidated Tea and Lands Company, Ltd.
The Amalgamated Tea Estates Company, Ltd.
The Kanan Devan Hill Produce Company, Ltd.
The Anglo-American Direct Tea Trading Company, Ltd.

We are requested by the Directors of the above companies to inform you that the issue of the reports and accounts for year ending 30th November last has been unavoidably delayed by the absence in India of Mr P R Buchanan, the practical tea planting member of the Board, with whom the Directors have always hitherto consulted in the preparation of these documents, and with whom they are at present in communication in regard to same. As some shareholders are desirous to obtain information at this juncture, we think it right, meantime, to give the following particulars:—

The Consolidated Company has 52 estates in the Doon, Assam, Sylhet, Darjeeling and Ceylon, with 28,806 acres under cultivation. The Amalgamated Company have 22 estates in Assam, Sylhet, Darjeeling and Ceylon, with 13,355 acres under cultivation. The Kanan Devan Company have 26 estates in Assam and Travancore, with 16,019 acres under cultivation. The Anglo-American Company have 27 estates in Assam, Cachar, Southern India and Ceylon, with 15,221 acres under cultivation.

Mr P R Buchanan, on whose advice these estates were originally purchased and planted, has already visited India four times with the view of promoting the interests of these Companies. Towards the end of last year Mr Buchanan, on account of the depressed state of the tea market, and the unfavourable prospects then prevailing, considered that it would be in the interests of the Companies that he should visit India and Ceylon that he might, from his practical experience, extending over many years, be able to advise and assist the managing agents, superintendents and managers on the spot in their services on behalf of the Companies. This offer the directors gladly accepted, and he left London for Ceylon by mail of 4th January.

While in India at this time Mr Buchanan's headquarters have been principally at Munnar in Travancore, but he has been in close touch with the managers of the various estates in Northern India and Ceylon, and has had several important interviews with some of the Companies' superintendents and principal managers and has thus been enabled to suggest certain alterations and economies in the working of the estates by means of which improved qualities of tea are being produced at the lowest possible cost, and without impairing the efficient upkeep of the estates.

There can be no doubt that the present crisis is very acute, and that the tea industry has seen nothing like it since the year 1860, when a considerable number of planters in India suffered very severely.

Your directors, along with the directors of other companies, were prepared to support a scheme which was formulated about five months ago, to restrict production, but unfortunately through the apathy of the Ceylon planters, the scheme had to be abandoned.

The directors do not anticipate any immediate relief from the depression which is now existing,

and think it important that the shareholders should fully realise how much our four companies and other leading tea companies are affected by the recent legislation on the part of the home and Indian Governments. You would notice from previous communications there were three factors which exerted prejudicial effects on the tea industry:—

(1) The action of the Indian Government in arbitrarily fixing exchange at 1s 4d, for the rupee, irrespective of the rate that would be automatically fixed by the balance of trade.

(2) The large production of low-class tea in India and Ceylon.

(3) The increase of 50 per cent. by the home Government on the duty on tea.

These conditions still prevail, and the position has been accentuated by an increased production of both Indian and Ceylon teas.

While the scheme for restricting the production has fallen through, to some extent the object will be accomplished in consequence of the fact that a great many planters have resorted to finer plucking, which, combined with unfavourable weather at the start of the season in Assam, Sylhet, Cachar, Darjeeling and Dooars, will bring about a smaller out-turn than was anticipated some months ago.

In view of the production being thus curtailed, markets will, no doubt, in course of time, improve, and better prices will be obtained for the produce. Meantime, the directors would advise the shareholders to rest assured that no efforts will be wanting on the part of the officers of the companies to do everything possible to strengthen their position and enable them satisfactorily to weather the storm. The companies' estates are in thorough order and well-supplied with labour and machinery, and will bear comparison with any estates in their respective districts.

The teas produced have proved during the past year superior to, and in some cases far better than, other teas produced in the same districts, and the directors look forward with confidence to the result of the struggle in which these companies, in conjunction with all other tea companies, are engaged.

The tendency of the extremely low prices now ruling will be to force tea into consumption in places where it would not otherwise reach, and, with this in view, the directors are doing their utmost to assist in introducing tea amongst the natives of India.....

The directors are also doing their best to encourage the consumption in other countries, and are specially engaged in endeavouring to find markets, for green tea, which, they think, can be manufactured on their estates to sell at a good profit.

As the Companies produce a large quantity of common tea, the present rate of duty, namely, 6d per lb., represents a very heavy percentage of the average price obtained for the tea.

The Chancellor of the Exchequer expected that the greater part of the increase of duty would be borne by the consumer, but in the case of Consolidated Tea and Lands Company, Ltd., the directors estimate that it suffers to the extent of 1½d per lb, which means about £60,000, and this added to the amount referred to in last report, arising from loss from exchange, say, £22,677 represents £82,677.

The tea industry, like other businesses—such as coal, iron, copper, cotton, tin, coffee, shipbuilding, &c.—will be subject to vicissitudes, and the directors hope that, just as these have had periods of depression followed by times of prosperity, the tea industry will emerge from the cloud which

is overhanging it at present, and become again profitable as it has been in the past. We would remind you that the North and South Sylhet Tea Companies, which were merged in the Consolidated Tea and Lands Company, Ltd, had one of the highest records among good dividend-paying Indian tea companies. From 1882 to 1886 inclusive, while the plants were young and yielding little or no leaf, no profits were made from the newly-planted estates, but out of the profits of the seasons 1887 and 1888 the Companies paid to their shareholders compound interest at the rate of 5 per cent. per annum for the whole period of about five years during which the estates were practically non-productive, besides placing £16,000 to reserve account for depreciation. For the seven succeeding years—namely, from 1889 to 1895—in which latter year the properties were acquired by the Consolidated Company, sufficient profits were earned to pay an average dividend of 10 per cent. per annum on the capital paid up and to put aside £24,000 to reserve account for depreciation.

The Chairman of these four Companies in conjunction with Mr Buchanan, Sir Robert D Moncreiff, Bart, Mr. A B Murray and Mr A M Brown—being five of the directors of the present Boards—were amongst those who formed and conducted these successful Sylhet Companies, and they continue to manage the Consolidated, Amalgamated, Kanan Devan and Anglo-American Companies on precisely the same lines as were so successful in the case of the North and South Sylhet Tea Companies.

An arrangement has been made whereby a considerable quantity of the Companies' produce will, in future, be shipped from Chittagong to London, and it is expected that this will effect a substantial reduction in the cost of transit of tea from the estates to the London market.—We are, yours faithfully, JAMES FINLAY & Co., Secretaries.

The first point that will probably strike shareholders is that in all this lengthy pronouncement there is no sound reason adduced why the reports and accounts should not have been produced long ago. Though the financial year ends on 30th November, it has generally been July or August before any statements were issued, though they should have been out by April or May. No doubt some delay must arise through all four Companies being in one office, but a mere adjustment of staff ought to prevent any congestion of business there. Now we are asked to believe that because Mr Buchanan is away in India we cannot have the reports and accounts, notwithstanding the fact that his presence in the East cannot possibly influence events and finances that relate to a period months prior to his departure from Great Britain. When Sir John Muir and his colleagues put forward shallow reasons like this for not fulfilling one of the elementary duties of Directors to their shareholders, the public are apt to place a construction on such action that is by no means favourable to the position and prospects of the Companies. In the long review of the situation which is advanced as a substitute for a legitimate narrative of operations, there is nothing that can be held to affect the Muir undertakings worse than any others, and if there is a good excuse why these Muir undertakings should not reveal their trading position it must be an excuse that applies equally to all. Since other companies have published their reports, though in the case of most the financial year ends on 31st December and not on 30th Novem-

ber, we can only conclude that the Board is not over-anxious to reveal the result of working in 1899 1900, because it compares badly with previous terms. Of the Anglo-American Direct Tea Trading Company we have no details, but the dividend records of the other three concerns since they were formed are as follows:—

	1898-9.	1897-8.	1896-7.	1895-6.
	per cent.	per cent.	per cent.	per cent.
Consolidated	.. 7	10	10	10
Amalgamated	.. 10	12½	10	10
Kanan Devan	... 5	13	38	—

This is not such a bad showing, and no wonder Sir John Muir is anxious to delay spoiling the picture, if it is unpleasant news he is keeping back. The passing of the Junc Preference dividend of the Consolidated Tea and Lands does not make us very hopeful.

As to Mr. Buchanan's presence in India, it may be well to point out that he can exercise very little influence on the current season's operations. Planting was all over before he left these shores, and the most he can have done is to supervise the plucking, which one would have thought the local managers should have been regarded as quite competent to look after. Mr. Buchanan is, however, in ample time to initiate drastic reforms for the coming year—that is to say, for the period the account of which the shareholders may expect in the summer of 1903! If the circular had said this plainly, it might not have been supposed that an attempt was being made to use this visit to blind the eyes of proprietors to real issues. It is satisfactory to find that Sir John Muir is willing to stand in with the scheme of restricting production. It is also easy to understand why. His companies are responsible for much of the over-cultivation in the past, and as they were in the first to feel the effects of glutted markets owing to their lavish expenditure on extensions, it was to be expected they would readily grasp at any solution of the problem they had themselves created. But even now this adhesion seems to be only a qualified one. It is true the Muir concerns are restricting planting schemes in Assam, but what of the policy that is being pursued in Southern India? The exports from the North will probably show a fair decline this season, but it is also pretty certain that from Madras the shipments will be nearly doubled. This is due almost entirely to the large developments in Travancore, where the Kanan Devan has huge estates. According to its own reports, it brought into cultivation under tea there in 1898-9 over two thousand six hundred acres and in 1899-1900 proposed to plant nearly three thousand acres more. During those same periods the additions in Assam were reckoned at only one hundred and thirty-four acres. The tea grown in Travancore is of a low grade quality, and must necessarily help more to depress prices than even an excess of better class descriptions.

To sum up the whole matter, then, there is no valid reason why the reports and accounts of these four Companies should not be immediately published, and the shareholders ought to bring pressure to bear on the Directors to produce them.—*Financia Times*, August 10.

PEARL AND PEARL SHELL FISHERIES.

IN CEYLON AND AUSTRALIAN WATERS.

(To the Editor of "Nature.")

In connection with Sir West Ridgeway's anxiety, as Governor of Ceylon, to revive the pearl fishery off the north-west coast of the island, and the appointment by the Secretary of State for the Colonies of so able a zoologist as Prof. Herdman to report on the subject—so classic to zoologists since Dr. Kelaart's paper and the display of fine examples of the pearl shells by the Indian Government in the London Fisheries Exhibition of 1883—it may be interesting to mention the activity of the Queensland Government in this and allied subjects. Besides the work of Mr. Saville Kent and the recent (private) investigations of Mr. Lyster Jameson, the Queensland Government early last year appointed an able young zoologist, Mr. James R Tosh, to make investigations on the life-history of the species which produces the pearl-shells of commerce, the formation and growth of pearls, and other questions bearing on the pearl fishery. He is now busy on Thursday Island. Moreover Mr. Tosh informs me that the Queensland Government has just sanctioned a grant of £1,500 for the erection of a marine laboratory on a small island about two miles distant (from Thursday Island), and in the centre of the pearl-fishing grounds, though at some distance from the coral area. This laboratory will have, besides the work-room and quarters for Mr. Tosh and his staff, three concrete tanks for experimental work.

W. C. McINTOSH.

Barham, Springfield, Fife.

—*Nature*, Aug. 15.

PROGRESS AND PLANTING IN THE FEDERATED MALAY STATES.

(From the Resident-General's Report for 1900.)

The fortunate possession of extraordinarily large alluvial deposits of tin-ore, easily worked by Chinese miners, whose luxuries and vices are taxable, has been the basis of the financial prosperity of the States, and the development of this source of wealth has been rendered possible by British methods of administration. To take, as an instance, the case of Perak, the most important and, at present, the wealthiest of the four States, the amount of duty collected on tin exported in 1877 was \$140,292, while during the past year the collections amounted to \$3,570,631. From the first days of protection the Government has kept in view the desirability, or rather the necessity, of encouraging agriculture, and slow but steady progress has been and is being made in this direction. The first year for which reliable figures of trade values (imports and exports) for Perak, Selangor and Negri Sembilan are available is 1882. The value of imports and exports for that year was \$11,207,719. For 1900 the figures for the four States are—

Imports	\$38,402,581
Exports	60,361,045
Total trade 1900	\$98,763,626

No cart roads and no railways were in existence in the States in 1875; at the close of 1900 the actual cart road mileages were as follows—

		Cart Roads.	
		Miles.	
Perak	586
Selangor	408
Negri Sembilan	249
Pahang	90
Total	1,333

in addition to some hundreds of miles of bridle paths and foot tracks. The construction of railways was first undertaken in Perak, where a short Government metre-gauge line of railway, eight miles in length, from the capital to the port, was opened for traffic in 1885. In September, 1886, a metre-gauge line, 22 miles in length, was completed by Government in Selangor, and a line connecting Port Dickson with Seremban, Negri Sembilan, 24½ miles long, was completed by a guaranteed company in 1891: total mileage up to 1891, 54½ miles. The total railway mileage open for traffic at the close of 1900 was:—

		Miles.	
Perak	114
Selangor	97½
Negri Sembilan	24½ Private Co.
Total	235½

to which may be added 23 miles in colonial territory, constructed and worked by the Federated Malay States. It is expected that by 1920 the completed mileage will be:—

Prai harbour, (opposite Penang, Province Wellesley), through Perak to Selangor boundary, with branch lines to Port Weld and to Telok Anson port	213½ miles
From the Selangor boundary to Seremban (Negri Sembilan) with branch line to Kuala Klang	126 "
From Seremban to Port Dickson (Sungei Ujong Railway Company)..	24½ "

Probable total railway mileage, Federated Malay States and Province Wellesley, 1902

.. 364½ "

The length of telegraph wires under the charge of the Postal Departments is:—

Perak	680 miles
Selangor	515 "
Negri Sembilan	141½ "
Pahang	53 "
Total	1,389½ "

Education in former days was confined to learning to read the Koran by rote, and few of the common people could read or write. There are now 193 vernacular and State-aided schools in the Federated Malay States, with 8,092 scholars. To most of the vernacular schools, hospitals, again, were formerly unknown institutions. There are now Government free hospitals throughout the States, exclusive of Gaol Hospitals and Lunatic Asylums. The Government Medical Staff includes fourteen European qualified Surgeons, a Pathologist, eight European Nurses, and two European Veterinary Surgeons.

A regular Police Force was likewise an unknown quantity. The Police Force at present is composed of 1,970, besides Buglers, Drill Instructors, Detectives and 14 Troopers

The cultivation of sugar-cane is only practised to any extent in Perak, to which it has spread from the adjoining Colony. It is rapidly becoming an important and successful industry and it is to be hoped will, in time, extend to the other States or portions of them. A considerable amount of European and Chinese capital has been invested and machinery of the latest type is employed. The export of sugar from Perak for the last three years is given as:—

		Quantity.		Value.	
		Pikuls.			
1898	274,720	..	1,214,701
1899	276,689	..	1,282,237
1900	278,156	..	1,315,974
		..	829,565	..	3,812,912

Owing to the continued large supplies of coffee from South America, the price for this product rules so low in the European markets that none but the best situated and best cultivated estates can ever earn sufficient to cover working expenses.

The European planters, with the pluck and determination which characterised the planters of Ceylon in former days, under somewhat similar adverse circumstances, have manfully turned to other forms of cultivation, Rubber (Para and Ficus Elasticus) and coconuts being most in favour, while still maintaining, in the greater number of cases, the upkeep of their coffee estates and waiting for better times. A large area has been planted with para rubber, which thrives well. Three years hence we should know what will be the result. The climate and rainfall of the Federated Malay States is all that can be desired for tropical agriculture, Indian labour is becoming cheap, fairly abundant and good, and the policy of the Government in investing its large mining receipts in the construction of roads and railways has afforded facilities to planters, which probably are not to be found in most tropical Colonies. An expert in the subject of gutta percha and rubber has been obtained from Kew, and his knowledge will doubtless prove of great value to the planters. Amongst other things he will superintend a Government experimental garden.

I regret to find that Mr. Belfield reports that the Selangor Ramie estate has practically discontinued cultivating that product for the present on account of want of demand for the fibre. Ramie is indigenous in the Peninsula.

The subject of irrigation has received attention during the past year. It has been found advisable, owing to the small number of the possible rice cultivators, not to indulge in heroic schemes as a rule, but to assist or undertake smaller ones where circumstances demand. The very important scheme sanctioned for the Krian district, Perak, is being ably carried out by Mr. R. O. N. Anderson, the Engineer in charge, who has had to contend with great diffi-

culties caused by the unhealthy nature of the work in the swamps. The revised estimates show a probable expenditure of over \$900,000, the area benefited will be about 60,000 acres and the date of completion is put at December, 1903. An irrigation work of considerable magnitude is under consideration for the district of Lower Perak Five hundred acres of land are being made available for paddy cultivation by a system of sluices and channels, in the Ulu Selangor district.

EUROPEAN PLANTERS IN CEYLON.

In our summary of planting statistics up to the end of May last, we gave 1,514 as representing the total number of Managers and Superintendents on the Tea, Cacao, &c. plantations included in the Directory. We have now been asked to say what number of these are Europeans. To enable a proper return to be made we have had the General Directory analysed, with the result that a total of 1,697 names of European planters has been arrived at. But this includes 86 men who are resident in Travancore, no fewer than 235 who are away in Europe, &c., 92 with no address, and 25 who are coconut or cinnamon planters. This brings us down to a total of 1,261 European (tea and cacao) planters in active service against 263 Ceylonese Superintendents—apart from coconut and cinnamon estates where Europeans only number 25 against a vast preponderance of Ceylonese. It is noteworthy that for 92 "planters" in the Directory, there was no address given. Possibly a good many of these have left the island; but a certain proportion must be, like Mr. Micawber, waiting for something to turn up and perhaps therefore we should put the result as follows:—

European Tea, Cacao Cardamom &c. planters in Ceylon ...	1,261
„ Out of billets (say) ...	39
	1,300
„ On Coconut and Cinnamon plantations ...	25
	1,325
Connected with Ceylon, but out of the island just now... ..	235
	1,560

CHEAP AND ADULTERATED TEAS IN AUSTRALIA.

(From the "Melbourne Age.")

The letters recently published in our columns about Cheap Teas have claimed special attention since the issue of the Queensland Health Commissioner's report. Amongst other equally startling facts menacing the health of the community, the report states that thirty chests of tea had been seized which was found to be so badly adulterated that it was ordered to be destroyed or immediately exported. The system of adulteration adopted, according to the official report was to mix magnetic oxide of iron with tea dust and sand, rolled by means of starch into little pellets of various sizes in imitation of genuine tea. The special class of the adulterated

tea, unfortunately, is not mentioned in Dr. Ham's report, but one of the best English authorities points out that these ferruginous particles are found more often in capers and what are termed in the trade "buds." It is almost unnecessary to state that the black irregular pellets found in tea and attracted by a magnet are not metallic iron. The chemical composition, experts admit, vary. They all contain magnetic oxide of iron, and many of them, in addition, phosphate of iron, titanate of iron, quartz and mica, with a little sand. These are the substances used mostly in tea adulteration, and the fact that a very recent examination in Queensland proves that teas so treated are shipped to these States may to some extent explain the poverty of the quality of our cheap teas.

The public is wholly blameless for the adulteration complained of. The demand of late years has been for cheap teas, and importers here and their buyers abroad have had to supply this want. A careful examination of imports will show that with the reduction in cost there has in the majority of instances been a sacrifice of quality.

One writer ascribes the fault to the introduction of blending and packing teas. Here to a certain extent there may be some justification for the charge, but it really applies only in instances where the amateur blender tries to follow in the steps of the expert. Our large blenders and packers have registered brands, and it is to their interest to keep up the standard of the teas so supplied to the public. To ensure this involves a heavy outlay of capital, not only for warehouses and machinery, but for the purchase of large parcels of teas for bulking and blending purposes, as well as the employment of experts.

It has long been recognised that the Victorian Tea Act, which is now incorporated in the Customs Act of 1900, is far too liberal. For instance, in order that teas should be deemed to be "mixed with other substances," it is necessary that there should be evidence of some foreign substance being mixed with them. Dirty teas, mixed with broken leaves, stalks, tea seeds, or even decayed leaves, would not come within the category of "foreign substances." Further, teas not having proper strength or quality cannot be excluded unless it is shown that they have been artificially deprived of these properties. It is in this latter direction our law wants revision, so as to bring up the standard of quality in our imports. Such a proposal, it need hardly be said, would immediately create an outcry from those who make a handsome profit even at existing low retail prices. There is little doubt that if something were attempted in the direction indicated the bulk of the trade and the public generally would be largely benefitted. Further, it would prevent the reshipment to this State of the rubbish condemned in Great Britain, as well as in the other States.

COFFEE CULTIVATION IN SPAIN.

