DEAR SIR—I have only today seen the *Ceylon Observer* of 8th inst., and therein your article headed "Tobacco-growing in Ceylon and its conditions of success." In it you make out that I came here in 1887, whereas I never visited Ceylon till last year. I was asked to come to Ceylon at the time you mention, but could not do so as I was engaged in making experiments in tobacco-growing for H.H. the Rajah of Sarawak. Otherwise, the information given is correct.—I am, dear sir, yours faithfully,

A MACDOUGALL GIBSON.

[We are glad to find that Mr. MacDougall Gibson takes a favourable view of the native-grown tobacco leaf at Jaffna and feels sure it can be so manufactured under European auspices as to secure a good price in home markets.—ED. T.A.]

COCONUT CULTIVATION AND STATISTICS.

Hanwella, Feb. 18.

DEAR SIR,—With reference to your editorial *re* coconut export of 1901, in your issue of the 12th instant, I humbly think your calculation of 500 nuts to a cwt. of oil is too liberal. For I know by experience, that 1½ lb. of good copra produce 1 lb. of oil and ½ lb. of pouac, and an average of 3½ nuts go to 1½ lb. of copra. Therefore 364 nuts are equal to a cwt. of oil, or say 375 nuts the most.

It has also been found that the average nuts to a cwt. of copra on my estate, for the last three years, to be 235, but we may allow 250 nuts the most; surely 550 are too high or I should say absurd. [550 was a misprint for 250 and was corrected at once for our weekly issue.—ED. T.A.]

I have no knowledge as to the desiccated kernel, but I can say on authority, that the kernel of 2½ nuts on an average are equal to 1 lb. of dried scrapings used in hand chekkus.

Thus you will see you have been making a very liberal calculation of the out-put of our palm produce.

My calculations, though based on actual facts, may not be quite accurate, but may be acceptable as closer to the mark.—I am, yours faithfully,

CULTIVATOR.

THE COCONUT PUZZLE: LARGE INCREASED LOCAL CONSUMPTION.

Galle, Feb. 20.

DEAR SIR,—With reference to your leader on the "Coconut Puzzle," the slow development of exports is no doubt due to the large

local consumption. There is also an increasing demand for *kurumbas* or tender nuts for the sake of the refreshing water, and it is quite apparent that the plucking of a large percentage of these tend to keep down production for export purposes.—Yours truly, A.

P.S.—Some households take six tender nuts per day.

A RECIPE FOR ROSELLE JELLY.

Ythanside, Kotagala, 19th Feb.

SIR,—Having read in today's paper that "House-keeper" wishes a recipe for "Roselle Jelly," I send my own which I have found very successful.—I am, sir, yours truly,

J. T. S. CAMERON.

"ROSELLE JELLY."

After gathering the fruit wash them and pluck off only the fleshy red petals.

Put these in a vessel and just cover with water. Soak for a night and next morning boil till reduced to pulp. Strain in a flannel bag. When all the liquid has run through squeeze the pulp in the bag into another dish and strain again to clarify the squeezed-out juice. Allow 1 lb. sugar to 1 pint juice, put in a copper or enamelled pan, bring to the boil and boil rapidly for five minutes. A soup plateful of fruit and water when boiled turns out fully ½ pint juice.—C.

FARMS IN SOUTH AFRICA.—We have mentioned the settlement on farms first because it is on the agricultural land that the balance in South Africa needs specially to be adjusted, says the *Spectator*. As it was before the war, Englishmen were, roughly, crowded in the towns and their neighbourhood, and the outlying districts were entirely populated by the Dutch. But, of course, there would be among the British settlers not only the men who wanted to become farmers; there would be the representatives of every conceivable trade and calling. And really one does not know of any accomplishment that will come amiss in the settlement of a great country like South Africa. There will be room for tinkers and tailors and candlestick-makers. As for the settlers on the farms, they must not run away with the idea that South Africa is a rich agricultural country. In a general way it is not. A man must not think he can be "a gentleman-farmer," and yet make a good living. He must work himself, and work reasonably hard. But he will have the advantage of being "boss." This may be an advantage in most cases only of form and sentiment, and will mean that the white man is not in competition with the black. This sentiment goes very deep, and cannot be laughed aside. But there is no reason why the white man, so long as his distinction of caste is observed to his own satisfaction, should not wear his pride as easily as the platelayer in India does, who works with, yet controls, his native labourers. There are arbitrary fashions in these matters certainly, but they need not dominate their inventors. An American servant will not black shoes, but he will cheerfully perform the equivalents of shoe-blackening. As for an English ploughman, he would probably rather plough than not. A great deal depends upon the important questions whether or not ploughing is bad form. With common-sense there is no reason why our settlers should not become as thrifty, and yet as contented, as the small holders in the Eastern States of America, who have deliberately taught themselves to mulate the careful peasants of France and Italy.

THE TEA STANDARD :

TRADE MEETING IN MELBOURNE.

A large and representative meeting of the tea trade was held this afternoon, at Messrs. Fraser & Co.'s auction-room, to consider the new standard of tea under the Customs regulations. Mr Charles King, who presided, explained the position under the new regulations, which required not less than 30 per cent. of tea extract, not more than 8 per cent. of ash, and not less than 3 per cent. of soluble ash, as contrasted with the old Victorian Act, under which the decision was left first of all to the expert, who passed the tea on to the analyst. He pointed out that the importers had been taken by surprise in finding teas rejected under regulations in the framing of which they had not been consulted, and while they were at one with the Government and the public in the endeavour to raise the standard, they desired the standard to be a practical and a workable one, that would not cause injustice to any individual. Mr R Ramsay (of Foochow) described to the meeting the method adopted by the United States Government, which annually bought in the market a quantity of tea to serve as a standard, and sold samples to any applicant, in order that buyers might use them as a guide, while in case of rejection three merchants of standing were appointed to give a final decision—a plan that had found to work well. The subject was discussed at length by the meeting, and eleven samples of rejected teas from India, Ceylon, and China, together with the United States standard, were inspected. It was unanimously resolved, on the motion of Mr F G Drake, seconded by Mr E Shelley, "That Messrs. R Ramsay (Fraser, Ramsay, and Company), William Harper (Robert Harper and Company), and Charles King (James Henly and Co.), be appointed a Sub-Committee to consult the tea trade of the Commonwealth, with a view to drawing up a memorial to the Minister of Customs, asking him to alter the regulations under which teas are declared prohibited imports, and also to draw up a joint letter showing the injustice of the present act, as proved by the samples on the table condemned under those regulations, and which, in the opinion of the meeting, representing the tea trade of Melbourne, are sound, merchantable teas, that are fit for consumption, and should be admitted." The Sub-Committee have since drawn up the following letter to the Minister:—

"Melbourne, 25th January, 1902.

"The Commissioner of Customs, Melbourne.

"Sir,—We, the undersigned Committee, appointed at a representative meeting of the tea trade of Melbourne, by whose agency the bulk of the tea brought into Australia is imported, beg respectfully to draw your attention to the disability under which we labour through the new Customs regulations having apparently altered (without due notice being given) the standard under which teas are admitted into the Commonwealth. We most respectfully urge that the importers should have been consulted, and that any change decided upon should have been notified them before such regulations were enforced, seeing that, to the ordinary commercial mind, the description of the standard is meaningless, and that the

regulation is one impossible to be understood by merchants at ports of shipment, so that needless and unavoidable loss is thrown upon the merchants here, who are quite innocent and helpless in the matter. Various teas, which the analyst has condemned as unfit for human consumption, have been submitted to our inspection as experts, and, speaking with intimate knowledge of the article, and with an honest desire to prevent teas injurious to public health being imported, we unhesitatingly assert that the said teas cannot reasonably be deemed unfit for human consumption. If such teas can be condemned under the present regulations we asked most earnestly that these regulations be altered in such a manner that commercial men, both here and at the various tea ports may understand exactly what is the standard, below which no teas are to be admitted. It is well known that the English and American systems work with perfect satisfaction, and we would be glad if a similar system could be adopted in the Commonwealth. The American system consists of a commercial standard, samples from each producing country being purchased season by season, by the Government, from whom commercial men can buy samples of same, and an Australian standard on similar lines would entirely meet the views of the trade. We believe any three independent tea men that you may choose in any of the states could safely be associated with your present expert to draw up a reasonable and fair standard recognisable throughout the world.

"We also urge that permission to reshipe to the original port of shipment all teas refused importation under the present standard be given without delay, so that the loss may be minimised to the importers, who have no possible means of control over the importation, and who are most desirous of complying with the wishes of Parliament, but under the present system are helpless and unable, from causes beyond their control, to arrive at any knowledge of what the standard really is."

Three points are at issue between the tea importers and the Customs department, one as to the particular teas which have just been condemned, another as to the right or otherwise to confiscate or destroy, and the third as to what standard should be adopted for Australia. The grounds on which the teas have been condemned are simply based on the results of a chemical analysis, which is not one universally adopted. The teas themselves are perfectly good, and, indeed, superior to many low-class descriptions that can easily pass the standard. But if they are not to be admitted, then the only course that can be fairly adopted by the department is to allow the importers, if they so desire, to reshipe the goods. They have been innocently sent and innocently received, and to wantonly confiscate them would be an act of dishonesty.

As regards the general question of the standard to be employed, it is difficult to see how that set forth in the official regulations is to be made workable. The test afforded by the usual process of liquoring and tasting should not be ignored, but doubts have been expressed whether the official test would permit the importation of any China tea—an absurd result, especially as China tea is often held to be the best suited for Australian consumption.—*Melbourne Age*, Jan. 31.

PLANTING AND SOCIAL NOTES FROM MARAWILA.

We have had very welcome rain last week on six days, or rather evenings, which aggregated very nearly two inches. This has been of immense benefit to vegetation, following as it did a drought of nearly a month's duration. Occurring in mid-drought, it has helped to "break the back" of the season of drought, so trying a period to man, animals and vegetation. The face of the country has been rapidly changed from brown to a bright green.

Cocoanuts are still scarce for desiccating, and the price is in sympathy with that for Copra. It was announced in the papers that the copra of Horekelle estate was sold for the whole year at R60 the candy—a record price. A correspondent of a contemporary of yours announced that merchants were willing and anxious to enter into forward contracts for R64.65 the candy. This was promptly contradicted, and your contemporary called upon his correspondent to name the firms who were so anxious to enter into these contracts. He has observed a very discreet silence, and people form their own opinion for the reason for this gratuitous announcement. I am in a position to state authoritatively however, that a gentleman in this district was asked to enter into a contract for R62 the candy. "Once bitten twice shy," he declined. He hopefully looks forward to copra reaching R100 the candy!

For a decent Circus to visit a wayside village, is an unheard of experience. Duval's Circus was brought to Marawila, by a trio of enterprising Sinhalese, paying the proprietor R1,000 a night, for three nights. The result exceeded expectations. On the last night there was a crowd that could not be accommodated, and those outside became riotous and attempted to rush the tent. The chief headmen being present, the crowd was restrained, with much difficulty and with a promise of another performance. A local syndicate promptly engaged the troupe for another three nights on the same terms. The tent had to be enlarged and was filled on these three nights too, people coming from distances of 12 and 15 miles. Doesn't the expenditure of about R10,000 or more, to witness a Circus, bear eloquent testimony to the general wealth of the district as a whole? Isn't this an additional argument for a Railway?

There is a great bustle in Chilaw owing to the approaching visit of the Governor and suite from the Kraal. Preparations are being made for arches, but as the visit is to be on a Sunday, His Excellency may be saved the ordeal of receiving addresses.

The offending lamp-post has been removed, and the fate that Chamberlain was threatened with—being hanged on one—has been averted. Possibly no one will be broken on the wheels of tramway too, as the road to the Resthouse will have to be opened for the Governor.

MINOR PRODUCTS REPORT.

LONDON, Feb. 1.

SPICES.—Cinnamon chips sold at 2½d to 2½d per lb for common quality. Black Pepper was bought in at 5½d per lb for light Sarawak, and at the same price for Penang. There has been a large business done in Singapore to arrive down to 6d per lb, but the market has since been firmer with buyers at 6 1-16thd Singapore white was bought in at 10d per lb for dull ordinary, and at 11 to 11½d per lb for good coriander kind. For arrival fair Singapore is quoted 10½d to 10 3-16thd per lb. Penang is unchanged at 9 11-16thd on the spot, and 10d to arrive.

VANILLA.—The supply brought forward on Wednesday was the heaviest on record, and attracted a much larger attendance of buyers than usual. There was

a good demand, however, and practically the whole quantity offered, about 2,800 tins, was sold. Long lengths being scarce brought rather dearer prices; medium sold well at late rates, but the lower grades were easier. The auction was adjourned on Wednesday at 5 p.m., and was concluded today. The following were some of the prices paid:—Fair to good chocolate, 8 to 8½ inches, 22s 6d; 7½ to 8 inches, 19s 6d to 21s 6d; 7 to 7½ inches, 14s 6d to 16s 6d; 6½ to 7 inches 10s 6d to 14s 6d; common dry brown 4s to 11s 6d; ordinary foxy to fair short, 5s 6d to 6s 6d; medium, 6s 9d to 7s 6d, and long 7s 6d to 10s 6d per lb.

Messrs Brookes & Green have issued a report on vanilla, in the course of which they state that the Seychelles crop for 1901, shipped from August to December, totalled "fully double" the heaviest quantity exported from the island in any previous season, it being estimated at about eighty tons. The feature of this season's supply of vanilla from Seychelles is the unprecedented large proportion of "short" beans, medium to good size quality measure from 6 inches to 8 inches, but the consignments landed in London during the past three months have contained about 75 per cent of very short beans ranging from three inches to five inches. The result has been that, whilst long-lengths quality has fairly maintained previous values, the short measurements show a reduction of about fifty per cent. To obtain good plump pods, it is incumbent for planters to see that early in the season the young shoots are thinned by pricking out a quantity of surplus sprouts. In the present case it would seem as though nearly all had been allowed to germinate. This view is somewhat confirmed by recent reports from Seychelles, which advise that the flowering for the next crop is small, possibly due to the weakening of the vines last year—indeed, some of the older plants are reported as seriously exhausted, a very natural result if the above surmise is true. During the past year or two there has been an increasing "doubtful trade" carried on by crystallising Tahiti vanilla, and making it in bundles to represent Bourbon and other better-class qualities, buyers paying twice as much as their actual value, or even more.—*Chemist and Druggist*.

JAFFNA AGRICULTURAL OPERATIONS.

The reaping of paddy crops has been commenced throughout the District. In a few villages the crops are scanty, but on the whole the yield of paddy crops is not much below the average. The planting of tobacco is over, though the cultivators met with some difficulty in procuring plants, the nurseries having been washed away by the heavy rains of December and January.—*Hindu Organ*, Feb. 12.

INDIAN GOVERNMENT CINCHON AND QUININE.

—The Budget estimates of the Madras Cinchona department for 1902-1903 anticipate a further increase in the demand for quinine, and the estimate of receipts has accordingly been raised to 210,000r, or 19,600r more than the estimate of expenditure for the year. In accordance with a Government order passed on March 10th, 1898, the Government, instead of extending its own plantations and competing with private industry, purchases the surplus bark it requires from cinchona planters at a price per unit which is annually fixed. Provision has been made in the Budget for working up 474,000 pounds of bark during the coming year to meet the increased demand, and for the purchase of two hundred thousand pounds of three and half per cent of bark at 2d per unit.—*Chemist and Druggist*, Jan. 11.

THE ORANGE RIVER COLONY AND LAND SETTLEMENT.

We direct attention to a very interesting communication which we may say, comes to us from an ex-Ceylon planter, and is produced below. As an official in the new Lands Department, our correspondent writes of that with which he is intimately acquainted, and his information ought to be of very great value to any intending settlers in the Orange River division in South Africa. We shall be specially interested from time to time, in learning from the same quarter, how the work of settlement progresses, and of the experience of the pioneers among the farmers. Any one interested can see the copy of the *Bloemfontein Post* with the details of the Land Settlement scheme, at our office.

LAND SETTLEMENT IN ORANGE COLONY.

(From a Correspondent at the front.)

Bloemfontein, Orange River Colony, 5th January, 1902.

Since I last wrote you many changes have taken place. After a continuous spell of nine months on the trek, first with one column and then with another, I was selected for temporary employment under the Civil Administration as Assistant Secretary to the new Department of "Land Settlement, Orange River Colony." I, therefore, came in from the Jacobsdal, Petersburg District, on 10th October last, and have since been hard at work arranging details and getting the offices started.

THE "LAND SETTLEMENT" DEPARTMENT is a new one, and their object is to arrange all matters in connection with settling as many men of British descent in South Africa as possible. Lord Milner is very keen on the subject, and so is the Deputy Administrator. As you can imagine the work is of exceptional interest to me. The Secretary is Major K. P. Aphorp, Royal Irish Regiment and at present of the South Africa Constabulary.

His services have been lent the Civil Government by the Constabulary like myself. He is a man of big experience and energy and has thrown himself heartily into the scheme. He is assisted in his work and decisions by a board of advisers chosen from civilians. The work of the Department is increasing rapidly. With the close of the war, however, and the disbandment of the Colonial Irregular forces,

THE WORK WILL SUDDENLY EXPAND TO VERY
LARGE PROPORTIONS,

for hundreds of time-expired and discharged men will at once want to start farming and will turn to us for help or advice. We are getting ready for them. All those who desire to remain in the Colony and take up farming are invited to register their names in our books, and to answer a few simple

questions. I enclose copy of same which may interest you:—

Questions to be answered by applicants for Grants of Land in the Orange River Colony:— (1) Surname; (2) Christian Name; (3) Nationality; (4) Permanent Address; (5) Trade or Calling; (6) Experience as a Farmer; (7) Available Capital; (8) Farm or Locality Desired; (9) Married or Single; (10) Number of Children (if any); (11) Names of two References.

Government who have ample funds at their disposal are

QUIETLY PURCHASING AS MANY GOOD FARMS
AS COME INTO THE MARKET,

and the larger ones will presently be subdivided by Government Surveyors to enable each settler to have a supply of water and a sufficiency of land to make a comfortable living for himself and family. Only the best land in good districts is being purchased, so that settlers will have every advantage to start with. Besides these new purchases the Administration will fall heir to over 350,000 acres owned by the old O. V. S. Government. Though nearly all this large area is on lease to Dutchmen, much of it will eventually fall into the hands of this department and be available for settling loyalists upon. The Colony at present is, of course, in much too unsettled a state to allow of any such settlement; but on the other hand there are thousands of acres of good land, within the protected area, which could be utilised at once for the season's crop. The Land Settlement Department has, therefore, received

PERMISSION TO PLACE A CERTAIN NUMBER
OF GOOD MEN

on such places, irrespective of ownership, and let them have the land rent free for one crop. Many time-expired yeomen and others have eagerly availed themselves of this opportunity and in the course of a few weeks we have put out nearly seventy men in small parties who will live and work together and mutually assist in case of an attack.

Government has lent them ploughs and the plough horses; seed and rations are also given them to be paid for when their crops come in. This, of course, is only a temporary arrangement and is of little interest to the public. The conditions of the Permanent Land Settlement are what the people are waiting to find out, viz: on what terms will Government grant them land. These terms have been carefully thought out and will soon be ready for publication. They are, I think, most favourable. The settler gets his

BLOCK OF LAND RENT FREE FOR THE
FIRST YEAR,

after that he gets 25 years to pay up value of his land. The value is fixed on the day he enters into possession, and is unalterable. All improvements are, therefore, his own. Besides paying a 25th part of the price of his farm every year, the settler will also have to pay Government 4 per cent, and if he has insufficient capital to start his farm Government will advance him up to 50 per cent of the value of his holding at 5 per cent. The Government are disinclined to

assist the absolutely penniless man; neither do they want the Capitalist or Land Jobber who can go to the open market and buy what they want. In return for occupying land under this arrangement, the settler will have to hold himself in readiness for service when called upon in defence of his country, and one week per annum must be devoted to training. Government provides a horse, rifle and ammunition.

THE LAND IS INALIENABLE

except with Government consent as long as any indebtedness remains thereon. The settler can, however, pay off all outstandings after three years and become a free man. Such, roughly, are the conditions and to anyone who likes the free open life of the veldt, a home and a competency, I can recommend the scheme as sound. I am sending you a copy of the "Bloemfontein Post" of 31st ultimo which contains much information about "Land Settlement" as the Administrator cares to make public at present.

PRODUCTS AND MISSIONS IN NEW GUINEA.

During the interview with Bishop Stone Wigg, who was in Colombo this week, and who gave a description of the work,—the work of the Mission stations there, how cannibalism was rampant, the Missionaries' objective, pupil teachers and evangelists, the work and its future, and of New Guinea as a land of plenty—he added:—"The land up in the river districts is rich passing description. There are enormous tracts of country there which will grow anything—sugar, rice, rubber, sago, and, indeed, I don't know what. I have been told that some of the native sugarcane was brought to Queensland some time ago, and proved to be one of the best stocks used on the plantation, but I have not been able to verify that statement. I don't think any sago has, but a great deal of it is made and used by the natives. In fact, there are really no exports at all; and I think this is largely due to the fact that the Australian colonies who had the control of British New Guinea (I mean before the Commonwealth), although willing to pay some £20,000 per annum, did not care to see large tracts of country in New Guinea taken up. I think it was a great mistake to be so afraid that someone would 'make a good thing' out of the country, for there is land enough and to spare. Small blocks for growing rubber or coconut trees would be useless, for the trees do not mature for some four or five years. The export of rubber, if you can dignify it by the title of 'export,' is smaller now than it was four or five years ago, and it is just the same with the beche-de-mer and the pearl fishing."—*Capricornian*, Jan 25.

COCONUT PRICES.—With reference to a recent maximum quotation for nuts which has been the subject of criticism in view of the fact that the Desiccating Mills in the same district were not paying so much, a critic now gives the explanation that evidently "copra driers" can afford to pay higher prices than the "Desiccating Mills;"—that is, probably, for nuts that are specially suited to their particular purpose.

THE CEYLON PROVINCIAL ESTATES COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

The Directors beg to submit their report for the year ended 31st December, 1901, together with a statement of accounts for the same period.

The Tea Crop amounted to 485,954 lb, against an estimate of 500,000 lb for the year, and is equal to an average yield of 498 lb per acre from the area in full and partial bearing. In the case of Glassaugh the estimated crop was exceeded by some 1,600 lb, and shortage in the estimate of Brownlow (a matter of between 15,000 and 16,000 lb) is attributable partly to finer plucking, but mainly to unfavourable weather during the last quarter of the year.

The Revenue and Expenditure account shows the year's profit to have been R93,453'67.

The cost of production in 1901 has been 25'02 c. per lb, which includes 1'69 c. spent on manuring, as compared with 24'42 c. and 1'97 c. respectively for Season 1900.

The Crop has sold at an average net price of 44'10 c. per lb, as against 42'56 c. in 1900 and 44'62 c. in 1899.

During the past year the Company's liabilities have been decreased by the payment of a loan of R15,000,000, thus reducing the "Loans on Mortgages" item in the Balance Sheet from R142,473'57 to R127,473'57. R10,000 of this was set aside from the 1900 profits, and the balance of R5,000 was met out of this season's surplus as shown in the Profit and Loss account.

Including a sum of R7,230'44 carried forward from season 1900, the Profit and Loss Account shows a balance at credit of R54,201'25 after payment of an interim dividend of 3 per cent, interest on Mortgages, Bonuses to Superintendents, and making provision to the extent of R7,500 for depreciations of Buildings and Machinery.

The Directors now recommend the payment of a final dividend of 6 per cent which will absorb R39,960 and make 9 per cent for the twelve months, and that R10,000 be reserved for the purpose of further Mortgage redemptions, the balance remaining after payment of Directors' fees being carried forward to season 1902.

It was considered desirable to add to the rolling and drying plant in the Brownlow Factory, and the outlay in that connection, and on improving the withering arrangements has been added to the Capital cost of Buildings and Machinery. It is not expected that there will be any capital expenditure during season 1902.

The Estimates for the new season point to a yield of 510,000 lb of Tea, costing 24'73 c. per lb, inclusive of an allowance at the rate of 1'90 c. per lb for manure.

The following is a definition of the Company's properties as at the 31st December last.

	GLASSAUGH. BROWNLOW.	
	Acres.	Acres.
Tea in full bearing	.. 452	.. 508
„ partial bearing	.. 20	.. —
„ not in bearing	.. 20	.. —
Total in Tea	.. 492	508
Fuel trees	.. 9	.. 2
Forest 33
Grass 27
Scrub and Waste	.. 18	.. 20
Total..	519	588

Mr F L Clements retires from the Board in terms of the Articles of Association, and is eligible for re-election.

The appointment of an Auditor for 1902 rests with the Meeting.

By order of the Directors,

Colombo, 15th Feb., 1902. **GEORGE STUART & Co.,**
Agents and Secretaries.

THE KNAVESMIRE ESTATES CO., LTD.

The surplus on Revenue and Expenditure account is R27,567-67 to which has to be added the balance (R6508-63) carried forward from season 1900.

The Profit and Loss Account after Providing for Depreciation, Superintendent's Commission, Irrecoverable Cost Advances and other outgoings shows a balance of R24,863-66, out of which the Directors propose to pay a dividend of 4 per cent. That will absorb R16,600, and leave, subject to the payment of Directors' fees, a sum of R8,263-66, of which they propose to place R4,614-46 to the Extension account and to carry forward the balance to season 1902.

The Extension account when increased as above will stand at R22,121 18c, which is the difference between the capital of the Company (R415,000) and the amount invested in Landed Property, Buildings and Machinery (R437,121 18c.)

The profit earned represents a return of 6-64 per cent on the capital of the Company, and is equal to R56 72c per acre on the area in bearing, as against 5-90 per cent and R50 40 per acre respectively in 1900.

The total crop secured was 285,953 lb or 14,047 lb below the estimate. The plucking area was 486 acres and the yield per acre 589 lb of made Tea. The total amount of Tea dealt with was 314,401 lb which included 28,448 lb made from bought leaf.

The difference between the 1900 and 1901 crops may be accounted for partly by finer plucking and partly by a bad flushing year as against an exceptionally good one in 1900.

The Tea sold to end of December was 268,653 lb, the nett proceeds of which equalled 29-24c per lb leaving unsold 45,748 lb which has been estimated to 30c per lb.

Including the cost of Tea made from bought leaf, the twelve months' crop was put on the market for 20 68c per lb.

The Company's property on 31st December 1901 consisted of:—

Tea in bearing	486 acres
Tea not bearing	30 do
Jungle	73 do
Building and waste land..		5 do

Total 594 acres

The crop expected in 1902 is 300,000 lb. and the estimated cost is 20-60 cents inclusive of capital outlay.

Plumbago mining was stopped on 24th May last, the Syndicate which leased the mining rights having decided to give the work up, and no one has since come forward to carry it on. Owt 440 were shipped to London by the Syndicate, but the consignments have not yet been realized, and the company has not received its share of the proceeds.

In terms of the Articles of Association Mr Dnpuis retires from the office of Director, and is eligible for re-election.

The appointment of an Auditor for 1902 rests with the Meeting.

THE TONACOMBE ESTATES COMPANY OF CEYLON, (LTD.)

THE REPORT. ACREAGE

The acreage of the Company's Estates is as follows:—

Tea in bearing	...	582 acres
Tea not in bearing	8	"
Tea seed bearers	3	"
		593 acres
Cardamoms in bearing	..	98 "
Reserve Forest	..	21 "
Fuel trees	..	20 "
Chena and Patana	..	1,142 "
Total		1,877 acres

The total quantity of tea secured during the season was 224,133 lb. being 5,867 lb. short of the Estimate. This is mainly due to finer plucking and in its turn accounts for the somewhat increased cost of production i.e., 26-50 cents per lb. as compared with 24-98 cents per lb. last season. The price realised was 37-84 cents per lb. net as against 38-01 cents per lb. last year.

The total Cardamom crop was 9,587 lb. which realised R1-48 per lb. net as against R1-70 per lb. last year.

The total expenditure amounted to R68,577-01. No outlay whatever was incurred on Capital Account.

The Balance available, after providing for depreciation, including R7,555-37 brought forward from last Season's Account, amounts to R29,309-74, and the Directors propose to pay a dividend for the year at the rate of 5 per cent on the paid up Capital of the Company absorbing R14,000, to write off the balance standing to the debit of Machinery Account R2,3 5-35, to place R8,300 to credit of Buildings Account and to carry forward R5,004-38.

The Directors have pleasure in stating that the Debenture Debt has been further reduced by £1,500 during the year, leaving the amount now outstanding under this head at £3,500.

The Coast Advances have been slightly increased during the year under review, from Rs 2,955-16 on 31st December, 1900, to Rs 3,319-78 on 31st December, 1901.

The Crops for 1902 are estimated at 230,000 lbs Tea, 8,000 lbs Cardamoms against an expenditure of Rs 68,799 20.

Mr H Cumberbatch resigned his seat on the Board on leaving the Island, and Mr R S Templer was appointed to fill the vacancy.

Of the Directors the Hon Mr W H Figg retires by rotation but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the Meeting.

THE TRAVANCORE CARDAMOMS ESTATES COMPANY (LIMITED.)

A trading corporation under the above name has been formed, with Mr S Iyer, ex-Dewan, as President, Mr E R Iyer as Vice-President, Mr A V Iyer as Secretary. The capital at present is 22,000, consisting of 200 shares, and the area taken up for cultivation is 290 acres.—*Chemist and Druggist*, Feb. 1.

INDIAN PATENTS.—No. 493.—Horace Drummond Deane, tea planter, of Stagbrook tea estate, Peermad, Travancore, and Charles George Landseer Judge, journalist, of 47, Free School street, and No. 5-1, Council House street, in the town of Calcutta, both in British India. A centrifugal drier for steamed tea leaf.—*Indian and Eastern Engineer*, Feb.

RUBBER PLANTING.—Ceylon Planters, in the few suitable districts, are awakening more and more to the fact that by the adoption of rubber-planting they can considerably augment the value of products of their estates. The Knavesmire Company at its annual meeting today, on the motion of Mr Denison, gave a mandate to its Directorate to proceed with the planting of rubber at their own discretion. Already some three or four thousand plants are flourishing on the estates of the Company, and we trust that ere long many of our planters may find in this new venture a valuable and remunerative product.

UVA DISTRICT REVISITED.

AFTER AN INTERVAL OF TWENTY YEARS.

*(By an old Planting Correspondent.)**(Concluded from page 462.)*

The Park Group including Melrose and Parsloes is scattered over one thousand and twenty acres of land under the management of Mr. Fred. Hall for Messrs. B. Fanshawe and J. C. Lawrie. The fields of tea look well and give a good yield per acre and the transport of tea is easy from the factory located by the cart road to Batticaloa. There are two hundred and sixty-nine acres of tea in bearing on The Park and a good show of timber trees—especially around the bungalow where nearly every Ceylon fruit tree is thriving, including fine mangoes and Australian guavas. Kew pines are doing well in large numbers, and hedges of Madras thorn extend to the cart road. There is a great number of rubber trees in various stages of growth and some fine old jak or *artocarpus integrifolia* and breadfruit. The fields on the Park are in places rather hilly and not exactly park-like though surrounded by extensive grazing grounds or patanas, and it is very difficult to keep stray cattle and buffaloes out of the tea fields. Cattle and goats from the cart road are a great nuisance on this estate as the Superintendent, Mr. Fred. Hall, well knows. Leaving The Park early one fine morning and walking to the top of the hill, we descended into quite a new region or into a deep valley between Lunugala and Bibile with the hill of Monaragala on the right. This is a place few Ceylon planters have seen, and is called

COCOAWATTE

opened up by Mr. Philby some years ago in cacao, rubber and tea. There are no less than 45 zigzags from the ridge to the factory, the bungalow being at about the 42nd zigzag. We were agreeably surprised to see a very fine field of about 100 acres of tea, much better than we expected to see in this hot valley. Mr. Worth was good enough to show me round the Southern end fields of Cocoawatte. Birkin and Pallikerewe comprise 662 acres, of which 250 are under tea with a large area of rubber trees growing very well and seeding freely. If transport was not so difficult, this estate called Cocoawatte might become a very valuable property; as it is, improvements in cultivation and some new machinery in the factory will, no doubt, be money well spent by the present proprietors. The scenery around is wild and picturesque. Returning the same way by the cork-screw paths to the ridge, and after a pleasant walk in the early morning along the lower ridge of a patana, we entered a very fine tea property called Deysbrook of 250 acres of tea, worked with Kehelwatte (Clifton) of 342 acres. Some of the tea fields here give a good yield of tea; for instance, the bungalow field, 30 acres, gives 800 lb. of made tea to the acre and the top field 700 lb. The large river is now spanned by a very fine substantial covered bridge, and the factory is an imposing building, with machi-

nery, the best and latest improved, worked by a turbine. Patent fans to hasten the withering of the green leaf were working. Mr. John Darley would be very much surprised if he saw his old place transformed into so fine a property. We believe J. D.* with his brother-in-law, Mr. Duncan, are doing well in New Zealand. Hopton including Bollagalla or Letchinee Totum is a fine estate with beautiful shade trees along the cart road and scattered over the tea fields; we did not call at the two bungalows or at the fine large factory below the cart road (four stories high). We also passed old Yapame, 460 acres in extent with 211 acres under tea, the property of Mrs. Isham. Hopton continues its tea fields below the Lunugala cart road. The extent of Hopton is some 776 acres with about 400 under tea. The next group is the property of Messrs. W. Stewart Taylor, G. W. Suhren and M. Brenner—total acreage 1,793 with 506 cultivated and 500 under tea.

Mr. W. S. Taylor is managing

GONAKELLE GROUP

including Passara estate and Mortlake: total 1,752 acres—1,036 cultivated with 847 acres of tea, 31 coffee and 158 timber and grass. The Gonakelle bungalow is a perfect museum of hunting trophies—elephants' heads, feet, trunk, tusks, &c., and elk horns—mostly the trophies of Mr. J. J. Robinson now on leave and expected back to Ceylon in June or July next. The beautifully kept lawn, with a piece of ornamental water surrounded by ferns with a small fountain in the centre rockery, is very pretty and two whistling teal swim round and shelter themselves under the foliage planted round the banks. There is a dense shade of *albizzia moluccana* round the lawn and below the bungalow and a flag-staff.

We omitted to mention from Madulsima and Hewa Eliya (or Badulla North) "Swinton" with 220 total acres (tea 163) the property of Mrs. Shephard and Mr. L B Moss; the El Teb Group of 1,724 acres, 600 cultivated including 537 under tea, 63 timber and grass, the property of Captain E H H Gordon—my old place, Deyanawatte, of 167 acres included.

We returned to

DAMMERIA GROUP

including Mahatenne, Vellongalla and Tillycairn, 1,190 total: 659 acres cultivated, with 604 acres of tea, 30 acres cacao and 25 acres of timber. Mr. J B Cotton has managed these places for a quarter of a century; he is still strong and active and we hope good for another long spell of hard work. The bungalow is large and well-situated, commanding a fine view of the low-country and there is a croquet ground and tennis court—every comfort, but rather warm.

Our mind was made up to pay a visit to Monaragala or Peacock-Rock, and we have done it, and walked fifty miles there and back exclusive of rambles on the hill when

* Is this not the Mr. Darley, who is in Mexico and sends us occasional reports on cacao and rubber?
—Ed. T.A.

there. It was 25 miles by the mile-posts including one mile through Passara and 2½ miles to Dammeria on our return. The conclusion will be on Monaragala and its many unbridged rivers between Passara and the "Peacock Rock"—or the hill so little known by even old planters, situated on the outskirts of the Uva Province and only a day's journey across country to Hambantota, called Monaragala.

MONARAGALA.

Let us review

THE JOURNEY

to this outlandish planting "district." We start from Dammeria estate and walk to the old military station called Aliput, from thence to Bndugama and pull up at a resthouse at Nakali. Here we change our wet clothes and refresh the inner man, and rest our weary bones. But what rivers to cross, up to the waist—the Nakali River in particular! The rains had commenced and the rivers were only just fordable. Arriving at Mupane bazaar we discharged the Sinhalese man engaged at Nakali resthouse and obtained a cooly to carry box and guide to Normandy estate. Of course, he took the wrong road, giving a walk of three miles extra, because we were very tired and anxious to get on dry clothing. We therefore, ascended Monarakele estate, 447 acres with 247 acres under cacao, managed by Mr. Stephen Sparkes. A long pull and a strong pull brought us to the ridge, and we were glad to enter Normandy estate, 231 acres in extent with 120 acres of cacao, also under the management of Mr. Stephen Sparkes. A change of clothing and a hot cup of tea soon made us forget all the troubles of the day, and, save that a very cold North-East wind was blowing we felt comparatively comfortable, located in a basin on one of the ranges surrounded by great big boulders—enough of them to build another break water. We had often been informed there were a few small pebbles to be found at Monaragala. Christmas came and went and with Mr. L. who was invited over by my hospitable host, we passed a pleasant time and visited Sirigalla next day. This estate, the property of Mr. H. Atkinson, possesses 181 acres of cacao, and there is another place just by, called Tring of 151 acres out of cultivation. There is some very fine

CACAO

to be seen both on Normandy and Sirigalla estates—in fact the largest trees I have ever seen whether in Ceylon or in Trinidad or Grenada in the West Indies. One large tree had over fifty pods on one branch and it is common at Monaragala—that is on Normandy and Sirigalla—to count 150 on one tree. Caracas is the name given to the red pod trees which I thought we called Trinidad, and Forastero (hybrid mixed) is the name given to what I thought was Caracas: both kinds bear heavily and very fine large pods. The cacao is shaded by rubber trees, dadap, kola-nut, nutmegs, annato jak and albizzia moluccana which by-the-by grows at Monaragala to an enormous size—even to sixteen feet in circumference. The dadap had been bark-ringed in some places and came down smash with very little notice in one instance. A tremendous big one measured its length on the ground parallel with us as we walked along the path at Sirigalla and made us jump with th

sudden shock. The strong N-E. monsoon blowing laid low many trees; in fact, it was quite dangerous to walk underneath them.

We could see a "dagoba," on the rock to the left of Sirigalla and steps cut in the rock leading up to the "dagoba." We are informed that there is a Buddhist college and a temple where the priest keeps school, but there are not many students.

Monaragala possesses some ten properties comprising about 2,103 acres distributed as follows:—

1,527 acres under Cacao.

297 do do Tea.

99 do do Coffee.

20 do do Cardamoms.

1,943

57 Nutmegs, Kola-nut and Annatto,

2,000

103 Para and Ceara Rubber, &c.

2,103

With shade trees of all kinds.

Alliawatte with 230 acres of Cacao

Moonekelle do 247 do do.

Normandy do 120 do do.

597

(Managed by Stephen Sparkes.)

Then come Kumbukkan ... acres. 125

Kumaradola Cacao 258

Moragalla do 181

565

(Managed by Mr. Betts)

Raxawa also managed by Mr. Betts 80

645

Some alterations have been made since I visited Monaragala—particulars of which perhaps have been sent to you. Sirigalla is in charge of Mr. Liesching. Walton is managed by Mr. Austin who looks after the factory at Mupane. Before leaving Monaragala we must pay tribute to the memory of Eastwood and John Reid who were numbered amongst the pioneers. Leaving Monaragala and Passara *via* Khyber Pass—Gourakelle—back of Namunukula *via* Ravenswood, Newburgh, Ella to Bandarawela Hotel for a rest and evening train to Nannoya where we spent the night. New Year's Day was agreeably spent in the company of Messrs. George Thomson, Vicarezzo and Bisset. We wish all prosperity to our friends in the Province of Uva and thank them again for their hospitality.

H. COTTAM.

OVER-PRODUCTION AND CARDAMOM CULTIVATION.—We are asked in a letter from a Northern planting district to put in a strong word of warning about the danger of over-production of cardamoms from the too rapid extension of clearings of this spice.—"Wherever you turn, new clearings are seen to be in progress—not in one district; but wherever there are trees to fell." We sincerely trust that planters will be taught caution by past experience in cinchona and now in tea.

NUWARA ELIYA DISTRICT PLANTERS' ASSOCIATION.

ANNUAL REPORT.

THE PAST YEAR has not been an eventful one as far as this Association is concerned, and consequently it has not been necessary to call many meetings.

THE NUMBER OF MEMBERS who have paid subscriptions individually or on account of estates is 18. It is to be regretted that one estate has withdrawn its support, but another has joined which leaves the numbers the same as last year.

THE ANNUAL OFFICIAL ESTIMATED TEA CROP for 1902 is as follows:—

	Estates.	Total Acreage.	Bearing Acreage.	Crop.
Nuwara Eliya				
Ramboda ...	26	6,696	6,569	3,065,000
New Galway				
Kandapola ...				the yield being at the rate of 466 lb. per acre.

THE SEASON for the district generally has been a bad one both as regards crop and prices. A good many estates were short of their estimates for the year, due no doubt partly to finer plucking, but mainly to the less favourable weather which prevailed throughout the year. Prices for high-grown teas have suffered a set back, and have not participated in the market average of the past 6 months.

TATAPARAI COOLY DEPOT AND REGISTRATION SCHEME which was inaugurated by Government is now complete, and your Committee trusts that Superintendents will give it a fair trial, as it promises to be of great service both to the coolies and the planting community. The hearty thanks of the latter are due to the Hon. Mr. Ellis for the trouble he had taken in the matter.

COOLIES have been sufficient for requirements and their health has been satisfactory. This district does not seem to have suffered to any great extent from bolting coolies, but it is considered desirable that steps should be taken to prevent the evil which certainly does exist, and this Association awaits with interest the recommendation of the sub-Committee appointed by the Parent Association. Advances stand at about the same figure as last year. The price of rice continues rather high.

The construction of the Nanuoya-Udapussellawa Light Railway is progressing on the Nanuoya-Nuwara Eliya section, and in parts the sleepers and rails have been laid. A certain amount of masonry and earth cutting has been done along the Kandapola plains. As the railway runs parallel to and crosses the road many times, it is hoped that adequate protection to prevent accidents will be afforded to those who have to use the road for riding and driving.

PLANTERS' BENEVOLENT FUND.—Your Committee would draw your attention to the useful work done by this fund and urge all members of this Association who are not already subscribers to become so.

OBITUARY.—Your Committee with regret have to record the death of Mr J B S D'Aguilar, a member of this Association.

The Finances are satisfactory and show a credit balance of R85'76 against a balance last year of R68'01.

COLOMBO TEA TRADERS' ASSOCIATION.
ANNUAL REPORT.

The following is the annual report of this Association:—

Your Committee have now the pleasure to present their Report for the year ended December 31st, 1901.

TEA SALES.—Owing to the growth of Catalogues, it was resolved at the last General Meeting that Auctions should commence at 11 a.m. instead of 11-30, as in the past. This rule has since been adhered to.

CONDITIONS OF SALE.—For the same reason, viz., the increasing number of lots offered for local sale, a new Rule was adopted, whereby the limit for "Large Breaks" was fixed at 1,600 lb instead of the 700 lb formerly recognised as constituting a "large" break. This arrangement, though at first criticized, has greatly facilitated the work of the Selling Broker, and sales usually finish in reasonable time.

(2.) An alteration was made in Rule 1, which now reads—"The highest bidder to be the purchaser, and any dispute that may arise to be settled by the Selling Broker who is not to declare the name of the buyer until after the lot is knocked down, unless in his opinion there may be any uncertainty as to the bidder."

(3.) Rule 7 also was altered to read as follows:—"No teas shall be catalogued until they have arrived, and all catalogues shall be closed by 4 p.m. on Friday. Samples and Catalogues to be delivered by 10 a.m. on Monday for the following Wednesday's sale."

TEA PACKAGES.—The recommendation of the Special Sub-Committee appointed to report on this subject was adopted at an Extraordinary General Meeting, and it is now a Rule that all teas offered for local sale, packed in "patent" or "metal" packages, —i.e., packages other than ordinary wooden packages with 4 oz lead lining—must be so declared by the Selling Broker in his Catalogue or previously to his putting the lot up for sale. It was thought inadvisable to attempt to discriminate further between the various descriptions of packages offered.

AUSTRALIAN IMPORT DUTY ON TEA.—In October last, the Tea Trade experienced considerable alarm owing to the reported intention of the New Federal Government of Australia to impose a uniform tax upon Teas, whether Ceylon, Indian, Japan or China, of 2d per lb plus 20 per cent *ad valorem*. The prospective damage to all British-grown teas and the corresponding advantage to Chinas and Japans were immediately recognised, and the Chamber of Commerce took vigorous measures, both by communicating with the Indian Tea Association and making urgent representations to the Ceylon Government, to obtain a reconsideration of the matter from the Australian Government. Thanks to the energy of all concerned, and especially to the prompt action of His Excellency the Governor (to whom this Association hereby acknowledges its indebtedness), in cabling to Lord Hopetoun, the Federal Government have amended their tariff to a uniform duty of 3d per lb on all imported teas. The further tax of 1d per lb upon teas packeted out of Australia remains a fact, and it was considered inadvisable to call in question the imposition of this protective measure.

GREEN TEAS.—During the year prospects from America and Canada have been more encouraging to growers, and with experience in manufacture coupled with more knowledge of the most saleable article, this new branch of the tea industry may become an important factor in Ceylon's exports. There is no doubt that Ceylons are gradually gaining favour in green-tea-drinking countries, which fact it is hoped may later on help to decrease excessive exports of black teas and thus help to relieve our regular markets of over-supply.

The total exports for the year were, as per Chamber of Commerce returns:—

	1901.	1900.
United Kingdom ..	105,734,570	113,760,193
Australia ...	20,641,184	17,606,912
Russia ..	9,653,896	8,917,185
America ..	4,502,331	3,980,680
Other Countries ..	5,767,237	4,166,669

Totals...146,299,018 148,431,639

Totals for 1899 and 1898:—1899—129,894,156 and 1898—119,769,071.

The following figures show the quantity offered locally in public sale for the last four years, with the average prices obtained for complete invoices sold:—

1898 ..	35,958,819 lb ..	Average 35 cents.
1899 ..	38,377,318 ,, ..	38 ,,
1900 ..	47,681,826 ,, ..	34 ,,
1901 ..	51,044,000 ,, ..	33 ,,

The following formed the Committee for 1901:—

THE CHAIRMAN OF THE CHAMBER OF COMMERCE (*ex officio*).

BUYERS:—Messrs Crosfield, Lampard & Co, Tarrant, Henderson & Co, Finlay, Muir & Co and F F Street Esq.

SELLERS:—Messrs Whittall & Co, J M Robertson & Co, Geo. Steuart & Co., and Bosanquet & Co.

The number of members belonging to the Association is 45, against 42 in the previous year.

The accounts for the past year made up to 31st December, 1901, and submitted to you duly audited, shew a credit balance of R1,396'34.

LIST OF MEMBERS.

Messrs Aitken, Spence & Co, Baker & Hall, Bathgate, Pim & Co, E Benham and Co, Bois Bros. & Co, Bosanquet & Co, Carson & Co, Crossfield, Lampard & Co, Colombo Commercial Co, Ltd, Hon J N Campbell, Darley, Butler & Co, Delmege Forsyth & Co, Delmege, Reid & Co, C H De Soysa Esq, Dodwell & Co, Finlay, Muir & Co, Forbes & Walker, Framjee Bhikajee & Co, Galaha Ceylon Tea Estates & Agency Company, Ltd, Gordon, Frazer & Co, E John & Co, Leechman & Co, Lee Hedges & Co, Lipton Ltd, Lewis Brown & Co, Mackwood & Co, McIntyre Bros, Murdoch & Branwell, Odell & Co, J M Robertson & Co, Rodewald & Heath, Rowley & Davies, Geo. Stenart & Co, Schulze Bros. & Co., Somerville & Co., Skrine & Co, Stcherbatchoff Tchhoff & Co, F F Street Esq and Tarrant, Henderson & Co.

The Trading Co, (successor to "AG A Koosnetzoff & Co") Messrs Tokmakoff, Molotkoff & Co, Turner, Edgar, Esq, J H Vavasseur & Co, E & H A Webb and Whittall & Co.

ACCOUNTS.

Dec. 31, 1901.—To Advertising R392'86, Printing 34'75, Clerk's Bonus R50, Sundries R3'96, Balance carried down with Bank of Madras R1,396'34.—R1,877'61.

Jan. 1, 1901.—By Balance R1,887'61; Dec. 31 Members' Subscriptions R450, Entrance Fees for Membership R40, R490;—R1,877'61. By Balance brought down R1,396'34.

Colombo, 12th February, 1902.

TEA IN AUSTRALIA.

Everyone drinks tea. Indeed the tea-drinking capacity of Australians has almost passed into a proverb. It becomes therefore a matter of very wide-reaching importance in a community so constant in appreciation of "the cup that cheers and not inebriates" that adequate precaution should be taken to protect us from the danger of inferior brews. There is reason to believe that for some years the quality of our tea imports has been declining. In the desire to meet the demand for cheapness importers have been sacrificing quality to price, and among recent shipments there have been some which have been declared "unfit for human consumption." China and India have been sending us their trash, and it is high time that a stringent check should be imposed upon this method of slow poisoning. Public opinion will support the Custom House officials in their endeavour to raise the standard of teas imported into the Commonwealth. Importers, however, are dissatisfied with the process of judgment. A chemical standard has now been adopted and tea which fails to come up to the mark is liable to be destroyed. Firms in the trade complain that the

analytical test is not in accordance with expert conclusions and that the teas have been condemned which cannot reasonably be deemed unfit for human consumption. They think it still harder that no opportunity should have been given to communicate with the shippers, and that they should not be allowed to re-ship the teas and try the chances of other countries where the standard of purity is less severe. There is a variance of standard, for in England teas have been accepted which have been condemned in the United States. It has also happened that a big line of tea rejected by the Melbourne authorities as unfit for consumption has been sold in London, and declared by customs officials there to be perfectly wholesome. There is no reason why equitable consideration should not be given to these representations. As long as the community is protected from bad tea mercantile requirements ought to be studied. Another matter to which some attention might be given is the manner in which consumers are cheated by tricks of the trade. Teas are being sold in fancy wrappers at short weight, and sellers are not always superior to the meanness of weighing in the paper when they sell over the counter. A person who buys a pound of tea is entitled to get a pound of tea, and those who by devious methods rob him of an ounce or so in the pound are practically guilty of fraud.—*Australian Paper.*

THE NILGIRI GAME ASSOCIATION.

OOTACAMUND, Feb. 23.—On Thursday, the annual general meeting of the Nilgiri Game and Fish Preservation Association took place at "Primrose House." Besides the President (Collector) and Hony. Secretary (the District Forest Officer), only seven members were present.

The Association considers that game on the Nilgiris has increased owing to measures adopted to protect it; (1) by the grant of discretionary power to the Collector to refuse licenses to notorious destroyers of game, who hitherto obtained licenses freely. These men, it is thought, will in future be brought more under control by this means. (2) By Badagas and Kurumbers having been frequently and successfully prosecuted for slaughtering game. Their propensity to do so for fresh meat is believed to be almost incurable, and to be kept under only by constant watchfulness, and even then the evil will, it is thought, only be mitigated, not eradicated. (3) By asking Managers of estates to prevent their coolies poaching, which otherwise is extremely difficult to detect. (4) By dealing with shikaris, who are known to egg on young and excitable sportsmen to shoot miniature and undersized stags, whereby undesirable trophies are the only thing procurable.

Of imported game birds—the Association has obtained jungle and pea fowl,—the red variety of the former from Ganjam and the latter from the Godavery. The latter have been liberated at Ithalar, in the neighbourhood of which they formerly used to thrive. The red jungle fowl are with Sir Frederick Price who has undertaken their domestication. The pea fowl are to be protected by the reservation of the tract in which they have been set free, but this alone, it is believed, will not save them from the depredations of vermin, since already the feathers of some of the young birds have been found strewed about the localities indicated.

As a further concession to the members of the Ootacamund Hunt, permission to shoot jungle sheep with shot is to be continued. During the past season 14 of this game were destroyed in this manner, and the Hunt did not complain of the honnds being diverted from their legitimate quarry. The disturbance and destruction of sambur, contended for by the Hon'ble Mr Stokes, will be continued in the future on the same lines as in the past, namely, to

limit the destruction to the Master, and the disturbance to the District Forest Officer.

By limiting the shooting of ibex to one saddle-back, a measure of protection seems to have been afforded these shy creatures, rapidly diminishing in numbers, since, during, the 12 months ending with June last, only three ibex were shot, and one of these turned out to be a brown buck. In this connection, the Honorary Secretary complains that sportsmen, who were asked to send in the heads and skins of ibex killed have failed to comply with the request, and that, for this reason, it will have to be made compulsory in future.

Major Bagnall is aware only of one large trout captured last year, and that was a female, weighing $5\frac{1}{2}$ lb., full of spawn, which was discovered too late to restore it to the water. He fears that any trout in Burnfoot Lake, that is fouled by the work going on in the construction of the Tiger Hill Reservoir, have perished, as some dead fish were seen floating on the surface of the water. He suggests that when the fouling is over, as it will be when the dam is completed at the Reservoir site, arrangements with the proprietor should be made to re-stock it. The carp of Pykara River were netted and placed in other streams that will suit them, and in the Ootacamund Lake.

The Game Association maintains a record of game shot each year, but this is necessarily incomplete, since sportsmen will not communicate their successes in the field; but from what has been reported it is noted that 14 heads of sambar, measuring over 30 ins., were secured in the 12 months. One head shot at Kotagiri had horns that measured $33\frac{1}{4}$ ins.; it was remarkably symmetrical, although 2 ins. short of the record, and the brow antlers were $17\frac{3}{4}$ ins. Another good head was secured on the Succoth Estate. It was the best of the season, but in massiveness a head from Kotagiri beat it. The left brow antler in this latter case was $16\frac{1}{2}$ ins. and the right $17\frac{3}{4}$ ins.

A black panther was shot on the Koondahs, last season 6 ft. 7 ins. in length. It was the largest black panther ever seen on the Nilgiris. Of bears, two, 6 ft. in length were shot, one at Kolakumbay and one at Kodanad. A tiger was killed on the Koondahs, which, judging by the size of head and skin, must have taped 9 ft. 8 ins.

A consignment of 20,000 trout ova is expected to arrive in Bombay on the 6th proximo. Mr. Van Ingen, the Taxidermist, who has had some experience in the matter goes to Bombay to receive the ova, and arrange for their safe conveyance to Ootacamund.—*Madras Mail*, Feb. 24.

SUNFLOWER AS AN INDUSTRY.

(From a Madras Correspondent.)

The sale on the Baltic of 300 tons of sun-flower seeds at £11 5s. per ton serves as another reminder to people, that the *Helianthus* or sunflower is one of those crops in which there is money. A small trade has been done in the seeds for close on two centuries in Russia, France, Germany and Italy, but in England the cultivation has been exclusively for ornamental purposes. In America it has recently formed the subject of a special report to the United States' Department of Agriculture. This report shows that the plant can be grown successfully but that it is a crop which makes a considerable drain on fertilisers. The report also shows that the cultivation of the flower would prove commercially advantageous, and that the methods pursued for growing Indian corn should be followed. It is largely cultivated in China and Tartary; it spreads with comparative rapidity; and, in Simla and other hill stations, where it was introduced into gardens, it may now be found growing wild. The Jerusalem Artichoke or *Helianthus Tuberosus* is believed to be a native of North America. It was introduced into Europe about three centuries ago, from there into India, and soon became an article of diet, the people of Kathiwar reckoning it a very nutritious vegetable and

most palatable when boiled in milk. The seeds are sold in Russia and eaten as nuts, and when torrefied in the same manner as coffee, may be used as a substitute for it. They are also considered beneficial to poultry and to birds generally, and possess, moreover, medicinal value in the treatment of farm animals. Cows and oxen, horses, sheep, pigs, rabbits and poultry are all fond of them, and they are considered superior to linseed for cattle, which are also fed on the oilcake. It is however, on account of the oil that the plant has now assumed such commercial importance. In its pure state this oil is said to be excellent for the table, and in Russia it is already in use as an adulterant of almond and olive oils. It may be advantageously utilised for woollen dressing, lighting, and candle and soap making. Somehow, the oil expressed many years ago from seeds of plants experimentally cultivated in Bangalore was a disappointment commercially, for it was inferior as a table oil, its thinness made it useless for railway trains, it dried too slowly for paint, and, though in the Ordnance Department it was found to serve all the requirements of the Arsenal, the price was prohibitive. Some species of the sunflower, such as *H. thurifer*, secrete a resinous juice, which some day may be utilised. The blossoms furnish a bright and lasting dye and the stalks of the plant yield a useful textile fibre, while bees are largely attracted to the flowers.

It was at one time believed that the sunflower possessed great value in the reclamation of marshy tracts of land besides the property or removing malaria from swampy areas. To test this theory, cultivation was undertaken in Bangalore about 30 years ago but the virtues of the plant proved to be imaginary.

In Russia where the cultivation for oil is on a large scale, the *grandiflora* is the variety grown. The species which the natives of India have for a long time cultivated is the *H. Annus* of modern botanists and the *H. Indicus* of Linnæus. This was at one time believed to be a native of India, and it is probably to this genus that reference is made in the history of the reign of Akbar.—*Capital*, Feb. 20.

TOBACCO-GROWING IN TRINCOMALEE.—“J. B. C.”’s seasonable letter elsewhere should excite interest in the peninsula as well as at Trincomalee. We shall welcome up-to-date replies to the request for Jaffna information on the topic.

CACAO STEALING.—It is almost incredible that the Cacao Planters of Ceylon should, directly and indirectly, owing to the deprivations of cacao thieves, be submitted to bear a loss of 25 per cent annually on their crop. Such is the case, however, and the Cacao Committee of the Matale and Kandy Association which met on the 17th inst., give good ground for the motions they passed praying the Parent Association to approach Government on the subject. Under existing legislation it has been found impossible to suppress the evil, and in many cases although planters were morally certain of the thieves they could not prosecute with any prospect of success. Rural Police have, after a fair trial, proved a failure and indeed the only preventative at present is “small shot and fire low.” Cacao planters are a law abiding people, however, and do not wish to take the law into their own hands and have so far refrained from this effective cure. Government cannot we think, if the matter is properly represented to them, abstain from devising some special method of preventing this wholesale robbery, a measure like the coffee stealing law is wanted.

INDIAN AND CEYLON GREEN TEA.

HOW TO ADAPT IT FOR THE AMERICAN MARKET.

—'GLAZING' WITHOUT ADULTERATION.—

THE CHINESE FACING 'FAKE' EXPOSED.

By H Drummond Deane (specially contributed to "TEA.")

In dealing with the subject of green tea and its manufacture and suitability for the American and Canadian markets, I must premise that, beyond a small experimental invoice from this estate, I have so far been unable, partly from want of a steam boiler and partly through being more or less in the hands of London Agents, to go in for these teas on a large commercial scale. Still almost every pound (if not quite every pound) of green tea that has been shipped in the last two years to America or Canada from Ceylon and most, if not all, of the Indian green tea now finding favour in those countries, has been made on my system and with a machine of my invention for the steaming process.

My first attempts in this direction were made in 1887 when I returned from visiting China and Japan and making a special study of the Japanese manufacture. I came to the conclusion that what was suitable for the small holdings of Japan would be too costly a process on account of the hand labour involved either in Ceylon or in India, and further modification in manipulation must be made to deal with the fine large-leaved varieties of the Indian indigenous tea plant.

In 1889 or 1890 I made and sent to London my first complete invoice of 'Ceylon Green Tea.' The prices were most satisfactory, averaging all round, as far as I remember, about 1s 2d per pound. The teas were sold as 'Kintyre' Estate Green Teas by Messrs. Wilson and Smithett, I continued to ship Green Teas for some time afterwards to a firm called, I think, Messrs Chas. Lamb & Co. of Philadelphia. Finally I took a first award for Green Teas at the Chicago Exhibition.

There is abundant evidence at present that Ceylon and India can and do produce a first-class article in Green tea of 'Moyune' type, as regards liquor, and with perseverance a large business will in the end be built up.

THE PLANTER'S DIFFICULTIES.

The difficulties to be overcome are three in number. First of all, there are the vested interests of the American merchant in the China and Japan trade. Secondly, we have to contend with the ignorance of the public in general as to what the true appearance of a Green Tea should be. They have been so long accustomed to the 'faced' teas of China and Japan and the small leaf from the dwarf variety of plant common to those countries, that it must take time for our plain looking but far more economical and purer teas to get the attention they deserve. In the third place there is the difficulty from a Planter's point of view of getting rid of fannings and small broken teas, which, as with Pekoe fannings and broken orange Pekoes in black teas, are almost the finest liquoring and most economical teas made, were it so understood by the American and Canadian house-keeper. But in China and Japan these grades of tea are consumed in the country itself and not shipped as they do not lend themselves to the 'faking' process known as 'facing,' so it is an unwritten law in America and Canada that broken teas must be avoided, and the problem at present is what to do with them, as we have no Green Tea drinkers on this side.

I am of opinion that our able Commissioner should do his best to introduce these teas to Americans, proving by the test of the teapot what fine flavoured economical teas they really are—in nearly every case better than whole leaf 'Imperials' or grades answering to Pekoe and Pekoe Souchongs of black teas.

COMPRESSED TEAS.

In order to encourage the production of Green Teas by Indian and Ceylon Planters, arrangements should be made to send out to Calcutta and to Colombo the most modern Hydraulic Presses for pressing these teas into 'Compressed Cakes,' like cakes of chocolate, the cakes to be stamped by the Indian and Ceylon Tea Associations. Until such time as the prejudice against this grade of tea is lived down, either the bonus should be paid to producers on their grades, up to, say 10 per cent of an invoice or the teas should be bought by the Association at least at the average cost price of manufacture, and made into compressed tea, any profit over and above, say 10 per cent being divided among the producers as a bonus after sale and realisation.

HOW CHINESE GREENS ARE PRODUCED.

'Facing' teas as is done with over two-thirds of the China and Japan teas is done in the following way. The tea is bought from door to door, village to village by travelling buyers. It is about three-quarters fired at time of purchase. It then finds its way down to the treaty ports, where it undergoes sorting and bulking. The bulked teas are taken to the 'Hong' or firing house which as a rule contains from 100 to 600 iron pans heated by charcoal fires. About a pound or two of tea is poured into each pan which is warmed, but not hot at that step. The warmth for the moment renders the three-quarters fired tea slightly flaccid. A spoonful of a mixture of soapstone, gypsum and indigo or Prussian blue is quickly put into each pan, and a coolly in charge of each commences rolling the tea in the pan, the fires being banked up, and the heat increased until the tea is finally fired. Meanwhile the glaze or facing has been thoroughly rubbed into the tea, giving it that shiny peculiar colour always apparent in Chinese and Japan Green Teas. The mixture is apparently harmless, but there is no use for it, except to keep up the tradition that 'Green Tea' should have this peculiarly coloured, plumbago-like appearance. Now Indian and Ceylon Greens can, if wished, be given a glazed appearance without any adulteration simply by the use of the juice of the Tea Plant. To illustrate my meaning, I am posting you under separate cover, three samples of Green Tea, identically the same tea—Plain, Glossed and Glazed. Perhaps the glazing is a little overdone, but the amount can be regulated. I do not consider the liquors of these particular samples quite fit, as they are purposely made off a Hybrid Tea grown on poor soil; but I feel certain the expert you show them to will say the teas are pure and good teas, and quite able to hold their own for quality with an average good Japan tea at least so I am advised by Calcutta and Colombo experts.

THE COST OF PRODUCTION.

Anyone working on my lines can, without any extra expense beyond ordinary rolling and drying machinery and a steam boiler, turn out a similar class of tea (the quality depending, of course, on altitude and soil.) with no extra expense beyond the £40 charged for my Patented Steam Apparatus. As the best Green Teas are made in the rainy season, factories that can't manage to wither black teas on account of insufficient space in wet weather, when leaf often takes two to four days to wither, can avoid all increase in capital expenditure in the shape of withering accommodation by making 'Green Teas' during the wet months.

One word more. Green Teas must be divided into two classes, viz. True Greens which are entirely unfermented, and Green Teas that are in part fermented, commonly known as 'oolongs.' These latter are represented in India by so-called 'Kangra' Green Teas, good teas of this class, but by no means up to the Greens of 'Moyune' type. There is no reason why Kangra, Cachar and Sylhet should not each produce magnificent Green Teas, when working on the system I advocate and I am glad

to say that the few gardens now experimenting are getting most satisfactory reports on the results. I am strongly in favour of bulking and re-firing at the shipping port, as, until this is done, it will be impossible to send continuous matched breaks of tea. In Southern India in spite of the wretched prices—many estates are getting, in many cases less than 5d average—no one has so far attempted Green Tea manufacture but myself. The reasons for this are two-fold—first, the reluctance of London agents to lose the sale of the teas, and the want of American firms willing to finance estates, i.e. issue credits against crops to Producers; and secondly, the question as to how to dispose of fannings, or say 10 per cent of the crop.

FAVOURABLE REPORT BY EXPERTS.

The Committee of the Indian Tea Association in Calcutta have had under consideration a report by their experts upon certain samples of green tea which had been submitted by Mr. Drummond Deane. The report was to the effect that the samples were good types of green teas which would be useful to show to managers who required standards. They are however, decidedly superior to most of the teas which had been previously examined and were probably too good to fix as standard for a blend. If such teas could be easily made, the success of the industry was certain. This report was noted by the Committee with much satisfaction; and they decided to forward copies of it to Mr. Deane for information. A circular was also to be addressed to the members of the Association, giving the views of the experts upon the samples, and stating that the latter were available for the guidance of managers.

In writing to the London Committee the foregoing facts were to be stated, and the question of blending green teas in Calcutta—which was raised in the Circular No. 61 of September 9—was to be dealt with. The difficulty of carrying through any definite scheme of this description was the uncertainty in regard to funds. And the London Committee were to be asked if they had any proposals to advance which might be calculated to surmount this difficulty. Looking to the fact that special machinery was required for the manufacture of green tea, it was, the Committee thought, unlikely that proprietors would care to engage in it unless the bounty could be definitely promised to them during the interval which must necessarily elapse before a good demand at remunerative prices could be created.

NILGIRI GAME ASSOCIATION.—As will be seen from the report which we give on page 630, this Association has done very useful work during the past year and the result of the protective measures adopted is that there has been an increase of game. Interesting details are given as to what has been done in connection with the importation of game birds and the shooting of jungle sheep, sambur and ibex. Trout culture has also received attention.

PALEGAMA GRANT ASSOCIATION.—We regret extremely to read in the report, which we give in the next column, that there is no alternative left but to wind up this Association, the directors finding it impossible to maintain the 500 acres in cultivation as stipulated in the Government lease, owing to the animal pests that affected coconuts and the unprofitableness of coffee and cocoa. The termination of the enterprise is much to be regretted, but it is some consolation to know that the timber belonging to the estate is considered sufficient to pay the outstanding liabilities and the expenses of winding up.

THE KANAPEDIWATTIE TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

The Directors beg to lay before the Shareholders their Reports and Accounts of the working for the year ended 31st December, 1901.

The crop secured from estate leaf amounted to 169,614 lb, on an increase over last year of 18,493 lb. and of 9,614 lb. as compared with the original estimate of 160,000 lb. From bought leaf 22,355 lb. Tea was also secured, making the total crop 191,969 lb, which (after deduction of amounts received for manufacture of outside Tea) cost to lay down in Colombo 22-18 cents, and obtained a net average price of 29-17 cents. The usual table showing the crop, cost and average of the tea is appended for purposes of comparison:—

	1898		1899	
	Crop		Crop	
From Estate				
Leaf	142,267 cost	23-11	151,030 cost	21-92
From Bought				
Leaf	30,330 av'age	32-71	38,565 av'age	36-16
Total lb.	172,597		189,595	
	1900		1901	
	Crop		Crop	
From Estate				
Leaf	151,121 cost	24-07	169,614 cost	22-18
From Bought				
Leaf	52,195 av'age	27-72	22,355 av'age	29-17
Total lb.	203,316		191,969	

The net profits for the year amount to R18,104-26 and, after adding the balance brought forward from last year, namely R95-68 a sum of R18,199-94 becomes available for distribution. Of this amount, R6,680 was absorbed by the payment of an interim dividend to the 30th of June last of 2 per cent, and the Directors leave it to the meeting to decide what dividend shall be declared out of the available balance R11,519-94.

Mr. W P Metcalfe resigns his seat on the Board owing to his departure for England, and it will be necessary to elect a Director in his place.

An Auditor will also have to be elected for 1902.

PALEGAMA GRANT ASSOCIATION OF CEYLON, LIMITED.

In submitting the balance sheet and profit and loss account to the 31st December, 1901, the Directors regret to have to inform the Shareholders that His Excellency the Governor, on behalf of His Majesty the King, the Lessor of the Grant, has refused to renew the Lease, which has therefore terminated. Under these circumstances the Directors have no alternative but to recommend that the Association be wound up voluntarily.

The timber now lying in the Central Timber Depot, consisting of 180 tons 13 cwt. 2 qrs. 14 lb. Ebony and two logs Satinwood, will, it is expected, be sufficient to clear all outstanding liabilities and pay the expenses of winding up.

The Directors can only express their regret at the unfortunate termination of this enterprise, upon which they have bestowed every possible care and attention. The unfortunate failure of cocoa and coffee and the difficulties arising from animal pests which attended coconut cultivation rendered it impossible, with the capital at their disposal, to maintain the 500 acres in cultivation, as stipulated in the Lease, and in consequence of this the Lessor has refused to grant a renewal.

BALANCE SHEET MADE UP TO DEC. 31ST, 1901.

LIABILITIES.—To Capital:—2,000 shares fully paid R200,000; Debts due by the Company:—Loan Account R1,352; Agents and Secretaries R3,004-99; National Bank of India R7,094-64.—Total R211,451-63

ASSETS:—By Property (Immovable) R201,883'84; by balance of profit and loss R9,567'79.—Total R211,451'63.

PROFIT AND LOSS STATEMENT made up to 31st December, 1901.—To interest R350'65; to Timber account R9,217'14.—Total R9,567'79. By balance at debit carried to balance sheet R9,567'79.—Total R9,567'79.

THE RAYIGAM COMPANY, LTD.

REPORT OF THE DIRECTORS.

Directors:—Messrs Edward Rosling, Albert Rosling, Gordon Fraser, and F M Mackwood.

RAYIGAM.		ANNANDALE.	
Tea in bearing	Acres.	Tea in bearing	Acres.
...	551½	...	250
„ partial bearing...	126	Forest	8
„ not in „	18	Grass	38
Forest	504½		
Total	1,200	Total	296

The Directors herewith submit their Report and Balance Sheet for 1901.

Afer writing off R1,506 for depreciation on Building and Machinery, there remains at credit of Profit and Loss Account R12,025'39. Out of this the Directors propose to pay a dividend of two per cent absorbing R1,000, carrying forward a balance of R25'39.

The crop of tea from Rayigam was 294,110 lb as against 305,974 lb in the previous year, and from Annandale 85,923 lb against 103,988 lb.

The shortness in crop on both estates is partly due to finer plucking and partly to unfavourable climatic conditions.

The net prices realized by Annandale and Rayigam Estates respectively were 44'11 cents and 28'03 cents per pound.

The Estimate of crop for the current year for Rayigam is 300,000 lb, and for Annandale 100,000.

Mr Gordon Frazer retires from the Board of Directors by rotation, but being eligible offers himself for reelection.

The election of an Auditor for 1900 rests with the Meeting.

NEW PLANTING COMPANY.

HENRY ROLL & Co. (72,579).—Registered January 25th, with capital £5,000, in £1 shares, to acquire the business carried on at 66, Storks Road, Bermondsey, as Henry Roll & Company; to adopt an agreement with H. Roll, and to carry on the business of tea, coffee, cocoa and other Eastern and Colonial products, planters, growers, importers, blenders and merchants, lead rollers, printers, produce brokers, tobacconists, warehousemen, wharfingers, etc. No initial public issue. The number of directors is not to be more than 4. H. Ross is the first; qualification £1,000; remuneration is fixed by the Company. Registered office, 66, Storks Road, Bermondsey, S.E.—*Investors' Guardian*, Feb. 8.

THE DUTY ON TEA.

We are glad to see a writer signing himself "Fairplay" refutes some of the rather wild statements made on the occasion of the deputation to the Chancellor of the Exchequer. He states:—

Whilst sympathising with those suffering from the depression in the Indian and Ceylon tea industry, I regret to notice a want of fairness displayed in the unkind and unwarranted re-

ference to China tea as "a cheaper but inferior article." It must be well-known to the deputation, although possibly not to the general public, that China tea is not a cheaper article, in any sense of the word, than either Indian or Ceylon. In truth, Indian and Ceylon tea is really the cheaper, inasmuch as it goes further, owing to the way it is mostly prepared, and also to the public taste being for a thick and strong tea, to which large quantities of milk and sugar are added: in fact, in the majority of cases, it is most essential that they should be added to make the tea at all palatable. China tea on the other hand is more delicately flavoured, and does not naturally draw a thick, dark infusion; hence it does not appear to go as far in household economy as Indian or Ceylon tea. It is not a cheaper article in this sense, nor is it a less costly one to bring to this market. There is an export duty on China tea of about ¾d per lb., and inland taxes varying from ¼d to ¾d per lb.; it also bears an additional freight of about ¾d to ½d per lb., thanks to a Steamer Conference which maintains rates at 45s per ton, whilst Ceylon rates are about 20s. The average price obtained for the tea crop in the China market is certainly just as high as, if not higher than, the Indian and Ceylon crops have averaged during the past two or three years. So much for the danger of China as a competitor for cheapness.

As regards quality, I venture the opinion that China tea is fully equal to that of British-grown teas, but the taste of the large majority of tea-drinkers in Great Britain favours the latter. This, however, does not say that the quality of the British-grown article is better, but that the character is preferred by most people in this country, although it is a fact that several leading physicians recommend the China growth, and that many experts in the Indian and Ceylon trades prefer China tea for their own use. The Chancellor of the Exchequer, I think, struck the true cause of the depression in the tea trade—namely, over-supply. In their anxiety to compass China's tea trade, the Indian and Ceylon growers have brought on their own disasters, for China consumes itself some three-quarters of her total production of tea, and endeavours only to prepare as much for export as it can find a profitable market for. During the present season the export to all parts of the world, from China, is about 140,000,000 lb. (British-grown tea, for the same period, being about 300,000,000 lb.), against 170,000,000 lb. last season, the reason of the deficiency being that, owing to the low prices ruling in foreign markets, it paid the Chinese better not to prepare about 30,000,000 lb. of their later crops for foreign use, finding a better market for it in home consumption. If India and Ceylon would take a lesson from China, and study supply and demand a little more, I venture to say that there would soon be no laments as to the unsatisfactory state of the trade. China has always been an honourable rival of India and Ceylon, and I think the remarks referred to, tending to depreciate its produce, are as unfair as they are incorrect.—*L. & C. Express*, Feb. 14.

"PEARLS AND PEARL FISHERIES."—We notice that a lecture on this subject was given by Dr H Lyster Jameson at the Derby Lecture Institute on Feb. 14th.

THE TEA DUTY.

INFLUENTIAL DEPUTATION TO THE
CHANCELLOR OF THE EXCHEQUER.
PRODUCERS, BROKERS AND BUYERS PROTEST
AGAINST AN INCREASE OF THE DUTY,
A SYMPATHETIC REPLY.

The suggestion that the duty on tea should be again increased was received with surprise and consternation in London as well as in India and Ceylon, and the views of producers of British-grown tea, and of the brokers and buyers who handle it at home, were laid before the Chancellor of the Exchequer by a joint deputation which waited upon him on Tuesday, February 4, at the Treasury, Whitehall. To avoid the inconvenience that has been caused on former occasions, Sir Michael Hicks-Beach decided to limit the number of Pressmen at the interview to three, one of whom has reported the proceedings for the *Ceylon Observer*.

The deputation was introduced by Sir H. Seymour King, M. P., and it consisted of the following gentlemen:—

INDIAN TEA ASSOCIATION (London): Messrs. Arthur Bryans (Chairman), J. N. Stuart, G. Henderson, C. C. McLeod, and Ernest Tye (Secretary).
CEYLON ASSOCIATION IN LONDON: Messrs. H. Bois (Chairman), R. A. Bosanquet, Brown, A. Thomson, and W. Martin Leake (Secretary).
TEA BROKERS' ASSOCIATION: Messrs. Arthur Thompson, F. S. Long, S. H. Cheshire (Chairman) and A. G. Stanton.
TEA BUYERS' ASSOCIATION: Messrs. J. Innes Rogers, (London Chamber of Commerce), Lecky and Appleton.

Sir Michael Hicks-Beach was accompanied by his private Secretary, Mr. Hicks Beach, and his official private Secretary, Mr. Lawrence Guille-mard.

Sir H. SEYMOUR KING, M.P., said:—I have been requested as president of the Indian Tea Association, London, to introduce to you a deputation representative in the very highest degree of the tea-planting industry in India and Ceylon. In the first place I should like to express their acknowledgments to you, Sir Michael Hicks-Beach, for your courtesy in giving us a portion of your very valuable time to hear first-hand what they have to say for themselves in deprecation of any further advance in the duty on tea, and also in pointing out to you how hard is the pressure on the industry of the duty as it at present exists. That the industry is an important one you will readily agree when I tell you that in India there are 520,000 acres of land planted in tea, with an invested capital of £20,000,000 and an output of 180,000,000 lb. of tea per annum. More than one-quarter of that total is represented by the gentlemen now in this room. In Ceylon there are 387,000 acres in cultivation, with £15,000,000 invested, and an output of 145,000,000 lb. The other gentlemen who are present are representatives of the Tea Brokers' Association and the Tea Buyers' Association, so that all the interests concerned in this article are represented here today.

MR. BRYANS FOR THE INDIAN PRODUCERS.

Mr. ARTHUR BRYANS said he appeared on behalf of the Indian Tea Association, and in the first place he wished to thank Sir Michael Hicks-Beach for receiving them, and giving them an opportunity of addressing him on a subject which was

of almost vital interest to them. The Indian Tea Association, with its Calcutta branch, might be taken to represent the whole of the tea industry in India; as Sir H. Seymour King had said, it represented an area of some 520,000 acres of tea, which yielded last year a crop of 187,500,000 lb. of the sterling value of £5,664,000. The Chancellor of the Exchequer would doubtless remember that in 1900 they addressed a memorial to him on the subject of the duty, and the arguments they had used then certainly applied with equal force now. To put it briefly, their industry was in a bad way. It was one with which he had been connected since 1869, and though during those 33 years they had seen their ups and downs they had never passed through such a prolonged period of depression as they had been suffering from since about the middle of 1900. This depression was still with them; indeed, he regarded the year 1902 as likely to be the most crucial of any that they had passed through. For these had times over-production, as the Chancellor of the Exchequer was doubtless aware, was partly responsible, but this did not make the bad times any the less onerous to them. With regard to this question of over-production he would like to draw the Chancellor's attention to the fact that from the time the tea bushes were planted some 3 or 4 years had to elapse before they came into bearing, and therefore the planting which had recently given them the over-production from which they were to some extent suffering had all been done prior to the extra duty being put on in March, 1900. And when this planting was done they had no reason to anticipate that their industry would be subjected to an increase of taxation—indeed, a lower duty on such articles as tea seemed to be the more likely policy. It was particularly unfortunate that just at this period it was deemed advisable to make an addition of 50 per cent to the then existing duty. It was hoped that this addition would be of temporary operation, and they had recognised the necessity and uttered no complaint. But when they saw that the increase was to be more lasting than they, or Sir Michael Hicks-Beach, had thought when it was imposed they had approached him and asked him for relief. He (the Chancellor) did not see his way to grant them what they wished, but he held out some hope in his Budget speech and again when speaking on the Finance Bill. He (the speaker) trusted that Sir Michael would pardon him for reminding him of what he had said. In the Budget speech on April 15, he said: "I turn to tea. Tea has already been taxed up to 75 per cent of its value. It is produced mainly in India and Ceylon, and it is a product in which our fellow-subjects at home and abroad are deeply interested, and the trade—largely, I think, owing to over-production—is not in a very satisfactory condition. I do not think we ought to increase the duty on tea." And in his speech on the Finance Bill the Chancellor of the Exchequer said: "If it should ever be my happy lot to be able to reduce taxation, I should be disposed to reduce the duty on tea rather than on beer and spirits." If the Chancellor's "happy lot" had not arrived yet, they certainly hoped it would soon come, and that on the present occasion he could at least hold out some hopes to them. At present tea was taxed up to 75 per cent of its value. Although there had been a rise in value of the lower grades, the medium grades showed little

improvement and the higher grades none at all. That this taxation did affect producers was easily proved. In 1890 the duty was reduced from 6d. to 4d. per lb. and the result was two-fold. There was an immediate increase in consumption, which rose from 189,500,000 lb. in 1889 to 194,000,000 lb. in 1890, although the remission of duty was felt during only eight months of that year. But consumption rose to 202,500,000 lb. in 1891, showing quite an abnormal increase of 8,500,000 lb. in that year. The other effect was an increased demand for lower grades, which formed the bulk of the consumption. To such an extent did this go that they increased in value almost as much in amount as the amount of the duty remitted. When, however, the Chancellor reimposed the duty in March, 1900, the reverse happened, and the price of lower-grade teas fell fully 2½d per lb., and the average price of all Indian tea was reduced from 8½d. the price in 1889, to 7½d. in 1900, and to 7¼d in 1901—proving, as they thought, that to a great extent that tax fell upon the producers.

THE CHANCELLOR OF THE EXCHEQUER: You have given over-production as the cause.

MR. BRYANS replied that that was partly responsible, but the fall would not have been nearly so much as it was but for the extra duty. The later rise in price had been obtained by a great decrease in the yield per acre. The season had been a bad one for crops, and the small increase in price was by no means a gain to them, for a small crop cost more per lb to produce than a large one. Indeed, the industry as a whole was most unsatisfactory, as was evidenced by the marked decline in all the Companies' shares. The market value of 45 Companies' shares in July 1897 was £11,000,000, in January 1900 it was £9,600,000, in January 1901 £8,550,000; and at present it was at some figure below £7,000,000. There were many millions sterling hardly earning any dividend—and it was at this moment that a great newspaper and a great statistician advocated a great increase of duty! What the Chancellor of the Exchequer said last year showed that he appreciated that the industry was passing through a severe crisis in its history, and that this crisis would continue there could be no doubt. Every possible assistance by way of duty was absolutely necessary if they were to survive. The rival beverages paid no extra duty and tea from China was practically bounty-fed. He hoped Sir Michael Hicks-Beach would not think they had stated their case too strongly, and that he would be able to send them away with some crumb of comfort after he had heard them.

MR. H. BOIS FOR THE CEYLON ASSOCIATION.

MR HENRY BOIS said that as the president of the Ceylon Association in London he had to speak on behalf of the tea producers of Ceylon, who were to a great extent represented by the Association. There were 387,000 acres of land under tea cultivation in Ceylon, producing 145,000,000 lb of tea, and representing an invested capital of £15,000,000. When the extra duty of 2d in the £ was imposed on tea in 1900, the tea producers of Ceylon did not make any representations to Government as to the effect the tea duty would have on the industry, and perhaps their inaction on that occasion had been somewhat misunderstood. It had been perhaps assumed that they made no protest because they thought that the extra duty would to a great extent fall upon the

consumer and that their interests as producers would not be affected by it. That was not the case. There was a general apprehension that it would fall largely upon the producer. They had been animated by other motives. The tea producers in Ceylon and India were not less patriotic than British subjects in other countries; they recognised that the Empire had been forced into a very costly war, and they did not wish to appear unwilling to bear their share of the burdens. But later they had seen that the extra duty had fallen almost entirely upon the producer, and they addressed to the Chancellor of the Exchequer a memorial pointing out the depressed state of the tea industry and asking that the duty should be reduced. He did not think they had any sanguine expectations that it would be reduced, but they desired to put the case before the Chancellor in order to show how adversely any further duty would bear upon them. He (the speaker) thought that no formal answer was received to that memorial, but in Sir Michael Hicks Beach's Budget speech some time afterwards he referred in sympathetic terms to the statement they had put before him, and although he laid stress—and, he (the speaker) thought, justly—upon the fact that the pressure had been caused by over production, he stated that the tea industry was a British industry which was already taxed to about 80 per cent of its value, and that when the time came for reduced taxation tea would be the first to receive consideration.

CHANCELLER OF THE EXCHEQUER: Before two other articles, I said.

MR BOIS, proceeding, said that with that statement by the Chancellor of the Exchequer the tea producers had remained satisfied, and they would be satisfied still but for the fact that proposals had been put forward to still further add considerably to the tea duty. They were quite aware that suggestions from unofficial sources, however distinguished the individuals might be, must not be taken as representing the views of His Majesty's Government; but it was a fact that the proposed increase in the duty had caused wide-spread consternation in Ceylon and India. He had received a letter from the Chairman of the Ceylon Chamber of Commerce on the preceding day, saying that if the Chancellor of the Exchequer listened to these suggestions it would just about finish us." The position of the tea industry at the present moment was one of very great financial depression. In 1900 the price of Ceylon tea fell ¾d per lb, and in the following year it fell ¼d per lb—and in this second year the actual fall in price was not the full measure of the difference in price between that and the preceding year, because owing to finer plucking which had been resorted to with a view to reducing output, the quality of the tea was much better in 1901 than in 1900, and consumers paid ¼d per lb less for tea which was from ¾d to 1d per lb better in quality. There had also been a slight increase in the cost of production. There was a certain fixed amount of expenditure on the estates, and if the quantity of tea produced was reduced, it followed that the cost per lb. was increased. As regarded 1900, he was not prepared to lay any great stress on the reduction in price in that year, because there was justice in the Chancellor of the Exchequer's remark that it was largely due to over-production. But 1901 was not a year of over-production, and it was fair to assume that

'o a very large extent, if not altogether, the difference in value is due to the additional duty. The producers' position was that they were only getting their tea into consumption at a reduced price. He thought it was a fact that the consumer was paying very little more for his tea on account of the increased duty; at a fair estimate the producer was paying from 1½d to 1¾d per lb, on account of the increase, the consumer paying the balance, not perhaps so much in price as in quality, he having received tea of slightly inferior quality in some instances for the same money that he had paid before. It was impossible to precisely indicate the cause of the fall in prices, but there could be no doubt whatever that the tea industry in Ceylon was in a very depressed state, and no fairer index of the condition of things could be had than the marked value of the companies' shares. Almost without exception the Ceylon tea companies were capitalised on the fair basis of 10 to 12 years' purchase. They were agricultural Companies, no element of speculation entering into their operations, and dividends had been declared upon the earnings of each year; and the dividends had regulated the market value of the shares. He held in his hand a statement showing the market value of the shares in 60 Ceylon Companies' at various periods, and he found that in 1896 the aggregate market value of the shares was R23,000,000; in 1897, R17,000,000; in 1898-9, R16,000,000; in 1900, R15,000,000; and in 1901 below R14,000,000. That was the position at present, and he was afraid there was no prospect of any immediate improvement; in fact, apprehensions were general that 1902 would be financially one of the worst years the tea industry had seen. Last year a great many of the estates had paid no dividends, some had paid lower dividends, others had produced tea at higher prices than they had sold it for, and results in the coming year would probably be still worse. However, this was not the position as regarded the more distant future, for which the prospects were statistically more hopeful. At the end of 1899 the over-production was 14,000,000 lb.; in 1900 the production of Ceylon and India together was 334,000,000 lb., and the consumption 314,000,000, an over-production of 20,000,000 lb., raising the surplus at the end of 1900 to 34,000,000 lb. In the following year consumption overtook production. The total production of India and Ceylon in 1901 was 328,000,000 lb. against a consumption of 337,000,000 lb. In the case of Ceylon the improvement in this respect was perhaps even more marked. In 1900, against a production of 148,000,000 lb there was a consumption of 142,000,000 lb, but in 1901 the production was 145,000,000 lb and the consumption 152,000,000.

THE CHANCELLOR OF THE EXCHEQUER: Finding its natural remedy.

MR BOIS: We hope so, sir. I think that in future the evil will be remedied providing nothing is done to reduce consumption. This is a reason why nothing should be done that would check the industry. Continuing, the speaker said he thought that in the coming year tea Companies would have a very hard struggle, and he hoped they would manage to weather the storm; but looking a year or eighteen months ahead, if nothing were done in the meantime to further depress the

industry he thought it would be found to be on a firmer basis. The two points they had guard against were over-production and checks to consumption. Planters themselves were taking measures to restrict the output, and as regarded consumption he thought that if no extra duty was imposed consumption would probably increase in a normal manner, and that at the end of eighteen months they might find the industry in a better position.

THE CHANCELLOR OF THE EXCHEQUER:— There is one point which no speaker has touched upon. If you can show that the increase of duty has checked consumption you would show there was something important in it.

MR. BOIS:—It has not checked consumption, but our tea has gone into consumption because we have paid the duty. The consumer has got it at practically the same price as before.

THE CHANCELLOR OF THE EXCHEQUER:—In other words, your over-production enormously lowered the price of tea in this country, and if no extra duty was imposed tea would have been very much cheaper. I don't think you can prove that the extra duty imposed two years ago has injured it.

MR. BOIS:—It has injured us to this extent, that consumption would undoubtedly have been checked had we not accepted a lower price for our tea.

THE CHANCELLOR OF THE EXCHEQUER:—So far from consumption decreasing I think your figures show an increase,

MR. BOIS:—It has been increasing year by year, and it has followed the normal course. We say it would have been decreased had we not accepted a lower price.

THE CHANCELLOR OF THE EXCHEQUER:—I have understood that through bad plucking some tea was practically valueless.

MR. BOIS said he must explain that climatic conditions were largely responsible for this. He (the speaker) would not say that producers were blameless, but as far as possible they had now applied the remedy. In conclusion, he thanked the Chancellor of the Exchequer on behalf of himself and his colleagues, and tea producers generally in Ceylon, for his courtesy in receiving the deputation and in listening to what they had addressed to him.

MR. A. THOMPSON FOR THE BROKERS,

MR. ARTHUR THOMPSON said he spoke as a representative of the Tea Brokers' Association, and he was therefore one who should be fairly cognisant of the working of the trade in its various branches. He deprecated raising the duty, first on account of the disturbance it would cause to the home trade, both wholesale and retail, whose business was already seriously interrupted by the present duty. This must be the case with all dutiable goods, but the tea trade had been so upset by the late addition of 2d. per lb. that any further addition would prove disastrous, and this would be accentuated. In the second place, tea was no longer a luxury but a necessity of life, especially among the working class. The present tax amounted to about 80 per cent of the average value of the tea, and any increase in the duty would weigh most hardly on the poorer citizens and would check the expansion of, if not bring about a decrease in, consumption. It was true that the late increase in duty had not

apparently had this effect; since the duty was raised the consumption of tea had increased about 13,000,000 lb (equal to about 5½ per cent), 5 of which might fairly be put down to the natural growth of population, and a considerable quantity also to the abnormally low prices that had ruled almost all through the season. Meanwhile cocoa had increased 25 per cent., and coffee 23 per cent., and comparing these articles with tea be found that while the market values was practically the same—say 7½d per lb.—the duty on tea was 6d, or 80 per cent, that on cocoa 15-8d, or 15 per cent, and that on coffee 13½d, or 20 per cent. So that it would be seen that tea, which was practically a necessary of life, was even now bearing more than its fair share of taxation.

THE CHANCELLOR OF THE EXCHEQUER:—Of course, you know that Mr Goschen reduced the duty on tea to 1d, but did not reduce that on cocoa and coffee. Practically the relation is the same as when the duty was 6d formerly.

MR THOMPSON:—Yes, but it seems to me that tea as a necessity of life is bearing more than its fair share, in spite of the fact that of late cocoa is markedly increasing in use. Continuing, Mr Thompson said that any increase in the duty would be against the well-being of what was a purely British growth. Only 7 per cent. of tea consumed at home last year was of foreign growth. At least half of the extra duty imposed in 1900 was being borne by the producers. They had a capital out-lay of £40 per acre, with an average yield of about 485 lb., so that the profit per acre worked out at about £2 per acre, or only about 5 per cent on capital. So any further burden must seriously interfere with a most important trade of the Indian Empire and also of the island of Ceylon.

MR. J. I. ROGERS FOR THE WHOLESALE BUYERS.

MR. J. INNES ROGERS said, he represented the tea buyers of London, whose Association represented three-fourths of the buying power in the market. They were there that day for two reasons; first, to express their very great sympathy with the producers in the sufferings which had been entailed upon them by the late increase in the duty of 2d—[Sir Michael Hicks-Beach; you have not proved that, I think]—and second, to point out the interest of the wholesale and retail trade of the country in the question. He believed the producers had stated their case very moderately and in a convincing way. No doubt the main cause of their sufferings had been that production had greatly exceeded consumption, and whether the extra duty had been put on or not there would have been a considerable fall in the value of tea. But in his belief, and in the belief of his colleagues, the putting on of the extra 2d in duty had largely aggravated the trouble and accelerated the falling in prices. The public were used to a certain scale of retail prices for tea. That scale had not been appreciably raised, and, as to the actual price charged to consumers, they (the consumers) had not felt the 2d increase in duty. It was quite true that the consumer had had a lower class of tea supplied to him, and he had been satisfied with it; he had not paid materially more, but the loss had been on the producers and to a less degree on the retail distributors. Retail grocers had had to cut and contrive not

to alter shop prices, but to keep up their standard grades, by altering quality, and so on, and they had succeeded in doing so. But this led to great stagnation in the market when enormous supplies were coming in, and the constant struggle on the grocers' part to buy cheaper and cheaper teas, and the consequent depression in value, were largely due to the 2d extra duty. But this state of things could not be repeated if a further increase in duty took place. It had been said, "You can't take the brecks off a Highlander," and if the duty were again increased the policy of the grocers must be altered. The scale of prices perforce could not remain unaltered, but would have to be raised if another increase in duty were decided upon, and the effect of this would be to decrease consumption. That, he thought, would be a very disastrous thing both for producers and distributors. The position of the grocery trade was a very peculiar one, and he thought it was worthy of more sympathy than the Chancellor of the Exchequer had sometimes been inclined to give it; because, excepting the publicans, grocers were the chief people to pay duties. An extra 2d in duty meant £200,000 extra capital looked-up for his wholesale colleagues and himself. They could not go on in that way, for another 2d would mean another £200,000.

THE CHANCELLOR OF THE EXCHEQUER: But you take interest on your capital?

MR. INNES ROGERS:—We try to, Sir.

MR. LECKY:—It's impossible to get interest on this capital.

MR. INNES ROGERS, proceeding said, he had made a careful estimate of their trade and had come to the conclusion that in the grocery trade the capital looked up in Customs and Excise duties was £3,000,000. He appealed to the Chancellor of the Exchequer not to add to that burden. Tea was an article that appealed to and was approved by everybody. The effect of an increased duty would be to drive people to drink common tea, and it would be very injurious to Indian and Ceylon producers. One point that nobody had yet touched upon was that the effect of an increased demand for common tea would be to add to the imports of tea from China. The China trade would force ahead at the cost of India and Ceylon. They appealed to the Chancellor of the Exchequer for consideration: he had given the Coal people some comfort, and they hoped he would do the same now, and send them cheerfully away.

THE CHANCELLOR'S, REPLY.

SIR MICHAEL HICKS BEACH, in reply, said: I have listened very carefully to all that the deputation have said to me. I recognise the importance of the great industry which you represent both to India and Ceylon, and to many persons in this country, and I can assure you that I have listened to you all the more carefully because I feel that it is not a question of taxing an article which comes from foreign countries, but one which comes to us from our own colonies and possessions, and in the production of which we are ourselves deeply interested. I do not suppose that you anticipated that I should be able to tell you anything in regard to a reduction in the duty on tea. I do not imagine that anybody anticipates any reduction of existing taxation in the year which is before us, and I think the object of your deputation today is

rather to impress me with the present condition of your industry and to put forward such arguments as you have put forward against any increase of the taxation in the coming year. For reasons which everybody who understands the export trade in coal is acquainted with I felt it possible to depart from the unvarying rule of Chancellors of the Exchequer, and gave to those who are interested in that trade a precise statement in regard to it. I cannot do so, and I think you will see it would be impossible for me to do so, with regard to any other forms of taxation. That must wait until the introduction of the Budget. I do not think you have shown that the increase of the tax two years ago did you any real harm. It no doubt was partly paid by the producing industry rather than by the consumers, from the extraordinary amount of over-production which in the same way, I think, has lessened the burden of the sugar duty on the consumers of sugar. But you have certainly put before me today some reasons which are important reasons against any further increase in the duty on tea. You, I think, anticipate that the over-production which naturally cheapened it—so that practically the tax had no effect whatever in decreasing consumption—may have ceased; that, in fact, those whom you represent have learned their own interests a little better than they had known them before, and that they will take care to send us in future rather a better article than was sent in 1900 or 1901. It is obvious, I think, that if these anticipations are realised a further increase in the duty on tea would have an effect in checking consumption which certainly we have not seen in regard to the last increase, and that would mean undoubtedly a burden upon great masses of our population and an increased cost on an article which, as you have pointed out, is already very highly taxed in proportion to its value—a point which any Chancellor of the Exchequer would be bound to consider. You have reminded me of what I said last year on this subject. I think I showed that I appreciated your difficulties, as well as the fact of the high existing duty on tea. I can only say today that I shall be glad to consider all you have put before me, with a full appreciation of the great interests that you represent.

Sir H Seymour King having thanked Sir Michael Hicks-Beach, the deputation withdrew.

THE PRODUCTION OF COCOA IN AFRICA.

A West Indian merchant writes to say that in a few years' time Africa seems likely to prove a formidable rival to South America and the West Indies as a producer and exporter of cocoa, and those interested in the West Indian possessions of the United Kingdom and anxious to see the islands more prosperous, will do well to watch how the cultivation of cocoa is being pushed on with satisfactory results throughout the continent of Africa. This year the German colony of the Cameroons hopes to ship 3,000 bags of cocoa, to be increased, it is estimated, to 10,000 bags in 1906. Our correspondent adds:—"Mr McClounie, head of the scientific depart-

ment of British Central Africa, reports the successful shipments from Kew and receipt at Lomba of 210 plants, which had been planted out and were doing well. Lagos is also going in for cocoa, and one of her planters is now travelling in the West Indies to see how the estates are managed in Trinidad and Grenada." He also says that the little Portuguese island of St. Thomé has greatly increased its exports of cocoa in ten years, the shipments in 1891 being under 4,000 tons, whilst last year very nearly 16,000 tons of cocoa were exported.—*London Times*, Feb. 11.

PLANTING NOTES.

A SOIL MAP.—The United States Department of Agriculture is making a "soil map." The map is to cover the whole of the United States, and the scale (10 acres) to be represented by one-eighth of an inch square. Each farmer, however, will be able to procure a chart of his own neighbourhood on a larger scale, so that he can arrange his planting in accordance with the suggestions which it conveys. In the first place, the soil map will show what kind of agricultural industry any given locality is best adapted for. It will make clear to the farmer in one locality, for instance, that he has the same soil that is used advantageously for certain purposes in other localities, assuming similar climatic conditions. The map will call attention to certain troubles of soils which have been investigated through chemical analysis.—*Pastoralists' Review*.

RESOURCES OF THE STRAITS SETTLEMENTS.—According to a recent number of *Nature*, Mr H N Ridley, Director of the Botanic Gardens, Singapore, delivered a lecture at the Imperial Institute recently, entitled "The Economic Resources of the Straits Settlements and the Malay Peninsula." He remarked that the forests, which originally covered the whole peninsula, contain many valuable products, such as timbers, wood-oil, benzoin, gutta-percha, and rattans. Owing to the felling of trees by the Malays, gutta-percha, so indispensable for electric work, has been nearly exterminated. Fortunately, however, the product can now be extracted from the leaves and the twigs without injury to the trees, which are being planted by the Government. A very large area of the Federated States is under Coffee, but on account of the present glut of the market, and the consequent low prices, most of the planters are adding Para-rubber to their estates—a tree which thrives marvellously well, and produces a very satisfactory amount of rubber of the first quality. India-rubber from the "*Ficus elastica*" also promises well; but although it is being planted, its product is less highly valued. Accounts were given of the cultivation and preparation of Sago (one of the Sago-Palm gives as much nourishment as 163 acres of Wheat), Tapioca, Gambia, Mangrove-Cutch, Pepper, Nutmegs, Cloves, Indigo, and Pineapples. The greater part of the preserved Pines of commerce come from Singapore where the price of the fruit varies from a farthing to a penny each; and the lecturer remembered a time when they had been as cheap as sixteen a penny! The mineral resources of the colony include gold and tin, the latter being found in great abundance.—*Gardeners' Chronicle*, Feb. 1.

CEYLON TEA : MONTHLY SHIP-
MENTS TO UNITED KINGDOM
AND ESTIMATE.

Estimate for	Feb. 1902—8 to 8½ mill. lb.
Total Shipments	Do 1902—8,000 lb.
Do	Do 1901—8,323,266 lb.
Do	Do 1900—8,419,967 lb.
[ESTIMATE for Mar., 1902—8½ to 9 million lb.]	

THE DEAF HEAR.—No. 479 of the *Illustrated World* of 623, Chiswick High Road, London, W., England contains a description of a remarkable Cure for Deafness and Head Noises which may be carried out at the patient's home, and which is said to be a certain cure. This number will be sent free to any deaf persons sending their address to the Editor.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peal's Fortnightly Price Current, London, January 29th, 1902.)

		QUALITY.	QUOTATIONS			QUALITY.	QUOTATION.
ALOEES, Soccotrine cwt.		Fair to fine dry ..	70s a 80s	INDIARUBBER (contd.)

MARCH, 1902.

[No. 9.]

VALUE OF SOIL ANALYSIS.

WE have been much struck by the blind faith which people place in soil analysis, relying upon it as a mysterious "open sesame" to the secrets of Nature as she works through plant and soil. The fact is that the old method of soil analysis as it is ordinarily understood by laymen has come to be discredited long ago since.

If we consider for a moment what a soil analysis is generally expected to tell us, we shall see how presumptive are the claims of the chemist who takes credit for being able to give us this information by his manipulations in the laboratory.

How is it supposed that the chemist can recognise the subtle relation between the vital forces in the plant and the soil in carrying out his analyses, with a view to telling you what has to be added to the soil to meet the requirements of the plant? Does he make allowance for the capacity in plants to attack and appropriate the ingredients of plant food in the different forms in which they occur in the soil, and for the differences in his capacity in different plants? The solvent medium adopted in reckoning the proportion of "available" plant food in the soil has always been an uncertain factor in soil analysis, which has shifted its ground more than once with a view to reaching more accurate results.

The recognised action and interference of soil bacteria in the preparation of plant food has only helped to further complicate the difficulties of the

agricultural chemist and the uncertainty of chemical analysis as a gauge of the fertility of soils. The "outside influences" in the preparation and appropriation of plant food in the soil are so important that the mere treatment of soil by purely chemical methods gives very imperfect and unreliable results. Indeed the biological action that takes place in the soil has come to be admitted to be as important, if not more important, than the chemical. So that the analytical chemist, if he is to give us accurate information as regards the fertility of our soils and the requirements of plants growing in them, must widen his scope of operations to a considerable extent, and to the best of his ability, take cognisance of the vital action exercised by the plant and the bacterial activity within the soil—forces, it must be admitted, that can hardly be estimated at their full value in the laboratory. It would seem therefore, that apart from his purely technical qualifications in science as a chemist would need to have a considerable practical experience of soils and manures, and a large endowment of common sense—on which indeed he has to rely to a great extent in drawing his conclusions as to the properties and requirements of particular soils.

We were only last week discussing this subject with an eminent agricultural authority who passed through the Island on his way to take up an important appointment in the Antipodes, and were much impressed with his strong condemnation of the reliance placed by some on the results of chemical analyses. Such people think it is enough for them to send a sample of soil to a chemist with a note saying, "Please analyse the accompanying sample and let me know what

manure I should supply." The ignorance displayed by such a bare request is only surpassed by the audacity of the reply prescribing the kind of manure to be used.

And even when all things are considered: the past history and present circumstances of soil and plant, mechanical properties, the question of rainfall, drainage, etc., etc., we still cannot with anything like exactitude calculate upon certain treatment producing certain results, unless our recommendations are based upon the outcome of actual experiment and personal experience—our best guides. A contemporary well sums up the situation we are discussing as follows:—

Many farmers hold erroneous ideas as to the value of soil analyses. We hear farmers speaking as though they only required to have the soil analysed to know what manures to apply to certain crops to obtain the best returns. This, however, is far from being so. In the first case, as every farmer knows, it would be nearly impossible to obtain a sample that would fairly represent even a ten-acre field. Besides this, an analysis will only show what the soil contains; it will not tell the farmer whether the plant food is in such a condition that the plants can make use of it, neither will it tell him what treatment the soil requires to make that plant food available. So many other things, such as the physical condition of the soil and subsoil, its ability to retain moisture or perhaps the reverse, have to be taken into consideration that (except to the scientist) a soil analysis is just as likely as not to prove misleading in dealing with the manures such a soil requires. The only guide to the farmer is experience. Find out what others have done under similar conditions, and prove by experiment whether the treatment beneficial in their case is equally so in yours.

Greatest amount of rainfall registered in any 24 hours on the 19th inst., 1901, 2·54 inches.

Recorded by ALEX. PERERA.

OCCASIONAL NOTES.

Mr. Williamson Wallace, the late Lecturer on Agriculture at the Heriot-Watt Technical College, Edinburgh, and subsequently Director of Agriculture, Cairo, was a visitor at the School of Agriculture, Colombo, last week. Mr. Wallace was on his way to Melbourne to assume the duties of the new Director of Agriculture for Victoria—an appointment about which so much has been heard of late through the press. Our personal acquaintance with Mr. Wallace commenced in 1886, when we placed ourselves under his tutorship for a practical knowledge of Agriculture on his 2,000-acre farm "Twiglees" near Locherbie in Dumfries-shire. Mr. Wallace, we were glad to find, is in excellent health and full of enthusiasm over the prospect of his new duties which will offer a wide scope for his scientific and practical attainments.

The specific gravity of coconut oil is, at 99° C, 873·6, its solidifying point varies from 68° to 82° F., iodine value 8·7, Reichert-Meissl value 7·5, and Butyro-refractometer value 35·5 at 40° C. In its natural state coconut oil readily becomes rancid, though the thoroughly purified forms are free from this defect. Messrs. Loders and Nucoline, Limited, adopt the following process in purifying the crude coconut oil. After heating to a vacuum, a current of low pressure steam is forced through, which carries off the volatile substances of objectionable or pronounced odour or flavour, and leaves behind a pure and comparatively neutral fat. Like lards these preparations are pure fats and contain no foreign matter. They are distinguished from other fats, both vegetable and animal, by possessing a rather high Reichert-Meissl value. We understand that the latest development in the preparation of pure vegetable fat from the coconut is a process by which the fat is mechanically liberated from the fresh nut without any previous dessication. The samples produced by this process are unequalled in purity and freshness, and lead one to expect that the product will meet with ready demand from confectioners.

A Planter, who has given much attention to the subject of manuring the coconut, affirms that the results of fertilising the palm show themselves not only in increased vigour in the tree and larger crops, but also in greater development of the kernel. He believes that by manuring the number of nuts required for a candy (650 lbs) of Copra can be reduced from, say, 1,100 in the case of good nuts to 1,000 or even 950.

NATURE TEACHING IN SCHOOLS.

In a report on "Popular Education for the Farmer" by Dr. True, Director of Experimental Stations, U.S., the following reference to the above subject occurs:—

"There is every reason to believe that the plan of 'nature teaching,' as proposed by Cornell

University, may prove a grand success and be of very great benefit to farmers' children. The element of education which is at present most lacking in our common schools is the training of the powers of observation. The children need above all things else to be taught to observe carefully and correctly, and to state their observations in clear and terse language. The ordinary child, whether on the farm or in the town, actually sees comparatively little in the world about him. The wonders of the trees and plants in park or meadow, of birds and insects flying about the house, float like shadowy visions before his eyes. 'Seeing, he sees not.' He needs a teacher who can open his eyes and fix his mind on the realities among which his daily life is passed. This accurate observation of natural objects and facts is the only foundation on which scientific attainments can rest. The scientist is chiefly a man who sees better than his fellow men. But it is also a great help in practical life. Many farmers acquire much of this power by their own unaided efforts. And these are the very men who most regret that they did not have in early life the help of a trained teacher. The farmer's child lives where he has the best opportunity for such training. It would benefit him in the practice of his art, and it would add an interest to his life which would do much to wean him from a desire to leave the farm for the turmoil and uncertain struggles of the town. With proper provision for the training of teachers in normal and other schools, it would be entirely feasible to have this nature teaching in all our common schools within a few years. It is such teaching that the child-mind craves. With it the school becomes a delightful place and the teacher an angel of light. The leaflets which the College of Agriculture of Cornell University is issuing show how vitally this nature teaching may be made to affect agriculture, though it is not in itself the teaching of agriculture. In one leaflet the teacher is instructed to have the children plant squash seeds, dig some of them up at intervals to learn how the seeds germinate, and watch what happens to the little plants as they push their way up through the soil and unfold their stems and leaves in the air. Four apple twigs form the subject of some other lessons, and it is wonderful how much a child can learn about the way trees go from such simple materials. At another time the children are encouraged to plant little gardens and carefully watch some of the things which grow in them. Or they study some insect which preys upon fruit or make collections of the insects about their homes, or watch them to see whether they are doing things good or bad for the farmer.

"Is it not likely that a child who is thus taught will soon begin to see a new value and dignity in farm life, and to be less envious of the boy or girl who is shut up within the narrow confines of city streets most of the year? And if the farmer's boy learns how to accurately observe the processes of nature with which farm practice deals and the foes with which agricul-

ture has to contend, are not the chances vastly increased that he will be successful in managing nature so as to get the greatest favours from this coy mistress of his life and fortune?"

Commenting on the above the *Agricultural Gazette* of New South Wales says:—

In Canada the question has excited the liveliest interest among the Farmers' Institute and Departmental authorities. In expressing his opinion of the idea of nature teaching, the Director of Teachers' Institutes (Mr. W. Houston, M.A.) says that very little consideration is necessary to show that of all forms of "nature study" agriculture is the best for stimulating a spirit of intelligent inquiry in the minds of children. The pupil cannot be made "learned" in the scientific sense, but he can secure a wide and useful acquaintance with the theory of agriculture, if his teachers know how to put him in possession of it. Mr. Houston inclines to the opinion that so far as imparting elementary instruction is concerned, the lack of systematic training in agricultural subjects is not likely to prove a very formidable obstacle in the way of teachers.

Indeed, on every side there is evidence of a desire on the part of school-teachers to encourage the children in the study of agricultural matters, and despite the difficulties that seems to be in the way of anything like a definite and comprehensive scheme of elementary agricultural instruction in the State schools (such, for instance, as that of France, where instruction in agriculture is compulsory at every primary school), there is every prospect of good work in this direction being effected. The field of agriculture is so wide that both teacher and pupil may find relief in the diversity of subjects, and, as Mr. Guthrie pointed out when writing on this subject some time ago, it is in "training in scientific method, in habits of exact observation and careful reasoning, rather than the amassing of facts and theories that best results can be attained."

THE CHOCHO [SECHIUM EDULE].

The Government Botanist at the Cape contributes an interesting account of the Christophine or Chayote, a vegetable familiar enough in Ceylon, more especially the Central Province, under the name of "Chocho." According to a reliable authority the last name is the correct one, and "Chayote" is only a nigger conception of it. Chocho, described as "a squash which is not exactly a squash but something far better," has apparently established itself as a standard vegetable in America and even in Europe, for we read of Algeria already forwarding hundreds of tons of the fruits to Paris and London as a special winter vegetable; while it has begun to become popular in the Southern Colonies. Referring to the shyness among people to accept a new vegetable, Mr. MacOwan quaintly explains the condition of mind thus: I dare say if we had on record the primeval history of the Cabbage or of the Turnip we should find that the man who first grew and ate these

esulent novelties was similarly disappointed when he pressed them upon the attention of his prehistoric neighbours. They no doubt asked why they should venture to eat such new-fangled stuff when there was such an abundance of acorns to be had—a food which had stood the test of centuries and had been eaten by their forefathers from time immemorial! It would not be necessary to reproduce the description of the plant and the method of cultivating it, but we would like to impress upon our readers the value of the Chocho as a vegetable, and the advantages of cultivating it regularly in our gardens. Single vines will produce as much as 300 fruits, of an average weight of 8 ounces each, but the ordinary yield when grown on a large scale as in Algeria may be put down at 25 to 100 fruits per plant. The tuber ("as large as a man's head") formed after the first season is edible and somewhat resembles a yam in character, twenty per cent of its bulk consisting of small-grained starch like that of wheat. These roots which in appearance are like the larger sorts of Cassava are commonly sold together with the fruits in Mexico.

We quote as follows regarding the edible properties of the Chocho:—"Very different opinions as to the value of the chayote for food have been expressed, some writers reporting it to be insipid, while others have compared it to the vegetable marrow and have pronounced it superior thereto. The whole controversy is a question of cuisine, or one may say, of the sauce in which the vegetable is presented. Eggs without salt, beef without mustard, and salad without vinegar might just as rightfully be condemned on the ground of insipidity. Of course the fruit must be taken for the table when young; the old fully grown ones, like all similar vegetables, are more or less stringy and tough. Whatever can be done with the best summer squashes may be done to better account with the chayote. In Jamaica it is often treated as a fruit rather than a vegetable accompaniment to roast or boiled meat, and is converted into puddings or tarts with sugar and lime-juice even as apples are used. Since there is a greater variety of fruits than there is of vegetables, this custom seems to be a mistake. Dr. Trabut believes that as soon as its table merits are known it will become a general favourite and appear to much the same good purpose as sea-kale, asparagus, artichoke and the like. He says that before any special preparation it should be kept in boiling water for about an hour. [Young fruits are sufficiently boiled in about 40 minutes.] The leathery skin can be detached easily and the vegetable shows a white flesh like that of a boiled turnip or knol-kohl. It may then be cut in slices and sent up with any suitable kinds of sauces just as is done with the small squash."

Some time ago it was supposed that the Chocho possessed noxious properties, and that people partaking of it as a regular diet were afflicted with a disorder resembling rheumatism. Mr. Nock, Superintendent of the Hakgala Gardens, (who we believe introduced the fruit to Ceylon) contradicted

so absurd a notion in a report at present we have no access to. It is sufficient guarantee, we presume, of the wholesome character of the Chocho that it has been so largely and so long consumed in the West Indies and Mexico, and is now finding acceptance in Europe; but, as Mr. Mac Owan puts it, "Seeing that reiteration is accepted as a sort of argument, and that if you mean to push your produce you must keep on bawling out its virtues till the public catches on and listens." We reproduce the above notes in the hope that our readers may begin to see the value of the vegetable variously known as Christophine, Chayote, Chocho, Tazoti and Mirliton in different parts of the world.

POULTRY CLIPPINGS. (FROM VARIOUS SOURCES.)

One of the best materials that a poultryman can use for supplying the requisite lime is oyster shell, or any other variety of shells. An experiment in this direction was made at the New York experiment station, and the result was such that the use of oyster shells during the laying season, where they can be cheaply obtained, was strongly recommended. It was found there that one pound of oyster shells contained sufficient lime for the shells of about seven dozen eggs. Shells are not the only source for the lime necessary for egg shells. Bones also contain a large percentage of lime, as is seen from the following analysis of clean dry bones of oxen and sheep:—Carbonate of lime, six to seven per cent; phosphate of lime, fifty-eight to sixty-three per cent; phosphate of magnesia, one to two per cent; fluoride of calcium, two per cent; organic matter, twenty-five to thirty per cent. Fresh green bones also contain, besides the lime compounds, some protein or flesh formers, which add to its value as a poultry food. The best way to render the bones available is to have them broken by means of the bone-cutter.

A correspondent in "Farm Poultry" gives an ingenious device for freeing laying hens of lice, after having used many other methods and failed. His plan was:—Take an ordinary common-sized cotton clothes line; unbraid it so that it will make one-third or half when flattened out; cut in pieces about 12 in. long, and wind each once around the roost, letting the two ends pass down into the neck of a bottle about two-thirds full of kerosene, the bottle being suspended from the roof by a string fastened around the neck. The clothes line acts like a wick, drawing the oil up out of the bottle, and it being saturated with the oil, no louse can help coming in contact with it when he attempts to go to the hen at night, or when he leaves her in the morning. Hens with scaly feet and legs are also soon cured of their trouble when this method is used. Bottles can be suspended three or four feet apart on the roosts,

Chickens should be fed every couple of hours for the first week, four to five times the second and third weeks, *gradually* reducing the number of meals till you get them down to the old bird's meal times—twice a day. To be successful with young chickens, they should be fed often, and a little at a time; it is bad management, and waste of food if more is given than they eat up clean.

You could keep 250 to 300 hens to the acre if you divided the acre and penned them properly. It is not good management to run more than 25 to 30 hens together, and then the room given should be large enough for that number. Much depends on the breed which you intend to keep; if of the Leghorn class one rooster to ten or twelve hens would be about correct, if of the heavier breeds such as Brahmas, one rooster to six or eight hens. If you intend to produce eggs only, you do not require any roosters with the hens. On the other hand, if you wish to rear chickens, you should use good healthy roosters.

Try to keep the temperature of an incubator as near 103° as possible—of course, the last few days of the hatch, I don't mind it going up to 105°. A Foster Mother or Brooder should be heated to a temperature of 90° or 95° *when the chickens are in it*—not 90° and then run the chickens in to the Brooder. You must remember that the body heat of 60 or 70 chicks means a few degrees when they are shut up.

Never feed whole grain in a trough or feed-box. When so fed, there will be domineering hens which will get more than their share, but when the grain is scattered each hen must seek her portion and all have an equal chance. You need not fear to scatter it over every square yard of ground, for not a grain will be wasted, and it compels the hens to work. All penned fowls should have their grain food placed under straw, or some kind of a litter, so that they will exercise themselves in scratching for the grain.

Poultry can be bred for high records of eggs, just as dairy cows are bred for high butter records. We have many good layers, and some in these breeds are better than others. If we select high record hens that are good all-the-year-round layers, and breed along that line, we can add an extra dozen eggs to each hen for the year, then that will be profit. By carefully selecting the pullets for layers from the best laying hens, our egg-gathering is increased each year, which also means a larger profit each year. The cockerels used for breeding purposes should be selected from good laying hens as well as the pullets. For, it would be bad management to select the female line only, we must have the male line as carefully attended to if we wish to be successful in building up a record egg-producing breed.

The best breed is the one you have tested and tried as the one best adapted to your district and your purpose. There is no *best breed* that is best for all purposes, and for all climates; remember, that a breed has only one dominant talent and seldom excels more than one single characteristic. To a very large extent each poultry farmer must determine for himself which is the best breed—well—the best breed for his purpose, and the one most profitable to keep in his district. A breed may approach perfection in some districts, and give very little profit when kept in other localities. The influence of the climate often has much to do with the selection of the breed. With all the advantages in favour of a breed for prolificacy, hardiness is always essential to success, otherwise, loss and disease may more than balance the gain in other essentials.

VEGETABLES:

HOW TO COOK AND SERVE THEM.

Vegetables may be plainly boiled, or cooked and served up in some fancy way. In the former, just as much as in the latter case, they require careful attention; it is a common but very serious mistake to suppose they can be left to themselves, or to the tender mercies of chance. The average servant and—dare I say it? also the average mistress as well, puts down her vegetables to cook when she thinks of it, and they are either very much over-done when the time comes for serving or as hard as stones.

Now, of course, I know if the dinner hour is not punctual the cook cannot be expected to have her vegetables, or, indeed, any part of her dinner, very nice. But where there is a fixed time for dining, and the members of the family keep strictly to it, there is no excuse whatever.

The time required for cooking each vegetable should be carefully calculated, also the time for cleansing and preparing it; this latter, however, may be done with advantage some time, even hours, beforehand, and the vegetable be either set over or left in cold water, according to its nature.

In cases where it is really quite impossible for punctuality to be observed at meals—and I am quite willing to allow there are such, as in the case of a doctor, for instance—I would recommend the adoption of the following plan. In large high-class households, as most of us are aware, there is an utensil called a bain-marie, which is used for the purpose of keeping hot sauces, gravies, or any dish which the cook has been obliged to complete before it is required. What is this bain-marie? A large, shallow, open saucepan or kettle of nearly boiling water, into which the smaller vessels can be placed, thereby keeping them hot without altering their quality or quantity. Doubtless this bain-marie is expensive to buy, but what I am about to suggest is a substitute in the shape of a deep dripping pan, which can be set on side of kitchen or gas stove, and partly filled with nearly boiling water.

The potato, of course, is our principal vegetable, and if one can cook it well it is a good test of

talent in cooking. Not that it is so very difficult; it just requires a little care, that is all, and the remembrance of just a few simple rules. Old potatoes are placed in cold water, new ones in boiling water; some old potatoes are best steamed, some best boiled. If boiled in their jackets, as some prefer, they will not be so good a colour as if peeled first. To boil old potatoes, first scrub them clean in lukewarm water; they must be quite free from dirt before you begin to peel them, or they will stain. Peel them very thinly, as the most nourishing part lies next the skin, and it is a sin to waste it. As they are peeled throw them into a basin of clean cold water, where they may stay until wanted for boiling—an hour or longer will not matter. Place them in the saucepan with only sufficient water to cover them, and a good table-spoonful of salt to each two quarts of water. Bring them to the boil and boil gently, so that they may not break, for half hour strain off the water, and let them stand by fire or in a warm place, with the lid of the saucepan half off, for 5 minutes, when they should be perfectly dry and like balls of flour. Some kinds are better if drained from the water after 20 minutes cooking and allowed to finish in their own steam with the lid of saucepan on; then, when quite soft, partly remove the lid and let them dry as before. Now, if required to be kept hot any length of time, they can be placed in the hot water bath; but here is a wrinkle which everybody should take—if they have been boiled in an iron saucepan they must be removed into another vessel, or they will be almost sure to turn black. It is, perhaps, a safer plan to boil potatoes in an enamelled saucepan; then there will be no difficulty in keeping them a good colour, and this saucepan can be placed in the hot water bath with the lid partly off, until the potatoes are required for serving. It is obvious that only potatoes of equal sizes should be boiled together, as small ones would be tender while large ones were still hard. To steam tomatoes, simply place them in the steamer, sprinkle a little salt over them, and keep the water boiling in the saucepan beneath. Rather more than half an hour may be allowed, and they will not be so likely to spoil if cooked over time by this method of cooking. New potatoes are well washed and scraped, placed in cold water for a short time to preserve their colour, then into fast-boiling water salted in proportion, and with a sprig of mint to give them an agreeable flavour. They will probably be tender in 20 minutes, which may be ascertained by trying them with a skewer. When nearly so, strain off the water, let them finish cooking in their own steam, and dry them like old ones. Baked potatoes must be well scrubbed, and placed in a moderate oven; large ones should be chosen, and they will take from $\frac{3}{4}$ to 1 hour to become soft. It is easy to tell when they are done, by taking them in a cloth and squeezing them with the hands. All kinds of cooked potatoes are best taken to table uncovered; if necessary to keep the heat in, use a folded cloth in preference to the vegetable cover, as it will absorb the steam, and the potatoes will be less likely to be heavy. Some people have a great partiality for mashed potatoes, and there is a little instrument, called a potato

masher, which does the work very nicely, making the flakes of potato fall lightly, and effectually removing all lumps. Care must be taken, however, to make it very hot before using and to mash the potatoes in a warm place, or they will be hopelessly cold and heavy. Perhaps the better plan is to turn them to the saucepan after mashing, and to stir them lightly over the fire, with a bit of butter or a little milk, until they are smoking hot again.

Greens, quite contrary to potatoes, require very fast boiling in an uncovered saucepan. By greens, I include all green vegetables, from cabbages to turnip-tops. They require very careful washing, both to remove the grittiness which some of them acquire and the insects which may cling to them in some of their crevices. To remove the latter, a good plan is to lay the vegetables in strong salt and water for 10 minutes or longer; the insects, if any, will then generally crawl out of their own accord, not liking a salt-water bath.

To boil a fresh young summer cabbage: Cut off the outside leaves and part of the stalk, and, if a large one, cut in quarters; if small, merely slit the stalk down a couple of inches in two places. Wash well in fresh water, then leave it in the salt water as recommended. Have ready a large saucepan with plenty of fast-boiling water, well salted in the proportion of a heaped table-spoonful of salt to every half-gallon of water, and, unless the cabbage is very young and freshly gathered, a bit of soda about the size of half a bean. After the water boils again upon the insertion of the cabbage, allow $\frac{1}{4}$ hour; then try it with a skewer; if not quite tender at the stalk, it will most likely require another 5 minutes; but as soon as ever it is done, take it up, place in a colander, and thoroughly drain from the water, for nothing is more objectionable than wet cabbage. Serve in a very hot vegetable dish, and, for the convenience of helping, cut it across once or twice. There should always be a drainer at the bottom of vegetable dish, for this and all green vegetables, as very possibly after the most careful straining there will still be a little moisture left.

To boil cauliflowers requires a little more care in order not to break the flower, and yet to have them quite tender. Wash and prepare them like cabbage, but they should never be cut up, unless, indeed, they are so close that they cannot be cleansed properly in any other way. Leave them in salted water for a time before cooking, place them in boiling water, with the head *downwards* in the saucepan—the reason for this is that should any scum rise on the water it will not discolour the flower if turned this way. Boil from 20 minutes to $\frac{1}{2}$ hour, according to size; when the stalk feels tender upon the insertion of a skewer, the rest is sure to be done, as this is the hardest part, and takes longest to cook.

Cut greens of any kind are cooked in the same way, a tiny piece of soda in the water helps to keep their colour and to make them boil tender; but too much of this is very objectionable, as it makes the vegetables boil to a mash, and renders them unwholesome. Greens should be well drained from the water, and afterwards may be placed with advantage between two plates and well

squeezed from any remaining moisture. Or a plate (hot, of course) may be laid upon them on the top of the colander, and pushed down, when the water, if any, will run out.

French and Kidney beans come in when peas go out, and are a nice change to eat with any kind of hot meat. They are prepared by cutting off the heads and tails, and the thin string at the sides, and then by cutting into thin strips. As these are done they should be dropped into cold water, slightly salted. Place in boiling water, salted as for other vegetables, with a tiny piece of soda to keep them green, and boil 20 minutes. When tender they will sink to bottom of saucepan. Take them up, drain in a colander, and serve piled high in a dish, covered melted butter.

(To be concluded.)

NEW CURE FOR FOOT AND MOUTH DISEASE.

The correspondent at Rome of the London Times, writing to that paper on the 12th of November, said:—"The Italian War office is stated to have addressed a circular to the veterinary officers of the Italian Army recommending to their attention the new treatment of foot and mouth disease (by injections of a solution of corrosive sublimate) recently announced by Professor Guido, Baccelli, Minister for Agriculture and Commerce. The circular is understood to give directions for the preparation and use of the solution, and to recommend the greatest care in observing the effects of the new remedy. Pending the publication of this circular, which may be regarded as an official recognition of the efficacy of the corrosive sublimate treatment for foot and mouth disease, the following data may be of interest. They are furnished by Dr. Remo Guzzi, a young Lombard physician, who appears to have been the initiator of the remedy, first brought by him to the notice of the Pavia Medical Faculty in a special thesis last July after the completion of satisfactory experiments upon his own cattle. The solution used by him was composed of one gramme of corrosive sublimate and seventy-five grammes of common salt in a kilogramme of distilled water. The cattle treated had developed the disease between forty-eight and twenty-four hours previously, and their temperatures varied from 106.7 to 104.9 Fahrenheit. With the solution five injections were made into the big vein on the right side of the animal's neck, the first consisting of thirty cubic centimetres of solution, the second of fifty, the third of seventy, and the fourth and fifth of 100 cubic centimetres each. Within a maximum period of ten hours, the temperatures of the animals thus treated fell suddenly four or five degrees Fahr., but afterwards began again to rise. A second injection, however, sufficed to conquer the fever, and to maintain a normal temperature. It is noteworthy, too, that none of the cattle thus treated have suffered from those after-effects of the disease usually noticeable four or five months after an ordinary cure. As far as can be at present ascertained, the corrosive sublimate treatment is free from drawbacks of any sort, while, on the other hand, it has regularly given

100 per cent of cures. Dr. Guzzi does not, however, dispense with other medicaments in treating the local manifestations of the disease, but recommends that during and for some days after the cure external sores be washed and the feet banded with cloths soaked in naphthaline.

GENERAL ITEMS.

In his recent report on the grants for Agricultural Education and Research, Major Crenjie estimates that the sum devoted to the County Councils in England and Wales for the year 1899-1900 was roughly something like £77,000, and that including the grants distributed by the Board of Agriculture and the payments made by the Board of Education for instruction in the principles of Agriculture under the scheme of the Science and Art Directory, the total amount of public money in England and Wales applied annually for the purposes of agricultural education is between £85,000 and £90,000.

The following analyses of genuine rice meal and rice husks made by Dr. Augustus Voelcker are interesting:—

	Genuine rice meal.	Rice husks.
Mixture	10.30	12.53
Oil	8.52	1.40
¹ Albuminous compounds	12.93	4.94
Starch, digestible fibre, &c.	54.39	28.95
Woody fibre	4.76	33.52
² Mineral matter (ash)	9.10	18.66
	100.00	100.00
¹ Containing nitrogen	2.07	0.79
² Including silica	2.90	14.67

A correspondent writing to the N.S.W Gazette says:—"Shows as now held have a tendency to momentary interest and are not the educational factors they should be. These Shows should be looked upon as schools for the dissemination of education. The comparison of notes and ideas cannot but have an effect advantageous and beneficial to all concerned. The success of a Show depends principally on having a good display of exhibits and good judging. . . . I have always advocated the single judge system, and still hold that opinion; in fact, when asked to judge at Agricultural Shows, I object to take office unless the appointment be as a single judge. As to the question, should judges give reasons for their decision, the answer is, yes. The good judgment of the Committee should direct them either to affix a card or make the remarks known through the press. Undoubtedly the judges' work should be made public. I have known both these methods followed and with good results. Until something of this kind is done Agricultural Shows will not be the educators they are intended to be. If the judges are well paid (and they ought to be) they should have a perfect knowledge of their work and do it thoroughly.

Vinegar is the produce of oxidation of alcohol,

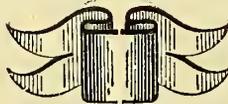

Alcohol is made from sugar, and sugar from starch; hence any fruit, vegetable, or grain containing starch (and they all do contain one or both of these) can be used for the manufacture of vinegar. The acid property of vinegar is acetic acid, diluted with four or five times its bulk of water. Acetic acid is not found in Nature, but is the result of several processes called fermentation. For instance, take corn meal, mix with several times its bulk of water, boil for a short time, pour into an open vessel and set it in a warm place and fermentation at once begins. The starch is converted into sugar and the product may be distilled or decanted off and will be what is known as sweet beer. This first fermentation is called the "saccharine fermentation," by which the starch is converted into sugar: the gluten in the grain acts as a ferment (*i.e.*, a yeast). Now, if this solution be undisturbed it will take on a second fermentation, called the "vinous (alcoholic) fermentation," whereby the sugar is converted into alcohol. If this compound be again let alone it will undergo a third fermentation, called the "acetous fermentation," whereby the alcohol is converted into acetic acid, which, as already said, is the acid property of vinegar. If this in turn be let alone it will undergo a fourth fermentation, which is called the "putrefactive fermentation," and is destructive. When the compound has reached the vinegar stage it must be decanted or strained off into a clean vessel and kept from contact with the air to prevent the putrefactive fermentation setting in.—*N.S.W. Agricultural Gazette.*

The system of exposing to the air wine which it is intended to convert into vinegar is all right until the vinegar is obtained; but after this it is a mistake to still leave the bung of the cask open and to still keep the vessel in a warm place. The *Mycoderma aceti* is the bacterium responsible for the transformation of alcohol into acetic acid, and by a process of oxidation of the former, for which air and a certain degree of heat are required, *viz.*, from 86° to 90° Fahr. When the vinegar is strong enough, if the said conditions of exposure to air and heat continued to prevail, the bacteria referred to will decompose the acetic acid into

water and carbonic acid, which is a further process of oxidation. That is why the correspondent's vinegar, good at first, is now a flat and nondescript liquid, which will very soon putrefy. Once the vinegar is made it should be racked and filtered or clarified; then the bung should be hermetically closed and the vessel stored in a cool place. Filling up with wine should not be omitted. This is done with the view of preventing any access of air, which at this stage is no longer required and is even detrimental. For fixing, either kaolin or Spanish clay should be used, never any isinglass, white of egg, or gelatine, which would make the vinegar more turbid. Four ounces of kaolin or Spanish clay are enough for one fixing of a quantity of 20 gallons.—*Ibid.*

D. E. Hutchins writing to the *Cape Agricultural Gazette* says:—In the *Algerian Bulletin Agricole* of the 15th May, 1891, is described a sun motor which is in successful use at Los Angeles in California. It is the result of a series of costly experiments which have been in hand for some years past under some Boston capitalists. This machine develops a ten horse power. It is hoped that certain improvements will bring it up to 15 horse power. It works a pump which yields 62·20 hectolitres of water per minute. The heating power of the reflectors is shown by the fact that copper placed in the focus of the apparatus melts in a few seconds, and a bit of hard wood lights like a match. The great reflector has a diameter of 10·55 metres, the whole surface being covered with 1,800 glass discs. The apparatus is automatic, and follows the movements of the sun when once started. It is hoped to utilise this machine in pumping water for the American railways in the deserts where fuel is as scarce as water. In 1889 I saw a similar machine at work at the Paris Exhibition.

The abandonment of blinker on horses is being advocated through the London press. Already their use has been discontinued to a great extent by Railway and Tramway Companies and by carriers.

COFFEES AND RUBBERS, OIL-PALMS, GROUND-NUTS, &c., IN EASTERN AND CENTRAL AFRICA.

(Extracts from the work of a recent Traveller.)

CONGO :—THE CATARACTS DISTRICT.

ALMOST everywhere in the districts of the Cataracts there are hills of some hundreds of yards of elevation, the soil of which is argillaceous and the vegetation such as I have just described. The rivers wind through narrow valleys, the alluvial soil of which is

remarkably fertile. And here it is that the natives often establish their villages, and plant their oil-palms and the "safo" (*Sachylobus edulis*, now called *Canarium edula*.) which develops vigorously. In the neighbourhood, that is on the lower slopes of the hills, or in the valleys, they cultivate the manioc, the sweet-potato, and the earth-nut. There are also some villages in the Savannas, even on the hill tops or on plateaux; one discovers them from a distance by their clusters of oil-palm and safo planted long ago by the side of dwellings.

There are also sandy districts, and they form extensive plains and are planted by the natives with ground-nuts. This plant gives abundant harvests, principally in the region of North Manyanga, of Banza Kasi and Banza Makuta. Formerly the natives of these regions used to bring their ground-nuts to Matadi, to the Dutch factory, to exchange for salt, which they sold in the interior.

In the wooded ravines other useful plants may be the objects of commercial transactions, such as the oil-palm for its oil and its seeds; the *Landolphia*, one kind of which, at least, gives a good India-rubber;

the "panza" or *Ponteclethra*, that fine tree with large pods, containing large oily seeds. If these natural products are scarcely, if at all, objects of trade, we must attribute it to the sparseness of the population and the profits to be reaped from portage. One must also remember the comparatively limited extent of the wooded areas. We are not in the primæval forest where trees and useful lianas abound.

When the railway will have put a stop to the portage between Matadi and Leopoldville, the population will resume its ancient occupations. The ground-nut will again be more largely cultivated and the natural products of the country will be better utilized. Thanks to favourable tariffs, the railway will facilitate the export. I cannot say at all what will be the product of the future for this region.

There is still one cultivation which may acquire a certain importance in the districts of the Cataracts; it is that of the Coffee tree (of Liberia). Near Luvituku station, I saw a plantation consisting of about 500 plants 2 years old and 1,500 recently planted. They are shaded by oil-palms and panza and are coming on very well. One may therefore say that the same kind planted in the wooded valleys near the streams will give good results, in spite of the long dry season. I do not think that very large plantations would be possible; therefore the State will be wise not to undertake them. It would be better to induce the natives to cultivate small plots around their own villages, and to give them seed and even young plants. I consider it would be useless to try to cultivate coffee on the forestless hills, nor would I recommend it on the plateaux unless they attain an altitude of at least 2,000 to 2,500 ft. It is too dry during a great part of the year.

DISTRICT OF STANLEY POOL AND OF THE EASTERN
KWANGO.

In these sandy regions, in open savannah, some interesting varieties of plants grow in abundance. They belong to the *Landolphia* group, India-rubber creepers

(lianas) have also some latex (lac), but instead of climbing, they run along underground, like long stems, and throw up aerial branches 20 to 60 centimetres high. I have distinguished five or six different varieties of this curious kind of *Landolphia*—true subterranean creepers—but only one of them has a great economic importance. The natives easily distinguish it from the others, although they are very much alike, and extract from it an India-rubber of pretty good quality, but capable of improvement by the elimination of the woody residue.

This India-rubber is actually produced in a part of the Stanley Pool district, and is seen in quantity in the markets. Last year the natives brought about 30 tons to Lukunga. But the greatest quantity of it undoubtedly comes from a district I have not visited eastern Kwango. According to what I am told by two functionaries, Messrs. Costermans and Deghilage, the India-rubber weed there covers vast sandy territories, and the natives work it on a large scale. Not long ago the rubber from this region was exported to the Portuguese possessions of Angola, and was there the object of a considerable traffic.

Here are some figures that I owe to M. Deghilage, who has for a long time traversed the Western Kwango region:—"I have seen in the market of Kenghe Diadia 30 tons of rubber exposed for sale. This product can be bought at 80 centimes the kilogramme, and it is sold in Europe at 4 fr. or R4.50. Transport by caravans to Matadi costs 8 francs for 35 kilogrammes (78½ lb.). The same agent values the actual production of rubber of the Kwango district, at 500 tons a year, a quantity which might easily be doubled. Such a production in a generally poor, sandy soil is worthy of note, and warns us to beware of condemning any region from a superficial examination of its soil and vegetation.

What I have said of the production of palm oil, of rona seed and of rubber may be applied to the neighbouring district. I hope even more from the extension of the cultivation of the ground nut in the sandy plains of the Stanley Pool and the Kwango districts. It is already much cultivated and might be much more so.

As for the cultivation of Coffee, I should be much less affirmative. I do not doubt that one might also cultivate it in the wooded fertile valleys, but I think it is an error to wish to make large plantations as they tried to do near the pool, at Kinchassa and especially at Galiema. In these two localities, 4 or 5 years ago, many coffee trees were planted in a soil essentially sandy, with soil to a depth of 40 or 50 centimetres (18 or 20 inches) rarely more. I will give you word for word what I noted on the spot on the 10th of last March:—"Beside the 350 coffee trees 4 to 10 years of age and the two Cacao trees 6 or 7 years old at Leopoldville, they planted two years ago at Galiema nearly 10,000 coffee and 1,600 cacao trees. Let us look at the Cacao. A first plantation almost equally as important has failed, a victim to the insects that devour the cacao leaves touched by the drought. What will become of their successors. They have had to be protected by thick shade and nevertheless many of them have perished. In fact, Cacao must not be thought of for large plantations in the district.

Liberian coffee suits better, but we must not found large hopes even on this. Not only that neither soil nor climate is of the best, but also that labour is very short near the pool. In fact, it is very difficult to provide the labourers now with sufficient food, for want of native cultivation in the surrounding regions. And any fresh extension in coffee cultivation would render the virtualising of the blacks still more precarious.

In short, under these conditions, one cannot believe that the opening of large plantations would be profitable. Rather should one abandon these efforts in order to concentrate every effort on the equatorial zone.

DISTRICT OF THE LAKE LEOPOLD II.

At the village of Québo plantains are cultivated by the natives and papaw trees are fertile and vigorous; giant grasses abound where the soil is turned up; the forest is nowhere more brilliant than in the neighbourhood of Malepie. I have there seen a stem of India-rubber creeper 10 centimetres in diameter, bearing several transverse incisions, a proof that the natives know and practise the good way of extracting the rubber.

Certainly neither the soil of Malepie nor that of Québo can be considered as very favourable for the cultivation of coffee. It is too sandy, and the six months of drought would make the process of watering too difficult. But tobacco seems to offer a more hopeful cultivation, especially if the analysis of the soil shows a sufficiency of potash. It is the same with the earth-nut, the cultivation of which should be left entirely to the natives. The oil-palm is not very abundant. On the other hand there are many rubber creepers in the forest and along the banks. Rubber constitutes the most important product of this district, and will for a long time remain so, especially if, as Messrs. Jacques, Delcommune and Gillain affirm, the eastern region is entirely covered with forests. According to information I have received, the region ought to give 300 to 400 tons of rubber for annum. The specimens I have seen were of very good quality and are worth 6 to 7 francs in Europe per kilogramme; they had been bought at about 20 centimes (2d.)

I would also note the large quantity of copal that exists in the Lake region, and which the natives collect at the foot of the trees along the banks. The value of gum copal is variable, and I have not yet had my specimens examined. But, when the railway is finished, it will be possible to export this to Europe in large quantities. I cannot give the cost of handling or collecting it, as that was only attempted two days before I left.

DISTRICTS OF THE KASSAI AND THE LUALABA.

Further on rise little hillocks well wooded in which oil-palms and *Landolphia* abound. Here begins the variety of rubber known as Kassai which is so much sought after in Europe on account of its purity and excellence. The forest here also extends towards the south to the Djuma or Kulu which traverses a forest said to contain much rubber. Further on the country resumes the appearance of the caravan route, but the elevations are all covered with forests. You find there all the types of equatorial vegetation, including oil-palms, rubber creepers, rattans, some *Raphia*, trees of coloured wood in great variety. The soil is no longer clayey, but purely sandy and brown from the earth which is more than three feet deep. There are many sites there on the hilly parts suited for agricultural undertakings. Several factories (agencies) exist in these latitudes. Their principal resource is India-rubber, which they buy at 35 to 40 centimes the kilogramme*; labourers can be produced for 10 centimes a day. Up to Luebo, on the Lulua, the aspect is the same and the panorama is marvellous, so various is the vegetation.

Luebo is surrounded by fine forests and is an important market for the red rubber of Kassai (worth 7 to 7½ fr. the kilo.) The natives harvest it by incision and prepare balls strung together in chaplets; or else the latex is warmed and made into bricks 20 centimetres long and 4 to 6 broad, and of a dark colour. The rubber is bought at 35 to 37 centimes the kilogramme in exchange for cloth and sometimes for cowries; allowing for the cost of transport (60 to 100%) the kilog. costs at most 75 centimes (7½). Rubber exists in abundance in the forests and seems to be methodically harvested by incision. From information furnished to me, I conclude that from 500 to 700 tons a year of the best quality could easily be harvested, provided goods in exchange were always forthcoming, and this only after the railway is finished.

*kilogramme=2 1.5 lbs,

The population is relatively large and is distinguished by remarkable aptitude for work and for trade.

In the forests oil palms and panza are abundant. There is also a kind of palm, the *Raphia*, very widely spread in the basin of the Congo, and which will be dealt with advantageously when the railway is made. Its leaves furnish fibrous thongs, used there in weaving little mats (*mandiba*), and they are used by horticulturists in Europe for ligatures. At present Madagascar furnishes the fibres known as *Raphia*, and it is brought to the French ports; the price of it varies from frs. 1.50 to 2 fr. the kilog. On the Congo one could buy them anywhere for a few centimes.

Beyond the Lusambo, on the shores of the Sankuru grows wild a very interesting kind of *Coffee-tree*, which seem to me new. It exists also, I am told, in abundance on the left bank of the Lomani, west of the Gandu. It is a small tree 3 to 5 yards high with branches spreading out often over the streams, with fine leaves larger than those of the Liberian coffee, and small flowers, smaller than those of the Arabian variety. The berries are of medium size, the seeds rather small and regular and have a very delicate aroma. For several days I drank coffee of this kind that had been gathered towards Gandu and it was excellent.

M. Middegh assures me that this coffee abounds in the woods on the left bank of the Lomani, and is even cultivated in certain villages. This variety has been cultivated, first by the Arabs, and then by M. Gillain at Lusambo station, where there were about 500 trees at the time of my visit. In the same plantation there were some Liberian coffee trees planted at the same time, but which had not developed so well as this wild kind. I attribute this to the nature of the soil of Lusambo: a siliceous earth, rich in vegetable soil for 20 or 30 centimetres, down. In such land one must give up Liberian in favour of the new kind, accustomed to grow on the sandy soils so common in the basins of the upper Kassai, the Sankuru and the Lomani. This coffee seems to me to have a great future before it, especially after the southern portion of the great forests is opened up to cultivation.

We are already acquainted with several of the useful plants of the great African forests. First comes the *Landolphia*, or india-rubber creeper; there are certainly several varieties, the one that seems to me to predominate has stalks that attain perhaps to a diameter of 20 centimetres, large leaves and medium-sized fruit. The latex gives about half its volume of rubber. It is this extraordinary richness which has enabled M. Rue, a State functionary, to succeed in a preparation of rubber which had been vainly attempted in the Congo. A company had been trying to prepare large lumps or masses, but without success, until then. M. Rue's method is as follows:—The rubber gathered from the stems is brought to a place in the forest where it is poured into wooden or zinc receptacles. Boxes that had been used in packing up cartridges have been used: they are 50 to 70 centimetres long, 25 wide and 7 to 10 centimetres deep. Left for some hours, at night, the latex coagulates; it does so more rapidly and regularly if it is slightly warmed. It is necessary to knead the coagulated latex to draw out the water or otherwise make cavities in the mass. That is the worst defect in the rubber thus prepared. It would be better not to make such large cakes, and to have them only 8 to 10 centimes thick. For it is indispensable to dispel most of the imbibed water by exposing the blocks for some months in airy sheds. The proximity of river banks, especially if they are subject to frequent fogs, is bad. Mr. Rue's method could not be adopted with latex poor in rubber, such as is collected by the lake Leopold, and especially in the districts of the equator. In 1895 the Arab zone produced nearly 300 tons of rubber. The production could easily have risen to 1,000 tons, if the Europeans had had goods in sufficient quantity in exchange.

In an island of the Lualaba, above Wabundu, grows, in a wild state, a kind of Coffee much like the Arabian. It is also found opposite Coquilhatville and on the banks of the Uelle and the Ubangi. It forms a shrub 6 to 18 feet high, with narrow leaves, small elongated beans, rather small berries of rather irregular shape owing to there being often three berries in a bean. The colour of the berry is grey, and there is so little aroma that many berries are required to produce a fair cup of coffee.

At Wanie Kukula, I saw in the forests another kind of wild Coffee whose reputation has no longer to be made: Liberian Coffee living in the forest under the shade of great trees. There are trees in flower 30 to 40 feet high, the trunks of which measured 15 to 25 centimetres in diameter 3 feet from the ground. They bore branches only at the summit of the stems, which is explained by the struggle for light of the denizens of the forest. The seeds are a little smaller than those of the cultivated Liberian trees. In every point the wild and the cultivated Liberian resemble one another, and in a plantation of 5 to 6 hundred trees near by, it was not possible to distinguish them. The trees belonged to some Arab chiefs to whom the Commandant Lothaire had advised the cultivation of wild coffee and had given seeds of the cultivated variety.

We must note then the existence, in their wild state, of three different kinds of coffee in the Congo State, and two of these have a great economic importance. For if equatorial Africa is the home of these precious plants, there is no doubt that they may be cultivated there with success. To satisfy oneself, it is sufficient to visit the plantations of Wabundu, and especially those of Stanley Falls. At the latter station, 400 trees were planted in 1890 on the recent deposits of the left bank of the river. They are very fine and were covered with berries when I passed; one of these trees was photographed after it had been stripped. The fruits weighed 21 kilog. (47 lbs.) which corresponds to about 3 kilo. of coffee (7 lb.) After the Arab campaign, coffee planting was resumed vigorously under the direction of M. Rom. Last year there were more than 5,500 plants over a year old and $\frac{1}{2}$ yds. high and growing vigorously.

From observations made at the station since 1893, it is found that it rains all the year, and that there are only 2 months (February and July, and sometimes also January) in which rain is less abundant, but there is never more than an interval of 10 or 12 days. At Romee, great fertility was attributed to some sandy land formerly cultivated by the Arabs. It was really owing to the burning of forest vegetation there; in a year's time some hundreds of coffee bushes expressed this fact most evidently, and they were removed to the opposite or right bank of the river, formed of alluvium and clay, where they flourish.