The cultivation of coffee for commercial purposes is about to be undertaken for the first time in the province of Malaga, at the little village of Campañas, some five miles from the capital. Don Guirco Lopez, a merchant of Malaga will, according to Consul Ridgeley, begin by setting out from twenty thousand to fifty thousand coffee plants on his plantation there. As long as Cuba and Porto Rico were Spanish possessions, the cultivation of coffee in the peninsula

No cart roads and no railways were in existence in the States in 1875; at the close of 1900 the actual cart road mileages were as follows—

		Cart Roads.	
		Miles.	
Perak	586
Selangor	408
Negri Sembilan	249
Pahang	90
Total	1,333

in addition to some hundreds of miles of bridle paths and foot tracks. The construction of railways was first undertaken in Perak, where a short Government metre-gauge line of railway, eight miles in length, from the capital to the port, was opened for traffic in 1885. In September, 1886, a metre-gauge line, 22 miles in length, was completed by Government in Selangor, and a line connecting Port Dickson with Seremban, Negri Sembilan, 24½ miles long, was completed by a guaranteed company in 1891: total mileage up to 1891, 54½ miles. The total railway mileage open for traffic at the close of 1900 was:—

		Miles.	
Perak	114
Selangor	97½
Negri Sembilan	24½ Private Co.
Total	235½

to which may be added 23 miles in colonial territory, constructed and worked by the Federated Malay States. It is expected that by 1920 the completed mileage will be:—

Prai harbour, (opposite Penang, Province Wellesley), through Perak to Selangor boundary, with branch lines to Port Weld and to Telok Anson port	213½ miles
From the Selangor boundary to Seremban (Negri Sembilan) with branch line to Kuala Klang	126 "
From Seremban to Port Dickson (Sungei Ujong Railway Company)..	24½ "
Probable total railway mileage, Federated Malay States and Province Wellesley, 1902	364½ "

The length of telegraph wires under the charge of the Postal Departments is:—

Perak	680 miles
Selangor	515 "
Negri Sembilan	141½ "
Pahang	53 "
Total	1,389½ "

Education in former days was confined to learning to read the Koran by rote, and few of the common people could read or write. There are now 193 vernacular and State-aided schools in the Federated Malay States, with 8,092 scholars. To most of the vernacular schools, hospitals, again, were formerly unknown institutions. There are now Government free hospitals throughout the States, exclusive of Gael Hospitals and Lunatic Asylums. The Government Medical Staff includes fourteen European qualified Surgeons, a Pathologist, eight European Nurses, and two European Veterinary Surgeons.

A regular Police Force was likewise an unknown quantity. The Police Force at present is composed of 1,970, besides Buglers, Drill Instructors, Detectives and 14 Troopers

The cultivation of sugar-cane is only practised to any extent in Perak, to which it has spread from the adjoining Colony. It is rapidly becoming an important and successful industry and it is to be hoped will, in time, extend to the other States or portions of them. A considerable amount of European and Chinese capital has been invested and machinery of the latest type is employed. The export of sugar from Perak for the last three years is given as:—

Further, it would prevent the reshipment to this State of the rubbish condemned in Great Britain, as well as in the other States.

COFFEE CULTIVATION IN SPAIN.

The cultivation of coffee for commercial purposes is about to be undertaken for the first time in the province of Malaga, at the little village of Campanillas, some five miles from the capital. Don Guirco Lopez, a merchant of Malaga will, according to Consul Ridgeley, begin by setting out from twenty thousand to fifty thousand coffee plants on his plantation there. As long as Cuba and Porto Rico were Spanish possessions, the cultivation of coffee in the peninsula

of Spain was forbidden, but under present conditions the Government interposes no objection. Senor Lopez has already made some experiments, and is convinced that coffee can be advantageously grown in the province of Malaga and elsewhere in Andalusia. Others who have examined the question claim that there is not sufficient humidity in the Andalusian climate. Practical experiments on a large scale will be made, and the result is awaited with great interest. Cuba and Porto Rico formerly supplied Spain with nearly all her coffee, paying the Government at consumption tax of sixty pesetas per one hundred kilogrammes (£1 4s 5d per cwt) on all coffee entering the Peninsula. At present the import duty on coffee is one hundred and forty pesetas per one hundred kilogrammes (£2 16s 11d per cwt) from all countries except from the Spanish island of Fernando Po, and Spain's supply last year came largely from Valparaiso and other South American ports. Coffee from Fernando Po pays a duty of 105 pesetas per one hundred kilogrammes (£2 2s 8½d per cwt). If coffee can be successfully cultivated in the province of Malaga, it is believed that it will be generally grown throughout Andalusia.—*Journal of the Society of Arts*, for August 23.

PRODUCE, PLANTING, AND COMMERCIAL NOTES.

TEA AND COFFEE.

The "Morning Post," in a long article on "Vegetable Food Products," discusses tea and coffee, and its remarks, especially about the former, should serve to increase the popularity of tea with its readers. After referring to the prejudice against tea on its introduction to these isles, the "Post" says: "Thus in 1678 Mr Henry Savile, writing to his uncle, Mr Secretary Coventry, blames the conduct of certain friends of his 'who call for tea instead of pipes and bottles after dinner, a base unworthy Indian practice, which I must ever admire your most Christian family for not admitting. Even as late as 1756 Jonas Hanway, in his 'Essay on Tea,' ventured to assert that 'What Shakespeare ascribes to the concealment of love is in this age more frequently occasioned by the use of tea. However, these were but stray voices in a widening chorus of praise, and when the East India Company's monopoly terminated in 1834, tea, which had then become a necessary luxury, was soon regarded as a necessity even by the labouring classes. The notable fact that all substances, wherever found, which contain the alkaloid 'theine'—it is the characteristic constituent not only of tea but also of coffee, the mate and guarana of South America and the kola of Central Africa—are highly prized by the human race, would seem to prove that this alkaloid, the chemical formula for which is C₈H₁₀N₄O₂, satisfies some common craving of all sorts and colours of men. But doctors disagree as to what precisely craving may be and as to how and why it is satisfied by the drinking of tea or coffee.

TEA DUST.

The "Financial Times" publishes a letter from a correspondent signing himself "Pnesellawa," who says: "May I suggest we all agree to burn our tea dust? On my estate it represents three per cent of production. This withdrawal would afford some little relief, and some of the objections of your correspondent be met. As I am addressing, I presume, practical tea planters, it is needless to occupy your space with details." Upon which our contemporary says: "The idea is an ingenious one, but we fear it is impracticable. The same suggestion was thrown out timidly some six months ago when the tea interests were in consultation, but it failed to receive support. Each man was willing that his neighbour should burn his tea dust, but failed to see why he should do so himself, seeing that it commands a substantial value in the market. As a matter of fact,

the course of Nature is solving the tea problem, the present short season restoring the average as against the two previous superabundant seasons. What is now concerning tea growers is how further expansion of estates may be prevented rather than how the output may be restricted."

It is possible that the leaves of the coffee tree will one day become marketable in the Lane. A chemical analysis shows that the leaf contains all the characteristic properties of the berry, but is richer in the in. The natives of Sumatra make a drink from these leaves, and the editor of the "Queensland Agricultural Journal," who, presumably, has tried it on his own account, declares the coffee-leaf tea to be a pleasant and refreshing beverage.—*H. and C. Mail*, Aug. 30.

TEA AT SALE PRICES, PLUS 5 PER CENT.

The following advertisement in the latest *Grocer*—referred to yesterday in our London Letter—is the outcome of the secret tea sale scheme, and must be rather a thorn in the sides of the dealers who see the cost price, date of purchase and lot number of the tea declared and purchasable at an advance of five per cent:

The Market Prices Company, Tea Brokers and Clearing Agents, 72, Mark Lane, London, E.C.

The undernoted teas have been purchased in this week's public sale, and are offered at public sale cost. On market terms.

Purchasers can have 6 chests or 6 ½-chests of any lot. It is only necessary to wire lot number when ordering.

Samples will be sent free of cost on application. [Here come half-a-dozen lines in Assams, brought on Monday, the 12th August; and the announcement then proceeds:—

CEYLON TEA (BOUGHT TUESDAY, 13TH AUG. 1901.)

	Mark	Price.	Lot.	No.	
23	Chests	Pek. souchong	Peacock Hill	4½	94
23	do.	Pekoe	Landerdale	4½	95
27	do.	Pekoe	Dartry	6	96
49	do.	Broken pekoe	Dartry	6½	97
19	do.	Pekoe souchong	Lauderdale	4	98
20	do.	Pekoe souchong	Ingrugalla	4½	99
24	do.	Pekoe	Ingrugalla	5	100
14	do.	Pekoe	Mahagastota	6½	101
16	do.	Pekoe souchong	Polatagama	4½	102
6	do.	Pekoe souchong	Dartry	4½	103
22	do.	Broken or pekoe	Tangakelly	11½	104
25	½ do.	Broken or pekoe	Onvabkellie	10½	105

The above prices are subject to our commission of 5 per cent. only.

No charge for paying duty, clearing, or samples. Market terms: A deposit of £1 per chest payable at purchase.

The remainder of the purchase-money to be paid on clearance or prompt day.

Discount allowed to prompt day at the rate of 5 per cent per annum.

GATHERING CLOVES.—The clove tree grows to from 40 feet to 50 feet high, with large oblong leaves and crimson flowers at the end of small branches in clusters of from ten to twenty. The cloves are at first white, then light green, and at the time of gathering bright red. Pieces of white cloth are spread under the trees at harvesting time, and the branches are beaten gently with bamboo sticks until the cloves drop. They are dried in the sun, being tossed about daily till they attain the rich dark colour which proclaims them ready for shipment. A clove tree begins to bear at the age of about ten years, and continues until it reaches the age of seventy-five years.—*Journal of Horticulture*, Aug. 29.

Correspondence.

To the Editor.

THE TEA CESS.

Sept. 1.

DEAR SIR,—The Indian Tea Association have declared that the Cess will not be handed over to themselves but to a special Committee. It is to be hoped that this Committee will have funds sufficient for the purpose, or they will come in for much of the style of criticism dealt out to Mr. Mackenzie. It will be a thankless task; the problem they will have to tackle is to renovate the Indian Tea Industry with 4 lakhs of rupees or perhaps only 2½ lakhs according to the rate, $\frac{1}{4}$ or $\frac{1}{2}$ pie per pound, fixed on. I have sent a circular proposing a 2-pie Cess, to be printed and sent to all the local Associations and to the London Association, and will ask you to print a copy of it in your paper. I can see no reason for doubting that the majority of proprietors can be persuaded into asking for a Cess of 2 pies per pound. I have carefully watched all the tea news, and it will be observed that proprietors do not respond to any scheme which seems to be capable of ending the crisis but I have never seen that any attempt has been made to canvas for votes.

The Indian Tea Association proposed a Cess over 6 months ago, and it is now being taken notice of, and would have been long ago, but for the want of some organisation to collect votes. Refusal is anticipated, but when the matter comes to "yes" or "no," there is no room for doubt, and many will assent who were supposed to be against the measure.

The chief fact that I keep in view now is that there is a spirit of "union" amongst both Producers and Buyers. The million pounds sterling Scheme and the Secret Sale Scheme show that those interested are aware of the actual necessity for combined action. There is a tendency to drop all endeavour to attain to universal combination, and to enter into Schemes for personal safety. If the Cess scheme is abandoned those who have money will no longer drag along the rest with them, but with a sufficient Cess all can advance together; there is ample room still for our tea in the world, and I firmly believe that the majority will decide for combined action if the matter can be placed clearly before them and if they are forced to give a vote by a certain date.

Who was the promoter of your Ceylon Cess? How long did it take for the idea to become "law"? Was there much hope of success when the idea was first proposed? Ceylon is compact, whereas India is scattered and it is more difficult to bring about assent to any common measure, but the crisis is more severe now than at the time you succeeded in getting a Cess. Necessity is the mother of invention, and so there is hope for my invention. But for the short yield this year, both from India and Ceylon I believe that the two pie Cess which I have advocated since April would now be receiving more support. When in Calcutta, I called on the Head of one of the firms who are Agents for large Companies. I was given to understand that they were more or less content with affairs as they stood, that their gardens were paying, and that their people at Home were not keen on the Cess; but I find one of these "people at Home" spoke

distinctly in favour of large measures at the London meeting of July 17th, a date very shortly after that of my interview. If I had had the resolutions expressed at that meeting, I might have received a different answer from the Calcutta Head of the Firm. (I mention this as a reason why I really expect that the two-pie Cess may be adopted.) Again Messrs. Andrew Yule & Co., have taken up the Indian supply business, and it would surely help them greatly if Tea and money were available from a general fund. I have looked through the Tea Directory and find that Ceylon is chiefly composed of private owners, but India is practically all "Companies." It ought to have been easier to get the consent of Indian Producers, and I reckon that the reason why Ceylon got the Cess by general consent, so much sooner than India, is because the small Proprietors had come to the end of their tether and were forced to submit to a general endeavour. But the past few years have been so disastrous to many Indian Companies (who practically benefited by the action of Ceylon) that common measures are now urgent to them.

I cannot believe that a small Cess will remedy our disease, and so I urge a larger Cess and the fulfilment of the promise made only six months ago to withdraw 10 millions of Indian Tea from our markets. If Indian Proprietors will consent, Ceylon will join. I now appeal to your Planters for one man who will give his heart and soul to obtaining a Cess of two pies per pound at least. We want a big fund worked by Experts; in the letter by "One of the New Order" in yours of August 20th, he says:

"The Committee is composed of the best men in Ceylon, but they are likewise the busiest and cannot spare time to go into details. So I think they should appoint a managing Secretary to devote his whole time to the collecting of information as to how and where funds have been spent."

If one man could be appointed to collect information as to the public opinion about the rate of the Cess, I feel sure that it would reveal a strong current of opinion towards general combination, provided the scheme proposed is sufficient. I put it before you that a Cess of $\frac{1}{4}$ or $\frac{1}{2}$ pie per pound is not sufficient, and that is proved by the experience gained from your Ceylon Cess and the voluntary subscriptions from Indian growers. It is not possible to say decidedly that a Cess of 2 pies will effect the desired improvement in our affairs, and the proposal of one million pounds capital for a Syndicate to control the market shows that some men would consider this insufficient; so it stands to reason that there are opinions varying from doing nothing, up to subscribing 150 lakhs of rupees, and all we have to do is to get some to go up and others to come down to a general level.

In yours of 14th August you are good enough to say that my explanation is lucid and satisfactory, except that the reserved tea will be kept by the producers until wired for. "Hitherto we understood that the tea was to be ready on the spot to meet the demand." I beg that you will lay no stress on the details of my Scheme. All details are subject to circumstances. All that we want is a sufficient fund subscribed to by all producers and a promise of tea when required. I suggested that, instead of storing the tea in one room, which would require enormous premises, the tea should be left with each producer until required. The only delay would thus

occur on the journey down to Calcutta (or Colombo) and the second instalment could be wired for and bulked immediately after the despatch of the first. There would thus always be tea *at hand*, without the expense or risk of storing the whole reserve. I rather regret having made any suggestions beyond the essentials of the Scheme, to have a sufficient fund and a reserve of tea. At present the Scheme most likely to be adopted is a Cess of from $\frac{1}{4}$ to $\frac{1}{2}$ pie, *i.e.*, a fund of 2 to 4 lakhs of rupees and no tea in reserve.

My Scheme is a fund of 20 lakhs from India and 15 or so from Ceylon and a reserve of 10 and 7 million lb. of tea and a special Board of Control. The largest Scheme proposed is of 150 lakhs of rupees as a fund and an unlimited reserve of tea. We have certainly a large choice of schemes.

A. COOKE.

RUBBER-GROWING ON A SEWAGE FARM IN BURMA.

Rangoon, Sept. 5.

(The Editor, "Tropical Agriculturist.")

DEAR SIR,—I send you today some papers giving an account of experiments conducted here with a view to utilising sewage in the raising of a crop other than a food-stuff—the outcome of a strong local agitation against the methods of the Chinese market gardeners—a successful but unsavoury cultivator, whose energies, it is thought, might be better employed in other directions.

An article on the *Castilloa tunu* and *hule* as rubber-yielding plants (you may remember our correspondence on this question of last October) has appeared in the new Parisian journal "d'Agriculture Tropicale," with a note on the subject from your correspondent, M. Godefroy Lebeuf. I enclose a translation if you care to insert it in your paper. The question is an interesting one, and seems now in a fair way to a solution.

I hope, before leaving Burma finally, to see something done towards the introduction of *Castilloa* on a larger scale. The climate of Rangoon is much more suited to it than to *Hevea*, but Burma is fortunate in the possession of climates suited to all species of rubber-yielding plants, and of a goodly number of indigenous varieties as well. We have some guttas and pseudo-guttas to which attention has deservedly been drawn of late. There is no reason why the province should not become a great caoutchouc-yielding country in time.—Yours faithfully,

J. A. WYLLIE.

[We are much obliged to Major Wyllie (Indian Staff Corps, &c.) for the useful and interesting papers he sends us, which will appear in full, in due course, in our monthly *Tropical Agriculturist*. A plan is given of the "Kambe Rubber and Sewage Farm" which can be seen at our office by any one interested, and it seems to indicate land very much like that found in the low-lying suburbs of Colombo. There are fields alongside the Kelani Valley railway which might well be utilized as a "Rubber Garden and Sewage Farm" after the example set in Burma.—Ed. T.A.]

TOBACCO-GROWING IN CEYLON AND B. N. BORNEO.

Kandy, Sept. 7.

DEAR SIR,—Your foot-note to my letter of 5th (see page 256) scarcely does justice to my side of the argument *re* Cultivation of Tobacco wrapper leaf in Ceylon and British North Borneo.

Mr. Vollar was successful in his tobacco wrapper leaf cultivation, because he was first in the field and his leaf was purchased locally, mostly by three tobacco experts from Sumatra who at first starting were deceived by the apparently good quality as far as work of leaf was concerned. They found out their mistake when they sold the stuff in the European tobacco market. Mr. Vollar also made money by the manufacture of leaf for others who however dropped very heavily when they sold the made leaf.

Mr. Vollar, like the wise man he is, pocketed what he made and gave up tobacco wrapper leaf cultivation. The others also gave up the cultivation without pocketing any money.

I grant that there may be risks attending the transfer of men with limited capital or unlimited for that matter to countries belonging to other Governments than British, but *British North Borneo is British*.—Yours faithfully,

W. D. G.

[It is quite news to us that Mr. Vollar's famous crop of wrapper leaf tobacco was sold by him locally and not in Europe, and we thank our correspondent for his fuller information.—Ed. T.A.]

COCONUT PALMS AND ENEMIES.

Colombo, Sept. 9.

DEAR SIR,—I send you some leaves off coconut plants on a new plantation along the Kelani Valley line. They are affected with what is evidently a parasitic disease which, however, is localized. The natives attribute it to the "evil eye" and state they have not seen it before in those parts, but the leaves of the young plants are being freely attacked by it. It would be interesting to know what the parasite is and what would prevent its further devastations.—Yours faithfully,

X.

P.S.—In the specimen sent the cocoon-like structures on the back of the leaf may be distinctly seen. [We have sent the leaves on to Peradeniya for examination by Mr. Carruthers.—Ed. T.A.]

COCONUT PALMS AND ENEMIES.

Sept. 11.

DEAR SIR,—With reference to the letter "Coconut Palms and Enemies" (see above), the leaves have been attacked by caterpillars of some small moth. The symptoms lead me to believe that the pest is the same that has given so much trouble in the Batticaloa district from time to time, (vide Annual Report R. B. Gardens, 1900, p. H7, first para of Entomologist's Report). But as the insects had deserted the leaves submitted to me, I cannot definitely determine it. I should be glad for further specimens, with the living caterpillars, sent in a closed box,

Meanwhile all affected fronds should be at once destroyed. If the plants are young, the caterpillars and their webs can be stripped off by hand. If taken in time it should be possible to stamp out the pest, (see directions in above-mentioned report).—Yours truly,

E. ERNEST GREEN,
Government Entomologist.

[We quote the important paragraph referred to as follows:—

“A tour through the Badulla and Passara districts and across country to Batticaloa was undertaken in April, occupying sixteen days. The main object of the tour was to study a caterpillar pest that was seriously affecting the coconut palms in the neighbourhood of Batticaloa. On badly attacked estates the fronds of the palms were being completely skeletonized. A few trees are killed outright; but this is exceptional. I was informed that they usually recover from the attack, but that their bearing capacity is seriously diminished for several years. It was found, as expected, that the properties that were suffering most severely were those on which no efforts had been made to check the pest, or on which unsuitable methods had been employed. On estates where prompt and intelligent action had been taken from the commencement of the attack, comparatively little damage was incurred. The only course to adopt is to watch for the earliest signs of the pest, which are quite easily detected, and immediately to cut off and burn the affected fronds. It is useless to wait until the leaves have been killed before removing them. By that time the caterpillars will have deserted such fronds and migrated to fresh ones. The insect responsible for all this damage is the caterpillar of a small moth belonging to the family *Gelechiidae*. The species appears to be undescribed, but specimens have been sent to England for determination. The caterpillar may be recognized by the black head and second segment, the hinder parts being of a pale yellowish tint. It conceals itself beneath galleries composed of silk and sawdust-like pellets of excrementitious matter. The resulting moth is of a pale gray colour with minute black specks on the front wings. It measures about one inch in expanse.”