The Forest Region of the Arab zone is certainly the richest region of the Independent State for its forests, its rubber, its suitability for coffee, and above all for the cheapness of labour. The wages are from 1d. to 2d. per day, and the Arab rule has taught the people to work.

A PRELIMINARY NOTE ON THE ENZYME IN TEA.

(Continued from page 584.)

ENZYME AND LIGHT,

According to Reynolds Green there is some relation between the quantity of enzyme in growing leaves and light. He states (page 404) that bright sunlight was found to have a powerfully destructive influence on the enzyme, and that other observers had noticed that there was more enzyme in leaves gathered early in the morning than late in the evening. Presuming the enzyme in tea has some effect on quality or flavour, it would, according to the above observations,

be advisable to pluck as early as possible in the day, and some planters have stated that teas made from leaves plucked early in the morning are better than others. This would also have a considerable bearing on the beneficial effect or otherwise, of shade on the quality of tea grown beneath it. To investigate this question, we examined leaf plucked at 6 a. m., 2 p. m. and 6 p. m., (and occasionally at 10 p. m.) for several days under conditions of severe drought and excessive moisture.

The result of these microscopical investigations show that the enzyme (or its zymogen) is present in abundance at all hours and under all conditions, so that it would be difficult to ascribe improved quality, if any, in early plucked leaf to a particular abundance of enzyme.

Since an enzyme is present in all tea leaf under all conditions, the next point to determine is its function in the plant, and its action during the manufacture of tea.

As regards the function of the enzyme in the living tea plant, it is difficult to make any definite statements at present since there are so few optically visible store-products in the leaf requiring its action to render them soluble. This point is further investigated, and we can only state that the activity of the enzyme is apparently connected with the glucosidal products in the leaf and possibly with the proteids.

The enzyme has been isolated, by one of us, and its action determined on a solution of tannin, prepared from tea, with the result of a browning of the liquid and the formation of a small proportion of sugar. We would not, however, place too much reliance on this reaction until confirmed by further tests, as the tannin of tea is so prone to undergo change, that the chemical processes necessary for its isolation might induce a somewhat similar change. The best practical method of proving the effect of the enzyme would be to isolate a large quantity of it from a highly flavoured tea, and to add this to a low country tea during manufacture and so determine any enhancement of flavour.

METHOD OF EXTRACTION.

The simplest method is to bruise the withered leaf in contact with hide powder or sheet gelatine for some hours, then to remove the gelatine, which has now become very tough and leathery, and to again bruise the leaf with a small quantity of water at about 80° F. The damp mass is then subjected to high pressure to express all the juices, which are then filtered as rapidly as possible, and precipitated with several volumes of alcohol. After some hours the bulk of the solution is poured off from the flocculent precipitate which has subsided, and this is again treated with water to dissolve the enzyme, the solution filtered and again precipitated with several volumes of strong alcohol. The precipitated enzyme can be re-subjected to this treatment to further purify it, and finally collected and dried at the ordinary temperature to a whitish powder, or it can be collected and dissolve in water to a nearly colourless solution.

Both the powder and solution prepared in this manner give a deep blue reaction with gum guaiacum, and as other products which are known to also give a blue reaction with this test have been removed by the method of preparation, except perhaps traces of proteid, we may conclude that the reaction in the original leaf is almost certainly due to the presence of the enzyme.

Tannin, gallic acid, caffeine and other products in tea have been tested separately, and found not to any re-action with the resin.

If the enzyme has anything to do with *flavour* in tea, the questions to be solved are:—

- 1st. Is it acting during the growth of the leaf?
- 2nd. Does it only act after development from an inert form (zymogen) during the withering process,

3rd. Does it act during or after rolling, since then the contents of the cells are more or less expressed and mixed with one another.

1st. The enzyme is no doubt active in the leaf during the life of the plant at all elevations, and the fact that the flavour of tea does not appear until we get into higher elevations would tend to show that its activity had little, if anything, to do with the flavour.

The maximum activity of other enzymes is associated with a definite range of temperature frequently above that prevailing even in the low country of Ceylon; hence we might infer that the activity of the enzyme in tea would be greatest in the hot low country, and yet we know that these teas have much less flavour than those grown in the high country.

2nd. The presence of a zymogen or mother enzyme was indicated in many of our experiments. Freshly cut sections of leaf frequently gave no reaction with the gum guaiacum test, until after frequent moistenings and exposure to air. This could only be due to the zymogen being rapidly converted by oxidation into the active enzyme. Again withered leaf invariably gave a quicker and more intense reaction than the fresh leaf, which would also indicate a similar change. Again sections frequently give a more intense blue reaction after treatment with hydrogen peroxide, which may also be due to the rapid oxidation of the zymogen into the active enzyme, or possibly to a direct action between the two reagents themselves.

The Chinese method of withering tea leaf may also be dependent for its success partly on the fact that the frequent throwing in the air and gentle patting with the hands allows an oxidation of the zymogen into the enzyme.

Assuming that the abundance of enzyme is desirable, it would seem worth our while to employ a system of withering which would permit of a degree of oxidation sufficient to convert the whole of the zymogen into the active form.

Experiments in this direction, and also on the effect of light in the development of the active enzyme in the leaf are now being made.

3rd. In the rolling process one might expect that very large percentage of the cells would be ruptured, and their contents mixed with one another and exposed to the air. It is, however, surprising that only a very small percentage of cells are really broken, and the material which is expressed has mainly been driven through the cell walls.

Examination of rolled leaf revealed about the same amount of enzyme as in the withered leaf, and only differed from it in being more diffuse. In order to get the zymogen or enzyme more exposed to the air, high pressure during rolling would be suggested, as this would no doubt insure the rupturing of more cells, and the more intimate mixing of cell contents. In practice, however, it has been frequently found that white great pressure increases the strength of the tea, the flavour becomes more or less masked or diminished.

Several tests have proved that the enzyme is entirely destroyed by sufficient heat in the ordinary process of drying but its action is probably increased to a marked extent for the first few minutes in the drying machine, as it has often been demonstrated, that the actual temperature of the leaf while wet is usually 80° to 100° F. below the temperature of the air in the machine, which would represent a temperature in which the majority of enzymes are most active.

The enzyme or its action is also entirely destroyed by steam, as is shown in the manufacture of green tea, and there are one or two points in this connection which probably indicate the true action of the enzyme in the manufacture of black tea.

The first of these is the fact that tea leaf thoroughly withed by steam will not acquire the brown coppery

colour of the infused leaf of black tea, although treated in exactly the same manner, with the exception of the preliminary heating to a temperature of boiling water.

This would indicate that the presence of the active enzyme was necessary for the proper oxidation of the constituents of the sap or leaf to produce the colour of black tea.

From the higher percentage of unchanged tannin in green tea it would appear that the enzyme has a considerable influence on this product.

Another point is in connection with the flavour. If there is any flavour in green tea it cannot be due to the action of the enzyme during manufacture, as this is completely destroyed in the preliminary process of steaming. Some planters state that the up-country green teas have no more flavour than the low-country teas of the same class, and if this is correct, it would appear that the enzyme has some effect in producing flavour, as its destruction has apparently prevented the development of the flavour that we know is characteristic of the black teas from up-country leaf. If it is a fact that leaf from an up-country estate has less flavour when manufactured into green instead of black tea, the diminution of flavour might be due to the destruction of the enzyme, or, as is more likely, to the loss of essential oil during the steaming process.

In the investigation which we are continuing, there are several points of interest which may be mentioned here. The most important is that of determining the nature of the reactions and the products, when the several constituents of the leaf are brought into contact with the pure enzyme at different temperatures. This is, of course, first being carried out in the laboratory, and if possible and deemed advantageous, will be applied in the factory.

The reaction between the enzyme and the tannin, essential oil, cellulose and protid, is being determined separately for each of these bodies, together with that between the enzyme and tea leaf *en masse*. It is obvious that the products of these reactions are many and not always easy to recognize, but if we can prove that any of them will impart a desirable flavour to tea, a great point will have been gained, though it will remain to be seen whether it can be used commercially.

The work must be continued in the factory at low and high elevations, and this we are prepared to do at the earliest opportunity.

WOODINESS OF THE PASSION FRUIT.

A. DESPEISSIS.

A disease hitherto unknown in Western Australia was, last season, first observed on some locally grown passion vines. That disease has of late years played havoc with the passion fruit plantations around Sydney, and our ports have this season been made the dumping ground of several important consignments of diseased passion.

The figures illustrating this "woodiness" show the disease in a mild form.

They are taken from a Paper on the subject, prepared by Dr. N. A. Cobb, Government Vegetable Pathologist of New South Wales.

The disease is still an obscure one. First observed around Parramatta some seven or eight years ago, it has since spread to the whole surrounding County of Cumberland, where its progress is more or less erratic.

It affects most vineyards in the locality named, and at the same time spares a few in the centre of infection.

Even in a diseased vineyard some plants escape; the disease is less common on moist, free soil, sited to passion fruit, than elsewhere.

SYMPTOMS.

A "woody" passion vine is stunted in growth, with short distorted canes, of pale-yellowish leaves

instead of a dark-green colour. The stocks are sometimes enlarged and knobby; much of the fruit drops early the rest hang on, become distorted, crack on the surface, and when cut open are either empty and show a considerable thickness of the rind, or what there is of the edible pulp is thin, has a "flat" taste, with a colour different from that found in healthy fruit. The seeds do not ripen properly, and remain light and sometimes glassy instead of turning black.

CAUSES OF THE DISEASE.

A disease passion vine often shows amongst woody fruits, some which have every appearance of soundness, and yet seeds from these apparently sound fruit contain in them germs of the disease which, when shown, they transmit to the resulting plant.

Exposed situations and frosts are also known to have a prejudicial influence on passion vines showing a tendency to woodiness, but, above all, exhaustion of the soil seems to accompany in most cases the woody disease.

The passion fruit plant is most exacting on the store of plant food in the ground. By reason of its rank growth and its prodigious bearing capacity (it bears two to three crops of fruit each year) it soon exhausts the soil of nourishment as well as of moisture. It has been noticed that, where manured, the vines are less affected by the disease than are vines growing alongside which have been stunted of fertilisers.

Dr. Cobb has observed on the yellow spotted leaves of diseased plants, as well as on the spotted bark of dead branches, a specific fungus which he believes to be associated with woodiness of the passion fruit.

REMEDIES.

The passion vine is a gross feeder. According to Mr. F. B. Guthrie's computation, each passion vine with fruit removes on an average annually from the soils 6½ oz. nitrogen, 1½ oz. phosphoric acid, and 2½ oz. potash, so that a vineyard planted with 300 (12ft. x 12ft.) passion vines to the acre would remove: nitrogen, 117 lbs.; phosphoric acid, 28 lbs.; potash, 52 lbs.

Knowing that sulphate of ammonia of commerce contains about 20 per cent. of nitrogen, superphosphate about 14 per cent. phosphoric acid, and sulphate of potash of commerce 50 per cent. of potash, we arrive at the following mixture, in order to restore to the land all the elements of plant food extracted by passion vines, and by a crop of passion fruit, viz. :-

Sulphate of Ammonia	600 lb.
Superphosphate of Lime	200 "
Sulphate of Potash,	100 "

Such a mixture, applied at the rate of 3 lb., per vine, would cost 4d. per vine or a little over. It should be applied a year or so after the vines are planted.

Besides a liberal application of chemical fertilisers, it has been suggested that, considering that the woody disease is propagated by means of diseased seeds, and, moreover, that in all attacked vineyards there are some vines which always look healthy and appear to be proof against the blight, cuttings be taken from such vines and planted with a view to obtaining passion vines endowed with the immunity of the parent.—*Journal of the Department of Agriculture of Western Australia.*

ALEXANDRIA BANANA DISEASE.

PRELIMINARY REPORT BY DR. LOOS AND G. P. FOADEN.

A few days ago we stated that the report of Dr. Loos and Mr. Foaden on the disease, which has caused such widespread destruction among the Alexandria bananas, had appeared and been issued by the Municipality. The disease, according to the report, is caused by a worm of the same species as that which caused great

havo from 1885 to 1888 in Brazil completely destroying the plantations in large districts in that country. The report draws the following analogy between this disease and the present out-break at Alexandria:—

“The history of the former disease is very interesting and instructive inasmuch as the disease could be traced back to 1869, that is to say to years before the out-break became really serious. Nothing was known of the pest nor were any attempts made to cope with it until the year 1887, when a surface of about 715,000 feddans was infected and the cultivation of coffee rendered impossible. The similarity to the present case is striking. It has been known for some 3 or 4 years that a banana disease existed in the district around Alexandria. The disease was first located in a small area, then at some little distance from the first observed area, and finally is now spread in the whole neighbourhood, it not only infecting plantations but has found its way into private gardens.”

We need not reproduce the first part of the report, which is purely technical, but the conclusion, dealing with the methods of stamping out the disease, deserves to be reproduced in full:—

“The most important question to be considered, is how to cope with the disease, in other words, how to prevent the propagation of the worms. This can only be arrived at through an exact knowledge of the life histories of the pests. In order to arrive at this, an examination at one season of the year will not suffice, and with the advent of warmer weather further observations may be made. It has been seen that all the different species pass a certain period of their life history outside the plants themselves, that is to say, in the soil, this being a common feature in the history of all parasitic animals since it is the only means by which they can spread. The time, therefore, in which to institute an attack is when the majority are found in the soil, for any attempt to reach the pest when within the plant must be doomed to failure, as it is then in perfect security. In countries where there are well-defined seasons with great difference between them it is more easy to ascertain exactly the different stages than is the case with such a climate as that at Alexandria where probably development goes on steadily, that is to say, the few worms are always present in the soil. It is, on the other hand, also very likely that their numbers become considerably increased at certain periods in connection with the subsequent generations. Any remedy to be applied would therefore have its maximum effect only if applied during those periods. This matter can, however, only be definitely decided when the life histories of the species have been followed throughout. Experiments could then be conducted as to the most suitable means to employ. In coping with nematodes attacking the beet crop in Germany a method was successfully adopted which may be mentioned here. Nematodes are found in, one might say, almost every plant in small numbers. Practically all nematodes living as parasites on plants are not exclusively parasitic on one individual species, for if they find the necessary favourable conditions for existence they will attack another host, just as a human being or an animal can carry injury to health, and only show signs of suffering when the number increases, so within certain limits can plants withstand nematodes, and only show signs of disease when their numbers become excessive. To combat the pest in the sugar beet plantations, other plants which were suitable as hosts were used to attract the pest. The seed was sown early in spring, some weeks before the beet were planted.

“The larvæ of the nematode hibernate freely in the soil and attacked the newly-sown plants which were subsequently removed and destroyed. There were thus removed from the soil vast numbers of the pest which would otherwise have attacked the beet. This did not result naturally in a complete clearance of the beet but the numbers remaining,

the beet were enable to resist. The adoption of this method in the case of bananas would present certain modifications but some thing might be done in this direction and then by providing the plant with suitable conditions for recovery such as good cultivation and an application of suitable manure they may recover.

“The idea has been expressed that the disease is one of recent introduction, but this does not seem probable. Species of the genus heterodera were found by Dr. Loos in a garden at Alexandria some years since, and these were similar to the heterodera of the bananas. It is probable that they have now found a most suitable host in bananas and have consequently rapidly increased in numbers. They have probably been living in banana plantations for some considerable time and the result of years of increase is now very apparent.

“Experiments in the direction indicated should be attempted; first to ascertain plants most suitable, the times at which they should be shown, and the time at which they should be removed. The latter information could of course be derived by a study of the complete life history of the pests.

“Various remedies have been suggested in the direction of applying to the soil some substance which would prove harmful to the pests. We think the most suitable substance to try at first is ordinary lime. This substance is most commonly applied as a remedy for insect pests either alone or mixed with common soot. Lime from gas works might also be employed. A certain quantity well incorporated with the soil around the plants might have a most beneficial effect, and would probably benefit the crop at the same time. It is at any rate a practical and inexpensive method. Much has also been said concerning an application of nitrates and many misleading and inaccurate figures published regarding the percentage of nitrates present in the soil. We do not deny that an application of nitrogenous manure may have beneficial effects, not as a direct remedy against the pests but merely as encouraging and stimulating the plant and helping it, provided the numbers of nematodes are not too excessive to outgrow and overcome attack.

“Experiments might also show if the worms in question or similar ones are capable of attacking other and more important crops in the country. Wheat and onions are known to suffer occasionally by the attacks of nematode worms belonging to the genus *Zylenchus*. The *Zylenchus* of the onions causes great damage in Europe and is found occasionally in the crop of Upper Egypt.”—*Egyptian Gazette*.

CAMPHOR.

(Continued from page, 587.)

PREPARATION OF THE CAMPHOR.

As soon as the plants have reached a fair size and formed stout woody stems below—say in three years or less in very good situations—they may be clipped. The simplest method will perhaps be to use hedge shears, placing a long basket below the hedge to catch the clippings. Only the leaves and young twigs are required; woody twigs yield little or no camphor.

In Japan, where, however, they only use the woods of full-grown trees as a source of camphor, the chip of wood are distilled in a primitive-looking but effective still, with bamboo tubes (these have the advantage that they can afterwards be split to remove any camphor from them) and a wooden condenser with water running over its lid. In Ceylon probably the best method will be to fix up a small still of any good pattern with a glass condenser and plentiful water supply, working it by means of steam from the factory boiler. As the distillation is a somewhat uncertain operation, especially to the beginner, and as it is probable that more efficient methods will be discovered, the details of the principal experiments tried, are given below. Material for these experi-

ments was obtained from the gardens at Peradeniya (1,600 feet), Hakgala (5,600 feet), and Anuradhapura, (300 feet).

CAMPHOR DISTILLATION.

The first distillations were from 112 lb. of prunings received from Hakgala on the 28th June, 1900. These were conducted in a large cask fitted with a metal cover leading to a metal condenser, which was cooled by a constant flow of water. Distillation was effected by means of steam from a boiler passing into the lower part of the cask below a perforated iron plate. The prunings were chopped up into fragments about 1 inch long, covered with water, the top, connected with the condenser, luted on, and steam turned on to gradually bring the water to the boil.

A strong pungent smell of camphor and eucalyptus came off as soon as distillation commenced, which persisted for some time even when the distillate was cooled to 50° F., a temperature below that which could be obtained practically. The loss was minimized by bringing the water to the boil very slowly, and only admitting just sufficient steam to keep it at the boiling temperature. It was found that the metal cover to the cask retained a good proportion of the camphor, but it was not so pure as when condensed in a wooden box similar to that in use in China and Japan. The purest camphor was obtained when the distillate was made to pass through a long glass tube surrounded with a jacket of cold (running) water, the crystals being deposited when the temperature of the glass did not exceed 50° C. or 122° F., a temperature that could easily be maintained in a condensing apparatus in country at all times of the year. In the low-country a more rapid flow of condensing water and a proportionately longer condensing apparatus would be required to obtain the same results, as the water is much warmer and the steam also is at a higher temperature.

In all the experiments the camphor had almost entirely distilled over during the first three hours, as several distillations conducted for twelve hours and longer resulted in no better yield, and the smell of the camphor under these circumstances was contaminated with that of decomposition products from the nitrogenous matter, &c., in the leaves and twigs. Three distillations could be made in the same apparatus during the day.

The amount of steam required for the distillation even of large quantities would be nominal, and would hardly be felt in an ordinary boiler working in a tea factory.

YIELD OF CAMPHOR.

The first distillation from part of the prunings obtained from Hakgala in June, 1900, only yielded '35 per cent., but this was increased to '62 per cent. by better regulation of the steam pressure and the condensing water. The camphor had a slight smell of eucalyptus, and was not so strong as ordinary camphor. The leaves were quite fresh when distilled.

Separate distillations were again made in August with fresh leaves and twigs, and the green branches of about half inch to 1 inch thick, the former yielded '85 per cent. camphor, but the latter a mere trace, both of camphor and oil.

7th September, 1900.—Three distillations of camphor leaves from Peradeniya were made in the usual manner the yield from the first being 1.10 per cent. of camphor and camphor oil. In the second distillation, when the leaves had partly dried, 1.06 per cent. of camphor and oil was obtained, calculated on the fresh leaves. In the third distillation the leaves had undergone partial decomposition, the result of becoming heated to a temperature of 106° F. The yield in this case was '68 per cent. camphor and '38 per cent. of oil, so that it would appear advisable to distil the leaves as fresh as possible, as the oil is less valuable than the camphor.

9th October 1900.—A sample of young camphor flush weighing 1½ lb, plucked from two trees in Hakgala,

one 8 feet in diameter and 12 feet high, yielding 8 lb. and the other 5 feet in diameter and 7 feet high, yielding 3½ lb. This was carefully distilled in a copper retort over a lamp, and the vapour condensed in a glass vessel. In the first four hours '63 per cent of pure camphor was obtained, which smelled only of pure camphor; on further distillation '08 per cent. more camphor was obtained, which did not smell quite so pure. Heating by the direct flame beneath the vessel appears to take longer in removing all the camphor than driving it over with steam under slight pressure.

24th October, 1900.—A distillation of camphor clippings from Hakgala yielded '77 per cent. camphor and '27 per cent. oil.

30th October 1900.—A distillation of 12 lb. of camphor flush was made in a copper vessel with a glass condenser, yielded '69 per cent. camphor and '31 per cent. camphor oil. The trees were in active growth when this flush was plucked.

9th January, 1901.—A camphor tree that had become slightly cankered was received from Hakgala in separate parcels of leaves, branches, stem, and roots. Several distillations of the leaves and twigs were made, both in the fresh state and when air-dried, some of them being continued for twelve hours. The yield of camphor and oil varied somewhat, but appeared to depend on the proportion of leaves to twigs, the latter containing much less than the former. A glass condenser was employed for all these distillations, the camphor and oil being obtained quite pure.

The first experiment yielded '875 per cent. camphor and '986 per cent. oil, a far larger proportion of oil than in any previous distillation of similar leaf.

A second distillation, which was continued at a low temperature for eleven hours, yielded 1.08 per cent. pure camphor and 0.32 per cent. oil.

Five other distillations at intervals of some days with the air-dried leaves gave the following yields:—

No. 1.—2.310 per cent. camphor and 1.14 per cent. oil equal to 1.02 per cent. on fresh leaf.

No. 2.—2.149 per cent. camphor and oil, equal to '98 per cent. on fresh leaf.

No. 3.—2.425 per cent. camphor and traces of oil equal to 1.05 per cent. on fresh leaf.

No. 4.—2.380 per cent. camphor and traces of oil equal to 1.01 per cent. on fresh leaf.

No. 5.—2.080 per cent. camphor and traces of oil equal to '96 per cent. on fresh leaf.

From these figures it will be seen that air-drying the leaf before distillation does not cause any appreciable loss of camphor, though a certain amount of oil disappears, either by volatilization or oxidation. The camphor obtained from the air-dried leaf also had a somewhat purer smell than that from the fresh leaf though this latter was easily rendered pure by redistillation with steam.

Three distillations were made of the branches and stem of the camphor tree, but no appreciable quantity of camphor was obtained from either, nor did the bark of the stem appear to contain more than traces. The roots, however, contained an oil, 5 lb. of roots yielding 1.22 per cent. This oil was located mainly in the bark and in a thin layer of wood beneath it. It had only a slight smell of camphor, and more resembled a mixture of aniseed and peppermint.

On the 7th August, 1901, 5 lb. of young flush was received from Hakgala in a slightly heated condition. It was at once put into a copper vessel with fifteen pints of water, and a glass dome luted on, which was connected with a glass condenser. The water was heated slowly from below, and a thermometer placed so as to register the temperature of the Vapour 2 inches above the water and camphor leaves.

At 50° C. (122° F.) crystal of camphor condensed on the glass dome, which at 90° C. 194° F. were carried back into the water by the condensed steam. At 100° C. the steam and camphor vapour was passing rapidly into the glass condenser, while the leaves were covered with oily drops of camphor and oil.

Distillation at 100° C. was continued for two hours, when 4½ litres (7·93 pints) of water containing camphor and oil had collected in the condenser. This was then passed through a wet paper filter to separate the camphor and oil from the water, 24·53 grams of the mixture being obtained, equal to 1·10 per cent. The oil was separated from the camphor as much as possible, the yield of each on the original flush being ·765 per cent. pure camphor and ·345 per cent. camphor oil. Another distillation was made in the same way of 10 lb. of coppice shoots one year old from a tree that had been cut down. The yield of camphor from this was very small, only ·192 per cent. and shows that the first year's growth from a tree cut down to the ground is practically valueless, but it is probable that young flush from such coppiced trees would increase in the camphor contents during the next and succeeding years.

Further distillations were also made of the entire prunings weighing 50 lb. of a five year and nine months old tree of average growth, the leaves 27 lb. and branches 23 lb. being distilled separately, the former yielding ·767 per cent. of pure camphor and some oil, the latter only traces of oil, showing that the whole of the camphor is practically in the leaves and not in the young wood. The reason of this should be investigated, as it is from old wood that the bulk of the camphor of commerce is obtained.

CHARACTERS.

The camphor obtained from all the above experiments has the usual crystalline form, and is perfectly colourless unless condensed in an iron vessel, when it is tinged with red from the oxidized iron. It floats on water, in which it is almost insoluble, and small fragments rotate rapidly when floated on this liquid. It burns with a yellow smoky flame, leaving no residue, and volatilizes readily at the ordinary temperature. It is easily soluble in alcohol, ether, and chloroform, and is precipitated from the former, in white flocculent masses, when the solution is poured into water. It sublimes readily, and has an odour of camphor, but not so powerful as ordinary camphor from old wood. Its specific gravity is ·987; it melts at 175° C., 347° F.; and boils at 205° C. 400° F. It dissolves readily in nitric acid, with some development of heat, and immediate separation of the solution into two layers, the upper of a red colour and the lower pale yellow or colourless. The addition of water precipitates the camphor as a white mass from the upper layer of the solution apparently unchanged.

SUBLIMATION EXPERIMENTS.

These were conducted at varying temperatures and under different conditions in order to try and obtain the translucent state common to commercial camphor. The most successful method was by mixing the crude camphor with slaked lime in the proportion of 4 to 1, and subjecting this in a closed vessel to a low heat for twelve hours, the heat being gradually increased up the sides of the vessel in order to drive all the camphor into the upper portion. Copper vessels are the best for the purpose, as glass is liable to fracture from condensed moisture running down to the heated sides.

Before sublimation can be effected it is essential that all the camphor oil should be expressed from the camphor. The camphor when first distilled appears to be practically free from oil, but after standing some days oil gradually separates and sinks to the bottom of the mass of crystals, and this appears to continue for months. Filtration with the aid of a vacuum effects a partial separation but in practice on a large scale it would be best effected by means of a centrifugal machine similar to that employed for the separation of crystalline sugar from molasses.

OIL

The oil obtained with the camphor from the leaves is of a clear yellow colour, having a specific gravity at 50° F. of ·9662. It contains a certain amount of

camphor in solution, which can be separated to some extent by cooling to 10° C. It would therefore be advisable to cool the mixture of camphor and oil, as much as possible, before submitting it to centrifugal expression.

The root oil, of which 1·22 per cent. was obtained from the air-dried roots was almost colourless and had no smell of camphor. It consisted of a mixture of two oils, one lighter and one heavier than water, the specific gravity of the mixed oils being 1·058 at 80° F.

YIELD AND PROSPECTS.

The figures above given show that the yield varies a good deal, but that on the average about ·75 to 1 per cent. of camphor may be expected from the young leaves and twigs, as well as a small quantity of camphor oil, which also has a market value. Samples of camphor mixed with the oil were valued lately at R126 per cwt. If we assume that clippings will yield about 1 per cent. of camphor and oil worth R1 per lb. we should be well within the mark. The cost of obtaining this should be about R53 per acre made up as follows:—

	Rs. c.
Pruning 1,210 trees and carrying to factory	37 0
Distilling, fuel, packing &c. ..	16 0
	53 0

I.e., camphor can be put on the market as cheaply as tea per pound if the yield be at the rate of 177 lb. per acre (cost of tea being estimated at 30 cents). Now 177 lb. will be yielded by 17,700 lb. of clippings. In the case of bushes 6 feet apart this means 141 lb. per bush per annum, or about seven times the weight of flush obtained from a prosperous tea bush. On the other hand, the bushes are only half as many to the acre, and the plucking is much closer, so that this estimate is not unreasonable, and the product is more valuable than tea. It seems not unreasonable to expect that where a bush, with 36 square feet of space to grow in, yields 12 to 15 lb. of clippings a year, the cultivation will prove remunerative—not abanza, but yielding a fair profit. In the Hakgala Gardens this yield is exceeded, so far as rough experiments show.

Director, Royal Botanic Gardens

PLANTING NOTES.

RHEA FIBRE.—Mr. Jefferies, of the Nurseries, Oxford, sends us illustrations of the growing plant and of the fibre it produces. The value of the fibre of the *Boehmeria nivea* has long been appreciated, but some difficulties still exist in the cleaning the fibre and divesting it of resin.—*Gardeners' Chronicle*.

SYDNEY BOTANIC GARDENS.—During the month of March the garden was visited by immense numbers of flying-foxes. There must have been many thousands of them, and some of the large trees were quite black with them. Several local sportsmen shot large numbers, and the destructive animals were all killed or flew away in about a week from the first appearance of the swarm. It is many years since the gardens were visited by a plague of these animals.—*Ibid*.

THE AGE OF TREES.—The estimation of the age of trees by means of the number of rings visible in the wood is well known to be subject to many exceptions. In a recent number of the *Revue Horticole* it is pointed out that by pinching, or pruning or grafting, a second layer of wood may be formed in one year in a shoot. The explanation given by M. GURGUARD is that the pinching or other operation brings about a state of rest, less sap is directed to the wound. But when the adjacent buds begin to grow, the afflux of sap is increased, and a fresh zone of wood is the result.—*Ibid*.

ORANGE CULTURE, PICKING AND PACKING IN JAMAICA.

Being Paper read by Hon. Dr. Johnston, at the First Orange Conference held under the auspices of the Board of Agriculture at the Collegiate Hall, Kingston, on Wednesday, 30th October, 1901.

In approaching the subject of orange culture, picking and packing for shipment, it is with no desire on my part to pose as an authority on the question, or to pit my opinion against those of the experienced planter to whom a knowledge of fruit growing and handling rightly belongs, but, having lived for many years in one of the finest fruit-producing parishes in the Island, and being impressed with the importance of the industry, and the necessity for its development being placed on a sound and permanent basis, I have been led for some time past to take a personal interest in the matter, and to do what little I can to secure this much-to-be-desired end. For while we may all be agreed that sugar must ever remain the staple product of the colony, (hear, hear,) and that in its revival, by means of reasonable preferential concessions on the part of the Imperial Government, and the establishment of Central Factories, lies the only hope for Jamaica's future prosperity, we must not lose sight of the fact that hundreds of our people depend on the frequent visits of the fruit steamers to our shores, whereby to realise a little ready money to meet their most pressing needs and the call of the tax-collector.

Hitherto, our fruit shipping experiences have been confined chiefly to the comparatively near markets of the United States and Canada. The short sea voyage and the expeditious transit of our oranges to these countries have in some measure obviated the necessity for very special care in handling and packing, although we have seen, more than once, hundreds of barrels of Jamaica oranges in an unsaleable condition on the wharves of New York through careless packing, while everywhere we heard grocers complaining that, even if our fruit arrived sound, the unattractive appearance of our packages and the slovenly method of putting up the fruit, adopted by us, precluded the possibility of our oranges ever taking rank with the Florida and Californian products until we were persuaded to bestow more time and care in preparing them for the market.

THE PROBLEM.—But now, gentlemen, we are face to face with the problem of how to pick and pack our oranges so as to carry successfully more than three times the distance to the States and a voyage of twelve to fourteen days instead of four or five; for the markets of the Mother Country are now open to us by the inauguration of the Direct Line of specially fitted steamers, affording facilities for shipping fruit to England never offered to us before, while we have practically the field to ourselves until much later. Could we but place our fruit in good condition at Covent Garden now, high prices could be assured, for our Jamaica oranges for quality have no peer, and the fault is our own that their reputation in England is not better than it is. In confirmation of this statement, permit me to quote from a letter received by last mail from a large fruit-dealer in Liverpool. He writes:—"We have been badly in need of oranges for the last three months, and will be for some time to come. Barrels from Jamaica turn out

very wasty, but we may hope for better packages in future. With you, I sincerely trust, the prosperity of Jamaica will, in near future, greatly improve, but I also know this improvement can only be accomplished by diligent and persevering energy on both sides of the Atlantic." The difficulties are many, but they are not insurmountable, and as the Italian, Sicilian and Spanish orange packers contend successfully with a long sea voyage and extremes of temperature, so can we; and it might be well for us to review briefly the methods, adopted by them, which have resulted in bringing vast wealth to Messina and Palermo, while whole cities have sprung up on the East coast of Spain during the past thirty or forty years, as the result of an orange industry conducted on business principles. Under order from Mr. A. L. Jones, it was my privilege to spend some three weeks in Spain, my instructions being to visit Italy, Sicily, Algiers or wherever else I would be likely to gain information that might be of value to the orange shippers of Jamaica. On reaching Valencia, I learned that the season had practically closed further East, so determined to confine my investigations to the region within a couple of hundred miles of Valencia, where three or four weeks still remained before the crop would be finished. My first visit was to the orange groves, or orchards, of Burianna, accompanied by an interpreter and guide provided by Messrs. Reis Bros., a firm of high standing and doing a larger business, probably, in oranges than any other house in Spain, and were therefore in a position to afford me special facilities in my hunt for knowledge.

IN THE FIELD.—On entering the orange field, I was struck by the amount of labour put into the land; every inch is ploughed by a crude, primitive and ancient-looking wooden implement, the share alone being tipped with iron which turns up a very shallow furrow effectively, however, stirring up the soil and keeping down the weeds, although the work could be much more speedily and effectively accomplished by one of our modern American cultivators. Not in every plantation in Jamaica can this suggestion be adopted, as much of our oranges grow in the pimento walks, and pasture lands, and the idea, therefore, would apply to only such fields as are entirely given over to orange culture. One thing, however, applies to orange-growing any and everywhere,—if the planter would improve the character and condition of his trees, and the quality of his fruit—he must at least fork up the soil within a radius of six feet round each tree; a trench 12 inches wide, six inches deep, at a distance varying according to the size of the tree and the reach of the limbs, filled with manure, is a very good half-way measure. I also observed that a circular hole is dug round the roots of each tree, the earth being drawn back some two feet, forming a basin-shaped hollow, exposing the roots some 18 or 20 inches from the trunk. The reason given for this is, first, that insect borers, etc., are more liable to attack the roots near the trunk of the tree, and the exposure of at this point leaves them no shelter, and their operations are more rapidly detected; secondly, it was found in the early experience of Spanish orange growers that a gum disease, in the form of a gummy or resinous deposit, accumulated and formed between the earth and the air on the tree which ultimately caused the bark to rot, with the result that 60 per cent. of the trees died in the 4th and 5th year of their growth, while in other cases portions of the trees would wither away. Now,

the gum drops down and disappears in the soil, while the farmer can very readily observe any evidence of decay in the roots, so as to remove the affected parts. This clearing of the roots has effectively remedied the evil, and the exposed roots rapidly accommodate themselves to the atmosphere, while the improvement in the health of the trees has been most apparent. Within the last few years it has been found necessary to apply to the roots of every thirty trees some 70 kilos, or about 100 lbs. of artificial manure annually, mostly superphosphates, but very little natural manure being available. This, unfortunately, has been found to cause a deterioration in the flavour of the fruit, an evil that must increase as the time goes on, for another decade at least. The species of trees found there are by no means as large as those of Jamaica, but this may be accounted for, in some measure, by the vigilant pruning and the removal of both tops and branches which are likely to interfere with the development of the fruit.

PLUCKING.—As to the method of picking the oranges. In no instance are they plucked, but with a short pair of clippers, resembling wire cutting pliers, they are snipped from the stem, three or four oranges being received by the left hand at a time. Before placing the oranges in the basket the portion of stem remaining on the fruit is cut close; boys with baskets slung from their shoulders being employed to climb for the fruit beyond the reach of the men. The fruit is in no case thrown into heaps as with us, but when twenty or thirty baskets are filled the cart comes along and carries them off to the packing houses; the first layer of baskets being placed in a swinging shelf underneath the cart, the second on the bottom, and the third on a layer of boards forming an upper tier, so that there is little or no pressure put on the oranges up to this stage of handling. I would remark that mules and horses are utilised for reaching portions of the orchard inaccessible to carts. They carry about six or eight baskets on wooden crates slung across the backs of the animals, and on arrival at the packing house the fruit is emptied on the floor to the depth of not more than twelve to eighteen inches; sand and straw being freely distributed to receive them. A typical packing house has a floor space of about 70 ft. by 120 ft., evade the necessity for shelves in laying out the fruit, the shelf system being deprecated by the packers as causing unnecessary handling of the fruit, and being more inaccessible to the sorter. There are no sizing machines in use, as they save nothing in time and labour, each orange requiring to be individually culled with or without them; but then the Spanish women are experts at this business. The buildings are divided into four distinct departments, viz:—sorting, wrapping, box-making, and packing. The sorting is the most important portion of the work and is generally accomplished by elderly women of long experience. The oranges are sorted, first, that damaged or imperfect fruit, or fruit with a blemish, such as a worm hole, a depression from contact with a branch while growing, or for any other reason that the sorters may consider them as unfit for shipment, may be laid aside. Under this head 20 per cent. of the harvest is rejected and finds its way to local markets.

CLASSIFICATION.—Much care and study has been bestowed upon the classification of the oranges; for we find that they are packed into boxes, of some seven different sizes. Blood oranges, for example,

are packed into cases of 200 each. Then under the heading of "410," which are the largest oranges, we have four sizes: "Ordinary," "Large," "Extra Large," and "Extra, Extra Large"; these names being printed upon the respective boxes, and indicate a variation of three or four inches in the size of the box. Cases containing 714 are usually of one size only, as also are boxes of 1064, which contain the smallest oranges of the crop. Each box is divided into three compartments by two partitions, the centre space being sorter than the outer two. It is thought that these boxes would be much too large for our fruit. This may be so, although the reasons given are not very convincing so far. There is a possibility of going too far in the opposite direction, and certainly the boxes that prevail here at present do not permit of as ready success of air through the fruit, seeing that the openings are only at the corners, the sides, top and bottom generally being each of one piece, while the Spanish box is made up of narrow laths forming practically a crate, but experience will shortly demonstrate to us whether ours or the Spanish box will best serve the purpose. In any case the barrel must go. The variety of classes accounts for the large number of baskets required in a well-equipped packing house, as separate baskets are required to receive from the hands of the sorter the particular size of fruit intended for the above grades. It will thus be seen that the basket plays an important part in the orange business, and facilitates the handling of the fruit to such an extent that I cannot understand why it has never been adopted in Jamaica. They are of two sorts—shallow and wide, so that the orange may not have too far to drop during the operations of sorting and wrapping, and deep and narrow, so that they can be easily carried upon the shoulders. I shipped a sample order of 200 in the hope that our planters might see the wisdom of adopting them. They are woven from Esparto grass and with ordinary use will last many seasons. To minimise still further the possibility of the fruit being bruised or injured the packers of Valencia line them throughout with sacking.

WRAPPING.—Between the sorters and the packers are the wrappers sitting in groups around heaps of the fruit, each heap of a certain class, and being supplied by the men who take them from the sorters, here again they are subject to further inspection, and blemished fruit which may have escaped the scrutiny of the sorters is thrown aside. I have here some samples of the paper used for wrapping, please observe that each bear the stamp or trade-mark of the packer, a guarantee of the quality of his fruit, and he is proud enough of his brand to stand by the consequence attached to carelessness on the part of his employees. No oranges are shipped from Spain which do not bear on each end of the case a stencilled trade-mark or brand of the packer, also number of oranges contained in the box. The brand also indicates whether the fruit is of good quality, or finest or superior quality. The wrapper has a pile of cut papers in her lap, and dexterously placing an orange at one end rolls it from her, gathering the ends in a tight twist at each side, which holds the paper in place prettily and perfectly. An ordinary hand can do 20 to 25 per minute. The wrapping paper is of a very fine, soft, silky quality, made in Spain. The cost there for enough to wrap an average of 240 boxes is 80 pesetas, or about £2 7s 6d according to rate of exchange; stamping, 20 pesetas or 11s. 7d. The wrapped fruit is then carried to that portion of the house where they are packed in their respective boxes according to size and class,

PACKING.—And now as to packing. This is done by girls, two of them putting up a box of 714 in 15 minutes and a box of 420 in 10 minutes. I must confess to being somewhat surprised when the carpenter came along to put on the lids; he first tacked the three laths at one end, then, putting his knee on each lath in turn applied his whole weight so as to press the oranges firmly into the box. When the box of oranges is packed ready for the lid it appears to be much too full, the top layer being nearly half their thickness above the level of the box-edge. I questioned the propriety of applying so much force to bring them down. The explanation given that it did no damage, as it was absolutely necessary that allowance be made for shrinkage, that the fruit received equal pressure all through the box, and that while a bounce to an orange would injure it, no harm came by even, steady pressure, which had the result of simply flattening four surfaces, but was not sufficient to cause confusion of the internal portion of the orange; unless by accident or careless packing one or two should be caught between the lid and the edge of the box. When the carpenter has finished nailing on the cover small boys come along with strips of raw hide and nail them around each end in place of hoops; finally the box is handed over to men who dexterously and firmly bind each round and round with some ten or twelve yards of cord plaited from Esparto grass. The boxes are then carried to the Grao or beach where they are loaded on to surf boats and conveyed to the steamers lying at anchor in the roads some half a mile away. I am in possession of every detail regarding cost of materials, also length and breadth of the various boxes, time required for their construction, etc., which will be supplied on application.

FOR JAMAICA.—The foregoing is a brief synopsis of the methods adopted by packers in the plains of Castellon; but there are other points in connection with the handling of fruit in Spain that must not be lost sight of, and I fear that unless we in Jamaica are prepared to follow in some measure these or similar methods in handling our fruit, we can never hope to make satisfactory shipments of oranges to England. For instance, when the season begins with us, we find scores of irresponsible people—in the country parts, at least—renting sheds and vacant houses, at the same time intimating their intentions of buying oranges from the surrounding districts; the people commence to collect fruit, plucking it roughly from the trees, throwing it into heaps some three or four feet high, until a cart comes along, the sides have been raised by the addition of rough sticks tied together at the corners; into this the oranges are thrown several feet deep and carted to the aforesaid packing sheds, where inexperienced women are employed wrapping in rough straw paper, and packing the oranges unsorted into barrels or boxes, rejecting only such fruit as gives unmistakable evidence of being hopelessly damaged; but such packers have no means of learning what treatment the fruit has received, not only in the fields and carts, but by the numerous small settlers who bring in their quota in rough hampers on mule or donkey backs for sale. When they arrive at the wharf the barrels are generally emptied in the shipper's shed and again packed, but very much after the same unsystematic method. This would never be tolerated in such places as Burrianna, for in no instance will the packers accept or purchase fruit which has not been picked by their employees. In the foregoing description I refer chiefly to what I have seen personally on the Northside of the Island. I acknowledge that in the

neighbourhood of Kingston and Port Antonio, planters may have within the last year or two adopted much more improved methods of putting up their fruit; but even they, I feel sure, will be glad to take advantage of the suggestions of the Spanish packer, from knowledge acquired after many years in the trade. In every instance the farmer sells his crop on the tree, either by weight or by sight,—if by sight, all that may be blown down subsequently is included in the contract; if by weight, only fruit picked direct from the tree is counted. In the former case the price paid is less, but the risk of loss lies with the packer, and *vice versa*. The cost of the fruit in May was from \$5 to \$7 per thousand, but earlier in the season they could be purchased for \$2.50 to \$3, an orange is an orange in Spain, and every one counts, not three for one as with us. I consider the fruit grown in the regions round Valencia to be very much inferior in every respect to the Jamaica product. It has a very thick rind, although it is said that this applies only to those of the so-called second flowering. Be this as it may, most of those that I saw were coarse in appearance, the surface being rougher than even our Seville orange, while the sweetness and juiciness can in no way compare, the seeds larger, much more core, and that very fibrous. The plains of Castellon have a perfect network of canals, a legacy of the magnificent engineering of the Moors. Connected with every 10 or 20 acres is an ancient water-wheel some 10 to 12 feet in diameter, for raising the water to the level of the land for the purpose of irrigation. The horses or mules that turn the wheel are blind-folded so that they may be kept in ignorance of the whereabouts of the driver boy, and so that he dare not stop in his monotonous round until the work is done for fear of the whip, which may be a mile away.

IRRIGATION.—In discussing with packers the merits of the fruit of the various districts as to their carrying and keeping qualities, I was informed that excessive irrigation ruined the carrying qualities of the fruit; that while a limited amount of water increased the rind so making the oranges somewhat together and less likely to be bruised in packing, we find that in the Bibara the best examples of the effect of water on the orange; there are two classes of orchard there, one, the "huerto" or gardens, mostly made up land in terraces, where the water let on moistens the soil, but does not remain pools for any length of time, quickly disappearing through the very porous condition of the land. The oranges produced thus are of a superior quality, and although the trees are planted some 20 feet apart, they yield a larger crop to the acre than those of the Plana, which are planted a little more than half that distance from each other. These oranges keep and carry well, while in the plains of the same district the "huertas" or fields are of a stiffer soil, the water lies longer and disappears slowly, producing a coarse orange which carries badly. Again, the increasing use of artificial manure is an important factor in the deterioration of the fruit in this direction as well as affecting the flavour, natural fertilizer being very much less so, but for reasons which the foregoing but partially explains, oranges from the high elevation keeps much better than those from the plains. Within the last few years a number of bitter orange trees have been introduced from Seville, as experience has proven that sweet oranges budded on to these possess excellent keeping qualities. This fact

argues well for the system now so much in vogue in Jamaica of budding sweet oranges on the shoots of Seville orange stumps or on young Seville seedlings. Oranges grown in districts subject to frequent fogs or mist carry worst of all; and in any case should on no account be picked while wet. In the early part of the season it is recommended that the fruit lie for several days in the shed before wrapping so as to permit of its being somewhat softened, the better to adapt itself to the packing process. As the season advances however, this is unnecessary, and the fruit should be put up within, at most, three days of housing.

But I am convinced, from all I have seen and learned of the fruit trade here, that with a few modifications and adaptations to local conditions, Spanish methods may with equal success be adopted in Jamaica. It may be objected that we have a much more difficult problem to solve than the Valencians, as the latter have but to provide for a seven or eight days' voyage, as against twelve from Jamaica. This argument, however, is ill-founded, as many of the packers employed in Palermo, Messina, and other parts of Sicily and Southern Italy, hail from Burrianna, where they employ exactly the same methods they have been accustomed to in Spain, with the one exception that the boxes are somewhat smaller, and they have to provide for a voyage of from fourteen to sixteen days in a temperature very often in excess of anything we have to contend with in the West Indies. Such facts should be most encouraging to us in our prospective orange business with England; and while in the streets of London I observed in several fruiterers' windows, Valencian and Sicilian oranges marked 2s. 6d. per dozen, alongside of which were Jamaicans at 1s. With improved handling, sorting and packing, I am sanguine enough to expect to see the tables turned within a couple of years, and the Jamaican oranges taking first rank amongst citrus fruits, entirely upon its own merits in the English market.

Before I close, permit me to suggest that a committee be appointed at once for the drafting of a bill, to be introduced at the next sitting of the Legislative Council, dealing with the question of packers' license (hear, hear) and the inauguration of a system of registered trade marks or brands (applause) that shall not only make it possible to lay the responsibility of badly-handled fruit on the proper shoulders, but will be the means of protecting the packer, who is ambitious enough to aim that his particular trade mark should represent a quality of orange second to none in the markets of Great Britain.—*Journal of the Jamaica Agricultural Society.*

USE OF THE ELECTRIC LIGHT AND OF ETHER IN FORCING PLANTS.

Practical gardeners have rarely the opportunity of making scientific experiments, and commercial men, in spite of the all-importance of the subject to them, are even less inclined to step beyond the path marked out by routine, unless some immediate benefit is likely to be forthcoming. Experiment stations, then, become more and more necessary, and they should be supported by those who will ultimately benefit from them. Such a one we might have at Chiswick. We do not think there would be any insurmountable difficulty as to funds, or as to a scientific director competent to devise, carry out, and publish the results of experiments likely to benefit practical horticulture. How is it, for instance, that no one

in this country has taken up the question of the use of the electric light, or for the matter of that, of artificial light of any kind, for forcing purposes in our dull winters? The evidence obtained some twenty years ago by the late Sir William Siemens was simply astounding (see *Gard. Chron.*, 1880, April 3, p. 432). Mr. Bnchanan, the gardener, now in Queensland, was allowed a free hand, and the results in the case of forced Strawberries, Wheat, and other crops were almost beyond belief, more especially as regards the hastening of the ripening process.

Of course this was an experiment on a limited scale, and the question of expense did not enter into consideration. The houses were there, the apparatus was installed, the extra cost of utilising the light was not material. The results were, however, so extraordinary, that it is a matter for astonishment that no one in this country has continued the experiments, and shown what modifications are necessary to make the use of the electric light, or the incandescent gas light, in forcing a commercial success. The subject is not even mentioned in the recently published gardening manuals to which we have referred. In France more has been done, and still more in America, where the use of the electric light has been proved under certain circumstances commercially advantageous in the case of Lettuce-growing. Prof. Bailey, in the *Cyclopedia of American Horticulture*, sums up the results that have been obtained in the United States by saying that "the application of the electric light to the growing of plants is a special matter to be used when the climate is abnormally cloudy, or when it is desired to hasten the maturity of crops for a particular date." Now these are just the very conditions which obtain in an ordinary British winter. Prof. Bailey goes on to say that, "Only in the case of Lettuce has it been proved to be of general commercial importance, and even with Lettuce it is doubtful if it will pay for its cost in climates which are abundantly sunny."

Professor Bailey writes, under the sunny skies of the States, of the electric light only, and from a commercial standpoint alone. The conditions of British horticulture differ widely, and in many places gas would be cheaper and more efficient than the electric light.

Another means of facilitating forcing operations has lately been made known by one of the professors at a Danish Agricultural School, and which consists in subjecting the plants to the fumes of ether. The plants so exposed shed their leaves, as though they had been subjected to frost. The best results with Lilacs are obtained in late summer. The ether then stops vegetative growth, and a moderate temperature being supplied, the flower-buds quickly expand, so that Lilacs may be had in bloom in the first half of September. M. Frans Ledien, of the Dresden Botanic Garden, has been experimenting in the same direction, and the results he has obtained are summarised in recent numbers of *Le Jardin*, from which we glean the following particulars:—

For early forcing, says Herr LEDIEN, the action of ether is so important that none who practice forcing on a large scale can afford to dispense with it. Flowers obtained by early forcing naturally command a high price. It should further be considered that fuel is saved by this method (whether the forcing be at a high or a low temperature,) and that this economy more than balances the cost of etherisation. The cost per plant works out at rather more than one penny (12 cents).

1. The varieties of Lilac usually forced in Germany: Marie Legraye, Charles X., and Léon Simon, were in full bloom twenty eight days after having been brought into the house; Marie Legraye was even earlier in flowering.

2. Various flowering shrubs may be bloomed in much less time than by the usual process. Plants of the same variety not etherised have not bloomed, or have bloomed badly, in the comparative trails, or perhaps some opened their flowers in eight or ten days (according to the variety) after those that were treated with the ether.

3. Etherised plants can be forced at a lower temperature than that which is essential for the blooming of those not etherised.

Besides Lilacs, Herr Ledien also made experiments with *Viburnum tomentosum* *syn.* *plicatum*, *Azalea mollis*, *Prunus triloba*, *Dentzia gracilis*, Lily of the Valley, Hyacinth, Rose, and cut branches of ornamental spring-flowering shrubs. *Azalea mollis* and *Viburnum* did well; *Prunus triloba* was less amenable to the action of the ether; *Dentzia gracilis* failed altogether. Lilies of the Valley etherised and placed in heat on November 21 flowered in the proportion of 40 per cent. on the twenty-first day, while of those not etherised only 2 per cent. flowered, and these in a temperature of 23° C. For late forcing of Lily of the Valley the ether had but little effect, so that it seemed better in that case to keep the plants in the refrigerating apparatus or in cool chambers. For Roses the results were not altogether decisive, although a very marked advance was reported.

Branches of *Azalea mollis* cut and etherised expanded their flowers in twenty-three days, while the buds on branches not treated did not open until twelve days after. The greatest success was with Lilacs, *Viburnum*, and *Azaleas*. *Viburnum plicatum*, though slow to bloom, placed in heat on December 2, was in full bloom about December 14; while those plants not etherised yielded only poor flowers at a much latter date.

Azalea mollis submitted to ether on Nov. 26, and brought indoors on the 28th, was covered with flowers on December 20, although the check plants only bloomed partially in the beginning of January. The more nearly the normal season of the flowering of the shrubs is approached, the less vigorous is the effect of the ether. The value of etherisation, then, is for early forcing in November and December, when the flowering can be hastened by some two or three weeks.

Plants lifted from the borders without preliminary attention during the summer, flower as normally as if forced in January or February. This, it must be confessed, is an immense advance in the forcing industry.

The application of the treatment is not without certain inconveniences and difficulties at the commencement. The vapour of the ether is inflammable, so that no light must be brought into places where plants are etherised until the vapour has been thoroughly dispersed by ventilation; no fire or light must be allowed anywhere in the neighbourhood of the ether.

There is still some difficulty in administering the ether to ensure perfect volatilisation. The plants should remain plunged in the vapour for a certain time, about forty-eight hours, and this must be in an absolutely air-tight place, to prevent the escape of the vapour. The larger the area, the more precautions should be taken both to concentrate the vapour during the period of etherisation, and to ensure its rapid dispersal after the operation.

For forcing on a large scale, cemented buildings with a door and several ventilators, the interstices of which are hermetically sealed so as to prevent the escape of any ether, are most convenient. The interior arrangement should be such that every corner can be filled with plants, so as not to waste the ether unnecessarily.—*Gardeners' Chronicle*.

COFFEE CULTIVATION IN BRAZIL.

Brazil is pre-eminently a coffee-producing country, the tree being introduced into Para, from Cayenne, in 1727. While coffee can be grown in nearly all parts of the country, its cultivation in the present century has been limited to a comparatively small zone, comprising the four States of Espirito Santo, Minas Geraes, Rio de Janeiro, and Sao Paulo. It is produced in other States, but in small quantities. The soil of Rio de Janeiro being already somewhat exhausted, Sao Paulo is in reality the great centre of production of the plant. Brazil furnishes more than 60 per cent. of the world's consumption of coffee, and it is claimed by some that the percentage is as high as 70 per cent. In 1890, Brazil produced 490,000 tons; Central America and Mexico, 80,000; Java and Sumatra, 60,000; Haiti and Santo Domingo, 43,000, Cuba and Porto Rico, 35,000; India, 30,000; Africa, 20,000; and other places, 100,000 tons. In 1898, the production of Brazil was estimated at 1,533,840,000 pounds, or 11,620,000 bags out of a total production of 1,960,619,288 pounds for all America, while Asia and Africa produced only 145,464,000 pounds or 1,102,000 bags. According to a recent report of the Bureau of the American Republics, coffee trees prefer wild, uncultivated lands, hill sides, or elevated lands. These are cleared of their trees and brushwood, and plants one year old are planted, averaging 400 to the acre. The plant does not begin to produce until it is 4 years old, its maximum production being reached between the ages of 6 and 20 years, after which it diminishes in productiveness. When the trees reach the age of 35 or 40 years it is generally necessary to renew the plantation. The coffee tree attains an average height of 10 feet, and its head a diameter of 5 feet. It blooms and yields a crop twice a year, but the most important is that beginning in April or May, and continuing to November. The only fertilisers used are the leaves of the coffee tree, the shells of the berry, and weeds, as it is necessary to keep the plantation free from all extraneous matter. The tree should be protected from cold winds. Its worst enemy is frost, which sometimes causes the tree to cease producing for a number of years, occasioning greater loss than the parasitical diseases with which it is afflicted. The berry resembles very closely the cranberry, and contains two grains, with their flattened sides towards each other. Each of the two is covered with a closely adhering membrane, called *pergaminho*, and outside of this is a thicker and more loosely fitting coat called *casquinha*. The two grains, with their coverings, are contained in a tough shell, called *casca*, and this is surrounded by a white pulp and outer red skin, thus forming the berry. To prepare the coffee for market, all these coverings are removed. The outer pulp is removed, after maceration in water, by a machine called *despulpador*. A trough, lined with cement, is placed on a hill-side above the mill, and through it a stream of water is kept running. Into this the coffee berries are thrown, and are carried down the stream into a large vat. In this vat the heavier berries sink to the bottom, whence they are drawn off through a pipe to the *despulpador*. This machine removes the pulp, the berries passing with the water to another vat beyond, where the pulp is thoroughly washed off and carried away with the water, while the coffee grains sink to the bottom, and thence, passing to a strainer, the water is all drained off, leaving them ready for the process of drying. Two methods of drying are in use in Brazil; the old process, which consists in spreading the grains on a cement covered pavement, called *terreiro*, where they are allowed to dry in the sun. For this about two mouths are necessary, and the grains have to be raked over and turned during the day, and gathered into piles, and covered at night, or whenever a shower comes. The more modern and satisfactory process of drying by steam is employed on many of the larger plantations. By this process,

the drying, which by the old method requires about sixty days, is accomplished in a few hours, with a vast economy of labour. Under this system, drying is done in large shallow pans of zinc, heated by steam coils beneath, more uniformly, and with no danger of injury from sudden rain. The coffee, after drying, is still enclosed in the inner and outer skins, which have been rendered more brittle by the drying. The machinery necessary for the removal of this is somewhat complicated and expensive. The coffee is brought from the drying house, and placed in bins, whence it is carried to a ventilator, where it is cleared of rubbish and dirt by sifting and fanning. From the ventilator, the coffee is carried to the sheller (*descascador*). The grains and broken husks are carried by a pipe to a second ventilator, where the latter are sifted out, and fanned away, and the former are carried by an elevator to the separator. This is composed of hollow copper cylinders, pierced with holes of different shapes and sizes. These cylinders are kept constantly revolving, and the coffee grains passing through the holes, fall into separate bins, being thus assorted according to their size and shape. The coffee thus mechanically classified goes into the markets of the world, where it is sold, the small, round grains as "Mocha," the large, flat grains as "Java." A small portion of the *pergaminho* which still remains, is removed by the *brunidor* (polisher) by trituration and fanning. Finally, after passing through all this series of machines, the coffee is carefully picked over by hand, and is ready to be put into bags. As an indication of the extent to which coffee cultivation is pursued in Brazil, the Secretary of Agriculture of the Sao Paulo Government may be quoted as follows:—"There are in Sao Paulo 15,075 plantations, of which 11,234 have upwards of 50,000 trees; 1,844 possess from 50,000 to 100,000; 999 between 100,000 and 200,000; 597 from 200,000 to 500,000 trees. On these plantations, 1,703 machines are to be found for cleaning coffee, 1,243 of which are worked by steam, and 460 by water. In Minas Geraes it is said that there are 2,739 coffee plantations, 1,234 with less than 50,000 coffee trees each, 844 with over 100,000 trees each, and 64 with over 500,000 trees each. Of these plantations 500 use water power and 1,243 steam." Brazilian planters complain that only their inferior grades of coffee are known abroad in their true character, their better qualities being sold under the disguise of such titles as "Mocha," "Java," "Martinique," &c. It is said, even, that this spurious trade is strengthened by the shipments of Brazilian coffee from various parts of Europe to Egypt, and thence to Arabia, *via* Aden and Jeddah, &c., so that it may there be packed in Mocha fashion, after which it is shipped to Syria or other places, or returned to Egypt as genuine Mocha. The total production of coffee in Brazil, which amounted to 4,622,000 bags in 1899-90, rose in 1894-95 to 6,977,000 bags, and in 1899-1900 to 11,060,000 bags, the bag containing about 132 lbs.—*Journal of the Society of Arts*.

COCONUTS IN SOUTH AMERICA.

An interesting report regarding the production of coconuts in South America was recently issued by the Consular Department at the city of Washington, U.S.A.

The countries dealt with were Brazil, Colombia, Ecuador, The Guianas, Peru, and Venezuela. And the report was based on information received through the consuls at the places mentioned.

COCONUTS IN BRAZIL.

Although a great many coconuts are raised in the Bahia consular district of Brazil, it does not produce one-third as many as the Pernambuco district, which is particularly rich in coconut palms, on account of its peculiar coast formation.

In the Bahia district, the trees are found wherever there is a settlement, but grow chiefly on the strip of low-lying sandy land along the coast. This land is the most desirable for coconut plantations, as

the proximity of the salt water makes the trees more productive and the fruit a better quality. Occasionally a piece of land is found at a considerable distance from the coast upon which the palms will flourish, but this is unusual. Single trees are scattered here and there inland; but these are raised with considerable difficulty, produce only an indifferent fruit, and die at an early age.

The number of trees and their productiveness increases as the Pernambuco district is neared and decreases in the same ratio southward. The largest plantations are a short distance north of Bahia City, where there is one that has more than 7,000 and several which have as many as 5,000 trees each; but no particular efforts at cultivation are made. The coconuts have simply been planted and allowed to come up and produce what they will, the fruit being gathered from time to time. The owners are usually engaged in other businesses; the proprietor of the large plantation above mentioned, for instance, is a local merchant.

It is impossible to get any information as to the extent of the coconut crop. The nuts are gathered in all seasons and are used both in the green or soft and in the ripe or hard state by all classes. The yield, however, must be enormous, as there are few households that do not use the nuts in some form or other, and in spite of the vast number of trees, the supply does not seem to equal the demand.

Before the shell of the nut becomes thick and hard, and while the meat is soft and about the consistency of clabber, many of the nuts are gathered and sold upon the street corners and in the drink shops. The nuts are cut open with a machete. The milk proves a most refreshing drink, while the meat is eaten with a spoon or, more often, with a silver cut from the shell. No attempt is made to husk the nuts so used, though frequently a portion of the husk is trimmed off to lessen weight for transportation.

The hard-shelled or ripe nuts have various uses. When of good quality, they are sold at retail. Many kinds of sweet-meats are also made from them, while the milk and the meat, variously prepared, are constituent parts of many articles of daily diet, such as fish stews, beans, rice, corn, etc. The ripe nuts are always sent to market husked. They are brought to Bahia by small sailboats, which ply up and down the coast, and on account of the demand are sold at comparatively high prices. The price paid for them at the plantations ranges from 9 to 14 milreis (\$2.18 to \$3.36) per hundred (without respect to size,) according to season, the wholesale price in Bahia City being a couple of milreis higher per hundred. The retail price is from 120 to 320 reis (2.38 to 7.61 cents) per nut, according to size and season.

There is such a demand for good nuts at Rio de Janeiro and other points south that it is far more profitable to ship the nuts there than to utilize them in the manufacture of copra; and even if the prices at local markets were not so good, there would, nevertheless, be no nuts for foreign export.

It is only the nuts that have been left too long on the trees that are utilized in the manufacture of by-products. From these nuts the oil is crudely extracted by grinding the meat submitting it to pressure and purifying the resulting liquid, or by grinding and boiling the meat, and skimming the oil. This oil is used for machinery, lamps, cooking, soap-making, etc. It is also used by the resident Africans for hair oil and for anointing the body. It sells at wholesale at the place of manufacture at from 800 to 1,200 reis (19.2 to 28.8 dollar cents), per litre.

There is still a great amount of uncultivated land well suited for coconut plantations. Few trees are being planted, yet it requires no labour other than that of putting a mature nut into the ground prior to the rainy season, and that after five or six years the trees will bear almost indefinitely.

COCONUTS IN COLOMBIA.

The consul at Cartagena, Colombia, was placed at a disadvantage in gathering data for his report on

account of the revolution in that country. "Under ordinary conditions," writes the consul, "the raising of coconuts is an interest of considerable magnitude, and a fair amount of attention is bestowed upon the groves and the collection, husking, sorting, and packing of the nuts. It may be said that, with rice, the coconut is the main source of food supply of the natives of the coast.

"Owing to the above-mentioned conditions, the extent of the coconut crop of this district is unknown. Coconuts are grown both for home consumption and export. They are not shipped in the husk. The price at the present time is from \$12 to \$14 gold per thousand.

"Coconut plantations in the Colon district of Colombia are confined to a strip of land contiguous to the Atlantic Coast, and to the Island of San Andres, belonging to Colombia, lying about 275 miles from Colon in a north-westerly direction. There are no plantations in the interior. On the coast, by far the greater proportion of coconuts is raised by the San Blas Indians, on a strip of country about 125 miles long extending from Point San Blas to Point Tiburon. Besides the plantations owned by these Indians, there is only one other on the coast—the Caribbean Coconut Plantation, at Point Toro, across the bay from Colon. This plantation consists of about 20,000 trees.

"The entire coconut crop of the coast amounts to about 4,000,000 nuts a year; that of the Island of San Andres to about 2,500,000.

"Coconut trees are raised by first putting the dry nut on the ground and allowing it to sprout until it attains a height of about two feet. The nut is then put in a hole just deep enough to receive it, the sprout remaining above ground. The only attention the palm requires is to keep it free from weeds and other plants until it is five or six years old. After this age it is able to protect itself, and the ground requires very little clearing. Trees properly attended to will bear in from five to six years.

"All nuts raised in this district are sent to the United States. They are never shipped in husk. The market price fluctuates between \$21 and \$40 per thousand. From March to September, it rarely reaches more than \$25; from September to March, \$25 to \$40.

COCONUTS IN ECUADOR.

"The cultivation of coconuts receives very little attention in Ecuador, most of the palms being grown as side issues upon the various estates. The few raised are for local consumption only: none are shipped. The price is 10 cents silver ($4\frac{1}{2}$ cents, in United States currency) per nut, retail.

COCONUTS IN THE GUIANAS.

"The coconut crop of British Guiana amounts to about 5,000,000 nuts annually. The cultivation of coconuts receives considerable attention in the district of Mahaicony, about 30 miles up the east coast from Georgetown, in the vicinity of the Decerara and Berbice Railway. The nuts are mostly made into oil at the oil and fibre mills at Mahaicony, and the product is sold and consumed in the colony. Less than 2,000 husked nuts were exported last year. These were shipped to the British West India Islands.

"The prevailing price in the local market is from \$8 to \$10 per thousand.

"Only about 50,000 nuts per annum are produced in Dutch Guiana, and an insignificant number in French Guiana. These are consumed locally.

COCONUT IN VENEZUELA.

"At La Guayra, the annual crop of coconuts amounts to about 1,000,000. At Barcelona and Comana, however, it is much larger; the latter could easily furnish 5,000,000 nuts a year. The cultivation of coconuts receives very little attention in La Guayra, and practically no efforts are made to extend their growth. There is no reason, however, why the present area should not be increased, as the palm thrives wonderfully along the coast, and nearly all of the land within half a mile or a mile of the sea could be utilised.

The nuts grown in the La Guayra district are mostly absorbed by the local retail trade of the cities of La

Guayra and Caracas, a great many being sold to the natives who drink the milk. The nut is also used for cooking, confectionery, etc. In Cumana, most of the crop is manufactured into oil. This oil is said to be of an excellent quality. A few nuts are occasionally shipped from La Guayra to the United States, but the trade is not profitable. The harbour dues on all kinds of freight is \$4 a ton, and planters find that it pays them better to hold the nuts for local consumption. Coconuts are never shipped in the husk.

"In La Guayra the price of coconuts is from \$2.50 to \$5 gold per hundred: in Cumana, from \$2 to \$3.

"The production of coconuts in the Puerto Cabello district of Venezuela is limited, as there are but few trees. Very little attention is paid to their cultivation and the supply is decreasing. The soil, however, is excellent for the growth of this palm.

"The nuts are marketed here green for the coconut water they contain; ripe, for the meat, from which oil for soap-making and other purposes is extracted, and as copra, for foreign shipment. The green coconuts are sold for 1 cent each, ripe ones at about the same price, and copra for about 2½ cents per pound.—*Indian Gardening and Planting.*

TROPICAL TIMBERS AND THEIR RINGS OF GROWTH.

With reference to Mr. Herbert Wright's paper in the *Tropical Agriculturist* of last October, we reproduce the following article on "The Rings of Trees," reprinted from *American Gardening*:—

THE RINGS OF TREES.

The following interesting article by Mr. H. H. Chapman, of Grand Rapids, Minnesota, in *American Gardening*, should be read in conjunction with Mr. Herbert Wright's valuable contribution, "Tropical Timbers and their Rings of Growth," which appeared in our issue of 22nd August 1901.

Every tree has its life-history securely locked up in its heart. Each year of its growth a thin ring of wood is formed next to the bark and a corresponding layer of bark adjoining it. As the tree swells and swells, the bark is forced outward and splits into wide fissures. Much of it falls off altogether, but each ring of wood remains a faithful record of the year in which it was formed. When the axe or saw of the woodman ends the life of the tree and brings its body crashing to the earth, this record is unrolled before us, and by it we can determine almost every incident in the life and growth of the tree.

Trees as well as human beings have their period of struggle and hardship, their prosperous times, their terrible misfortunes and hairbreadth escapes, their injuries, and recoveries; their complete submergence in a struggle in which the odds were too great for their feeble strength to cope with.

Here is a sturdy oak, whose tale revealed is that of steady perseverance in the face of difficulties—a slow gradual growth, never checked, never daunted, till the final goal is reached and it stands supreme, literally monarch of all it surveys.

Here is a mighty spruce which has a tale of perseverance, but of a different sort. The oak conquers by force of character by its fighting qualities. The spruce succeeds by its ability to endure. It is like the patient Jew, frugal living on what would be starvation to others, till when their day of strength is past, and sudden disaster overtakes them, he enters into his inheritance and prospers amazingly.

See the record of this spruce—fifty, sixty, seventy years, each represented by a ring so small that it takes great care to distinguish them at all, and the whole seventy do not occupy the space of three inches at the heart of the tree. What a tale of hardship this sets forth. Other trees have pre-empted the light in which the existence of a tree depends. The poor spruce must be content with the twilight that filters through the branches of its enemies, the poplar, birch and pine. But it is content. It knows that the young

poplars or pine spring up beside it in the shade they could not endure, but would quickly die. It knows that the time will come when old age or disease will weaken the poplars, or perhaps a heavy wind will lay them low, and the spruce, old in years, but insignificant in stature, will escape injury, and still young in vitality, will soon spring ahead in the race.

Now see its rings—it has made as much growth in ten years as in the preceding seventy, and soon becomes a large tree.

What does the stump of this old white pine teach us? Evidently something extraordinary has happened to it, for way in near the heart a black scar runs around the edge of one of the annual rings for nearly one-fourth of its circumference, and outside of this the rings are no longer complete, but have their edges turned in against the face of this scar. Each subsequent ring reaches further across it. By the time they have met in the centre many years have elapsed, and there is a deep fissure where the scar once existed. But the later rings have bridged the gap and, growing thicker in the depression, soon fill up the circumference of the tree to its natural roundness, leaving no sign of the old wood. What happened to the tree? While it was still young its mortal enemy, the forest fire, swept through the woods, destroying most of its companions and burning a large strip of the tender bark on its exposed side so that the bark died and fell off. But being better protected than the other and having still three-fourths of its bark left uninjured, it soon recovered and its stump reveals how successfully it strove to heal the wood and grow to maturity to perpetuate its species.

But as it takes many swallows to make the summer, so it takes many trees to make a forest, and the forest has almost as much individuality as the tree itself. Though each tree and each species struggle with each other for life and supremacy, yet in a sense they are helpful to each other, and protect each other from their common enemies.

The enemies of the forest are the wind and the fire. Other enemies there are, such as insects and disease, and sometimes the forest suffers so severely that its whole aspect is changed and new species come in and replace the old. Much of this history the rings will reveal to us, as is the case in some of the following actual examples from studies recently made in the pine forests of Northern Minnesota.

In one locality where rather small Norway pine stood very close together, making a thick stand, it was found that almost without exception the trees were of the same age—138 years. No matter how large or how tender the tree, it was just as old as its neighbour.

The rings on all these trees were very large at the heart, but as fifty or sixty years went by, they got narrower and narrower, until some of the smaller trees seemed hardly to grow at all. The reason was plain; there were too many trees—and as none would give up the struggle, all suffered alike.

But they were not the only sufferers. Here and there we see a slender, struggling white pine making a vain attempt to capture its share of sun and rain. Count reveals that these white pines are also all of the same age, but unfortunately only 126 years old. The Norways had twelve years the start of them and the delay was fatal.

How did it happen that these trees came in so thickly and all the same year? Perhaps further study will help us to find out. So we go to another cutting over a mile from first. Here we find many trees about the size of those we have left, and counting the rings we find them to be of the same age—138 years. But here there is something more. In a secluded nook stands a group of immense white and Norway pine trees—perhaps a dozen. These prove to be very old, but, remarkably enough, also of even age—each stump showing 315 rings. Where is the rest of this patriarchal forest? Close about the few remaining may be seen the forms of many more stretched upon the ground and slowly decaying. These have evidently been blown down, possibly after

being killed by fire. Their fate gives up the clue to the disappearance of the others. It is plain that some time before 1763 a great disaster overtook the pine forest in this place. Most of it was wiped out of existence, either by fire or wind. But here and there a clump remains, and from them in a favourable seed year came the seed which started the new and thriving crop of Norway pine.

To find out if possible whether this conflagration or blow-down was more than local we go to a cutting some ten miles from our first, and here again the oldest and largest of the stand, which is all rather small, prove to be 138 years old. Whatever the cause then, it must have operated over a large area, but this is not a thick stand; in fact, there are many gaps, and much of the timber is limby and knotty, a sure sign that it has not been grown very close together, and soon we find that many—in fact most of trees—are but 101 years old, there being two distinct age classes.

How did this come about? Let us look at the older trees. Here upon one of them is a fire scar made when the tree was eighteen years of age. Upon another we find a similar scar, made in the same year, and on close examination we can hardly find one of the older trees free from the marks of this fire. How plain it is that this fire occurring just 120 years ago, or in the year 1781, when the young forest was eighteen years of age, killed nearly all the young pine and gave the forest a blow from which, in this place at least, it never fully recovered. But it did the best it could, for the age of the second class of trees—101 years—shows that the young survivors of the fire grew rapidly, until at the age of 38 years they were enabled to produce a crop of seeds, or possibly the old trees from which the first ones came were still living and seeds down the ground a second time, so that a fairly good stand of trees was finally produced.