It is for our coconut-owning correspondent now to respond promptly to Mr. Green's request for further specimens.—ED. I.A.]

PLANTING NOTES.

THE PEARL FISHERIES of the Gulf of California are let out as a concession by the Mexican Government, and are said to be very valuable. The shells of the pearl oyster are shipped to Europe and sell for from 16 cents to 18 cents a pound. The gross earnings of the fisheries are estimated at \$200,000 per annum.—*Financial News*.

LEMON JELLY.—Rub the yellow rind of three large lemons upon $\frac{1}{2}$ lb. sugar, pour over it the strained juice of six lemons, and put it into an enamelled pan with 1 oz. isinglass, 1 pint of water and a glass of sherry. Stir these over the fire until the isinglass is dissolved, strain the jelly through a bag, and if not perfectly transparent mix it when cool with the whites and crushed shells of three eggs with a $\frac{1}{2}$ pint of cold water. Let the jelly boil for three minutes without stirring, then let it settle for five or six minutes, and strain it again. Set it in dishes or in small jelly glasses.—*Journal of Horticulture*, Aug. 29

ROYAL BOTANIC GARDENS, KEW.—Bulletin of Miscellaneous Information. Contents:—Jarrah and Karri, Maromba Vine Disease in Portugal, Chinese Printing Blocks, Lungan Pulp, and Miscellaneous Notes.

WHY WE PRUNE.—First, to modify the vigour of the plant; second, to produce larger and better fruit; third to keep the tree within manageable shape and limits; fourth, to change the habit of the tree from fruit to wood production or *vice versa*; fifth, to remove surplus or injured parts; sixth, to facilitate harvesting and spraying; seventh, to facilitate tillage; eighth, to train plants to some desired form—*Journal of Horticulture*, Aug. 29.

“ARE THE TROPICS DOOMED?”—is the heading of an editorial in which a foreign contemporary discusses the manner in which the tropical production of various articles of commerce are being ousted from the markets of the world by the scientific discoveries of the age, both in the laboratory and the field. The writer instances cinchona, indigo, and sugar as cases in which the tropical industries appear to be falling to the ground in the face of the manufacture of the article in temperate countries. But we suspect it will be a long time before tropical sugar and cinchona or even Bengal Indigo planters become extinct? Perhaps the date may be simultaneous with the year when the Russian Caucasus and American Southern States produce enough tea for the requirements of Russia and the United States respectively!

THE COFFEE CROP IN COORG.—An estimate of the coffee crop in Coorg for 1901 has been received in Calcutta from the local Administration, and the figures are appended, with the estimates of 1900, for comparison:—

	1900. tons.	1901. tons.
Estimated yield (2 cwt. an acre for Europeans in 1900 and $\frac{1}{2}$ cwt. in 1901) ..	2,751	1,988
Estimated yield ($\frac{1}{2}$ cwt. an acre for natives in 1900 and $\frac{1}{3}$ cwt. in 1901) ..	1,120	701
Total ..	3,871	2,689

Estimated average yield per acre of ordinarily well cultivated coffee in full bearing	2 $\frac{3}{4}$ cwt.	2 cwt.
Export of coffee taken from the toll gate returns ..	2,366 tons	3,665 tons
Average annual export of coffee in the ten preceding years ..	3,326 tons	3,358 tons

Taking the average crop to be about 4,560 tons, the estimate of 2,689 tons for the present season represents about 59 per cent. of the average against 76 per cent. in 1900.

Poor old coffee is gradually going down in Coorg, as in Mysore, and everywhere in India; and yet we know that Coorg planters have, of late years, been importing coffee seed from Uva, Ceylon.

THE DEAF HEAR.—No. 479 of *The Illustrated World* of 626, Chiswick High Road, London, W., England, contains a description of a Remarkable Cure for Deafness and Head Noises which may be carried out at the patient's home, and which is said to be a certain cure. This number will be sent free to any deaf persons sending their address to the Editor.

ELEPHANT IN SOUTHERN ABYSSINIA.—Captain Wellby (says the *Spectator*, Aug. 3, in reviewing the new book of this gallant traveller who fell lately in South Africa) talks with the greatest equanimity of walking into a herd of elephants and shooting right and left. According to him a charging elephant, and still more easily, a charging rhinoceros can be evaded by a step aside. It is pleasant to say that he shot with discretion and humanity, and not for a record bag; though his first encounter with elephants was disastrous as he fired at the head three times with a rifle or cartridges deficient in power to penetrate. When he had secured as much ivory as his men could carry without inconvenience, he let the elephants alone and watched instead of shooting them. It will be surprising if the reading of this book does not tempt many big-game shots to make the journey to the shores of Lake Rudolf. If they go, it is to be hoped that they will bring back more detailed information about the tribes. For example, the Turkas are described as a race of giants but we have no measurements given.

OCTOBER, 1901.

[No. 4.

OCCASIONAL NOTES.

RITING to us in connection with reference to the School Garden and Nature Study movement, Mr. John Spencer, Deputy to the Chief of the Bureau of Nature Study (Cornell University, College of Agriculture) says:—"Your cordial letter of recent date just to hand. I am considering how I may ask a favour with a minimum of trouble to you. The situation is this. During the past early summer, when speaking to any part of our 20,000 Junior Naturalists, I have always held them enrapt when I told them that a knowledge of their work has gone so far round the earth, that when they were fast asleep at midnight, people would be thinking about their midday meal and perhaps at that moment would be talking about them. I am wondering if you have near at hand any English-speaking children who would write me a letter about some common thing in their lives. Such would give great pleasure to our boys and girls. Such a letter would go from school to school and from town to town. Ceylon and your particular town would have an interest for them that it never had before, all because they would conceive they had some friends living there. There would be nothing within their power that young boys and girls would not do in return. Some would be glad to send photographs of scenes connected with their home and school life. With this idea in my mind I leave you to help me in its solution.—Yours cordially, JNO. W. SPENCER.

We have before now recommended the utilizing of all kitchen waste (bones, ashes, &c.) for garden purposes, and we would again point out the way in which a valuable fertilizer could be prepared by interlayering wood ashes and bones in a cask, covering with a top layer of earth and keeping the whole moist till a complete fertilizer containing nitrogen, phosphoric acid and potash is got. The Editor of the *Cape Colony Agricultural Journal* states in a note referring to this subject that kitchen bones contain about 50 per cent of phosphate of lime and 3 per cent nitrogen; average wood ashes 7 per cent of potash and 30 per cent lime. One or more casks should always be at hand for the preparation of this valuable fertilizer. The wood ashes used should be fresh and dry, and old accumulations should always be dried, or better still, calcined, so that they may become caustic for acting on the bones. If every village dwelling had some arrangement for collecting household rubbish, the gain to the occupants would be two-fold—clean surroundings and a useful compost for the garden.

In the Year Book of the Department of Agriculture so far back as 1898 we find the following reference to the use of kerosene against the mosquito: For the mosquito, kerosene has proved a very efficient preventive. Applied at the rate of an ounce to fifteen square feet, to the surface of small ponds or stagnant water in which mosquitoes are breeding, it forms a uniform film over the water and destroys all forms of aquatic insects, including the larvæ of the mosquito

and the adult females which come to the surface of the water to deposit their eggs. The application retains its efficiency for several weeks.

A Ceylon man at present travelling in Australia, writing from Perth, says:—"In Western Australia, which is quite a baby colony, what the visitor can never forget is the wild growth. There is not a weed but has its pretty blossom, and in such luxuriance and variety that I would sooner walk through into miles of sand than through a Botanic Garden or a park. No pen can describe the infinite variety of its attractions. There is every colour and every shade of colour from pink to purple and the lightest yellow to orange and deep red. Then there are grasses of exquisite beauty and form, and "everlastings" of all shapes, sizes, and colour some of which I send you."

Mr. Christian Fernando, late of Ceylon, writes from Durban:—"The cold season is past, and the days are warm, sometimes disagreeably so, and the mango trees are in blossom. Perhaps you are not aware that we have mangoes here? Yes, we do, and jak as well, but they are miserable specimens compared with those in Ceylon. The mango trees blossom when they are merely saplings 8 to 15 feet, and I have not yet seen a taller specimen. Fancy being able to just reach out your hand and pluck the fruits off the trees. But they are never very long lived, and I believe this peculiar phenomenon is explained by the energy and haste characteristic of stunted vegetation in alien and unfavourable climes to blossom and reproduce their kind ere they die.

"A Native Horticulturist writes to the *Mercury* recommending all fruit-growers to have an apiary as well, but this does not seem to be necessary for a good mango crop, for all the blossoms I saw were largely visited by house-flies and blue bottles, and not by bees. Is this the case with our Ceylon mango blossoms? They are too high up for casual observation. The jak, too, fruits when trees are from 15 to 20 ft. high. The fruits are small, but esteemed a great delicacy by the Indian population, and fetch from 6 to 12 shillings each. (I have seen them priced as much last October.) Of course these fruits with Naartjes (a variety of mandarins) and bananas are only grown in the coast districts. From all I can gather there is much scope for Horticulture in Natal, if a convenient market could be found. If a direct line of steamers started running between Natal and London for conveying produce, just as has been done between England and the West Indies, there would be a deal of money to be made from fruit culture."

A local vine grower, who is experimentally growing grapes imported from Australia, and is studying the requirements of the plants in its altered surroundings, decided to train his vines *espalier* fashion, as he expects that that will give better control over the training and pruning than if the vines were allowed to run over a framework or pandal.

We would draw special attention to the advertisement of "Gardener" on our back cover. The mixing and preparation of an insecticide according to a standard recipe is, we must confess, a most troublesome and tedious business, and we suppose one reason why amateur gardeners do not take measures against the infestation of their gardens by pests of various sorts, (as evidenced by rose trees with their leaves all eaten away, ferns covered with scale insects, brinjals affected with "soot," and tomatoes drooping and dying owing to fungoid disease) is that they shirk the preparation of the "remedies." "Gardener" now offers ready-made preparations which have only to be diluted with water in the required proportion, according to the directions that will be given.

MAINTENANCE OF SOIL FERTILITY.

The triumph of successful agriculture, as a contemporary truly remarks, is the growing of good crops continually over a series of years, and yet keeping up the fertility of the soil. As long as there is fresh land to cultivate there is little need for the use of fertilizers, but with changed conditions cultivators have begun to understand the necessity of keeping the soil that has given returns for any length of time without added fertility. It is an axiom of agricultural science that land should be compensated for what is removed from it by the use of manures and by growing rotations of crops differing in their requirements.

The more common form of manure consists either of animal excreta or decomposed animal or vegetable matter of any kind. In view of the fact that cattle are not housed in the same way as in England, a great proportion of the manure yielded by them is lost to the cultivator. Under such circumstances the greatest care must be taken of

what can be saved, and it is utilised to the best advantage. At the same time all materials that can be made use of to the benefit of the land should be impressed into service.

As regards special fertilizers, which contain particular substances concentrated generally in comparatively small bulk, though their value is generally admitted, yet owing to their cost in most cases and the lack of knowledge as to their economical use, they have not come into extended use in the Colonies. Though plants contain various substances which they, for the most part extract from the soil, yet the demands of the crops are supplied mainly by three. These are nitrogen which must be in the form of soluble nitrates or ammonia salts, potash, and phosphoric acid, which must also be in a soluble condition. Unless these materials are in such a state as to supply plants with the necessary amount of food for their development, they might as well not exist in the soil. Through the absence of one essential ingredient land may be too poor to pay for cultivating, though it may be rich in the other elements of fertility. Thus a piece of land may be very rich in potash and phosphoric acid, yet if wanting in nitrogen it will be practically barren. By the use of special manures such deficiencies when known can be made good, and in the land brought into condition for cultivation. Again, special fertilizers may be said to be necessary for particular crops that extract large proportions of certain materials from the soil. But to use these fertilizers properly a knowledge both of the material that is being used and of the requirements of the lands. To apply any ingredient which is already amply provided in the soil will not only be a waste of money, but may actually lessen fertility. The right material must be supplied in the right proportion, and the careful cultivator can always pretty correctly find out what his land requires by making experiments. There is no doubt that in most cases the outlay on special fertilizers (in spite of their cost) will prove a judicious investment.

Again, it must be remembered that manures should be applied in such a manner as to afford the greatest amount of benefit. The practice of leaving manure in heaps for any length of time entails both waste of material and labour as well as irregular fertilising. For fruit trees it is recommended that manure should be applied just before the hot weather sets in, as it will shelter the soil from the sun and furnish plants with food when they most require it. As a general rule, it is not advisable to bury manure too deeply, and it should be distributed as evenly as possible. Artificial or special fertilizers should be applied to the surface and afterwards incorporated with the soil.

We have to acknowledge our indebtedness for many of the ideas in the above to "Alfulta," a familiar contributor on agricultural subjects.

FIRST STEPS IN AGRICULTURE.

First Stage—5th Lesson.

BY A. J. B.

So far I have told you very little about seeds, but a farmer must know all about the seeds he buys or produces. He must be able to judge

whether they are living and whether they are such as will produce a good plant. It is also very necessary to be sure that they are not mixed with other seeds. In lesson 1 I explained to you how even useful plants become weeds whenever they grow with a crop which requires all the ground for itself. Thus you learned that oats may be looked upon as weeds if they grow up in a wheat field. The farmers on the Darling Downs do all they can to get rid of these "strangers" as they call them, because if they ripen and are harvested with the wheat, the miller will not give such a good price for the grain as they would if it were not mixed with oats. Seeds are very often destroyed by little tiny insects. They bore a hole in them, and eat that little living part which you remember is called the "germ." If the germ is destroyed, the seed cannot grow, and all the farmer's labour and expense will be lost if he is not careful to get good, fresh seed. But how is he to tell whether they are good and fresh? Look for yourselves. Here I have a packet of one kind of seed, and here is another of the same kind. One is very old, the other is quite fresh. Now examine each lot of seeds carefully, and try to find out which is good, and which is bad. You point out the dusty lot, and say, that is bad? You are quite right, but how do you know that I did not put the dust into that packet? You think the seeds in it look duller than those in the other packet, and they feel lighter than the other. Now, without my telling you how to distinguish the bad seed from the good, you yet have done so. You see, therefore, that by making use of the intelligence God has given you, you can make a little discovery like this. If, as you grow older, you continue to use that intelligence, to keep your eyes and ears open to learn from others who have studied many things belonging to agriculture, you will not fail to be successful farmers. But there is yet another way to tell whether the seeds are bad or good. You noticed the dust? Well, I did not put that dust there. How then did it make its appearance? Examine a seed carefully. What have you found! Oh! so your sharp eyes have found a tiny hole in several of the seeds. How did the hole get there? Did I make it with a pin? No, it was done by an insect, and now you see that the dust is caused by the insect devouring the germ of the seed, and masticating and digesting its food. The dust then is composed of the remains of the inside of the seed.

You told me that the seed in one packet felt lighter than the seed in the other. Let us see if that is so, but first we will blow away the dust. Here is a small pair of scales. I place the seeds of one packet in this scale. Now drop the others into the empty scale. What happens? You notice that one scale is still resting on the table and the other is raised in the air. That shows you, that although there are exactly the same number of seeds in each packet, yet one lot is lighter than the other, and therefore must have lost something. That something is the life of the seed—the germ.

I will give you one more proof of the lightness of the bad seed. Here is a cup of water. Throw a dozen grains of the good seed into it. Observe, they have all sunk at once to the bottom. Now throw in the same number of bad seeds into the water. Notice that only a few sink, but most of them float. An experienced farmer or gardener would not take all this trouble with his seeds, because, by merely taking a few in his hand and examining them, he can at once decide whether they are good or bad. And when you are old enough to leave school and begin farming for yourselves, you will soon learn to distinguish the good from the bad.

You have perhaps heard someone say: "Oh! I will save the seed of such and such a flower, because it is so beautiful." Of course, if any plant is allowed to go to seed, the seed may be gathered and saved. But many people, particularly flower gardeners, who do not grow flowers to sell, keep cutting off the flowers to put them on the table, or to give to their friends, until the blooming time is nearly over, and then they allow the very last flowers to go to seed, and this seed they save. When it is sown in the following year, they are very much disappointed to find that they do not get nearly such fine healthy plants, nor such splendid flowers as they did from the original plant; and they wonder why this is so. The reason is very simple. As the plant approaches the end of the season, the flowers are not so strong and large, and when they go to seed, the seed is very small and weakly, because it had not sufficient nourishment supplied to it from the soil by the dying plant. Therefore, bear this in mind: Let the best plants and best flowers produce the seed you wish to save. When a wheat-grower wants to produce a new kind of wheat of which he has only been able to get a few pounds weight, he carefully sows it in rows at proper distances apart, and keeps it nice and clean, and waters and tends it until at last it ripens. Then he goes through it and selects the very finest heads with the best-filled grain, and saves these for next year's crop, and by-and-by, instead of a few pounds weight, he has several thousand bushels of fine wheat. Had wheat-growers kept on growing wheat from their own fields year after year on the same ground, the wheat would gradually have become smaller and the grains fewer and pinched up, till at last it would not have been worth growing. But in all wheat-growing countries, there are people who make it their business to improve the wheat and make it more valuable for food. However, it will be many years before you will understand how this is done, and I merely mention it to you in order to impress upon you the great importance of a careful selection of seeds.

We were talking about holes being bored in seeds by insects, but there are a vast number of holes in the skin of the seed, just as there are, thousands of holes in your own skin. These holes are called "pores," and it is through them that the moisture of your body passes out when

you are very much heated. The moisture is "perspiration."

The holes or pores in the seed are there for the purpose of enabling the seed when it has been grown to take in the amount of water required to make it swell and grow. In the dirty seed, these are stopped up and the seed will not grow properly, if at all, for want of water which cannot get in at the closed-up pores. It is precisely the same with your own pores. If you do not keep your skin clean and thus open the pores, the moisture within you which wishes to pass out as perspiration cannot do so, and you will find that you do not feel so healthy and strong as you would if you regularly bathed and washed.

The depths at which to sow seeds depends entirely upon the kind of seeds you are sowing. Some require to be barely covered with a thin layer of fine soft soil, others should be planted at a depth of from $\frac{1}{2}$ an inch to 3 or 4 inches, but this you will learn when you begin to study the methods of sowing and planting adopted in different parts.

Questions on Lesson 5.

1. Why should a farmer be a good judge of seeds?
2. In what way may seeds be destroyed?
3. How are you able to tell whether seeds are good or bad?
4. By what experiments can you determine the weight of seeds?
5. State the wrong and the right methods of saving seeds.
6. How can wheat seed be improved?
7. What are the natural holes in the skin of seeds called?
8. What is the object of these holes?
9. What would happen if the holes are stopped up with dirt?
10. At what depth should seeds be sown?

—*Queensland Agricultural Journal.*

EXTERNAL PARASITES OF POULTRY.

The parasitic infestation of poultry causes far more loss than most breeders imagine. Birds are rarely examined, and the cause of their poor condition is not ascertained or even considered. The evil is allowed to spread unmolested, in many instances it spreads with great rapidity, and a general weak and unhealthy condition results. The chief parasites of poultry are insects, mites, and worms.

These parasites are most injurious to young chicks and "brood" hens. The persistent loss of chicks, and the failure of hens to bring off their young, are often due to the irritation caused by the presence of parasites upon their bodies—enemies that are frequently unsuspected. The insect and mite pests weaken the constitution and predispose to other maladies, such as diphtheritic roup and "gapes"; in many cases they have been the forerunner of these worse epizootic diseases. Parasites on the young birds stunt their growth. What is termed "scaly-leg" is due to a parasite—a mite. Another species of

mite at the roots of the quills causes birds to pluck their feathers.

There are three distinct groups of insect and mite pests upon fowls, namely :—(1) Fleas (*Pulicidae*); (2) Lice (*Mallophaga*); and (3) Mites (*Acarina*). The two former only are true insects, having the six insect legs; the *Acarina* have four pairs of legs and are quite distinct from true insects. The fleas and some of the worse mites are armed with a piercing and sucking mouth, the bird lice having biting mouths and thus differ from ticks found on animals. The pests with piercing mouths weaken the birds not only by causing irritation but by actual robbing of blood. The biting lice, on the other hand, only cause severe irritation, which keeps the birds in constant unrest. Most birds have distinct parasites upon them, each species of louse only flourishing on a particular species of bird; duck lice, for instance, cannot live permanently upon fowls, and *vice versa*.

Different species also seem partial to particular parts of the bird's body. The favourite positions seem to be the head, neck, rump, and under the wings. Some of these parasites live permanently on their hosts (lice and some mites), whilst others (fleas and some mites) go to and fro. Some *Acari* live entirely upon, and even under, the skin, deep amongst the feathers and at their roots; some lice live like "ticks" with their heads against the skin and their bodies erect; whilst a single genus (*Lipeurus*) lives between the barbs of the feathers. All these parasites are encouraged by dirt.