These studies lead us to infer that pines reproduce themselves as forests generally under exceptional or unusual circumstances, and that that is their natural way of maintaining themselves as species. The young white and Norway pine, especially the latter, cannot endure much shade when small, and could not possibly grow up as a thick forest under their own shade or the shade of other trees, yet we nearly always find them in dense groves. The rings tell us the secret. In the long period of 200 to 300 years during which the pines live, the "accident" of fire or wind becomes a certainty, and when a strip of forest is laid low or burned up, the neighbouring trees stand ready to scatter the seed far and wide in the wind and the new growth springs up and flourishes.

This is nature's method. But nature's methods are so perfectly harmonized that but little is needed to throw them out of balance.

Nature clears in strips and gashes seed there, and fires are rare and far apart. Man clears over wide areas and fires of his origin sweep repeatedly over his slashings. The young pines spring up even after the second and third fires, but by perseverance the fires finally destroy them all, and what nature intended to be the young pine forest becomes a barren wilderness.

SIMPLE CURE FOR GAPES IN CHICKENS.—Punch some holes in the bottom of an old tin bucket. Get a piece of glass large enough to cover the top. Put a hot coal in a saucer, and pour a drop or two of carbolic acid on it. Place the chickens in the bucket, and set the latter over the saucer. The fumes of the acid will rise through the holes. Do not put the bucket on till the first fumes have passed away. Watch the chickens through the glass so that you may not smother them. If they seem overcome take the bucket off the saucer and remove the glass. One operation is usually sufficient. By doing this, you will lose no chickens from gapes.—*Queensland Agricultural Journal*, Feb. 1.

THE GAME FOWL SHOW.

(By a Specialist.)

The Game Fowl Show at Temple Trees was a pleasant gathering and was a distinct success. The afternoon was fine and the arrangements were very simple but complete. There was no great crowd or crush and the birds could be seen in comfort.

The men were strongly in evidence, while the fair sex with a few exceptions were conspicuous by their absence. This perhaps was only to be expected for the Game Fowl is essentially a man's bird, and is scarcely likely to be regarded by the fair sex as anything but an ugly and cruel-looking creature. These birds are born fighters, even the hens are very pugnacious. As it was two of the hens were going it hammer and tongs by getting their heads out through the wire netting and a special board erection had to be put up to keep their heads apart. The cocks were unable to indulge in a 'mill' as their wire netting was of smaller mesh and prevented their getting at one another. The number of the birds was about 60; of these there were twice as many cocks as hens. The points about the birds that strike the ordinary poultry keeper most were the size of the cocks, some were monsters—the heads are unlike those of ordinary poultry in being very broad surmounted by a peculiar-shaped comb and with a beak very powerful and curved which, with the overhanging eye-brow, gives this bird a vulture-like appearance betokening savage cruelty.

The feathering too is peculiar to this breed, there is no surplus of feather, no fluffy birds are seen; the feathers on the contrary being scanty and hard and held very close to the body. The legs also attract attention, being very thick and powerful and armed with huge spurs. The tameness of the birds was very remarkable especially of the cocks. They had not the least objection to being handled or touched; this is the rule with fighting cocks; many of them must have been great pets with their owners. The exhibition of ferocity is only reserved for their own species. It was remarked as a curious point that several of the hens had one long spur which would have graced the leg of a full grown pugilist; but in no case had any of them these long spurs on both legs. The condition of the birds as a whole was good, though several were a little out of condition and one or two had diseased combs.

It was originally intended to classify the birds under three classes; for the three breeds that were likely to be met with in Ceylon viz; the pure-bred Malay; the pure Indian Game (or Azeel); and a class for the Local game fowl of no special type. It was found however exceedingly difficult to define many of the birds. The preponderance was largely Malays and nearly all the others save one had a strong dash of the Malay about them. There seemed to be only one real Indian game cock in the show. And it was wisely decided to put all into one common class.

As to the colouring, the majority of the cocks were "Black Breasted Reds." And there were several in which the colouring was very good, but in the majority there were a good many white feathers, which, though doubtless never shown in battle, greatly marred their beauty on the exhibition stand. In fact many of the finest of the cocks were thus mismarked. There is no doubt

that here in Colombo, if not in Ceylon at large, *the colour* to breed is the Black Breasted Red. Curiously there were no black cocks nor any buff ones and there was only one pure white. Amongst the hens there were seven blacks, but only one white, while there were several buffs and browns of various shades. There were two very good smoke-coloured hens, and also a similar cock which did not however come up to the hens.

A little care in breeding the Black Breasted Reds should in time breed out the stray white feathers and make the bird true to colour.

As to *Type* the large majority of the cocks were nearer the Malay type than the Azeel. It is far easier to secure a good Malay than a good Azeel. The latter is a costly bird and is bred chiefly in Hyderabad and Deccan. They are bred by the Pakeer Poultry Farm (E.I. Ry) and are sold accordingly to quality at R20 to R100 per bird!

There were over 20 hens exhibited. The first seven were blacks. No. 2 would probably have attracted more attention, had she not been inclined to be broody. No. 3 came in for a good deal of attention, she had a fine head and neck and the feathering was close; had she been a larger bird she would probably have come out higher; being rather undersized, she came out third and won the third prize. No. 7 attracted many admirers; no other hen stood so well. It had the type of a true Indian game. The head was good, the neck long and the feathering very close and tight, carried her tail well and had fine strong legs. The 2nd prize was carried off by this bird. After the blacks came the light drabs, buffs and browns.

No. 9 was a very taking bird and was greatly fancied, almost every body that voted gave this bird a vote, the majority considering this the best hen. It easily won the first prize. It was a heavier bird than No. 7 and was of a light reddish drab colour, doubtless a Malay hen. The head was powerful, the shoulders broad, a good-shaped body and tail carried well. The marking was even and the feathering close. No. 13 was one that was fancied by many, a dark drab big bird, with a fine head but not in the best of condition. No. 15 had a strong backing, the head was excellent. This was one of the hens with a single huge spur. The remainder attracted little notice except No. 23, a pure white hen with many good points, but with the blemish of whiskers. This hen stood fourth on the list of competitors.

It was a noticeable fact that many of the hens had whiskers and bibs and far too much hackle feathering, all of which are serious blemishes in a game hen. The judging of the hens seemed to be a very simple matter and the unanimity of awards was very striking. The cocks seemed to perplex the Judges very much. It was easy enough to enumerate a large number as not in the running. It was in fact strange how one or two came in as game fowl at all, they possibly qualified as being very game in fight.

The favourites among the cocks were No. 2, 11, 13, 15, 17, 18. Mr Livera won the first prize with No. 2 which was a fine young Malay cockerel which looked as if it would grow and fill out still more. It was a black-breasted red, the colouring being very handsome. It had the typical head with long close feathered neck, splendid shoulders held well out, strong thighs and legs, but it was by no means the biggest of the cocks. The silver cup presented by Mr A

Y Daniel was won by this bird. Mr S Sarasinghe's No 15 took the 2nd prize, while the third fell to Mr C E Siebel's No 13. These three Malay cocks were very close together in the voting and it is hoped that they will meet again at the big Poultry Show in August. It may be interesting to know there were at least ten cocks that did not secure a single vote (where were their owners?) while there were seven that only received one vote. The judging was certainly a novelty, it gave great zest to the Show and increased the interest of all in the proceedings, and further it gave satisfaction to all. While heartily approving of the method in the small Shows of a single breed, it would of course be unworkable in a large mixed Show.

MOSQUITOES AND COLOUR.

Mr. Herbert L. Thowless writes from Newark, New Jersey, U.S.A., under date January 29:— "In a recent number of *The Times* appeared an article entitled 'Mosquitoes and Colour.' This article interested me because this State suffers from this pest. I clipped the article and sent it to Professor John B Smith, State Entomologist, Rutgers's College, New Burnswick, N.J. Professor Smith writes me that he knows the facts as stated in the article, relative to colour affecting mosquitoes, to be true. It is a common observation along the seashore that the person wearing a black coat is more pestered than those in grey or yellow. The Legislature of the State of New Jersey is to be asked for a special appropriation of \$10,000 (£2,000) to be used to investigate the mosquito problem. In the vicinity of New Jersey, at the town of South Orange and at other places, ponds and stagnant water were coated with crude kerosine oil during the summer of 1901, and there was noted a marked decrease in the pest. This section has the misfortune to possess many thousands of acres of tide-marshes, and these marshes are fertile breeding places for mosquitoes. There does not appear to be much literature on the subject of mosquitoes, but the United States Agricultural Department prepared and distributed a monograph on mosquitoes and scattered it throughout the land. Copies can be had on application to the Secretary of Agriculture, Washington, D.C., U.S.A."—*London Times*, Feb. 12.

CEARA RUBBER IN WEST AFRICA.

A letter from Lagos, dated 6th January, contains the following:—

"Can you please give me the latest result and all information about the cultivation of all kinds of rubber, and especially about the experiment of extracting rubber from yearling rubber trees? The last information to hand about this experiment (*Tropical Agriculturist*, Aug. 1899) was that it was being tried with yearlings of *castilloa elastica*, the Mexican rubber tree. With what result and whether it has been tried with yearlings of other kinds of rubber tree, as you proposed, I have not been able to know. (We recommend our "Rubber Manual" to the attention of our correspondent.) Our planters here have thousands of ceara trees on their lands; but the latest and best result obtained so far is only ($\frac{1}{2}$) half an ounce of fine

elastic rubber per tree, which I obtained some time last month from the tapping of some isolated trees at Abeokuta—a town upcountry four hours distant by rail from Lagos. The people are naturally disappointed and contemplate cutting down their ceara trees. But I advised patience and raised their hope by promising to write to you for the latest information on the subject, especially about the experiment of extracting caoutchouc from yearlings. I hope you will be kind enough to favour us with some interesting and hope-raising information on the subject."

TROPICAL MALADIES.

INTERESTING LECTURE BY DR. JOHN ANDERSON.

In a paper read before the Medical Society of London, Dr. John Anderson deals with the remote effects of tropical life on Europeans. Dr. Anderson is lecturer on tropical medicine at St. Mary's Hospital Medical School, and points out that in hot countries, for example India, the temperature of the body is higher, the respiration slower, the capacity of the chest for air is higher, so that the relative proportion of blood and air in the lungs is altered. The tone of the nervous system is also depressed. When a man, after long residence in India, returns to Europe, he is less adaptable to the second change of climate.

Malaria and its consequences are very detrimental to the health of Europeans in hot countries. Among the consequences are albumenuria and neuralgia. Serious conditions of the nervous system also result from sun or heat strokes, for example, epilepsy, blindness, deafness, and even dementia. In milder cases the patient cannot bear prolonged mental effort, and heated, stuffy rooms cause headache, insomnia, irregularity of the heart's action, depression or irritability of temper. Such symptoms often disappear with cool temperature, avoidance of exposure to the sun, or of alcohol and excitement. Anæmia with enlargement of spleen is another consequence of residence in the tropics. Chronic hypertrophy of the spleen is an effect of malaria. Many diseases, for example typhoid, are complicated by malaria. Abscess of the liver is also a remote effect of Indian life, not easy to diagnose or discover. Chronic dysentery is another after-effect of long tropical residence. Mediterranean fever, ascribed to a microbe (the *micrococcus melitensis*), is not deadly, or associated with malaria or typhoid, though in its earlier stages it may be mistaken for these. Dr. Anderson's lecture, while suggestive, shows how much medical men have yet to learn with regard to tropical maladies.—*Globe*, Feb. 14.

GROWING TOBACCO UNDER SHADE.—An enthusiast on the subject of growing tobacco under shade estimates that within the next five years there will be no less than 6,000 acres producing wrappers under cheese-cloth in this country. At, say, 1,500 lb. to the acre, the yield would be 9,000,000 lb.—enough to wrap the cigar product of the country, and something left for export. The samples of the tobacco grown under shade in Connecticut which have been shown in the market are absolutely without a defect.—*Queensland Agricultural Journal*, Feb. 1.

THE U. S. A. GOVERNMENT AND RUBBER.

The present attitude of the department of agriculture at Washington towards the investigation of rubber resources and production merits the approval and support of every branch of the rubber trade. There is no longer any reason why rubber—any more than wheat, or tea, or hemp—should remain a forest product, to be gained by unsystematized and uneconomical methods. Much has been done by individual private enterprise in the direction of bringing the production of rubber under more intelligent supervision, but vastly more remains to be done. The rubber belt is so wide and the conditions so varied involving, among other things, so many rubber species, and the whole production is so remote from the centres of consumption, that any changes based upon unconnected individual enterprises must be slow.

While the gathering and marketing of rubber—and its planting, for that matter—must always be under private control, and based upon private capital, governments can render great help to the interest, particularly in the way of collecting and disseminating correct information. Reports by trained scientific observers, intent upon discovering facts rather than making profits, when published officially, gain a wider circulation and are accepted as more trustworthy than even similar reports from any private source. Of the mass of printed matter in *The India Rubber World's* library regarding the sources and conditions of natural rubber supplies, by far the greater part is the result of official or semi-official investigations. There is not one book in the lot written by a private individual who has travelled in and studied any rubber country on his own account.

The United States government in the past has given little attention to the subject of rubber, considering that more than half the world's production is consumed in this country. But now that we have extensive tropical possessions, the same reason exists for studying the development of a rubber interest in them that has appealed to every colonising power in Europe. The present disposition at Washington is to discover, not only what plants of economic value exist in our tropical territory, but what plants in other countries of corresponding latitudes may be introduced profitably therein. The department of agriculture, in making the estimates of money needed for the coming fiscal year, has included the following clause, which, it is understood, refers in an important degree to rubber:

BOTANICAL INVESTIGATIONS AND EXPERIMENTS,—.....; to investigate and publish reports upon the useful plants and plant cultures of the tropical territory of the United States, and to investigate and report upon them, and introduce other plants promising to be valuable for the tropical territory of the United States, such plants and botanical and agricultural information when secured to be made available for the work of agricultural experiment stations and schools \$65,000.

It might tend to influence Congress favorably in respect to voting the appropriation if citizens engaged in the rubber trade would write, approving the measure, to senators and representatives from their States, or whom they know personally; or letters might be directed to the chairmen of the committees on agriculture, of the Senate and House of Representatives, respectively.—*India Rubber World*, Feb. 1,

RUBBER IN ASSAM, 1901-02.

The quantity of rubber collected and sold by direct Government agency in the Kamrup and Darrang districts was as follows:—

	Mds.	R.
Kamrup	39	6,987
Darrang	28	5,040
Total	67	12,027

During the year, the exclusive right of collecting and removing rubber on payment of duty from outside the Government plantations in the Darrang district was sold for R22,100 against R16,900 in 1899-1900.

The total outturn of rubber for the year was 3,592 maunds, against 5,558 maunds in the previous year. This large decrease was entirely due to the small quantity of foreign rubber imported into the province as may be seen from the figures given below:—

	1899-1900.	1900-1901.
	Mds.	Mds.
Manipur	409	392
Bhutan	406	42
Dufia and Aka Hills	1,148	583
Naga, Mishmi, and other neighbouring hills	2,853	1,786
Total	4,816	2,803

—Planting Opinion, March 1.

PASSION FRUIT.

Question.—What is the best method of collecting and preserving passion-fruit seeds? when is the best time for planting them?

Answer.—In Southern Queensland, on the coast, plant in September; in North Queensland in March. To save the seed, take out the pulp of several fruits, press it lightly so as not to injure the seed. This will remove a large amount of the moisture. Put the pressed pulp and seeds into a tin and let it dry. It will keep for a very long time. When you intend to sow the seeds, soak the cake for a time in water.—*Agricultural Journal*, Feb. 1.

GUTTA-PERCHA NOTES.

Dr. Treub, the director of the Botanic Garden in Buitenzorg, is in negotiation with his Government to establish with Government aid a Palaquin Gutta plantation on a space of about five thousand acres in the Plabocan district, in the province of Saekaboemi and near the plantation of Tjipetir; the splendid results of the Tjipetir plantation have already been stated in previous numbers of this journal.—*La Gazette Coloniale*.

In their annual report Messrs Kramrisch & Company write as follows:—Gutta-Percha: The year opened with a very poor demand, and the market continued weak throughout almost the whole of the year. It was only during November that, owing to larger contracts for cables being placed, extensive buying orders appeared on the market, thus increasing values of Gutta-percha, and since then a fairly large business has been done. There seems to be every prospect of a continued good market, with fair prices being paid for good and desirable qualities of gutta-percha.—*India-Rubber Trades' Journal*, Jan. 20,

A NEW PROCESS FOR THE RECOVERY OF INDIA-RUBBER.

Our esteemed contemporary, the *Gummi Zeitung*, in its last issue contains a rather enthusiastic article on a new process for the recovery of india-rubber, the invention of Mr Albert Theilgaard, of Copenhagen.

Any new process of this description is worth careful attention, but evidence so far submitted in proof of what this process actually accomplishes is hardly sufficient for us to share the sanguine expectations of our contemporary. Great stress is laid, in two expert opinions accompanying the article, upon the fact that this new recovered rubber may be re-vulcanised, and that it contains a very small proportion only of combined sulphur. All this may be true, but Messrs Somerville, of Liverpool, have for years been selling a re-covered rubber of this description, and Messrs Rowley, Manchester, and the Rubber Chemical Company, of Mitcham, for some considerable time have been manufacturing an excellent product of this sort. Nor is there much to be said about the low percentage of combined sulphur in the new product, as long as no reliable information is to hand respecting the percentage of combined sulphur in the stock before recovery. The new process appears to consist in a treatment of the waste with alkaline sulphites and appears to rely upon their well-recognised property to dissolve sulphur (free), as also upon its reducing (oxygen absorbing) powers. But as to the first of these properties, this could only allow of the removal of the free sulphur, but not of the combined sulphur, and the reducing properties of alkaline sulphites are well recognised to be of a very low order only, so that the reduction of rubber, deteriorated by oxidation, to oxygen-free rubber by this means is a statement calculated to make us rather sceptical. If true, it would involve, as a matter of fact, the discovery of, so far, totally unexpected properties in a particularly well-known and much-used chemical substance. There is, of course, nothing impossible in this, but merely ground for reservation of judgment. India-rubber has been in the past, and will be for some time to come, the subject of startling announcements. We hope to revert to this subject, as to the matter of re-covered rubber in general, in the near future.—*India Rubber Trades' Journal*, Feb. 3.

DOES SUGAR-CANE EXHAUST THE SOIL?

Question.—For some years my land (scrub) has produced good crops of cane, but of late the crops have been almost too light to pay for cutting and loading. Yet I can get very good crops of corn or potatoes off the same land. Has the cane exhausted the soil?

Answer.—There is practically no such thing as an exhausted soil, but the available plant food near the surface may have been exhausted. In your scrub soil there is plenty more of the plant food which sugar-cane requires, but it is out of reach of the roots, and requires to be brought up either by subsoiling or by growing nitrogen-producing plants. Again, the soil cannot be exhausted, as you say you can get good crops of corn and potatoes from the land. It is the plant food needful for cane which has been carried off year by year till little is left. A glance at the following table will at once show you the reason for the failure of cane-crops.

Crops remove from the soil plant food in the following proportion:—

		Nitrogen.	Phosphoric Acid.	Potash.	Lime.
Sugar-cane	...	127	44	298	71
Wheat	..	43	23	36	16
Barley	...	47	23	54	11
Maize	...	61	31	66	14
Rice	...	41	26	68	10
Potatoes	...	26	13	48	2
Cotton	..	54	19	40	25

From this, you can at once see that sugar-cane extracts from the soil about five times as much nitrogen, three times as much phosphoric acid, and six times as much potash as do potatoes.—*Queensland Agricultural Journal*, Feb. 1.

TEA IN AMERICA.

A well-known Dundee gentleman who has just returned from a tour in the States, writes as follows:—"Throughout the whole 4,000 miles I travelled the tea was much finer in quality and flavor than on my former visit. Of course, green teas were largely in evidence but even away down south in Texas they had splendid black tea which they described on their bills of fare as 'English Breakfast Tea' and the same on the Pullman cars. I could not find out if these teas were from Ceylon."

UGANDA AND THE UGANDA RAILWAY:

500 MILES OF COUNTRY OPENED UP TO THE GREAT LAKE;
RUBBER, COFFEE, TOBACCO AVAILABLE.

Commander Whitehouse, R.N., brother of the Chief Engineer of the Victoria Nyanza Railway, and who himself has done splendid work in surveying the great lake, has been lecturing on the above subject—reference to which is made in our telegraphic columns this evening—before the Colonial Section of the Society of Arts with Sir Henry M. Stanley, G.C.B., in the Chair. The railway from Mombasa (sea level) to Port Florence (3,726 feet above the sea) on the Victoria Nyanza is 582 miles in length with some 30 intermediate stations. It rises to 7,900 feet at the 355th mile; descends to 6,000 feet, mile 430, at Lake Elmenteita; rises to 8,320 feet (higher than Pidurutalagala) at mile 490 on the Mare ranges; and then runs down 4,600 feet in the last 100 miles through country no European had ever penetrated previous to September 1893. The journey from Mombasa to Port Florence will take 2½ days with 1 day more for a steamer journey to Mengo, the capital of Uganda, against 70 days at the least by the old caravan route from the coast to the capital. The Chief Engineer and his staff arrived at Mombasa on 11th December 1895 and the first locomotive reached the great Lake shore on 19th December 1901. No wonder, though, Sir Guilford Molesworth K.C.I.E., in the after discussion, spoke of the great work done in the face of unique difficulties:—unknown country, newness of

staff, two languages to learn, want of water, absence of animal transport owing to tsetse fly, difficulty with lions (28 coolies carried off by 2 lions in one night, and Mr. Ryalls torn from a carriage on the line by a man-eater who carried him off through the window, while two companions in the carriage were left untouched, but helpless to interfere)—difficulty with "jiggers" which often caused men to lose their toes; 15,000 workmen to be organised; difficulties with fever in parts, and wild beasts everywhere (during Sir Guilford's visit 280 out of one gang of 320 men were down with fever and 7 out of 8 engine-drivers!) The successful completion, in spite of all this, reflected the greatest credit on Mr. George Whitehouse and his staff. The warlike tribes *en route* are already quieting down; and the slave caravans and trade have for ever ceased. Stanley's memorable journey to the lake was in 1875 and now he sees his most sanguine anticipations already anticipated: 90,000 Christian people in Uganda with 320 Churches, and many thousands of children in school, and this great railway and a first steamer (the "Wm. Mackinnon") on the Lake, where within 10 years there would be 50. The survey of the lake coast line, 2,200 miles in 13 months, was also a great work, and they had also the telegraph wire with daily news to the very centre of Africa. Game is still very plentiful in great varieties close to the line at certain points: gazelle, harte-beeste, ostriches, bustard, wildebeeste, zebra, grouse, spur-fowl, hyenas, etc. Lions often cross the railway: five or six at a time; or a lioness and cubs. The game laws are now strict: visitors pay £50 to shoot a limited number of beasts; but a reward is paid for every lion shot between certain stations. "Plenty of fish" in some of the rivers, very like mahseer, which give good sport with light tackle and a gold and silver spoon. The climate for 300 miles—between 238 and 550 miles—is very pleasant. The Swahilis (the Seedee boys of steamers) are the most useful of the natives and their language is becoming universal. Sir Harry Johnston, G.C.B., spoke to the kind treatment of the natives by the surveyors and engineers and Sir T. Fowell-Buxton, Bart, G.C.M.G., spoke to the wonderful fulfilment of many of Stanley's prophecies of only 27 years ago; and alluded to Bishop Tucker's new Cathedral now in course of construction in Uganda. Finally as to products:—Coffee grows well in Sesse and Uganda and *Rubber everywhere*: *Landolphia* rubber vines are on all the islands in the Lake. Castor oil plant grows everywhere. Tobacco grows well and is much used by the people. Good crops of potatoes and other vegetables have been raised. Extensive and good hill forests are ready for planters. Cheap labour for settlers in Uganda is freely available. The Lake coast region is very healthy and great fisheries may eventually be developed here; but this region is subject to frequent storms, scarcely a day without thunder and in the first survey during 1898, there were 17 violent

storms during 21 days! But on the hills at Nairobi, for instance, the climate is delightful, European children prospering there. Undoubtedly here is a great region ready for pioneering, and probably the collection and transport of "rubber" to the coast will be one of the first industries started.

CEYLON GREENS PRAISED IN CANADA.

Says the *Canadian Grocer*:—"The first samples of Oolong produced in Ceylon were before The 'Salada' Tea Company one day last week. They somewhat resemble the finest Formosas. If these teas can be produced in Ceylon there is a great trade for them in the United States. Mr Larkin says that, while they are slightly different from Formosa, they are the finest teas of the kind he has ever tasted."

PRODUCE AND PLANTING.

TEA IMPORTERS AND WHOLESALE DEALERS OF NEW YORK

are much incensed over the action of the House Committee on Ways and Means in reporting a Bill for the repeal of Spanish war taxes on nearly everything, except on teas, on which the duty is to remain in force until January 1, 1903. It is proposed by the tea merchants to make a protest to Congress, as, they say, there is no reason whatever why discrimination should be made against tea. Mr. G. T. Matthews, head of one of the large wholesale tea Companies, when interviewed on the subject, said: "This action of the Ways and Means Committee is an outrage. It is made on the plea that the country is so well stocked with tea that it will take at least a year to work it all off upon the market. Everyone who knows anything about the business is aware that there has not in many years been such a small stock of teas on hand in the country as now, for the reason that the importers have for several months been expecting that Congress would remove the duty. I venture to say that all the tea on hand in the United States today can and will be consumed by the public in less than two months and the tea trade in general will have to stock up again at war tariff rates."

THE DIRECTORS OF THE AGRA-ELBEBDE (CEYLON) TEA ESTATES, LTD.

are not only courageous, but they exhibit their faith in the present and future productiveness of their property. At a time when tea prospects are not considered by the investing public as altogether rosy, and in view of the fact that investors are critical and fairly well able to judge for themselves the issue of this prospectus proves the directors' claim well-founded. In the interests of the British-grown tea industry we hope that the anticipation held out will be justified by results, and that another steady dividend-paying concern will be added to the list of Ceylon tea companies.

CALIFORNIAN OLIVE OIL.—The season just ended has been most satisfactory to olive growers. The Los Angeles Olive Growers' Association expects a yield of between fifty thousand and sixty thousand gallons of oil, worth \$2.50 per gallon. The Association has 1,100 acres in the San Fernando valley. The yield at Andrew McNally's ranch near Pasadena is estimated at about ten thousand gallons of oil. The value of the crop of picked olives in Southern California is estimated at about \$75,000, and the value of the oil when marketed will approximate \$500,000.—*Chemist and Druggist*, Feb. 8.

CEYLON TEA IN NEW ZEALAND.

FRESH DEVELOPMENTS.

After several months' touring not only in Ceylon but in India—Delhi and the North generally, as well as in Assam—Mr. M. S. Ridley, of Messrs. Ridley and Sons, Christchurch, went back to New Zealand by the Orient Pacific steamer "Orizaba," which sailed on 10th March. Mr. Ridley came to spy out the land, as it were,—largely in reference to Ceylon tea the future of which in New Zealand, as in Australia, he regards as holding a bright prospect. Our visitor, planters will be interested to learn, went back—one of the first to establish direct business, most tea for New Zealand being bought in the Australian market—having established a business connection with Colombo where his teas will be purchased and sent out to his firm in New Zealand. We have further the satisfaction of stating that Mr. Ridley intends to start a thoroughly Oriental Tea Kiosk at Sumner—seven miles from Christchurch, and the fashionable watering place of the neighbourhood—where New Zealanders will doubtless be more largely attracted to the article than hitherto. Mr. Ridley has already occupied part of the site and operations will be begun on his return. Later on, when our visitor returns to Ceylon after or before his approaching trip to Japan and the United States, it is probable that two (or more?) native girls will be secured to be employed at the tea kiosk—to add the finish of it. Mr. Ridley has been most charmed with our Sanatorium, so much so that the coming addition to the attraction of Sumner, N.Z., is to be named, appropriately, the "Nuwara Eliya" Ceylon Tea Kiosk"!

PEARLS AND PEARL FISHERIES.

DR. LYSER JAMESON'S LECTURE.

The third of the series of lectures arranged by the Derby Technical College Committee was held in the Lecture Theatre on Friday evening. There was again a large attendance and the patronage given to the lectures by the local public must be a source of much satisfaction to the management committee. Indeed, there is every reason to believe that the recent prediction of Councillor J E Russell as to the success and popularity of the present series of lectures will be more than fulfilled. The subject selected on Friday night was "Pearls and Pearl Fishing," the lecture being delivered by Dr H L Jameson, M.A., a member of the College staff, who is recognised as a great authority on the subject. Colonel A Buchanan, J.P., presided, and he remarked that his duty of introducing to the audience Dr Jameson was a very pleasant one. The lecturer, having spent a considerable time in the Australian Pearl fisheries, was in a position to speak from a practical acquaintance with the subject. The chairman was glad to see so many ladies present, who, naturally enough, were very much interested in pearls and he hoped they, as well as the gentlemen present, would spend an interesting and pleasant evening. Dr H L Jameson, who had a very cordial reception,

began by giving a brief survey of the pearls, in which he showed that they were highly prized, in the remotest days of which we have any written record, among the ancient people of India, China, Palestine and Egypt. He mentioned the extravagant passion for pearls which existed during the later epochs of the Roman Empire, and quoted instances of the wearing of pearls by primitive and barbarous natives in Polynesia and Papua, and by the Indians discovered by Columbus in Central America. Mother-of-pearl, which is the shell of the larger species of pearl oyster, is an important object of commerce, thousands of tons, ranging in value from £3 to £200 per ton being imported into England annually. Indeed, in some localities pearls are quite a by-product, the mother-of-pearl being the main object of the fishery. After an account of the internal economy of the pearl oysters, the lecturer dealt with their habits and mode of reproduction, referred to the possibilities of British river pearl fisheries if intelligently developed, and drew attention to the fact that the pearl oyster is computed to produce about twelve million eggs annually. Lantern slides, exhibiting pearls of various sizes and values, were next shown, together with microphotographs of their structure, while some of the most valuable pearls on record were mentioned, among them one purchased by the then living Shah of Persia from the traveller Tavemior, supposed to be worth £60,000. Dr Jameson then exhibited lantern slides and specimens illustrating the most important species of pearl oysters; and went on to describe the methods of fishing adopted for the several kinds of shell in different parts of the world, dealing especially with the Australian and New Guinea fisheries, of which he has considerable experience. The last part of the lecture dealt with the future of the pearl and mother-of-pearl fisheries. Dr Jameson explained that most of the pearl beds are in a sadly depleted condition, and that there is considerable danger of a decrease in the supply and increase in the cost of mother-of-pearl. He referred to the probable effect of the exclusion of alien labour from the Australian fisheries, and said that we might expect a serious falling-off in the supply of the most useful kinds of shell as the result. The only escape from the difficulty would be the application of intelligence and scientific skill, and the artificial cultivation of the pearl and mother-of-pearl oysters on lines somewhat similar to those adopted for the edible oyster in Europe. He described the various experiments that had been made in this direction from time to time, and referred to the researches of Professor Comba, in Italy, both in pearl shell cultivation and in artificial pearl production. The lecturer believes that both the cultivation of the oysters and the artificial production of pearls are among the commercial developments of the near future, and that they will revolutionise the trade in these commodities and mean colossal fortunes to the lucky individuals who are first in the field.—*Derby Express*, Feb. 15.

UVAKELLIE TEA COMPANY.—A dividend of 7 per cent is in these times to be counted a very good result indeed. A substantial amount has also been carried forward to the reserve account.

THE "TEA CESS" AND HOW TO WORK IT.

A Manager, who was at one time for "doubling the Cess," writes on the 6th March:—"You have put the Cess matter plainly and fairly in your leader of the 4th and, barring your insistence that we should do nothing if India doesn't create a Cess, I am quite at one with you. We cannot in any way compel India to tax herself though she looks like doing it of her own free will at present; but if her scheme should fall through as per usual, are we to cease our efforts here? I maintain we must push our own teas for all we are worth with or without the co-operation of India and that our funds should be mainly used in subsidising 'green teas' as suggested in my first letter which, if I remember rightly, originated all this row."

Paris, Feb. 11.—For those who dread the dentist's chair, even under the protection of laughing gas, a description is given by Dr d'Arsonval, of the Academy of Sciences, of a new use for electricity as an anæsthetic. The tooth must first be covered with a plastic substance, which the dentists use for taking moulds of the teeth. Then comes a layer of plumbago, and the whole is coated with a paste made with salt water. One electric pole is then attached to the tooth, and the other is held in the hand by the patient. The current is turned on, and produces the most complete local anæsthesia, lasting ten minutes. An interesting account was also read of Gantier's experiments at the Constantine Hospital with the subcutaneous injection of methylarsenate of soda for malaria. A few centigrammes, injected daily, entirely checked the disease in several cases where strong doses of quinine had proved powerless after as much as two months' treatment.—*Morning Leader*.

A NEW CINCHONA DIRECTOR AT OOTY.

Mr. George Romilly, the well-known planter of Meppadi, Wynaad, has been appointed officiating Director of Government Cinchona Plantations, Ootacamund, *vice* Mr. W. M. Standen who has proceeded on leave.—*M. Mail*, March 12.

TOBACCO CULTIVATION.

We know that many of our readers have been much interested in the information we were the first to publish, touching the opinion of a tobacco expert on the sufficiency of the leaf grown in the island, if only it can be properly cured. Mr. A. Macdougall Gibson's opinion has come as a surprise to those who have long been taught to believe in the radical inferiority of Jaffna tobacco; and if his view, supported by experience extending over a score of years with tobacco in the East, stands the test of a searching experiment, there must follow a perfect revolution in the tobacco trade of the island. As we have noted before, Mr. Gibson holds that it is the curing, and not the leaf, that is at fault; and if his method should produce a leaf smokable by those used to Indian, Cuban and other acceptable brands, a great fillip will be given to the cultivation of tobacco by classes other than the

Japanese. As evidence that there is money in the weed, we quote as follows:—

On the subject of Tobacco-growing in Burmah, from the report of the Department of Agriculture, just issued:—"The most successful result was obtained in Yandoon, Thongwa district. One pound of seed on the bank of the Irrawaddy produced 3,650 lb. of tobacco on 3.15 acres. In this subdivision the cultivation of tobacco is assuming important dimensions and efforts are being made to cure the tobacco. The Havana leaf is apparently not so appreciated as the Virginia. The price, however, obtained was higher than that for tobacco grown from local seed. In Bilin, Thanton district, half a pound of seed gave 125 viss, valued at R1 per viss. A small success was obtained in Monanauk Paingkyon. In Myitkyina 1,060 lb. of tobacco were obtained from about 1 lb. of seed and valued at R167. In other districts the experiments were generally a failure. Taze township seems suitable for its cultivation, and in Shwebo and in Ramree township, Kyaukpyu and Rathedaung township, Akyab, some degree of success was attained. Generally, the experiments have failed from a bad selection of soil, or carelessness at the time of sowing and planting. The experiments were as a rule conducted on alluvial soil and there seems no doubt that the Havana or Virginia tobacco will grow as well as the local variety if it is properly cared for. Where it has been extensively successful the leaf is considered of better favour and texture than the local variety, and fetches a higher price."

THE CEYLON PLUMBAGO EXPORTERS, "COMBINE." 'GROUSING' IN THE LONDON MARKET.

From our earliest days we have come to look upon Ceylon as one of the most beautiful and magnificent places under the sun. Not only in school but also in church its praises have been sung, for who of us does not know that charming hymn—

"What though the spicy breezes,
Blow soft on Ceylon's Isle,
Though every prospect pleases,
And only man is vile."

In ancient times and at the present moment the "spice isle" has been regarded as a coveted spot, and writers of genius have been wont to identify it as the "Paradise Lost," full of beauty and untold wealth. No wonder, therefore, that many people have become accustomed to regard it as an ideal place in which even the "vile man" is a negligible quantity. But those few among us who have had to do with the less poetical side of the beautiful island, who have had dealings in its produce, spicy and otherwise, and who have become acquainted with its Native commercial community, have lost a great deal of the original admiration and enthusiasm for that wonderful isle. In fact there are many, we are inclined to believe, who wish they had never heard the name, for although lovely, picturesque and fertile, it is also a land of great surprises. Its population, mixed as it is, is more shrewd and more cunning than any other dark race or tribe in India. They have long recognized that unity is strength and have frequently sprung upon us more

startling combinations, pools and cliques which have entirely upset the most careful calculations of the white commercial community in the East as well as in Europe. These combinations have comprised Spices, Drugs, and Oils, and all have in their turn cost us dear. Now, the latest attempt at screwing the European consumer is a combination of dealers and pit owners of Plumbago, which for its purpose has no other end than to arrest the steady decline of prices by refusing to sell their holdings below a certain level, the height of which has been agreed upon and to which all members of the clique have faithfully promised to adhere. As a result prices have advanced at a great rate and stand now several shillings above the range ruling just previously to the creation of the combination. To the satisfaction of all concerned, America and Europe have paid the prices demanded, a fact which only seems to make the members more pretentious, but they evidently overlook that even among consumers of Plumbago there are some nervous individuals and that so little important an article as Plumbago is not without its bear speculators, all of whom have still a vivid recollection of the extraordinary boom in 1900 and are therefore anxious to procure supplies and to cover at the least signal of danger. But to believe that these few buyers represent the Plumbago trade, or only a fair proportion of it, is a fatal error, which will be brought home to the combination shortly in a forcible manner. The Iron industry is bad everywhere, but particularly so in Germany, a large consumer of Plumbago, and there is still plenty left of the 24,000 tons exported to Europe and America last year to exclude famine prices. It would appear to us, therefore, that the natives have chosen a particularly inopportune moment for their move, and it is difficult to fathom the motive which prompted them to act, unless indeed it is the feeling that prices have been allowed to drop too low, and that something desperate had to be done to arrest them. Since 1895 values have not reached so low a level as this year, for the price of OIL was then R300, as against—

R.	325	in	1896
"	400	"	1897
"	600	"	1898
"	750	"	1899
"	900	"	1900
"	375	"	1901
"	300	"	1902

Although on that argument the attempt is not altogether without justification, yet its instigators should not have lost sight of the all important factor—"no demand owing to bad trade." When business is brisk a combination has a fair prospect of success, but never in bad times.—*London Commercial Record*, Feb. 14.

RUBBER GROWING is receiving the careful attention of the Senegal Government. Many plantations have been laid out at Casamance, and in the region of Mayes near the coast between Dakar and St Louis, where the soil is more favourable. Producers also are encouraged to prepare only the best qualities for the market.—*Rubber Journal*.

PLANTING NOTES.

RUBBER PLANTING IN MEXICO.—A useful letter on this topic appears elsewhere, which deserves the attention of rubber-planters—now an increasing number—in Ceylon.

ESSENTIAL OILS OF LEMON AND ORANGE.—Mr E J Sheehan, of Utica, N. Y., is the inventor of machinery that is stated to furnish a better means of extracting oil from orange and lemon than any hitherto used. Mr Sheehan is thinking of starting at Riverside, Cal., where he can find a plentiful supply of water power, convenient shipping facilities and plenty of fruit. *Chemist and Druggist*, Feb. 8.

TIMBER TREES OF CEYLON.—Mr. F. Lewis related many facts at the last meeting of the Royal Asiatic Society (Ceylon Branch)—some of which are reported elsewhere—of very great interest to the trading and planting community. He has brought to our office today four specimens of woods usually deemed quite common (keena, mee, cassia fistula, etc.), but so sawn as to take a French polish which turns them into very handsome cabinet woods. We trust Mr. Lewis will deal with this matter in a short separate paper, at a future meeting.

THE NEED OF TEA INSPECTION.—A planting correspondent says:—"What is done with caffeine? The firms in Colombo that buy red leaf and sweepings say they make caffeine of it. What is done with it after it is manufactured? Some Australians told us they bought tea in the Harbour which was labelled Pure Ceylon Tea and was utter rubbish. It would be interesting to know where this tea came from."—Nothing but inspection of all tea without responsible ("Directory") marks at the Colombo Customs will, so far as we can judge, meet the requirements of the case.

A NEW CURE FOR DYSENTERY.—Numerous applications from various parts of the world have been received by Mr H N Ridley, Director of the Botanical Gardens of the Straits Settlements, for seeds of a plant known as *Bruca sumatrana*, the seeds of which are said to be a specific for the cure of dysentery. It is a shrub with large leaves, with numerous leaflets, and is distributed over Borneo, Sumatra, Java, Philippines, South China and Australia. Specimens have been recorded from Perak and Pahang only. The plant is being propagated from seeds and it is hoped that in a few months seedlings will be ready for distribution.—*Chemist and Druggist*, Feb. 8.

EXPERIENCE THE ONLY SAFE TEST OF CLIMATE FOR TOBACCO.—Mr R S Nevill, Tobacco Expert of Queensland, says:—"One must still judge, so far as the climate is concerned, mainly from the experience of others as to the class of tobacco to be raised, as the ordinary meteorological record will be of very little value in determining this point. The plant is far more sensitive to these meteorological conditions than are our instruments. Even in such a famous tobacco region as Cuba, tobacco of good quality cannot be grown in the immediate vicinity of the ocean or in certain parts of the island, even on what would otherwise be considered good tobacco lands. This has been the experience also in Sumatra and in our own country, but the influences are too subtle to be detected by our meteorological instruments."

ALOE FIBRE.

In November last there appeared in this journal a short article on the aloe fibre industry started by Mr. Tytler in the Madras Presidency, recommending him to increase his capital and bringing the business out as a company, and thereby give the public a chance of investing in a sound and profitable concern. We see by an article in the *Madras Mail* of the 16th December last that a company is being formed with this object by Mr Tytler, he having evidently taken our suggestion to heart. Mr Tytler will be remembered by many of our readers as the owner and rider of many good ponies in the days gone by, perhaps his best being the once famous Chorister. This new planting industry promises to be a god-send to indigo and other planters, and it therefore comes at an opportune moment, when planters generally are thinking of something in their own line as an auxiliary of the now much-depressed tea, coffee and indigo industries. It therefore behaves all planters in general to support Mr Tytler in his new undertaking, in their own interests and self-defence; for the success of the undertaking means that a new planting industry will be put before them, and that each and all will be able to learn the ins and outs of the business with its capacities, and form a basis to go upon for those who wish to follow his example. None need fear that bug-bear of all planters—over-production—for it will be a long time before India will be able to make any appreciable impression on the market, seeing that the present output from various countries is between £300,000 and £400,000 annually, and the demand seems to keep well ahead of the supply. So much is this the case that prices instead of showing a downward tendency have been steadily rising. There seems to be no doubt that both the Bahamas and Mexico have reached their maximum production. In these places it is not a question of land, though that is not over-cheap or in excess of the demand, but one of labour which is not only scarce and difficult to get, but exorbitantly high. Then, again, there is German East Africa to count with, which country is beginning planting; here land is certainly plentiful enough, but the quantity and cost of labour, as well as transport, is such that any appreciable fall in price will bring ruin to most planters; and further, they have to learn their business. The country that has cheap land and labour, and transport, both land and over the sea, so as to be able to produce fibre in the market at a minimum of cost, will eventually be able to outlive and oust other countries in this industry. India has nothing to fear in these respects, seeing that she fulfils the above conditions as regards land, labour and transport. She has, moreover, further advantages inasmuch as the plant grows to perfection in most parts of the country, and the results are in no way affected by good or bad seasons whilst the fibre produced by the plants has been pronounced to be superior to anything that has come from Mexico and the Bahamas. Taking all these facts into consideration, India will be the last to feel the results of over-production, should that stage ever be reached, which is very unlikely. The countries producing the worst fibre, and that at the highest cost, will be the ones to feel the pinch of bad times and will, most assuredly, go to the wall first. Whilst the results in tea, coffee and indigo are seriously affected by the seasons, a good or bad one making all the difference as to whether the result will

show a profit or loss, the aloe plant laughs at a prolonged drought or bad seasons, so that the annual return can be calculated with almost mathematical precision. Quantity of fibre is everything and quality means strength, color, softness and length. The fibre prepared by Mr. Tytler has been pronounced to be superior to either Mexico or Bahamas fibre in general preparation and all the above-mentioned points; in fact, of such quality is this fibre that Messrs. Ide and Christie, the foremost London fibre brokers, state that it shows perfect preparation and could not be better, and that Mr Tytler deserves great credit for his system. These are most important facts. Mr Tytler, having thus successfully mastered the practical details of the business, deserves well of both the Indian Government and the investing public, as having successfully introduced a new planting industry to this country. An expert on aloe fibre, in the *Madras Mail* of the 30th August last, gives Mr. Tytler high praise both for his knowledge of the business and the quality of the fibre he has been producing. The company is to be congratulated in having secured the services of Mr Tytler as it ensures the successful working and carrying on of the company's business. An article on the subject, which appeared in the *Pioneer* of 26th October last, is also worth reading. The company proposes bringing out its prospectus early in the year; this prospectus is highly spoken of by those who have seen it in draft form, both for its arrangement and fulness of detail. The capital will be ₹400,000, ensuring sufficient funds for carrying on the business properly, which is an important point. The prospectus shows that a profit of about 40 per cent will be made annually on its called-up capital during the first few years of its existence, until such time as the plantations it proposes planting out come into bearing, when the profits will be considerably increased and will go on increasing as the increased extent of the area planted comes into bearing. The company has secured on lease over 300 miles of aloe hedging; this is most important, as though only a stop-gap, it enables the company to work at a profit from its commencement instead of having to wait until its plantations should come into bearing: the leases secured are sufficiently long to more than cover the period that must elapse before its plantations come into bearing. Though, of course, the regularly planted plantations will be the mainstay of the company, yet the importance of having secured these valuable leases cannot be over-estimated. The present cost of production of the fibre landed in London will, according to the prospectus, be about ₹200 per ton which cost will be much reduced when the plantations come into bearing, so the delay in cost of moving from place to place, which is considerable when working along long lengths of hedging, will be saved. Even taking the above price, and allowing that the price of fibre does not fall below £28 per ton, which is the lowest price that it has reached during the past eighteen months, and that only twice, the profits over cost of production would show over ₹200 per ton, and more as prices go up. The average price during the above period was somewhere about £35 per ton, and Mr. Tytler's fibre fetched £32 10s per ton when other fibres were selling at a little over £28 per ton. The profits may, therefore, reasonably be expected to be greater, and as the company's hedging is capable of producing annually somewhere about 800 to 900 tons of fibre, the above figures show

clearly that the company is well within the mark with its figures as to the profits that may be expected. The company is probably one of the most promising and substantial undertakings that has been put before the Indian public, and is well worthy of the attention of investors. We do not anticipate that the share list will be long in filling up.—*Indian Planters' Gazette.*

[Experiments made in Ceylon by practical men, over which a good deal of money has been spent, do not make us so sanguine of success as our Indian contemporaries.—ED. T.A.]

THE WORLD'S PRODUCTION OF RUBBER. AND THE FUTURE OF AMAZONAS.

The territory in the Amazon Valley from whence the largest portion of the world's rubber supply has, as yet, been obtained, is according to most reliable reports constantly decreasing in area. It is an undeniable fact that, owing to the extravagant method employed by the natives in gathering crude rubber, the natural source of supply has been, to a considerable extent, depleted, with the usual results attending. The risks, besides this, attending the gathering of the crop, especially in the Amazon Valley, are considerable. Heavy advances must be made to the improvident natives who depart into the limitless forests to remain for months with a chance, perhaps, never to return. The trees cannot survive the murderous butcheries of the native gatherers, whose sole aim consists in extracting the gum which is to pay the advances they received as quickly as possible, even if the death of the trees is involved. In order to reach the yet living and untouched trees, the native is compelled to travel deeper into the forests every year and the supply is maintained with increased difficulty with each successive season. These are facts, which sooner or later must become of the most serious consequences, respecting the economical conditions of the State of Amazonas, inasmuch as the production and exportation of rubber constitutes the almost exclusive source of revenue of that State. These circumstances and the fact, that there is scarcely a plant of equal value that responds so quickly to careful cultivation as the rubber tree, greatly stimulated other countries to develop this culture on a large scale, and it is from this quarter that Amazonas will experience the most dangerous blow to its heretofore commanding position as the world's supplies of rubber. Thus we learn from reliable sources that already in the year 1898 the value of exports of rubber from Africa alone amounted to 98 million francs. Angola, which contributed at that time to the amount of 28 million francs, is said to export now nearly twice this amount. The Congo State exported 16.8 millions; Gold Coast 13.7 millions; Lagos 7 millions and French Guiana 6 millions. The steady increasing production of the French Congo States and of Cameroon, as well as the Dutch possessions in India not counted!

THE TOTAL AREA UNDER RUBBER CULTIVATION in Africa is estimated to be 4,000 square miles with a population much denser than in the Amazonas, no difficulty being therefore experienced to obtain a regular and efficient supply of labour. A considerable increase in the production of rubber is therefore to be expected without any doubt in the near future.

A very large amount of capital has within the last few years been invested in the rubber plantations of the Southern Mexican States. In years gone by the rubber industry of Mexico was already of considerable importance, but also in that country the improvident native method of gathering was fatal to the industry and the large returns dwindled as the number of trees decreased, until the export of native rubber ceased to be of much account—a warning example to Amazonas and to other countries where such abusive methods of gathering are practised! The states of Tabasco and Chiapas, adjoining the isthmian region of Tehuantepec, have been the former sources of rubber supply in the Southern Mexican States. In soil, temperature, rainfall and other general conditions, these States possessed ideal qualifications for the cultivation of the rubber tree. The soil is the accumulation of long centuries of tropical decay, while the annual rainfall ranges from 150 inches and upward. The temperature required, hot and moist, is here found, while the dense shade which the rubber tree is said to need is afforded by the forests which abound in the extended valleys of the watercourses of navigable streams emptying into the Gulf of Mexico.

The fitness of these lands for the cultivation of the rubber tree has been remarked for many years, but the project seemed not to attract capital. The increasing scarcity of supplies together with an enormous development of demand, however, stimulated capital to invest, so that at present not less than 200,000 acres in the Tehuantepec provinces have been acquired, principally by Americans, who have invested 5,000,000 dollars in planting and development! Reports from plantations in those provinces state that trees, five years old, had attained a diameter of from 8 to 10 inches, and yielded from 3½ to 4½ pounds of pure rubber each. Trees 6 years old were 10 to 11 inches and yield 4 to 5 lb, and 7 years 14 to 16 inches with a yield of 6½ to 8½ lb.

It will be seen by this rapid exposition that the production of rubber has for some time past been the object of no small efforts by all countries with possessions in tropical regions and as those efforts are supported by plenty of capital, and directed with method, enterprise and energy, the result cannot be doubtful:—a foreign production that will render the consuming markets, if not entirely independent of Brazilian production, at least reduce it to an almost negligible quantity.

Tropical agriculture ceased to be exclusively limited to South America from the time that nearly every one of the European countries secured extensive possessions in the southern hemisphere. In proportion as the development of the colonial possessions of these countries advances, interchanges between these and the mother country will necessarily become more numerous, and as the product of these colonies is nearly similar to that of South America, a competition can be foreseen that cannot fail to seriously menace the future exporting trade of the latter, at least in similar products. This should be borne in mind by Brazilian agriculturists, who should direct their efforts to multiculture, instead of confining themselves to one product only, especially when that product is seriously menaced by a not distant competition.

We can therefore but agree with the timely warning raised by the *Provincia do Pará* against

the short-sighted system of mono-culture followed in the Amazonas, a warning which in our opinion applies not only to this, but to almost every State of the Union.—*The Brazilian Review*, Jan. 21.

CRUDE RUBBER IN THE WEST INDIES.

According to the report of the Governor in Trinidad and Tobago rubber is the only new cultivation, which, as far as present indications go, is likely to prove a staple export in the future. It is, as yet, however, in an experimental stage. There are some eight plantations in Trinidad and two in Tobago. Several large sales of Crown land in Trinidad have been recently made on the understanding that they are to be devoted to this cultivation. It is also extending yearly in Tobago, chiefly in combination with cocoa. The rubber is chiefly planted is the Central American tree *Castilloa Elastica*. Of this sort there are 100,000 trees planted in Tobago, as well as some thousands of the Brazilian "Mouchet." The former promises to be the more profitable. The West African silk has also been recently introduced, and its importers are hopeful of its success. The greater part of the plantations are still quite young—from one to four years old—and no large return can be anticipated until they have been seven or eight years in existence. The quality seems to be good. A sample of *Castilloa* grown and prepared on Richmond estate was sent to England last year, and was valued by experts at 3s 6d per lb.—*India-Rubber Trades' Journal*, Feb 13.

PLANTING NOTES.

THE UPRIVER RUBBER COUNTRY—of the Amazon—may be in the backwoods, but it is the scene, nevertheless, of many phases of business enterprise. For example, the police of Manaus arrested recently two men who had in their possession 192,000 milreis in counterfeit money, with which they were proceeding to the river Purus to buy rubber.—*India Rubber World*, Feb. 1.

GUTTA PERCHA.—Monsieur de Jonffroy d'Abans, French Consul at Singapore, who is very much interested in agricultural questions, writes that the extraction of gutta percha out of the leaves is not seriously enough taken into consideration. Everywhere in the Malay Archipelago and in Dutch India Government and private plantations of gutta percha trees have been established, and will be able in about four or five years to furnish all factories with leaves. The European factories, which treat the leaves in a chemical way, have at present still much to cope with the scanty supply of leaves. They will have to close their factories or start plantations themselves. Dr. Ledebøer's factory in Holland is, in spite of the big capital of this company, often short of leaves. Another factory exists near Singapore, but it has met with no success, for the expenses are too high, the factory being too far from the plantations. A small factory is in Pontianak and another in Sarawak, in Dutch Borneo, but both have the same difficulty in getting leaves. In short the future of this very important industry of extracting gutta percha from the leaves depends on the planting of sufficient trees.—*Journal d'Agriculture Tropicale*.

COMPANY MEETINGS.—The Horrekelly Estate Company has declared a dividend of 6 per cent for the past year, which we think very satisfactory on the whole. An interesting tabular statement is given of the working of the concern during 1899, 1900 and 1901. In the report of the Clyde Tea Estates Company testimony is borne to the favourable results of fine plucking. It has only been considered necessary to write off a nominal sum for depreciation and the customary provision has been made for deterioration in value of building. A dividend at the rate of 2½ per cent has been declared. The directors of the Agra Tea Company have not felt themselves justified in recommending a dividend in view of the greater portion of the profits having been spent upon a new extension to the factory and on new clearings, but a substantial addition has been made to the reserve fund.

TWO OR THREE YOUNG PLANTERS wanted for Blantyre, Nyassaland, forms the burden of a *bona fide* advertisement from the Company which appears in the *Ceylon Observer*, and the salary to begin with seems a fairly good one, seeing that the cost of living on the Company's estates, we are told, is not likely to exceed £50 a year, to a careful man. Some parts of Nyassaland have got an indifferent reputation for fever; but this Company's places are said to be healthy, and Mr. S. Hynde, the Chief Manager, is an experienced resident. A drawback to young planters offering from Ceylon is that they are expected to pay their own passages from Colombo to Blantyre (just, we are told, as "creepers" and others pay their passage out to Ceylon), the salary of the men selected and who agree to go, beginning from the day they report themselves at Blantyre. The passage from Colombo to Chinde, the nearest port to Blantyre, we fear, could not be got for less than £35 (R525) second class or (£48 10s R727 50) first.

THE CEYLON PLUMBAGO MARKET—is the subject of a moderately amusing grumble on the part of London buyers, through the latest *Commercial Record*—which we quote on page 673. They complain of a combine amongst Ceylon native mine owners and exporters, not to sell plumbago below a certain price, and warn them that it is a most inopportune time for the move. The amusement comes in where the "screwing down of the consumer" becomes the subject of the writer's grousing. He appears completely to ignore the London attempts to screw down the producer—poor producer, we had almost said, but we have not noticed many bankruptcies among plumbago merchants yet!—by combinations in the Lane. The latter preceded the Ceylon move; and as to foreign buyers having met their requirements for some time to come—the signs do not all point that way. We have only just had an agent of a Pittsburg firm, which is said to buy something over 10 per cent of the Ceylon output, sounding the local resources, in view—we understand—of the evident profits being made by the trade in New York who are shipping from here direct. The demand is not so dead,

THE PALMERSTON TEA COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

ACREAGE OF THE ESTATE.

	Queensland. acres.	Palmerston. acres.	Total. acres.
Tea in Bearing ..	254	205	459
Young Tea ..	4	0	4
Total Tea ..	258	205	463
Jungle ..	19	0	19
Timber ..	0	7	7
Grass, &c. ..	4	0	4
Total Acreage ..	281	212	493

The Directors have now to submit their Sixth Annual Report and Accounts, being those for the year ending 31st December last. The yield of tea during the period has been 206,189 lb., costing cts. 23.88 as against cts. 26.74 last year, and realising cts. 44.10 as against cts. 44.17.

As will be seen from the accounts, the profits for the year, including the sum of R1,627.21 brought forward from last account, amount to R21,901.72 after writing off the sum of R2,470.09 for depreciation on Factory and Machinery. An interim dividend of 2½ per cent, was paid on 12th August, absorbing R10,250; and the Directors recommend that a final dividend of 2½ per cent be declared, making a total of 5 per cent for the year, and leaving a sum of R1,401.72 to be carried forward.

In terms of the Articles of Association, Mr. G C Alston now retires from the Board, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

THE UVAKELLIE TEA COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

The Directors have now to submit their Report and Accounts for the year ending 31st December, 1901.

The crop amounted to 166,319 lb. Tea costing 26.29 cents per lb., against 162,110 lb. costing 26.95 cents in 1900.

The amount of profit earned is R20,744.93, which is equal to fully 8½ per cent on the Capital of the Company.

After estimating the unsold Tea at a safe figure, the crop has realized 39.99 cents per lb., against 43.39 cents in 1900, and 41.67 cents in 1899, the lower price being due to the fall in the market.

After adding R719.26 surplus proceeds of Tea estimated last year and R597.15 balance brought forward, the profit amounts to R22,061.34 and after writing off 7½ per cent for Depreciation on Buildings and Machinery the amount available for distribution is R20,023.46, which the Directors recommend should be disposed of as follows:—

By the payment of a Dividend of 7 per cent absorbing ..	R16,800.00
By carrying to Reserve a sum of ..	2,000.00
By payment of a Bonus to Superintendent of ..	500.00
And carrying forward the Balance of ..	723.46

R20,023.46

The estimate for the current year is 165,000 lb. Tea to cost R48,588.50.

During the year Mr F W Bois resigned his seat upon the Board, on leaving for home, and Mr H G Bois was elected to fill the vacancy.

In terms of the Articles of Association Mr Bois now retires from the Board, but being eligible offers himself for re-election.

It will be necessary to appoint an Auditor for 1902.

CEYLON PLANTERS' RUBBER SYNDICATE LIMITED.

REPORT OF THE DIRECTORS.

Acreage:

The Acreage of the Syndicate's property is as follows:—

Opened Land ..	615 Acres
Reserve ..	269 "

Total .. 884

At the 31st of December, 1901, 615 Acres had been felled of which:—

544 Acres were Lined	253 Acres were Supplied
550 " " Holed	414 " " Filled in
350 " " Planted	585 " " Cleared up

Only 350 acres have been planted owing to the plants being too small to put out. Had the seed purchased from Culloeden Estate turned out well, the whole area might now have been planted up. One block of 45 Acres accidentally caught fire, before it was ready to burn off. As the clearing up would have been costly, and there were no plants available for putting out, our Manager considered it best to allow the undergrowth to grow up and clear and burn again in March or April.

Catch Crops have not proved a success, though the pumpkins seem to have grown well enough. The price obtainable was so low that it did not pay to pick them and the Chinese cultivators went off without clearing the land. Your Directors think that none of the usual catch-crops should be planted, with the exception of Liberian Coffee, which our Manager considers will pay a good return without injuring the Rubber. Whether this be planted or not rests with the Meeting. Mr Darby estimates that 200 Acres can be planted with Liberian Coffee, 7½ by 7½, and brought into bearing by 1905, for \$900,000 or R13,500/- giving at the end of that year a gross return of the value of R20,000/, the Rubber in this 200 Acres to be planted 15 feet by 30 feet.

Copies of Mr Carey's Report have been sent round to all the Members of the Syndicate, also of Mr Kelway Bamber's Report on the Pendamaren soils, which was most satisfactory.

A new Director and Secretary will have to be appointed in the place of Mr H C Harrison who is leaving the Island.

As Funds are insufficient to carry on the work of the Estate, until the Rubber trees begin to bear, it is proposed to raise the nominal Capital to R250,000/- and during the Autumn to raise 80 new shares at par to existing Shareholders in proportion to their holdings.

	R.	c.
Expenditure to date is ..	97,881	11
Estimated Expenditure for 1902, Rubber alone ..	22,667	00
Estimated Expenditure for 1902, Provision for Coffee ..	7,725	00
Estimated Expenditure for 1903, Rubber ..	18,289	00
" " " Coffee ..	600	00
" " " 1904, Rubber ..	19,826	00
" " " Coffee ..	450	00
" " " 1905, Rubber ..	16,729	00
" " " Coffee ..	4,500	00

R188,667 11

From the beginning of 1906 the Estate should be self-supporting. The estimated profits on Coffee being sufficient to carry on, from that date, until the Rubber trees give their first yield,

February 20th, 1902.

THE CASTLEREAGH TEA COMPANY,
OF CEYLON:

THE REPORT OF THE DIRECTORS.

The directors submit herewith the balance sheet and profit and loss account for the year ending 31st December 1901, duly audited.

The balance of profit (including a debit balance of R54'65 brought forward providing for depreciation of buildings and machinery as shewn in the accounts) is R22,012'54. Of this sum R7,200, has been absorbed in paying an interim Dividend at the rate of 3 per cent. The Directors propose, after placing R551'67 to Reserve Fund, being 2½ per cent, on the Profits, as resolved on in General Meeting, to declare a further Dividend at the rate of 5 per cent payable on the 11th March, absorbing R12,000 and after paying a bonus of 5 per cent on the profits divided including Reserve Fund, for the year to the Superintendent, in terms of a promise made to him, absorbing R987'58 to carry forward to 1902 account R1,273'29.

The total tea crop was 182,272 lb. against the estimate of 200,000 lb. The cost of the tea delivered to buyers was 25'03 cents per lb. or 23'67 cents exclusive of provision for depreciation of buildings and machinery or 21'95 cents exclusive of both depreciation and manuring. The tea was sold locally realising 38'62 cents per lb. leaving balance of gain 14'95 cents. Cost in 1900 was 23'43 cents and value 37'02 cents per lb.

The Company's property consists of:—

430	acres	tea under leaf.	Yield in 1901, 424 lb. per acre.
7	"	planted in 1897 and 1898.	
24	"	ravines, scrub roads, etc., in the eight tea fields of the estate.	
57	"	jungle, jungle belts and swamp.	
518			

The estimated crop for 1902 is 200,000 lb. tea or 458 lb. per acre from 437 acres.

It will be seen that the property representing capital now stands in the balance sheet at approximately R547'00 per acre cultivated and that the profit per acre is R50'00 as compared with R48'00 in 1900 and R60'00 in 1899, the profit upon capital being 9'19 per cent or including the sum reserved against depreciation 10'21 per cent.

Mr R Hayshe Eliot retires from the Board by rotation and eligible for re-election.

The Shareholders will be requested to elect a Director and also an Auditor for the current year

THE HORREKELLY ESTATE COMPANY.
LIMITED.

REPORT OF THE DIRECTORS.

Managing Director.—Mr. C E H Symons. Directors:—Messrs. F J De Saram, Stanley Bois, F W Bois and Hon. F C Loos. Secretaries:—Messrs Lewis Brown & Co.

The Directors have pleasure in submitting the accounts of the Company for the year ending 31st December, 1901, shewing, after writing off R6,011'43 for depreciation on Buildings, Plant and Machinery, a profit of R23,231'71, which, with the balance of R1,667'80 brought forward from 1900, gives a total of 24,899'51 available for distribution.

The Directors recommend that a dividend at the rate of six per cent on the Capital of the Company be declared. This will absorb R24,000,—and leave a balance of R899'51 to be carried forward to 1902.

The working of the estate for the years 1899, 1900 and 1901 compares as follows:—

	1899.	1900.	1901.
	R. c.	R. c.	R. c.
Expenditure on Estate and in Colombo office ...	36,754 67	35,761 59	39,756 93
Number of Coconuts produced	1,305,429	1,502,298	1,439,218
Quantity of Coir			
Fibre made Ballots	28,324	22,592	24,876

Two Directors—Messrs. F C Loos and F J De Saram, retire by rotation, and are eligible for re-election.

The Shareholders have to appoint an Auditor for 1902.

The current year's prospects are favourable.

THE CLYDE TEA ESTATES CO., LTD.

THE REPORT.

Directors:—Mr F M Laurie, Mr E D Harrison, Mr Robt. Davidson; Agents and Secretaries: Messrs Lewis Brown and Co.

ACREAGE:	
Tea above four years old	546 acres.
Jungle, &c.,	169 "

Total 715 acres.

Your Directors beg to submit their report and the accounts for the year 1901.

The quantity of tea made was.—From estate leaf 162,423 lb and from bought leaf 8,196 lb against original estimates of 190,000 lb and 10,000 lb respectively. The shortage on estate estimate is due to the unfavourable season experienced, and to the careful system of plucking in force from early in the year.

The expenditure on manuring during the year (R1,997'92) has been charged against revenue as have also sundry items on extensions, &c, amounting to R560'24. The cost of estate tea exclusive of these, but including transport to Colombo, and selling charges was R40,930'07, or say 25'20 cents per lb. The average price realised for the whole crop was 31'32 cents per lb.

The amount at debit of machinery is R21,614'73, against which sums aggregating R9,643'67 have already been provided for depreciation. In view thereof the Directors do not consider it desirable to meantime continue writing off depreciation on the usual basis, and have set aside only a nominal sum of R540'37. The customary provision has been made for deterioration in value of buildings.

Including the balance of R2,543'13 brought forward from last year, the sum now available for distribution is R7,249'89, from which the Directors recommend payment of a dividend at the rate of 2½ per cent. This will absorb R6,750,—and leave R499'89 to be carried forward.

In terms of the articles of Association Mr R Davidson retires from the Board, but is eligible for re-election. The shareholders have to appoint an Auditor for 1902.

THE KIRKLEES ESTATE COMPANY,
LIMITED.

DIRECTORS.—Hon. Mr W H Figg, Messrs. G H Alston and John Gordon. Estate Superintendent,—Mr J Armitage Ogden.

Acreage : 31st December, 1901.	
Tea in bearing ..	380 acres
Do partial bearing ..	35 do
Tea not in bearing ..	33 do
Timber & Cardamoms, about	122 do
Grass & uncultivated land	147 do

Total .. 717 acres

The Directors have now to submit to the Shareholders the accounts of the Company for the year.

The crops secured amounted to 125,525 lb. Tea, in addition to 8,386 lb. manufactured from purchased leaf, 12½ bushels of Coffee and 2,523 lb. Cardamoms. The nett price realised for the Tea was 34.18 cents per lb., as against 33.49 cents in 1900, while the Cardamoms already sold have realised R1.10 per lb. nett. The shortfall in quantity of Tea crop secured is due to finer plucking, rather too lenient treatment of the bushes, and insufficient rain during the months of October, November and December.

After making due provision for depreciation of Buildings and Machinery and paying the 7 per cent. dividend on the Preference Shares, the profit for the past year amounted to R1,248.39 to which has to be added the balance of R3,625.45 brought forward from 1900. From this total of R4,873.84 a sum of R173.57 has to be written off for amount short realized for sale of produce estimated for 1900, and the Directors have decided to set aside a sum of R500 to a Coast Advance Reserve Account, and to write off the sum off R1,223.80 expended on Capital Account in 1897 on a trace for a new road, as there seems no prospect of the road being constructed. The Directors now recommend that out of the available balance of R2,976.47, a dividend of 2 per cent. be declared and that the balance of R976.47 be carried forward to the current season's account.

The estimated crops for this year are 160,000 lb. Tea and 3,000 lb. Cardamoms, on an expenditure of R44,215. In terms of the Articles of Association, the Hon. Mr W H Figg now retires from the Board, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the meeting.

By order of the Directors,

WHITTALL & Co,

Agents & Secretaries

Colombo, 12th Feb., 1902.

AGRA TEA COMPANY OF CEYLON.

ANNUAL REPORT.

Directors:—Major E F Tranchell; Joseph Fraser, Esq.; John K Symonds, Esq.

The Directors have the pleasure of submitting their Report for the year ending 31st Dec. 1901. The acreage of the Company's property is as under:—

Tea in full bearing ...	313 acres
Tea in partial bearing ...	8 do
Tea not in bearing ...	15 do
	<hr/>
Forest ...	336 do
Forest ...	21 do
Grass, waste land, &c. ...	10 do
	<hr/>
Total area ...	367 acres

The estimated Crop for 1901 was 200,000 lb, and the actual quantity realised was 197,823 lb, or a deficiency of 2,177 lb. This crop realised R78,426.19, equivalent to 39.64 cents per lb, as against 39.33 cents in 1900. The expenditure, as shown in the accompanying accounts, was R57,181.72, or nearly 29 cents per lb against 28 cents in 1900.

After deduction of R4,000 for Depreciation on Buildings and Machinery, the profit on working account for the year amounts to R16,713.36, representing about 4 per cent on the value of the property as shown in the Balance Sheet.

After payment of Interest on Loans, viz., R5,993.99, the net Profit for the year amounts to R9,156.97, to which has to be added the sum of R495.91 brought forward from 1900, bringing the balance at credit of Profit and Loss account up to R9,652.88.

During the past year the sum of £1,000 has been paid to the Standard Life Assurance Co., in reduction of the mortgage, which now stands at £6,000.

The Directors do not feel justified in recommending a Dividend at the present time, for the greater part of profits earned has been spent upon a new

extension to the Factory, and on New Clearings. Moreover, it was necessary to obtain a temporary loan of R3,500 at the time that the instalment was paid on account of the mortgage. They therefore propose to transfer R6,000 to the credit of the Reserve for Extensions, thus bringing total of that Reserve up to R30,000, and leaving R3,652.88 to be carried forward to next year's accounts.

The estimated crop for 1902 is 200,000 lb of tea to be produced at 28 cents per lb, which includes a fair allowance for manuring.

In terms of the Articles of Association Mr John K Symonds retires from the Board of Directors, but is eligible for re-election.

The appointment of an Auditor will rest with the meeting.

THE ESTATES COMPANY OF UVA, LTD.

THE REPORT,

DIRECTORS.—Messrs W D Gibbon, G H Alston and R S Templar. Estate Inspector:—W D Gibbon. Estate Superintendent:—Dammeria: J B Cotton. Battawatte: A V Ryall. Gampaha: F J Whittall.

Acreage: 31st December, 1901.

	Tea in full bearing.	Tea in partial bearing.	Tea not in bearing.	Total Tea.
Dammeria Group ..	575	—	29	604
Battawatte and Forest Hill ...	413	178	—	591
Gampaha ..	454	120	33	612
Total ..	1,442	298	67	1,807
		Timber, Grass, Forest and Waste Land.		Total.
Dammeria Group ..	30	556		1,190
Battawatte and Forest Hill ...	—	164		755
Gampaha ...	45	209		866
Total ..	75	929		2,811

The Directors now submit to the Shareholders the accounts of the Company for the past year.

The following were the crops secured: 627,094 lb. Tea; 54 cwt. Cocoa, 25 bushels Coffee and about 240 lb. Cardamoms, while 92,746 lb. Tea were manufactured for other Estates. The average nett price realized for the Tea was 36.62 cents per lb., against 34.60 in 1900.

After providing for depreciation of Buildings and Machinery, the nett profit for the year amounted to R33,470.51, equal to 4.71 per cent on the Capital of the Company, to which falls to be added R3,963.13, being the balance brought forward from 1900 less a sum of R13 over-estimated for Tea unsold at the end of that year. The Directors have decided to write off R1,298.70 the cost of a survey made in 1897 for a proposed road, as there seems little prospect of its construction being carried out, and to add to the Extension Fund the sum of R10,000, which will form a nucleus of a fund for redemption of the mortgage. There is then available for distribution a sum of R31,139.94, and the Directors now recommend the payment of a dividend of four per cent for the year, and that the balance of R2,719.94 be carried forward to the current season's account.

Expenditure on Capital account during the past year amounted to R9,787.25, which was spent on the erection of an assistant's bungalow and the addition of withering fans on Dammeria, the upkeep of tea not in bearing, and in the instalment due on the construction of the Battawatte Road, on which there is now only one more instalment of R2,540.52 to be paid in July this year.

The estimates for the current year provide for an expenditure on working account of R193,080.18 on crops of 690,000 lb. tea 60 cwt. cocoa and 500 lb. cardamoms, while, besides the instalment due for

the Battawatte Road, it is anticipated that an expenditure on capital account of R8,981 will be required for additions to machinery and upkeep of a small acreage of tea on Gampaha not yet in bearing.

Messrs. H Cumberbatch and W H Figg having resigned their seats on the Board, the vacancies were filled by the appointment of Messrs. R S Templer and G H Alston. In terms of the Articles of Association Mr W D Gibbon now retires, but is eligible for re-election.

The appointment of an Auditor will rest with the meeting.—By order of the Directors, WHITTALL & Co., Colombo, February 19th, 1902. Agents and Secretaries.

THE DRAYTON (CEYLON) ESTATES COMPANY, LIMITED.

REPORT OF DIRECTORS.

The Directors beg to submit a duly audited statement of the Company's accounts for the year ending 31st December, 1901.

After making provision for Depreciation of buildings and machinery, and setting aside R2,000'00 as a reserve against bad debts, the profit earned for the year amounts to R69,964'57, equal to rather over 9½ per cent on the paid up capital of the Company. An interim dividend at the rate of 3 per cent was paid in October last, absorbing R21,450'00, thus leaving a balance of R48,514'57 more to be dealt with, to which must be added the sum of R3,055'85 brought forward from 1900. The Directors propose the payment of a final dividend of five per cent, making 8 per cent for the year, and that the balance R15,320'42 be carried forward to the current year's account.

The crop secured from the Company's Estates amounted to 567,863 lb., being 11,017 lb. more than the crop of 1900, which is equivalent to a yield of 422 lb., per acre, and is a satisfactory increase, considering the season.

The cost of production of the 567,863 lb. of Tea delivered in Colombo was 27'60 cts. per lb.

The nett price realised was 40'74 cts. per lb.

Upwards of R1,360'47 was spent on new Pine Boarding Tots, Tea, Bins, and the erection of new lines all of which expenditure has been charged to working account.

The Buildings on the Company's Estates are now all in good order, and should require very little expenditure on upkeep for some time to come.

In view of the probable sale of Yuillefield, the Company are acquiring the necessary powers to enable the sale to be completed and are also applying to the Court for leave to reduce the Capital of the Company.

The lease of Cwm Estate has expired, and, the Directors do not propose renewing it.

Since the last general meeting Mr V A Julius has been elected director in the place of Mr F Lieisching. In terms of the Articles of Association Mr Figg retires from the Board by rotation.

The appointment of an auditor for the current year rests with the meeting.

VOGAN TEA COMPANY OF CEYLON.

DIRECTORS.—Messrs. R W Harrison, V A Julius, E M Shattock.

The Directors now beg to submit to the shareholders their report and accounts for the year ended December 31st, 1901.

The total crops secured for the year have been as follows:—

Vogan	223,667 lb as against	319,477 lb in 1900.
Iddagodde	110,781 "	142,922 "
Bought leaf	15,383 "	20,268 "
Stamford Hill & Barkindale	82,640 "	107,474 "
	<hr/>	<hr/>
	432,471	590,141

Estimate of crop on Vogan and Iddagodde was 410,000 lb based on a finer system of plucking than was in vogue during 1900. The crop secured, was, as will

be seen above 75,552 lb short of the estimate, this being due to the extremely unfavourable weather for flushing which prevailed during the greater part of the year, more especially during November and December, in which months only 46,959 lb of Tea were secured as against 97,035 lb during the same two months of 1900. This large shortage of crop has brought up the cost of the Tea to 26'62 cents per lb. while the net average price realized has been 32'23 cents.

On Stamford Hill and Barkindale the crop has also fallen short of the estimate to the extent of 17,360 lb., the total amount secured being 82,640 lb which has cost, after the deduction of the profit on manufacture of outside leaf, 29'90 cents per lb to lay down in Colombo, and has realised a net average price of 42'20 cents per lb.

After payment of the interest on Debentures, viz: R5,565, the amount of profit earned is R19,783'17, to which must be added the balance of R336'93 brought forward from the previous year, making a total of R20,120'10 available for distribution. Of this amount, the Directors recommended that the sum of R2,000 be put to Depreciation Account, and, that a dividend of 2½ per cent absorbing R18,000 be paid leaving a balance of R120'10 to be carried to next account. In view of the fact that the Factories on Vogan and Stamford Hill are built of brick and iron respectively and that all repairs and renewals are charged to working account, it is not considered necessary to put a larger sum aside for depreciation.

Considerable attention is being paid to the cultivation of Rubber on Vogan and Iddagodde, and during the year some 5,000 stumps will be put out on suitable land. It is hoped that, in time, this together with what has been planted in previous years will form a most valuable reserve for the Company, and every effort will be made in this direction.

The acreage of the Company's properties is as follows:—

VOGAN AND IDDAGODDE.	A.	R.	P.
Tea in full bearing	666	3	33
Tea in partial bearing	119	0	10
do under two years	25	0	0
Jungle do	515	1	38
STAMFORD HILL AND BARKINDALE			
Tea in full bearing	220	0	0
	<hr/>	<hr/>	<hr/>
Total Acreage	1,548	2	1

In terms of the Articles of Association Mr V A Julius retires from the Board of Directors, but being eligible offers himself for re-election.

It will also be necessary to appoint an Auditor for 1902.—By order of the Directors,

LEE HEDGES & Co., Agents and Secretaries.
Colombo, March 2nd, 1902.

THE INDIAN FIBRE CO.

The prospectus of this Company has now been issued. The capital of the Company is R4 lakhs, in 4,000 shares of R100 each, of which the vending Syndicate receives half in fully paid up shares, so confident is it of the soundness of the concern and of the prosperous future before it. Mr. F W Tytler is the head of the Syndicate, and the Company is to have the benefit of his services, so that, as the prospectus states, it "would thus start work with assured supplies of raw material, the most approved machinery, cheap labour, and experienced management, and can confidently rely upon a constant demand for its produce at prices which must under ordinary circumstances leave a handsome profit."

There is one fact which will strongly appeal to prospective shareholders, and that is that the Company will be in the fortunate position of being able to declare a dividend in the first year, and one which may range from 30 to 46 per cent, on a called-up

capital of R320,000. The proof of this excellent pudding will be found in the prospectus, in which it is set forth that, taking the selling price of the fibre at only £30 a ton—and it has been as high as £41—and a production of only 720 tons a year—whereas 900 tons, it is estimated, might be made from the hedging only—the net profit on the year's working will be R1,47,600. The fibre is certainly excellent, it has been very highly spoken of by experts in London, where it has realised the top market price, and at the recent Agri-Horticultural Show in Madras it was awarded the Bronze Medal (the highest award for fibres) the Judges regarding the exhibit as "a very beautiful sample." Thus, everything combines to render the issue of the prospectus an assured success.—*Madras Mail*, March 8.

A NEW TEA COMPANY.

THE AGRA ELBEDDE (CEYLON TEA)
ESTATES, LIMITED.

Subscription lists were to open in London on February 17th and close on or before Wednesday, February 19th, at 4 p.m., for the above Company to be formed with capital of £15,000; 15,000 being £6 per cent. Cumulative Preference Shares of £1 each and 15,000 each of "A" and "B" shares of £1 each, "B" shares getting a dividend up to 6 per cent. after providing the dividend on "A." The Directors are Messrs. S Patterson, J. P., Chairman, J W Hargreaves, J Puttfarcken, J D Hand, and R S Pieris, Managing Director. The Company has been formed to take over as a going concern from January 1st 1902 the Agra Elbedde and Agra Tenne Estates in Ceylon in Agras and Badulla districts respectively. The total area under cultivation is 426 acres and there are "650 acres available for extensions." The present output is 100,000 lb per annum. Mr. Edmund Scott, who has reported on both estates, estimates 144,000 lb. for Agra Elbedde alone, in 1905.

The Secretary of the Company is Mr. E H Walker, and offices (*protem.*) 25, Abchurch Lane, London, E. C.

PLANTING IN THE ANAMALAIS.

Mr. E J Martin, formerly on Farnham, Kelani Valley, whom we welcome back on his return to the colony (by the "Konigin Luise") after 16 months' absence, proceeds to take partial charge of Elkaduwa, Wategama, pending the development of his own property, Monica, in the Anamalai Hills. On Monica Mr. Martin has 250 acres of tea, a large quantity of cardamoms and experimental plantations of rubber, cinchona, &c; some of the tea comes into bearing next year. The Anamalai Hills is shortly to be served by a light railway from Coimbatore to the foot of the Ghauts and even now has a cart road right through the district, though it is but 3 years since the first clearing in it was made.

—
SNAKE FOSSIL FINDS.—The Geological Survey of Cape Colony has found fossils in the cretaceous beds of the coast near Natal. One is the lower jaw of a large reptile or snake allied to the mosasaurus, and another part of the carapace of a turtle such as the protosphargis.—*Natal Mercury*, Feb. 21.

"THE CEYLON TEA KIOSK."

AN IMPORTANT DEPARTURE IN THE INTEREST OF CEYLON TEA.

We make an announcement elsewhere which should interest planters everywhere throughout the island as likely to prove of the utmost benefit to the staple industry of the country, from the prominent notice which it is bound to bring to our tea among the higher classes in England, and (indirectly) in the Continent and America. The "Ceylon Tea Kiosk" of Grafton Street, fully described in this issue, should attract considerable attention in London from its commencement in this the Coronation year, and we understand that—if successful, and we have little doubt that it will be, in contrast with many of its butterfly sisters which have faded away in the same West-end—a similar room will be opened at Paris before long, and after that, perhaps within the next two years, other Ceylon "Kiosks" will be started in the leading provincial towns in England. A good start is a great matter in opening such an institution as that which is to find its home in Grafton Street, and we have no doubt that the enterprising Syndicate, on whose behalf Mr. Saunders will be working when he goes home on April 7th, will be satisfied with patronage little short of anything but the very best. Of course H. E. Sir West Ridgeway will be at home and in London, in time for and at the time of the opening and we hope may be present. We wonder if it would not be possible, indeed, to secure the good offices of a lady of royal birth for the performance of the opening ceremony. Such an one has only recently visited our shores, with her spouse, and for their household while in our midst it will not be forgotten that Mr. Wm. Saunders was the much appreciated Comptroller-General. If the "Ceylon Tea Kiosk" were to be opened by the future Queen of England, not only would its success be further assured, but—a matter of greater import to Ceylon tea generally—attention to the tea exported from the first of Crown Colonies would be widely and speedily drawn, with increased intensity, not only in every quarter of the United Kingdom but all over the Continent wherever the doings of our Royal family are watched with absorbed interest. The prospect is one which, on behalf of the Colony generally, we earnestly hope may be realised.

—
NEW YORK, Wednesday, Feb. 19.—Mr Edward Harriman, who heads the syndicate controlling 20,000 miles of railway in the western states, is about to launch the greatest colonising scheme on record. He proposes to engage a corps of lecturers, with biographs and stereopticons, to advertise the mineral, industrial, and agricultural resources of the states traversed by the syndicate's railway lines. Colonising agents will follow the lecturers and arrange to give prospective settlers cheap transportation. Emigration agencies have already been established at Hamburg, Paris, Genoa, and other European cities, where lectures will be given and the great colonising scheme vigorously boomed.—*Daily Mail*.

To the Editor.

RUBBER PLANTING IN MEXICO—AND
DEVASTATION OF ORIGINAL TREES
IN SOUTH AND CENTRAL
AMERICA, &c.

Vera Cruz, Mexico, 20th Jan., 1902.

SIR,—I receive the *Tropical Agriculturist* regularly from our home office in Chicago; and although I take all Tropical Agricultural papers that I can get hold of, there is none I prize more than yours.

I noticed a short article about *Castilloa Elastica*, growing from cuttings, &c. Here we have not found that mode of planting answer as well as by plants. The trunk of the tree does not appear to grow as *healthy* and *robust* as from seed.

I think the *Castilloa Elastica* one of the easiest of propagating plants ever grown in the tropics. Here we plant from the nurseries, as well as planting seed at stake; last season we planted about 160 acres at stake, and I do not think there are 5 per cent of failures.

Great care must be taken that the rains are *well on* before planting at stake is undertaken, or it may have to be done over again. We have orders to plant 1,500 acres in the coming season, of which 500 acres will be planted at stake. Last season we put two seeds at stake, one on each side; this season we will plant four seeds in each place, then we will not have any loss at all; in fact, we expect to have several thousands to transplant. In the past season we got between eight and ten thousand bushels of corn from our rubber fields, and the second crop is now in tassel. I can't say how much we will get, but there is every chance of getting 4,500 bushels at least. We have also the 160 acres, we planted at stake planted in beans, from which we expect; several hundred bags; these catch-crops are very valuable to us, as our people eat nothing but corn, beans and beef.

Rubber is having a great boom here on the Isthmus of Tehuantepec, but the area is not very large where rubber can be grown profitably. I do not think there are as many trees planted, as are destroyed yearly, in tapping. The present rate of destruction is terrible, both in South and Central America, as well as in East and South-East Africa.

JAS. MAUNDER.

PEARL OYSTERS AT TRINCOMALEE.

Harbour Road, Jan. 27.

DEAR SIR,—Since my last communication to you re Pearl Oysters at Trincomalee, I have been endeavouring to gain as much information about their appearance as I possibly could, particularly among the fishers of the sea, whose avocation takes them to the numerous fishing grounds, bays and creeks of our coast; and I learn from some old hands that Dr. Kelaart, while in military

charge here in the early part of the fifties, introduced some fresh spawn of the pearl-yielding mollusc from Aripu, and deposited them at different points in Trincomalee, near "Powder Island," by the dockyard, "Crow Island" by Orr's Hill, at Koddiyar bar, and near Kurritivu, between Foul Point and Koddiyar, and that the oysters now found are their yield. That during the months of February and March, when the S W and sea breeze blow alternatively in a day, and during lull, large beds of pearl oysters can be observed at Sami Rock point off Fort Frederick, in six fathoms of clear water.

The natives say that hitherto there have been no pearls found; but when oyster beds are torn and carried away by strong currents and cast ashore, the oysters, both small and mature, are collected by ignorant women searching for cockles and mussels, who use the fleshy body as food, a good many pearls are perhaps thrown away with the careless washing before the cooking. The fishery in Kinniyai Bay, formerly rented out by Government, has been abandoned for many years.—Yours faithfully,

J. B. COLOMB.

[We have handed to Professor Herdman the oyster shell and pearl Mr. Colomb sent with his last letter. Trincomalee, as already mentioned, will be visited in due course and a careful investigation made of all that concerns local fisheries and oyster deposits.—ED. T.A.]

"A BUCHAN FARMER"
SCRUTINEERED.

[There never was a press writer who was not subject to criticism and correction, and "Cosmopolite" is far too genial an old Colonist not to be willing that his readers should hear "the other side" as it is given by another old Ceylon planter and Aberdeenshire farmer in the *Buchan Observer*.—ED. T.A.]

SIR,—In your issue of last Tuesday I read with some little interest 'Cosmopolite's' letter to you and copy intended for *North British Agriculturist*. I have also been put in possession of the *Tropical Agriculturist* of Ceylon, where the letters appeared, and I am quite sure your numerous readers in Buchan and elsewhere would be gratified if you would reprint them without garbling. In that case, the prayer of Robbie Burns would be in a measure answered—

'O wad some power the giftie gie's,
To see ourselves as ithers see's,' &c.

As 'Cosmopolite' says, 'all know perfectly well his real name; indeed who does not know the author of 'Netherton' in the 'wids of Buchan.'

I cannot admit that Mr. Duncan's grievance is a quite competent judge (although he has been an eyewitness of the 'Everyday Life of a Farmer') to say that the statements therein made are all 'strictly correct and not exaggerated in the very least.' Two years ago, February, 1900, he wrote as follows:—'Our little Agricultural Society held its seed show (at Mintlaw, I suppose) in spite of the distressing weather, and was remarkable on account of the indifferent judging and the fact that the members of committee took all the prizes. It is a truism in rural circles that it is better to be a friend of the judges, or a member of committee, than to own the best stock at the show and this rule

seems to have held good in this instance.' Does the excellent and venerable secretary of the Buchan Agricultural Society and his committee consider the above is 'strictly correct and not in the least exaggerated?'

Referring to the death of the late Mr. Bruce of Inverquhomery (in same letter) he says—'He was one of the most successful landlords in Scotland.' Everyone who knew Mr. Bruce could quite endorse this remark. Not only were his stock of the very best description, but his fields were in the highest state of cultivation. Mr. Duncan boasts he has never spent 'one penny' on artificial manures at Monyruey. This revered and 'most successful farming landlord' to my knowledge laid down his turnip crop not only with abundance of cattle manure, but adding to it in many instances some 19 cwt. artificials per acre! This may have had something to do with his success, but of course 'one must cut the coat according to the cloth,' and so far as my observations go, most farmers add to the cattle manure the amount of artificials they consider necessary to produce full and profitable crops.

In a letter of date June 1st, 1900, I notice the following observations:—'We find a great deal of nonsense (sic) in the columns of the agricultural press about the good that has been done by science, in discovering various artificial manures, which have aided our farmers in attaining their position in the fore rank of agriculture. It is not for me to set myself up as an opponent to the theories of those scientists, but *having tried I believe every kind of artificial manure*, I consider I have some right to say a word on the subject. My present farm (Monyruey) had been badly *konnached*, to use a good Scotch word, for about twenty years, so when I signed my lease, I knew I had a considerable uphill work before me, but by an ample dressing of cattle manure I so surprised the soil, which had for years been accustomed to a scanty application of artificials, that it forthwith proceeded to produce excellent crops. Not only do I manufacture a large quantity of bulky manure on the farm, but I buy much more from any of my neighbours who are willing to sell, and who prefer the cheaper style of manuring by artificials. In course of time people began to remark my fine crops, and supposed my bill for artificials was a heavy one, to which my reply invariably was 'Not a penny.'

—As I stand indicted for some seven years of the twenty, wherein the farm of Monyruey was so *badly konnached*, and being Mr. Duncan's immediate predecessor, I distinctly plead 'Not guilty, sir.' As regards the 'nonsense written about artificial manures,' you will find in the last issue (report No. 2, copy of which I can produce), of the Turriff and Garrioch Analytical Association, season 1901—'Experiments with artificial manures in turnip culture (*mark you, without cattle dung*) when no manure of any description was applied, on the eight farms the crops weighed on an average 11 tons 11 cwt. and 8 lb. per acre. With the addition of phosphates and potash to the value of 26s 1d per acre, the average crop rose to 20 tons 12 cwt. 3 qrs. and 12 lb. and with an application of phosphates, potash, and nitrogen, at a cost of 35s 3d per acre, the average crop was 22 tons 3 cwt. 3 qrs. 20 lb.—well-nigh double the average of the no-manure plots.' Please allow Mr. Duncan to give us the details of the '*every kind of artificial manure* he tried before he discarded them, and the results he obtained.'

In addition to paying my predecessor on my entering Monyruey (the venerable Dr. Anderson—long may he live and look happy) £162 13s 1½d for cattle manure, in the first year of my tenancy, I also paid the Northern Agricultural Company the sum of £226 18s 6d, chiefly for bones and lime—indeed I may state that before I entered into possession of the farm, I applied along with the grasses I sowed on one field of 20 acres, 4 cwt. per acre of bone meal (I hope this paid Dr. Anderson—manuring his way-going crop) at any rate it paid me, as that field of 20 acres or so grazed 45 two-year-old bullocks and a mare and foal, the whole of the following year (George Bruce, Aberdeen, supplied the grass seeds) with the exception of 14 days they pastured elsewhere. Is that field now doing as well; or is it not to a great extent overgrown with *reeds and rushes*?

As regards cattle manure which most farmers very carefully look after and 'don't sell to neighbours'—at least in my twenty years' experience—during my tenancy of Monyruey there were from 100 to 120 cattle always on the farm, also 3 to 4 pairs of horses, besides sheep and a herd of the very highly appreciated Yorkshire pigs. The corn crops would have averaged over 100 acres yearly, and being worked, as I have already stated, according to terms of lease on a six-course rotation of *three* grasses, your farming readers can estimate the quantity of cattle manure made and applied during my tenancy.

I would be glad to have, and your numerous readers, sir, will appreciate, the information as to the quantity of cattle manure Mr. Duncan has been able to purchase from his neighbours yearly since Whitsunday, 1888; and also, as to the *manufacturing a large quantity of bulky manure on the farm*. Does he refer to what can be done with 'herring refuse,' seeing he says he does 'not keep a cow,' and consequently is dependent on some neighbours for milk to his own porridge?

In his July epistle, 1900, he writes:—'I have no hesitation in stating that a rent of one pound per acre per annum is the highest that anyone should pay and expect to hold his own, or perhaps make a little profit, and this I may remark is the figure I pay for my own farm. One thing, however, I would caution an amateur farmer against, and that is taking a farm because it is low-rented. For example, I know one man, a far from practical farmer, who had leased a place at 25s an acre, but found in the course of a few years that he was losing money, so, having succeeded in breaking his lease, he went to the other extreme and rented one at 11s, but the farm he threw up used to give him six quarters of oats to the acre, whilst the one he took so cheaply only gave him 3 to 4 quarters, and so the last stage of that man was worse than the first. A very low-rented farm is one that is not worth taking at present, and only farms that can be worked up to the highest state of cultivation are worth taking on lease now-a-days. The low prices ruling for grain, beef and mutton, compel one not only to secure a good farm at a fair rent, but also to cultivate it at high pressure, in order to pay the labour bill and have something over. Farming on the cheap won't do at all, and if high farming won't pay, certainly low farming will not do.'

The latter sentences of this paragraph most farmers will endorse—but as to the 'example of a farmer leaving the 25s farm and taking one at 11s an acre,' I do not think this is strictly correct, and

'not exaggerated in the very least.' Perhaps he had the writer in his eye; if so, this is the correct information, both for foreign and home consumption. During my tenancy I paid 28s 10d per acre for the 311 acres arable of Monyruy, and afterwards obtained my present holding (Burnside, Turriff), of 240 acres at 11s 8d, a difference of 17s 2d per acre, or on the 240 acres a difference in tenant's favour of over £260. As to the crops, and these can be verified, Monyruy (and please remember I was bound to bring it from a five-shift rotation into a six of three grasses) in no season yielded more than 5 qrs. 7 bushels per acre—the average for the seven crops I reaped being 5 qrs. 3 bushels and 4 bushels per acre. On 'Burnside' I have reaped a crop of 6 qrs. 7 bushels oats and barley per acre, and from several fields the yield has been from 8 to 10 quarters. But further, it was my fate to become proprietor of this farm, and by good cultivation and mostly on an 8-course rotation of 4 grasses, and other improvements, the property had been considered worth some 60 per cent more than I paid for it, and I believe it will be a better bargain to the purchaser than it has been to me.

But who can say that my *last stage* is worse than the first? Whether I can be counted a *far* from *practical farmer* or not is matter of small moment, but is for my neighbours and the public to judge—the grievance of Monyruy, or Mr Duncan.

This is an instalment; there is more shot in the locker.—I am, etc.,

JAMES BEATON.

Burnside House, Turriff, 14th Feb., 1902.

[We do not find space for mere personal bickerings; but "Francis Grose" in the *Peterhead Sentinel* seems to take a sensible view of the matter when he writes in reference to an interesting article in the *N. B. Agriculturist* :—

We did not see fit to refer to the article in the *Agriculturist*. It was written in a distinctly acrimonious spirit, the writer apparently quite failing to see that Mr Duncan was first of all a humourist, while at the same time the writer could not know whether the racy claims made by the Buchan farmer were in any degree accurate or not.

Mr Duncan, writing to a Ceylon paper, might, without breaking any bones, allege that his predecessors had "konnached" the lands of Monyruy. Probably nobody in Ceylon knew whom those predecessors were. And even then, the statement is probably only half serious, and doubtless means only that Monyruy was not cultivated as the present occupant prefers to cultivate it. Mr Duncan is a joker, without an ounce of malice in his composition. For the rest, he is a *rara avis* among Buchan farmers. The son of a professional man, himself well educated, much travelled observant, and accustomed to sheep as regards farming, it is only natural that his ideas of farming and of things in general should be greatly different from the ideas and methods of his neighbours. I have always understood that Mr Duncan succeeded with his sheep, paying twenty shillings in the £, and finding a good deal of leisure for the entertainment of the lieges in his district. Farming has by no means reached its *ne plus ultra*, either in Buchan or anywhere else, in this year of grace 1902. I have no doubt criticism and suggestion are just as much wanted today as ever they were; and certain I am of this, that few people are likely to go about the

business of criticism with less of animus than is the yeoman of Monyruy.

It is customary to keep the pleasant things we have to say of a man until he is dead. I have always jibbed against the injustice of just praise being deferred in the utterance till obituary notices have to be written. Without at all believing that Mr Alfred Duncan stands in need of special pleading, I am glad to avail myself of this opportunity of saying that I have always found him the same—good-natured, waggish, energetic, entertaining, courteous, versatile, a man of his word—altogether the most interesting and satisfactory farmer I have met with in Buchan. Whether it be to deliver a lecture, to take the chair at a public meeting, to sing a song or to write one, to "serieve" a column of breezy "copy"—story, notes, article or what not—there is not, I believe, such another in his class in Aberdeenshire. A faculty for racy extravaganzas in his *metier*: we would not have him without it; and if the editor of the *North British Agriculturist* could only hear him making sport for the Longside public in St. John's Hall, he would never want to write such scornful comments as those he penned a month ago on this "Buchan farmer." Long may the Flockmaster of Monyruy live to apply the surgery of tar, and to say with Corin: "I earn that I eat, get that I wear, owe no man hate, envy no man's happiness; glad of ther men's good, content with my harm; and the greatest of my pride is to see my ewes graze and my lambs suck."

FRANCIS GROSE.

—Ed. T.A.]

TOBACCO-GROWING IN TRINCOMALE DISTRICT.

NOTES BY A CULTIVATOR.

DEAR SIR,—Correspondence about "tobacco growing" in the columns of your paper of the 19th instant prompts me to address you on the feasibility of the cultivation of tobacco being successfully and profitably grown in the Trincomalee District under European auspices, owing to the existence of most appropriate and suitable tracts of land to the south.

THE PLAIN OF "VELLAI"

lies 12 miles away from "Matur" village, in "Koddiarpattu." It is now used as pasture ground by cattle speculators who bring droves of black cattle from India, and from Kraals at different points. It abounds in Guinea grass washed in by the "Mahaweliganga" from upcountry. The last deviation of the river is about 3 days' journey from its entrance into Koddiar Bay, and this abandonment occurs over a hamlet called "Pavana" near Kuringamuwa—Brooks channel, lying between—and the off shoot forks or splits itself into two branches, the one called the "Verugel aar," the boundary of the Trincomalee and Batticaloa Districts, and the other called "Vellai aar," deriving its appellation from the locality, and both of these flowing streams of fresh water meet at a point, above the sea, at a place called "Periavelli," where the feeder of "Allai" tank takes its rise, and flows as a united river called the Verugel river, between Trincomalee and Batticaloa. Thus it will appear that the vast plain of "Vellai" is quite surrounded by fresh water, the virgin soil is alluvial and rich, and well-adapted for tobacco cultivation, an account of which, as it is carried on here, I append.

TOBACCO.

In Trincomalee, it is mostly grown in open lands about the Town from No 1 Division northwards, up as far as "Nillavelly" village, which is 9 miles away and where large tracts of Crown lands have been recently purchased of Government for cultivation. The soil of gardens in Town is loamy or marly earth, but towards Nillavelly it is sandy, and better adapted I fancy for coconut planting, but yet Tobacco is extensively grown. The fertilizer used by cultivators is compost from dung-hills, or native manure. The seeds are raised in nurseries near wells, during the months of October and November, and the native cultivator who has no scientific knowledge pertaining to soil, chooses the most convenient spot which is dug and manured with dry, powdered cattle dung, and encloses the spot with a temporary fence, and thence sows his seed. When the seedlings sprout and shoot forth three or four tender leaves, they are considered fit to be transplanted.

Meanwhile the land is turned over by a mamoty, an adjunct for a spade or shovel, and this is great manual labour. The earth thrown up is levelled, and the area squared and lined parallel with each side, and thus each line intersects the other and the plants are set 4 feet apart, and well shaded. They are watered by earthen pots for a week 3 times a day, and afterwards for a week both mornings and evenings only, and in 22 days the shades are removed. The ground is then weeded and water let in to irrigate the plants every other day for 8 or 9 days. Afterwards the whole ground is tilled and 4 to 6 plants are banked in one bed and left for two or three days to bask in the sun—water is afterwards irrigated daily until maturity. Watchful search of destructive worms is unceasingly made at this time as otherwise the leaves will be perforated by these pests.

After 15 or 20 days the main stalk is nipped off and the shoots after every eighth day pinched off. It is now that good and well-grown trees are spotted, and the top shoots are allowed to throw additionally a couple or three leaves, and then lopped. These leaves are said to be superfine or very best; those below, on the parent stalk, from two to five in number, according to the fertility of the soil, are said to be of best quality; those beneath, of second quality, and underneath ones, as inferior.

It takes a little over six weeks before the plants are well-matured with narcotic propensities, and altogether five months before the crops are able to be gathered for manufacture. Abundant rain about this time is considered unpropitious and tending to wash away the principles of the leaves, seasonable showers and drizzles are much looked for. The plants are cut during the afternoon at about 3 o'clock so as not to expose them to too severe sun-rays. They are hung up for airing in cadjan sheds, well secured from the sunbeams with plantain leaves, &c. for 20 days, and are then unloosed and laid on the ground in stacked heaps for a week. Then the leaves are pared of thick veins and bundled according to qualities and left on the ground for four days; afterwards untied and re-hung up for four days; finally, piled again for a week, when the gaseous change takes place, and resorted, superfine, and leaves of

1st quality 20 to a bundle
2nd do 30 do

Common—picked up haphazard and made into bundles of about 50, more or less.

The cultivation of tobacco is considered very paying. I should like to hear from any correspondent in your columns of the modes adopted at Jaffna which I hear are quite different.

J. B. C.

ACTUAL OUTTURN OF THE INDIAN CROP—AND THE PROBABLE CROP OF 1902.

Indian Tea Association, Calcutta, Feb. 18.

DEAR SIR,—I am directed by the General Committee to annex the following comparative statements of the actual outturn of the crop, so far as returns have been received for the two seasons 1900 and 1901 respectively:—

	1900.	1901.
Assam ..	68,708,916	65,203,402
Cachar ..	27,299,230	23,806,587
Sylhet ...	34,038,023	29,699,728
Darjeeling ...	7,738,018	7,323,542
Tera ...	3,637,680	3,374,985
Dooars ...	30,220,001	30,542,037
Chittagong ...	1,065,300	831,020
Chota Nagpur .	185,089	248,187
Kangra Valley	3,000,000	2,435,405
Dehra Dun ..	1,785,000	1,798,560
Total ..	177,677,257	165,263,453

2. I am to draw your attention to the fact that the particulars given in these two statements are derived from identical sources. So far as Assam, Cachar, Sylhet, Darjeeling, the Terai, the Dooars, Chittagong and Chota Nagpur are concerned, the figures for each year represent the totals of returns submitted by 23 agency houses; while for Kangra Valley and Dehra Dun the figures have been furnished by the local Planters' Associations.—Yours faithfully.

W. PARSONS, Secretary.

[The exports from Southern India have to be added to the above. In respect of the present year's crop, the General Committee in Calcutta have published the following:—

(a) THE PROBABLE EXTENT OF THE CROP FOR 1902.—With the letter dated 17th January, Mr. Tye forwarded copies of a circular, drawing attention to the following resolution which had been adopted by the London Committee, namely:—"That this committee, viewing with grave concern the disastrous results that would follow a large crop of tea in 1902, strongly urge upon producers the necessity of restricting outturn as much as possible by a system of more careful plucking than otherwise, and to avoid more especially the production of coarse tea, which did so much harm to the industry in season 1900." The circular had been issued to all the members of the London Association; and it contained a statement of the reasons which had induced the London Committee to pass this resolution. An appeal was also made in it to producers to abstain from the coarse plucking which had been restored in 1900. A circular on similar lines had been issued by the Tea and Produce Committee of the Ceylon Association in London. After consideration, the General Committee decided to reprint the circular, and to issue it to tea producers in India, with a covering letter supporting its chief proposition.

--ED. T.A.]

RUSSIA AND THE INCREASE OF THE
TEA CESS.

SIR,—I venture to suggest that the Thirty Committee would benefit estate owners in Ceylon more by arranging that an allowance of one, or say two, pounds per package should be made on all teas sold direct to Continental, Australian and American buyers in Colombo instead of taking money for advertising purposes. In Russia the tea business is in the hands of the importers who will push the tea out of which they can make most money, and as they always get a *gain in weight on China teas* they resent the *loss in weight* on Ceylons. English goods are not popular in Russia just now, and it would be much more advantageous to allow the importers and blenders to put their own marks on the packets sold, as the name of Ceylon connected with anything English won't help the sale of the teas.—Yours, etc.

A SHAREHOLDER IN CEYLON TEA
ESTATES.

Moscow, 4/17th February.
—Local "Times."

CEYLON TEA ON THE CONTINENT.

SIR,—In your paper of the 16th January I have read a letter headed "A talk with Mr. J.H. Renton" which I think is likely to mislead estate owners. Having been over 22 years in the tea business with Russia, Germany and France and nearly 20 years of same in China and 5 in Ceylon (on and off!), I fancy I know as much as, if not more about the prospects of the Ceylon tea trade there than Mr. Renton. Owing to the credit system it is absolutely necessary to work the trade through the importers, and Mr. Renton is at present only annoying these gentlemen who are quite willing to buy the best teas in the cheapest market, but naturally wish to introduce their own blends out of which they can make something. Ceylon is known to be a British possession, and for this reason teas so marked are anything but popular, as I well know, having just been round Germany and Russia. I recommend the planters to save the worse than useless expense of advertising and agents like Messrs. Rogivne, Renton, etc., who I am prepared to state, have not induced one-thousandth part of the present Ceylon consumption. They had far better allow the buyers in Ceylon 1 lb. on each package to cover possible loss in weight which often happens and annoys the importer (who gets about 3 lb. in China bought teas), and also arrange that the buyers in Ceylon can obtain more of the better teas so that same may be sent to the Continent direct, and not through London hands who have to take a commission, to say nothing of freight paid on the teas, and delay in transport. It is a pity that some of the chief estate owners cannot visit the Continent and endorse what I have written above.—Yours, etc.

BUYER AND SHAREHOLDER.

Berlin, 21st February, 1902.
—Local "Times."

THE PROPOSED INCREASE OF THE
CESS.—IV.

3rd March.

SIR,—You have rendered excellent service to the cause of truth by the transfer to your columns of Mr. Lampard's letter to your evening contemporary. If it is not often that one provided-circulation to the arguments of one's

adversaries. It is not often, perhaps, that the adversary so effectually proves the weakness of his own case. In the columns of the acquiescent "Times of Ceylon" the plausible array of formidable figures will help to establish a foregone conclusion. To the more intelligent readers of the inquisitive *Observer* they will only exhibit the weakness of the cause they are intended to further. If they offered the best argument, or any argument at all, for an increase of the Cess, then the increase must rest on a very slender basis.

In one word the opposition to any increase just now rests on the alleged fact that the cess, as at present administered in the United States, has (1) aroused the opposition of the trade, and (2) has not produced results at all commensurate with the expenditure. On the first part of this allegation, Mr. Lampard is silent; the second he seeks to disprove by quoting figures which show a considerable growth in the foreign exports of Ceylon Tea (*i.e.* exports to countries other than the United Kingdom) since the Cess was started. The irrelevancy of his argument is obvious. The satisfactory development of the trade in the *United States* cannot be proved by lumping the figures for the whole world *minus* the United Kingdom. The Stars and Stripes have yet to dominate the world; but the fallacy of the argument is worse than its irrelevance. Mr. Lampard knows as well as you and I do that, if the figures for the several countries be separated—as they easily can be—the greatest growth in trade will be found to be in those which have *not* been helped by the Cess; and that of the countries in which Cess-money has been spent, the United States show *about the least* growth.

Mr. William Forsythe follows his leader; but while he leaves the formidable figures alone, save for an indirect confession that they had reached his heart, he supplies the omission in Mr. Lampard's letter by an indirect admission that the back(bone) of the trade has been stroked the wrong way. "The disappointed applicants for the bounty of the 'Thirty Committee' are endeavouring to turn and rend them." Precisely; and that frame of mind does not promote trade.

But the burden of Mr. Lampard's deliverance is gratitude to the much-maligned Thirty; and Mr. Forsythe, as one of "the much-abused body," acknowledges with tears the graciousness of the farewell benediction. But, are not these gentlemen under some delusion? Where is the abuse to be found? I have noticed considerable warmth in the speeches and letters of the rural members of the infallible Thirty; but I cannot recall any similar heat in references to them. Only the success of their methods has been argumentatively questioned, as also the wisdom of continuing work on lines proved to be unsuccessful. If the Thirty can serve only if all they do is approved without question, let Forty be tried, on the chance that ten may be found with a skin not too sensitive to criticism.

Though you, Mr. Editor, have repelled the charge of having incited an appeal to Cæsar, such incitement would be perfectly legitimate. The minority must accept the decision of the majority in matters affecting the common-weal; but private property is sacred. No majority can decide to put their hands into my unwilling pockets. Let what is wanted to be wasted in the United States be raised by voluntary subscription. There is no socialism in Tea.

OUTSIDER.

RUBBER PRODUCTION.

We direct attention to an important article on this subject from the latest number of the *Brazilian Review*—quoted on page 676. It raises an alarm against the short-sighted system of practically killing out rubber-yielding trees in the Amazon Valley; and foretells the result. But we question if the natives employed to collect rubber can be got to alter a practice which gives them the greatest present return. In Africa, on the other hand, there are some attempts at the culture of rubber-yielding trees, apart from the large field for collection from forest trees and vines; while in Mexico, chiefly through American enterprise and capital, very extensive planting has taken place. At the same time there seems no limit to the uses to which rubber can be applied, and though the supply of the raw material should increase considerably—of which there is no immediate prospect—we doubt if there would be much fall in price. The moist districts of Ceylon and the Straits up to a certain elevation should grow rubber-yielding plants as profitably as any part of the world in our opinion.

MR. R. V. WEBSTER AT THE FRONT.

Mr. R. V. Webster writes as follows:—

Heath's Hotel, Johannesburg, Feb. 16.

At present I am so pressed with work that I hardly know which way to run. On the 17th December I landed at Cape Town as "Special War Correspondent for *Black and White*, and *Daily Express*." At first I could only obtain a licence for Cape Colony, but later Lord Kitchener gave me a special licence for South Africa.

Leaving Cape Town on the 30th December, I proceeded to Aliwal North, (North East Cape Colony), where I arrived on the 4th January. The following day I accompanied the District Mounted Troops and Connaught Rangers with a convoy to Jamestown. From there we proceeded to Lady Grey, and joined Lord Lovat's Scouts. The combined forces then trekked out after Fouchee, Myburg and Wessels; we had some hard work but they were too quick for us, and we returned to Aliwal North with a number of horses and cattle that we captured. As the troops went into camp to rest I took train to Port Elizabeth and completed a little business I had on hand. I then proceeded to Johannesburg and Pretoria, when I got the offer of a commission in the Cape Colonial Force with instructions to report myself at Cape Town; four days later my commission was approved of by His Excellency the Governor and Executive Council. I was then attached as Staff Officer to the Commandant of No. 12 Ares, and with that Officer proceeded to Port Elizabeth, East London, Queenstown, and on the 8th February arrived at Aliwal North. The following day I was given command of No. 2 troops of the "District mounted troops," and took up my quarters at Kraal Bridge; we had an exciting time as Wessels with two hundred men took up a strong position five miles further up the river and we were waiting for the Connaught Rangers to cut off their retreat further up still, but the Boer does not sit with his eyes closed, and before the Connaughts could get into position they were off. When I was on the previous month as correspon-

dent I left a card at a farm frequented by the Boers, and told the good lady of the house that I should be pleased to meet Wessels if he would send me a message to the Balmoral Hotel, Aliwal North, with instructions where he would leave particulars as to where I could see him. The night before I left Aliwal North a native brought me a note on which was written, "Dear Mr. Webster, I would like to see you, but that is impossible just now. Yours, P. W. WESSELS." The Boers on the farms say I am the exact double of Wessels; when they first saw me in uniform, they thought that Wessels had joined us.

On the 10th February I received a letter asking me to proceed to Johannesburg as soon as possible, as Lord Milner has a most difficult job on hand, and they think I have the qualifications for the post. That same evening I received a second letter enclosing a special permit, and informing me that His Excellency Lord Milner wished to see me as soon as possible, as they had on hand a most difficult task, and thought I could be of great assistance. I obtained seven days' leave, and took train that night; the second night out we ran into the engagement at Klip River Station, where some two hundred of the 28th Mounted Infantry were killed and wounded; this Battalion had only arrived from Aldershot about a month, and had not yet learnt that none but fools move without scouts in advance. I should like to relate some incidents that have taken place within the past month, but correspondents are not allowed to relate what they know, but must write that which will please the British public.

At 9 a.m. the following morning we arrived at Johannesburg, and I lost no time in getting to the Hotel and a tub which was most refreshing, not having had my boots off for four nights. Taking a rickshaw I went to Castle Building, and reported myself to His Excellency's Private Secretary, most anxious to know what the "difficult job" was. Half an hour later and I was ushered into the presence of His Excellency Lord Milner, the one man who is feared throughout South Africa more than Lord Kitchener, I was agreeably surprised to find in the great ruler of South Africa, the much dreaded Lord Milner, a man with whom you at once felt quite at ease, and with whom it was a pleasure to converse, even on important matters connected with the future settlement of South Africa.

The "important job" which His Excellency has on hand is the settlement of settlers on the Government lands and farms in the Transvaal, and the purchase of certain farms from the Boers. After three hours' interview, I left with an invitation from His Excellency to return to lunch at 2 p.m. After lunch His Excellency asked if I would accept the appointment of Visiting Agent for the Transvaal Government, Land Secretary to the Land Settlement Board, at a salary of £160 per month, and travelling expenses. My first duty is to engage a staff, after which I leave to inspect the Barberton district, which is northeast of Johannesburg, close to the Portuguese territory. I have not yet decided if I shall accept the post as a permanent appointment.

Should you know of any Ceylon men who are anxious to take up farms in South Africa, I shall be glad to hear from them, giving full particulars, as to age, married or single, past experience in farming if any, where and of what nature, and

if any capital what amount prepared to invest ! Business letters should be addressed to the "Secretary, Land Settlement Board, Government Building, Pretoria," and private letters to Lieut: R V Webster, D M T. Government Building, Pretoria. Will you please instruct your manager to forward my paper to Pretoria? With salaams.

P S.—I leave for Pretoria tonight, and will stay with Mr Davidson, who, I hear, is very busy with his department, as the Colonial Secretary has been very ill for some months and unable to attend to office.

TROUT ON THE NILGIRIS.

A correspondent writes:—"Sportsmen will be interested to know that a consignment of trout ova from Messrs. Andrews, Guildford, has arrived in good condition at Ootacamund. The ova are partly *Salmo fario*, and partly *Salmo irridens* (the rainbow trout which has been such a success in warm climates). The greatest difficulties having been overcome, it is to be hoped that good luck may be with those in whose care the ova are. For several years past nothing has been done, owing to various causes, and two consecutive consignments of ova arrived hopelessly bad. This year, however, the Nilgiri Game and Fish Preservation Society was lucky enough to find friends to help it in the officers of the Royal Indian Marine, and these being sportsmen, and therefore taking a personal interest in seeing the ova cared for on boardship, delivered the ova in splendid condition at Bombay—and this was what money has been unable to insure hitherto. Mr Van Ingen, the well-known taxidermist, kindly undertook the journey to Bombay, and it can easily be understood that, at this time of the year, constant attendance and an unlimited ice supply, day and night, were necessary. The ova have been settled in the hatcheries, and should develop in about a fortnight."—*M. Mail*, March 14.

NATIONAL ANIMALS.—Our Indian and Far Eastern States—says the *Spectator*—are not at all behind the rest of Great Britain in their desire to commemorate famous "natural commodities" of one kind or another, but the picturesque and the terrible play a part in these devices. Pahang takes for its representative beast a tiger, either roaming or slinking through the jungle. North Borneo shows the native rusa deer, an inhabitant of its impenetrable jungles of swamp grass. The Seychelles "sport" their famous tortoise under the usual coconut palm, and the Federated Malay States a tiger bounding from the jungle. The Rajah of Travancore emblazons a device which is variously interpreted as a sacred shell and a coiled cobra. Time will show how many of these emblems will become permanently associated with the countries which use them on their stamps and securities. But it cannot be questioned that many of the totems are well chosen, and show considerable "grace of congruity." It is public feeling which really gives currency to any of these fancies. If the greater number prove acceptable, there will be a very large addition to the zoological side of the political cartoons of the future.

[In the case of Ceylon there is the sacred 'Hansa' or goose in the temples, and the curious lion on some of the old Sinhalese flags as indicating a lion-descender (Sinhalese) race?—ED. T.A.]

THE YATADERIA TEA COMPANY OF CEYLON, LIMITED.

THE DIRECTORS' REPORT.

The Directors have pleasure in submitting the balance sheet and profit and loss account for the year ending 31st December, 1901.

The profit for the year is R56,246 67, to which must be added RS05 28 balance from 1900, and the Directors propose that a dividend of 20 per cent absorbing R33,000 00 be declared, R19,000 00 reserved for working capital, and the balance R54 95 carried forward into 1902 accounts.

It will be seen that the property representing capital stands in the balance sheet at approximately R194 00 per acre cultivated, as compared with about R197 00 per acre in the previous year's accounts, and that the profit is R59 71 per acre in bearing, and 29 63 per cent on the capital.

The total tea crop was 580,108 lb or 13,937 lb less than the estimated quantity, the short crop being due to a finer system of plucking and unfavourable weather, the area under leaf being 942 acres. The total quantity of tea for disposal was 601,200 lb, including 21,092 lb, made from purchased leaf, of which 382,909 lb were sold locally averaging 29 96 cents per lb and 218,291 lb shipped to London of which 140,482 lb had still to be accounted for; but the average obtained for the 77,809 lb as yet accounted for is 25 61 cents per lb. The cost of the tea per Superintendent's Estate Report was 18 13 cents per lb, and the total cost delivered to buyers or put on board ship including all charges was 19 37 cents per lb; or, exclusive of Depreciation, 18 88 cents per lb; the nett value realised from sales (a portion being estimated) was 29 51 cents per lb.

The Company's property consisted on the 31st December, 1901, of:—

981 Acres Tea.

Acres	Tea	planted in	yielded in	1901	580	per acre
					lb.	
172	Tea	1885	do	1901	580	per acre

14	do	1901	do	do		
22 Acres Coconuts, Rubber & Factory Site						
10 Acres Cardamoms						
255 Acres Forest, &c,						

1,268 Total Acres

The estimated crop for 1902 is 580,00 lb. Tea.

THE TALGASWELA TEA COMPANY OF CEYLON, LIMITED.

THE ANNUAL REPORT.

was submitted as follows:—

	Acres.
Tea in full bearing 455
Abandoned 135
Cinnamon and Tea abandoned 43
Ravines 113
Forest boundary belts 53
Forest 1,229

2028 Total Acreage.

The Directors beg to lay before the Shareholders their Fourteenth Annual Report with a duly audited

Statement of the Company's affairs to the 31st December 1901.

Owing to the very unfavourable weather during several months of the year, the yield has not come up to expectations, the crop secured being only 133,760 lb against a revised estimate of 166,000 lb made tea. 30,199 lb of tea were manufactured and sold on behalf of the Galinda Estate and the profit on the manufacture of this tea is shown in the accounts. The crop realised a net average of cents 28.39 against cents 28.63, in 1900, all tea having been sold in the local market.

All expenditure on the Estate has been debited to crop account and, after payment of interest to Preference Shareholders and writing off 5 per cent depreciation all round on buildings and machinery, the Directors regret to say that a sum of R322.42 remains lying to the debit of Profit & Loss Account.

The Estimate for the current year is 150,000 lb which the Directors hope will be secured at a cost slightly below last year's expenditure. Cost of tea laid down in Colombo during 1901 was 25.78 cents per lb as against 26.12 cents per lb during 1900 and the poor results of the working is entirely due to the shortage in crop.

Mr W MacGregor retires in terms of the Articles of Association and, being eligible, offers himself for re-election.

The appointment of an Auditor rests with the Meeting.

THE KELANI TEA GARDEN COMPANY, LIMITED.

THE REPORT OF THE DIRECTORS

was submitted as follows:—

ACERAGE.

334 Acres	Tea in full bearing
30	" planted 1897
34	" " " 1898
10	" " " 1899
14	" " " 1900
422	" Reserve
313	" Ravines, Waste and Grass
11	

746 Acres.

The Directors submit to the Shareholders the accounts of the Company for the year ending 31st December, 1901.

The Crop secured for the year amounted to 150,095 lb, of made Tea, realizing R47,316.81, or an average price of cents 31.52 per lb., as against an expenditure, exclusive of items under Capital Account, of cents 25.80 per lb. including R1,840.44 spent on cost of Manure and application.

The Balance at credit of Profit and Loss Account after allowing for depreciation of Buildings and Machinery is R6,807.30, which the Directors recommend should be carried forward to next Account.

The Directors regret the result of the year's working has not been more favourable owing to the adverse conditions of the Tea market prevailing during the early part of the year, coupled with the unfavourable weather for flushing experienced during the latter months.

Whilst a better average price was obtained for the year, an increase in expenditure occurred owing to the shortness of crop and a more careful selection of leaf being made.

The estimate for the current season is 200,000 lb. made Tea, to be delivered in Colombo at a cost of cts. 23.42, which includes a sum of R4,750, or the equivalent of cts. 2.75 per lb. to be spent on manure.

In terms of the Memorandum of the Articles of Association, Mr. Hoseason retires from the Board, but is eligible for re-election.

The appointment of an Auditor rests with the Meeting.

THE ROEBERRY TEA COMPANY.

THE DIRECTORS' REPORT

was submitted as follows:—

	ACREAGE.
Tea in bearing	... 497 ares
„ 4 years old	... 109 „
„ 3 years old	... 36 „
Cardamoms	642 acres
	.. 4 „

646 acres in cultivation.

The Directors have now the pleasure to submit the Sixth Annual Report and Accounts, being those for the year ending 31st December, 1901. The yield of tea during the period has been 291,324 lb, costing 24.42 cents per lb, as against 26.89 cents per lb last year; and realizing 37.66 cents per lb, as against 41.60 for the same period.

After providing for commission due Superintendent, and making a liberal allowance for depreciation of buildings and machinery, the amount at credit of Profit and Loss is R27,391.06. To this must be added the sum of R570.76 brought forward from last year, making a total of R27,961.82 now available for distribution.

The Directors recommend the payment of a dividend at the rate of 5 per cent. on the paid up capital of the Company, which will absorb R15,000.00; that a sum of R12,500.00 be placed to Extension Account, thus bringing it to R20,000.00; and the balance R461.82 be carried forward to current season's account.

The Directors are pleased to state that a further £1,000 of the mortgage has been paid off during the year, thus reducing it to £1,500, and in accordance with the policy indicated in their last Report, the balance of the Company's indebtedness will be finally liquidated as soon as may be—during the present season if possible.

The estimate for this year is 300,000 lb. tea on an expenditure of R76,200.00, which includes cost of clearing and planting 15 acres of tea and 10 acres of cardamoms.

The retiring Director is Mr. Stanley Bois, who is eligible for re-election.

The appointment of an Auditor for the current year rests with the meeting.

THE PROPOSED INDIAN TEA CESS.—We are glad to see that *Indian Gardening and Planting* is doing its best to promote the cause of the Indian tea cess. The following is the winding up of its latest article on the subject:—

These considerations we earnestly tender to the Indian Government. It is their affair as much as it is the planters', for the industry is a revenue producer, besides being a blessing as an employer of labour. It is not merely a question, we submit, of a unanimous vote on the part of the tea producers. The present situation, produced by the powerful rivalry of Ceylon, and the receding position of Indian tea on foreign markets, lifts it into a question of State policy, which should justify the Government from ignoring the minority, who are indeed not actively opposed to our securing a Cess similar to that of Ceylon, but are only apathetic in seeking for it, or actually neutral in their feelings towards it.

THE LONDON CINNAMON SALES.

The mail of 28th Feb. from Europe brought particulars of the quarterly Cinnamon Sales held in London on the 24th Feb. The brief telegraphic intelligence we published three weeks ago, made us fear a worse sale than is disclosed in the catalogues. The quantity offered was by no means excessive for the first sale in the year, and fell far short of the offerings in February, 1901, when an unusually heavy catalogue had to be faced; but at the November auctions exceptionally high prices were realised. A drop was almost inevitable unless unexpected circumstances helped to maintain prices; and as "worked" spice showed an advance of 1d to 2d a lb. in November, the falling-off of a penny last month yet secures for Cinnamon quills of the best marks satisfactory prices. It will be seen that "worked" Firsts fetched from 1s 5d to 1s 7d, and both Seconds and Thirds ran these figures close; while Fourths ranged from 8½d to 11d per lb. The quantity of fine bark which offered (109 bales) was small, and the whole of it seems to have been disposed of at the auctions. The "unworked" spice which generally includes the coarser makes aggregated 1,202 bales, and so large a proportion of the inferior marks necessarily led to a fall in price. The drop of ¾d to 1d, at which nearly 1,000 bales were cleared, cannot be regarded as heavy; and on the whole the Auctions were not as disappointing as we feared they would be from the private wire to which we gave prominence at the end of last month. Unworked bark from 7d for Fourths to 1s for Firsts, should leave a fair margin to the producer; but as we have remarked before, there seems no limit to the expansion of Cinnamon exports. Last year we sent away 2½ million lb. quilled bark, and over 1½ million chips; and that prices did not recede more markedly if proof that new uses are being found for the spice, and that the demand is not far short of the supply which would have been deemed ruinous twenty, or even ten years ago. Still, there is a limit to the consumption of what must be regarded as a luxury, save so far as Cinnamon is used for medicinal purposes, and if the acreage under the spice continues to expand in the Southern Province, there may be a reversion to the prices which almost ruined the industry 20 to 25 years ago. We note that the exports this year, so far, are much shorter than in the three years preceding—due doubtless to the severe drought which has been experienced the last few weeks, following insufficient rainfall from the North-East in the low country. The prices which Chips fetched, 3½d to 3¾d per lb., have seldom been exceeded, and point to a useful demand; but how anything which fetches less than a penny a lb. in England can be profitably exported from here is a puzzle. Rather, there can be no doubt such business cannot pay, and that, we are glad to find, is the position of "Wild Bark" which represents a dishonest trade in adulterated stuff.

The following is the report of the well-known London firm of Forbes, Forbes & Co., Limited:—

9, King William Street, London, 25th Feb., 1902

CINNAMON.—Yesterday's auctions, the first of the year, went off with a quiet tone, the competition being poor; 1,311 bales Plantation quill were offered compared with 2,162 bales at this period last year and 1,690 bales in November.

The usual "worked" spice comprised the small quantity of 109 bales only and these sold irregularly at late prices to 1d per lb. decline.

The "unworked" Cinnamon comprised with 1,202 bales (including 51 bales which had to be worked owing to sea damage, &c.) of which nearly 987 bales were cleared chiefly at ¾d to 1d per lb. lower.

The regular "worked" marks sold, first 1s 5d to 1s 7d; seconds 1s 3d to 1s 6d; thirds 1s 2d to 1s 5d and fourths 8½d to 11d per lb.

"Unworked" first 8½d to 1s; seconds 8d to 10d; thirds 7½d to 9½d and fourths 7d to 8d per lb.

CHIPS, &c.—Of 776 bags only a small proportion sold, chips 3½d to 3¾d and quillings, &c., 9d to 10d per lb.

BARK.—847 packages offered and 63 sold at ¾d to 1d per lb.

WILD CEYLON.—586 packages offered a few lots meeting bids of ¾d to ¾d per lb.

	1901.	1900.
Stock of Ceylon	3,420 bales	4,245 bales
" " chips	2,318 "	4,360 "
" Wild Ceylon bark	9,945 pkgs.	9,616 pkgs.
		12,938 pkgs.

NEXT AUCTIONS.—26th May, 1902.

Forbes, Forbes & Co., Limited,

ALFRED E. HOARE, Managing Director.

PROFITABLE TOBACCO CULTURE.

One of the features of American tobacco production is that a very remunerative variety of leaf is given in Connecticut, although the climatic conditions of that State, situated as it is in the east, along the shores of the Atlantic are, both as to cold and poorness of soil, the very reverse of those which obtain where the large plantations are down south. Now, an effort is being made to produce the most valuable class of leaf, in connection with which the director of the Connecticut experiment station thus reports:—

The best Sumatra type is a leaf smaller than the Havana, 16 inches or 18 inches being the most desirable length light to medium colors with open grain, free burn, great elasticity or 'life,' and very thin texture. That is what the trade wants. In 1900 the Connecticut station began trying to raise this quality of leaf. One-third of an acre was enclosed with a substantial wooden frame, to support a cover of very thin cheese cloth 9 feet above the ground, and closed on all sides to the ground with the same material. The soil was fertilised as usual for our other leaf, and half the acre was set with Sumatra plants, and the other half with New England Havana. Both were set much closer than is usual in rows 3 feet and 1½ foot apart, and plants 12 inches apart in the row. The cover was a perfect protection against insect pests. Cut worms did some damage to the young plants, but no flying insects preyed on the tobacco. At harvest it was very hard to find a leaf which showed insect bites. The tobacco was also perfectly protected from wind whipping and from light hail. The temperature under the shade was considerably higher than outside, and fluctuated less.

Two rows each of Havana seed leaf and of Sumatra, grown under the shade, were topped, rather high. The leaf from the topped plants, however, after curing, was seen to be distinctly inferior to that from the untopped plants. The untopped tobacco of both

varieties grew to the cover 9 feet from the ground, and the Sumatra, stalks bent over and grew to a length of 10 feet or 11 feet. The occasional wind and rain storms of the summer did no serious damage to the cheese cloth. The leaves were picked or 'primed' when they were thought to be ripe, strung on strings, cured in the usual way, and then fermented in a pile or 'bulk.' When ready for market, samples were taken from the several primings, except the first which included only inferior bottom or sand leaves. Each hand was a single string of leaves just as it was strung by the girls, and therefore represented the general run of the leaves and not a selection. After taking samples this little broken lot of Sumatra leaf, from only one-sixth of an acre, sold for 3s per lb. The samples were sent to a number of leading dealers and manufacturers, with the request to examine carefully and give their opinion of the quality of the leaf, and to also state fully its defects.

These reports from men who are in touch with the present condition and requirements of the tobacco trade, and who had no personal interest in the crop, settle beyond dispute the quality of the Sumatra tobacco which we raised. The experiment has demonstrated without doubt that Sumatra leaf of excellent quality can be raised under the conditions of soil and climate which prevail in New England. It remains to be seen whether such tobacco can be economically raised in New England: that is to say on a considerable scale at a profit. To determine these points will require further experiment. Farmers may be advised to undertake to raise Sumatra tobacco under shade at present, in only a small way and purely as an experiment, which will not seriously injure them, even if not successful.—*Melbourne Leader*, Feb. 15.

A LARGE BLOCK OF "PEARL."

Wellington, Feb. 27.—A large block of pearl, weighing 12½ gr., has been found inside a cockle at Port Chalmers.—*Adelaide Observer*.

LIQUID FUEL FOR TEA DRYING MACHINES.

The experimental stage in the burning of petroleum as a fuel has passed, and the recent developments of oil fields in many parts of the world have placed this commodity within easy reach of many consumers. It has been used with conspicuous success in the manufacture of tea. For stationary boilers, the problem of raising steam effectively and economically has been solved by the use of oil. The combustion is so complete and the heat generated so great that the system presents a direct saving as compared with coal or coke, to say nothing of indirect economies, such as cleanliness, ease of handling, absence of stoking and saving in labour, complete absence of smoke, economy of space, no ashes, and an even temperature and constant even pressure of steam. As a steam producer, oil has no rival. A considerable portion of the heat value of coal goes off in smoke and cinders, while the entire calorific effect of the oil is obtained, and one ton of oil has been proved by many careful tests in actual consumption to be equal to twice that amount of the best Welsh coal.—*Tea*.

THE ROEBERRY TEA COMPANY.—A dividend of 5 per cent was declared at the meeting held on the 13th March, and this we consider a very good result indeed in view of the hard times through which Tea Companies have had to pass recently.

CEYLON AND INDIA AS TEA-GROWERS AND TEA-RIVALS.

"Let it always be remembered that Ceylon and India are rivals, and deadly rivals, in this tea-growing business and always will be, so long as both countries have tea to sell." The logical inference from the foregoing proposition is surely that Ceylon should begin a campaign decrying Indian-grown tea just as China and Japan teas have hitherto been condemned for their inferiority to Ceylon tea? But our good friend, Mr. William Forsythe, from whose letter we have taken the above extract, is neither logical in his argument nor correct in his figures. While regarding India as a "deadly rival," he yet urges her planters to get a tea cess. One would suppose, that being a rival—it would be very much better for Ceylon that India should have no cess and no means of advertising her products? But the fact is Mr. Forsythe sees that any step forward, gained for Ceylon, is so much ground gained for the tea industries of both countries. Whether we will or no, Ceylon has to act more or less in co-operation with India in winning a way into markets where China and Japan teas still have a home. Far better, therefore, in place of treating our neighbour as a deadly rival, frankly to urge her to co-operation and endeavour to work shoulder to shoulder in conquering the Russian and the European markets and in advancing yet further, by means fair to all dealers, in the American Continent.

If it be the case that Mr. Forsythe, like his typical countryman, is spoiling for a fight and inviting a champion from India to tread upon his coat, we fear that he will find that he gives himself very much away in the figures for which he has made himself responsible. Where, for instance, has he got a million acres of tea in India?—when, as a matter of fact the total area cultivated does not cover much more than half this extent. Then again the Indian champion's turn comes when he asks Mr. Forsythe to explain how it is—that of the 22½ millions of Ceylon tea taken for foreign markets in 1901, in excess of Indian tea, by far the larger proportion—perhaps as much as 80 per cent—was taken for countries in which there has been no expenditure of cess money or only an infinitesimal beginning. We refer to Australia and Russia. We believe the Australian Colonies and New Zealand took 11 millions more Ceylon than Indian tea. That will leave only 11½ millions of the excess to be accounted for. Russia accounts for a good deal more than half of this quantity. So that in reality the wonderful "advertising" enterprise of this little island is represented by not much more than four or five million lb. of Ceylon tea in excess of Indian tea taken by countries where the cess money has been expended. Will our good friend Mr. Forsythe kindly give consideration to these figures in his next letter and inform us what answer we should give to an Indian critic who might turn round and say: "I find that your advance in the export of your teas has been far larger to countries where

you have spent no money in advertising, namely Australasia and Russia, than in America to which most of your money has gone. To say the least, it surely requires some explanation, before you continue blowing your trumpet as to the great advantage which has been reaped by the action of the tea cess?"

"In any case when dealing with this subject, be quite fair, and show the figures not in the totals for all 'foreign countries', but with some discrimination as to countries exploited with cess money, and those where not a cent of such fund has been spent. Nothing can get over the eloquence of such figures as these:—

TO AUSTRALIA AND NEW ZEALAND.	
Ceylon Tea exported in 1901 =	20,650,000 lb.
India " "	9,167,795 "
Excess for Ceylon:—	11,482,205 "

TO RUSSIA.	
Ceylon Tea exported in 1901 =	9,609,734 "
India " "	=(?) 3,000,000 "

SHADE-GROWN LEAF TOBACCO.

That the issue of shade-growing is still keenly canvassed, there is no denying; it is equally evident, too, that opinion is veering towards conviction that the new industry has come to stay—even though it may never revolutionise present conditions. The action of the special committee in fixing May 1st as the date for the auctioneering of the Tariffville crops has caused considerable disappointment and much grumbling among growers who were awaiting the results of the sale before venturing into the business themselves. The only object of the Government and special experts who have the matter in charge was to secure a thorough and reliable test of this tobacco; that when it came to be offered to the public it would be in the prime condition that care and the time limit would permit. This sale will be the most important test the product could be subjected to, and considering the interests at stake it was but wise to take all necessary precautions against premature cure and all the other incidental ills that tobacco falls heir to. To paraphrase the old Scottish proverb, the proof of the pudding is in the eating of it, and, of course, no amount of interested expert opinion will be taken too seriously until the tobacco itself has been thoroughly tested. That test it will be subjected to in May next, but in the meantime the subject is worth examining in all its bearings.—*Tobacco Leaf*.

CHINESE CASSIA LIGNEA.

A warning to German traders has recently come from China. The export-houses at Canton, both Chinese and European, have complained a good deal with regard to two principal articles of export—viz., cassia lignea and bristles. The sales in both these articles are on condition that good average of the season is shipped from China. Now it has been said during the last two years, for example, at Hanburg, nearly every shipment of the said articles has been found unsatisfactory, and has been arbitrated on. This has, of course, given great trouble to the agents of Chinese exporters, and if there is not found a remedy it

is expected that the German markets will lose the business altogether in favour of Trieste.—*Chemist and Druggist*, March 1.

BOLIVIA AND ITS NEW TERRITORIES.

The United State's Consul at Para has transmitted to the Department of State a report on the recent settlement by arbitration of the boundary between Brazil and Bolivia. Under this settlement a large area of territory has been transferred from the former to the latter country. The report was made by the Hon. Florian Zambrano, High Commissioner and Financial Agent to the Bolivian Government, in answer to questions submitted, and the Consul says that the extent and value of the lands transferred to Bolivia, together with the desire of that Government to encourage colonization by means of subsidies, land grants, exemption from duties and taxes, and other special privileges, give the decision of the Commission a great importance. The part of the communication which deals with concessions to capitalists and colonisers will probably be found of interest to those who contemplate the opening up of relations or setting business terms in the territory in question. "The Government of Bolivia," it says, "grants large tracts of uncultivated land to capitalists who intend to colonise our territories; admits free of duty and other taxes all machinery, factories, tools, and agricultural implements, and protects and guarantees the personal safety, work, and property of all foreigners. In the high region, or rather the plateau of the Andes Mountains, there are rich mineral deposits. In the middle region wheat is cultivated and also the best Indian corn, potatoes, grapes, &c. On the great eastern and north-western plains coffee, cocoa, sugar cane, and many other tropical products are cultivated, and rubber, vanilla, &c., are extracted. There are also many gold mines and placers of incalculable richness. The rivers which the treaty with Brazil now incorporates into Bolivia are the Acre and Yacu with their affluents, the Upper Purus and Upper Juruá and their affluents. The rubber exported from the Acre and its affluents alone reaches 3,500 tons per annum. The total export of rubber from the other rivers just named amounts to another 5,000 tons per annum, and is increasing yearly. I am told that many rubber planters from the Acre wish to sell their plantations. The Government of Bolivia has decided to establish and subsidise a line of foreign steamers to ply between European ports and Para. There is no contract yet for this project, and the Bolivian Government is disposed to accept the best proposal which may be presented."—*London Times*, Feb. 24.

PLANT TREES.—brethren, in your mission compounds, in the unsightly spots and ungainly corners; and plant valuable trees while you are about it. A friend told us last week of a tree said to be about three hundred years old, standing in one of the historic cities of Bengal, for which the present owner has recently refused R4,500! Unfortunately, the owner does not happen to be a missionary. The tree is a choice species of mahogany, every inch of the wood of which is of value. The man who planted it probably never dreamed of the enrichment he was providing for a far-down-the-line descendant.—*Indian Witness*.

CHINA TEA FOR RUSSIA.

It is stated that all tea coming to Vladivostok and Nikolaevsk is subject to a duty of 24 roubles the pood (50s. per 36 English pounds), while it has been decided that tea coming overland, *via* Dalny, shall pass into Russia entirely free of duty. Obviously this new enactment will create a very considerable amount of business for the Manchurian Railway.—*L and C Express*, Feb. 28.

PEARL TRADE IN AUSTRALIA.

HOW IT IS BEING HAMPERED: IN FAVOUR OF HOLLAND.

Brisbane, March 3.—Mr. James Clark, whose firm, Messrs. James Clark & Co., holds the largest interest in the pearl-shelling industry, was interviewed today in connection with the recent visit of the Dutch warship to Thursday Island. He stated that the restrictive laws of the Commonwealth, by prohibiting employers indenturing suitable divers from Japan, Manila, and the Malay Archipelago, were already cramping the pearl-shell business, and unless some amendment is made to enable the employers to obtain sufficient suitable labour the industry would certainly be lost to Queensland. The best divers came from Japan, and before the federal enactment there was an agreement between Queensland and Japan permitting a certain number of Japanese to come here—about 200 per annum—and if this supply was stopped they would soon be compelled to relinquish operations for want of labour. The Dutch Government had established a training station at Meranke, and was endeavouring to secure a transference of the head quarters of the pearling industry to its territory. Unrestricted trading facilities were offered, and freedom for employment of coloured labour. As a greater part of the fishing was done beyond the Queensland three-mile limit, the pearlshellers would be enabled to work practically on the same ground as at present. Mr. Clark's firm employs 550 men, and is quite willing to go on as formerly if the Federal Government permits him to obtain the necessary labour. Otherwise there is nothing for him, he says, but to accept the offer of the Dutch, and become a naturalized subject of that country.—*Adelaide Observer*.

PEARL FAMINE IN LONDON.

A REMARKABLE RISE IN THEIR VALUE.

Pearls of great price are more than proportionately difficult to obtain just now. Moreover, they are likely to remain so for some considerable time to come. It is not that a lady desiring to obtain a valuable set would be unable to do so—only the price would probably be a memorable one. Why is there this remarkable rise in pearls? There has been no corner in them, though as a matter of fact Americans have been buying extensively in the wholesale trade of late, but this was only as a business speculation. At a famous Strand jeweller's a *Morning Leader* representative was told that for one thing the last yield of pearls had been a very poor one, and for another that pearls had

been gradually increasing in value for the past thirty years. "And particularly in the last four or five years. And," it was added, "if I were to purchase pearls today I should reckon they would be 10 per cent. more expensive this time next year. Of course, if a customer wanted a set, they could always be got, though I have never known the price to be so high, and I am speaking for over thirty years. Still, there is undoubtedly a craze for them at the present time, and when the season commences there will be a bigger demand than ever, for Americans will have them at any price."—*Morning Leader*, March 3rd.

A FIND OF BIG PEARLS.

Twenty-five pearls, some as big as large-sized shots, were found in a mussel on Saturday by a fishmonger at Sittingbourne.—*Daily Mail*, March 3rd.

FOR AN INDIAN TEA CESS. THE MEMORIAL TO THE VICEROY.

The following is the text of the Memorial that has been addressed to His Excellency the Viceroy and Governor-General of India by persons, firms, and Companies owning tea estates in British India:—

HUMBLY SHewETH—That your Memorialists who are very largely interested in tea cultivation in British India, the gross total of which is now estimated to be some 520,000 acres, representing a capital investment of some twenty-five million pounds sterling, venture to approach Your Excellency with the following representations, in order, if possible, to enlist the good offices of Your Excellency's Government in aid of the efforts of the Indian Tea Association to raise funds by the imposition of an export duty on Indian tea the proceeds to be devoted to the work of pushing the sale and increasing the consumption of Indian tea, in countries other than the United Kingdom.

2. The course which your Memorialist urge should be adopted is one which has been followed for the last nine years in Ceylon, in which Colony an export duty on tea of 10 cents per 100 lb was levied in 1892, under the Ordinance No. 15 of 1892 of the Government of Ceylon, in order to provide the Ceylon planters with funds for the adequate representation of their Teas at the Chicago Exhibition of 1893. The application of the funds derived from this duty proved so successful that, in 1894, the temporary duty of 10 cents per 100 lb. was by the Ordinance No. 4 of 1894 of the Government of Ceylon converted into a permanent duty, the rate being increased from 10 cents to 20 cents per 100 lb., which it was directed should be applied towards increasing the consumption of Ceylon tea in foreign lands in such manner as might from time to time be desired and determined by the Joint Committee appointed by the Planters' Association of Ceylon and the Ceylon Chamber of Commerce, referred to in the last-mentioned Ordinance. The sum thus raised in Ceylon amounts on the average to very nearly Rs lakhs per annum.

3. In India, a voluntary levy for the same purpose, instituted and administered by the Indian Tea Association, is and has been in force since 1893, but the subscribers to that levy hitherto have not represented more than about 75 per cent. of the Indian tea growers, and the sum collected has been considerably less than half that realised under the Ceylon tax. The Indian tea-industry therefore has been compelled, through want of funds, to confine its attention mainly to the markets of North America, while Ceylon on the other hand has been able to make sustained efforts to satisfy and increase the demands for its teas not only in the American markets, but

also in the other markets in the world, with the result that India has only been able, owing to lack of funds, to make considerably less progress than Ceylon, the figures of last year showing that, while Ceylon, with a production of about 150 millions of pounds of tea, sent over 49 million pounds, or nearly 33 per cent., to foreign countries, India with a production of 190 millions of pounds sent only about $3\frac{1}{2}$ millions, or about 18 per cent., to foreign markets.

4. Owing to the great increase in the production of Indian and Ceylon teas during recent years, the supply to the markets of the United Kingdom has been largely in excess of the demand, and it has only been possible to find an outlet for a portion of this surplus by a continued reduction of price, while the world's stock of British-grown tea has materially increased.

5. Taking the position as it at present stands, the result so far has been that the average price of Indian tea has been continuously falling until a considerable proportion is being sold below the cost of production, and it is clear that tea-growing in India on a remunerative basis can only be continued by comprehensive measures being promptly taken to open new markets.

6. Your Memorialists feel that it is unnecessary to enlarge upon the importance of maintaining the Indian tea-industry on a remunerative basis, as well because of the very large amount of capital embarked in it, as of the importance of keeping in cultivation extensive tracts of land yielding a direct revenue to Government, and providing large numbers of the native population of India with employment, and they submit that it is thus to the interest of the Government of India to render assistance to the tea industry, especially having regard to the fact that the assistance which it is the object of this Memorial to invoke will not involve any burden on the public revenues.

7. Past experience has shown that it is not possible by means of a voluntary levy to collect sufficient funds to carry on the work of developing foreign markets for Indian tea to anything like sufficient extent, and that no organisation is possible as a result of voluntary effort which will ensure uniform subscriptions being paid by all proprietors. Were the levy made compulsory, your Memorialists are confident it would be cheerfully paid by many who will not contribute to a voluntary assessment.

8. That such an organisation can be made effective is proved by the success of the measures adopted in Ceylon, the operation of which has been to ensure the provision of the funds which have enabled the Ceylon Tea-Industry, by fostering and developing foreign markets, to divert increasing quantities of tea produced in that Colony to such markets, and your Memorialists submit that, under the circumstances, the only practical means of attaining the end they have in view is for those interested in the Indian Tea-Industry to follow the example of Ceylon. This, however, can only be done with the aid of Government in the manner above indicated, and it is the object of this Memorial to interest Your Excellency's Government to render such aid.

9. Such a duty as that levied in Ceylon, if fixed at the rate of only one-fourth of a pie per pound of tea, would yield more than twice the annual amount which the voluntary cess has produced, or a sum approximately equal to that raised in Ceylon, and your Memorialists therefore suggest that the amount of duty levied on Indian tea should be at the rate of one-fourth of a pie per pound. This would produce a sufficient sum to develop new markets for Indian tea, as well as to promote its consumption amongst the natives of India. The importance of efforts in this direction, which Your Excellency has strongly urged upon the tea planting community, has been recognised by the Indian Tea Association having assigned for this object Rs40,000 of the comparatively small sum produced by the voluntary levy now in force.