Fleas (Pulicidae).—The fleas, which are true insects, belong to the order of flies (*Diptera*). They feed upon the blood. One species only lives upon the fowl, namely, the bird-flea (*Pulex gallinae*), which attacks also most other birds. The hen-flea, as it is generally called, is abundant in dirty fowl runs, and especially in the nests where straw is used. The adult flea is dark in colour, and, as in all fleas, is devoid of wings. The fleas are provided with very sharp piercing mouths. They are what are termed "partial parasites"—parasites that only go to their hosts to feed. The fleas are not noticed on the birds because they generally attack them at night; then, however, they do much harm, causing constant irritation and loss of blood, and depriving them of rest.

Life-history of the Hen-flea.—The female flea lays her eggs (nits) chiefly in the nests amongst dust and dirt and in the crevices of the walls and floor. These nits give rise to pearly white maggots, with brown horny heads, which can often be found in the bottom of the nests among the dust. These larvæ are mature in two or three weeks, when they reach about $\frac{1}{2}$ of an inch in length. In warm weather they may be full fed in even ten days. They then spin a pale cocoon amongst the dirt, in which they pupate. The pupa is at first pale brown, then dark chestnut brown. In this condition the flea remains ten or twenty-one days, when the pupa hatches into the adult. They breed all the year round, but chiefly in warm weather. It is well to remember that, whenever there are dark and dirty hen roosts, there are sure to be numbers of *Pulex gallinae*.

(2) *Lice (Mallophaga)*.—The bird lice belong to the group Mallophaga, quite distinct from human lice (*Pediculidae*), and from mammalian lice (*Haemotopinus*, &c.) These *Mallophaga* have not a piercing mouth; their mouth is simply used for biting. They subsist upon the productions of the skin and fragments of feathers. They cause violent itching, and bite sharply, and must produce considerable pain when in large numbers, as is too often the case. The feathers, especially the saddle trackle, generally show notched edges with lice infestation. Eight distinct species of lice attack fowls. The presence of these lice (*Phthiriasis*) is generally ascribed to two uniform or insufficient nutrition, or else to damp, dark, and dirty runs, especially those badly ventilated. Food, either when uniform or insufficient has no effect upon their presence. Dark, damp places, however, when dirty, are sure to harbour all these pests, especially when badly ventilated. It is also said that breed affects their presence, but observations tends to show that all breeds are more or less subject to infestation. In every case they set up severe irritation and inflammation of the skin, which often leads to stunted growth, and even death! Lice and other parasites flourish on unhealthy birds.

Life-history of Lice.—All the lice breed fairly rapidly. The eggs or nits are laid upon the down feathers as a rule; they are often beautifully sculptured objects, oval in form. In about six to ten days they hatch into small, pale, active lice, which at once commence to irritate the birds. The adults are occasionally found in the nests. Some species are found copulating in the nests, others always on the birds. They live a considerable time. *Menopon pallidum* has been kept active for months upon fresh feathers, the quick epidermis being especially eaten. Before reaching the full-grown state, as many as ten to twelve months apparently take place, there being little difference in each stage except the gradual darkening of the markings.

(3.) *Mites (Acari, Acariases, Dermanyssus)*.—Mites are very minute creatures, having four pairs of legs. Some are partial parasites, living on the birds at night, as *Dermanyssus avium*, the common fowl mite; others are permanent parasites, as *Sarcoptes*, living at the base of the feathers, and popularly called "depluming scabbies." Others, again, live under the skin, forming scabby growths, such as are seen on fowls' legs (*Sarcoptes mutans*). These are armed with a pricking mouth, with which they torment the birds, especially at night, causing loss of condition, hindering setting, and creating loss in other ways.

The most injurious form is the red or common fowl mite.

The Fowl Mite (Dermanyssus avium).—This very minute creature is yellowish white to dark red in colour, according to the amount of blood it contains, drawn from the birds. They are found in abundance in pigeon-houses and poultry-roosts. Both sexes are armed with a sharp rostrum; the female is most blood-thirsty. They feed upon the birds only at night, and hide away in cracks and crevices in the nests, perches, floors, walls, and ceilings during the day. Numerous colonies

can be found in the nests free and coupled together, with countless eggs and quantities of exuviae and young forms, especially in straw nests. They are most prolific, and can remain for months without any food; hence the removal of the birds from the runs is useless as a remedy. The ova hatch rapidly. The young are at first silvery white, with six legs like a true larva. They moult their skin a number of times, the exuviae or cast skins forming a whitish or silvery powder often seen on the perches. As the mites grow older they become darker in colour. Light and air are distasteful to them; damp, dark, and badly-ventilated roosts are where they flourish best. Breeding is especially rapid in spring and summer. This mite is often unobserved, owing to its strict nocturnal habits, and hence the cause of the fowls keeping backwards, and even dying, is not understood. Birds should, when looking dejected and emaciated, be examined at night, and if mites are found treatment should be at once resorted to. Transmission to man and other animals is not unusual; but, although the mites for a time cause severe irritation, they will not remain for any length of time, and readily yield to treatment. Hens should not roost in stables and sheds where other animals are kept.

Prevention and Treatment of Fleas, Lice, and Mites.—Infestation is always worse in dirty and neglected runs and roosts, and such are a standing danger to more cleanly neighbours. Cleanliness and freedom will always put these pests under a disadvantage—not only cleanliness of the nests, walls, and floor, but also of the ceilings and perches. To suppress these pests the houses should be cleaned down at least twice a year with a wash made of hot lime and soft soap, the ceilings, walls, and nests having a good coating; the wash should be fairly liquid, so as to run into every crack and crevice. To every gallon of lime-wash add $\frac{1}{4}$ lb. of soft soap, previously dissolved in boiling water. Early spring and autumn are the times for these applications. The perches are best treated with boiling water and soft soap, or with an emulsion of kerosene. It is important that houses should be well built, with as few cracks and crevices as possible, for in such harbours these pests congregate and may escape from any wash used. Special attention should be paid to the nests; they should be frequently cleansed and changed to keep off fleas and other parasites. Neither nest-boxes nor perches should be fixed, relays of each should be at hand, so that they can be changed to ensure complete disinfection. The nest-boxes should be now and then cleaned out, and dressed with hot lime. Either dusting the prepared nests with Persian insect powder (*pyrethrum*) or putting a little sawdust or sand soaked in naphthaline at the bottom will keep off these depredators. Wood-shavings, or wood wool, in the nests instead of straw is most beneficial. No lice or fleas will live in it owing to the aromatic odour given off from the wood. Care of course must be taken that the remedies employed do not affect the eggs with nest. Regarding the

infestation of the birds themselves, white precipitate seldom fails. The heads and necks of young chicks should be early dressed very sparingly and repeated when necessary. White precipitate is a strong irritant poison, and needs the greatest care in the use, especially in young chicks. It is best obtained as an ointment from the chemists. Hens selected for sitting should have a small quantity of this ointment rubbed in under the vent, head and sides, and then well dusted with insect powder (*pyrethrum*). Sitting hens are greatly tortured by parasites, and their young are often lost by neglect of these simple precautions. Dust baths are the natural remedy for lice and mites, and fowl should never be kept without them. Sand and road dust, mixed with a small quantity of paraffin will generally keep the birds free from vermin. In place of paraffin *Pyrethrum* powder may be used with the dust.

(To be concluded.)

POTTING OF PLANTS.

If new pots are to be used, be sure and seek them for several hours first, for unless the pottery has been well moistened it will suck out all moisture from the soil. Old pots are as good and even better than new, but they should be well washed inside and out before using again. Warm soap suds with a table spoonful of washing soda dissolved in it will wash the most soiled pot as clean as a new one. Fresh soil is the best for plants, and that which is obtained from under the stiff, wiry sharp-looking grass is very fine for use. Such tufts when well rotted make the best composts to mix with garden loam, leaf mould, &c. A little sand is needed for nearly all plants as it keeps the soil light and lets the roots extend freely. Leaf mould should be prepared by every gardener by gathering the autumn leaves and piling them in a heap to decay. It is well to throw a little soil over them to prevent them from blowing away. In eighteen months they are ready to use. Thoroughly decayed cow manure is also needful for healthful growth, and that collected in dry cakes in pastures piled up but kept dry for 12 months is exactly to our purpose. Little bits of charcoal and coarse gravel are of great use in preparing compost and potting plants. Put some bits of charcoal into the bottom of the pot, then a little fine straw or moss, and now add an equal mixture of loam leaf mould or cow manure and a sprinkling of sandy gravel. Shake this down well, wet it a little, and put in the plant, spreading out the roots as evenly as possible. Add more compost by degrees, pressing it firmly about the roots; do this till the pot is nearly full. Sprinkle the whole surface of the leaves and shade for two or three days. For repotting give the earth in the pot a good wetting, then run a knife around the edge and spread the fingers of the left hand over the soil, with the other hand turn the pot topsy turvy and a ball of earth will drop into your hand. If it does not fall out directly strike the edge of the pot against some hard substance

and it will drop. Disentangle the fibres of the root at or near bottom, and set the plant firmly into a pot one or two sizes larger with a little charcoal and rich earth at the bottom of it, water well and shade for a few days. Give also a top dressing of fresh soil if needed, and your plants will repay the care. As a general rule pots from 4 in. to 7 in. are large enough. Plants will often flower better if the root is bound a little. This is especially the case with double geraniums. Give careful culture, keep them clean, well-watered, properly ventilated and well-fed, and you will never regret the care expended upon them.

PLANT LIFE.

[A SERIES OF SIMPLE LECTURES INTENDED FOR A CLASS OF JUNIOR STUDENTS.]

Lecture I.

Not long ago you listened to a lecture on Nature Study and School Gardens delivered here by the Director of the Royal Botanic Gardens. Do you think you fully realize the significance and importance of what is called "Nature Study" and the connection between it and School Gardens? Let me see if I can make this matter clear to you. You must not imagine that Nature Study implies anything very new or extraordinary. It is simply the study of nature or natural objects. It consists of closely observing these natural objects so as to clearly understand all about them, and to draw correct conclusions regarding them as the result of such observations.

There are many people who may be said to see and yet not see. That is to say, their eyes are open, but they do not observe or notice what they see. Objects are pictured in their eyes as in a looking-glass, but no impressions or ideas of these pictures are conveyed to the mind. If you have read a description of the structure of the human eye you will know that there is a part of it (the retina) upon which a picture of every object which one sees is cast (look into your neighbour's eyes and you will see your own image), and that there is also a nerve (the optic nerve) which conveys the impression of that picture to the mind. Have you heard of the expression "the mind's eye"? Well, it is with this eye that we must see things in order that we may grasp and retain impressions of them. If we only see things with what we may term "the reflecting or mirror eye," then we see to little effect. It is really the want of a little effort—the want of a little exercise—on the part of the mind that makes people fail to notice and observe what they see. Listless people, who cannot rouse themselves to take an interest in what is around them, are particularly lacking in this respect. They cannot concentrate their minds on any object they are looking at; they keep wandering in their minds, and allow objects to pass before their eyes unnoticed.

Other people again are observant in a degree, but their observation is only superficial and does not take in details. There are others still, but unfortunately not a very large number, who not

only take in the details of a picture before their eyes, but they make a point of closely scrutinizing and studying every natural object they come across; and further, they enquire into its structure and functions; in fact, they learn all they can about it, reason about it, and draw conclusions from their study which will probably prove useful to them in a practical way. These are true nature-students, and their method of study is the basis of all-science. It is by observing, comparing, and classifying natural objects and phenomena that we are able to lay down certain principles which go to constitute sciences.

But what have School Gardens to do with Nature Study, you will ask? School gardens furnish a field for nature study, and children cultivate a taste for nature study by spending their leisure hours working amid the pleasant surroundings of these gardens. The method of nature study learnt in school gardens can afterwards be applied to natural objects outside them. All natural objects are full of interest, and whether it is a plant, a rock, or a stream, there is a fascination in the study of them, and the minds of the children who study them are enlarged; they find a new interest in life, and a pleasant and profitable way of spending their leisure hours. But I think you will find that the study of plants is particularly interesting and profitable, particularly to children who live in the country. I will mention one reason why plants have a peculiar interest for us, viz., they are like us, that is like animals, living things, and hence different from other natural objects. Of the many sciences which fall within the scope of that vast subject called Natural Science, the study of animals and the study of plants are together known as Biology or the science of life, because the objects they treat about are animate objects or living things, while other sciences deal with inanimate objects such as rocks, stones, soil, rivers, rain, gases, &c. You see, therefore, that animals (like ourselves) and plants, are very closely related in this natural way. You may say that you are not inclined to admit that plants are living things in the sense that human beings are. Well, of life we know very little beyond the fact that it is something distinct from the organism itself, whether plant or animal. These organisms may be said to be the dwellings which the mysterious power called life inhabit. When life is present in the organism we say that it is alive or living, when it is not present we say it is without life or dead. The presence of life is characterised by certain vital phenomena which are never known to exist in inanimate objects or organisms from which life has departed. We all know the characteristics of the living being—the various functions which are carried on by the organs of the living body. Everyone is familiar with the five senses, for instance, taste, touch, hearing, feeling, seeing. But these are not the most important, in that they are not the most characteristic of life, nor are they common to all living things or even to all animals. You must not fancy that all animals are as highly organised as ourselves, for man is the highest of animals. In the study of animals if we begin with man we must descend

gradually lower and lower in the scale of organization through animals like the horse and cow, birds and reptiles, fishes, insects, earth-worms, starfish and coral insects until we come to the lowest of animal organisms which are devoid of all organs and even of any definite form, consisting only of a jelly-like mass, such as you may have seen lying on the seashore.

But in the case of all animals, whether of the highest or lowest types, there must be respiration or breathing, nutrition or the sustenance of the body by means of food, as well as growth and reproduction.

Perhaps the most important of these vital functions are respiration and nutrition. You will, I think, readily admit that nothing can be called alive which does not breathe. Why, breathing is the most striking characteristic of life. If we doubt that a man or other animal is alive, we watch closely to see if he breathes, and when he breathes we say he lives.

Then again take nutrition. We all know that no man or animal can live without food, which we say is necessary to sustain life. For the present I will not go into an explanation of how these two vital functions are carried on; it is sufficient for us to recognise that they are necessary to life. I also mentioned growth and reproduction. By growth I mean a certain development through time from the young to the old stage, and by reproduction, a continuation of the species or kind—the begetting of new organisms from the original.

Now inanimate objects such as rocks and stones show none of these phenomena. They do not breathe, they require no food, they do not grow, nor do they reproduce their kind. But plants do all these things—they breathe just as we do, and cannot live in the absence of air; they require food and water as we do, and without nutriment they starve and die; they also grow and reproduce their kind. How all this is done we must gradually learn, and by so doing we shall find a new interest in plants, and by understanding their wants better, we shall be able to care for them better, just as by learning the wants of children we are enabled to bring them up better.

LIMEWATER FOR EGG PRESERVATION.

The solubility of lime in water at ordinary temperatures is one part in 700 parts of water. Such a solution would be termed saturated limewater. Translated into pounds and gallons this means one lb. of lime is sufficient to saturate 70 gallons of water. However, owing to impurities in commercial lime it is well to use more than is called for in this statement. It may not, however, be necessary if good freshly-burnt quicklime can be obtained to employ as much as was at first recommended, namely, 2 to 3 lb. to 5 gallons of water. With much lime as is here referred to one could rest assured that one lb. to 5 gallons (50 lb.) would be ample, and that the resulting limewater would be thoroughly saturated. The method of preparation is simply

to slake the lime with a small quantity of water, and then stir the milk of lime so formed into the 5 gallons of water. After the mixture has been kept well stirred for a few hours it is allowed to settle. The supernatant liquid which is now "saturated" lime water is drawn off and poured over the eggs previously placed in a crock or water-tight barrel. As exposure to the air tends to precipitate the lime (as carbonate) and thus to weaken the solution, the vessel containing the eggs should be kept covered. The air may be excluded by a covering of sweet oil or by sacking upon which a paste of lime is spread. If, after a time there is any noticeable precipitation of the lime, the lime water should be drawn or siphoned off and replaced with a further quantity newly prepared. It is essential that attention be paid to the following points:—

- (1.) That perfectly fresh eggs only be used.
- (2.) That the eggs should throughout the whole period of preservation be completely immersed.

Although not necessary to the preservation of the eggs in a sound condition, a temperature of 40° F. to 45° F. will no doubt materially assist towards retaining good flavour, or rather in arresting that "stale" flavour so characteristic of packed eggs.

Respecting the addition of salt it must be stated that our experiments—conducted now throughout three seasons—do not show any benefit to be derived therefrom. Indeed salt appears to impart a limy flavour to the egg probably by inducing an interchange of the fluids within and without the egg.

Water glass (sodium silicate) has been extensively experimented with using solutions varying from 2 per cent to 10 per cent. Although in the main the results have been fairly satisfactory, we are of the opinion that lime water is fully its equal, if not its superior as a preservative, and that this latter preservative is both cheaper and pleasanter to use there can be no doubt.—*Live Stock Journal*.

INFLUENCE OF FORESTS ON THE CLIMATIC CONDITIONS OF A COUNTRY.

With regard to the actual decrease of rainfall consequent on the destruction of forests, Major-General Fisher, R.E., an old resident of Bellary and Ramandrag, supplies the most interesting information in the following note:—

"I arrived in the Bellary district in June 1856, and visited the Ramandrag at once; the hills were covered with a good strong jungle; there was a heavy cloud during the night resting on the hills and for the greater part of the day, rainfall during the South-west monsoon constantly and frequently, during the North-east monsoon it was much lighter in the months of March, April and May, the mango showers were usually very heavy and accompanied with much thunder and lightning. The average rainfall we calculated was then 45 inches in the year; all the springs about the hills ran abundantly throughout the year, and the Nareehulla, the

main feeder of the Daroju tank, with all its tributaries, had water running in them all through the year. The climate of the Drag during the monsoons and the cold weather was quite cold enough to make very necessary, although its elevation is not more than 3,300 feet above the sea-level. The water supply was most abundant during the whole of the hot weather, and the tank was almost always full surplusing very largely during the South-west monsoon.

These observations refer to the years 1856 up to 1864 inclusive, when I left the Bellary district and did not visit the Drag again till January, 1879, I found every thing changed; the jungle has been almost entirely destroyed; the rainfall is most precarious, and certainly not so much as 24 inches in the year; the tank has not filled for the last three years, and is generally 10 or 12 feet below full tank level, the springs are almost free, always dry, dribbling only at the best, the climate is so changed that in the cold water it is hardly necessary to shut the doors and windows, except for the high wind and slight mists of the South-west monsoon, it would not be necessary to close the house at all. The main feeder of the Daroju tank dries up altogether by the end of February, and all its tributaries have no water in them."

Mr. Macartney, the Agent of the Sandar State in the Bellary district, Madras Presidency, also maintains that the rainfall within the last ten years has become lighter and more irregular with the increased destruction of forests by wood cutters and charcoal burners, and indiscriminate grazing of cattle, sheep and goats. Mr. Macartney speaks from an experience extending over 22 years, and supports his observation by the following facts:—

"In the first decade of my residence here, the tank near my house used to be regularly filled every year and to be running over for several weeks at a time. Laterly, though it has accumulated an immense amount of silt, and is now consequently of diminished capacity, it rarely fills. The same remarks apply equally to the Ramandrag tank and to that of Siganken.

The Rushikulya, a river in the Ganjam district, Madras Presidency, is formed by two main branches. One of these coming from the well-wooded hills of Sadara and Pandakol, carries water for nine or ten months in the year, whereas the other, the Mahanadi, taking its rise in the much more open country of Gumsar and Chokapad, is dry for nearly eight months.

A difference of 10 per cent in the average rainfall, combined with a more equal distribution, especially over the drier month, would suffice to bring about the historical changes already noted.

Ebermayer's exhaustive experiments have shown that the mean annual temperature in a closed forest is 10 per cent less than in the open. In both cases the measurements were taken at 5 feet from the ground. The difference is greatest in summer, and consequently to us in India of much greater importance than to the inhabitants of more northern latitudes.

That when a much greater part of India was covered with forests the climate of the country

was on this account different seems equally indisputable. Fa Hian, the great Chinese traveller in India in the 4th century A.D. says, in describing the country, that its temperature was neither cold nor hot.

This as already stated is corroborated by the ruins of an old civilization in many localities where this could not now exist without the large works of artificial irrigation. It may, I think, be assumed that the same state of things would re-establish itself if a considerable proportion of the country were again brought under dense forests which is physically possible; but that this could be effected to the extent desirable by any measures of the forest conservancy that any Government could under existing circumstances apply is out of the question. As this aim cannot therefore in practice be reached, the foregoing paragraphs might be brauded as fanciful and useless, but if it can be accepted that the climate of India would regain its pristine state by a complete afforestation of a large proportion of the country, every step in that direction must exercise a small advance (however immeasurable) in that direction.

During the earlier period of the present administration shifting cultivation (kumti) was practised to a large extent in the central provinces, and several thousands of sugar mills were thereby laid barren year after year.