10. Your Memorialists are not insensible to the fact that it may be urged as an objection to the course which they desire should be adopted that if they had taken precautions to restrict output, they would have provided themselves with a simple and efficient remedy for the evil of which they complain; but with reference to this they would urge that the rapid increase in the production of tea of late years is mainly due to the large extensions both in India and Ceylon, which were undertaken when exchange with Europe was at a low level. The closing of the Indian mints and the subsequent advance of exchange to $1s\ 4d$ had an adverse effect on the tea industry, and many tea estates, which with a low rate of exchange could have been worked to a profit, are not, as matters now stand, capable of earning sufficient to meet their outgoings, and must in time be abandoned and go out of cultivation, unless some change in the conditions of the industry can be brought about.

11. Your Memorialists also recognise that, in view of the fact that in India tea is shipped from several ports, while shipments from Ceylon are practically all made from one port, the collection of an export duty on tea such as they suggest would present somewhat greater difficulties in India than is the case in Ceylon; but they believe any difficulties on this score could be readily overcome with the co-operation of the Executive Department of Your Excellency's Government and without incurring any material extra expenditure. In Ceylon no charge is made for collecting the tea duty imposed under the Ordinances in force in that Colony, the whole of the duty collected being handed over to a Joint Committee—the "Thirty" Committee—of the Ceylon Chamber of Commerce and the Ceylon Planters' Association. The Government of Ceylon, however, reserve the right to see that the funds derived from the collection of the duty are not distributed otherwise than a manner likely to be beneficial to the tea industry, and your Memorialists venture to urge that in the case of the duty on Indian tea which it is the object of this Memorial to induce Your Excellency's Government to levy, a similar course should be adopted.

12. Your Memorialists desire to submit in support of the prayer of this Memorial that the proposal they have made is one which affects the Tea-Industry only, and that its adoption can have no adverse influence on any other trade or industry or on the community in general. The duty will be paid by tea growers and its proceeds will be expended by a Committee for the benefit of the industry at large. On the other hand, the increased prosperity which your Memorialists believe will result from the imposition of the proposed duty would ensure to the advantage of the State (without imposing any burden on its resources) in assisting an industry from which it derives a considerable revenue, and which provides employment for large numbers of the people of India.

Your Memorialists humbly pray Your Excellency to take this Memorial into consideration with a view to the necessary measures being adopted to provide for the levying of an export duty at a rate not exceeding one-fourth of a pie per pound for a limited period of five years on all tea exported from India, and for the amount of the duty so to be levied being applied towards increasing the consumption of Indian tea in India as well as in countries outside the United Kingdom, and otherwise in such manner as may from time to time be desired and determined by a Committee to be approved by Your Excellency's Government; or that such other measures may be taken as Your Excellency may consider practicable to give effect to the wishes of your Memorialists as herein expressed.

And your Memorialists as in duty bound will ever pray, etc.

[Signed by 302 persons and firms having under tea cultivation a total of 280,604 acres.]

CRUDE RUBBER.

EXPLORATION, PLANTING AND CULTIVATION NOTES.

The *Tropenpflanzer* publishes in a private letter of the director of the Botanic Garden in Victoria (Cameroons) the interesting fact that trees of seeds of *Kista elastica* planted there in November, 1898, are now already three metres high and begin to bloom, and contrary to Hevea, give their milk very easily. The Heveas planted there have now already fruited; the real *Ficus Vogelii* supplies good caoutchouc in plenty. Also *apium-utile* exists in a few species in the Garden. Dr. Preuss reports from the Moliwe plantation that the Castilloas, which are there in great quantities, flourish well, but not the Kixias. *Mascarenhasia elastica* and *Tabernaemontana Donnell Smithii*, which might become a useful gutta-percha plant, also grow well. There were only a few species of *Pavena Deerii* and a few Hevea trees. As the Castilloa grows well, according to the report of the late Mr Stanler, chief planter at Moliwe, the Plantation Company had ordered, at the suggestion of Professor Warburg and through the aid of M. Koschng 400,000 Castilloa seeds from Costa Rica in this year. The greatest part of these seeds received in Hamburg perished in the long voyage, but it is hoped that after all it might still be possible to send 100,000 Castilloa trees this summer in a living state to the Cameroons.

The caoutchouc export from Iquitos, in Peru, amounted in 1900 to 859,327 kilos, value 2,245,138 sols. The chief quantity has been shipped to Havre, with 576,615 kilos, and the rest of 282,712 kilos to Liverpool. These figures consist of the following rubber descriptions:—Jebe fino, with 296,828 kilos, value 941,943 sols; Jebe entrefino, with 21,988 kilos, value 64,493 sols; Sernamby de Jebe, with 142,992 kilos; value 352,714 sols; Caucho, with 81,950 kilos, value 134,959 sols; Sernamby de Caucho, with 315,500 kilos, value 751,033 sols. The Rio Javary district exported last year 528,313 kilos, value 1,533,047 sols. Of this 374,116 kilos, with a value of 1,187,195 sols, were Jebe fino; 9,325 kilos, value 27,553 sols, Jebe entrefino; 95,571 kilos, value 235,742 sols, Sernamby de Jebe; 40,335 kilos, value 66,418 sols, Caucho; 8,966 kilos, value 21,339 sols, Sernamby de Caucho. The average prices during the last two years were as follows:—

VALUE IN SOLS.

Kinds.	1st half.		2nd half	
	1899.	1900.	1900.	1900.
Jebe fino ...	51 ...	52 ...	43	
Jebe entrefino ...	48 ...	48 ...	37	
Sernamby de Jebe ...	42 ...	42 ...	30	
Caucho ...	30 ...	30 ...	20	
Sernamby de Caucho ...	43 ...	42 ...	30	

The prices stand for one Portuguese arroba of fifteen kilos, and one sol may be counted as 2s. The caoutchouc export from Iquitos and the Javary district taken together amounted in 1900 to 3,785,185 sols against 2,889,402 sols in the preceding year. The caoutchouc harvest in Iquitos was still worse in 1900 than in 1899. That in spite of this the export values of Iquitos were nearly the same as in 1899, is due to the fact that last year more people were employed in getting fine rubber than in 1899. In the district of Rio Javary, on the other hand more rubber was

produced than in 1899. The weather was more favourable to the rubber gatherers in this district than in the Ucayali regions. From a report of the Imperial Vice Consul at Iquitos.

CAOUTCHOUC of *Manihot glaziovii* from a plantation in the German East Africa, has been tested by the Colonial Economical Committee, and proved to be of a good quality of white colour, and good elasticity. The chemical test resulted in 89.5 per cent of first-class caoutchouc and 1.7 per cent of second quality.

Mr H Lecomte has published in No. 4 of the "Bulletin du Museum de Paris" an interesting article on this question,—the coagulation of caoutchouc (latex)—which is the result of observations made during his voyage to the Congo in 1893 and 1894. He made a study of three different kinds:—

Ninga—*Landolphia owriensis* Pal. Beauv.

Malombe—*Landolphia florida* Benth.

Zaon—*Landolphia Klainii* Pierre.

The first one gave a good product, the second a useless product, and third a good caoutchouc.

The results of these processes by M Lecomte showed quite distinctly that the phenomenon of the coagulations is closely adapted to the special nature of the latex, and it is therefore necessary to find out which medium is most suitable for each special latex. According to Mr Lecomte's experiments the heat seems to be the best active coagulator for these two *Landolphia*. If the water is well removed a caoutchouc of a white colour will be obtained, which remains without becoming odorous, and which is due to the absence of albuminous substances in the solution.

For some time the sales of the rubber coming from French Guinea have been much smaller. This depression is due to several causes, to contact which the "Permanent Committee of Trade and Agriculture in French Guinea" have issued the following regulations:—1. Adulterated caoutchouc is prohibited from being exported. 2. Adulterations are taken to include moist sorts of rubber, caoutchouc mixed with roots, glutinous rubbers and those which contain other strange materials than particles of the bark incorporated during the process of obtaining the rubber, and of these not more than about one per cent. of the total weight. 3. Neither the Custom House offices on the frontier, on the coast; nor in the country can in consequence allow any caoutchouc of the above description to pass for shipment to Europe. By these vigorous means the authorities hope to raise the reputation of the Conakry caoutchouc, which has much deteriorated in price in the European market, whereas its neighbours enjoy a much better reputation.—*India Rubber and Gutta Percha Trades Journal*, Jan. 20.

CULTURE IN PEATY SOIL.—A discovery of M Dumont which may be useful in Ireland and Scotland, where peaty soils are common, is given in the *Comptes Rendus* for December 23 ult. It is to add carbonate of potash, or matter able to form this by double decomposition, to the soil. The carbonate renders the humus nitrifiable, and favours the action of ammoniacal ferments or manure, making the soil fertile. A paper by M M. Deherain and Demoussy in the same number shows that truffles can be grown in peaty soil when lime and potash are added, and the soil is inoculated with garden bacteria.

THE MARKET FOR CARDAMOMS.

A sale of 200 cases of cardamoms last week had no depressing effect on the market, and, in spite of the heavy catalogues, a considerable quantity changed hands at an advance of 1d to 2d per lb. The shipments in 1901 amounted to 59,704 lb, against 537,455 lb in 1900 and 499,959 lb in 1899. What this year's total will be, the future alone will show. If any estimates were obtained of the probable planting area, some idea as to the total yield might be formed. Will 6,000 acres, or even more, be devoted to the cultivation of cardamoms? In 1898 the planting area was counted to be a little over 5,100 acres, whereas in 1856 not a single acre was planted with the berry. Since then proprietors of tea gardens have recognised the value of cardamoms as a by-product to tea, and they have expended no end of time, money, and ground on their improvement, with the result we have seen in today's auctions. A beautiful berry, well clipped, excellently bleached, and full of rich seed is, says the *London Commercial Record*, not obtainable at a considerably cheaper price than demanded for the old fashioned Malabar sorts from East India. Ceylon has cut the ground from underneath the Indian rival, who has almost become a thing of the past, although the delicacy of flavour which these berries possessed will remain in our memory, for it will hardly ever be reached by the Ceylon descriptions. —*Home paper*, Feb. 28.

MISSION WORK ;—AND IRRIGATION.

(Extract from a letter of Sir J. J. Grinlinton.)

Feb. 20th, 1902.

The very interesting article in the daily *Observer* of 1st February (headed "India at the end of 1901: some recollections"—or rather I should have written reflections—"on notes by the way" during a trip of 6,000 miles) has caused me to feel that I must give expression at once to the feelings uppermost in my mind. I regret that I have never been in India proper, but my life in Ceylon has enabled me to follow most of your remarks, more especially your "firm belief" in the progress of Christianity amongst the natives of the country where the Missionaries have been steadily working for years. One of my last acts as a public man before leaving Ceylon was that of presiding at the annual gathering at that beautiful little spot, Cotta, where the Church Missionaries have been at work for many years. My recollection of the place, when I was a young fellow and took but little interest in Missionary work, enabled me to contrast the two periods, and I took the opportunity of doing it to the people themselves. In the earlier period I noticed only very few Sinhalese mothers taking part in the service with their children, but on the last occasion I was unable to count the mothers and grown-up girls: they were so numerous, and all took part in the singing which had been taught them by our lamented friend, the Rev. S. Coles, who was then present and looked so happy in leading the singing. The large open building was full of bearded men who had been educated at Cotta and hundreds had to remain outside the building. It was indeed a pleasant sight, and left a deep impression on me; so much so that I have often since then, in public and in private, narrated the circumstances. The influence brought to bear on CHILDREN BY MOTHERS WHO HAVE BEEN TAUGHT IN THE MISSION SCHOOLS is great, and it is only when two or three

generations have been so educated, that one sees the great advantage, as well as the manifest progress made in Mission work—and the improvement in the intelligent *look* of the people.

Your allusion to irrigation naturally attracted my attention. India led the way in this during the great General Cotton's time, but during recent years comparatively little has been done, but I am thankful to say that in Ceylon great progress has been and is still being made. Through the courtesy of the Governor the Minutes of the Irrigation Board are regularly sent me. Not alone does Irrigation enable good food to be obtained by the poorer people who live in places remote from towns and "highways," but it supplies them with *good water* instead of the filthy water they had during dry seasons in former times.

BIG GAME IN THE STRAITS.

LARGE ELEPHANT SHOT BY MR. EPHRAUMS.

Galle, March 20.

Mr Lennie Ephraums, Manager of the New Oriental Hotel, has just heard from his cousin Mr Cyril Ephraums, the well-known sportsman in the Straits to the effect that he shot another big elephant on the 27th February. The tusker was bagged 13 miles from Seramban in an abandoned coffee clearing in dense undergrowth, and was tracked for 2 miles when he came to him quite quietly. The animal was bowled over with a single shot from an 8-inch bore rifle, 12 drachm of powder and 2½ oz. steel tipped bullet. He received the shot about 3 inches above the left eye, dropped in his track and never moved again. The tusks are described as a lovely pair and very fine ivory. The measurements are:—

Total length including tail 21 ft 4 in; from tip of forehead to base of tail 10 ft; ear to ear-tip to tip 9 ft 9 in; breadth of skull 3 ft; circumference of foot 3 ft 6 in and height 9 ft 4 in.

MR. ALEX. WHYTE, F.Z.S., &C.

This well-known Naturalist, formerly of Kandy, and latterly so much identified with East Africa has, we learn, just left England for Uganda, delighted to get away from this wretched English climate,—his five months' holiday having mostly been spent in a sick room!

CEYLON PLANTERS' RUBBER SYNDICATE.—

We publish on page 678 the report of this Company and the proceedings at the annual meeting on 28th Feb., when it was resolved to raise the nominal capital to R250,000, as the funds at present are insufficient to carry on the work of the estate. During the autumn it is proposed to raise 80 new shares at par to go to existing shareholders in proportion to their holdings. Liberian coffee seems to be well thought of, and it is expected that from the beginning of 1906 the estate should be self-supporting. Only 350 acres have been planted, and the reason, it appears, for the whole area not having been planted is that bad seed was secured. Catch-crops have not been a success and it is now proposed to do away with all these except coffee.

PLANTING NOTES.

"TALGASWELA" AND THE WORKING OF A TEA COMPANY'S ESTATE.—The letter we publish elsewhere from "Critic" will be useful to others pursuing the same vocation as he. The gist of our correspondent's remarks is that the superintendent responsible for expenses should have full freedom of action in obtaining his materials, so that his responsibility should be in no way nominal—a fairly reasonable plea.

BUDDING ORANGES.—Some advance has been made in the propagation of the improved kinds of oranges during the present year, and a fairly good stock of strong-budded plants is now on hand. This it is trusted will do away with the complaint so frequently heard of oranges proving sour when raised from seed, a case of which occurred during the present week. The stock used is that of the Seville orange which does not suffer in our climate from stem rot or Mal-di-gouma, as do the best of our St. Michael's and Tangerine kinds. The "Washington Navel" is among the varieties successfully budded. These plants will, of course, be put on sale in the Nurseries as soon as a sufficient number are on hand to meet the demand. I learn that in some instances the pupils who attended the Agricultural Lectures are meeting with fair success in budding and grafting.—*Trinidad Bulletin.*

GREEN TEA PROSPECTS IN CEYLON.—A planter of wide experience writes:—

"The green tea bonus now requires watching on the part of the 'Thirty Committee.' So far as it goes Messrs. Finlay, Muir & Co.'s agency for the American Green Tea Syndicate appears to adopt the method that will meet the requirements for the green tea bonus. Some rumour has got about that green tea is being used by the blenders in Colombo to mix with black, this green tea having received the bonus from the Cess. This may account for the exports of green tea not tallying with what has been paid by the Planters' Association on green tea invoices. The green tea factory is at work at Nawalapitiya. It is rumoured that they are purchasing 1,000 lb. of leaf daily. The factory is supplied with excellent rollers and driers driven by an old machine, steam roller, supplied by a boiler, for steaming the leaf."

COCONUT PLANTING IN FIJI.—Mr. V. H. Tarte, who left Ceylon this week (after nearly a month's visit) on his return to Fiji, visited Goluapokuna Coconut Estate and saw there the typical methods of local cultivation, which he said offered a great contrast with Fiji. In Fiji, he said, practically nothing was done in the way of manuring, artificial or otherwise. The Fiji trees tapered to the top and did not bear such fine nuts perhaps as our finest—though their natural growth showed quite as well on the average. On learning the very little extra expense, Mr Tarte became determined to go in for manuring when he got back to Fiji and promised to inform us of the results. There was a thoroughly adequate market, he told us, for all the coconuts (and copra, especially) that Fiji could produce—Messrs. Lever Bros., for one instance, having secured practically all the crops they could contract for up-to-date.

KELANI TEA GARDEN CO.—No dividend has been declared for the past year, but a substantial balance has been carried forward, and we think the shareholders have every reason to be very hopeful.

MR. R. V. WEBSTER—is now, in all probability, Visiting (Land) Agent for the Transvaal Government. His communication elsewhere gives information of leading interest to Ceylon planters who may be looking towards South Africa.

FUNGUS ON CACAO.—We have received a monograph on *Diplodia cacaoicola*, P. Heun.; a parasitic Fungus on sugar cane and cacao in the West Indies by Albert Howard, B.A., A.R.C.S., F.L.S., Mycologist to the Imperial Department of Agriculture for the West Indies, late scholar of St. John's College Cambridge, with plates.

PLANTING IN FIJI.—Ceylon planters will find further valuable information on planting in Fiji in our issue. Bananas appear to be the simplest and least troublesome product; cacao gives promise; vanilla is abundant, but is scarcely taken seriously; tea, we are glad to note, does not receive great attention, though there is little against it, beyond "over-production"; and tobacco grows very well, requiring nothing but the opening of more land. This does not exhaust the list, but gives a fair selection.

PLANTING IN JAVA: COFFEE, CINCHONA, AND SUGAR.—In the colonial report recently published, the Java Government has stated its views about the coffee cultivation. The intention is to encourage the free cultivation in the same manner as was already done in the residencies Passeroean, Proboling, and the Preanger, namely, by allowing a restitution per bouw to be divided on the three first years of the coffee plantation, but with the necessary caution, and only on such estates as promise a proper production for a long time. As regards the compulsory cultivation and the delivery of coffee, there is only an unimportant increase to be observed in Tagal, Pekalongan, and Madioen during 1899 to 1900. Of the other 11 districts more or less of a decrease is to be reported. The decrease in the leaf appeared in 1900 in all districts. Both in 1899 and 1900 the out turn of the Government's coffee crop remained under the estimate. The Government's cinchona cultivation has shown a satisfactory result owing to the advance of prices. The quinine market at Batavia has exceeded the expectations in 1900 and for 1901; still better results were expected. Referring to the economical condition of the natives the report says the amounts paid to them by 137 sugar manufactories in 1900 amount to a total of more than 33,000,000 guilders, being about £241,000 on the average for each manufactory. In the meantime a petition of the principal firms and companies at Amsterdam, Rotterdam and The Hague, concerned in the Java sugar cultivation, has been sent to the Minister for the Colonies, asking for a temporary reduction of the railway freights for the article. Java sugar is again passing through a serious crisis. In 1900, 22 manufactories of the Netherlands India Agricultural Company fetched a price of £6.74 per picul without interest on shares and bonds but including the expenses for the improvement of the manufacture.—*L. and C. Express*, Feb. 28.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilleja Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilleja seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilleja does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimosa Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February; also plants.

Coffee Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel, and Ornamental Trees, Trees for Roadsides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREAMY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

WILLIAM, HENARATGODA, CEYLON.
Liber's, A.I. and A.B.C. Codes used.

Correspondence.

*To the Editor.*PLANTING IN FIJI: COFFEE, CACAO,
TOBACCO, TEA, &c.

March 14.

DEAR SIR,—You will recollect the letter in your *Observer* issue of 21st November, 1901 from a Fijian correspondent and the useful information you supplied regarding Fiji, three days later. Having lately had a long and courteous letter from the same gentleman, I purpose giving you a few extracts from it for the purpose of placing before such of your planting readers as may be seeking "pastures new," a truer version of the state of affairs in Fiji today than we are accustomed to hear in Ceylon; our information being taken from the experience of men who went there 20 and 15 years ago and had to leave it, disgusted with the ante-European governments of Sir J B Thurston etc. All that is now changed. And here is what he says:—

"I regret to say that in the whole of this group there is not a single planter or a plantation such as is understood in Ceylon but the country is crying out for good men with a little money and I know every possible assistance will be given by the Government and Banks to proper *bona fide* planters who may come here.

"Under the late Sir J B Thurston's administration everything was done to check and baulk the influx of Europeans but that order of things has passed. We have now new lines of steamers and shall have cable communication before the end of 1902.

"You have probably been told that coffee had leaf disease here; soil may possibly have had—but the principal grower 20 years ago fell out with the Governor, Sir J B Thurston, and the estate was destroyed by order of the Government, more out of personal enmity than because of the leaf disease! Another small coffee planter who had not satisfied the native owners of land, lost all his coffee; but we happen to have as neighbours the very natives, who declare that, to get rid of him, they filled bamboos with salt water and irrigated his nursery and young plantations with it at night. All I can say is, let any one come and see the coffee growing wild and the cacao too. My brother and I have put in the first 100 acres of cacao in Fiji with seed and plants obtained from the Government Botanic Gardens, and the present administrator and all residents are mostly interested in the growth and progress of this, because very high returns are being made in Samoa from cocoa. This is the only small patch in Fiji being propagated commercially but there are some thousands of single trees scattered through the group and growing in native villages, giving immense returns per tree.

"Unfortunately we cannot give all our time to the cacao as we have to make expenses out of the shipment of bananas, which also act as shade to the young cacao, and are now more than paying all costs. There are some 20 or 30 banana planters who grow nothing else. The largest of these has under 500 acres, and one and all know little of the plant they cultivate, nor do they

study the question. They stick in a sucker and wait 9 to 15 months for the fruit, where a Ceylon man would thrash out the matter and find out the banana most suitable for the country and the market and ascertain how to produce large healthy bunches of uniform size, etc.

"Coffee, pimento, vanilla, pines, rubber, and all citrus fruits are thriving splendidly on our place. Vanilla grows wild everywhere; it has been introduced in the group, but only one planter cures it at present. Rice cultivation was started 3 months ago and promises well, and cardamoms were introduced last month and seed just germinated.

"Tobacco is first-class but we have only one maker. All the cigars sold here are manufactured in the group but they are not sufficiently made to export. Copra—very little—is being planted, all the present owners of copra estates having bought in at nominal figures 10 years ago when the price dropped and the few enterprising men could not afford to hold on; but prices are good now and there is much money in copra (coconuts).

"Personally I know nothing about tea but, as far as I can judge, I should leave it alone in favour of copra, cocoa or coffee. There is only one tea estate managed by a man from Ceylon and owned by a storekeeper who is desirous of selling, as he has other interests to attend to. It is 600 acres, of which 300 are planted up (age not stated). Their out-put is about 40,000 lb. per annum but they can barely supply the local demand. All Fiji-grown tea is protected by a duty of 6d per lb. The above is a good going concern with modern machinery and is run by Indian coolies indentured."

I gather from my correspondent that there is not the slightest use in going to Fiji on the chance of picking up employment as a planter, but to one who has a little capital and a fair knowledge of planting there is every prospect of success. I am not at liberty to disclose publicly all of my correspondent's letter—and this is not an advertisement, but is meant for the benefit of those planters who are obliged to look out elsewhere—at the same time I shall be glad to give any further information in my power.—I am, dear sir, yours faithfully,
MACARONI.

"KAINIT": A NEW MANURE FOR
COCONUTS.

Colombo, March 18.

DEAR SIR,—We beg to hand you enclosed copy of our leaflet. The value of Kainit which we think will be of interest to all your readers of the planting community. Kainit should prove a great success with all those who grow coconuts and keep cattle, etc. The experiments made at home are a striking proof of its use in connection with farm manures.—We are, dear sir, yours faithfully,

FREUDENBERG & CO.

[We quote one paragraph, and further particulars will doubtless be supplied to enquirers, by Messrs. Freudenberg & Co. :—

"Kainit" prevents the loss of nitrogen and humus matter. A considerable amount of nitrogen and humus matter is lost when farm manure lies in large piles exposed to the air for any length of time. This loss can be prevented by scattering Kainit over the piles. The cost of Kainit

used will be very much more than balanced by the nitrogen saved. The yearly manure product from one cow contains 27.5 lb. of *nitrogen*, or as much is contained in 176 lb. of nitrate of soda. How important then to take every precaution to prevent its loss, especially in Tropical countries, where the stable manure decomposes very quickly.

—ED. T. A.]

THE TALGASWELA COMPANY MEETING.

Colombo, March 19.

DEAR SIR,—Mr Christie at the Talgaswela meeting certainly made out a case of the Company paying over the nose for estate work and materials supplied. What I cannot understand are the explanations given by the Directors. The accounts are correct. Every item has been paid. Examine the accounts for yourself; there they are, and the few minutes Mr Christie had, looking over them, disclosed to him charges he thought in excess of what was correct, and a number he named. He says in December last the Company paid R325 per ton for its tea-lead. This must surely be a mistake? Mr Christie states he could have purchased it in December for R310. I think he is right, as I myself purchased under a ton at R307.50 per ton, discount if paid within the month; so it's really R300 a ton, net. I purchased in January (early) at R292.50, discount it paid within the month. So Mr Christie must be taken as correct, with his price stated at R310 as the highest. Why do not the directors enforce purchase of tea lead, boxes, rice, all materials necessary, through their superintendent, who has an interest in keeping expenditure down? I know many superintendents who purchase their own supplies; but what I say is, when a manager sees, say, tea lead sent to him at R20 or R25 in excess of what he himself could buy it, he gets disheartened, and apt to get careless of keeping his own estate expenditure down to what it ought to be. Someone will say it is the fault of the manager, who ought to advise the Agents of what he himself could do, and ask if there had been no mistake in the price. Would it not bear better to allow the Superintendent. a free hand?

CRITIC.

GREEN TEA FOR CANADA.

Peermaad, March 19.

DEAR SIR,—The enclosed copy of a letter from Mr. Larkin may be of interest, as it shows Ceylon advertisement is beginning to pay in Canada. The only mistake is that we started our prices *too low*, and it will be difficult to raise them. However, if Japan's are once driven out, I hope prices may rise in Canada. I have applied for a patent in Ceylon and India for a new machine which will make green tea manufacture much less trouble. Indeed one machine is made and purchased by the Baraora Tea Co., Sylhet, who have now two of my steamers. This new machine is intended to take the moisture off the steamed leaf without having to evaporate it as at present. Should the patent be granted the machine will be advertised. It is 3 months since I applied for a patent and as yet I have had no reply.—Yours faithfully,

H. DRUMMOND DEANE,

(True copy.)

"Salada," Ceylon Tea, Toronto, Feb. 10, 1902.

H. Drummond Deane, Esq.

DEAR SIR,—We received your letter some two weeks ago and have been waiting anxiously for the arrival of the samples. These came here on Friday last and we have given them a great deal of attention, and we can say with pleasure that we have seen nothing better in the cup and nothing equal to them in style, and they are particularly well adapted to the Canadian and United States trade, and should you see fit later on to send us a small consignment, we will pay you the best market price for it. It would be better, though, to make the shipment small at first when we would have something to work on, but you can well understand that the public on this Continent, being educated up to asking for Ceylon tea, and Ceylon tea only, hardly know of India being a tea-bearing country. Practically all the advertising that has been done in America has been done by Ceylon and they have to a considerable extent created a demand for their tea and, therefore, the wholesaler is not willing to pay the same price for an Indian as he would for a Ceylon of the same quality, as it is considerably more trouble to sell the retailer who is ignorant of quality and whose customers ask for Ceylon tea. Yes, we take both "The Indian Planters' Gazette" and "Indian planting and Gardening," both of which we read with considerable interest. We hope with you that the endeavour to bring about a Tea Cess in India will be successful, as we believe that a portion of it being spent on this Continent would greatly increase the demand for Indian and Ceylon Tea as the qualities of these teas, both black and green, warrant us in believing that sooner or later they will drive out China and Japan tea entirely from this Continent. We might say in Canada today there is practically no China tea imported, the demand being entirely for Ceylon, and we are also making great headway with the greens. We regret that the samples of Ceylon greens did not reach you. We are sending now another set of two. These teas were made on a very low-grown estate in Ceylon, Devalakande; yet you will see they, being well made, are excellent green teas. They were the only two lots in this invoice and their cost laid down here 6½d, but the garden has no more to sell now, having contracted ahead with some other firm for some months; we having cabled them an order for 500 chests, that was their reply. In the invoice we are sending you, there were two-thirds of the No. 2 grade and one-third of the No. 1. I will, in the course of a few days, send you samples of a small invoice of Indian greens that I purchased recently. They are made on the Manabarrie estate in Dooars. The only sample I have at the moment are the ones we purchased on, but as soon as the teas arrive samples will go on.—With kindest regards, we are, yours truly,

(Sigd.) P C LARKIN & CO.

SOUTH INDIAN GREEN TEA IN CANADA.—We are glad to learn elsewhere of the excellent reports that Mr. H. Drummond Deane, who may be called the pioneer of green teas in South India, has received from a leading Canadian firm. Planters will also learn with satisfaction the further information that Mr. Deane has in hand, a new machine which will greatly reduce the trouble at present experienced in production.

DONNYBROOK TEA COMPANY, LTD

REPORT OF THE DIRECTORS.

Your Directors submit herewith a Statement of the Accounts for the year 1901, duly audited.

At last report the capital of the Company stood at R171,600.

being 1,026 Proprietors' Shares, and 690 Finance Shares

The Excess Expenditure for 1901 has been met by the further issue of 30 Finance Shares and 70 Cumulative Preference Finance Shares, bringing the capital of the Company up to R181,600.

ACREAGE.

The acreage of the Company's Estates are as follows:—

Tea in full bearing	.. 7	—	
Do	.. 40	37	planted in 1894
Do	.. 13	—	do 1895
Do	.. 52	—	do 1896
Do	.. —	86	do 1897
Tea in partial bearing	... 25	22	do 1898
Tea not in bearing	... 15	—	do 1899
Do do	... —	7	do 1900
		152	152 acres

Making 304 acres cultivated in tea—

4 acres forest
67 acres Chena, Patna and waste land,

which totals 375 acres as per the Company's Books.

The estimated crop for 1902 is 200,000 lb. Green Leaf, being 177 lb. tea per acre on the 282 acres over 3 years old. The estimated expenditure shews an excess of R4,400 over receipts.

Mr. W Shakespeare retires from the Board by rotation, and is eligible for re-election.

The appointment of an Auditor for the current year rests with the meeting.

THE NAHAVILLA ESTATES COMPANY, LIMITED.

THE DIRECTORS' REPORT

was next submitted as follows:—

In presenting a statement of the accounts of the Company for the year ended 31st December, 1901, the Directors beg to report as follows:—

The conditions attendant on the production of Crop were very adverse compared to those of the preceding year, more particularly towards the latter part of the season.

The yield of Tea in consequence fell short of estimate, and was 15,134 lb. less than the crop of 1900, namely, 524,840 lb. against 539,974 lb.

Owing to an unfavorable turn in the market at one period of the season, the price per pound realised for the produce was also somewhat less than last year, namely, 34.84 cents against 35.42 cents, a difference of a little over half a cent.

Coffee, upon which much reliance cannot now be placed, was also deficient in quantity, and sold for R3,181.35 less than the previous year.

A short crop generally means a relatively high cost of production, but in this case it works out at 28.00 cents per pound as compared with 29.42 cents last year. There has, however, been very little manuring done this year.

A sum of R43,978.61 appears as surplus of Revenue over Expenditure. Out of this has been paid R12,375.87 for interest on mortgages, and R3,500.00 has been carried to a Depreciation Account.

After payment of Superintendents' Bonuses, Secretariat and Auditor's Fees, &c., there remains at Profit and Loss Account a sum of R21,592.17 to be disposed of.

The Directors recommend the payment of a Dividend of 2½ per cent on the paid-up Capital of the Company. This will absorb R9,912.50; and the

balance after payment of Directors' Fees they propose to carry to Extension Account to go against the further Capital outlay.

Owing to the deficiency of Capital at the outset of Company, development out of revenue still has to go on though not to such a large extent as of late years, during which demands have been heavy. It was mentioned in last report that R30,000 was estimated as the further capital outlay required, and nearly a third of that has been spent this year.

The most pressing need, not yet estimated for, is the installation of Water Power for the Factories on Ury and Nahavilla. Mr J M Mason, when forwarding the last Visiting Report on these properties, writes as follows:—

"You will notice that I have written rather fully on the subject of water power for both Factories. If the Funds can be raised, I think it would be good policy to erect Pelton Wheels on both places. Personally, as a Shareholder I would willingly forego any dividend this year, if by so doing the water power installation could be put through at once," "so convinced am I of the benefit of doing so."

There is no doubt that it would effect considerable economy in the working. Firewood for the Engines becomes daily more scarce and distant, and consequently increased in cost. The Directors propose, therefore, to put the work in hand as regards one, if not both Estates, as soon as finances allow.

The condition of the several Estates is favorably reported on, and the Tea Crop for the coming season is estimated at 597,500 lb. costing R156,241, or say R27.82 cts. per lb. Besides this the sum of R11,216 is set down as necessary expenditure on Capital Account, namely, for Machinery on Nahavilla, Fans on Ury, and Road Instalment on Galella.

ACREAGE.

	Naha-	Ury,	M P G.	Galella.	Total.
Tea in full bearing	317	375	217	287	1,196
„ „ partial bearing	48	146	35	—	229

Grass, Fuel trees, P'na, &c	71	132	84	254	541

Total .. 601 766 341 613 2,321

The Directors regret to have to record the loss the Company has sustained in the death of their late colleague Mr. A Orchard, whose lengthened experience of planting in the Island made his advice of much value. Mr. J M Mason has been asked to take his place on the Board.

Mr. Gordon Pyper retires by rotation from the Directorship, and is eligible for re-election.

The appointment of an Auditor for the following year rests with the Meeting.

COLOMBO COMMERCIAL CO., LTD.

ANNUAL REPORT

To be presented to the seventh ordinary general meeting of the Company, on Monday, the 17th March, 1902, at 12 noon:—

The Directors have pleasure in placing before Shareholders—

Profit and Loss Account for the year ended 30th September, 1901.

Balance sheet made up to 30th September, 1901.

The above accounts shew the following figures:—

	£	s.	d.
Profit for the year after debiting all charges, interest on debentures, &c.,	8,548	9	8
Add balance brought forward from last year	2,166	11	9
	10,714	15	5
Less transferred Reserve Fund	2,000	0	0
Am available for dividend &c.,	8,714	15	5

Interim Dividends of 3 per cent. on the Preference Capital and 2½ per cent. on the Ordinary capital were paid on the 17th September, 1901, and the Directors recommend that the following dividends be now declared, viz. :- 3 per cent. on the Preference Capital, making 6 per cent. for the year, and 5½ per cent. on the Ordinary Capital, making 8 per cent. for the year, the latter free of income tax.

After payment of the above dividends there will remain a balance of £2,023 13s 5d, which the Directors propose should be carried forward to next year.

The liquid assets in Ceylon appear in the Company's accounts at the same exchange as in last year's balance-sheet, viz. :- 1s 1d per rupee.

The general reserve fund stands at £5,500, including the amount transferred in the present accounts.

Mr. L. Famin, a member of the board, retires from office on this occasion, and being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.—Local "Times."

THE CONSOLIDATED TEA AND LANDS COMPANY.

More trouble seems to be brewing for Sir John Mair and his friends, this time in connection with the Consolidated Tea and Lands Company. That Company was floated in 1896, with a beautiful "front page" on which figured the name of, amongst others, Field Marshal Earl Roberts, v.c., k.g., or as he was then Field Marshal Lord Roberts, v.c., and the shares went up to a premium. The career of the Company has been one of almost unbroken misfortune, its record of dividends paid on the ordinary shares being 4s. in 1897, 4s 4½d in 1898, 6s. in 1899, 5s 8d. in 1900, and nil in 1901. Last year the ordinary shares, £6 paid, were quoted at 2 11-16ths as the highest, but towards the end of the year they fell to 2s 6d, while the first and second preferences fell from 8½ and 6 to 4½ and 4 3-16ths respectively. Why the Company should have gone from bad to worse in this manner is a question which requires answering, and, apparently, the proprietors are now waking up to that fact. Enlightened, no doubt, by the revelations brought out at the inquiry into the affairs of the East India and Ceylon Tea Company regarding the excessive charges and commissions of Messrs. P. R. Buchanan & Co., and Messrs. Finlay, Muir & Co., in both of which firms Sir John is interested, the Consolidated victims are now bestirring themselves. A meeting of some of the larger shareholders was called in Glasgow, on February 14th, by Messrs. Bannatyne & Guthrie, C.A., "to consider what action should be taken to protect the interest of the shareholders of the Company," with what result we do not yet know. It is doubtful if it is now too late to save the undertaking, but if prompt action is taken, something may be rescued from the wreck, and in time a sound healthy business built up on the ruins, but a decision should be come to and acted upon promptly.—*Investors' Review*, March 1st.

GRAFTING CACAO.—A successful attempt has been made to graft the ordinary Cacao on stocks afforded by the stronger growing *Theobroma bicolor*. *T. bicolor* grows readily in Trinidad, where it now appears to be well acclimatized. It was introduced in 1893, and we have now several trees giving regular crops. It remains to be seen what may be the value of this experiment, but as *T. bicolor* is a much stronger grower than *T. Cacao*, it is of course possible that some advantage to the cultivator may be expected. The method used was that of 'grafting by approach.'—*Trinidad Botanical Department Bulletin*.

CHRISTMAS ISLAND PHOSPHATES AND PROSPECTS.

Mr L. H. Clayton, District Officer, Christmas Island, in his report for the past year writes:—

The deposits of phosphate on the Island appear to be enormous and were supposed at one time to have been caused by the secretions of birds. A later theory is, however, that they are the result of the action of rain on certain deposits of ooze originally formed at the bottom of the sea and subsequently thrown up by a sub-marine eruption. Owing to the great depth of water and the suddenness with which the sea sometimes gets up, the anchorage cannot be described as safe. Calm weather may, however, be reasonably expected, although not relied upon, from May to November. With a view to inducing steamers to come close to the cliff and so facilitate loading, two temporary piers are now in course of erection. They are intended to act as a buffer between the rocks and any ship whose moorings give away. It is not certain that they will answer the purpose, and as they are constructed of Norwegian pine steeped in creosote it is doubtful if they will last for more than a few years. New plant for the obtaining and loading of phosphate is now being erected and the out-put is likely to be considerably increased, although perhaps not to the extent anticipated by the Company. The returns for 1902 will probably, however, not be affected as the work of construction is proceeding very slowly. As ships have sometimes had to stay at the Island for over a month at a time, it appears desirable to call attention to the fact that no supplies of any kind can be obtained locally. Not much is known as yet of the parts of the Island distant from the settlement and the complete absence of water from the higher levels renders exploration difficult.—*Penang Gazette*, March 10.

PLANTING NOTES.

INDIAN TEA CESS.—The full text of the memorial praying for a tea cess presented by Indian Tea Proprietors to the Viceroy appears on page 694.

YATADERIA TEA COMPANY: 20 PER CENT.—The shareholders in this Company are much to be envied (see page 689). The handsome dividend of 20 per cent was declared and we congratulate Mr. J. R. Fairweather, the superintendent, and all concerned in the excellent management which has brought about this happy result.

THE NAHAVILLA ESTATES COMPANY.—At the annual meeting which was held on 22nd March; the shareholders very generously did not claim the dividend of 2½ per cent (absorbing R9,912'50) which the directors recommended, and it was agreed that the balance should be carried forward to the extension account, for the purpose—we presume—of installing water-power for the factories on Ury and Nahavilla. This, we think, will be an effective and economical undertaking.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for April:—

Vol. XIII.]

APRIL, 1902.

[No. 10.

TOWN AND VILLAGE SHOWS.

AGRICULTURAL Shows as held at Colombo, Kandy and Galle are undoubtedly very imposing spectacles. The attendance at such Shows is generally very large, the exhibits very numerous, and the attractions very great. But can it conscientiously be said that they attain the object they are intended to serve? We think not. In saying so we do not intend to assert that they are altogether barren of good results, for some benefit is bound to accrue to visitors who are given the opportunity of seeing collections of the best of the island's produce, and what the possibilities are of careful and methodical treatment of plants and animals.

But to serve its purpose a Show should be the *rendezvous* not merely of people of fashion—who come to admire, to criticise and to be amused, certainly not to learn—but also for *bona fide* cultivators of the soil, the real tillers of the land, whom we are trying to bring within the educative influence of Agricultural Shows. It is these people we want to see well to the fore at Agricultural Shows, comparing notes with one another, asking and giving information as to the best way of cultivating a particular plant, enquiring where the best seeds are obtainable, what the best seasons are for growing them, the best manures for fertilizing, and in fact the best way of treating a crop generally. We want the opportunity to be also taken for the exchange

of good seed, a most important factor in improving cultivation.

We have had some experience of large Town Shows, and we regret to state that such experience has not led us to form a very high opinion of their utility or influence for good. In towns the men of influence and money generally succeed in ousting the real producer. The prizes being good and the opportunity to attract notice favourable, such men neglect nothing to bring themselves into prominence. Frequently they appropriate the produce of the villagers and pass it off as their own, while they even go the length of purchasing in the open market the best specimens that money can buy, and exhibiting them as the fruits of their own skilled labour. The feelings of exhibitors to one another at such big Shows are, so far from being those of friendly competitors, rather of uncompromising rivals, jealous and impatient of one another's success.

The dissemination of seeds and plants of good varieties of plants is by some people considered to be detrimental to their interests, and successful methods of cultivation are to them "diplomatic secrets" not to be revealed. The anxiety to win awards is so great that normal standards of rectitude are ignored and unscrupulous means employed. We have had a competitor, in his chagrin at failure to secure a coveted medal, come to us with the absurd request that he may be permitted to *purchase* a spare medal or two. How under such circumstances, could conscientious promoters of

Agricultural Shows hope to effect any good to the real producer? Every successful competitor, whose exhibits are the fruits of his own labour, may be pardoned a little pride in his success, but the boastful arrogant spirit of the exhibitor of another's produce is beyond all toleration.

Some dozen years ago we were present at a Village Show held in the hamlet of Dalugama near Kelani, under the patronage of the late Mr. George Wall, and with the energetic Mr. Charles Stouter as Secretary, and were much impressed with—what we would call for the want of a better word—the "genuineness" of the proceedings. There we saw the produce of the cultivator shewn in his own name, and awards going in the right direction. The "Middleman" was out of the way, and why? Well it was too small a business for him, and this decision on his part is the secret of the success of Village Shows—"a good riddance" we say "of a most undesirable element." But unfortunately since the Dalugama Show we have not heard of another Village Show—at least in the Western Province—and "more's the pity" till Saturday, the 22nd March, when a successful little exhibition of garden produce was held at the Danowita school situated in the Hapitigam Korale, some six miles from Ambepussa Railway Station. The exhibits were the produce of the school gardens in the neighbourhood (Danowita, Dorawaka, Murugampola, &c.) as well as of the gardens of the village children in their own homesteads, and for this reason the Show, though small, was of an interesting character.

Advantage was taken of the presence of a large gathering of villagers for distributing a quantity of different kinds of seeds brought by the Superintendent of School Gardens from the Colombo Stock Garden. The acting Director of Public Instruction, under whose patronage the Show was held, was himself present and evinced the greatest interest in the proceedings. After the distribution of awards, consisting of articles likely to be useful to the exhibitors (who were all young children) the acting Director spoke to a large audience on the importance of village children being given an early training in agriculture, by means of school gardens, and the advantages that must follow close applications to the cultivation of land and persistent efforts to grow better and larger crops. Mr. Drieberg, Superintendent of School Gardens, spoke in a similar strain and called upon the older generation to contribute all the help they can in pushing on the new scheme for the agricultural training of village youths, and to encourage their children to give their spare time to the healthy and profitable exercise of gardening. Mr. Jayatileke, Principal of the Colombo Buddhist College, exhorted the people to take advantage of the opportunities offered to them to improve their status as agriculturists and horticulturists. Hearty votes of thanks were accorded to the speakers, to the Mudaliyar of the Korale, Mr. Louis Dassanaika, and to Mr. Alexander Perera, Manager of the Colombo Stock Garden, all of whom had contributed their share of help to make the Show a success.

It was quite apparent that the proceedings, taken as a whole, appealed strongly to the sense and feelings of the large assembly, and that the object of the Show as an influence for good was in a great measure attained.

We trust that the success of the little Show at Danowita will lead to similar Shows being held at different centres in other parts of the Island, with a view to awakening the energies—more or less dormant—and latent capabilities of our village population.

OCCASIONAL NOTES.

Mr. Fredrick Lewis's coming work on Ceylon Timber Trees should prove a valuable reference book to all foresters and others interested in woods. Mr. Lewis is well qualified for the task he has undertaken, having devoted his life, so to speak, to the subject of Forest Conservancy, while his knowledge of Forest Botany is acknowledged to be both comprehensive and sound. Up till now the literature on the subject of our timber trees has been very scanty, and Trimen's Flora contains only short notes on their distribution and value. Under the circumstances a work of the nature of that Mr. Lewis proposes in his introduction to give us will be a valuable acquisition.

We would draw attention to the interesting report on Cho-cho, referred to in our last issue, from the pen of Mr. W. Nock, Superintendent of Hakgalla Botanic Gardens, who has done much to introduce and naturalize exotics in Ceylon. The vegetable is one which deserves to be popularised through our Village School Gardens.

We reproduce a notice of Mr. Herbert Stone's paper (read before the Society of Arts, London) on the Identification of Woods. The subject is one which should prove of the greatest interest to foresters, and Mr. Stone is an acknowledged authority on all questions relating to Timbers. For these two reasons we have no doubt that the notice will prove acceptable to those of our readers who are concerned with forest work and timber-supply.

A consignment of plants of the best varieties of table bananas is shortly expected from Queensland for the Colombo Stock Garden, whence they will find their way to the village School Gardens that have been started in various parts of the Island.

We welcome the "Journal of the Department of Western Australia" as an exchange. It is a well got up monthly of handy size, and contains much useful reading matter.

Brucea Sumatrana is the name of a plant about which there has been of late much enquiry outside Ceylon, owing to the medicinal virtues of the seeds as a cure for dysentery. The plant, an introduced one, occurs as a common weed about Kandy. Trimen thus speaks of it: The whole

plant is bitter, and the seeds (called "Macassar kernels") are much used in Java as a cure for dysentery. Another native plant of the same order (*Simarubaceæ*) *Ailanthus excelsa*, known as Wal-bilin, or Kumbalu, contains a fragrant resin which is also used in dysentery.

The West Indian Department of Agriculture appears to be steadily developing under the able direction of Dr. Morris, once of Ceylon, now Commissioner for Agriculture in the West Indies. We learn from the last report of the Department, that seven Agricultural Scholarships have been founded with the object of encouraging the most promising boys in the smaller Islands to get a thorough knowledge of the science and practice of Agriculture. Schools of Agriculture exist in St. Vincent, Dominica and St. Lucia, where 70 boys are trained for 3 or 4 years free of all cost. Agricultural Shows are held regularly in seven of the Islands with a view to show the possible results of the better cultivation and preparation of produce. Already twelve pamphlets, comprising some 417 pages, have been issued and 30,000 copies distributed. Among others, the following subjects have been dealt with: The Cultivation of Vegetables, The General Treatment of Insect Pests, Hints on School Gardens, Bee-keeping in the West Indies, Manures and Leguminous Plants, Hints on the Cooking of Sweet Potatoes.

In our last issue we referred to a new remedy for foot and mouth disease. The following telegram from London, dated 9th March, brings further hopes of relief for the much-trying Stock-owner:—"It is officially announced in Berlin that a cheap and sure means has been discovered by which cattle may be given immunity from Rinderpest."

The *Family Doctor* thus explains why boiled or condensed milk is not so nourishing as unboiled milk: It is not in the albumen, fat or sugar, but in the albuminates of iron and phosphorus and perhaps also of fluorine that the vital changes take place. These albuminates are certainly in the milk and are present in a vitalised form as proteids. On boiling the change taking place is simply due to the coagulation of the globulin or proteid molecule which splits away from the inorganic molecule, and thus renders it as to the iron and fluorine unabsorbable, and as to the phosphorus molecule unassimilable. As a result, it is said, there is defective nutriment in boiled milk for the formation of bone and teeth, a most serious defect in the case of growing infants fed only on a milk diet.

Sodium arsenite, a cheap chemical, has been proved to be most effective in the eradication of prickly pear in New South Wales. The proportion used is 8 lbs. of the chemical to 80 gallons water; the plants being thoroughly sprayed over with the mixture. The same treatment is recommended for briars, lantana, thistles, and other weeds, as well as for eradicating couch grass from gravel paths, roads, &c.

SECIUM EDULE—"WHITE VARIETY."

The only existing plant of this variety in this country was accidentally destroyed at Peradeniya in the middle of last year. Application was at once made to Mr. Hart, Superintendent of the Botanic Gardens, Trinidad, for a few fruits. Our request was kindly and promptly attended to, and a small box containing six fruits reached us in February, 1895. Two of the fruits were in good condition, and after being started were finally planted out on the 7th of March. They are now healthy plants, growing vigorously and bearing a good crop of full size. The three largest fruits weighed as follows: No. 1, 27 oz., No. 2, 24½ oz., and No. 3, 24 oz. This compares very favourably with any I have seen in the West Indies. This variety will grow and crop in the lowcountry, whereas the green variety does not do much good below 2,000 feet elevation. It will therefore, I trust, prove a useful addition to the lowcountry vegetables. The plant is perennial and is of the easiest possible cultivation; given good soil, it will grow rapidly and will ramble over any trellis or tree or cover any rubbishy corner. It usually begins to bear in from three to four months after being planted. In my report for 1895 full details are given as to the best mode of planting it, and perhaps it would not be out of place to repeat them here:—"It thrives best in a rich, deep, well-drained soil, but may be made to grow anywhere by preparing the site for each plant in the following manner:—

Make a hole four or five feet in diameter, and eighteen inches to three feet deep, according to the subsoil. If the subsoil is good and free, you may go to the depth of three feet, but if it is clayey or likely to hold water, eighteen inches will be quite deep enough. Place a layer of rough stones at the bottom of the hole to a depth of six

to nine inches for drainage, and over this a few inches deep of small twigs or half-rotted leaves, to prevent the fine soil from getting between the stones and choking the drainage. The hole may be filled up with the following compost: One-third ordinary garden soil, one-third half-rotted cattle or stable manure (cattle manure preferred for hot, sandy soils, and stable manure for cold, clayey soils), and the remaining third may be formed of leaf-mould, sand, woodashes, lime, and the sweepings of the poultry-yard. When the hole has only been taken out eighteen inches deep, it will be necessary to raise the soil about eighteen inches above ground; indeed in every case, except in very dry districts, it is best to raise it. The whole fruit, which is sent out in a germinated state, must be planted about three inches deep in the centre of the hole. It begins to grow at once, and in a week or ten days it will have made a good start. It is a creeper, and each plant will require a space of about twenty feet square.

In the *Kew Bulletin* for May and June, 1896, there are some remarks about this plant, which though no doubt refers to the green variety which was sent to them from the Ceylon garden some years ago is quite applicable to the white one. It is there shown that the cho-cho has been taken up by the natives of India by whom it is regarded as one of the most wholesome of foods. "Cho-cho is now quite established as a popular vegetable in Bangalore and the adjacent villages. The fruit has also been widely distributed to other towns in the province. It is largely used in the central jail where the fruit is carefully grown and considered to be one of the most wholesome food for prisoners. It is not generally known, however, that the large fleshy root of the plant, sometimes weighing nearly twenty lbs., can be cooked and eaten like a yam." The cho-cho is also largely grown in England under glass to supply Covent Garden market. The large flat seeds if carefully cooked are regarded as a great delicacy. Starch is also prepared from the roots at Jamaica.

Here we have a plant eminently suited to the people of this country, a perennial requiring very little culture, whose roots, fruit and seeds give a plentiful supply of good wholesome food, and I trust it will be more largely cultivated in Ceylon in the future.

Of its lasting qualities I may mention that the original plant introduced into this garden from Jamaica in January, 1885, and from which I believe all the plants in the East—perhaps millions—are descended, is now in perfect health and bearing as regularly and heavily after twelve years* as it has ever done.

The fruit can be sent to table in a large variety of ways, from a very good pickle of the young fruits to an acknowledged delicacy from the seeds.

I am led to make the above remarks because of the absurd rumour which has been spread among the natives of this country, viz., that the plant contains poison, and also that a continual use of the fruit produces rheumatism. With regard to the latter I may say that thousands of families feed on this in Jamaica all through the season, and

during my 7½ years' residence there I never heard of any one being in the slightest degree affected by them in any way, but beneficially. Myself and family have eaten them whenever we could get them for the last 23 years,* and we have always found them thoroughly wholesome.

As to their containing poison this is a great mistake, and I think the following may account for the spread of the rumour:—The late Dr. Trimen in his administration report for 1894 gives two paragraphs on the same page, one about "Nux Vomica" and one on the Cho-Cho, and he also adds two footnotes. The one referring to "Nux Vomica" states: "The pulp in which the seeds are immersed contains a small proportion of strychnine so small that it is said that this pulp is eaten by birds. Dr. Ondaatje has, however, settled by experiment on dogs, cats, and pigeons that it is fatally poisonous in sufficient quantity." I think it possible that some one may have read this footnote as referring to the cho-cho and possibly told some coolie about it. I cannot account for it in any other way.

Considering the value of this plant for food, I may be permitted to respectfully suggest that as a means of encouraging its cultivation, that a small pamphlet describing its value and useful qualities may be printed in Sinhalese and Tamil and distributed among the headmen of at least all up-country districts.

The following are a few of the ways in which the fruit can be served:—

1. The young fruit when about an inch in diameter makes a very good pickle either alone or mixed with other pickles.
2. When two-thirds grown they can be sliced in the same way as cucumber and eaten as a salad.
3. The half ripe fruit can be sliced and fried in butter, after the manner of brinjals (garden egg) or half boiled and cut up for salad like beetroot.
4. The matured fruit make a nice dish when stuffed with forced meat like a vegetable marrow.
5. Plain boiled like a vegetable marrow and used up either plain or with white sauce.
6. Made into a variety of curries as pumpkins, cucumber, etc.
7. When boiled and used with lime juice, cloves, etc., makes a capital imitation apple sauce.
8. Mixed with lime juice and sugar it supplies an ingredient for tarts.
9. A preserve can be made from it after the manner of vegetable marrow.
10. The dish which is considered a delicacy in England is made from the seeds which are taken out from the fruit, after being boiled, and fried in butter.
11. Roots boiled resemble yams.
12. Roots can also be roasted or baked like yams.

W. NOCK,
Superintendent, Hakgala Gardens.
February, 1896.

* Now seventeen years old.—27-3-02.

* Now 28 years.—27-3-02.

CO-OPERATIVE CREDIT SOCIETIES.

In a late number of the *Agricultural Magazine* we drew attention to the desirability of devising some system of Agricultural Banks for the cultivators in Ceylon. As one travels through the country it appears evident that in spite of the abolition of the paddy tax the condition of the native cultivator has not improved, and in many places one finds land passing into the hands of the Mohammedan usurer, who, starting with a clean sheet and a natural energy which has been steadily diminishing in the Sinhalese cultivator, are beginning to prove that paddy cultivation is—what it was "once upon a time"—a very paying industry.

Mr. Reg. Murray, writing in the *Banker's Magazine* points out that what is wanted to ameliorate the distressful condition of the Indian (and Ceylon) cultivator, is not momentary support so much as intelligent organization. Credit is already available, but of a kind which leaves the recipients worse off than they were before.

In June last there met at Simla a Committee, composed of experts, appointed to report on what remedial measures can be devised for improving the condition of the Indian yot. This Committee has already published its report, and it may be confidently expected that Lord Curzon will not allow the proposed legislation to wait long for its practical application.

The object of such legislation is not as is popularly believed, that the Government should establish a kind of credit *mobilier* to pay the outstanding debts of the cultivator and release him from the grasp of the moneylender,—a policy, the defects of which need not be enlarged upon here.

Going to the cause of the trouble we find that the ordinary rate of interest payable by the cultivator is scandalously high, and that in addition the money-lender secures to himself the sale of the crops at a price unfavourable to the borrower, while in many cases the land itself is at his mercy. And this is the chief point, that lending for agricultural purposes has long since reached the state of usury, the effects of which is the gradual effacement of the borrower and his credit and the reduction of himself to an unproductive cypher. Thus has it come about that the industry becomes handicapped and unprogressive, and hence follows the obvious suggestion that no improvement is possible until the cost of borrowing on the part of the cultivator is reduced below the rates charged by the native money-lender.

As a first step something must be done by the borrowers themselves to improve their credit and make them free agents, since in their present condition they have nothing to offer as security. It is not to be expected that under any circumstances they will be able to improve their credit to the extent of clearing their debts, but it is possible for them to improve it to the extent of deriving a profit from the result of their present and future labour and intelligence and with such surplus to gradually pay off old debts. To enable

them to do so, it is proposed that Government pass an act and frame special rules for the encouragement and formation of Co-operative Societies on similar lines to those of the Friendly Societies in England and the Raffeisen Societies on the Continent.

The argument is that the united security of a number of men can raise advances on considerably easier terms than one man, who, as things go, is required to pay rates of interest which make it impossible for him to ever reap the just fruits of his labours. Co-operative Credit Societies, therefore, have for their object the banding of individuals together in order to obtain money at reasonable rates of interest and to distribute the money so obtained among the members under fixed rules. The margin of profit between the rate at which the Society borrows for and lends to its members should gradually create a reserve fund, which, being indivisible, must annually improve their credit. The action of Government must be confined to shewing the people how to act and to provide legislation and rules for their guidance and protection, and thus encourage self-help and self-reliance.

Societies already formed in the N.-W. Province and the Punjab show that the Co-operative credit is well understood and appreciated both by borrower and lender. In Madras it is likely that native banks will soon remodel their system in order to obtain the privilege and exemptions which the legislature propose to afford to Co-operative Societies.

With such a system in operation it does not seem likely that Government will be applied to, unless under special circumstances, to make loans for the promotion and support of the Societies, nor beyond the inspection of a Registrar or other District Officer, will the Government direct, regulate or interfere with the free action of the Committees of management. The Raffeisan system has been so eminently successful on the Continent that, with conditions at least equally favourable for its growth, it is reasonable to suppose that it will be equally suitable and successful in India and Ceylon.

With the successful application of the Co-operative banking system to Indian agriculture, it only remains for some one to agitate for its adoption in Ceylon under Government auspices.

BY HIGHWAYS AND HEDGES.

It is surprising to see the enormous extent of land under citronella grass in the Southern Province, and that too, in spite of the big drop in the price of the oil—now procurable for about 60 cents the bottle. There is no doubt that this hardy grass, growing as it does without any special attention, has spoiled the people for better cultivation. In these citronella districts the abortive attempts to grow coconuts, Liberian coffee, cocoa, etc., only go to prove that even if these economic products are suited to the districts, they will not tolerate the kind of treatment that is meted out to them by the careless citronella planter.

The wholesale adulteration of citronella by means of kerosene has been the downfall of the Ceylon trade in the oil. Who could have been the ingenious inventor of the fraud? There is no doubt that many a southern fortune that has come out of it. It is said that after some trouble the chemist found a means of detecting the adulterant and the extent of adulteration; but quite lately we have been informed that the test, which answered hitherto, fails, owing it is thought to another adulterant being employed or a third substance being bought into requisition to effectually disguise the fraud. We have not been able to discover the suspected *tertium quid*, while a new adulterant, if it could take the place of kerosene, would not from a financial point of view answer the purpose of the citronella planter. Domba oil was suspected to be employed, but it would not pay to employ it even if it be a good adulterant. The old method of adulteration consisted in mixing the kerosene with the distilled citronella; now, however, the dodge is to pour the kerosene over the grass when it is ready to be operated on by steam, and distill the vegetable and mineral oils together. Could this change of tactics account for the confusion of the chemists?

Quisqualis indica is not commonly seen outside gardens, but *Alamanda* has long since started on its own account. We were surprised, however, to see *Quisqualis* as a veritable escape from cultivation on the banks of the Nilwala ganga near Atureliya.

There is no doubt that considerable improvement is possible in the method of curing native tobacco, as an expert lately remarked; but those who smoke the "fragrant jaffna" cigar could little suspect what ingenious devices are practised by the tobacco growers of the North. A late resident in that part of the Island assured us that he once watched a cultivator working round a manure heap which had lately been saturated with rain, and saw him fish up a parcel of leaf from underneath the midden, explaining, on being questioned, that it had been put there to ferment. Who will be surprised at the rankness and pungency of a Jaffna cigar after that?

The tree known as Samadara (*Samadera indica*) found in the Galle district among other places, is interesting from the fact that a decoction made from the leaves has insecticidal properties, and is according to Dr. Trimen destructive to white-ants. The whole plant which is very bitter is used medicinally as a febrifuge.

IDENTIFICATION OF WOODS.

[The following is a *resumé* of a notice in *Nature* (kindly placed at our disposal by Mr. Lewis, Assistant Conservator of Forests), from which it would appear that it is more difficult to identify woods by means of anatomical characters than is generally supposed, on account of the great differences which the structure of the primary and secondary wood present.—Ed. A.M.]

"The grouping of vessels and the medullary rays and the arrangement of the wood parenchyma are frequently so characteristic that various genera can be recognized by a glance at the transverse section, *i.e.*, horizontally as the tree stands; and further it is by no means rare to find the same structure running through a whole genus, or, less frequently, through a whole order. A hundred genera could be cited which exhibit a strong family likeness, and of the Proteaceæ and Sapotaceæ it may be said that the description of the structure of the wood of one species will practically serve for the whole order. On the contrary there are whole orders which appear to consist chiefly of exceptions, as in the case of Celastraceæ, and where it is difficult to find two genera with any important feature in common. The structure of the woody portion of Cryptogams has been employed for years in the study of fossil plants; that of the monocotyledonous trees and conifers is notoriously uniform, and is as sure a guide to their position in the natural system as any external character. Why then should not the same rule apply to the angiospermous dicotyledons, and for what reason should the thread be lost as soon as we pass from one division of the vegetable world to another?"

It seems a by-no-means extravagant idea that inasmuch as it is quite indifferent to the welfare of a plant what the structure of its woody portion may be, so long as it performs the mechanical duties imposed upon it, ancestral traits should be preserved undisturbed in the wood more than in any other part.

Ignoring the debatable question, there is no doubt whatever of the economic importance of this study.

Mr. Stone points out that with the large number of timbers in use and those destined to be turned useful, the old rule of thumb methods of identification are not likely to answer. He refers to the case of the Colonies where those who have a knowledge of timbers are few in number, and vernacular names of trees often confusing.

Mr. Stone points out that for practical purposes it is rarely necessary to use high powers of magnification: a pocket lens of a two-inch objective being frequently sufficient to display the special character of the structure. Higher powers tend to obliterate this "individuality" which depends on the arrangement or complex of the elements. For instance, the radial or tree-like arrangement of the vessels in the wood of *Quercus* is recognizable by the naked eye, but is not striking under a half inch objective. The concentric undulating lines of vessels characteristic of the elms is also usually visible to the naked eye. But in both these cases the same characteristics are shared by many other genera often not by any means closely related.

It will therefore be at once admitted that anything like a natural system of classification of wood by their structure is quite impossible at present. There is too little recorded information and too many glaring exceptions where one would not expect to see exceptions.

Mr. Stone refers to the systems of well-known authorities as being but partially successful, and suggests the medullary rays as the most constant feature for forming the basis of an artificial key, though it does not altogether coincide with botanical classification.

"Nevertheless," says Mr. Stone, "a useful key may be constructed by first distinguishing those woods with two kinds of rays from those having but one. The latter then fall again into two groups, one having rays with intervals between them of not less than the transverse diameter of the largest pores present, the other converse by having the intervals never greater than the pore diameter, *i.e.*, the rays diverge and run round or avoid the pores.

These two types of rays are very clearly marked and have quite different aspects. The arrangement of the vessels or pores can then be usefully employed, as the concentric, radial, tree-like, or undulating group, or uniform distribution of the pores is very constant in many genera, as are also the equally varied forms assumed by the soft tissue (wood parenchyma), which comes next in order of importance. It would be out of place here to go into further detail, and it need only be pointed out that by following this sequence all members of the same genus except the aberrant forms fall together into the same ultimate groups.

But the structure of many groups, and even whole genera are so similar that the species can only be distinguished by long acquaintance, and it is then necessary to note specific gravity, colour, smell, taste, hardness, behaviour with re-agents, &c. Frequently one pronounced feature, *e.g.*, smell or hardness suffices for identification of a species. But then there are hundreds of species that have no such pronounced feature, and hence the crying need for a guide to enable one to trace the name of any wood. Here is an excellent field for local foresters, for there can be no two opinions as to the economic importance of this study.

NATURE STUDY AND SCHOOL GARDENING.

Progress in this new movement is not confined to America (where it had its origin) or Australia, for we read in *Nature* that considerable attention is being paid to it in England.

A periodical called the *Nature Study Journal* has been started in Kent, under the auspices of a society for promoting Nature Study, the members of which are expected to contribute suitable lessons for teaching purposes. Sir W. Hart Dyke writes an introduction to the first number issued. *Nature* referring to the new movement says, that the introduction of Nature Study into rural schools cannot but be productive of good, and though it is not primarily directed to keeping children on the land, it will have this effect indirectly by leading them to see that a country life has its own interests and is not merely stupid routine; remarking further that the children who do stay in the country will through Nature Study lay a foundation of thinking about rural pursuits which can be built upon later,

We also read of a Conference on School Gardens being held, when Mr. Rooper, Inspector of Schools, read a paper on School Gardening in England and Germany, in the course of which he is reported to have said that English School Gardens though few are the more practical, when these grounds are considered as fields for mental and manual training. Sir John Cockburn, late Premier and Minister of Education in South Australia referred to a difficulty which we have experienced ourselves, *viz.*, the want of time for work; but he observed that in South Australia the authorities had gone so far to overcome it, that, while originally one hour was allowed for school gardening, at present only *half* the teaching hours was devoted to theoretical instruction.

Lastly, we read of an influential Committee being appointed to promote a Nature Study Exhibition to be held in London, about the end of July next. At this exhibition urban and rural elementary day schools and other institutions will compete for prizes and certificates, which will be offered for collections of Natural objects (plants, insects, etc.), drawings of same, plans for gardens, plants grown in boxes, pots, etc. While the efforts of individual pupils will be recognised, it is intended by means of a competition to judge of the best scheme for instruction and working methods. It is expected that there will be no difficulty in getting the necessary funds for what *Nature* calls "such an excellent object."

We, in Ceylon, have been losing no time in availing ourselves of the advantage of the new movement, for since June last a local School Garden scheme has been in operation, and so far has been carried on with satisfactory results. As reported elsewhere, already a small exhibition has been the outcome of the activity engendered by the scheme. As regards the gardens themselves, a competent authority, who has been inspecting the first-started gardens which have had some little time for developing, has declared to us that, making allowance for altered conditions, he is inclined to think our School Gardens compare favourably with, and if anything, are superior to, similar gardens in England. This is indeed high praise, and it is to be hoped it will only urge on our teachers to higher efforts.

VEGETABLES, HOW TO COOK AND SERVE THEM.

(Concluded.)

Spinach, though, of course, a green vegetable, requires somewhat different management. It reduces very much in the process of cooking, so a good quantity—not less than 2 or 3 lbs.—must be allowed for a good sized dish. Wash it in three waters, as it is very gritty, pick off all the coarse stalks, and leave it in cold water for $\frac{1}{4}$ hour to freshen it up. A large saucepan will be required; into this place the spinach, without any water, except what clings to the leaves, for it will cook in its own juice. Sprinkle a tablespoonful of salt over, and cover the saucepan for a minute or two to keep in the steam. After the juice begins to draw it must be very frequently stirred with a

large wooden spoon, and as soon as tender (which, if young, it will be in 10 minutes), it must be drained and squeezed very dry between two plates. Some people will eat it in this state; but the French method is to chop it finely, or even pass it through a sieve, to mix in 1 oz. of butter, pepper and salt, and to return it to the saucepan to make hot. It is then served in a mound in the vegetable dish on toast, with a few rings of hard-boiled egg, or *croutons* of fried bread as a garnish. If served as a separate dish, either for supper or any other meal, poached eggs are the usual accompaniment, and the spinach is placed on slices of buttered toast. In the country, where they can be picked by the roadside, spring nettles make a very nice and wholesome dish of greens, and may be cooked in the same manner as spinach.

Asparagus should be dressed as soon as possible after it is cut. If necessary to keep it, the stalks are better placed in cold water, like flowers, in a vase. Scrape the white parts of the stems, beginning from the head downwards, and cut off the very hardest part. Throw them into cold water as they are done, and tie them into bundles of about 15 or 20, according to the thickness, with string, cutting them all the same length. Have a saucepan ready with fast-boiling water, salted with 1 tablespoonful of salt to $\frac{1}{2}$ gallon of water, with a lump of sugar; this latter will help to soften the water, and make the asparagus boil tender—soda, of course, must never be used for them. Set the bundles of asparagus upright on their stalks in the water, with the heads just out of the water, as these will cook in the steam, and if quite covered would be done long before the stalks, and possibly drop off. Boil quickly, with saucepan uncovered; they will take from 15 to 18 minutes after the water boils again. When done, take them up carefully, remove the string, and dish them upon a piece of toast which has been dipped in the water the asparagus was cooked in. The white ends should be laid outwards each way, the points or heads meeting in the middle. Special tongs are sold for helping this vegetable. A tureen of melted butter should accompany them to table, and a little may be poured over them in the dish. A good sauce *blanche*, or melted butter, to serve with any vegetable which requires it, is made as follows: Melt 1 oz. butter in a small saucepan, stir into it $\frac{1}{2}$ oz. of flour and a pinch of salt, and add $\frac{1}{2}$ pint of milk; let it boil and thicken, stirring all the time; boil a minute, then serve. A richer sauce *blanche* is to mix one tablespoonful of flour into a smooth batter with a gill of water, or rather less, then to put it in the saucepan with $\frac{1}{4}$ lb. of butter, a pinch of salt, a very little grated nutmeg, and a small teaspoonful of white vinegar or lemon juice. When it thickens it is done. This is a French recipe, and very delicious.

Artichokes are considered better for having been gathered a day or two, and in this respect are unlike any other vegetable. They should be well washed and soaked before cooking; the stems should be removed, and the leaves trimmed away at the bottom. They are cooked like asparagus, and will take 20 or 25 minutes after the water boils again; five or six are sufficient for a

dish. Some cooks use a very little soda in the water, in addition to the sugar as recommended for asparagus. The artichokes should be placed in the saucepan head downward, and when the leaves draw out easily they are done. Dutch sauce or melted butter is served with them, and the leaves are pulled out with the fingers and dipped in the sauce. Dutch sauce is made by thickening some plain melted butter, like the first recipe given, only using water instead of milk, with the yolks of eggs. It is merely stirred over the fire, and not allowed to boil, or it would curdle.

Jerusalem artichokes are quite a different vegetable; they are the root of a plant, instead of the flower, and are cooked like old potatoes. The only thing to be careful about is to keep them white, and this may be done by laying them in fresh cold water after peeling, until they are required to be cooked. They will take about the same time as potatoes, and are served with melted butter made with milk as in first recipe. Occasionally they are mashed like turnips, but I do not think they are so nice as when whole.

Sea-kale is a delicate vegetable, in flavour very much like asparagus, and cooked in exactly the same manner; that is, it is trimmed, tied into bundles, and placed in boiling salted water, with some sugar; time to cook, 15 or 20 minutes; serve with melted butter poured over it in a dish.

Green peas, to be eaten in perfection, should neither be gathered nor shelled long before they are to be dressed. If obliged to be shelled overnight, the best plan to keep them fresh is to place the colander which contains them over a basin of cold water, and to completely cover them with the shells. Wash them by letting the tap run through the colander, throw them into boiling water, prepared as for asparagus, but slightly increasing the quantity of sugar. If the peas are old $\frac{1}{2}$ teaspoonful carbonate of soda must be added to the water, but if too much be used the peas will have a broken appearance. A sprig or two of mint should be boiled with them to give a good flavour: this is removed before serving. Young early peas will take 10 or 15 minutes to cook; larger and later kinds, such as marrowfats, 20 or 25 minutes, while old peas must be allowed $\frac{1}{2}$ hour, or even longer. When cooked, drain from the water in a colander, turn into the vegetable dish, with a good piece of butter, a little pepper and salt.

Carrots, parsnips, and turnips must never have soda in the water in which they are boiled, as it would turn them a very bad colour. A little fat may be substituted for softening the water and making them boil tender; and it is for this reason they are so frequently cooked with meat. Young summer carrots should only be washed; then when they are cooked their skins should be rubbed off with a coarse cloth; they are usually served quite plain, but may be covered with melted butter if preferred; they will take 25 minutes to boil. Old carrots, on the contrary, should be scraped, not peeled, and the longer they are boiled the better; two hours certainly is not too long a time. If boiled with beef, put them in as soon as the meat boils again after going in the water. If boiled separately, salt the water, and add a good

ounce of dripping to $\frac{1}{2}$ gallon of water. If very large, cut them in half, but it is better to cook them whole, if there is time, as the flavour will be superior. Turnips are hardly a summer vegetable, and they are generally served mashed; they require peeling thickly, as their skins are very woody; boil with meat if possible; if not, use a little dripping in the water. Make them as dry as you can before mashing, then mash with a fork; mix with a small bit of butter and a little milk, return to the saucepan, and stir over the fire until all the milk has dried up. The use of cream instead of milk makes them very delicious; they are served piled high in a hot vegetable dish, with a strainer at bottom, as, even with the utmost care, there will almost sure to be a little moisture to drain away.

Parsnips are also a winter vegetable; they are peeled and cut in slices across, and boiled in the same manner as carrots and turnips, and will take from 1 hour to $1\frac{1}{2}$ hours to cook; generally served plain in the vegetable dish, or round the meat. Sometimes, however, they are mashed like turnips, with a little butter and milk.

Vegetable marrow is a late summer and autumn vegetable, and suitable also for any kind of hot meat. Peel it, and cut in thick slices across with a sharp knife; remove the seeds from each slice, so as to form rings; boil these in salted water for 20 minutes, drain in a colander, and serve in a vegetable dish upon toast. Moisten the toast in the vegetable marrow water, and pour thick melted butter over all.