Early in the seventies this method of cultivation was stopped and extensive growth of young forests sprang upon its place. It is true the whole area is grazed over to a considerable extent and cannot therefore exercise that influence which would exert under more favourable conditions, but it would appear that the influence has nevertheless been beneficial.—[*Forestry in British India by B. Ribbenthorp.*]

(To be concluded.)

SOIL IMPROVEMENT.

The *Fruit Grower* has some useful remarks on the above subject, and as they are such as cannot be brought too often before the mind of the cultivator, we are inclined to follow the example of our contemporary and dwell on the subject for the benefit of our readers.

It is a common complaint that "land is not what it used to be," or "the soil has greatly deteriorated of late." Now the explanation of this very often is that it is not the soil that is at fault, but that its condition is bad. The importance of perfect conditions of soils is patent when we consider the needs of the seeds or plants whose growth it has to support. Seeds require aerated, warm and moist conditions, and the more perfect these conditions the greater success will attend their germination and development. We often come across soils that are sodden during wet weather and caked during dry, but which nevertheless contain plenty of plant food, and it is the work of the cultivator to treat the soil so that the available plant food may be made fit for ready assimilation of the rootlets of plants and trees.

Soil aeration is an absolute necessity if heavy and healthy crops are to be obtained by cultivation. To aerate the soil we must till it, and this soil turning by various methods lies at the bottom of all improvement.

In fact, *ceteris paribus*, the better aerated the soil the more fruitful will it be. "Air-feeding" of soils is thus of the utmost importance to them and the crops they bear. The *Fruit Grower* is very strong on the subject of drainage. "We are so freely convinced of the value of drainage," it says, "that we have said that all soils for fruit-culture cannot be drained too freely—and we repeat it—whether the land be light or heavy." The object to be sought in drainage is to ensure the disappearance of water through and down into the soil. The important results of such drainage (and especially under-drainage) are the increased mechanical action and air absorption that follow. When a soil is well drained the rain percolates through it readily

and sinks tolerably fast into the soil below. Then, it must be remembered that air pressure exerts a force equal to 15 lbs. sq. in. As a result, when rain passes down air is forced to follow, and thus it is that the well-drained soil is aerated by a natural process. The air is, therefore, both drawn and forced into the soil, and the more freely this mechanical process is performed, the better for the fertility of the land.

In badly-drained land, on the other hand, the rain instead of sinking down into the earth is carried away, and thus soil aeration is prevented, and the fertility brought from the air by the rain lost. Though the air collects small proportions of fertility from the air, what it does bring is valuable, and the more that can be obtained in this way the better. The rain brings down from the air carbonic acid gas, ammonia salts and Laccognitric acid, and that is why plants look so much fresher after a shower in dry weather than they did before.

FIRST RUSSIAN TEA.

THE TEA PLANTATIONS OF CONSTANTINE POPOFF IN THE CAUCASUS.

HAVING been closely connected with the tea trade from a very early age, the project of introducing the plant into Europe had long interested me deeply. I clearly saw, however, that before such a scheme could be carried out with any prospect

of success, the conditions under which the plant flourishes in its natural habitat, the various properties of soil most favourable to the growth of the tea shrub, and the processes attending the manufacture of tea in China, would have to be closely studied. It was not until 1889 that I was in a position to carry out my long cherished scheme. For this purpose I visited Hankow in 1899; thanks to the influence exerted in my behalf by some Chinese friends, I was enabled, in spite of the disturbances then agitating the country, to make a thorough study of the cultivation of the plant, and of the manner of plucking and drying the leaves, as practised in the province of Yung-low-toong. I there worked side by side with the Chinese workmen. Twice subsequently—viz., in 1891 and in 1893—I visited China. On the first of these two visits to China I turned my whole attention to the flower teas, as well as to the black, yellow and green teas of Foochow, studying later on the methods of tea cultivation in Moning and Ningchow. On my third visit to China, in 1893, a visit which I consider as the most satisfactory of all, by its results, I succeeded in studying the culture of tea, not only in the provinces I have already named, but in those of Mankong, Sanho, Ta-sar-ping, Yung-low-see, and Nip-car-see, observing the progress of the plant from the first buds to the plucking of the leaf,

noting the conditions of soil and temperature, the atmospheric phenomena, as well as the methods employed in the culture and preparation of the leaf. Ceylon, Java, the Himalaya district, Japan, the Sandwich Islands, and Assam were all afterwards visited, in turn, more than once. The result of these voyages, and several subsequent ones, is that I possess; (a) A collection of specimens of the various kinds of soil in which the tea plant flourishes best; (b) An herbarium of the branches of the tea shrub; (c) A collection of the various parasites that infest the tea plant; (d) A collection of tools used for cultivating the tea shrub; (e) Specimens of the tea-leaf in every phase of its manipulation; and (f) Various kinds of manufactured teas.

I have imported on to my estates in the Caucasus:

- (a) 10,000 tea shrubs from three Chinese provinces—viz., Mankong, Ningchow, and Yung-low-toong.
- (b) 5,000 tea shrubs from Japan.
- (c) 500 " " Ceylon.
- (d) 200 " " the Himalaya district.
- (e) 200 " " Assam.
- (f) 50 " " Java.

Unfortunately, several of the shrubs perished before they reached their destination, I have still, however, 1,257 bushes imported from China, 67 bushes from Japan, 40 from Ceylon, 7 from Java, 16 tea shrubs from the Himalaya district, and 22 from Assam.

The 1,500 bushes which had arrived intact out of the 10,000 imported from China had cost me, by the time they were landed in Batoum, and I had paid the Customs duties on them, close upon £5,000 sterling.

Moreover, as I was particularly anxious that these plants should be given every chance, I had engaged fourteen Chinese labourers to accompany them to Russia, plant them in my estates,

superintend their growth, sow pure Chinese tea seeds, gather the crop, and manufacture the tea. Messrs. Butterfield and Swire, the owners of the steamer on which the plants were carried as far as Port Said, had agreed to demolish the partitions separating the second-class cabins, thus forming a second deck, and obviating the necessity of their being placed in the hold of the vessel. By this means a sufficient quantity of air and light could be assured.

Whoever attentively examines my tea plantations in the Caucasus may make a very clear comparison between the tea plants imported from the various localities, and anyone versed in tea will find no difficulty in forming an accurate idea of the respective merits of each class of tea.

In 1892 I purchased three tracts of land in the district of Batoum—viz., Salibaouri, Kapreshoum and Chakva, comprising, altogether, about 900 acres, and at once commenced preparing the ground for tea-planting. The three estates differ totally from one another both as regards the nature of the soil and the climatic conditions, a circumstance which enables me to judge what elevation is the most favourable for tea culture in the Caucasus.

Before I purchased them in 1892, the three tracts of land were entirely covered with virgin forests of rhododendrons, wild laurel trees with stems thicker than a man's arm, with beech trees and alder trees, twelve feet in thickness and very tall. Thickly intertwined with furze and thistle, the trees effectually shut off every ray of sunshine, while rendering the forests absolutely impenetrable. Such was the tangled and swampy ground it now became necessary to clear and cultivate.

Not satisfied with having imported plants from China and the other localities before mentioned, I procured large quantities of Chinese seeds, as well as smaller lots from the other places, in order to be able to draw a comparison between them. I am obliged to admit that the seeds from China have been comparative failures, notwithstanding all the measures resorted to in order to induce germination. This unsatisfactory result, always the same after many trials, induced me to try and plant shoots from the imported Chinese plants, and this experiment has proved quite satisfactory.

My tea plantations are in my three estates in the district of Batoum; they are: Privolnoe (Salibaouri), Zavetnoe (Kapreshoum), and Otradnoe (Chakva). They are at the following distances from Batoum:—

Privolnoe 3 versts' distance from Batoum
Zavetnoe 6 " " "
Otradnoe 12 " " "

The space occupied by each estate is about:

Privolnoe 120 dessatins (equal to 2.7-10 of an acre).
Zavetnoe 50 " "
Otradnoe 100 " "

The three estates differ greatly both in altitude (from zero to 1,150 feet), in their proximity to the sea, in their accessibility to the influence of the sun and of the wind, and in the properties of the soil. My chief aim in purchasing these three estates was to see clearly, by practical experience, the climatic conditions, etc., which are best suited for the culture of the tea shrub in the Caucasus.

The following tracts of land have now been divided into tea plantations, and planted with tea shrubs of various ages:

In Privolnoe there are about 70 dessatins planted.
In Zavetnoe " " 30 " "
In Otradnoe " " 40 " "
making 140 dessatins in all. I purpose shortly to portion out the rest of available land into new plantations, i.e., about 130 dessatins more.

It is only the seedlings that have been raised from imported seeds that are cultivated on my estates; the tea shrubs that have been grown on the estates are not even allowed to flower, much less to turn to seed. Only a few seedlings have been

raised from our own seeds, in Otradnoe, by way of experiment, viz.:

In 1898 there were 345.

358.

All the rest of the "seedlings" have been raised from imported seeds. In reference to the latter, I may add that, in 1893, besides the chief quantum of China seeds, I imported seeds from other lands as an experiment; but none of the seeds except those imported from China yielded sprouts, or at least, if they did, the sprouts all perished.

In 1895 I once more imported seeds from Ceylon, Assam, the Himalaya district, but it was a last and futile attempt, and from that time I have only imported China seeds.

From 1892 up to the present year I have continued importing seeds from China every spring. It has even sometimes happened that I have received a cargo of seeds in the autumn in addition to those brought over in the spring.

In the year 1899 the seeds imported from China yielded about two millions of sprouts, and in 1900 about three millions, in the nursery gardens.

At the present time my plantations contain the following number of tea shrubs raised from seeds:—

(a) IN ZAVETNOE.

Planted in 1893	from China	seeds	7,228
"	1897	"	8,319
"	1897	Assam	2,464
"	1898	China	56,600
"	1898	Himalaya,	78
"	1898	Ceylon	4,102
"	1899	China	59,052

(b) IN OTRADNOE.

Planted in 1893	from China	seeds	19,802
"	1897	"	35,144
"	1898	our own	345
"	1898	China	388
"	1898	China	34,018
"	1900	"	284

(c) IN PRIVOLNOE.

Planted in 1893	from China	seeds	11,181
"	1896	"	5,023
"	1897	"	18,655
"	1898	"	20,313
"	1899	"	210,455

The original tea shrubs have been planted in small experimental patches in my three estates.

At present there are the following original tea shrubs on my three estates:—

(1) From China, Mankong	401
"	"	Ningchow	.. 447
"	"	Yung low-toong	.. 409

Total...1,257

(2) From Japan	67
(3) " Ceylon	40
(4) " Java	7
(5) " the Himalaya district	16
(6) " Assam	22

Total...1,409

All the rest have perished.

The bushes mentioned above are distributed over my three estates thus:

(1) In Zavetnoe, Assam shrubs	22
(2) " Privolnoe, China and Japan shrubs	662
(3) " Otradnoe, China, Ceylon, Java and Himalaya shrubs	725

Total...1,409

In 1894 I tried the experiment of raising new tea bushes from grafts taken exclusively from China bushes. Of these I have now

(1) In Privolnoe	2509
(2) " Zavetnoe	1350
(3) " Otradnoe	2120

Personally I am inclined to look upon no tea as really genuine but such as comes "from China, and, indeed, only from two or three provinces in China, while, as regards the preparation of the tea, hand labour, such as it is practised in China, seems to me infinitely preferable to mechanical labour.

Notwithstanding this preference, however, a preference which has led me to bring Chinese cultivators to the Caucasus at an exorbitant cost, I found myself forced, after several failures, to procure from England the necessary machinery for the preparation of tea, as well as the framework for a new factory.

Messrs. Davidson & Co., of Belfast, furnished me with the apparatus for drying, rolling, fermenting and sorting the leaves, apparatus for cutting and pressing the green twisted leaves, and also a hydraulic press to form the tea into tablets, and another to make tea in the form of a 'pill'.

The tea 'pills,' for the preparation of which I had to order a new machine, present, I think, a rather interesting and novel feature. They weigh each half a zolotnik (about 14 to the ounce), and should prove very useful for the army, as well as for sportsmen and travellers. A single 'pill,' steeped in boiling water, is sufficient to give a cup of good strong tea, and I believe that before long these 'pills' will be known and appreciated at their true value.

The first tea I prepared and placed on the market was in 1895; the quantity in the year being, however, only 20 lb. Since then the progression has been rapid. Thus I sold: Tea in packets—

In 1895	20 lb.
1896	37 lb.
1897	1200 lb.
1898	2900 lb.
1899	3610 lb.

In addition I sold in 1898 10,000 lb. of compressed tea (tablets).

The tea in 'pills' has been already shown at several exhibitions, commencing with that held at Nijni Novgorod in 1896, then at Stockholm in 1897, St. Petersburg, 1899, and Paris 1900. They were sold at the Exhibition in Batoum, 1900, too.

As regards the demand for Russian tea and the rapidity with which it is bought up, the only thing I can complain of is the small production, which is far inferior to the demand, owing to the newness of the enterprise and the fact that most of the shrubs are very young as yet.

The entire production of the three qualities I have placed on the market—viz. at 2 roubles, 1 rouble 60 cop, and 1 rouble a pound, has been disposed of in Moscow, St. Petersburg, and Warsaw, as soon as offered. Almost everyone who has tried it prefers it to all other tea, many customers buying 10 lb. at a time, in case they may have finished their supply before a fresh one is procurable.

It would be idle to deny that I am somewhat proud of such results. The examination of my teas from the point of view of flavour, as well as the chemical analysis which has been made of it, have proved that if this tea, grown on Russian territory, be not actually superior to the best Chinese kinds, its quality is in no way inferior. There is therefore every ground for hoping that ere long Europe will accord it full rights of citizenship.

CONSTANTINE POPOFF.

Moscow, 15th May, 1901.

GROWTH OF BALATA PRODUCTION.

There are indications that the production and consumption of Balata are increasing, though at what rate it is difficult as yet to say, owing to the want of system which prevails in most quarters in the statistics kept of this commodity. Mr. Henry Souther Tufts, formerly of Boston, who was a recent visitor to THE INDIA RUBBER WORLD offices, stated that he was interested in a company employed in the collec-

tion of Balata in the section, rich in that gum, due south from Ciudad Bolivar, on the Orinoco, in Venezuela. The company has been devoted to this business alone for a year or more, with such success that more capital is to be employed. Mr. Tufts reports that the Orinoco Co., an American company holding large concessions in the delta of the Orinoco, are also devoting their attention in a large measure to the collection of Balata. It seems that the Venezuelan product is shipped chiefly to Hamburg, owing to the predominance of the German element in the trading in the Orinoco valley. But the German trade statistics do not happen to specify Balata. In the German reports of imports of "Kautschuk and Gutta-percha" the following quantities have been credited to Venezuela, and in the opinion of Mr. Tufts the greater part—or possibly all—is Balata:

	1897.	1898.	1899.	1900.
Pounds ...	103,400	219,730	552,420	773,030

Meanwhile the arrivals of Balata at Rotterdam have about held their own, private statistics supplied by Messrs. Weise & Co. being as follows, and the Venezuelan sorts predominating:

	1897.	1898.	1899.	1900.
Pounds ...	497,970	524,920	324,390	407,220

Coming to Great Britain, the official statistics still include Balata in the imports of Gutta-percha, the latest available figures showing the following results (by converting cwts. into pounds):

	1897.	1898.	1899.
British Guiana	.. 538,608	547,120	329,504
British West Indies	.. 87,696	136,976	102,928
Venezuela	.. 9,072	32,256	178,864
Colombia	.. 1,563	17,248	53,200
Dutch Guiana	.. 24,976	58,352	..

Total	.. 661,920	791,952	664,496
-------	------------	---------	---------

How much of these British imports were actually Balata there is no means of knowing, but presumably all, though the figures for Colombia yet require some explanation. The amounts credited to the West Indies were first imported at Trinidad, mainly from Venezuela.

A summary of the above figures shows imports at the three centers mentioned of 1,263,290 pounds in 1897. Allowing as much for Great Britain in 1900 as in the preceding year, the total for that date would reach 1,644,796 pounds. Formerly the Guianas were almost the only sources of Balata, and figures are at hand covering the exports from those colonies very thoroughly for the earlier years of the industry. These figures show the average exports during the five years 1892-1896 inclusive:

British Guiana 229,324 pounds.
Dutch Guiana 185,472 "

Total	.. 415,296 "
-------	--------------

It will be seen, therefore, that the total movement of Balata is taking on greatly increased proportions. It does not appear, however, that the United States have participated in this increase. The official import returns for the fiscal year 1898-99 embraced only 21,913 pounds of Balata, valued at \$7633. But the classification is not very exact at the custom house in relation to this material, and for the year 1899-1900 the Balata item disappeared completely. From the reports of arrivals published monthly in *The India Rubber World* it appears that Balata was imported into the United States during the calendar year 1900 as follows (in pounds):

From Trinidad.	From Surinam.	From Great Britain.	From Hamburg.	TOTAL.
30,500	6,900	23,000	17,291	77,691

The leading firm handling Balata, however, state that their arrivals alone were 75,000 pounds, and that probably 100,000 pounds altogether were imported.

The usual methods of collecting Balata are treated fully in *The India Rubber World* for August, 1899,

by Mr. Joubert. It appears, however, that in Venezuela the practice of felling the trees is general, on account of the much greater immediate return, and the area over which the trees are distributed is so great that no possibility of exhaustion is admitted by those engaged in the business. By tapping, the tree can be made to yield only up to the highest point reached conveniently with a ladder, while by felling the tree the sap can be obtained sometimes for a length of 100 feet or more. Besides, under a method used by the Orinoco Co., all the bark is stripped from the tree, after as much Balata as possible has been extracted, and whatever remains in the bark removed by a chemical process. The high price of Balata is accounted for partly by the relative scarcity of labour. As high as 28 cents per pound has been paid to collectors employed in Venezuela, though payment was made in goods. Again, the better supplies of Balata are remote from navigable streams, one company being obliged to pay 3 cents a pound (= \$60 per ton) for the haulage of Balata to the nearest boat landing.

Sheet Balata is obtained by spreading the sap in shallow pans and exposing it to the sun, the process lasting sometimes nearly two weeks. The dried sheets are 1/8 to 3-16 inch in thickness, and are sometimes rendered thinner by running them between rollers, the chief purpose of which operation is to render the sheets less liable to curl up. Tin plate is well adapted for Balata pans, though the natives use wooden troughs, lined with tree leaves to keep the gum from sticking to the wood.

Block Balata is formed by boiling the sap in kettles holding from 8 to 12 gallons, until it reaches the consistency of molasses candy at the stage when it can be "pulled." It is then formed into masses in size suited to the packing cases, and placed in water to cool. The boiling requires about 2 hours for the first kettleful; the proper heat having then been reached, subsequent lots are boiled sufficiently in about 45 minutes. The cooling and hardening requires 3 or four hours. Packing cases of wood are usually 18 or 24 by 12 inches, and 4 inches deep.

The new treatment adopted in Venezuela does not extend to the whole production from each tree, but is rather a supplementary process. That is, after the usual method of extraction, the Balata remaining in the bark is obtained by grinding the bark and removing the Balata by distillation. Only the inner bark is ground up, the rough outer bark being first cut off. The further processes are kept secret, but naphtha is supposed to be used.

The average yield of Balata milk is about 3 gallons per tree, or 27 pounds, which yield 15 to 21 pounds of Balata. Mr. Tufts mentions having removed all the bark from a felled tree, before extracting any sap, and running it between the steel rolls of a sugar mill, with the result of obtaining three times as much Balata, but it contained more impurities than that obtained by ordinary means.

LATEST BALATA REPORT FROM VENEZUELA.

In the June issue of *Der Tropenpflanzer* (Berlin) appears a report by E. Englehardt, of Ciudad Bolivar, Venezuela, to the effect that during the year 1900 the production of Balata in that country was very largely increased, while the output from the Guianas had become relatively insignificant. The preservation of the trees, he says, has in no wise been considered. They are simply felled and allowed to rot on the ground, although the timber would be of great value if it were possible to convey it to the seaboard. The balata gatherers are compelled to invade the forests deeper and deeper every year, every tree for miles from the original starting point having been destroyed. The only shipments are now made from Bolivar. The rate of increase has been as follows:

In 1897	650,613	pounds.
1898	1,043,170	"
1899	1,659,295	"
1900	2,628,784	"

It will be noticed that these figures, obtained evidently from official sources in the country of production, are much larger than those given in the preceding article, which was prepared before Mr. Englehardt's report was available. It is stated, also, that very little sheet Balata is produced in Venezuela, the block Balata being produced more readily.

During 1900 rubber was shipped from Venezuela only in small quantities, owing to the seat of the revolution which existed for months being in the district whence the necessary labour for rubber gathering is secured. [The rubber from the Orinoco, marketed usually as "Angostura," is of the Paratype, and classified as "fine" and "coarse."] The shipments by the river Orinoco were: Fine, 114,970 pounds; coarse, 32,532; total, 147,502 pounds. However, some Venezuelan rubber, from the back districts, finds its way to the Amazon, being exported through Para, but the total export Herr Englehardt estimates at not over 100 tons for the year. The production for 1901 is expected to be much larger—possibly 400 tons, owing to an increased interest in the business and the investment of new capital on a systematic basis.—*India Rubber World*.

FLOWERING AND SEEDING OF MANWELL BAMBOOS (*DENDROCALAMUS STRICTUS*) IN THE CENTRAL THANA DIVISION, BOMBAY PRESIDENCY.

This bamboo known as Manwell all over the Thana district flowered in the Mokhada Hills, which form the western projection of the Ghats over an area of about 3 square miles in the reserved forests of the village of Assa, in December, 1900 and January, 1901, and the seeding occurred in March. The flowering was not entirely gregarious, but very nearly so, and was confined to the mature clumps. A clump here and there seemed to escape. In the Wada Range, which is in the central portion of the district, I observed the flowering was sporadic and scanty. In the Bassein Range on the Sea Coast, the flowering was a little more copious than in Wada, but not gregarious. I am informed that at Yewa, a village in the Kalyan Taluka of South Thana, the Manwell bamboo planted in the village also flowered this (1900) season, and that about half-a-dozen clumps in the forests close by flowered as well. In these cases, the flowering was not confined, it is said, to the mature clumps only, but also to the younger ones. In 1899 I met with a solitary clump of the same species in seed in the Bhiwandi Range of the South Thana Forest division.

METHOD OF COLLECTION OF SEED.

While in the Assa Forest, in March 1901, I found the wild tribes gathering the bamboo seed for home consumption, and also for sale in the neighbouring native State of Jawhar. The outer culms of each clump are cut one by one at about 4 feet from the ground, and each culm bearing seeds is laid on the ground, which has been previously cleared and swept. The culm is well beaten with a stout stick till all the seeds from it have fallen. The fallen seeds with husks are carefully collected and winnowed by children. It appears that on being taken home, the seeds are crushed in a mortar. One adult is said to be able to collect 2 to 8 seers, i.e., 4 to 6 lb. of seed per diem. Seed was also collected and sold in the Jawhar State which is adjacent to the Assa Forest at Rs 2 per 16 adholies, i.e., 64 lb. I have a few pounds available for distribution if required.

G. M. RYAN,

—*Indian Forester*.

PRODUCTION OF COFFEE IN INDIA.

After noting that the figures are imperfect and defective, and that, for example, the statistics of the Nilgiri district are very imperfect, the Director-General of Statistics reports as follows:—

AREA.—At the end of 1900 there were 245,405 acres of land under coffee in India, all, with the exception of 387 acres, in Southern India. The production of coffee is restricted for the most part to a limited area in the elevated region above the South-Western coast, the coffee lands of Mysore, Coorg and the Madras districts of Malabar and the Nilgiris, comprising 88 per cent of the whole area under the plant in India. About 52 per cent. of this area is in Mysore, where there were 128,087 acres in 1900, and the plant is grown on 99,088 acres, being 40 per cent. of the whole, in the British districts of Coorg (68,596 acres), the Nilgiris and Malabar (30,492). In Madras there is no extensive cultivation except in these two districts, and in Salem and Madura. Coffee is also grown, but on a very restricted scale in Burma, Assam, Bengal, and Bombay.

PRODUCTION.—The fall in prices since 1897 has removed the stimulus which had been given for a few years to the further expansion of the coffee-growing area, while disease has combined with adverse climatic conditions to reduce the yield. The quantity produced last year was but little more than half the quantity produced ten years ago. Taking 100 to represent the area and production in 1885, the ratio of yearly increase or decrease is as follows:—

	Area.	Production.
1885	100	100
1886	97	90
1887	103	109
1888	104	76
1889	110	85
1890	114	63
1891	111	13
1892	110	97
1893	109	109
1894	117	101
1895	119	115
1896	121	75
1897	116	69
1898	118	68
1899	115	50
1900	103	62

PERSONS EMPLOYED.—According to the statements there were 22,128 persons permanently, and 91,685 temporarily, employed on the coffee estates in 1900, making a total of 113,813 persons, which is equal to one person to about 2.16 acres.

EXPORTS AND CONSUMPTION.—The following figures are the average of the ten years ending 1900-01:—

	lbs.
<i>Indian Coffee</i> —	
Production	30,040,608
Exports	30,163,056
<i>Foreign Coffee</i> —	
Imports	1,529,819
Exports	787,520

It is of course not the case that exports have exceeded production during this period; the figures merely illustrate the difficulty of obtaining an accurate view of an industry when those who are engaged in it think fit to withhold information which is indispensable in the consideration of any questions affecting the industry. The figures, however, imperfect as they are, indicate that the Indian producer of coffee has no local market on which he can depend for the consumption of any portion of his production. He is entirely dependent upon the external markets which are contained in the countries mentioned below, these being the principal countries to which Indian coffee is exported (in lbs):

	1897-98	1898-99
United Kingdom ...	12,773,376	17,392,480
France...	8,607,872	9,356,816
Ceylon ..	293,888	509,680
Asiatic Turkey and Persia ..	863,856	131,264
Australia ...	199,024	265,440
Arabia ..	630,896	229,488
Germany ...	297,584	618,688
Austria-Hungary ...	591,360	1,023,568
	1899-1900	1900-01
United Kingdom ..	17,640,000	15,678,768
France...	10,847,936	8,430,016
Ceylon ..	1,224,272	1,088,528
Asiatic Turkey and Persia ..	137,984	610,288
Australia ..	272,496	447,104
Arabia ..	85,232	274,960
Germany ...	292,544	126,560
Austria-Hungary ...	298,704	123,512

As France takes on an average about a third of the whole quantity exported, it is obvious that the Indian coffee producer has an intimate interest in the outcome of the question at present under discussion of the application to Indian coffee into France of a rate of duty higher than that which is imposed upon Brazilian coffee.

PRICES.—Coffee is not sold, as tea is sold, before shipment for export, and therefore there is no Indian quotation of price. The average prices in London for East Indian plantation coffee since 1874 are here subjoined with their variations, taking the price of 1874 as the datum=100. Prices dropped last year, as a consequence of the great expansion in the production of Brazilian coffee to the lowest level known:—

	Per cwt.	Variation.
	s. d.	
1874	92 1	100
1877	110 0½	120
1879	100 10	110
1882	85 4	93
1884	76 4½	83
1887	94 9½	103
1889	99 10	108
1890	106 2½	115
1893	105 4½	114
1894	101 0	110
1897	94 8	103
1898	78 1	85
1899	65 2½	71
1900	48 0	51

—Planting Opinion:

LIME FOR FOWLS.—It has not been demonstrated that oyster shells, or lime in any form, produce egg shell or rather shells for the egg, as there are thousands of hens that are in no manner provided with oyster shells. It is true, however, that oyster shells, being sharp, assist in grinding the food. Carbonate of lime is insoluble, and the lime for the egg shells must consequently come from what can be digested and conducted to the eggs through the blood. As nearly all kinds of food contain lime in a soluble form by combination with vegetable acids, as well as in the form of inorganic salts that are soluble, the process of covering the eggs with shells goes without the aid of substances that are insoluble. There is one source of soluble lime, however, that is frequently overlooked—the water—which holds lime in a soluble form when it abounds in carbonic acid. Hard limestone water contains lime, and the hens can, by drinking it, secure more lime in a convenient form than from oyster shells. When a hen lays eggs with soft shells the cause is due not to the lack of lime, but to the condition of the hen, as she is then, as a rule, in an over-fat condition. To this cause may be traced all the eggs with soft shells.—*Journal of the Department of Agriculture of Western Australia.*

CAMPHOR OIL.

BY PROFESSOR SHIMOYAMA, Ph.D.

(Communicated by Our Yokohama Correspondent.)

There is scarcely any need to say that camphor is one of the chief export staples from the Japanese Empire, and according to statistics, during the first four months of this year 1,435,000 yen worth have been exported. The Formosan Government estimates the annual production in that island at 50,000 piculs of camphor and 20,000 piculs of so-called original oil of camphor, the latter containing 50 per cent of camphor. At present two Japanese merchants in Kobe are engaged in redistilling camphor out of the original oil by arrangement with the Formosan Government. In the course of redistillation two grades of red and white oils are yielded. White oil, more popularly known as camphor oil, finds its way throughout the interior, and is very widely used by the Japanese for disinfection; while red oil is exported to Europe and elsewhere to the extent of from 7,500 piculs at the best to 3,500 piculs at the least annually. This red oil of camphor is used in foreign countries for the manufacture of safrol, which is very widely used abroad in the soap and perfume industries; and is also used as a raw material for the manufacture of heliotropin, the price of which has been reduced from 500 yen per kilo. to something like 17 yen per kilo.

About twenty years ago, when no one knew how to use this red oil economically, and distillers used to throw it away, Mr. K. Goto, a merchant in Kobe, made a trial shipment of it, in order to find a market, but without any success at the time. In 1883 Mr. Peltman, of Messrs. Schimmel & Co., Leipzig, Germany, invented a process for making safrol out of it; thus red camphor oil found its way to Europe. In the first instance prices were abnormally low, foreign buyers paying only 3 yen per picul for it. Since then, owing to increased demand, it has advanced to nearly six times the price; present export quotations are from 17 to 18 yen per picul.

Out of a picul of this red oil 50 cattiees of safrol are produced, so that there is no doubt that foreign buyers were, and are, making enormous profits, as the cost of production is trifling, and they get for safrol 60 yen to 70 yen per 50 cattiees.

When I visited Formosa in February last year for botanical research, by instruction of the Imperial University, I was asked by Dr. S Goto, Chief of the Civil Affairs Bureau, to submit a report about the manufacture of safrol out of red oil of camphor. Consequently I began an investigation in April, 1900, and completed it by July. A detailed report was submitted to the Formosan Government in November. As a result, it was decided to make experiments on a large scale at a cost of 50,000 yen, and the plant has been laid down in Kobe. The result is satisfactory so far, but when the plant is completed not less than 500 cattiees of safrol can be made daily. When safrol is manufactured out of red oil a blue-coloured oil is obtained, which I estimate to amount to 1,000 "koku" in a year. After a long research and hard labours I found that it is a very powerful disinfectant. So I named it "Disinfectant." A sample of it was sent to the Government Laboratory, and I was informed that it has great power as a disinfectant, and is particularly potent in destroying the plague bacillus. In my opinion, it is a stronger disinfectant than carbolic acid, and will be used widely in the interior. It is a custom of the Japanese peasants to use kerosine for killing worms and insects, which sometimes do serious harm to the rice-harvest; and I believe this "Disinfectant" can be used instead of kerosine at a far cheaper rate. The Colonial Government, it is said, is to make practical tests in their experimental agricultural stations. The result will, no doubt, be satisfactory.—*Chemist and Druggist.*

CRUSHING CASTOR SEED.

The 'Dutch mill' is nothing more than two heavy iron uprights connected by two rods on which slide, by means of holes, thin sheet iron plates. One upright carries a screw thread into which a massive shaft, cut into screw form, works. This screw is actuated by long levers fitting into socket holes in a boss at its outer extremity after the manner of a windlass. The castor seed after being carefully shelled or divested of its black skin, and winnowed so that no black particles remain, is bruised and made up into little packets with thin muslin cloth. These are placed between the plates of the machine, one between each division, to the number of 40 or 50. The screw is then tightened upon them, two men working the levers windlass fashion till the oil is expressed. There is a limit of course to the power of manual labour, and the process does not extract the whole oil, much of which remains in the resulting cake. The shelling and winnowing process demands care, as upon the freedom from the black skin depends the purity of the oil; besides which this skin is of a horny and elastic nature and very resistant to pressure. This matters little under the enormous pressure of the hydraulic, but when manual labour is used the incompressibility of the skin would result in a loss of oil, by reason of the resistance offered to the action of the press.

Although this process is called a cold process, it must be remarked that unless a moderate heat is applied to the plates of the machines to heat the seeds, the oil will not flow freely. Heat is applied in practice by shallow troughs of lighted charcoal placed one on each side beneath the row of plates, but not under the seed being crushed. The 'Dutch mill,' owing to its simplicity, is cheap to construct and easily worked by unskilled labour—*Indian Gardening and Planting.*

ORANGE AND LEMON CURING AND PACKING.

BY A. DESPEISSIS.

Late in the autumn the attention of the grower is turned from his deciduous to his evergreen trees, of these, those which are of greatest importance to him are the trees of the citrus family.

As in the case of the deciduous trees which furnish the summer fruit crop, the choice of varieties to grow is made from a long list. In deciding what varieties to plant, several factors will influence the grower's choice, and, amongst others, the peculiarity of the local climate; the requirements of the market to supply; and the character of the soil.

No climate is too warm for trees of the citrus tribe, provided that the parching effect of the torrid atmosphere is mitigated by a sufficiency of moisture in the ground. On the other hand, oranges, lemons and their like, cease to be profitable if grown in cooler climate better suited to the cultivation of pippins or of berries. A few strong trees may be found to thrive excellently under the conditions which prevail in such localities when sufficiently protected, but these are exceptions, from which it would be unwise to draw general deductions.

As regards the susceptibility of citrus trees to withstand hard frost, pomaloes and mandarins come first; they are followed by oranges and kumquats, lemons come next, with limes and citrons last on the list.

A description of each variety of these several species of citrus trees does not come within the scope of this chapter, and the information has already been given.

To the average West Australian grower pomaloes, kumquats, citrons and limes are of as great account. The first three are valuable for their peel, which is candied, whilst limes, and sometimes citrons, are more largely cultivated for the sake of the acid juice of their fruit. As old trees only of these varieties are to be found in West Australian groves, all information referring to the manufacture

of lime juice and to candied peel may well be left out. Mandarins, oranges and lemons are, therefore, of all citrus fruits, those which, having proved themselves well suited to the conditions of soil and climate of this country and to the requirements of our local as well as of our export markets will be reviewed in the following paragraphs:—

MANDARINS.

Of all our citrus fruits mandarins or tangerines are, for the purpose of the local market, the most valuable, the trees are hardy, they bear even when young heavy crops of fruit, they do not occupy much room in the orchard, being dwarf in comparison with other citrus trees. For this reason the crop is easily gathered, the trees are more easily sprayed and protected against the infestation of scale insects—that curse of our orange groves—they are, besides most delicious fruit, easily peeled and greatly liked by everyone, young and old. Our market is at present badly supplied with this fruit, and as growers have, besides, for some unaccountable reason, been somewhat chary in planting them, it is quite unlikely that the demand will, for a long time to come, be satisfied. Nor can the Eastern States supply us with any large quantities of these fruits, as our mandarin season seems to be more protracted over here than it is in the east. Moreover, the fruit is not a very good carrier, the rind being puffy and the fruit tender, and on that account a heavy percentage of the shipments sent over here is lost to the importers.

In order to be profitable, the mandarin tree must be grown on the best of soils, deep, moist and fertile. Of varieties, the best in the order in which they ripen are Parker's Special, Thorny, Queen, Scarlet, Beauty of Glen Retreat and Emperor.

Mandarins can only carry when packed with the greatest care and attention, and when this is done with intelligence, the result is always satisfactory. They are best packed like figs, in shallow boxes, in layers of a dozen each for fruit of the first grade, and eighteen of the second grade, it is not advisable to have more than two such layers. Each mandarin should be wrapped in soft wrapping paper. Some packing houses have their trade mark and name printed on the paper, and as they use large quantities of that material, the extra cost is only nominal. If the mandarins are of especial quality and are meant for a select market, they are often wrapped in tin foil, and packed in neat boxes having an edging of lace paper, with an artistically colored design on the paper cover.

The fruit is, of course, as in the instance of oranges and lemons, carefully clipped and never pulled from the tree, it is allowed to sweat before packing, and none but fruit free from blemish is ever packed.

ORANGES

Are of all the citrus fruit those most extensively planted in this State, where they thrive with great luxuriance. They require good soil, moist, but well-drained, and wherever the best varieties are cultivated in congenial locations and are well fertilised, the West Australian oranges invariably supplant the imported fruit on the local market.

Thickness of the rind and sweetness of the juice, as well as abundance of crops, can to a large extent be influenced by manuring.

Heavy dressings of coarse farmyard or pig manure promote thick and puffy rind, and the growth of spongy wood tissue, particularly liable when under unfavourable circumstances to gumming and die-back diseases. Whenever the trees require a dressing of a nitrogenous fertiliser either nitrate of soda or sulphate of ammonia should be given the preference.

Potash fertilisers influence a thrifty growth, a healthy, deep color of both foliage and of rind, and a greater degree of sweetness. For that purpose sulphate of potash, muriate of potash or kainit can be used. When using kainit the dressing should be more liberal than when either of the first two fertilisers are used.

Phosphates increase the productiveness of the trees and the general excellence of the fruit. Either bone dust, phosphatic guano or Thomas' Phosphate give very good results. When it is intended to benefit more particularly the current season's crop, superphosphate of lime, which is more soluble than the other phosphatic fertilisers, applied in the late winter, or as late as the early spring, will be found most useful. Two to six lbs. of these fertilizers, according to the size of the trees, constitute a very good dressing.

Unlike lemons, which should be picked before they turn yellow, oranges are always better when left to hang until ripe and sweet. There is a degree of ripeness however, which, if over-reached, proves detrimental to the long keeping of oranges.

Nothing but the best fruit, absolutely free from scale insects will carry and open satisfactorily when marketed. Fruit trees cannot carry a heavy crop and sustain large colonies of scale insects at the same time.

For picking the fruit some growers twist the stalk until it snaps; fruit thus plucked have a poor chance of keeping. Clippers that will not injure the fruit should be used in preference to a knife. The stalk is cut short, just above the star; if cut too long, it will probably puncture some of the fruit in the case and thus engender decay.

Some orchard hands when stripping a tree place the fruit in a turned up apron fastened over their shoulders and round their loins; this plan is not to be recommended, as the fruit rolls about and thus gets more or less bruised; light buckets are most convenient for that work; they can be hung until full to the step-ladder and then lowered and emptied in boxes with open salts and there left to sweat until packed for market. These boxes are filled so that one can be placed on the top of another without the oranges below being crushed by the case above.

If a spring cart is not available for conveying the fruit to the packing shed, and more especially if the road be rough and uneven, a bedding of straw in the bottom of the dray will save the fruit from being bruised. When freshly picked the rind of oranges and lemons is indeed brittle and its cells filled with moisture, essential oils and air.

After standing a few days, beads of sweat can be seen on the rind, which then becomes smoother, more pliable and leathery and less liable to be bruised by pressing in the case.

When properly sweated, which will take three to four days, the packer handles each fruit, wipes it dry and grades it according to size and quality. Fruit picked after heavy rain takes longer to sweat and is more easily bruised. It is then wrapped in a piece of tough but soft tissue paper, the four corners being gathered up at the stem end and twisted, thus acting as a spring buffer which saves the fruit around from possible bruises. The paper should not be too large, and of course varies in size with the size of the fruit; that more common dimensions being 9 x 9 inches, 10 x 10 or 10 x 12 inches.

This done, each fruit is firmly set in its proper place in the case, tier upon tier. Should the last layer rise above the edges of the case, quarter of an inch or so, so much the better; the lid is placed on top and pressed down gently and firmly and nailed down. Oranges packed in this way, will not, when opened on sale, be found as several cases of otherwise choice fruits despatched last season to the Agent-General in London, to have "too much paper, be of mixed size, and slacker packed," but they should carry in good condition even as ordinary cargo.

The cases should be made of light and well-seasoned wood, stowed away under shelter until used, so as to protect them from weather stains, and the name or trade mark of the grower, the grade of the fruit, and number in the case should be neatly stencilled on the end pieces.

Two defects should be guarded against with fruit cases. They should not be made of such wood as

might impart to the contents an unpleasant flavour, and they should not be constructed of too flimsy material. When the slats are less than $\frac{1}{4}$ in. in thickness, and especially if these slats are wide, the cases are often damaged and go to pieces when slung in loading and unloading, and much fruit is in consequence injured or lost. A trifling saving may possibly be made in first cost of the thinner packages, and pounds' worth lost in the end on the consignment.

LEMONS.

A few notes on lemon curing will end this chapter. A number of new methods have been propounded for curing lemons by enthusiastic experiments and the results have at times surpassed the most sanguine expectations, and at other times proved disastrous. When all is said and done, the only secret in the art of curing lemons consists of no more than careful handling.

Several desiderata, when found combined, ensure profit to the lemon grower, and unless these are secured there is no money in lemons, which are imported in large quantities from the Mediterranean ports in the height of summer, when they are most required, and sell at a comparatively low price.

The first of these is suitable soil and climate, then come suitable varieties, careful picking and handling, and long storing.

The best soils for lemons is a loose, deep, and well-drained loam, moist and fertile; it also does well on coarse granite soil, intermixed with a sediment of rich sand, but in these soils will require irrigation oftener than in the heavier soils.