Tomatoes are frequently eaten raw, or prepared as a salad; if cooked, they are best baked. Simply lay them in a tin with a small bit of butter on top of each, and bake till tender (about $\frac{1}{2}$ hour). Serve with the juice poured round. They may also be cut in slices and fried, and are good done in this way with chops, steaks, and broiled bacon.

GENERAL ITEMS.

The use of trap lanterns, for trapping insect pests in the garden, would seem to be of questionable benefit, to judge from results obtained at the Ontario Agricultural College. Of the insects captured during three months, a large percentage was found to be decidedly beneficial insects. "If," says the reporter, "all the traps were in operation for four months, probably forty millions of decidedly beneficial insects were captured and destroyed."

Mr. J. D. Ormsby, of Lime Hall, St. Ann, writes to the *Journal of the Jamaica Agricultural Society*: "I think I have found out an insecticide for spraying plants which is superior to the kerosene emulsion. Hitherto, I have used the Hubbard's formula of kerosene emulsion, but I find if I am ever so careful with it, it burns the young leaves and tendrils, unless it is so much diluted as not to affect the insects. Knowing how averse all insects are to castor oil, I thought I would try an emulsion of it. I tried the soap-boiling water

and oil as in the Hubbard's formula, but it would not emulsify, then the thought struck me to add carbonate of soda, and it is quite a success. My formula is—one quart of castor oil, 1 lb. hard soap, $\frac{1}{4}$ lb. carbonate soda, 1 gallon water—boil soap and soda in the water and when melted and boiling hot stir in the castor oil. You can dilute in 10 or 20 parts of water for spraying, and you can take a brush and paint the stalks of plants the ants or other insects are troubling without diluting—no insect will face it, and it does not burn the young leaves or sprouts. I shall be glad if this is found useful to the public at large."

A heavy application of paint is recommended by those who have had experience in the matter, as the best dressing for pruning wounds.

The following reply by Mr. J. H. Maiden, Government Botanist, N. S. W., to a correspondent is no doubt correct enough for that Colony, but it sounds strange enough to us who are familiar with hundreds of thousands of acres of tea: The tea plant is closely allied to the camellia, and requires somewhat similar treatment. The plants must be well watered and kept steadily growing. The tea plant likes good deep soil, and, in my experience, it does best where it can get a touch of the frost.

An American Correspondent, quoted by the *N. S. W. Agricultural Gazette*, recommends a cure-all remedy for sick pigs, whether they suffer from rheumatism, paralysis, scour or what-not. This is a mixture of fresh new milk and turpentine. Grade the dose from a teaspoonful of turpentine for a six week's old pig to a table spoonful or more for a mature hog. The milk may be given *ad lib.* The remedy is said to be the best known for all the ills that pigs are heir to, and when anything is wrong should be resorted to at once.

We read of what is spoken of as a "new variety of fowls," the Ancona, considered the best laying breed of any. An Exchange refers to the experience of a lady who has had hens laying for two years beginning when five months old. They are non-sitters, and in shape and general appearance resemble the Leghorn but in colour the Houdan.

Still another way of preserving eggs is to take them quite fresh, clean thoroughly with a damp cloth, rub dry, rub a few drops of boiled Linseed oil turned into the palm of the hand, and lay on a shelf protected from dust. Too much or too little oil should not be used. About the third day a fine skin, which hermetically seals the eggs, forms over them.

The *Jamaica Agricultural Journal* recommends clean wood ashes as the best condition powder for horses. It may be given twice a week in the feed, at the rate of an even tea spoon each time

PINEAPPLES, ORANGES, CASSAVA, MANGOES, &c.

REPORT ON THE CULTIVATION OF PINEAPPLES AND OTHER PRODUCTS OF FLORIDA.

By ROBERT THOMSON,

(Formerly Superintendent of the Botanic Gardens of the Government of Jamaica, now Adviser to Messrs. Elder Dempster & Co. on the cultivation of Fruit and other products.)

HAVING recently visited Florida, on account of Messrs. Elder, Dempster & Co., for the purpose of acquiring information relative to the methods of pineapple cultivation so successfully pursued in that State, I have the pleasure to report according

ly. In addition to Pineapples I embraced the opportunity of investigating other important cultures in Florida capable of being turned to good account in Jamaica. The resourcefulness of the people there in developing new Industries greatly impressed me throughout my trip. They have little beyond tropical sun and sand at their disposal. For success they depend upon their characteristic energy, industry and perseverance. With these traits they transform the barren resources of the soil.

Before leaving for Florida, I called at Washington, where I had the honour of an interview with the Honourable James Wilson, Secretary of Agriculture in the Cabinet of Mr. McKinley (with the Secretary I may mention I had recently been in communication relative to the cultivation of new products.) I was

welcomed with the utmost consideration and introduced to the Chiefs of Bureaus of the Department, eminent specialists, who most generously placed at my disposal every source of information. Professor Webber, the well-known expert on hybridization, prepared my itinerary with references to the leading cultivators in Florida, whom he thought might be most useful to me in my line of investigation. It is only necessary to say that the exceptional attention I received everywhere, placed me in a position to acquire valuable information. In this connection I wish to offer my sincere thanks to Professor B. T. Galloway, Chief of the Bureau of Plant Industry as well as to Professor Webber.

ORLANDO the first pineapple region I visited, is situated on the most northern latitude at which pineapples are grown in Florida.

Until about 12 years ago the pineapples were cultivated in the open without protection, but the recurrent frosts rendered the cultivation too precarious, for the slightest touch of frost ruined a year's crop.

My references for Washington included one to the pioneer of a new system of pineapple cultivation Acres of sheds were constructed by this pioneer (Mr. Russell) and he commanded success. This system of cultivation is now exclusively adopted at Orlando, partly to afford protection from frost and partly to screen the pineries from the burning sun. Thus numerous pineries, ranging in size from one to twelve acres, are closely boarded all round 7 to 8 feet high. At regular distances posts are placed some 12ft. apart, on which are fixed connecting rods; on these are placed narrow rafters, between each of which a space similar in width is left for the admission of light. Through these spaces the light is admitted in glittering rays of sunshine, ample, it is abundantly proved, for the well being of the plants. A still more remark-

able feature of cultivation is demonstrated under these sheds, one that further exemplifies the constitutional flexibility of this plant. During several months of winter when frost is dreaded, when every hour of night is watched for possible disaster by all concerned, the whole of this shed structure is covered with canvas, sometimes even with laths fitted interstices of the fixed roof laths, with the result that all the plants in the interior are shrouded in comparative darkness for several months. Within this covered roof when the thermometer falls to about 400 in a two acre pinery a hundred fires are lighted, sometimes stoves. The smoke from the fires combats the frost, though the plants frequently suffer from the smoke.

In one instance last winter one of the best growers risked his one and a half acre pinery throughout the winter without using canvas. He experienced many a sleepless night, but there was no frost, and he said he had stolen a march upon his neighbours from the fact that his plants looked much better than those that were covered. However the other pineries that were darkened, bore crops just as well as his. Thus the dark treatment does not effect the accommodating powers of the plant. The cultivation under sheds is a remarkable success, it is not only perfect garden cultivation, but it rivals the most skillfully conducted green-house cultivation. Nine thousand are planted to the acre, every plant practically speaking flourishes. It is not uncommon to see a pinery with 95 per cent. bearing fruit. The average is 80 per cent. The soil is an important factor. It is nearly all sand containing as it does from 96 to 98 per cent. of silica. The growers furnish all the food by fertilizers which bring forth luxuriant crops; The fertilizers are manipulated and applied with scientific precision, just what is desired to ensure complete productiveness. There are altogether about 200 acres of cultivation under sheds. Large extensions are made annually. At the time of my visit there was one application for 100,000 suckers. A one-acre or a two-acre shed (and there are many such) is considered a lucrative investment for a small capitalist. The larger cultivators have sheds occupying from 5 to 12 acres each.

The cost of erecting sheds per acre averages fully \$300 and for the canvas as much more. They last about 7 years. Suckers cost 10 cents each, 9,000 per acre (\$900). The fertilizers cost about \$100 per acre annually. Thus an acre costs fully \$2,000 on the first crop. The first crop in about 20 months covers all expenses. The range of prices obtained is from 20 to 75 cents each. This is for "fancy" fruit, practically all Smooth Cayenne. The net profit is stated to be about 40 per cent. The leading cultivators nett more than \$3 per crate averaging 16 fruits. Some of the growers replant, after reaping each crop, some after two crops.

Throughout the year, even during the cool season, the sun shines with tropical brilliancy. During most of the year the temperature approximates to that experienced in Jamaica. During my stay it was higher than it is in Jamaica at any time. The average rainfall for 7 years has been 49 inches and it is evenly distributed. The suckers are set in long beds usually with 7 in the cross rows 18 inches apart and from 22 to 24 inches between the rows. The sandy soil is kept perfectly free from weeds by means a scuffle hoe every fortnight, with which also the fertilizers are turned in two or three times a year. This hoe is worked from the passages on either side of the bed.

Notwithstanding the sandy character of the soil, forests of pine trees covered the land anterior to cultivation. Oak trees are also dispersed here and there. The inference to be drawn from the presence of these and other trees, is that there is more stamina in the soil than is apparent. However the trees penetrate to a considerable depth. Certain varieties of Peaches and Pears flourish in the open when fertilizers are applied. Maize is cultivated on selected spots and yields 15 bushels per acre. In most parts the sandy soil is very deep.

The fruiting season is affected by shel cultivation. Crops are obtained to some extent at the time desired by the cultivator according to the time of planting. The principal season is in August and September. A grower informed me that the "Smooth Cayenne has the great advantage of blooming any time." The plants that bloom in the summer here produce finer fruit than the ones that bloom in the cool Spring. The size of the crates used by the Florida Fancy Pineapple Association is 12 by 20 by 24 inches, number of fruit 10, 12, 14 and 16.

The growers claim that the fruit from the sheds is superior to that grown in the Azores under glass, where the same variety is cultivated. One grower had a fresh stock of suckers which he imported from the Azores for propagating purposes.

JENSEN on the Indian River is situated much farther south, about 27° on the east coast. Here are vast fields, many miles of solid cultivation. Altogether there are several thousand acres cultivated on either side of the railway. Perhaps there is no such concentrated area of equal extent under sugar cane cultivation in Jamaica.

The pioneer pineapple cultivator here, indeed pioneer cultivator on the Peninsula of Florida, Captain Richards, gave me an historical account of his initial experiments; how he 18 years ago (at that time the district was a wilderness) brought the first schooner load containing 40,000 suckers from the Key islands, how they failed except a limited number, as he knew not how to treat them in the changed conditions of soil. He returned to the Keys for another schooner load. He persevered amidst the greatest difficulties. Mosquitoes were awful, heads and faces had to be shielded by a netted coutrivance. His first shipment to New York attracted great attention. A son is now a large grower, shipping from 8,000 to 10,000 crates per year (average per crate 30). This veteran is at present experimenting with Pineapple wines, etc.

This is the greatest Pineapple region in the world; about 200,000 crates containing six million fruits are shipped to the northern cities annually, and plantations are constantly being extended. Practically all the plants cultivated are the red Spanish variety. This variety is generally admitted to be inferior in quality to several others, but growers claim that "it is the hardest, easiest to cultivate and best suited to varying conditions." The Jamaica Ripley is well known amongst growers and is considered the most luscious of fruits, but though repeatedly tried it has not been successfully cultivated. The Smooth Cayenne is cultivated in the open to a small extent but not quite satisfactorily.

For a long period of years frost was unknown here, but the calamitous freeze of 1891-1895, destroyed all the plantations and ruined most of the planters. However most of the growers were determined to resist all obstacles,—the class of men that make a nation prosperous. They obtained from the Keys and the Bahamas fresh supplies of suckers and made new plantations. Another freeze two years ago, much less severe than the previous one, committed considerable destruction; suckers sprang up from the ground this time. Some pineries suffered more than others. From year to year the growers live in terror of the return of this disaster, though they look forward to comparative exemption from frost upon their devoted culture.

The soil here is practically the same as that at Orlando. The soil is a mystery, chemically and physically; it is not known how Pineapples can grow in soil which is practically devoid of plant food. "Just how it is that the pineapple can thrive in such soil that seems to be exceedingly deficient in all the necessary qualifications of good land has not been explained. It will probably be necessary to institute careful physiological experiments with the plants itself before the matter shall be thoroughly understood." Again I quote from the Agricultural experiment station Report "we have here a plant that increases in size during the period of greatest drought, when there may be no rain for 6, 8, and at times 10 weeks, in a soil containing 99.44 per cent. of insoluble residue!"

The average area of each pinery is from 20 to 60 acres. I noticed that the smaller areas were under much better cultivation than the larger. This is what might be expected, when it is remembered that a 60 acres pinery contains some 7,000,000 plants. Throughout these thousands of acres of pineries weeds are conspicuous by their absence. They are carefully suppressed in the early stage of cultivation. The plants are set about 18 to 22 inches apart, some 12,000 to the acre, including passages. This extremely close planting is considered advantageous.

It is claimed that this dense mass not only supports the plants and fruit, but that it prevents the growth of weeds. The first crop is obtained in about 20 months, and at this stage the fields present a fine symmetrical appearance. For the second and subsequent crops, a couple of suckers are left to each plant; this aggregates into a dense mass of plants after the first crop is harvested, so much so that one wonders how the fruit is cropped. Each sucker yields a fruit, so that greatly augmented crops are obtained. From the period of planting the cultivation is kept up from 8 to 10 years. I noted that they passed their prime in 4 years, hence frequent replanting would be better, but a crop at least is lost by replanting, and when they are densely massed a touch of frost affects them less than it does those wider apart. The 12,000 plants per acre is estimated to yield from 8,000 to 9,000 fruit per acre. These with the additional suckers yield from 9,000 up to as many as 15,000 per acre. I have frequently counted 8 and 10 fruits on a square yard. One man reaped 600 crates per acre this year, though some growers got less than 200 crates per acre, and this may be put down as the general average.

The great bulk of the crop is harvested in June. Last June the growers were unfortunate in having heavy rains (17 inches) which affected the keeping quality of a considerable number of fruits. Not long before they experienced a drought, the fruit was smaller on this account. The fruit when packed is sent by rail to Jacksonville the great distributing centre of Florida, —one day for this. They are then transferred to other trains for the north,—3 days more. When packed in the trains, a space is left between the crates for ventilation.

The standard size of the crate is 10½ by 12 by 36 inches, two divisions. A crate holds 18 large fruits, next sizes 24, 30, 36, 42 and 48. Average size 30. The 48's are so small that they are hardly worth shipping. Before packing each fruit is wrapped with paper.

The average amount netted per acre is about \$400. "We have had from one acre of pines containing 10,000 plants 250 crates averaging 30 to the crate, or 7500 pineapples, netting us over transportation, commission, &c. \$2 per crate or \$50 for the acre." Others state that 100% profit is realized.

The importance of ammonia and potash are constantly discussed, and potash applied at the fruiting season is said to improve the keeping qualities of the fruit. The fertilizers are mixed by the grower to suit his own opinion as to the relative merits of each ingredient. Certain fertilizers are simply thrown over the tops of the plants, but wherever practicable between them. The cost of fertilizer ranges from about \$50 to \$100 per acre per annum.

Many vegetable forms here are purely tropical, including some of our West Indian species, intermingled with scrubby oaks, &c. Innumerable trees were completely destroyed by the great freezes that swept desolation over Florida. The cool winter season here, barring frost, is quite favourable to many tropical plants. This is accentuated by the cloudless sky. The rainfall averages about 60 inches. Amongst tropical fruits that flourish here may be mentioned the mango and the avocado pear. This indicates the nature of the climate. The characteristic vegetation is the spruce pine and the beautiful palmetto which is distributed in vast numbers. Thus the two great representatives of northern and southern latitudes appear in companionship.

Besides the open system of pineapple cultivation so extensively carried on here, the Orlando shed system has been inaugurated since the great freeze of 1895, and so successfully that there is already about the same area of sheds as at Orlando, about 200 acres, and they are in point of size much larger here. Dozens of acres are being extended at a cost of more than \$300 per acre. Peaches thrive in the sheds but not outside. The Jensen (Indian River) growers cultivate the red Spanish pine under sheds in contra-distinction to the Orlando growers with their smooth cayenne. As already stated frosts are less frequent and less severe than at Orlando but the temperature falls to danger point under 40° from time to time, when the plants begin to suffer. No canvas covering or fires are used here. It is found that on a cold morning, the sheds conserve the temperature to the extent of a few degrees. This is important in itself, but other great advantages accrue by the adoption of this great plant growing contrivance. The Red Spanish plants grow far more luxuriantly therein, the fruit is one third larger and it is decidedly improved in flavour, and the plants are cultivated with considerably less fertilizing ingredients. Fruit burning is also obviated. Careful observation of the open fields and of the shedded fields side by side, conclusively prove the far greater luxuriance and more perfect cultivation under the latter. The adoption of this system of cultivation is quite as important for the Red Spanish variety as it is for the Smooth Cayenne.

The shed method has thus brought to light new cultural possibilities of the pineapple. Darkness during several months of winter at Orlando does not interfere with the perfect cultivation of the plant. Interrupted sunshine throughout the year by means of sheds for both varieties, enhances the luxuriance, productiveness, size and flavour of the fruit, and the cost of fertilising is materially reduced thereby. One great grower to whom I was referred by the Department of Agriculture informed me in the presence of another leading grower, that if he had from the first, confined his attention to 10 acres of sheds, he could have done better than by cultivating 60 acres in the open. Most of his cultivation is now under sheds. And the consensus of opinion is markedly in favour of shed culture. The same grower declared that more money is made out of the Red Spanish, than from the fancy fruit at Orlando, the demand for them being infinitely greater by reason of cheapness.

Oranges too, succeed perfectly in sheds, but the lofty structures requisite are very expensive. I have seen dozens of acres. Horticulturally the system ensures the most vigorous development of plants. At the great Hotels at Palm Beach, &c., ornamental plants are extensively cultivated in sheds. A notable instance of the importance of shed cultivation was expounded to me at Washington on my return from Florida. One called my attention to the fact that in the vicinity of Tampa on the west coast the shed system for cultivating Tobacco, is adopted with remarkable results, both as to quality and quantity "the crop is so valuable that the land is now covered with cheese cloth placed on wood framed 9 ft. high." In Jamaica, under sheds Tobacco may become an important industry. The quantity per acre would be greatly augmented as well as improved in quality, and it can be grown in places where it cannot be grown successfully without sheds.

The conclusions I arrived at with regard to the actual benefit conferred on plants by the adoption of shed cultivation are as follows:—It mitigates the fierce burning rays of a tropical sun upon plant life. It prevents continuous and excessive evaporation. It interrupts the force of winds which conduces to increased evaporation and aridity. Thus the whole mass of plants within creates atmospheric conditions of their own, conditions which are suffused throughout the shed.

PINEAPPLES ON THE KEYS.

From the port of Miami 25° 70' I proceeded in a schooner to Elliot Key, and Key Largo, the latter about 25° 20' to examine the methods of cultivation adopted there. Hundreds of Acres are under cultivation on these islands since about 1860 when they were introduced. On the keys an absolutely different system of cultivation is carried on. The plants are grown among the coralline rocks, between the crevices, the crow bar being used to open the crevices for the plants. The vegetation on the rocks consists of small scrubby trees. This is cut down and burnt. An inch or two of decayed vegetable matter covers most of the rocks. About a year after clearing this soil is completely washed into the crevices so that on some plantations earth is invisible, the entire surface being rock difficult to walk over. In other places there are small collections of humus interspersed among the rocks. The suckers are actually planted to the extent of 1,500 dozens to the acre (18,000). The cultivation of each piny is kept up about 5 years. Fertilizers are not used. The cultivators have the great advantage of having their fruit a few weeks earlier in the market, than those cultivated on the mainland and consequently realise a higher price. There can be little doubt that the earlier crop, arises from the high temperature emanated by the rock.

HYBRID PINEAPPLES.

During my interview with Professor Webber, the eminent Chief of Hybridization at Washington, on my way to Florida, I had the gratification of seeing the first hybrid Pineapple fruit. The first product of a new type of Pineapple; the result of many years of devoted skill; a new departure in the history of this fruit. This precious specimen created intense interest.

On my return to Washington from Florida, I was informed by the Chief of the Bureau of Plant Industry, by this time other hybrid fruits each distinctly different had been received from the Experiment Station in Florida; that the flavour of several of the types was extremely satisfactory.

At Miami I visited the Government Experiment Station where these fruits were grown, and saw the plant that gave the first fruit; there are about 300 hybrid plants altogether. Over a dozen had ripened fruit by the middle of July, and many more were coming to maturity. Each plant so far yields distinctly different forms, so that they will be numerous. Some of course will be superior to others. Those that have fruited are producing suckers for multiplication. It is also interesting to record the fact that many of these plants are smooth leaved, spineless, an important consideration from the grower's point of view, for it enables him to traverse his fields with great facility as compared with struggling through the spiny masses of leaves. It is further interesting to relate that the acquisition of smooth foliage was preconceived in the hybridizing operations, in view of its advantageous results. It was a source of pleasure to me to behold these precious achievements. In the near future we shall obtain specimens; for it may not be amiss to say, the Chief of the Bureau offered me most generously everything that can be spared by the Department. There can be no doubt that these important acquisitions are destined to advance the pineapple industry and extend its popularity everywhere.

I am glad to say I have received seeds from another source of rare varieties which I have sown and hope to grow for further experimental purposes. At the station mentioned there are also many new types of hybridized Oranges the merits of which are as yet unknown, not having borne fruit. Guavas are also hybridized here and many other tropical plants are experimented upon.

PINEAPPLES IN JAMAICA.

The number of fruits exported from Jamaica average only about 65,000 a year. This is what Florida grows on 10 acres. Quite recently the cultivation has received increased attention and judging from the area planted at least 400,000 should be exported very soon. Even this number however is closely approximated by individual growers in Florida. It will remain an insignificant

industry until we export millions annually.

Much of the cultivation is far from satisfactory. Small patches have been successfully cultivated but I suspect there is hardly any cultivator of an acre or two who has not been greatly disappointed. Probably we have had about 100 acres in cultivation for years, yet the export figures only show what is capable of being cultivated on 10 acres. The condition of the soil in Jamaica is the perplexing element. This is the secret of Florida's success. Intermediate between that barren sand and the ordinary soil of Jamaica, we have to strike the best possible medium. In other words to ensure success for this culture, the soil selected must be peculiarly sandy, gravelly or rocky even to the extent of impoverishment in the natural supply of plant food, which deficiency can be advantageously added according to the requirements of the soil.

As stated, in Florida soil is the all important factor and in order to make this cultivation successful in Jamaica on a large scale, soil is the important consideration.

There can be no doubt that the kinds best adapted to cultivation in Jamaica are the acclimatized varieties. The Smooth Cayenne, which by the way I introduced to Jamaica 30 years ago, is less successfully grown than the others. It seems to grow too luxuriantly, all into rank foliage. More sterile conditions of soil should remedy this.

Messrs. Elder Dempster & Co, have with a view to improve and establish this cultivation on a commercial scale decided to cultivate several acres on the Liguanea Plain under my supervision. My long experience in tropical agriculture, coupled with the advantages accruing from a careful study of this culture in Florida, where during my sojourn on the great pineapple fields I acquired much information, will enable me to turn to practical account improved methods of cultivation, the application to our most suitable land of the accumulated knowledge of Florida. I therefore hope to be able to instruct intending cultivators as to the most approved soils and methods applicable to Jamaica.

Pineapples are exposed in Jamaica to the burning sun throughout the year far more than is the case in Florida. I feel convinced that the inauguration of the shed system merits attention for the purpose of warding off the full blaze of the sun and for securing congenial atmospheric conditions. I therefore beg to suggest that I may be empowered to make an experimental trial of a one acre shed, 2 or 3 of the best varieties to be cultivated. On the dry Liguanea Plain, in places where the soil is extremely sandy, I am of opinion that these sheds will prove invaluable. To cover an acre with laths costs about \$300 per acre in Florida. There timber is cheap. We have bamboo which doubtless will answer the purpose perfectly, and it is cheap. Of this material I purpose making my experimental shed. Possibly creepers trained on wires might be substituted for laths eventually. The remarkable improvement appertaining to the pineapples under sheds in Florida can probably be attained by cultivation under sheds here. Thus the Ripley, judging from Floridian experiences, will be considerably augmented in size and improved in quality (a little difference in the size of the fruit doubles its value) and the fruiting season is in some measure regulated by shed culture. In Florida, as already stated, no expense is spared to ensure these conditions. Such a valuable crop is worthy of any improvement of soil, &c.

With regard to this cultivation on the rocks of the keys, similar rocky land abounds in Jamaica,—extensive areas under rank bush and considered uncultivable. These wastes with sufficient rain can be converted into pineapple fields. Little capital is requisite beyond what is necessary for the purchase of suckers. One man can cultivate several acres. Were these hills in Florida hundreds of acres would be planted yearly. Besides we are practically exempt from the plague of mosquitoes that torment the lives of growers on the keys. Sheds are not used on the keys. The rainfall is about 60 inches. In Jamaica,

too, as on the bare rocky lands of the keys, limes and tomatoes could be extensively cultivated, both for England and America. Tens of thousands of barrels and crates are exported from the keys, and large sums of money are amassed there from,

In addition to the methods of cultivation applicable to Jamaica, to which I have referred, I have the pleasure to recommend the initiation of another system, which I anticipate will prove most successful. Bearing in mind the peculiar conditions of soil under which the plant is cultivated on a great scale, viz., in the sandy soil of Florida, and on the rocks of the keys, I have arrived at the conclusion that we have in Jamaica another peculiarly favourable condition of soil on which it can be cultivated with the greatest success. Between Old Harbour and the foot of the Manchester Hills, and in other localities, there are thousands of acres of comparatively level limestone rock, on which there is a thin layer of earth about 9 inches deep. Only small trees grow on this land. The soil is too shallow for other cultures. The rainfall is about the same as on the keys.

Sand or rocks in Florida effect the most perfect drainage conceivable. The other type of soil which I recommend,—a thin film of earth resting on a bed rock, it is impossible to surpass from the drainage point of view. Being fertile it is more valuable than sand. The air permeates freely. These conditions assured, abundant rain, rain that would prove prejudicial without rock, will constantly invigorate the plants. Large areas are thus susceptible of cultivation based on the merits of the soil.—*Jamaica Board of Agriculture.*

(To be Concluded.)

CACAO CULTIVATION IN CEYLON.

MEMO. OF SUGGESTIONS BY THE P.A., SUB-COMMITTEE FOR EXPERIMENTS TO BE UNDERTAKEN FOR CIRCULATION TO THE CACAO COMMITTEE FOR REMARKS AND RETURN TO THE SECRETARY AS SOON AS POSSIBLE.

Name of Estate.

Acreage.

Elevation.

Monthly Rainfall (for as many years back as can conveniently be given).

No. of trees per acre.

Are the trees all of one variety, and if so, which; or are they mixed hybrids?

Approximate age of trees.

Number of pods harvested each month.

Weight of dry Cacao harvested each month.

Weight of black Cacao (dry) harvested each month.

Is there any shade other than wind belts, and if so, what trees do you use? (If certain areas are more or less closely planted kindly mention this)

Which in your opinion is best, and why?

Have you any Cacao trees with no or scarcely any shade? What is your opinion as to its vigour and yield?

Have you noticed any difference in the colour of the flowers—what coloured flowers in your opinion set most?

Which variety Foresters or Ceylon Red is in your opinion the heaviest cropper? Do you use manure? How often and in what quantity? What do you consider the best manure for Cacao, and what time do you think best for its application?

Have you noticed marked effects from the use of manure in gain in vigour or increase of yield in already vigorous Cacao?

Do you prune your trees, and if so, on what system, and have you noticed any benefit caused by it?

DISEASE. Is there any disease on stem, branches or pods in your Estate?

Have you adopted cutting diseased parts entirely out or shaving them, and if so, with what results?

What other treatment if any has been carried out in your Estate?

How often do you go round the whole Estate with curative work and how long does the round take?

What is the cost per acre of this curative work in the year?

What do you do with the empty pods?

Do you destroy diseased husks—by burning or otherwise?

What time of the year do you notice the effects of the disease most?

Is the disease worse in different parts of the estate—what are the environment and conditions in these areas as to aspect, dampness, shade and wind?

Whether the growing of suckers and gormandizers have been tried and whether they have enabled the trees to resist canker?

Whether artificial heating by steam has been tried in fermenting, or whether any artificial ferments have been used? With what effect?

The Committee will be greatly helped in their work of gaining knowledge of Cacao in relation to profitable cultivation if you will make experiments and carefully record notes of their results in the following matters:—

The growing of cuttings.

Suggestions.

Layering.

The elevation at which Cacao will grow vigorously by planting a few trees on spots at different elevations and recording their prosperity.

By taking off any non-fruit producing branches and suckers and noticing if the total production of fruit increased.

PRUNING.

GRAFTING.

MANURING.

A. PHILIP,

Secretary.

GRAFTING EXPERIMENTS.—According to a recent number of *Le Jardin*, M. Lindemuth lately showed before the Prussian Horticultural Society some interesting specimens of grafting, in which the graft had exercised a more or less marked influence on the stock. The plants were:—1st, Yellow Wallflower on Red Cabbage, in which the plant had developed below lateral branches of Wallflower, with a shoot of cabbage and a head of Red Cabbage. 2ndly, Brussels Sprout on Yellow Wallflower. 3rd, Abutilon Thompsoni on *Althæa narbonensis*. The former is a shrub, the second is a herbaceous plant. Owing to the influence of the Abutilon the branches of the *Althæa* became persistent, and indeed, are two years old. 4th, *Solanum erythrocarpum* on Tomato (*S. lycopersicum*). The Tomato being the more rapid grower, communicated this property to *S. erythrocarpum*. 5th, *Malvastrum capense* became variegated by grafting with Abutilon Thompsoni. 6th, Hybrid *Petunia* on *Nicotiana glauca*. If *Petunias* are grafted on the stems of *Nicotiana* of rapid growth, fine shoots of *Petunias* on the stems can certainly be obtained. Mr. Winter, of Bordighera, has already made this experiment, and has grafted *Petunias* on many branches of *Nicotiana glauca*, which in that district grows as a shrub. The effect should have been very fine, but a storm bruised the heavy branches of the *Petunias*. 7th, A new plant, with variegated foliage, *Sida napæa*, obtained by grafting with Abutilon Thompsoni, was a success in one instance, while another specimen remained green. 8th, *Althæa rosea* (Hollyhock) became variegated by the influence of the graft of Abutilon Thompsoni. Young seedlings of *Althæa rosea*, of *Malvastrum capense*, and variegated *Anoda hastifolia* have, so far, remained green.—*Gardeners' Chronicle*.

THE DATE TREE.

A writer 50 years ago stated that the date tree was the only tree whose cultivation was not neglected in Egypt. It might truthfully be said now that it is more neglected than any other tree. The cause is obviously due to the introduction of other staple foods, formerly unknown or rare, such as maize, beans, sugar cane, and many vegetables, especially the tomato and onion. Bread is now very cheap and the poorest beggar can buy it. European immigration has directly brought about the bettering of the lower and working classes and wages have gone up in many cases twenty-fold. The Berberee, especially, who formerly considered himself quite wealthy with the possession of a hundred date trees, now assesses their yearly profit at as many shillings, and finding the comparison between £5 per year and the wages and food received by his relations as cooks, bowabs, servants, etc., in Cairo, very unsatisfactory for himself, leaves his date trees to his wives and fathers-in-law and seeks work in the large towns. The characteristic national love of economy of effort has also greatly contributed to the neglect.

It is very interesting to read of the incidents which attended the introduction of many parent trees into this country. Rich and notable sheikhs made it a rule to bring back, if possible, on their return from the pilgrimage to Mecca, a young date tree taken from the base of some good tree en route. The usual chapter of accidents, as well as the ordinary mishaps, such as disease, plague, highway robbery, want of food and the death of the camel or the tree on the way, reduced the number of trees successfully introduced to a minimum. The species generally received either the name of the sheikh or the place of origin. It is probably owing to this custom that whilst there are only about 22 different varieties of date palms in Egypt the trees comprising them have about 250 different names. Of late the pride taken in their cultivation and the feelings almost of veneration for them have died away. The five commonest species grown in Egypt and the Soudan are probably; the Bedreshin, Cairo, Rasheet, Rasson Wadi, and the Fayoum date trees. The Bedreshin tree is very common, fruitful, and very high; its fruit is good and is ready about September. The Rasheet, largely grown in the Delta, is about half as high, has spreading leaves, and its fruit is large and lime-shaped and is not ready until the winter. The Cairo tree is also a smaller one and has smaller but sweeter fruit. The Rasson Wadi is said to have been brought from Arabia by a Moudir of Zagazig. It is like the Bedreshin date but has inferior fruit. The Fayoum is a smaller variety, has many spreading leaves, and its fruit is thin but very sweet. Some dates are only fit to dry, others to press, and others again to be eaten fresh. To cater for the native requirements is altogether unnecessary, for not only do these trees yield their supplies for local consumption but several hundred tons of inferior dates valued at about £7 per ton are imported yearly from Turkey. An adequate financial return for trouble and expense can easily be gained in Egypt by all cultivators who will extend and grow the better kinds of date. The Basha or Vanille date tree, the Sultani, and the Rasheet are excellent varieties and pay well. That superior fruit gives best returns can be seen by reference to the reports of the British Chamber of Commerce of Egypt, which give the annual average export of dates from Egypt for fifteen years as 645 tons, valued at about £18 per ton. For 1899 and 1900 the value was only £16 per ton, and yet the superior quality of Tunisian dates of the best kind imported was valued at nearly £32 per ton, "nearly double the price".

From one or two important grocers in Cairo it has been learned that a Greek merchant has taken the trouble during the last two seasons to buy and neatly pack in 3-oke boxes some of the best and largest dates, which he has supplied to the grocers for sale

at the retail price of 5 piastres per oke. Last year he only put on the market about half a ton, but all were very quickly sold. This year he has been able to procure about 4 tons and has already disposed of them all. This should be extremely encouraging to those who intend growing good trees. A few years ago England had only the boxes of pressed dates sold retail by street-hawkers on trucks at about 21. per lb and by grocers at perhaps a penny more. Immediately the import of dates in fancy half-pound and pound cardboard boxes from Algeria began, fruiterers, although at first over-cautious because of the price, found the sale quite easy and the demand increased enormously. Now, on account of their good appearance and superior flavour, they are becoming generally popular even with the middle classes. Much of this trade could be captured by cultivators in Egypt, for in no other country of the world is the climate so suitable for the date. Other products of the fruit and the tree might also be supplied, especially vinegar (similar but superior to that made by the fellahen), wine, preserve, brandy, and brooms.

There are many faults committed in the cultivation of the date palm in Egypt. Not only is water a necessity, but manure also, and so many of the trees which do not bear cannot do so simply because the roots have taken from the ground all available nourishment. The bases of the trees also are yearly left more exposed owing to the contact of the water. A good grower sets his young trees in a trench which is gradually filled up with fertilisers or good soil. The roots should never appear as they do almost everywhere in Egypt in old trees. Another serious fault, sometimes causing the same effect, is the want of sufficient root space. Cases could be mentioned where Arabs have taken the trouble to dig in the hard rock "with a pick-axe holes about three-quarters of a metre square, and set in these young young date-trees. On the premature death of these trees after an initiatory growth of promise they would probably sum up the cause by the ejaculation, "Wallah"—It is the will of God. Where the roots encounter resistance of the subsoil they will often push the tree out of the ground for several feet, and this is by no means an uncommon sight. Thinning fruit in its earliest stage is often very necessary. Natives generally allow it to fall but each fruit has robbed the tree of a certain amount of nourishment which might have been given to the remaining dates. Not many growers are willing to understand that 30 okes of large fine dates will bring in three times as much money as the same weight of small and ordinary ones. Yet many trees properly cared for can, and do, produced fruit as large as lemons or bananas if thinned in the same way as we thin grapes in our English vine-houses.

Young trees should be taken from the bases of the best varieties when 7 to 10 years old. They should be set in trenches about a metre wide where there is plenty of good surface soil. They should be put in the ground up to the leaves, which should be wrapped round with matting or straw. This favours the growth of the roots. Care should be taken to provide free exit for the new leaves at the stem. They should begin to bear fruit in three years and be in full bearing in 10 years. Trees grown from kernels are more healthy and vigorous and may live for 200 years. They are however a very long time growing to maturity and it is impossible to tell before flowering whether they are male or female. The young shoots at the stems, on the other hand, are always of the same sex as the parent. As the trees get old the lower parts of the trunks are inclined to become stony and the sap is unable to flow through them easily. It is well in such cases to apply a fermenter in which nitrogen and phosphates predominate; the former to accelerate the movement of the sap, the second to promote the formation of new cells, and new tissues, and to facilitate flowering and fruit

fication. When the new tissues have gained a predominance over the petrified ones, the vital activity is strong, and the tree grows again under normal conditions. Manganese applied as a fertiliser exercises its oxidising action and procures the free circulation of the sap. The tree can also be beheaded but before doing this a hole must be made through the trunk about twelve feet from the summit and a cylinder of wood inserted so as to protrude on each side. Round this must then be fixed plenty of soil and manure which must be kept continually moist for about a year. The top part will then have sent out roots and can be planted just in the same way as a young tree. Should a date tree by any accident have its crown broken off or core damaged it may shoot out again if the top be covered with clay to keep in the sap. The process of grafting described some time ago by "Appell," in the correspondence column of the *Egyptian Gazette*, does not seem to be known either in Egypt or the Sudan, though trees have been known to bear branches and shoots throughout the stem where they have been neglected. Some are to be seen at Ab Ain el Wadi in the Iddaila Oasis.—*Egyptian Gazette*.

THE VALUE OF CHEMICAL MANURES.

Under the auspices of the Bristol and a District Gardeners' Mutual Improvement Association, a most instructive lecture was given in St. John's Rooms on Thursday, January 9, by Mr. F. W. E. Shrivell, F.L.S. F.R.H.S., of Golden Green, Tonbridge. His subject was "Chemical Manures in the Kitchen and Fruit Garden," and was based upon the results of seven year's experimental work carried out in conjunction with Dr. Bernard Dyer, E.L.C. F.L.S. F.O.S. H. Cary Batte Esq. President of the Association, presided over a good attendance, and was accompanied by Mrs. H. Cary Batten, who also takes a deep interest in the work of the society. The president, introducing the lecturer, alluded to the great importance of the subject to the district, where so much attention was devoted to agriculture and horticulture.

Mr. Shrivell, who illustrated his remarks by a series of diagrams, explained that for many years dung was the chief manure both for the farm and garden, but they were now trying, by means of a series of experiments at Tonbridge, to discover whether it was better to use large quantities of dung, or to use a smaller quantity with chemical manure, or to use chemicals entirely. With regard to the system upon which their experiments were conducted, the land on which each vegetable or fruit was grown was divided into sections, each being in area a fiftieth of an acre. One section was manured with heavy dressing of dung; a second with light dressings of dung; a third with chemicals only; and the other three with a light dressing of dung, an ordinary dressing of phosphatic manure (either basic slag or superphosphate of lime) and varying quantities of nitrate of soda. Diagrams were shown, proving that after seven years' experiments, the best result was obtained by employing a small quantity of dung with the use of chemical manure, this being specially noticeable in the case of Broccoli, Potatoes, &c. Nitrogen, phosphates and potash were the elements of farmyard manure. The value of dung was that it was such a marvellous mechanical agent. On light sandy soil, for instance, in dry weather it tended to keep moisture in the ground and prevented evaporation. In the clay soils it tended to lighten it and aerate it to a very considerable extent. That was the great advantage of farmyard manure or what was ordinary called dung. But it had a great disadvantage, and that was its cost. Speaking,

WITH REGARD TO FRUIT

the lecturer said experiments had been made by treating its culture in the same way as the vegetables were treated—heavy dressings of dung, light dressings of dung, plus chemicals, and chemicals alone. He

had experimented on Gooseberries, Black Currants, Red Currants, Raspberries, and Plums with light dressing of dung, plus chemicals, and with chemicals alone; and in doing so, interesting information upon the effects on the different fruits. For the purpose of bush fruits—Currants, Raspberries, Gooseberries, &c., the quantities for 100 square yards (broadcast) should be 10 lb. superphosphate, 10 lb. kainit, to be applied during autumn or winter, and in early spring 7 lb to 10 lb nitrate of soda. With regard to strawberries, experiments showed that they could not grow Strawberries entirely by the aid of chemicals, but that with a light dressing of dung added to chemicals, they would be much more satisfactory to the grower. Chemical manures were also useful for the purposes of growing Onions, Beet, and Celery. With regard to the latter, he knew that most gardeners were much in favour of sewage, when they could obtain it, but he strongly advised them never to use sewage, for there was a great objection to its use in growing any vegetable that was eaten raw. Sewage should never be used for anything that was not cooked. By its use in this respect, they were apt to spread such diseases as typhoid and diphtheria. In the use of chemical manure for Celery, they would have to use discretion, but they would find that a small quantity judiciously used would ensure a splendid crop. Then, again, they could make a good liquid manure for Cucumbers and Melons. One ounce of nitrate of soda in a gallon of water used once or twice a week would considerably assist them in growing these. Chrysanthemums again were the most difficult plants to deal with; a light liquid manure of half-ounce of nitrate to one gallon of water, might be used when the buds began to form, but they should stop to use it when the buds began to break. In the kitchen garden, chemicals for 100 square yards, with half a load of farmyard manure, should be used thus: Superphosphate, 14 lb. kainit, 10 lb. This should be dug in with the manure in autumn or early spring; and later on they should sow on the surface 10 lb of nitrate soda in two or more dressings.

After referring to the dressings for herbaceous borders (basic slag, 14 lb; kainit, 8 lb, pricked in in autumn; and nitrate of soda 8 lb, in March and April to the 100 square yards, Mr. Shrivell spoke on another subject which he said was important, and especially to the professional gardeners. This was

THE SUBJECT OF LAWNS.

He knew that many gardeners were troubled with Daisies and different weeds on lawns. He thought that wherever they had got a ground with a tremendous quantity of weed on it, that told the tale that the ground was really very poor. If he gave them something to make their lawns grow, they should not grumble at him if they had to cut the grass more often. There was a suggested dressing for a lawn of 100 square yards—14 lb of basic slag with 9 lb kainit, and a later dressing of 5 lb of nitrate of soda. This combination was a plant food to produce the finer Grasses and Clover, while it would do away with the Daisies and commoner weeds in a lawn. It did not follow that if they put this on one year that they need put it on the next. The basic slag and kainit had a tendency to stimulate the growth of Clovers: and if they did not want Clovers, they must keep these two away; but if they wanted a little Clover or Trefoil, put it on. That would do away with the Daisies. Whenever they saw a meadow full of Daisies and Buttercups they knew perfectly well that, as a rule, it was a poor meadow. They must use nitrate alone if they did not wish to grow Clover. His own feeling went to the balanced manure. It was very rarely that lawns had a dressing, the only thing they ever got was a little lawn manure, which was simply sand plus nitrogenous manure. The lecturer gave many other instances of the value of chemicals, and concluded his address amid applause.

(We must apologise to the Bristol gardeners for having held over this interesting and valuable reports,

Necessity has no law!—(Ed.)—*Journal of Horticulture Cottage Gardener.*

PINEAPPLES AND THEIR VARIETIES.

We have received the following letter from Mr. J. C. Harvey, of "Buena Ventura" Plantation, Isthmus of Tehuatenpec, San Juan, Evangelista, P.O. V.C. Mexico Dated 25th Nov., 1901, and which is worthy of publication:—

In the October issue of the "Tropical Agriculturist," I note an article signed J. B., copied from the Journal of your Society, re Pineapples, and although my principal interest here is Rubber and Cacao I take a special interest in all fruits, if only for home use, and have according to invoice of some two years ago some (2) varieties of pines—besides two sorts which I know nothing of. As a Britisher I hope I may be privileged to ask you a few questions, and also desire to submit a proposition. First, however, is there any difference between Smooth Cayenne and Kew Giant? also, as between Golden Queen and Egyptian Queen? Do you know anything of a pine called Black Antigua? also Mauritius? What is Ripley Queen as against Jamaica Ripley? Is there such a pine as Trinidad? To my mind, pine nomenclature seems very much mixed. What is Black Jamaica? All these pines I have at least sent to me by a Florida specialist. Now as to my proposition. I have a pine here embracing in my opinion every good quality a pine should have, it was introduced four years ago direct from Guatemala—or lack of a name I call it "White Guatemala Spineless"—it is absolutely smooth and has much the appearance of Smooth Cayenne, that is to say, the plant. You doubtless are aware, that smooth Cayenne, has a very few short spines at the extremity of every leaf, and that the flesh is yellow, this plant has absolutely no spines whatever, and the flesh is almost snow white—sweet yet with a sprightly subacid, yet not stinging taste as some have—the fruit is technically smooth, not shouldered, nor yet conical—in fact, perfect in form—reaches with me with practically no cultivation 7 lb., if the suckers are taken at the right size ripens from end of January to June, and even July according to planting, core never woody—from the fact that I have had them in the house 10 days for perfect ripening should be a good marketer; it is a vigorous plant and makes plenty of slips or offsets—though not such a great number as Golden Queen does—anyway, a strong plant that can be calculated to give from 8 to 15 for propagation annually. I cannot find any account of a pine in either Florida or the West Indies, agreeing with these characteristics, and I feel sure it would be a most valuable addition to your list of pines. I may say as regards soil that this pine seems to grow remarkably well in heavy soil, and in a much damper situation than many others I have, indeed some rot away completely at the roots under similar conditions, and have to be planted in selected situations—it also appears to do well in moderately dry places, though I think on the whole it is best adapted to moderately damp situations in rather heavy rich soil. Our rainfall here is 100 inches distributed over eight months, the bulk of the rainfall however occurs from May to October after which occasional rains till middle of February. March, April, and the most of May hot and dry.

Now what I desire to say is that I should like to get the following:—2 Rothschilds, 2 Ripley (red), 2 Ripley (green), 1 Sugar Loaf, 2 Bullhead, 2 Black, 2 Cowboy, 2 Cheeso, 2 Sam Clark, 2 Jerusalem—19 Slips for which I will send an equal number of offsets of the White Guatemala Spineless, they can be sent either way by mail—that is between Mexico and Jamaica.

I, of course, do not know whether you can attend to this yourself personally, if not, will you kindly communicate with some grower that would care to do so, and advice at the earliest opportunity as I should greatly like to conclude the transaction before the dry seasons,

Are your publications for sale, if so, kindly advise cost of subscription.

We have replied as follows:—

We are in receipt of your letter of the 25th November, and have pleasure in replying to your queries as follows:

- 1.—The Smooth Cayenne Pine Apple and Giant Kew are the same.
- 2.—The Golden Queen and Egyptian Queen are two of the Queen varieties, (the Ripley being a third.) They present similar characteristics but are not the same.
- 3.—The Black Antigua is the common pine shipped in quantities from Antigua.
- 4.—The Jamaica Ripley is the same as the Ripley Queen, the Ripley being one of the Queen varieties.
- 5.—We have never heard of any distinct variety called "Trinidad."
- 6.—It is indeed very desirable that pine nomenclature should be brought to some uniformity, now that in so many places pine culture is being put on a commercial basis.
- 7.—Black Jamaica is often called Black Spanish. It has dark green leaves, shading to a darker hue, almost a blue-purple in the centre, and the leaves are hollow—not open and flattish. The fruit is dark green, and is fit to eat before it shows any yellow or red. The leaves have little hooked prickles, not spines like the teeth of a saw, but set distinctly from each other.
- 8.—We do not know the White Guatemala Spineless, but all smooth-leaved varieties, so long as they are hard-fleshed and can carry well, are worth cultivating, because of the facility for working when close-planted. Your description of this variety almost fits our "Bull-head," but our variety, although sometimes having entirely smooth leaves, has generally some prickles set irregularly on the leaves; sometimes indeed the leaves are almost all prickly. The flesh of the Bull-head, when the pine is cultivated, is smooth, hard and white, with hardly any eyes, and has a sweet acid flavour much as you describe. The "Bull-head" also grows well in heavy soil, and though some Florida men have said it is the same as the Red Spanish, others have said it is not,—and we do not think it is.
- 9.—We will send you three or four of the varieties you name, but Bull-head and Cowboy are the same, and so are the Cheese and Sam Clark Pines. We shall attend to this personally, not knowing any one who will take the matter up in the spirit of an exchange. The subscription to our Agricultural "Journal" (copy sent herewith) is 4s. per annum, and one shilling extra to foreign subscribers.

We have here:—

- Ripley—Red and Green.
- Golden Queen (which might be called Yellow Ripley.)
- Bull Head or Cowboy, (which is sometimes called Red Spanish, but is not.)
- Sam Clark, Queen, Cheese, Goffe Pine, Red Pine; which we have called "Red Jamaica."
- Sugar Loaf which you know.
- Black Pine or Black Jamaica.

China Pines, very similar in general to the Black, but presenting some difference when examined closely in shape and colour of leaf, in placing of spines, and in colour of fruit. These characteristics of China Pines will be closely noted during the coming fruiting season.

Ahhakas and Smooth Cayenne, imported from Florida and grown to a good extent here during these last few years.

Rothschilds and Envilles, only grown here to the most limited extent as specimens.

We have arranged to get the pine suckers asked for sent, and on receiving the "White Guatemala Spineless" suckers, will send them to the Public Gardens to be tried.—*The Journal of the Jamaica Agricultural Society.*

Wilson, Smithett & Co's Ceylon Tea Memoranda for 1901.

LONDON, MARCH, 1902.

A review of the course of the CEYLON tea market during the year 1901 is somewhat depressing, and is only relieved by the hope that the experience gained by the crisis, through which the industry has been passing, may prove of real and lasting benefit in the future. The evils caused by the over-production which resulted from the extensions indulged in, both in CEYLON and INDIA, during the era of prosperity enjoyed by tea-growers a few years ago, were considerably aggravated during the past two years by the disorganization of the home trade in the early months of each year, occasioned by the anticipation by distributors of an increased Duty in the Budget proposals, resulting in a large volume of artificial business for the purpose of duty paying, and corresponding heavy capital expenditure, which reduced purchasing powers and affected trade in the country for a considerable time at a period of the year when the arrivals from CEYLON were heaviest.

The average Price of all Ceylon Tea sold on Garden Account in 1901 was 6.80d per lb., against 7.25d in 1900 and 8d in 1899.

During the year under review the ill-effects of the Duty seare were even more marked than in the preceding year. The full effect of the coarser plucking resorted to both in CEYLON and INDIA, after the period of high prices in 1899, was not experienced until the early months of 1901, when the heavy arrivals of inferior to common tea were neglected in the rush to pay duty on previous and current purchases of more desirable qualities. At the commencement of the year the quotation for commonest Souchong stood at the very low figure of 4d per lb., and during the following two months it gradually declined to the hitherto unrecorded level of 3d per lb., whilst the coarsest qualities, of which unfortunately there was no small supply, sold at still lower rates. Had these ruinously low prices been confined to the abnormally coarse leaf, which was primarily responsible for the fall, there would have been slight occasion for regret, but the establishment of such low quotations had the effect of reducing the values of the necessary grades of useful Pekoe Souchongs and Pekoes to 4d and 4½d per lb., and several months elapsed before any distinct recovery set in, too late to save many gardens from incurring actual loss in the year's working.

The serious crisis with which planters were confronted and the obvious nature of its primary cause, ensured such steps being taken, without any collective action, as to modify to some extent the output of the

season 1901-2. Manuring operations were to some extent restricted, coarse plucking was reduced, and, finally, Nature herself intervened with climatic conditions unfavourable to heavy flushing, and assisted in putting the industry again in a slightly more satisfactory statistical position, thus not only limiting the supply, but giving the bushes a much needed rest, which should be compensated for by improved body and flavour in the near future.

If, however, a system of rather finer plucking was adopted during the past year on those estates most responsible for the commonest leaf in the previous season, it does not seem as if that policy was universal, at all events on those estates which were remarkable for good tea during that period, and which then actually benefited by the inferiority of the bulk of the crop. The quality of the great majority of up-country teas was distinctly inferior in the autumn of 1901 to that of the previous year, and owing to the improvement in the classes below, the crack marks were considerably less prominent for quality, and consequently commanded less competition and realised lower prices. The district of UDA PUSSELLAWA was most remarkable in this respect, the teas of this district being much less distinguished for their usual characteristic point and flavour; possibly the cause may be attributed to climatic exigencies unlikely to be repeated in the ensuing season, with which we are not acquainted.

The rest, to which the bushes have for some time past been involuntarily subjected, will, in the ordinary course of events, be probably followed by prolific flushing, and it seems advisable therefore that consideration should be given this year to the expediency of resorting to a system of plucking, more like that which used to obtain in the earlier days of the industry, when a maturer leaf was gathered, more especially in the case of those high-country estates to which we have been accustomed to look for a supply of fine CEYLON tea, but which have of late produced so much ordinary quality leaf. Although, owing to unfavourable climatic conditions, the actual output from CEYLON has, during the past few months, fallen considerably short of estimates, STOCK OF ALL GROWTHS, visible and invisible, remains very large—some 30,000,000 lbs. in excess of that existing three years ago, when the important advance in the price of common tea took place, and it seems reasonable to expect that by Midsummer, unless very unlikely circumstances should arise, an ample supply of common CEYLON will be assured, to provide for the requirements of

the dull summer season, followed by a plentiful supply of low-priced INDIAN leaf in the autumn. If this should prove to be correct it would seem to be to the advantage of the high elevations to check the desire for large yields, and to produce a more moderate quantity of really good tea as in earlier years, leaving the supply of "good common" tea—not unduly coarse leaf—to the low-country and medium elevations. It must have been apparent to the producers of a good deal of up-country tea during the past season that their manufacture did not compare satisfactorily with the most useful type of thick plain liquoring tea of the lower elevations, by reason of the character of their liquors which were so generally wanting in body and, insufficiently characterised by point and flavour, as well as on account of their lack of distinction in make and appearance.

HOME CONSUMPTION OF CEYLON TEA during 1901 fell short of that of the previous year by 1,500,000 lbs. and declined in the year to 35.55 per cent. of the total, from 37 per cent. in 1900. This may be attributed, not to any decline in popularity of the leaf at home, but to the encouraging fact that the RE-EXPORTS showed a remarkable expansion. The total DELIVERIES, HOME CONSUMPTION and RE-EXPORTS together, exceeded the LANDINGS by 3,600,000 lbs. This inroad on the STOCK unfortunately did not prevent a decline in values owing to the excessive supply of INDIAN tea.

FOREIGN TRADE.—The steadily increasing hold that the CEYLON growth is obtaining in the extraneous markets of the world forms at least one subject for congratulation. The RE-EXPORTS from LONDON to the various Foreign markets during 1901 were 4,300,000 lbs. in excess of those of the previous year, notwithstanding the fact that the IMPORTS showed a falling-off of 9,200,000 lbs., and formed 41.70 per cent. of the EXPORTS of all growths, against 32.56 per cent. in 1900 and 6.30 per cent. ten years previously. A reference to the table we give of the DISTRIBUTION OF BRITISH IMPORTS OF CEYLON TEA will show that

the increased demand for CEYLON tea has not come from one or two quarters only, but was practically universal.

The development in the direct trade from COLOMBO to the different tea-consuming countries of the world is also very encouraging. AMERICA and CANADA took rather less in this way than in 1900, but the fact that AUSTRALIA last year absorbed nearly 21,000,000 lbs. is a most satisfactory feature.

GREEN TEA.—This new feature in CEYLON manufacture has attracted a fair amount of attention. The demand for CEYLON GREEN TEA was not unnaturally somewhat spasmodic and quickly satisfied, but, on the whole, satisfactory prices were realised for the best samples. As was generally anticipated it was in AMERICA that this class of tea enjoyed the readiest market, and there seems to be little doubt that in time it will prove a formidable rival to the JAPANS and CHINAS, which have for so long held the field in the STATES and CANADA. At home, especially quite recently, the scarcity of CHINA Green Teas and their consequent important rise in values caused LONDON buyers to turn their attention to the CEYLON variety, it being thought that the fact that it blended less ostentatiously with Black Tea would make it acceptable. So far, however, this characteristic seems to have proved a bar to its finding favour with the old-fashioned consumers of Green Tea in this country who apparently prefer the unmistakable presence of the CHINA sorts in their blends. The demand for GREEN Tea in this country is, however, so unimportant that Planters will be well advised in confining their attention to the requirements of AMERICA and CANADA with regard to this description.

Our Summary of CEYLON tea sold at auction during 1901 comprises 600 marks. Owing to the endeavour to establish "unreported sales" last summer a good deal of tea was disposed of privately for a time, and it was frequently difficult to obtain authentic prices. We trust, however, that our statistics are not affected by this to any important extent and we can only hope that these Memoranda will prove as useful and correct as it is our constant endeavour to make them.

Estimated relative YIELD and AVERAGE PRICE realised for the different CEYLON Tea Districts, compiled from the Public Auctions held in LONDON between JANUARY 1st and DECEMBER 31st, 1901 :—

	1901. lbs. about	Average Price per lb. about 1901.	1900. lbs. about	Average Price per lb. about 1900.	1899. lbs. about	Average Price per lb. about 1899.

FORESTS AND CLIMATE.

Tripoli was formerly a land of crops and woods. Now it is a desert containing ruins of the Punic and Roman periods. M. Mehier de Monthuisieux, after traversing deserts of moving sand and awful stony roads, has visited Jebel Iffren, a mountain rich in traces of the Roman occupation, otherwise poor indeed — *not a tree, not a blade of grass*. The principal ruins are those of the ancient town of Sabratha, and those of Leptis Magna, the old Punic and Roman capital. These ruins show the former importance of the great emporium. The dead cities, formerly superb, are now humbled beneath the sands of the desert. During the Punic era the sands were not given to wandering, the earth was teeming with vegetable life. More in the interior may be found interesting remains of the old Roman towns on the plateau of Torohna; these contain numerous constructions somewhat in the form of a portico, and with considerable certainty may be described as oil factories. The country was formerly covered with olive trees: Tripoli was one of the great granaries of the Roman Empire, an abundant source of corn, of oil, and of wine.

“To-day the whole region has become sterile, because of the disappearance of the great forests in the interior which held up the water and distributed it by the river-full.” At present this former granary of Europe contains a miserable and scattered population living or starving, on a few lean patches of barley or alfalfa. M. Mehier thinks that the rest of Tripoli will soon be in the same state as Sabratha, Leptis, Oca, and the rest, for without forests water disappears, and without water man disappears.—*From an article*

by ROGER DUCAMP, *Head of the Cochinchina Forest Department, in the "Revue des Eaux et Forests."*—*Indian Forester.*

PLANTING NOTES.

COLD STORAGE OF FRUIT.—Various experiments have been made in France as regards storing fruit, flowers, and vegetables, in ice chambers. M. Loiseau, President of the Montreuil Seine Societe d'Horticulture, showed at the autumn exhibition of the National Horticultural Society at Grand Palais some Peaches that had kept perfectly in a refrigerator built according to the plans of M. Douane, of Paris. The Peaches had been kept in the chamber fifty-three and fifty-eight days, and represented the varieties Mignonne, Bonouvrier, Belle Beauce, Imperiale, Alexis Lepere, and Galande. A wholesale dealer offered four francs each for them. The experiments will be continued.—*Gardeners' Chronicle.*

“RUBBER CULTIVATION IN WEST AFRICA.”—This handbook is by Mr. J. H. Holland, Curator of the Botanic Gardens, Old Calabar, Southern Nigeria. It contains mention of six of the principal rubbers of the world: Para, Ceara, African Vine, African Tree, Central American, and Assam, representing the three natural orders Euphorbiaceae, Apocynaceae, and Urticaceae. Para rubber is not successful in West Africa; Ceara grows in some districts, but is a failure as a rubber producer, as also is Central American. Assam, after ten years' trial, does not yield so well as when growing naturally. Landolphas, from their climbing habit, are not well adapted for cultivation. The native tree (*Funtumia clastica*) possesses many qualities to recommend it. The rubber is of good quality. The book before us includes five large and useful plates.—*Gardeners' Chronicle.*

AMERICAN VS. ENGLISH MACHINERY IN CHINA.

Apròpos of the frequent announcements going the rounds of the newspaper press, anent the capture of machinery orders by American firms in markets which the British manufacturer had previously dominated (certain identical reports being frequently repeated *ad nauseam* in the same journals in different forms), it is refreshing to get a glimpse of the other side of the question, and to find that one, at least, of the representatives of our chief staple industry requires not the admonition to "wake up." An old established firm of English Flour Mill Engineers have just secured the contract for the supply and erection of a large flour mill on the most modern system in North China. More than one firm of American makers were competing for the work, and, although they claimed to produce by their process better qualities and higher percentages of flour, the English firm in question was able to satisfy the buyers as to the superiority of their machinery, and its ability to produce qualities and percentages equal, or superior, to the Americans. This English house takes the contract at a price below any of the American houses, and has undertaken to ship the whole plant in ten weeks from date of acceptance of order. The firm in question is Messrs. E R & F Turner, Limited, of Ipswich, who, some months since, shipped a similar complete flour mill to China, the order for which was also secured in competition with America.

EXPORT OF JAPANESE TEA.

(To the Editor of "*Home and Colonial Mail*,"

Dear Sir,—The producers of tea in India and Ceylon are now endeavouring to copy the Japanese in their methods of manufacturing unfermented teas, and they may also take a lesson in another direction from the clever and capable people who have forced themselves so far to the front as to have become allies of Great Britain itself. Growers in Japan have ascertained that *quality*, not quantity, in production of tea is what pays, and it is a very significant fact that the exports have fallen from their maximum point in 1891 to the extent of 20 per cent reduction in 1900, but the valuation of the smaller quantity in the latter year was fully 30 per cent above that of the larger in the former year.

The moral is a plain one. If India and Ceylon can keep down their quantities, improve their qualities, and gain an increased 30 per cent on the selling values, the crisis in tea production will soon be a memory only.

Japan tea in the United States and Canada has fairly well held its own in consumption because of the very great attention and careful preparation given to the production for its principal foreign market, and all this in spite of the libellous and misleading advertisements regarding it formerly widely circulated in the interests of India and Ceylon tea. Those really did more harm to the latter than to Japan teas in disgusting the regular traders, who were trying to sell both, and they have done further harm in inducing the Japanese merchants to advertise very successfully the purity and merits of the tea they produce and sell. Indian and Ceylon teas, if of fair quality, well made, and sold at reasonable prices, should be their own best advertisements.—I am, sir, yours, &c.,

JOHN McEWAN.

10 and 11, Lime Street, E.C., March 6th, 1902.

THE SETTLEMENT OF THE COCOS ISLANDS.

It would be hard to match for qualities of romance the story told in *Blackwood* by Mr

Hugh Clifford of the settlement of the Cocos Islands. This real Viking Saga begins in the Orkneys in the first years of the nineteenth century. A chance whaling ship put in at one of the lesser islands in search of sailors, and two unwilling brothers were taken on board, their father seeing no other possible way of finding for them an opening in the world. The scene is then changed to Northern China, where the whaler is filling water-casks, and is there boarded and captured suddenly, and without disturbance, by a ship of war belonging to John Company. The reason of this piratical proceeding is then explained to the whaler,—the other ship's navigating officers had died of cholera, and substitutes had to be obtained from somewhere. Finally, the Orkney lad, George Ross, was handed over—he had a capacity for navigation —and the young Viking worked the ship without accident through perilous seas till they reached Calcutta. Warren Hastings heard the story, and gave the hero of it a naval commission. George Ross rose rapidly, and was associated with Raffles in Java, and shared his chief's misery at giving up the island to the Dutch. Had the officials in the Foreign Office in London troubled to break the seals of Raffles's despatches and read them, it is likely that no retrocession would have occurred. Through the years of his active life the Viking had longed once more to return to the island in the North from whence he came. Therefore he took a ship, whose building he had superintended, in discharge of his arrears of pay, manned her with Malays, and set sail for Thule. On the way thither he came upon a coral island, became in love with the place and brought there all his Northern kinsfolk, who together with Malays made the ancestors of the present inhabitants. The son of the first George Ross was a philosopher, and while he wrote a great work his people fell into idleness. He died, and his son, who still lives, and who had been educated in Scotland, succeeded him. He had all the energy and commanding genius of the founder of the family, and has succeeded in making his people industrious, prosperous, and happy. Though Muhammedans, they have abandoned polygamy; and though Asiatic, are neat and tidy. We have given the outline of this wonderful story only; the details are romantic, too, and Mr Clifford has told the story well.—*Spectator*, March 8.

NEW SELANGOR COMPANY.

The Kajang Coffee and Rubber Co., Limited, has been registered in London, with £23,000 capital, to acquire three estates in Selangor, namely: the West County Estate, managed hitherto by Allen & Co.; the Belmont Estate, and the Weld's Hill Estate. The business of the new Company will include growing and dealing in coffee, tea, india-rubber, and fruit, and prospecting for minerals. The first directors are Messrs. C W Prosser, A A Allen, E Field, and F H Hicks.—*Straits Times*, March 18.

MINOR PRODUCTS REPORT.

LONDON, March 6.

CAMPHOR (CRUDE).—It is stated that the Japanese Diet has passed the measure which will give that Government the control of the production of Camphor in Japan as is the case with the Formosan output. It is also reported that the market in Japan is rising, and that considerable purchases have been made

there, as the ultimate effect of this monopoly must be an advance in all markets. This announcement has, of course, led to an advance also on the London market, and sellers now ask 162s 6d per cwt, c i f, for crude Japanese for March-April shipment; but business is reported at slightly under this figure, and market here is quiet.—Camphor (Refined).—English refined is so far unchanged at 2s 1½d for ton lots of bells and flowers, but market is firm in view of advance in crude, and should the German refiners raise prices, the English will in all probability do so.

COCA LEAVES.—Green Truxillo leaves are quoted at 10½d per lb spot. In auction 8 bales of thin green Truxillo sold at 10d per lb.

OIL, CITRONELLA.—Small sales on the spot have been made at 10½d per lb.

OIL, LEMONGRASS is quiet, at 7d to 7½d per oz. on the spot. A case of Hardouin's brand from Penang sold at 4d per oz., subject to approval.

CROTON SEED sold at lower prices, 25s 6d per cwt being paid for fairly bright seed, but about half mixed with dark.

KOLA.—For African quarters a bid of 1½d is to be submitted.—*Chemist and Druggist*, March 8.

MARKETS AT HOME.

LONDON, March 6.

ANNATTO SEED.—Offered, 42 packages. Sold, 0. Bought in at 2d.

ARECA NUTS.—Offered, 42 packages. Sold, 6. These were of good good quality, and realised 20s, being lower.

COCA LEAVES.—Offered, 36 packages. Sold 16. Fine Ceylon Huanoco character sold at 9d to 9½d and damaged at 3d, and broken green Truxillo at 10d.

KOLA NUTS.—Offered, 37 packages. Sold, 0. Bought in at 2½d to 6d according to quality.—*B; & C. Druggist*, March 7.

INDIAN PRODUCTS.

Major W Malleon has the following deliverance on this subject in Murray's "Review":—

The chief existing organic products of India other than food grains are cotton, jute, opium, tea, coffee, indigo and tobacco. The demand for Indian cotton must always remain somewhat limited on account of its short staple, and efforts to acclimatise other descriptions in India have not yet met with much success. The Indian cotton mills, especially those in Bombay, are at present greatly depressed, partly on account of the recent complications in China, partly because of low prices and competition. Moreover the cotton crop is largely grown in the districts which suffer most from famine, and a failure of the rains would affect it just as much as the crops of food grains. The farther extension of cotton growing is therefore no remedy. Jute is growing in deltaic lands, and is consequently practically unaffected by the vagaries of the monsoon. The industry, however, is probably as well looked after as any in India, and needs no special encouragement. Opium is a Government monopoly and need not be further considered. The tea industry has suffered considerably of late years from over-production, the demand not having kept pace with the supply, chiefly on account of the neglect to open up new markets. But efforts are now being made to introduce the tea-drinking habit amongst the natives of India, and energetic measures for pushing the sale of Indian tea in countries such as Persia and the United States are already showing signs of promise. Coffee is a comparatively small and uncertain crop, only grown in the hills of southern India, and offering no solution to the problem before us. Indigo has been much depressed of late, owing to low prices and the competition of the synthetic substance made in Germany. There is every hope, however, that improved methods of cultivation and production will once more place the indigo industry

on a satisfactory basis. Tobacco is largely grown throughout India to meet native requirements. It is only in southern India and in parts of Tirhoot that any effort is made to cater for Anglo-Indian and European tastes. The time-honoured "Trichy," so beloved of the Anglo-Indian of a dead and gone generation, is now seldom seen. Since the manufacture at Dindigul and other southern centres has been largely taken up by English firms there has been a very great improvement in the quality of the out-turn. Indian cigars and cheroots are now held in wide esteem, considerable quantities being sold in England and elsewhere. But there is ample room for further improvements, and only capital is needed to make India a very formidable rival to the chief tobacco-growing countries of the world. The soil and climate of certain selected parts of India are admirably adapted for the growing of the best description of tobacco, and there is little doubt that if the cultivation of the varieties at present grown in Cuba, America and Turkey was seriously undertaken the result would be more successful. Within quite recent years the native of India has taken largely to cigarette smoking. Most of these cigarettes are of American origin, but there is no good reason why India should not supply her own requirements in this respect.

RUBBER OUTPUT OF THE AMAZON VALLEY.

Writing from Para at the end of December, the U. S. Consul says about 700 tons more rubber than had ever before been shipped from the upper tributaries of the Amazon in one season was then on the way down the river, and at least 200 tons more was expected to follow. After reviewing the situation in the markets, he concludes that there is every reason to believe that this season's rubber crop will exceed that of the previous year by a very considerable margin.—*Sell's Commercial Intelligencer*.

INCREASE THE ATTRACTION OF SHOWS.

It is recognised by many, says the *Live Stock Journal*, that larger attendances of the general public are desirable at agricultural shows in order to meet the increased expenditure which the growth of these exhibitions has necessitated. There is a feeling also that the former attractions are not now sufficient to draw all the visitors, not directly associated with agriculture who used to attend the meetings, because competition has become keener, and other bodies who cater for the public have displayed greater enterprise in providing what is wanted. The agricultural shows are to a certain extent the modern substitutes for the ancient fairs, which have been in many places also superseded by auction marts. The old fairs had several days which were devoted to business, and one was given up to pleasure. This latter element, it is thought, has not received sufficient attention from the managers of all our shows.

The object of an agricultural show is the thoroughly practical one of improving the live stock and agriculture of the country. It would be a regrettable circumstance if this fact were ever to be overlooked in the slightest degree. Consequently, no one would suggest any curtailment or modification of the existing full classes for all varieties of breeding stock. Addition rather than supersession ought to be the policy in increasing the attractions of shows to the public.

The horse department is that which is most likely to provide attractions for the gate-money public. The sections for breeding animals should be maintained as at present, or extended where desirable, and if the example of the Shire Horse Society in giving prizes

to breeders were followed, it would add to the interests of farmers. The group classes also give a new and useful feature.

Prominent amongst the recognised attractions of many shows are the jumping competitions, which with their regulation single hurdle, gate, double hurdle, wall and water have become well-known institutions. The greatest credit is due to the originator of the bending competitions for polo ponies which have deservedly become popular since they were first instituted. Occasionally, too, public interest is stimulated by a driving competition, but for this a large area of ground is required to do it well, such as the big ring of the R A S E. It goes without further saying that in sport-loving England such competitions ought to be keenly contested.

Among other suggestions a correspondent says that bare-backed riding competitions would be likely attractions, even though they might be characterised by some critics as circus performances, though why a man's ability as a bare-backed rider should be derided whilst his seat in the saddle is applauded, no one who has witnessed the ride of the cavalry men from the Canterbury Depot at the 'Military Tournament is likely to understand. Pursuit races, embodying mounting and dismounting, saddling and unsaddling tests, should surely be the means of assisting "gates"; and, should it be desired to combine instruction with entertainment, an exhibition of breaking unmanageable horses might be appreciated by a good number of visitors whose duties bring them into collision with evil-tempered beasts. Then the parades of cart horses in gear might be increased and enlist the interest of the users of horses in towns and lead to further emulation amongst them, with the result that they desire to possess superior teams.—*Agricultural Journal and Mining Record.*

PRODUCE AND PLANTING.

The usual monthly statistics of the values of the representative group of Indian and Ceylon

TEA PLANTING COMPANIES' shares, compiled by Mr. George Seton, of the Indian Tea Share Exchange, 120, Bishopsgate Street Within, E. C., show that the market value of forty-five companies (thirty-six Indian and nine Ceylon) remained almost exactly as it stood a month previously. In a few cases there was a slight fall, but this was rather more than counter-balanced by a corresponding slight rise in others:—

Face value of forty-five companies ..	£9,500,000
Market value July 1, 1897 highest ..	£12,000,000
„ January 1, 1901	8,550,000
„ July 1, 1901	7,000,000
„ January 1, 1902	6,990,000
„ February 1, 1902	6,880,000
„ March 1, 1902	6,890,000

The grand total of the share and debenture capital of 152 companies (86 Indian and 68 Ceylon) of which particulars are obtainable amounts to nearly £18,000,000 so that, on the basis of the above figures, it is estimated that the fluctuation in value for the whole has been approximately as follows:—Face value of capital of 152 companies £18,000,000; market value as a July 1, 1897, £22,750,000; market value as at March 1, 1902, £13,000,000; or a depreciation of nearly 43 per cent. in less than five years' time.

There is no doubt that the work done on behalf of Indian and Ceylon tea in connection with

EXHIBITIONS

is most effective. The Paris correspondent of the *Pall Mall Gazette*, bears testimony to this in referring to the development of tea drinking in France. He says:—"One of the most striking of recent innovations in Paris is the number of tea-rooms that have sprung up. They nearly all date from the Exhibition, where there was much selling and drinking of tea, principally Ceylon teas. Most of the tea now drunk in Paris comes

from the British Crown Colony, and should therefore be a subject of gratification to English people. While, of course, the five o'clock tea in the home circle is not new, this foregathering in restaurants for the consumption of tea and toast is quite a recent development. A fashionable rendezvous is a large hotel in the Champs Elysées, where the Parisian comes of an afternoon with his women-folk to drink tea and listen to the strains of an excellent band. Most of the great hotels have an institution of the kind, and certain of the most popular tea-houses have a passable orchestra. Music, possibly, is regarded as a sort of compensation for poor toast and muffins; that is one of the secrets that the French have not learned. The vocabulary of the tea-house, like that of football and ping-pong, is English. One easily slides into 'tea and toast'; it is a good working formula, and, if you draw near, you may hear Monsieur trying a little English on his female friends who seem to stand it remarkably well or casting a semi-critical eye over the *New York Herald*. The tea hour will not displace the hour of the apéritif because that comes at the end of the working day, but the new-found devotion of the leisured classes to tea drinking is a most notable social change.