Except in the more arid localities, irrigation is deprecated for the first two or three years, so as to force the tree to send its roots deeper into the soil in search of moisture and of nourishment. The wisdom of this treatment is made more apparent in the matter of both water and fertiliser in after years, when the trees are in full bearing. Early irrigation also stimulates an already excessive tendency on the part of the lemon to make too rapid a growth of wood.

The cultivation amongst the lemon trees, as indeed amongst all citrus trees, should be frequent but shallow, as the roots are mostly surface feeders, and too deep cultivation would tear them to pieces.

A climate moist and warm suits the lemon best, as the tree is susceptible to hard frost and loves moisture.

As to varieties, the list is a long one, but three or four stand out prominently, each having its advantages as well as its disadvantages, viz., the Eureka, the Villa Franca, and the Lisbon. Of this last several strains are known, good, bad and indifferent, and every care should be taken, when propagating by buds, to ascertain the merits or the defects of the parent plant.

Picking is the essence of curing, and when lemons have been rightly picked, they will with ordinary care keep for a long period.

All lemons which have reached 3 to 4 inches in diameter, those that have already turned yellow, or show thorn pricks, those that have been punctured by scale insects, or are soiled by the sooty mould, are not fit for curing and long keeping, and should be sold to the best advantage and without delay.

The lemon tree blooms and sets its fruit continuously all the year round, although in the early spring and the late autumn more especially the picking is heaviest. The tree it is known makes in favourable seasons several growths in the year, and likewise produces two main crops, with a few stray lemons in between.

For curing, the autumn pick of lemon is the best. This is done not all at once, but the trees are gone over several times, and the fruit picked as it reaches the right degree of development. At that time the skin is perfectly smooth and the end is filled out; before this time there seems to be a little depression or a little ring at the end. When this stage is reached the rind is thinner and less puffy than

later on, the juice cells are tender and gorged with acid. The months May and June in Australia are the best for picking lemons for curing. The fruit should be picked when still green, with just a tinge of yellow showing. They should be stem cut and handled as carefully as has been mentioned in the case of the orange.

The sizes most suitable for the market are those ranging between $2\frac{1}{4}$ to 3 inches transverse diameter. Some people use a ring for the purpose of measuring the fruit, and every lemon that just goes through is clipped, the eye, however, soon gets trained to the size required, and when in doubt, the forefinger and the thumb round the lemon will, if they nearly meet at the stem, approximate the size wanted.

When picked, the lemons are placed in the sweat boxes, as described above when speaking of oranges and there left for a week or so.

The size of the sweat box is of no special importance, but it should be shallow and not more than 9 to 10 inches deep, with a few slits on the side to allow ventilation, and check the growth of the moulds of decay.

Packing is done when the skin is dry, clear and smooth. Several grades are made, each fruit is handled separately and none but those absolutely without blemish are wrapped in tough tissue paper and cased for long keeping.

When it is intended to store for a long period, the sorted and graded fruit may be placed on shallow trays superposed one on the top of the other in a cool, dark room, with sufficient ventilation provided to carry away the foul gases and the moisture thrown off the lemons. In this way they will keep through the winter until the approach of the warm weather in the early summer. A cool temperature is maintained in the room by opening the door and window at night, and closing them in the day time if found necessary.

Some packers place the fruit from the sweating boxes into barrels or large cases, and run over them five dry sand and thus leave them until they are marketed when the demand sets in later in the year.

Other packers anoint each lemon with a light film of vaseline. For that purpose they rub the fruit all over with a piece of flannel with the vaseline on. It is claimed that vaseline never becomes rancid and is tasteless and odourless, and after a few weeks it is difficult to pick out the fruit that have been thus rubbed with vaseline, as by that time they have lost their oily and shining appearance. Vaseline checks the growth of moulds of decay and prevents the skin drying up too quickly. Some use steam for colouring the lemons, but the process is not to be recommended. Others dip their lemons in some antiseptic fluid and thus keep them sound for a long time, but lemons thus preserved, although bright and fresh when fresh from the dip, soon turn brown and show a horny rind.

In conclusion the art of curing lemons consists in:—
Growing the right kinds.

Manuring, cultivating and tending the trees well and maintaining them in a state of health and thrift.

Picking at the right time and in the proper manner as where the stem is pulled from the lemon the cells are exposed to the air and decay sets in.

Sweating and grading; storing in a cool, dark place. Specially constructed storing sheds have been constructed for keeping cured lemons in, but any ordinary chamber answers the purpose just as well, provided it is not damp or too much exposed to sudden changes of temperature. Such a chamber should be dark and well ventilated.

The lemons are marketed as are the oranges, and in connection with our local market it may be mentioned that the best months for handling the local crops are September and October, and before the November-cut main crop of Sicilians come in, and also in April and May, after the Sicilians are done, and before the cold winter sets in.—*Journal of the Department of Agriculture.*

PRUNING

By A. DESPEISSIS.

In previous chapters the general principles of pruning vines, and also fruit trees, have been dealt with. In this issue the consideration of the best ways of training and pruning a few more of the fruit trees generally cultivated in our orchards is proceeded with.

PRUNING THE CHERRY.

The instructions given about the shaping of young trees apply to the cherry. The stem should be low and headed back to 12 to 15 inches when planting; the main limbs are also cut short, as the tree is very subject to sunburn. To guard against this it is a good practice to pinch all side shoots not necessary for the extension of the tree to a pair of leaves or two; fruit spurs will thus in time be formed all along the lower branches, while these tufts of leaves will afford to the branches protection against the sun.

Cherry trees in general produce their fruit upon small spurs, or studs, from half-an-inch to two inches in length, which proceed from two, three, or four year old wood. New spurs will continue to shoot out right up to the extremities of the branches; in the centre of every cluster of fruit spurs there is a wood spur, which, as it extends each season, bursts into blossom and carries the year's crop; this should be remembered when pruning. These spurs will carry fruit for several years.

Once the cherry tree has commenced to fruit it should, unlike the peach and the apricot, be very sparingly touched with the knife, as it is besides very subject to "gumming." This peculiarity of the plant is aggravated in individuals presenting long stems exposed to the sun, on trees with many forked limbs, and on those which have had large limbs taken off. It is found that by doing all the necessary severe cutting during the summer, and after the crop has been gathered, the wounds heal more readily. Whenever a branch thicker than the size of the finger is cut off it is advisable to apply to the fresh cut a covering of white lead, gum shellac varnish, or hot wax or of clay.

The *Heart* and *Bigarreau* sorts, which are sweet varieties, are luxuriant growers, attaining large size, and possess large drooping leaves. Mazzard stock are preferred for these, the trees being long-lived, larger, and healthy when planted on fairly good loam.

The *Duke* and *Morellos* classes are slow growing sorts of the sour kind. The first have stiff and erect branches with smaller leaves, thicker and of a darker green color than the preceding classes; the second or *Kentish Cherries* are of a bushy habit, with smaller leaves still and more drooping and more numerous twigs. The branches must be kept far enough apart to admit the sun and air freely amongst them, and the stem and main branches strengthened by cutting hard for several seasons. If the tree grows too luxuriantly, an occasional root pruning will throw it into fruit. They do best on Mahaleb stock, which gives smaller trees, but is more accommodating as regards soil. This stock gums on wet, retentive soil. If it were not for the sprouting habit, sour varieties on their own roots do very well. Cherry trees when shaped for the first few years as a rule keep a good form, and bear well without pruning.

PRUNING THE FILBERT.

Suckers should be carefully eradicated every season, and the bushes pruned somewhat after the fashion of the quince, or else they will be a mass of branches, and remain almost barren. Yet the filbert, in the majority of cases, is completely left to itself, although to be fruitful it requires proper and regular pruning. The blossoms, like those of the walnut, are monœcious, i.e., the male flower or the catkins, and the female flowers are borne on the same tree, but from different buds. These fruit buds bear

in a cluster at the extremity of small twigs, and are produced on shoots of one year's growth, and bear the next.

Unless the bushes are pruned, they bear very heavily one year, and remain barren several seasons to recuperate. The mode of pruning consists in cutting back severely the first few years, so as to favour the growth of side shoots, which are shortened to prevent the whole nourishment being carried to the top of the branch, the consequence being that small shoots grow from their base, which carry fruit. By this method of spurring, bearing shoots are produced, which would otherwise have remained dormant.

PRUNING THE WALNUT AND CHESTNUT.

Much of what is said about the pruning of the fig applies to these trees. Their habit of growth is symmetrical, and the growers will, by cutting off misplaced branches, broken or dead, and by shortening bending limbs, do much to keep them growing symmetrically. As their feeding roots are close to the surface, light hoeing only should be done in close proximity to the trees. They should be trained with a general upright tendency, so as to interfere as little as possible with cultivation. Limbs branching low down will protect the stem from sunburn.

PRUNING THE LOQUAT.

The loquat, or Japanese medlar, has hitherto been raised from the seed as a tree suitable for wind breaks. The choicer varieties are, however, now propagated by grafting or by budding, either on its own roots or on the quince, to which it is botanically somewhat related. In the first instance it forms large trees, which take four or five years to mature its fruit. In the second instance it comes into bearing at an earlier age. When grown for shelter the higher trees worked on loquat seedlings should be selected and trained with a stem 3 or 4 feet high. In the second case, whether it is on its own or on quince roots, it should be headed lower down. As the tree carries permanent foliage, and later on heavy crops of fruit, the main limbs should be as strong and sturdy as possible, and trained with a generally upright direction. These in course of time, as the branches extend and carry more foliage and more fruit, will gradually be bent down, hence the importance of throwing strength and vigor into them at an early stage. This is done by encouraging the growth of three or four leaders, low down on the stem (if not grown as a wind break); all other shoots are either cut off or pinched back, and the young tree is subsequently shaped much in the same manner as has been explained in connection with the shaping and framing of young trees generally. The fruit bunches issue from the terminal points of young shoots. They bear at their base wood buds, which will in growing season push out young shoots. These, if too numerous, should be thinned out to two or three only, so as to insure for each its due share of light, air and sun. The decaying flower stalks are cut off, as well as also all dead branches.

PRUNING THE FIG.

Fig trees naturally form symmetrical heads. They are best shaped when young with the main arms arranged symmetrically round the stem. Figs for table purposes are headed low, so that the fruit can be picked without difficulty. Figs for drying are headed higher, so that the picking of the dead ripe and fallen fruit can be easily done over the smooth ground. The fig tree suckers pretty freely, and these should be removed in the winter time. Wherever the ground is rich the tree will often run excessively to wood, and in that case root pruning will force it into bearing. Drooping branches are cut off, and those growing obliquely upright retained. Dead wood and branches that cross and interfere with one another are suppressed, but the end of the shoots should be sparingly touched with the pruning knife on account of the mode of bearing of the tree. This is as follows;—The fruits are

by the daily turning over of the adjacent soil and the addition of clean earth to it. But even on freshly trenched land the method of planting on mounds, as described above in connexion with wet lands, has given very good results. Another mode successfully employed has been to have the trenched land turned over, ploughed if possible, several times in succession at intervals of say a week, or if time does not allow of this, to have the pits for transplanting dug and left open for a day or two, then lightly filled with clean earth up to the surface and a little higher, the young plant being put down so that its roots do not at once come in contact with the crude manure. Growth in such cases is comparatively rapid, as will be seen from the statement attached, giving the height and girth of trees of different ages. The statement of stock in the plantation does not include the fresh supply above referred to, no plants having as yet appeared above ground, 6700 pods were received and opened for planting, giving 20,100 seeds or thereabouts. These were sown without delay. I am reporting on them separately after a reasonable time has been given for seedlings to come up.

5. *Species other than Hevea*. There is abundance of Ceara (*Manihot glaziovii*), and in response to a request of the Director of Agriculture I have forwarded a Wardian case of it to the Superintendent Northern Shan States for experimental cultivation. In the same case I have sent a few specimens of Para rubber, but without much hope of their thriving in so extreme a climate. The Superintendent having been kind enough to offer, when returning the Wardian case, to give me a supply of plants obtainable there, I have asked him for *Ficus elastica*—a tree I think might be successfully grown on the higher land in B Block of this plantation, where *Hevea* has not done well.

I have two remarkably healthy specimens of *Castilloa*, and if the seeds you have been kind enough to order for me from Trinidad do as well, I should be inclined to suggest that this plantation be devoted mainly to *Castilloa*, leaving the culture of *Hevea* on a large scale to be dealt with at Mergui, where the climate undoubtedly suits it better. This of course assumes that we get the true *Castilloa*—the Mexican *Hule*, and not the Panama *Tunu* which has proved worthless in Ceylon and elsewhere. Reports from Trinidad shew that they have secured the real *Castilloa elastica* there.

Two specimens of *Payena Leerii* are also thriving, and in fact so closely resemble many indigenous jungle-plants that I should not be surprised to hear that this gutta-percha yielding plant is after a native of Burma, as well as of the straits and Borneo.

Of creepers from Africa (*Landolphia Kirkii* and *Vahea Senegalensis*) I have a fair stock. They give no trouble, and look healthy.

6. *Roads and Buildings &c*. There is not much to be noted under this head. A Norton's tube-well was sunk at a cost of Rs. 65 and water found. A new Road has been made by the P. W. D. from the Kokkaing main road about a mile south of the plantation gate, to the village of Kambe. This will be useful as a second approach to the plantation and to the land purposed for its extension.

A mounding-mill, for the conversion of nightsoil into manure without the delay involved in trenching and waiting upon nature for the completion of the process, is under construction. I do not expect it to be of much use during the rains, but in the dry weather it should be capable of providing all the manure the plantation requires, and in a more portable and cleanly form. Manure prepared by this process is almost inodorous from the first.

7. *Experiments*. I have submitted about twenty trees to marcottage. Of these, six have thrown out roots, and cuttings have been detached and planted in the nursery. So far they are doing well, but past experience is not encouraging as regards repro-

duction from cuttings. Last year's cuttings of which in your remarks on my report you asked that a careful record should be kept, did very well for about three months after they were put down, then (during my absence on leave) sickened and died. Being the rainy season it could not have been for want of water. Possibly they had not the vigour necessary to resist the weeds and the jungle surrounding them. The present cuttings will be given a better chance by planting them in prepared soil. As regards our experiments in root-grafting upon cuttings, you have yourself noted their want of success. I do not think it desirable to sacrifice well-grown trees for the sake of a few doubtful cuttings, so have not continued the experiments.

J. A. WYLLIE.

Major I. S. C.

Secretary Cantonment Committee, Rangoon

From F. B. Mansou, Esq., Officiating Conservator of Forests, Tenasserim Circle, to the Revenue Secretary to the Government of Burma,—No. 1092, dated the 17th July 1900.

WITH reference to correspondence resting with your letter, Forest Department No. 401-4R.—1, dated the 17th April 1900, relating to the small plantation of India-rubber at kambe, beyond Kokkaing, I have the honour, to forward, in original, Major Wyllie's letter No. 47-6, dated the 6th July 1900, with three enclosures, this being his first annual report.

2. I have recently visited the plantation and beg to offer the following remarks:—

Paragraph 2.—The shedding of leaves in the cold weather is only natural.

Paragraphs 3 and 6.—A continuous fence is, in my opinion, necessary for excluding cattle. Until this can be provided, the barbed wire fence of the original plantation, namely, the square on D, D 10, D 20, D 30, has been utilized to protect those parts of the boundary most in need of it.

Paragraph 7.—The trenching operations will doubtless be beneficial to the rubber plants, and are not so offensive as I expected.

Paragraph 9.—The plantation has been neatly laid out and the compartments are being numbered.

Paragraph 10.—The sowing of seed at stake has not been so successful as raising plants in nurseries, but there can be no doubt that the seed was of poor quality. The seed put out at stake was probably also more subject to the depredations of rodents.

Paragraph 13.—The propagation of *Hevea* by cuttings should be continued, a careful record being kept of the number of cuttings put down, the per-

centage of success, and remarks standing any abnormal conditions affecting the result.

The plantation has been made for the most part in scrub jungle, but partly on cleared land covered with turf. On the latter it is known to be difficult to raise forest trees owing to the absence of shelter. The covering of turf is also disadvantageous. If labour can be spared, the turf should be hoed up around the *Hevea* plants to aerate the soil. The plants which have been put down in the jungle look healthy, but they must have head room. Overhanging brauches must be cut back, and the plants be kept free from creepers.

Paragraph 15.—It is a pity to plant *Ceara* in the place of *Hevea*, except it be to provide shelter for *Hevea* which will be planted later.

Paragraph 16.—An order has been given for the plants referred to in your letter No. 401-4R.—1, dated 17th April 1900. *Hevea* and *parameria* seeds will be ordered from South Tenasserim.

Paragraph 17.—This shows that a satisfactory beginning has been made.

Paragraph 18.—The arrangements appear to be quite satisfactory. Receipts to the extent of Rs. 100 are already shown, and the sale of fodder grass may bring in some more revenue.

Paragraph 19.—The men seem to be good workmen, and I understand that the mouey advanced for their journey from Madras is being recovered.

Paragraph 20.—The masonry well should be made as soon as possible for irrigating the plantation in dry whether.

Paragraph 21.—The area of the plantation is small. It will be an advantage if it can be extended hereafter. A larger plantation could be more economically managed.

3. If Major Wyllie's report is printed, I should like to have ten copies.

From Major J. A. WYLLIE, Secretary, Cantonment Committee, Rangoon, to the Conservator of Forests, Tenasserim Circle,—No. 47-6, dated the 6th July, 1900.

KAMBE RUBBER PLANTATION.

I have the honour to submit, as the annual report for the first year of experimental cultivation:—

(i) Extracts from notes of stock taking, in continuation of those accompanying my No. 93-6, dated the 10th October 1899.

(ii) A plan showing actual progress of planting operations up to date; and

(iii) Statement of the labour employed.

2. From the figures in statement (i) it will be observed that the young plants put down in the original 2-acre enclosure (737 in number) did well up to the close of 1899. But at January's stock-taking this year many were found sickly and apparently in want of special watering, shading and manuring. I accordingly took on some extra hands, and by giving individual attention to each plant in turn a fair number were induced to put forth fresh leaves. Others were saved by transplanting fresh pits being dug to a depth of 18 inches and filled in with manure. Where the natural shade of the jungle was insufficient, gabions to serve as shade and wind screens were placed round each tree.

3. Between January and July the original enclosure was gradually planted up to its full capacity with seedlings of *Hevea* from a nursery (raised from seed planted early in September 1899). It will soon become desirable to move two sides at least of the fence you put down in July 1899, so as to form a plot 500 feet by 500 feet and thus accommodate (at 10 feet by 10 feet intervals) 2,500 trees in all. The present capacity of the enclosure is 900 trees.

4. You will see from my letters Nos. 148 and 149-6, of the 8th February and 16th March 1900, that the extension of the plantation up to the south-eastern boundary of the Military cholera camp (minus a small portion specially asked for by the

Executive Engineer, Construction Division, to give access from the camp to the Kambe tank) has been arranged for; also that the Deputy Commissioner, Hanthawaddy District, has assigned for temporary occupation by the Forest Department a portion of waste land lying between the west edge of the "dangerous zone" and the Kokkaing high-road. This I have added to the area under cultivation and planted it up from last September's seedlings on the lines shown in plan (ii).

5. *Roads, fences, and buildings.*—Through the extended portions of the plantation I have cut (and partly completed) cart-tracks, taking off from the high road at the south-west corner of the additional land assigned by the Deputy Commissioner. With that officer's permission three huts have been erected beside the first cart-track, one as a store, the others as dwelling-houses for the gardeners and trench-coolies employed in cultivating and manuring the land. At the Deputy Commissioner's suggestion I have marked each hut distinctly to show that it is Cantonment property and not to be taken as the occupant's own. This should defeat any attempt to prefer squatters' claims hereafter.

6. Two streams crossing the cart-roads have been bridged by wooden culverts, paid for as Cantonment conservancy works, as they serve mainly for the passage of the Cantonment night-soil carts. As regards fencing-in, the southern limit of the plantation has been left indefinite for reasons which I will explain at the end of this report, but temporary fencing is being carried out on all the other sides, quick-growing trees having been previously planted to mark the line for a permanent hedge. Belts of these trees have also been planted wherever the existing jungle is so thin as to expose the *Hevea* to damage from high winds.

7. *Manuring.*—As arranged prior to your departure on privilege leave, the night-soil trenching of the Cantonment is now being carried out on the planted as well as the unplanted land. I have submitted a full report of the methods employed to the Cantonment Committee (Meeting of 9th March 1900). Where risk of injury to the young trees might result from the passage of the carts, the manuring is done outside on the mounding system, i. e., the night-soil is mixed with dry earth and stirred till it becomes an inodorous, clayey mass, when it is spread out to dry and removed in baskets to be worked into the soil near each tree.

8. The unplanted lands are being prepared by the ordinary method of trenching, filling, and covering with earth. Similarly, with the land intended for nurseries and for cultivation otherwise than with rubber (some portions are unsuitable for rubber-growing), except that fresh wood-ashes and leaf-mould are added after covering the trenches. The results of manuring, so far, seem satisfactory. On the 7th ultimo the plantation was inspected by Major Davies, R. A. M. C., Bacteriologist with the Government of India, and Colonel Branfoot, C. I. E., Principal Medical officer, Rangoon district. These officers noted and, I believe, approved from a sanitary point of view the arrangements made for combining sewage-disposal with cultivation. I trust the scheme will meet with the approval of the Government of Burma.

9. *Laying out of the plantation.*—*Vide* Enclosure (ii). Parallel lines 100 feet apart run throughout the length of the area taken up, crossed at right-angle every 100 feet by similar lines, thus dividing the total area into squares of 100 feet side whenever possible. On either side of every such line or cross-line the jungle has been cut back to a depth of 5 feet, thus leaving a 10 feet lane. Starting from a point 5 feet from the intersection on either side of the central line a pit has been dug and a rubber tree planted. By this means a path has been kept open for the gardeners, retaining the back-ground of original jungle as shade for the young plants. As

the trees come to maturity and seed, it is likely that spontaneous seedlings (as at Mergui) will spring up, converting the sides of the 10 feet land into a nursery for the adjoining square of jungle. That square can then be subdivided into four squares of 50 feet side, and the dividing lines planted on the same plan. These again can be further subdivided and planted up until the minimum interval of 10 feet by 10 feet is reached.

10. You may remember (*see* paragraph 4 and 5 of my report No. 93-6, dated the 10th October, 1899) our planting out at stake, between the 31st August and 5th September 1899, 3,780 seeds of *Hevea Brasiliensis* on unprepared land. It was arranged that these plants should not be tended in any way, but simply left to nature, as an experiment made to ascertain whether *Hevea* forests could safely be started on such a plan. From these seeds I regret to say only 32 plants are now in existence.

11. This result was not altogether unexpected, as the seed in question was doubtful, having been kept too long before it reached Rangoon. But, as I succeeded in raising nearly 25 per cent. of plants from the same consignment of seeds, planted under shade in a prepared nursery and watered daily, the age of the seeds, is evidently not the only reason for the failure.

12. The few trees remaining from this experiment, have only been saved by artificial shading, watering and manuring. Of 75 trees found alive on the 1st January 1900, the heat and drought of February and March have killed 43. It may not be correct to condemn planting out at stake as a means of forming *Hevea* forests elsewhere in Burma, on the strength of this series of observations, but the results of nursery cultivation are clearly more satisfactory as far as Kambe is concerned.

13. I have tried the reproduction of *Hevea* by cuttings a method which answers admirably for *Ceara* rubber, by the way. Of my experiments in *Para* rubber I can report 56 successful, 56 doubtful, and 121 failures. The uncertainty of the rains this season has led to an unusual number of failures among newly transplanted seedlings, so that the cuttings, come in opportunely to fill blanks. I find it necessary to arrange for artificial shading whenever a seedling or cutting is planted out, unless the natural jungle happens to be very thick. As the trees grow, the jungle can be cut back, but to what extent it is advisable to clear the undergrowth will be matter for future observation. I must say, however, that where weeds and under growth among the plants here have been removed, none of the bad results observed in Ceylon and elsewhere have followed.

14. There are now in the plantation—

<i>Hevea</i> trees of first planting (July 1899 ...	696
<i>Hevea</i> trees of second planting (Sep, 1899 ..	32
<i>Hevea</i> trees put down to replace dead trees...	29
<i>Hevea</i> seedlings of 1899 planted cut 1900 ..	1,169
<i>Hevea</i> cuttings do do do ..	233

Total trees of *Para* rubber . . . 2,159

15. *Ceara rubber (Manihot glaziovii).*—The stock of seedlings and cuttings this year is a fairly large one, so much so, that in planting out I may have to encroach to some extent on the land reserved for *hevea*. I have marked out a nursery at Kambe for the propagation of this tree, and stocked it from cuttings of the young trees planted last year, and of older trees in the Cantonment Gardens. This is a very hardy plant and requires on special care. I can easily make a large stock of young plants available, should Conservators of Forests in Burma or elsewhere require supplies.

16. *Other rubber trees and vines.*—The seeds for *Castilloa* ordered by last year have not yet been received. The same remark applies to the *Mangabeira* rubber, for which an order has, I understand, been

sent to Brazil by your *locum tenens*. The folliclea of *Parameria glandulifera* sent me by you on 18th July last have produced nothing. I have ordered seeds of *Choransesia esculenta* to be collected and planted under the wild mango trees in the centre of the plantation. There are about 25 or 30 specimens in the Cantonment Gardens, planted by me in 1896, and doing fairly well, but they have not yet fruited.

17. *Area taken up*.—Gross acreage 32.14 acres. Deducting unsuitable or otherwise occupied land 4.5. Net acreage for planting 27.64 acres. Planted as follows:—

Block,	Contents.	Stock, 1st July.	
		<i>Para.</i>	<i>Ceara.</i>
A	<i>Para</i> on 100 feet lines, part planted.	625	..
	<i>Ceara</i> on northern triangle not yet planted. Southern belt part planted	40
B	<i>Para</i> on 100 feet lines, part planted.	186	..
	<i>Ceara</i> on Southern belt, planted 10 feet by 10 feet	180
C	<i>Para</i> on 100 feet lines, part planted ..	463	..
	<i>Ceara</i> not yet laid out for planting
D	<i>Para</i> on 300 feet by 300 feet fully planted at 10 feet by 10 feet intervals. Rest of block planted on 100 feet lines ..	880	..
	<i>Ceara</i> scattered trees on fence line	30
	Total trees	2,159	502

This calculation is exclusive of dead and doubtful trees and of nurseries containing about 60 *Para* and 1,000 *Ceara* trees to be planted out shortly.

18. *Establishment*.—The grant sanctioned by Government for the current year is Rs. 500, with a promise of its increase, if necessary. To the amount drawn may be added a sum of, say, Rs. 100, the yield of land included in the plantation, but unsuited for India-rubber growing, making the sum available about Rs. 600. This would of course be inadequate were it not so arranged that the plantation is worked as a sewage farm. Thus the co-operation of the night-soil trenching staff is secured. Their pay is a charge to be met from the General Cantonment fund. Statement III shows the sanctioned scale for actual trenching work apart from the labour employed in collecting and carting out the night-soil, as well as the staff engaged and paid out of the rubber grant. This will give an adequate idea of the cost of the experiment as a whole.

19. For the better working of the project I have engaged a small gang of Mappillas from Malabar. Those men show a keen interest in their work, and, though I must acknowledge the pains taken by the Burman head mali and the Coringis under him to make the cultivation a success, I prefer the Mappilla to the Coringi, on account of his physical strength and energy if for no other reason. It is too early yet to report definitely on the gang, but they show capacity and I hope will justify their importation.

20. *Future requirements*.—As the plantation extends, more attention, and possibly a larger temporary establishment will be required for watering and shading young trees in the dry weather. A masonry well in a central position will sooner or later become necessary, and for access of the carts to the ground to be manured (especially in the wet season) the main cart-tracks should be covered with laterite. There is abundance of laterite in the adjoining cholera camping ground, but for its extraction the orders of the Government of India in the Military Department are necessary. The General Officer

Commanding Rangoon District has been applied to in this matter in the interests of Cantonment conservancy.

21. Another point for consideration is the acquisition of land in extension, should the present experiments be approved by Government. Extension to the north and to the east is barred by the cholera camp and the kambe tank, but the soil of the whole "dangerous zone" of the Kokkaing rifle-range to the south (*i.e.*, to the stop-butts of the rifle-range itself) is of the same class as that of the land now occupied.

22. The plantation at present is, for all practical purposes, safe from stray bullets and will be so until the impending change in the weapon used by native troops take place. Although a much-used throughfare crosses the line of fire at 300 or 400 yards beyond the butts, no accident as far as I can ascertain has ever been reported to the District authorities. But with the '303 rifle in use, as may be the case next year, not only the military cholera camp, but nearly half a mile of metalled high-road (the circular road round the Victoria Lakes) will fall into the "dangerous zone," and accidents may then be looked for.

23. Under these circumstances, there is every probability that the Military authorities will move for the range to be abandoned and the musketry of the whole garrison carried out upon the Thamaing rifle-range, which is suited to weapons of greater carrying power. Should this occur, it might be desirable that the land be created a forests reserve and planted up throughout its length with India-rubber.

Statement of establishments employed upon the Combined Rubber Plantation and Conservancy trenching-ground at Kambe.

Establishment.	No	PAID FROM CANTONMENT FUND.		PAID FROM RUBBER GRANT.	
		Rate per mensem.	Rate per annum.	Rate per mensem.	Rate per annum.
		Rs.	Rs.	Rs.	Rs.
(1) Head gardener (Burman rated on Cantonment establishment as trench cooly).	1	10	120	5	60
(2) Trench maistry (Koringi sweeper caste) ..	1	15	180
(3) Garden coolies (Mappillas) ..	4	11	528
(4) Trench coolies (Mappillas) ..	2	11	264
(5) Trench coolies (Koringi Hindus) ..	2	10	240
(6) Trench coolies (Koringi sweepers) ..	5	10	600
Total ..	14	..	1,404	..	588

(1) Duties include supervision of all day work, whether trenching or gardening—two-third pay to Conservancy, one-third to garden.

(2) For night work. Receives night soil carts as they arrive (midnight to 4 A.M.) and sees contents discharged into trenches and buried by the sweepers.

(3) General gardening operations. To help in opening trenches if required, but not in filling them.

(4) To open trenches on clean lands only.

(5) To open trenches, and repair and extend cart-tracks, fence, &c.

(6) To cover in trenches and to mound night soil &c.

HINTS ON PLANTING CITRUS TREES.

By HON. T. H. SHARP.

THE HOLES—Dig holes 2 feet wide by 1 foot deep, 20 feet apart each way a week before planting if possible. The earth out of the holes should be placed in two heaps, on either side of the hole. See that the land is well drained.

PLANTING.—Expose the roots of the plant as little as possible. Examine and cut away all injured and broken roots. Dip the roots of the trees in a bucket of thick wood ashes and water and leave them there. Draw the surface earth surrounding the hole into it, leaving the two heaps intact. When the hole has been filled add a little from each heap so as to make a large mound—place the plant to stand on top of the mound and lay all the roots out in their natural position, then open the mound, place the tree in the earth, breaking down one side of the mound so that your hand can get under the tree—get hold of the end of the tap root and see that it is not bent—press the earth firmly around it and ram with the hand to settle it. Then carefully raise the roots with the back of your hand, placing them in their natural position, ramming in earth all the time under the roots until you get to the base of the tree. Should some of the roots be longer than the width of the whole be careful not to bend them in, but break the land with a fork and lay the roots out at full length, covering them with fine surface earth about two inches deep. When you have finished planting, the crown roots or part of the tree which originally joined the earth, should be four to six inches above the surrounding land, because the mound will gradually subside, and it is fatal for the tree to sink below the level of the surrounding earth so as to be in a hollow. Nine out of ten citrus plants are planted too low in the first instance. Be sure to press the earth above the roots and around the tree with the naked feet, for unless the tree is firmly set in the earth, the wind will start it shaking, and as it begins to shake a little space will appear between the earth and the tree leading down to the roots, and the air will get in and kill the tree. Be sure to press the earth around the roots and around the tree after planting; it is absolutely necessary. Be very careful to see that fine earth is pressed against every part of every root, or small cavities will be left against the roots and the foul air will start to rot that portion of the root and injure the tree. After planting put one basket of stable manure around the top of the mound, and water. Do not let the manure be within six inches of the stem of the tree. After watering throw some light trash over the mound, then examine the top of the tree, and cut back to within one inch of the first joints which show good buds. The stem should be within three or four feet above the level of the ground. Do not wrap paper or anything around the tree to shade it from the sun, because it will offer such resistance to the wind as will cause it to shake the tree. Be careful not to cut back your tree too much; if you cut below the soft wood and succulent buds it will not live; better to leave too much than too little on the tree.

AFTER PLANTING.—As soon as the tree starts to grow do not go fooling with it by cutting and pruning and disturbing its system, remember that every leaf it puts out has its corresponding root, and what you want is to create growth with vigour. Placing manure or anything but fresh, fine, sweet earth in the hole before planting is a mistake; the tree cannot feed on coarse manure at its start, and it congests around the new roots, and very often starts acidity at the base of the tree. If no rain falls, water every third day after planting until the tree starts to spring. The citrus family are not great water drinkers, and after starting them they do not require very much more

than the rain they get. When practicable plant two Castor Oil seeds about four feet from each hole; they will grow and form a good shade for the trees and keep off insects. Two weeks after planting throw on the balance of the two heaps of earth to cover cracks.—*Journal of the Jamaica Agricultural Society.*

Eltham Park, Jamaica.

RAISING TURKEYS.

1. Never let the young turkeys get wet. The slightest dampness is fatal.
2. Feed nothing the first twenty-four hours after they are hatched.
3. Before putting them in the coop, see that it is perfectly clean and free from lice, and dust them three times a week with insect powder.
4. Be sure the hen is free from lice. Dust her, too.
5. Look out for mites and the large lice on the heads, necks, and vents. Grease heads, necks, and vents with lard, but avoid kerosene.
6. Nine-tenths of the young turkeys die from lice. Remember that.
7. Filth will soon make short work of them. Feed on clean surfaces. Give water in a manner so that they can only wet their beaks.
8. The first week feed a mixture of one egg (beaten) and sifted ground oats, mixed with salt, to taste and cooked as bread; then crumble for them, with milk or curds, so that they can drink all they want. Feed every two hours early and late.
9. Give a little raw meat every day; also, finely chopped onions or other tender green food.
10. After the first week, keep wheat and ground bone in boxes before them all the time, but feed three times a day, on a mixture of cornmeal, wheat middlings, ground oats, all cooked, and to which chopped green food is added.
11. Mashed potatoes, cooked turnips, cold rice and such, will always be in order.
12. Too many hard boiled eggs will cause bowel disease.
13. Remove coop to fresh ground often in order to avoid filth.
14. Ground bone, fine gravel, ground shells, and a dust bath must be provided.
15. Finely-cut fresh bones, from the butcher's, with the adhering meat, is excellent.
16. They must be carefully attended to until well feathered.
17. Give them liberty on dry, warm days.
18. A high roost, in an open shed, which faces the south (north here), is better than a closed house for grown turkeys.
19. A single union of a male and female fertilizes all the eggs the hen will lay for the season; hence, one gobbler will suffice for twenty or more hens.
20. Two-year-old gobblers with pullets, or a yearling gobbler with two-year-old hens is good mating. Gobblers and hens of the same age may be mated, but it is better to have a difference in the age.
21. Turkeys can be hatched in an incubator and raised to the age of three months in a brooder, but only in lots of twenty-five, as they require constant care.
22. Capons make excellent nurses for turkeys and chicks.
23. It is not advisable to mate a 40-pound gobbler with common hens, as the result will be injury. A medium sized gobbler is better.
24. Young gobblers may be distinguished from the females by being heavier, more masculine in appearance, more carunculated on the head, and by a development of the "tassels" on the breast. A little experience may be required at first.
25. Adult turkeys cannot be kept in confinement, as they will pine away. By feeding them in the barnyard a little, night and morning, they will not stray off very far, but they cannot be entirely prevented from roaming, and the hen prefers to make her own nest.—*Poultry Keeper.*

CINNAMON IN LONDON.

The news brought by a recent mail touching the last quarterly sale of cinnamon reads better than the telegram we published three weeks' back. The prices realized for the finer qualities of spice are decidedly encouraging—being almost on a level with the highest prices recorded in recent years; while those obtained for lower marks and "unworked" were by no means bad. The result was probably due, in great measure, to the moderate offerings, only 834 bales having been catalogued last month, against 1,141 at the corresponding sale last year, and 1,088 bales in May last. Our export tables for the last seven or eight months showed that there had been a wholesome check to the steady increase in production, whose effect on prices is naturally depressing; and the consequence was a catalogue of reasonable proportions. The demand for fine cinnamon, which can bear the cost of the operations of unbalancing, examining and re-baling, known to the trade as "worked," was such as to have ensured the clearing of the whole of the 395 bales which offered, at prices which were in some cases as much as a penny in advance of those realized at the second quarterly auction for the year—Firsts realising as high as 1s 7d, Seconds 1s 5d, Thirds 1s 4d and Fourths 11d. Of "unworked," 300 bales changed hands at prices ranging from 8½d to 11½d—leaving less than one-half that quantity unsold by auction; but such leavings are generally taken off almost immediately at sales' rates underhand. Any way, the statistical position of the spice is good, as will be seen from the figures appended to the Report we give below—both quilled bark and chips showing appreciably lower stocks than at this time last year. Only of so-called "wild Cinnamon" is the quantity greater; while the fact that the enormous quantity of wild chips, 8,037 bags, which was shown in last year's stocks, remained unaltered this year, confirms the report that this recent and discreditable addition to our exports is quite neglected. The discovery by importers and exporters that the prices offered are insufficient to cover even the Dock charges incurred, is likely to give the quietus to a trade which should never have begun, and which, we are glad to think, has not benefited those who doubled in it.

While the restricted output of the first seven months of the year has undoubtedly helped prices, it must be noted that there has been quite a rush of shipments the last few weeks; and the exports to date for the last four years compare as follows:—

Total Export from 1st Jan. to 16th Sept.	Bales.	Chips.
	lb.	lb.
1901	1,627,200	915,156
1900	1,602,639	1,040,414
1899	1,509,545	1,403,288
1898	1,722,301	794,539

The following is Messrs. Forbes, Forbes & Co.'s Report on last sales in London:—

LONDON, 27th August, 1901.

CINNAMON.—The third series of auctions for the year were held yesterday, when 834 bales

Plantation kinds were offered against 1,088 bales in May, and 1,141 bales at this period last year. Of this supply 395 bales were "worked" and 439 bales "unworked."

There was a very fair demand and the whole of a 395 bales "worked" spice changed hands at last sales prices to occasionally one penny per lb. advance. For the "unworked" the demand was not so good, barely 300 bales being cleared, good sorts going at firm prices, but common sorts a shade cheaper here and there.

"Worked" Firsts ranged from 11d to 1s 7d; Seconds 9d to 1s 5d; Thirds 8½d to 1s 4d; Fourths 8½d to 11d per lb. "Unworked" Firsts 9½d to 11½d; Seconds 8d to 11d; Thirds 8½d to 11d; Fourths 8½d to 9d per lb. Of so called "Wild" Cinnamon 687 bales and bags were offered, but were quite neglected, a few bags only meeting a bid of a half-penny per lb. not sufficient to cover the Dock charges incurred.

CHIPS, &c.—664 bags offered, about 160 bags less sold; chips 2½d to 3½d. Quillings 7d to 8½d per lb. The ss. "Prometheus" with some Cinnamon on board arrived in the River on 24th inst. too late for the sales.

	1900.
Stocks of Ceylon	1,736 bales 2,544 bales.
Do do chips	3,236 bags 5,205 bags.
Do Wild	2,633 bales 2,581 bales.
Do do bark, &c.	8,037 bags 8,037 bags.

The next auctions will be held 25th November.

THE BURLIAR GARDENS.

I observe that you would like to know the situation, elevation, etc., of Burliar. Burliar is situated on the Coonoor Ghat, within a few miles of the S. E. base of the Nilgiris, at an elevation of about 2,400-2,500 feet. The garden is only about seven acres in extent, and a considerable variety of tropical and sub tropical plants are cultivated in it.—R. E. P.

TESTING PRECIOUS STONES.

The United States Consul-General at Frankfort in his last report, calls attention to a lecture on precious stones, recently delivered before the Industrial Association of Berlin, by Dr. Immanuel Friedländer, in which it was stated that the testing of diamonds is comparatively simple. The common test for hardness suffices. If the stone resists strong attacks, it is certain to be genuine; if it does not, the damage is insignificant as only an imitation has been destroyed. The test, however, is doubtful with rubies. If a ruby can be affected by a steel file or by quartz, it is not genuine, but such a test with a topaz is likely to injure a valuable stone. The test for hardness is of no avail with emeralds, as these stones are not much harder than quartz, and in addition possess the quality of cracking easily. For examining rubies and emeralds the optical test is best. A glass magnifying about one hundred times suffices. Every expert knows that almost all precious stones have, according to Dr. Friedländer, little flaws. Nearly every ruby, and all emeralds have many defects, which are so characteristic that the genuineness of the stone is readily established. Such a test is necessary with rubies, because the imitations are very deceiving. Their colour is absolutely durable, and often much finer than that of the genuine stone, although it may be stated that a somewhat yellowish tint is always suspicious. The only reliable way in which genuine rubies can be distinguished from imitations, is by the minute air bubbles of the latter, which become clearly visible under the magnifying glass. These are not to be found in the natural gem; on the other hand, the

imitations lack certain defects, characteristic of genuine rubies—certain vacuums, whose outlines are much more indistinct than those of the air bubbles in imitations. Fine emeralds have similar characteristic defects, such as enclosures of liquids and curious dentries. Sapphires also show peculiar netlike formations.—*Journal of the Society of Arts*, for August 23.

CHESTNUT CULTIVATION IN FRANCE.