The *New York Journal*, "Tea, Coffee and Sugar," is optimistic about the prospects of

TEA PRODUCTION

in the Southern States of America. It says: "The tea producers and shippers in China and Japan are watching with interest the experiments of Dr Shepard at Summerville in the growing of tea and the development of the commercial possibilities of the industry as shown by the establishment of the gardens of the American Tea Growing Company near Charleston. The Agricultural Department of the United States has an agent in the Orient, studying conditions in that section of the world, and in a report he has made to Secretary Wilson he calls attention to this matter of the tea growing industry of the United States and the interest taken in it in the Far East. The Chinese and Japanese growers express the opinion that the undertaking will not be successful because of the difficulty of securing cheap labour, but this problem has been practically solved by Dr. Shepard, as perhaps they do not know. If they were more familiar with the conditions that have been developed here as to the possibilities of tea production, they would probably understand that their monopoly of this trade cannot longer be maintained in the American market." China and Japan tea growers may be watchful, but we doubt if they are anxious. If so, they are easily alarmed. As Indian and Ceylon growers are not mentioned in this connection, perhaps they do not count. Anyway, they are accepting the situation philosophically at present.

The March circular of the British Chamber of Commerce, Paris, has the following with reference to the protracted question as to the French duties on colonial produce: "The Bill to which we referred in our monthly circulars for January and February has now been voted by the Senate and promulgated as a law under date of February 22, 1902. In this connection decrees have been issued to the following effect:—The duties provided for by the minimum tariff will continue to be applied provisionally to colonial produce mentioned in article 1 of the laws of February 24, 1900, and July 17, 1900, coming from China, Corea, Ethiopia, Siam, the Republic of Liberia, Muscat, Straits Settlements, Malay Federated States and Hong Kong. The duties provided for by the minimum tariff will continue to be applied during six months from February 24, 1902, to colonial produce mentioned in article 1 of the laws of February 24, 1900, and July 17, 1900, coming from the United States of America, Porto Rico, Peru, Guatemala, Nicaragua, Honduras, British India, Ceylon, Mauritius, the Seychelles Islands, Jamaica, Dutch Indies, German possessions in Africa, Spanish possessions of Fernando Po, Annobon, Corisco, Elobey, and on the west coast of Africa."

Mr H C Richards, M.P., writing from Darjeeling, February 6, says: "I was in Calcutta when the telegram came out recording the production of the Giffen suggestion to still further tax tea, whilst leaving untouched the hundreds and thousands of foreign products 'made in Germany' and manufactured in France or the United States. I was asked by some of the representatives of the great tea industry in British India if I would help to lay their protest, accompanied by statistics, before the Chancellor of the Exchequer, and this I did by the second January mail, since which time I am glad to say that His Excellency the Viceroy has telegraphed his support of the prayer of the Chambers of Commerce. I have by last week's mail sent to Downing Street the accompanying statistics, which prove most conclusively that each penny increasing duty renders the work of the British tea-grower in India less remunerative; and I trust that my many grocer supporters will recognise that in my visit to Darjeeling I am seeking on the spot the necessary statistics to oppose this latest suggestion to further tax them. Average rate of dividends on the sixty tea-growing companies which appear in the Calcutta share lists: 1898, 3.75 per cent; 1899, 4.70 per cent; 1900, 2.42 per cent., representing a capital of £20,169,300, equal to £1,344,620. Average rate of dividends on sixty-two Indian tea-growing companies registered in London: 1898, 4.04 per cent; 1899, 5 per cent; 1900, 3 per cent., representing a capital of £5,422,829. Again: Exports from India and Ceylon during 1900, 334,000,000 lb; world's consumption during 1900, 314,000,000 lb; surplus, 20,000,000 lb; add excess of production over consumption at end of 1899, 14,000,000 lb; total, 34,000,000. During 1900, consumption exceeded production by 9,000,000 lb owing to the opening up of new markets, but there still remains a surplus in London of something like 23,000,000 lb. The above figures show clearly that any curtailment of consumption, such as would result from an increased duty would be fatal to the industry and would not only involve the loss of capital, but would throw out of employment thousands of natives of India."

Mr Henry Cooke, of Moscow, the British Commercial Agent in

RUSSIA,

is doing his best to promote trade between the two countries. He addressed a meeting at the Manchester Chamber of Commerce on Monday, at which he set forth the obstacles and encouragements to British trade with Russia, a partially developed country presenting to us, he said, in some senses, greater possibilities than more fully developed regions. When in London Mr Cooke, as was mentioned in our issue of February 14, was approached on the subject of the probability of the Russian Government reducing the high duty levied on tea from India and Ceylon, and he urged that some efforts should be made by those interested to secure representation on the subject. In Manchester Mr Cooke referred to the tariff difficulty as regards general trade, but in view of the desire frequently expressed recently in Russian circles for a further and fuller development of trade between Russia and Great Britain, he thinks that some attempt should be made here to remove obstacles. He said that Russia was in some respects more like a vast colony that wanted opening out. It was mainly owing to foreign capital, foreign machinery, and foreign skilled workmen that Russia had been to some extent opened out. Officially foreign capital and industry were welcomed in Russia, although to a fuller development of her own industries many obstacles were placed in the path of foreigners. Apropos of Russian trade, we notice that Mr George Collins Levey, the British Commissioner for the British Exhibition in St. Petersburg, has made a long statement in reply to the criticisms of the Lord Mayor of London and other gentlemen who have withdrawn their support from the exhibition. In this he says: In reference to the recent withdrawal by

the Lord Mayor of London and Lord Avebury, from their positions as members of the British Advisory Committee for the St Petersburg Exhibition, I have to state that the Russian Administrative Committee would have felt the action of their lordships very strongly if they did not feel convinced that it was taken on erroneous information forwarded by British subjects resident in St Petersburg, whose trade interests, either as manufacturers or merchants, make it quite natural for them to be unfavourably disposed towards the exhibition.—*H. and C. Mail*, March 14.

THE WORLD'S FAIR IN ST. LOUIS.

The International Exposition to be held in St. Louis, Missouri, next year, will, as is common with Americans, recognize a sentiment. Having in 1876 commemorated Independence, and in 1893 the discovery of America, they now choose the centenary of the purchase of Louisiana as the occasion for their third World's Fair. As this was, perhaps, the largest peaceful transfer of productive lands known to history, it commends itself from a practical as well as from a sentimental point of view. Its political effects are scarcely less in evidence than those of a material character. But the latter challenges attention by the fact that the 12 States and two territories carved out of the purchase now have a population of more than 15 millions, and that they have become a granary for the world, and also supply much of its minerals, so that its property and annual products exceed those of many of the old kingdoms which have played a great part in the world. The price paid for this tract, just exceeding a million square miles, was the equivalent of £3,000,000.

Preparations have been made upon a scale hitherto unknown. Congress has recognized it as a matter of interest to the whole country, and not merely to that portion included in the original transfer. The Federal Government has contributed \$5,000,000, or one-third of the capital sum deemed necessary. St. Louis, as the largest city was chosen as the place, and the duty of providing the remainder of the funds has been accepted by her people. A second \$5,000,000 has been raised by an issue of municipal bonds, while the third \$5,000,000 was subscribed to a company upon which is laid the responsibility, under rigid laws and regulations, of organising and carrying on the Louisiana Purchase Exposition. This body includes 93 of the leading professional and business men. At their head, as president, is ex-Governor David R Francis, who was Secretary of the Interior in the Cabinet of President Cleveland.

The chosen site appropriates about one-half of the 1,300 acres which make Forest-park, with enough adjoining land to cover about 1,000 acres. Fortunately it was possible to make arrangements by which the grounds of Washington University, with its 110 acres and new building, to the value of more than a million dollars, were acquired temporarily for the use of the fair. These grounds are within the boundaries of the city, closely related with one of the most comprehensive systems of internal traction known even in America. Some railways already run through these, and all others

will be connected. The fair will thus be within easy reach at small cost, whether in money or exertion.

The plan and scope adopted contemplate "the presentation of manufacturing industries in actual conduct as well as of the machinery out of action; the exhibition of processes as well as of completed products." As many novel features as possible will be shown, but nothing will be sacrificed to them. As it has larger capital resources than any previous exhibition, its managers have procured the best and most experienced men available, and are themselves working with much spirit. In addition to the amount already mentioned it is estimated that the various States will appropriate sums ranging from \$50,000 to \$1,000,000 each, so that these sums will aggregate about two-thirds of the capital sum. Foreign Governments, which spent about \$6,000,000 at Chicago, are expected to do as well at St. Louis. It is estimated that the public money drawn from all sources, together with that raised by the St. Louis subscribers, will reach about \$30,000,000.

Work is going forward as rapidly as is possible in the formative period of an undertaking of such magnitude. Buildings and sewage systems are under contract, lakes and other landscape features are in course of construction, and branch railways are surveyed. Invitations have been extended to all foreign countries, and many of them—about 12 or 15, including France and Japan—have been accepted. Diplomats are in negotiation with Governments, representatives are busy over new schemes, and exhibit agents are devising plans in every part of the world. Among novel features a balloon tournament has been provided for, upon which it is proposed to spend \$200,000 in expenses and prizes. Congresses, drawing their delegates from all over the world, are being arranged, and patriotic, religious and social bodies are preparing to hold conventions or to make exhibits. Energy and bustle, with a desire to rival or excel all previous efforts in this line, are everywhere evident.

As a part of the work, and from a desire to interest visitors and exhibitors from the United Kingdom, offices have been opened at Sanctuary-house, Tothill street, Westminster, S.W. The representative is Mr. George F Parker, formerly United States Consul in Birmingham.—London *Times*, March 13.

PHILIPPINES : THE FAVOURED LAND.

Luzon, on which Manila is located, contains an area of 47,238 square miles, which is nearly 2,000 square miles larger than Pennsylvania and 3,000 square miles larger than Ohio. It possesses millions of acres of land awaiting the coming of the American husbandman. Its minerals comprise coal, gold, lead, copper, iron, sulphur, marble and kaolin.

The area of the Island of Mindanao is 36,237 square miles. This island alone possesses enough wealth when utilized to make it a world power. On the gulf of Sibugney there are practically inexhaustive deposits of coal; in Cagayan de Misamis and Surigao, as well as on the headwaters of the Rio de Grande, gold is found, while copper in large quantities abound.

Of several of the larger and more prominent islands very little outside of their fertility is known. This is true of Negros, with an area of 4,854 square miles, Paragra 3,937 square miles and Mindoro 3,972 square miles.

The combined area of these three islands is 12,763 square miles. The combined area of the Hawaiian group is 6,740 square miles. The estimated value of the sugar crop of Hawaii this year is placed at \$28,000,000. What would be the estimated value of the sugar crop and other crops of Negros, Paragna and Mindoro, possessing nearly double the area of Hawaii, if the soil were cultivated by American intelligence ?

The area of other islands of destined importance is as follows :—Samar 5,040 square miles, Panay 4,708, Leyte 2,713, Cebu 1,742, Bohol 1,439, Masbate 1,290. Each of these islands is teeming in riches. Each possesses vast areas of timber, agricultural and mineral lands, which make exaggeration puny in describing.—*Manila Volcano*, March 8.

COMPETITION OF INDIAN COAL IN CEYLON.

In view of the fact that Colombo is one of, if not the most important British coaling station in the East, it is somewhat disconcerting to find that Ceylon is becoming so large a user of Indian coal. This coal imported into Ceylon is drawn from Bengal, and the quantities imported since 1894, according to Prof. W R Dunstan's report to the Society of Arts, have been as follows :—

	Tons.
1894	61,586
1895	47,566
1896	67,417
1897	105,213
1898	213,852
1899	163,908
1900	335,346
1901 (For 9 months, Jan. 1 Sept. 30)	260,869

From this it appears that the tonnage is increasing rapidly, the greater part being for the supply of steamers calling at Colombo; but about 40,000 tons a year are now being consumed on the Ceylon Government Railway.

The chemical analysis of some well-known Bengal coal is as follows :—

	Per Cent.
Carbon fixed	65.75
Volatile matter	26.05
Ash	6.55
Moisture	1.65

100.00

The objections to Indian coal as compared to Welsh coal are that the former leaves more ash, and consequently about 25 per cent more is required to accomplish the same amount of evaporative work, but steamers are finding it so much cheaper than Welsh coal that it is being more largely used every year, and there is every likelihood of it coming into general use for all but mail steamers, which require Welsh coal on account of the speed required to be maintained. Indian coal is used by industrial establishments in Colombo, such as ice factories, the electric car generating depot, &c., but the quantity thus consumed is not large.

The consumption of Indian coal by steamers is likely to expand rapidly, for, as new steamers are built, provision is made for draught in the furnaces such as will admit of its being used more generally; and, in a measure, this will tend to the displacement of Welsh coal.

The following remarks are taken from the reports of locomotive engineers of the Ceylon Railways, which have recently largely used Indian coal:—

"In 1897 the increased expenditure was chiefly brought about by the cost of Welsh coal having jumped from an average of R18.50 per ton in 1896 to R27.62 in 1897. This tremendous increase in the price of British coal would have had a still more serious effect upon the working, had it not enabled Indian coal to compete successfully with it, and during the year 8,081 tons of Indian coal were consumed at an average cost of R13.69 per ton. Indian coal, under the most favourable conditions, shows an inferiority to the best Cardiff coal of 17 per cent on the low-country main line, and on the upper main line sections on the grades of 1 in 44, from 30 to 33 per cent inferior. The use of this coal on these grades gave considerable trouble, as the large consumption per mile on the upjourney, namely, 140 lb per mile, left so much residue in the fireboxes after a 20-mile run, that it was absolutely necessary to clean the fires to such an extent that time was invariably lost.

"The altered grate arrangements also permitted considerable quantities of burning coal to drop into the ash pans; and from them on to the sleepers, which gave rise to several complaints from the permanent way staff. The coals burned were Borrea, Anthracite, Giridih and Singareui, the most economical and suitable being Giridih, but the continued use, even on the lower sections, will to a great extent be governed by its relative cost compared to Welsh coal. At the price paid for it during the year it is in very close competition with firewood.

"A saving of R113,000 was effected in the running charges by the use of Indian coal during 1898. The general adoption of Indian coal instead of Welsh coal has very considerably reduced our locomotive expenses; so much so in fact that the consumption for the year shows an increase of 3,800 lb per train mile, yet in consequence of the cost of Indian coal (including handling) having been less by 10 per cent per train mile, the result has been a saving of R113,000.

"In 1898 fuel consumption increased to 99 lb per English mile and 5.30 per train mile. This increase was due to the large use of Borrea coal, which gave considerable trouble throughout the year."

Indian coal at the pit's mouth is probably lower in price than in any other country, often reaching 2 rupees a ton. The local wholesale selling price of Bengal coal was 4s. 5d. a ton in 1901, as against 4s. 2d. in the previous year. The wholesale price for imported coal in Calcutta averaged 32s. 1d. per ton.—*Iron and Coal Traders' Review.*

PROFESSOR HERDMAN IN CEYLON.

(To the Editor of the *Liverpool Daily Post.*)

SIR,—Enclosed is a third letter from Professor Herdman, just received, as full of interest as the former ones.—Yours, &c.

ISAAC C. THOMPSON.

53, Croxteth-road, Liverpool.

Gulf of Manaar, January 30th, 1902.

My dear Thompson,—I have now been ten days in Ceylon and, although first impressions are not always correct, still I should be ungrateful were I not to say how interesting everything is, and how exceedingly kind and helpful I have found everyone from the Governor downwards. They all seem to take a personal interest and pleasure in facilitating my arrangements and, as the result, the Oriental tendency to delay, and difficulty in getting unusual things done in a hurry, of which I had heard so much, has been reduced to a minimum. They have chartered a fine steamer for my work—the "Lady Havelock"—of over 300 tons, with a crew of 40, and we have made a start today. We dredge from a boom lashed to the boat

davits at the stern, and trawl from a derrick on the fore-mast. I look after these operations, and Mr Hornell works the tow-nets. We have a laboratory with two good work-tables on deck under an awning, and the microscopes, dissecting instruments, tanks, jars, note-books and specimens scattered about give the place a familiar and home-like appearance, reminding one of the deck of the old "Hædra," except that most of the faces round me are black instead of white.

After a couple of days spent in official visits and business in Colombo I found that the necessary arrangements on the steamer would take a week to complete, so, leaving Mr Hornell to superintend these, and see to the unpacking of our scientific gear, I set off to find several men in the island from whom I knew I could get important information bearing on the pearl-oyster work. First, there were two former students of mine at University College, both now occupying important scientific positions here, viz., Dr. A. J. Chalmers, Registrar of the Medical College and lecturer on biology and allied subjects, and Mr J. C. Willis, Director of the Botanic Gardens at Peradeniya. Both those gentlemen kindly met me on my arrival, and have been most hospitable and helpful. Dr Chalmers has given me the use of a room in his laboratory at Colombo, and Mr Willis has offered a work place in his laboratory at the magnificent Peradeniya gardens. I went to Kandy and Peradeniya to see what use could be made of the laboratory, and to meet Mr Oliver Collett, who has written on the pearl fisheries. Then I found upcountry, at Anuradhapura, (one of the "buried cities" of Ceylon) the two Germans, Dr Paul and Dr Fritz Sarasin, who have been exploring for years in Ceylon, and were the only people who could give me information about Trincomalee, where I wish to dredge. Finally, I met Professor Alex. Agassiz, just returned from his expedition to the Maldivé archipelago, and he kindly lent me 600 fathoms of especially strong and flexible steel rope, which will be a valuable addition to our tackle. Professor Agassiz, you will be interested to hear, says he has had a most successful trip, and has secured all the information, photographs, and specimens of the Coral Reefs that he desired. He says the Maldives is the last of the great coral archipelagoes which he had set before himself to examine and that now he is prepared to write his book on the general subject, "Coral Reefs and Islands." There can be no doubt that he has a much more extended personal knowledge of the reefs of the world than Darwin, Murray, or any other previous writer.

Anuradhapura, where I met the Sarasins, is an extraordinary place, consisting of the magnificent ruins of a very ancient city, which until a few years ago was buried in jungle. Many miles of it are still in the jungle and unknown, I was told by the Archaeological Commissioner, who is digging it out with about ninety coolies, half of whom are down with malaria every day. [I noticed that my mosquito curtains at the "Rest House" had large holes in them.] This city was the capital of the ancient Cingalese kings, and was commenced, I believe, in the third or fourth century B.C.—lot us say the time of Aristotle. It was deserted when the Tamils invaded the northern part of Ceylon. The most remarkable pieces of work are the enormous temples, the bathing tanks, and the beautifully-carved stones, showing kings, queens, Buddhas, seven-headed cobras, and curious little fat dwarfs, who may be meant to represent the aborigines—the Veddas. One of the temples (Dagobas) is said to contain enough bricks to build a wall ten feet high and one foot thick from London to Edinburgh.

The last matter I can mention now is the jungle, and I have found my first experience of it most fascinating. I wish the Biological Society could come and have a day of it with me, and see the Wanderoo monkeys come crashing down from the tops of the trees one after another, swinging themselves up again

by a slender branch just when you think they must certainly come to grief on the ground. I had three hours' drive through a jungle road in a bullock cart after dark, from Anuradhapura to Mihintale, with two men who were able to tell me about most of the sounds we heard around us.

Now that we are at sea again our hands will, I hope, be kept very full of work; but I shall try to write to you soon something about the marine zoology of the Gulf of Manaar.—Yours &c. W. A. HERDMAN.

'POOR' COFFEE, RUBBER, COCO-NUTS, & C.

(Extract from Selangor Planters' Association Annual Report for 1901.)

PLANTING PRODUCTS: COFFEE.—Prices ruling during the year have shown a decrease from those of 1900 an average of \$18.29 per picul, or \$2.60 per picul less than the average for last year, which was \$20.89. Notwithstanding these low prices, which necessitated the strictest economy, the estates are almost all in good order, and planters are showing great determination to tide over the present crisis which has lasted so long. The reports from coffee brokers are so conflicting that we consider it best to quote from none of them: but the following is an extract from one of the leading merchants in Singapore in answer to a letter written by one of your Committee:—"I would be delighted to assist you with my views on the future of coffee in Brazil, if I had any, which, however, does not happen to be the case. I had a talk with—the other day, and he told me that no fresh planting had been reported from Brazil for *some years now*: and that there was no doubt but that the trees were getting old and worn out, and that it was very improbable that we should see such large crops again. The fact remains, however, that the visible supply is simply enormous, as you will see from the Circular I send you." The following is an extract from a letter from Santos, in answer to some questions made by one of your Committee, received on 13th February, 1902. "Tell—that the coffee crop for next year is very poor, and will only be about half its usual size, so that prices are sure to go up. I hope to get up to San Paulo next year," etc. It will be remembered by many of you that Ceylon's greatest crop was its last big one. Galsha in that year topped all estates by giving 17½ cwt. per acre, but never gave 4 cwt. per acre again. There is at least something to hope for in all the above. **CROPS.**—The crop realised for last year was 19,365, and the estimate for 1902 is 27,146 piculs. Your Committee consider that the sample of your coffee has improved on almost every estate, and they urge on you the importance of doing everything in your power to continue to improve it.

PARA RUBBER.—We can now speak with great confidence to you, for during the year vast strides have been made in this cultivation, the acreage planted now being 7,487, 247,458 trees having been planted during 1901. This is not so much to the point as the fact that careful and detailed experiments have been made in tapping our trees of all ages, not only by such men as the Directors of the Botanic Gardens of Singapore, Penang and Perak, but by many of the planters now present, who have proved their figures to be correct.

"I have not seen any published accounts on *Hevea* (excepting Brazilian) where as good results are obtained as in Malaya, either in rate of growth, seed production, dimensions, yield and adaptability." The most casual observer must notice the magnificent growth of nearly all the rubber planted in the Malay Peninsula, and especially that on the well-drained alluvial soil of which we have so much. During the year two well-known rubber experts from Ceylon visited Selangor and Suvei Ujong, and they stated that they had never seen a better growth, and they seemed astonished at the large returns per tree got by Mr Derry and others and at the free flow of latex from our young trees. We think there can be no

doubt that a paying future is before the industry, and that ultimately the Malay Peninsula will oust Brazil from her present position as the premier rubber-producing country of the world. This is a bold forecast, but not an unreasonable one. Before it comes about there will, of course, be a heavy drop in the price of the product, and we would put before planters a few facts to enable them to judge our ability to hold our own in competition with Brazil.

RAMBONG.—The planting of *Ficus elastica* has been considerably extended during 1901, 34,804 trees having been planted, or equal to say 700 acres. Rambong is growing magnificently and promises to give quite as good returns as Para, the yield per tree being much larger, which makes up for the lesser price and a smaller number per acre.

COCONUTS.—The area under coconuts is 3,008 acres. There is no doubt about the success of this product if the ravages from beetle could be checked, and we think the matter so serious that we consider the Government should be strict in carrying out the powers they have under the Enactment. Somewhat pessimistic views have been expressed by men qualified to pass an opinion as to the crops which our coconuts on the rich alluvial are likely to yield. On a small holding in Klauang district, now about 10 to 12 years old, the average yield per tree amounted to 51.5 nuts in 1901, and for the first eight years of its existence this little clearing never had any sort of intelligent supervision. Your Committee, therefore, think that it is not unreasonable to hope that returns over a large acreage may be such as will astonish those who hold that the maximum yield will not amount to more than 20 to 30 nuts per tree.

MINOR PRODUCTS.—The planting of catch crops is chiefly done in the coast districts: but it has been found that the planting of small catch crops, such as pumpkins and kladi, do not pay, as it is almost impossible to make the Chinese keep the land clean during their growth, and the whole of what is gained by the catch crops goes in what it costs to put the land in order after them—to say nothing of what the soil loses by them.

It is generally recognised that coffee, even at the present low price, is the best catch crop, and a large acreage is likely to be planted up with Para rubber clearings next year.

SIR E. N. WALKER ON JAMAICA.

At the Society of Arts after the reading of a paper on Jamaica, our former Lieut. Governor said:—

As it was more than 14 years since he severed his connection with Jamaica, he could not speak with authority on its present condition. Like Mr Thomas, he had been surprised that Jamaica fruit had not found a firmer and wider hold in England. He had brought pines from Jamaica and distributed them in Devonshire amongst people who were accustomed to hot-house pines and the remarks they had made after the practical experience of eating them were very favourable to the fruit. One thing in favour of the Jamaica pineapple was that one never committed the offence of eating sugar with it and he thought that proved the superiority of the Jamaica pine. The enterprise of introducing the banana into this country had not reached the success which he thought it certainly deserved, owing to its excellent character. In appearance it certainly did not compare favourably with its rival which was exported in large quantities and in excellent condition from the Canary Islands. He thought the shippers had not yet hit off the precise condition of ripeness in which the fruit should be shipped. With a friend he had purchased in the City of London a Canary Island banana and a Jamaica banana, and they were both of the opinion that the Jamaica banana had the better flavour. Unfortunately it did not possess the fine, almost golden

bloom of its Canary Island rival, and therefore, housekeepers in purchasing the fruit for table were liable to overlook the Jamaica banana. He could also bear testimony to the worth of the Jamaica cigar and had heard on very high authority that there was no reason why Jamaica should not grow as good tobacco and turn out as good cigars as Cuba. He was particularly pleased to hear the tribute Mr Thomas had paid to the Jamaica Negro who was not such a bad fellow as he was very often made out to be. In support of that contention one simply had to ask, Who did all the hard work in the Panama Canal? It was done by the Jamaica Negro. The contractor for one of the smaller railway extensions carried out in the Island of Jamaica, Mr Murray Campbell, had said that in a large experience with various classes of labour he was perfectly satisfied with the Jamaica labourer at 1s. a day. In the past difficulties had arisen which had stood in the way of better relations between the employers and the employed; but that was not to be wondered at when a similar state of affairs had existed between the employers and employed in England. He felt extremely grateful to Mr Thomas for his extremely interesting paper.—*Journal of the Society of Arts*, Feb. 7.

PLANTING NOTES.

THE TAMED ZEBRA A SUCCESS.—Evidently the taming of wild zebras is proving successful. The "Official Gazette" (Mombasa) contains an advertisement that Baron Bronsart von Schellendorff, of Kilimanjaro, is prepared to supply tamed but unbroken zebras at 200 to 300 rupees each, and tamed and broken-in animals at just twice that price. Orders can be executed in nine months.—*Daily Mail*, March 11.

A RAILWAY TO NYASSALAND.—It will be seen from the following paragraph from a recent number of the "Scottish Geographical Magazine," that the time allowed the Shire Highlands Railway Nyassaland Company, to raise its capital expired on the 3rd instant:—

"The Shire Highlands (or Central Africa) Railway. —Many of this Society and readers of this Magazine will be gratified to learn that an agreement has been concluded, on the 3rd of September between the Government and the Shire Highlands Railway, Nyassaland Company, for the construction of a railway in the British Central Africa Protectorate. If the Company provides within six calendar months from that date a certain sum of money to be devoted to the construction of the Central Africa Railway, the Government by the Crown agents will enter into a contract with the Company. The prescribed sum is to be raised by an issue of Debentures of the Company constituting a first charge on all the present and future assets of the Company. The railway is to start from Chiromo and thence proceed to Blantyre, and subsequently to Lake Nyassa. The Company is to have the use of plans, surveys and reports in the possession of the Government, but the Government may require an additional survey to be commenced within three months from the date of the contract and completed within nine months, and the railway commenced within fifteen months from the same date. The railway is to be built in sections of twenty miles."

We cannot tell yet if the Company had been successful. We hope so.

DISTRICT PRICES AND REDUCTION OF TEA OUTPUT.—It is worthy of note—says *Indian Gardening and Planting*—that Dooars, the only Indian tea district that does not show a reduction in the crop of 1901, is the district which has obtained the greatest benefit from the rise in prices at home since the middle of last year. Up to the beginning of February the average of all Dooars tea sold on garden account this 1901-02 season is 684d, a full penny better than in the corresponding period in 1900-01. The average of all Indian teas sold on garden account during the same period is only a half-penny better than in the previous year, so Dooars has done the best of all districts in this respect notwithstanding a bad start.

A STATE LABORATORY FOR STUDYING PLANT DISEASES.—A correspondence has been taking place in "Nature" between Mr. W. Carruthers of the British Museum and Sir W. T. Dyer of Kew on the need for a State Agricultural Laboratory where the diseases of plants can be investigated and remedies found by experiment and other means. The question arose in a statement made by Mr. Carruthers at the Royal Microscopical Society, of which he is President, as to this national want. Sir William Dyer considers that Kew already fulfils this want by naming fungi which are sent to them, but Mr. Carruthers refers to a recent case of cherry disease in which the steps which prevented the spread of the evil, were taken by the Royal Agricultural Society and by private individuals, and not by Kew or the Board of Agriculture. As a colony we are ahead of the old country in employing Government officials to devote themselves to these important matters.

OPHIR AND TARSHISH.—In reviewing a new book, "The Gold of Ophir," by Professor A H Keane, the *London Times* says:—

The site allotted to Ophir must stand the test of many conditions. Professor Keane decides, we think rightly, in favour of the south of Arabia, the country known as the Hadramant, the ancient Himyaritic territory. Ophir was a great city or emporium of which Moscha, about half way along the southern coast of Arabia, was the port. It was not the place at which the gold and other products to which it gave its name were found; it was the emporium to which the products of the East and the South were brought, and from which they were distributed by the enterprising Yemenites through the medium of the Phœnicians and other navigators who made use of the Red Sea as a great trade route. Professor Keane, in coming to this conclusion, agrees with some distinguished predecessors, though no one before him has adduced nearly so much evidence in support of it. The same may be said of the arguments by which he proves that the gold imported into Ophir and re-exported for the use of Solomon and other potentates could only have been furnished by the rich gold-bearing country lying to the south of the Zambesi, which Professor Keane identifies with the Scriptural Havilah. Recent explorers of this territory, which is now British—especially Messrs. Hall and Neal, to whose work Professor Keane expresses himself as greatly indebted—have satisfied themselves that gold equivalent to many millions sterling must have been extracted from these mines by the Sabæan Arabs and the Phœnicians who succeeded them. Tarshish Professor Keane identifies with the modern Sofala, though here his evidence is not quite so strong; while the land of Punt he locates with much probability in the north-east horn of Africa.

ORIGIN OF PEARLS.

William Bateson, Esqr., F R S, Vice-President, in the Chair.

Dr H Lyster Jameson, M A, read a paper "On the Origin of Pearls." The author's observations referred especially to *Mytilus edulis*, the Common Mussel. The Pearls were found to be due to the presence of parasitic Distomid larvæ, which entered the subcutaneous tissues of the mussel and became surrounded with an epidermal sack similar in its character to the outer shell-secreting epithelium of the mantle. If the *Distoma* died in the sack it became calcified, and formed the nucleus of a pearl; the pearl arising, like the shell itself, from the calcification of the cuticle of the epithelial cells. The parasite sometimes migrated out of the sack, in which case the nucleus of the pearl was inconspicuous.

Dr Jameson had investigated the life-history of this parasite, and found that it arose as a tail-less Cerearian larva, in sporocysts, in *Tapes decussatus* and *Cardium edule*. He had succeeded in infecting Mussels from *Tapes* in an aquarium. The adult stage of this parasite was apparently *Distoma somatina* Levisen, which occurs in the intestine of the Eider Duck, and which the author had found in the Scoter or Black Duck (*Eidemia nigra*.)

The complicated life-history of the parasite, and the absence of organs of locomotion in the *Cerearia* stage, sufficed to account for the anomalous and hitherto inexplicable distribution of pearl-bearing Mussels.

Dr Jameson had found that pearls were caused by similar parasites in several other species of Mollusca, including some of the Pearl-Oysters; and he believed that the artificial infection of the Pearl-Oysters could be effected in a similar manner to that which he had found successful in the case of the Common Mussel. When this was achieved the problem of artificially producing pearls would be solved.—*Zoological Society of London*, March 14, 1902.

CEYLON GREEN TEA VERSUS CHINA AND JAPAN.

THE MARKET IN CANADA : GREEN TEA WITH A GREEN COLOUR WANTED,

CANADIAN CRITICISM AND CEYLON OPINION,

In the last issue of the *Canadian Grocer* which reached Ceylon some astonishing statements are made in commenting upon the views of Mr Galt on Ceylon Green Teas. The writer, who it would appear poses as an authority on the Green Tea Trade in Canada, refers to Mr Galt as "A Mr Gault," as if he were some obscure retailer of Green Tea, whereas as we understand Mr Galt directs the management of the largest Indian and Ceylon Tea business in America—the Anglo-American Direct Tea Trading Company. At the outset this would appear to indicate malice or ignorance on the part of the writer, who then goes on to state:—Mr Galt declares that green tea as turned out by the factories in Ceylon is not properly made. It is,

he says, "neither a green nor a black tea." And again in answer to a question regarding the demand in the United States and Canada, he adds:—"Not a pound of Ceylon green tea would be sold in America at present were it not bolstered up by money and other presents given away with a pound of tea." Mr Galt's remedy for the defects which he alleges to exist is the firing and packing of the green teas after the manner of the factories in China and Japan. We gather this not only from the reading of the interview with him, but from a conversation we have had with a teamen who in turn, not long since, discussed the subject with Mr Galt himself in London, prior to his departure for Colombo. The firm with which Mr Galt is connected has arranged to manufacture and pack Ceylon green tea after the manner of Japan and China, and the result of the experiment will be watched with a great deal of interest. As far as we can gather, opinion is divided in both Canada and the United States in regard to the wisdom of the new departure which the Anglo-American Direct Tea Trading Company is taking. To the tea manufacturers in Ceylon, and those dealers in the United States and Canada who are ardent champions of Ceylon greens, the proposition to adopt the tea-making methods of the competitive countries is no doubt somewhat humiliating. And furthermore, to make the leaf after the styles of China and Japan would certainly tend to deprive the Ceylon article of its individuality, as far as appearance at any rate is concerned. But looked at from the standpoint of utility, the question seems to resolve itself into this: Which method is going to be, in the long run, most conducive to the welfare of the tea industry of Ceylon? And this can only be ascertained by experiment. The logical conclusion, therefore, appears to be—go ahead with the experiment. We cannot agree with Mr Galt's statement that "not a pound of Ceylon green tea would be sold in America were it not bolstered up by money and other presents given away with a pound of tea. We are not prepared to speak for the United States. But, as far as Canada is concerned, they are simply exaggerations. And, according to Tallyrand's maxim, "Everything which is exaggerated is insignificant." A year ago the sale of Ceylon Green Tea was undoubtedly stimulated by the fancy 60 lb canisters given to every retailer who purchased a certain quality of the tea. But we are not aware of any prize or consideration of any kind being given to consumers. At present there is quite a scarcity of Ceylon green tea on the Canadian market and the demand being in excess of the supply, prices are much higher than they were a month or two ago. No doubt the demand is to some extent stimulated by the extraordinary scarcity and dearness of China green teas. But that does not alter the fact that the teas are selling and that without prizes attached thereto. Nor does it strengthen Mr Galt's case, because the tea package firms are by far the largest purchasers of Ceylon green teas. Whether Ceylon green teas will ever take the place of Japan and China greens remains to be seen. There are some who strongly maintain that they will. Others again are just as strong in the contrary view. Although there was a large increase in the importation of green tea of Indian and Ceylon growth last year, the quality is still relatively small when compared with China and Japan green teas. The importation of Ceylon and

Indian green teas into Canada during 1900 and 1901 were as follows:—

	1900.	1901.
Indian green, lb.	23,214	81,578
Ceylon "	27,175	334,634

Japan and China greens imported during the same periods were as follows:—

	1900.	1901.
Japan greens, lb.	8,520,781	6,645,337
China "	1,235,197	863,586"

MR. GALT'S VIEWS ON THE CANADIAN CRITICISMS.

Seen by a representative of the *Observer* this morning Mr. Galt said that he had read over the criticisms of the "Canadian Grocer." He was of opinion that the article had simply been inspired by one of the "ardent champions" which it referred to. The writer was

UNABLE TO REFUTE A SINGLE STATEMENT he had made in connection with the manufacture of Ceylon Green Tea. It seemed that the "Canadian Grocer" had stooped to a purely personal attack. With regard to the remarks which that paper described as "exaggeration" Mr. Galt has no recollection whatever of making so broad a statement as is attributed to him. He is, however, in possession of a letter, received last mail from Toronto in which the writer states that after making careful enquiry he finds that no wholesale Grocer in the city of Hamilton handles Ceylon Green tea and that only two wholesale Grocers in Toronto make a practice of handling it, while their outlet is but for a limited quantity at from 5³d to 6d. Mr Galt's correspondent also informs him that about a year ago the wholesale grocers of Toronto and Hamilton were each induced to handle 200 to 300 half chests of Ceylon Green Tea

BY PRESENTING THEM WITH CANISTERS which were again in turn handed over by them to the retailers as an inducement to the retail trade to purchase the tea. Since the canisters have stopped, the sale of the Ceylon Green Tea has stopped. The package tea concern in Canada put up what is called a mixed Ceylon Tea. Mr Galt thinks that possibly a good deal of the so-called Ceylon Green Tea is disposed of in this way. (The "ardent champions" probably drink the rest themselves.) The *Canadian Grocer* states that the manufacturers in Ceylon will be humiliated by the introduction of such machinery as would enable them to make

TEAS THAT WOULD COMPETE SUCCESSFULLY with those made in China and Japan. Such is surely an erroneous idea. The object of the manufacturer is surely to produce a Green Tea acceptable to the taste of the people and which will get a market on its merit and not require to be bolstered up by canisters or forced upon the people. So far as the "ardent Champions" are concerned Mr Galt thinks they have been well-paid for their work and, therefore need not be seriously pitied. It is, he says, a generally accepted principle among business-men to give people what they want instead of trying to make them buy something else. The demand is for

A GREEN TEA WITH A GREEN COLOUR and it is only such a tea that is likely to find a ready market in America. Whether Ceylon will, eventually, be successful in introducing its present style of manufacture remains to be seen, but Mr Galt thinks it will furnish employment to Commissioners for many years to come before

such an end is attained. In conclusion Mr Galt said that the only point of importance which he observed in the article in question was that after weighing all the *pros* and *cons* the "Canadian Grocer" came to the conclusion that the Anglo-American Tea Trade Company were doing the logical thing in carrying on their experiments to make a Ceylon Tea that people will buy.

THE NEW CEYLON GREEN TEAS.

7th April, 1902.

Messrs. Forbes & Walker, Colombo, have furnished us with the following opinion, at our request, of the green teas being produced under Mr. Galt's direction, as alluded to in our interview with Mr. Galt on Saturday:—

"The favorable opinion we have formed of the samples of 'finished green tea' made by Messrs. Finlay, Muir & Co's factory and shown to us from time to time by Mr. Galt will, we think be shared by most of those who carefully consider

he subject. These teas are made to closely imitate China and Japan greens, in make, color of leaf, and style of liquor; young Hysons (including the small leaf Sow-Mee), Hysons and Gunpowders being cleverly copied. In liquor they compare most favourably with Chinese and more than favourably with Japans, the crowning point being their purity and freedom from scum or coloring matter; and we feel confident that such teas will have the effect of overcoming a great difficulty now existing in bringing Ceylon Green teas into consumption in places where at present Chinas and Japans are used; for it stands to reason that it should be a comparatively easy matter to introduce teas whose character is so akin to those of our Eastern rivals into such countries, and when once adopted they will doubtless be preferred by the consumers in the same ratio that our black teas are in other parts of the world.

"Green teas now being made in the various factories of Ceylon are generally speaking sound and good, particularly in cup; but they are undoubtedly at a disadvantage as regards appearance of leaf when competing with China greens—a disadvantage which should not be experienced with the finished green teas.

"As far as we know this is the first attempt made in Ceylon to produce a tea of true green character in the full meaning of the term, and we cannot but think it will be attended with success."

COCONUTS AT PENANG.

Mr. Curtis writes in his report on the Botanic Gardens, Penang:—

The cultivation of Coconuts is one of the most important and profitable industries in this part of the world, and one in which perhaps a greater number of individuals are interested than in any other. A few Europeans in this Settlement own large plantations, and in the Native Malay States some have planted on a considerable scale; but on the whole it must be looked on mainly as a native proprietor's crop, and in their interests it is important that the destructive beetles be kept in check. When I first came to Penang \$10.12 was about the price per 1,000 nuts and this was then considered a paying price. In recent years the price has ranged from \$25.30 with a ready market for any quantity. A large proportion of the Penang and Province Wellesley crop is shipped to Rangoon, where the product is used as food in the form of curries, sweetmeats, etc. Both in England and Germany coconut butter is being manufactured on an extensive scale, but the low temperature at which it becomes liquid militates against its introduction here.—*Singapore Free Press*, March 26.

THE FOREST WEALTH OF TRAVANCORE.

Travandrum, March 18th.—Mr T Ponambalam Pillay, the Acting Conservator of Forests in Travancore, delivered a very interesting lecture on the "Forest Wealth of Travancore" a few days ago.

FOREST PRODUCTS.

Major and Minor produce was the definition which embraced all the produce obtained from our forests. Timber and fuel were the two that

were classed under Major produce. The Acting Conservator estimated that there were about 1,000 different kinds of trees and shrubs which it was worth while to study. So finely was this distributed that on an examination of a particular Reserve he found that there were the 24 species of the trees reserved in Travancore in each square mile. To reserve 24 trees was not an exorbitant demand on the part of the Government. The fact was that only a few kinds of timber were exploited and used in Travancore. There were several valuable species—valued in other lands which are not noticed here—notably iron wood (*Xylia delabreiformis*). There were enormous quantities of firewood to be had for the mere transporting charges, and yet no one cared to do a business in it. In the towns of the State fuel was so scarce that coconut shells and the leaves of trees, etc., were being utilised as fuel, and if depôts were established by private persons a profit of 10 per cent could be fully depended on. Again, enormous quantities of timber in the shape of waste, from fellings by Government contractors, and chips were allowed to rot. The sapwood of all coloured trees and the entire volume of all colourless trees, provided they contained cellulose, could be utilised for wood pulp, which in its turn was suitable for paper making. Roughly speaking, one quarter of the original weight of timber could be obtained in wood pulp by a process which the lecturer described. It was largely in demand and Great Britain and Ireland annually imported the material for 4 millions sterling.

OTHER PAPER-MAKING PRODUCTS.

First there was the fibre of the bamboo, the *Eta* or *Vai*, the wild sugar-cane (*Saccarine arundinaceae*), the refuse of sugarcane mills, the aloe, the plantain, also a number of palms and cycads which could be utilised, and which were now absolutely rotting away or burnt for manure. The common dhoby's earth was to be had in abundance in the country, and from it could be obtained the caustic soda so essential in paper making. Thus, there were in the country two of the most important materials required for paper manufacture. The locally established paper mill was not successful owing to inexperience and scant knowledge of the surroundings. Expensive English chemicals had to be obtained. In North India some of the paper mills made their own caustic soda.

OILS AND RESINS.

Enormous quantities of the heart wood of teak were wasted annually, and yet from this an essential oil much in demand was obtainable. Sandalwood oil was another valuable product if sufficient attention was paid to it. Among other trees from which resinous matter could be obtained with profit for local or Indian consumption were:—*Odina wodier*, the dhoby's nut (*Semicarpus anacardium*), *Acacia Arabica*, *Albizzia Sebeck*, *Vateria indica*, *Ailanthus Malabaricus* *Ailanthus excelsa*, *Petrocarpus marsupium*. From this last the well-known gum kino was obtained, and though the tree was felled in abundance, no regular recognised branch of trade existed in the product.

TANNING AND DYEING.

There were openings in these industries for enterprising people. They were very profitable industries, and there was a large quantity of tanning products in the country which remained

unutilised either in tanning in the country or in exporting the tanning agents. The same could be said of matter suitable for dyeing and for varnishing.

ROOTS.

Ginger, turmeric and the kina (*Curcuma angustifolia*) were plentiful in parts. There was not much difference in the product known as the arrowroot of commerce which was exported from Europe and the arrowroot made from the kina cultivation would improve the quality of the bulb.

CARDAMOM'S AND CINNAMON.

These were valuable products, and there was a host of others (some of which were mentioned) which could be traded in. The importance of obtaining useful botanical specimens was dwelt upon.

SOAPS.

There were things requisite for the manufacture of soap, viz., fats, oils and alkaline, all three obtainable in Travancore. Lemon grass oil was in great demand, and though there was some business done in it, it was not nearly so large as it could be made.

MINERALS.

There was gold in Travancore, but not in paying quantities. At Shencotta, there was iron ore, and pig iron could be made, for there was an abundance of charcoal. Mica abounded and, lastly, plumbago, which was so successfully worked by the Morgan Crucible Co.

ANIMAL PRODUCTS.

Honey was abundant and apiculture was a field for a new departure, as well as that of the rearing of silkworms. There were a large number of trees on which silkworms fed.

The lecturer said Travancore was unique, inasmuch as she contained within her boundaries variations of climate and soil in which most things wanted by the civilised world could be obtained. Rubber had thrived in Travancore, and new varieties were bound to do well. Camphor cultivation was worth a trial. The lecturer concluded by saying that the rising young men of the day should try and strike out a new line for themselves in industrial matters. Government service was a good thing, but all could not be Government servants.—*Cor.—M. Mail*, March 21.

RUBBER DEVELOPMENT IN BOLIVIA.

During the year ended 1st July 1900, the government of Bolivia granted new concessions for working rubber as follows:—

	estradas
Department of La Paz	7,264
Department of Santa Cruz	9,590
Department of Cochabamba ..	500
Total	17,354

Since each *estrada* is supposed to embrace 150 rubber trees, these concessions would account for 2,603,100 trees brought under private control within a year. It is understood, however, that many small rubber properties in Bolivia are for sale, due probably to a lack of working capita on the part of the *concessionaires*, while perhaps some of them have been located only with a view to selling them.

A statement has reached The India Rubber World that the following amounts of rubber paid

export duties (15 per cent *ad valorem*) at the Bolivian custom house in the Acre river district—lately in dispute between Bolivia and Brazil—between January 29 and April 16, 1901, and were shipped via Para :

	Pounds
Goma elastica (fine rubber).....	2,954,879
Serranby (coarse rubber).....	328,275
Caucho.....	13,728

Total..... 3,296,882

India Rubber World, March 1.

LESSER PRODUCTS OF THE COCONUT TREE.

There is really no part of the coconut tree which does not serve man for some economic purpose. At the same time considerable ignorance prevails regarding certain minor products of this palm, and the purposes to which the natives apply them. For instance, the soft, downy light brown cotton, at the outside of the lower part of the compound leaves of the tree, is very popular with physicians and housewives, for there is nothing to beat it in staunching blood from a wound. The mature cotton is a strong weblike tissue of fibres, bearing some resemblance to coarse cloth. Toddy drawers use it as a strainer, while in some parts of country it is woven into very tolerable wearing apparel, chiefly used by fishermen. Then, the roots are largely used by the natives for tooth and paint brushes, and are also sometimes chewed with betel as a substitute for arecanut. They have still more valuable uses, for the native vydian prescribes a decoction of coconut roots with ginger and jaggery in cases of fever. When fresh oil is added the mixture is prescribed as a gargle for sore mouth or throat. The shell of the coconut takes a high polish and can be "turned" in a most remarkable manner. It can also be converted into good buttons. Another minor product is the water inside the kernel. The supply diminishes as the fruit approaches maturity. There is no more delicious summer beverage. The water may be drunk freely without any deleterious effect, and the natives esteem it as a good purifier of the blood. Bricklayers use it in the preparation of a fine whitewash, and when a little of it is mixed with the water in which castor seeds are boiled the quality of the castor oil is highly improved. For the curing of tobacco, a little of the water sprinkled on the leaves improves them and adds to their flavour. The spathe or tough fibrous covering of the blossom makes rough but serviceable headgear, water buckets, light boxes, sheathes for knives, and when soaked in water, a coarse cordage which is substituted for ordinary rope for thatching houses. The flower, which possesses a powerfully astringent property, is used in native medicine. We have then the cabbage at the summit of the tree. This is a tender vegetable, which may be prepared in various ways, and is especially good for pickle, but it can be obtained only at the cost of the tree, and a native must be driven to great extremities before he cuts down a coconut tree. The finer midribs of the leaves are made into tooth picks, coarse pins, brooms, bird cages, and neat blinds, while the larger midribs of the compound leaves are occasionally substituted for the paddles of small canoes and boats. Fine strong cordage is also obtained from them. In short, the numerous useful products of this palm reminds us of Ludovico di Varthema's dictum: "Ten useful things are derived from this tree; the first utility is wood to burn, nuts to eat, ropes for maritime navigation; thin stuffs, which, when they are dried, appear to be made of silk; charcoal in the greatest perfection, wine, water, oil, and sugar,

and with its leaves which fall, that is when a branch fall, they cover the houses; and these ward off water for half a year.
C.

—*Capital*, March 27.

PRODUCE AND PLANTING.

Rumour is again busy about the new taxes. Twenty millions of the deficit in the Exchequer have, it is estimated, to be raised by new taxation and once more there has been

TALK OF A FURTHER TAX ON TEA.

The one thing certain is that everything connected with taxation proposals is gloriously uncertain. Money has to be raised somehow, and if, in the general rake-in of funds, the Chancellor of the Exchequer, as is hoped, leaves the tea duty where it is now, there will be much to be thankful for. April 10 is mentioned as the probable date of the Budget speech.

A new paragraph has been added to the regulations for the entry and

EXAMINATION OF IMPORTED TEAS, AS ADOPTED

BY THE UNITED STATES

Treasury Department. The regulations are practically the same as those of last year, with the exception of the following: "In examining Japan's Green Teas and Congous, while limiting the comparisons in the matter of infused leaf and scum to the specific standard called for, examiners are to admit teas upon the question of quality, in the three kinds above cited, provided they are equal, in the case of Japans, to either the Pan Fired or the Basket Fired standard; in greens to either the Country Tea or the Ping Suey standard; and in Congous to either the North China or the South China standard.

ON THE PROSPECTS OF THE TEA TRADE,

the *Grocer* points out that the statistical position of tea is difficult to gauge just now, in consequence of the dislocation of trade through the exceptional circumstances under which duty payments on the article were made a twelvemonth ago. "Despite the false impression which the statistics are calculated to create, the prospects for Indian and Ceylon tea must be pronounced," our contemporary says, "as very good. Although much difference of opinion has existed respecting the Indian crop as to shortage, the ultimate deficit does not turn out to be so large as was thought earlier in the season, and, according to the latest circular issued by the Indian Tea Association of Calcutta, the total crop of 1901-02 was 165,250,000 lb as compared with 177,500,000 lb in 1900-01. It may be added that the exports to London from April 1 last to February 28 this year reached 152,251,000 lb, in comparison with 160,830,000 lb in 1901. A year ago the tea trade was in a very unsatisfactory state, with prices at an unprecedentedly low point—i.e., 2½d to 3½d per lb for common sorts—owing entirely to over-production. Since last August, however, quotations have been at a more normal level, with a slight upward tendency and occasional set-backs. Approaching nearer to the present date, there has been an increasing demand for the commoner kinds, which have become scarcer, and are much wanted for the chief 'canister.' In proof of this statement we have only to add that the value within the past fortnight has advanced about ½d to ¾d per lb, and for the next month or two all the lower grades of tea available will be required for immediate use. Ceylon shipments have of late been on a somewhat diminished scale, in spite of a lighter quantity and return in 1901 as compared with the previous season and the scarcity of finer qualities of both Indian and Ceylon descriptions has turned out to be unmistakable. In view of this fact it would pay growers to make superior teas,

instead of resorting to indiscriminate plucking, whereby the markets at times are flooded with coarse, common sorts, which often happen to be far too abundant to be thoroughly appreciated. Last spring, it will be remembered, enormous quantities of tea were being taken out of bond to evade the payment of an extra duty, should it be imposed, and so disarranged was the customary order of business that it was several months after before the rate of delivery righted itself; but no such disorganisation of the home trade will be experienced this year. About Christmas-time and shortly afterwards there were some attempts to clear tea out of bond, but they did not assume any formidable shape, and since then the duty payments have been of not more than average amount. Thus, money in tea, which early in 1901 was practically locked up and useless, will now be liberated, and can be applied to the more legitimate purpose of buying and furthering the progress of the trade as well as protecting the interests of consumers as a body. By these means the tea market generally will be kept in a sounder and more healthy condition than it has been for two or three years past."—*H and C. Mail*, March 21.

TEA IN AMERICA.

New York, Feb. 19.

There has been a little more doing in an invoice way. Market firm and unchanged. The same standards have been adopted for next season as have been in use the past year.

IMPORTS OF TEA SINCE THE EXHIBITION YEAR.

Year ending June 30—	Net imports, Pounds.	Value, Dollars.	Average import price, per lb.—Cents.	Per capita population Pounds.

—*American Grocer*.

CEYLON TEA IN 1901:

HIGHEST CROPS AND AVERAGES

According to the Annual Report of Messrs. Wilson, Smithett & Co. (which we are reproducing in this issue) the Diyagama Factory (New Dimbula Company) sent the largest quantity of tea to London last year—no less than 1,247,000 lb. realising the splendid all-round average of 9½d per lb.; while Goatfell gave the highest actual average 1s 0½d for 100,000 lb. The other high returns were Sutton 11½d for 108,500 lb.; Talawakelle's 10½d for 467,000 lb.; Waverley 9½d for 400,000 lb.; Concordia 10½d for 215,000 lb.; Henfold 10½d for 258,000 lb.; Lippakelle 9½d for 240,000 lb.; Mount Vernon 9½d for 248,500 lb.; Portmore 10½d for 241,000 lb.; Ragalla 9½d for 304,000 lb.; Diyannillakelle 10d for 129,000 lb.; Ferham, 10d for 121,000 lb.; Holnwood 10½d for 120,000 lb.; Nutbourne 9½d for 80,000; Pitaratmalie 9½d for 139,000 lb.; Thotulagalla 10½d for 95,500 lb.

DO TROUT BREED IN CEYLON?

A correspondent writes to our contemporary that a companion with him at the Horton Plains on April 1st caught a rainbow trout 4 inches long, though the last trout fry (brown) were turned down by Mr. John Fraser in May 1901 and rainbow fry some time earlier, and wishes to know if it could have been born and bred on the Hortons. We enquired of Mr. Fraser his opinion this morning, and he informs us that he recently took out trout, varying from 3 to 20 inches in length, from his own stewpond, from fry put in 2 years ago; they had grown up irregularly and their ages could not at all accurately be told from the size. Mr. Fraser does not share the hope that our rivers may soon be "self-stocking."

THE TEA MARKETS EXPANSION COMMISSION.

(FROM THE SIXTH REPORT.)

We have received a copy of the sixth Report of Messrs Andrew Yule & Co., the Commissioners, to the members of the Advisory Committee, referring to the operations during January and February, 1902.

Tea contributions promised to 28th February, 1902. — Total 683,744 lb, the same as on the 31st December last. Acting on the suggestion of the Commissioners, cash has, in some cases, been given in lieu of tea, at the rate of 4 annas per lb. Up to 28th February, 1902, the following proportions of the promised contributions have been received:—

	lb.	RS.	AS.	P.
In tea about 47% =	323,987	valued	81,260	9 9
In cash do 3% =	21,760		5,510	0 0

Total 50% = 457,347 86,770 9 9
against 39 per cent received to 31st December last. The average value of the tea is 4 annas per lb, against 4 annas 1 pie to 31st December last. Cash subscriptions received to 28th February, 1902 amount to R9,010, against R1,210 received to 31st December last.

PURCHASE OF TEA.—To meet the demand for classes of tea other than those contributed, to 28th February, 1902, 26,358 lb of area were purchased at a cost of R8,974-7-11. The teas were all purchased at public auction. Tea stock on 28th February, 1902, is approximately as follows:—

Received into godowns from contributors 323,987 lb; Ditto by purchase 26,358 lb—Total 350,345 lb. Tea disposed of in the seven months 160,374. Tea in stock on 28th February, 1902 189,971, against 163,888 lb on 31st December last.

PICE PACKETS.—The demand for these continues satisfactory, the total issued to 28th February, 1902, being 526,015. The packets are sold in any part of India at one pice each as in Calcutta.

BREWED TEA.—The total number of cups brewed tea sold at one pice each, to 28th February, 1902, is 116,222. Cost of working to 28th February, 1902, is roughly R17,000 as against R10,000 to 31st December, 1901.

NEPAUL.—The Prime Minister and Marshall of Nepal, in reply to a letter asking him to encourage the efforts of the commission in that Dominion, stated that, while he personally wished the movement every success, he feared not much could be done, as the Nepal Government had long being unsuccessfully endeavouring to bring

tea into general use with a view to fostering the tea plantations existing in the eastern part of their territory. A case of pice packets has, however, been sent to Nepal as a trial.

OTHER AGENCIES.—Work through other channels and Agencies has been continued. The Dacca Agent reports that the Commission's tea has gained a firm footing in Dacca, which is the main supply station for the Districts of Dacca, Mymensing, Tipperah and Chittagong, and that in the more important towns of these he has established sub-agencies which are under the regular inspection of travellers, who also visit all Fairs within their reach. An Agent of the Commission has also made a tour through Kathiwar and Gujerat, visiting Poibandar, Junagah, Rajkot, Bhavanagar, Wadwan Ahmedabad, Baroda, Surat, Karachi and Cutch, with a view to introducing the Commission's tea into these places. Another Agent has been actively canvassing Jubbulpore, Agra, Delhi, Jhansi, Cawpore, and Gwalior. Another Agent has visited several Fairs and Melas, and held demonstrations and sold tea at these gatherings.—*Madras Mail*, April 8.

CEYLON TEA IN 1901.

Extracts from Geo. White & Co.'s Annual India, Ceylon, and Java Tea Report.)

March, 1902.

We would preface our usual annual report by offering our congratulations to those interested in this important industry, especially the producer, on the partial dispersion of the heavy cloud which over-hung it when we compiled our review just a year ago. From various causes a marked reduction in the output of the chief growing countries has been apparent, and the trade would appear to be once again gradually emerging from a condition of depletion to one of comparatively healthy appetite. The all-absorbing question now is how to guard against a relapse into the lamentable state experienced during the season 1900-1, and in this connection we would draw attention to our remarks under "Prospects."

CEYLON.—The comparative shrinkage in the total crop gathered was less than in the case of India, but increased shipments from both Colombo and London to outside ports reduced the quantity available for the markets within the United Kingdom. Elsewhere we refer to the main question of supply and its effect on prices. In the case of Ceylon it may be noted that the average in February, 1901, was 6½d per lb, while in the October following it stood at 8d per lb. Quality, on the whole, was distinctly above the average, varying a little according to season, the most attractive reaching London, as is customary, about October. Owing to this usual variation, it may be here noted that seldom, if ever, is it possible to contrast sales made simultaneously in London and Colombo, the high probability being that these markets are not selling similar tea, be it better or worse, there having been nearly two months' difference in the time of manufacture. Really low-grade tea, so often met with twelve months since, has been conspicuous by its absence. As in India, the production of choice quality was on a limited scale, and ordinary fine kinds, having a better class below to compete with than usual, suffered to some extent. Useful to good Broken Pekoes have often been below par, the fact of the important

export trade being so far chiefly confined to leaf, having constantly favourably influenced the value of such, to the seeming detriment of broken. This feature will doubtless become less prominent as outside markets learn to use the whole assortment.

STATISTICAL POSITION.—Shipments for the past year to the United Kingdom totalled 107 millions against 114½ in 1900, which, together with an increase in Deliveries in the 12 months of 2½ millions, resulted in a reduced stock of 5 millions at the opening of the present year, compared with 1st Jan., 1901. Generally speaking the immediate position under this heading is satisfactory, especially when it is noted that the imports during the 12 months ending 31st December last were actually some 5 million lbs less than the total deliveries for a like period. For the twelve months the following on Estate Account passed the hammer in London :—

1901.	1900.	1899.
1,059,800 pks.	1,125,100 pks.	1,000,000 pks.
(Av. 7d ₤ lb.)	(Av. 7½d ₤ lb.)	(Av. 8d ₤ lb.)

* Includes the unprecedentedly low rates ruling last spring.

The Board of Trade returns for all Tea (which embraces every Bonded Warehouses in the U. K.) for the past three calendar years were :—

	Home Consumption.	Export.
1901 ...	255,873,000 lb.	43,388,000 lb.
1900 ..	249,792,000 "	*38,907,000 "
1899 ...	242,561,000 "	32,223,000 "
	Total	Bonded Stock,
	Deliveries.	Dec. 31.
1901 ...	299,261,000 lb.	115,951,000 lb.
1900 ..	288,699,000 "	†119,430,000 "
1899 ..	274,784,000 "	113,010,000 "

* Excluding about 4½ million lb. of Brick Tea transhipped to Siberia. † Re-adjusted.

This denotes a further extension of over 6 million lb. in the use of the article at home. It is calculated that the consumption per head of the population of the United Kingdom, which was 4½ lb. in 1880 and 5 lb. in 1890, had risen to 6½ lb. in 1901. Exports to the Continent, &c, from here, of British growth mark an expansion of about 7½ million lb., not including "overside" transshipments, and compare with an increase to outside ports from Colombo of 5½ million lb. and a decrease from Calcutta of rather over 2 million lb.

PROSPECTS.—The producer has it largely in his power to make or mar, and we would urge upon all interested the high importance of remembering that only by a rigid adherence to the policy of keeping supplies within the limits of consumption, can be found any hope of preventing the already improved situation from again taking a retrograde movement. Finer and more careful plucking, combined with climatic influences, have been the factors at work, and together they have undoubtedly, at least for the time being, saved the situation. Let it be well understood, if growers are again placed in the position they occupied in Season 1900—1901, when they had to force a quantity out of all proportion to consuming possibilities down the throats of the trade, they will assuredly once again feel the inevitable result of transgressing the laws of supply and demand. The heavy extensions carried out about the middle of the last decade are only just coming into full maturity, and under normal weather the approaching crop may easily get out of hand in respect to quantity. In spite of all warnings and the ex-

perience that the contrary usually happens, the feature of any one season as regards an enhanced price obtaining for any particular grade has almost invariably been reflected in the production of the following one. Looking then at the comparatively high level on which common descriptions have stood during most of the past season, there is an element here of further danger. Under similar circumstances have we not heard the grower, who can produce "stand-out" quality, perhaps not unnaturally, exclaim that he will make no more fine tea, so-and-so having got within a trifle of his average and made many maunds more per acre. And thus the seeds are sown for an enormously augmented crop of an inferior article.

It was on this basis, after the *unfortunate*—we use the word advisedly—abnormally high price for common tea season 1899-1900 closed with, that the unwieldy crop of 1900-1901 was gathered, the disastrous results of which should still be green in memory. It is manifest that conspicuous success in curtailing the out-turn must to an appreciable extent follow a climatic condition of slow growth, and in the possible absence of this most necessary factor, in order to lessen the element of chance as regards such, all the greater care will be called for in the direction of restricting output. The mere regulation of plucking, only a given number of leaves and a bud in any unusually free flushing period will scarcely suffice; in the latter event it may at times be essential, even at the expense of cultivation, to put a larger share of the labour force to gather leaf and so get round the garden at shorter intervals. It is obvious that the longer the leaf is allowed to "run," in like ratio will the income of green leaf be increased in bulk and weight and decreased in quality.

In our foregoing remarks we have included the question of supply, as it is inseparably bound up with "prospects" and in it lies the whole crux of the matter. If it can be more widely realised that in the ability to show an increased out-turn in the weekly returns from Gardens does not alone lie salvation, the future welfare of the Trade will become more assured. In this connection we would draw attention to a most significant letter under the heading "Japan Tea," which appeared in the *Home and Colonial Mail* of the 7th instant, and which is of pregnant interest when applied to India and Ceylon. The writer proves by published statistics that from their maximum point in 1891, the exports from that country had fallen in 1900 to the extent of 20 per cent., while the valuation of the reduced quantity had risen by fully 30 per cent. He summarises the position thus :—"The moral is a plain one. If India and Ceylon can keep down their quantities, improve their qualities, and gain an increased 30 per cent. on the selling values, the crisis in tea production will soon be a memory only." To grapple successfully with disease you must strike at the root, and it needs no special knowledge to diagnose the source of the trouble our trade has been suffering from. The regulating of sales, &c, may at times afford relief, but we must go further to find a permanent cure. Speaking generally, no disturbing feature mars the outlook if only the market is not overfed. The use of tea is becoming more and more common throughout the civilized world, and some compensation may here be found for the low prices which have accompanied excessive supplies, and no doubt aided the opening of new markets. The grower has however sown freely to his cost,

let him now pay attention to the reaping. To judge from Ceylon figures the determination to limit quantity is being well sustained. India should in the coming season see that she also follows a like policy. As regards the producing of Green Tea for America and Canada there has not yet been anything like a sufficient supply to test the possibilities of these markets. The measure of success attained should however encourage perseverance, but large shipments should be forthcoming, even if disposed of at an initial loss, to ensure a tangible result. An energetic effort is being made in India to encourage tea drinking amongst the native population. With such an enormous field to work on there is good hope of a fruitful return on the expenditure in money and kind now being incurred in the exploitation of the different Presidencies.

MANUFACTURE—The line we would advocate may be gathered from the foregoing remarks. Owners, especially in Assam, may feel tempted to go for quantity in view of the prices other districts, more notable for such, have realised. May we remind them of the result of adopting this course in 1900? If an equally good crop as the last one from the Dooars, Cachar and Sylhet could be guaranteed, the matter might be different. At times shipments have included some proportion of dry, almost "bakey", liquoring kinds, a baneful characteristic not infrequently imparted in the final operation of firing.

PACKING.—Slack-packed chests, bearing no sign of leakage, not infrequently come to our notice, and as they usually incur an allowance of $\frac{1}{2}$ d per lb., are to be guarded against. This is not claimed on the basis of irregularity of weight, but because the package is not full and consequently liable to travel badly. To the blender a slack packed chest can make no difference, but he seldom forgets to claim.

SIZE OF BREAKS.—Remains as before, viz.:—India, 20 chests, 30 half-chests, 50 boxes. Ceylon, 18 chests, 24 half-chests, 40 boxes. Anything under these is a small break and is to be avoided as much as possible. Ceylon still sends a rather large proportion; this might often be advantageously reduced by fewer grades being assorted. There is practically no object in packing in boxes; they cost the garden more in every way, including freight, handling, &c., and seldom give a corresponding benefit in price. This also applies to half-chests, the demand for which is more limited than formerly, and except in cases where the lighter package is necessary, owing to difficulties of local transport, there appears to be no advantage in using anything but the ordinary full sized chest for the usual run of tea.

	Total Ceylon.
	lb. average.
1901-1902 ..	748,900—7½
1900-1901 ..	861,500—7
1899-1900 ..	802,400—7½

COTTON IN GERMAN EAST AFRICA.

BERLIN, March 24.—A conference of experts and persons interested in the cultivation and sale of cotton met today in the Colonial Department of the German Foreign Office, under the presidency of Dr. Stuebel, head of the Department. The following resolutions were passed unanimously: (1) That the conference notes with interest the report on the satisfactory re-

sults obtained by the cotton expedition of the Colonial Economic Committee to Togo, and expresses its thanks to the Committee. (2) Provided that the necessary funds are granted by the parties interested and by the Government, a commission of agricultural experts is to be dispatched, under the auspices of the Colonial Economic Committee, to the United States, with the object of studying the cultivation of cotton in that country. The result of their investigations is to be turned to account by the establishment of experimental stations for the purpose of introducing in German East Africa the cultivation of cotton as a native industry.—*H and C Mail*, March 28.

JAPAN AND THE MALARIAL MOSQUITO.

Tokio, March 19.—Extensive experiments, which have been conducted by the military authorities in Formosa for the purpose of determining the influence of mosquito in propagating malaria, show remarkable results. A battalion of soldiers' completely protected against mosquitos during the malarial season for 161 days, escaped the disease entirely, whereas an unprotected battalion in the same place during the same time had 259 cases.—*London Times*, March 15.

PLANTING NOTES.

STRAITS EXPERIMENTAL PLANTATIONS.—Mr. Stanley Arden would seem to have made a fair beginning with his important work at the Straits, to judge by the extracts given from his Report in our daily and *T. A.* It was hampered at first by the want of a suitable site; but Mr. Bailey's Selangor Rubber Syndicate came to the rescue, with an offer of 200 acres on certain terms, and these are likely to be agreed to.

CEYLON V. JAPANESE GREEN TEA.—The important information we publish elsewhere tonight marks a stage in the history of the production of green tea in Ceylon. The Ceylon article has been hitherto largely preserved from the methods of manufacture in vogue further east, but it remains to be seen whether, if the market held by Japanese greens in Canada is to be properly captured by us, the article from our colony is not to approximate more closely to the Japan product than it does at present. In the new green tea factory in Colombo ample provision is made for this contingency.

THE NEEM OR MARGOSA.—The Planter who sent us the extract on the medicinal uses of the Neem from an Indian paper writes:—"I am much obliged to you for the interesting information bearing on the identity of the Indian Neem with the local Margosa. My ignorance has led to the publication of information which, I am sure, will be welcomed by a great many of your readers. I made the acquaintance of the Margosa tree on a visit to the North many years ago, and I know the natives believe in the bark as a febrifuge. The oil is one which commends itself specially to Tamil olfactories as I have reason to know as an employer of Tamil labour; but I think I would prefer the rheumatics to the smell of the oil! *Non tati auxilio*."

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you add another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from sea level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February; also plants.

Coffee Arabica, Liberian Hybrid and Maragogople Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dated 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel, and Ornamental Trees, Trees for Roadsides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREAMY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

WILLIAM, HENARATGODA, CEYLON.
Liber's, A.I. and A.B.C. Codes used,

J. P. WILLIAM & BROTHERS,
Tropical Seed Merchants,
HENARATGODA, CEYLON.

Correspondence.

To the Editor.

ERADICATION OF THE PRICKLY PEAR
IN AUSTRALIA.

6th March 1902.

SIR.—In the *Tropical Agriculturist* of January 1902, p. 472 this occurs. "The Government (Brisbane Nov. 27) today decided to offer a reward of £5,000 for the discovery of a method of eradicating the prickly pear," &c., (*Adelaide Observer*) Before eradicating the prickly pear tree, would it not be a wise plan to see whether some use cannot be found for it. But first it might perhaps be useful to try and decide what a "prickly pear" is. There are prickly pear trees (*Opuntia*) in South Africa, in Australia and in South India. Are these three one and the same species, or are they all three different? The name of "Prickly Pear" is very misleading. In the Mediterranean there is a fine species which produces delicious fruit in summer. It is of three different varieties, the red, the white and the yellow fruited. Under cultivation it produces fine fruit and grows into a large hush. In the Mediterranean it is called *Fico d'India*, and presumably it is the "*Opuntia Ficus Indica*." But in England I found it anything but hardy. So recently I obtained two species from the Cambridge Botanic Garden which are there declared to be perfectly hardy although their fruit is of no value. One is *Opuntia bicolor*, and other *O. Engelmanni*. My object in getting these, is to try and graft the tender *O. Ficus Indica* on to these hardy ones; and experiment with them again in the open. The appellation of 'Prickly Pear' is of no use, as all kinds, good, bad and indifferent, are, it seems, called by that name.

Now, could not the Government of Australia import the fine and insouciant varieties of the *O. Ficus Indica* from the Mediterranean—they are grown in Cyprus, Malta, Sicily and other places—and see if they cannot be grafted on the Australian *Opuntia*? That might perhaps be one way of utilizing some at least of the acres of wild prickly pear. It should also make useful hedges.

But there may possibly be another and more sensible way of utilizing this flat-branched tree. In the Mediterranean I have seen people feeding goats with the flat branches of the "*Fico d'India*," cut in pieces, and also with the fruit skins. The goats did not seem to mind the prickles in the least. The sheep has been largely patronised in Australia, but I have never heard that the goat has been cared for there.

Yet the goat is one of the most useful animals, both for its milk and its flesh. Kid is highly prized as a meat. Then its skin is also valuable. One should see the milk men in the south of Europe—in Leghorn, Naples, Sicily, Hyères, &c.—going from door to door, with a small herd of goats and milking them as the people wanted the milk. It would be an interesting experiment if somebody in Australia would try to feed goats on this prickly pear. The way to commence would be to take a young green branch, scrape off the prickles, cut it in pieces, and force a bit into the goat's mouth to enable it to get a taste of it. If it is hungry, the chances are it will eat it, and continue to do so afterwards.

E. BONAVIA, M.D.

COCONUT PLANTING: TREES PER
ACRE AND NUTS PER TREE.

London, March 7.

DEAR SIR.—In your *Overland Observer* there are letters from H. L. D., dated 31st January and 3rd February, with reference to Kiritmetiana Coconut estate, which are not without interest.

From the figures he gives it would appear that last year the estate of 603 acres gave 838,970 nuts or 1,391 nuts per acre. He also states the yield per tree was 44.5 nuts, so it follows there are only 31 trees per acre.

As I understand, Coconuts run on an average 80 trees to the acre; so it would appear (unless the 603 acres have an enormous number of vacancies) that only some 40 per cent of the trees, which are said to be from 10 to 30 years old, are in bearing. Perhaps H. L. D. would kindly publish some figures in elucidation?

COPRA.

[An explanation is certainly needed; for the 603 acres are described as "fully planted," and if all the trees are not in bearing—as we suppose must be the case—it was a mistake to average the total crop without specifying how many acres, or trees, were in full and how many in partial bearing?—Ed. T.A.]

ALKALINE PHOSPHATIC MANURES.

London, E. C. March 21.

SIR.—In reference to my lecture last week at the Society of Arts the enclosed cutting from the *Standard* of the 20th March shows that the new manure is favorably regarded.—Yours truly,

JOHN HUGHES.

(Cutting.)

An interesting discussion on "The Utility of Alkaline Phosphatic Manures" took place at a meeting of the Society of Arts last week, introduced by Mr. John Hughes, F. I. C. The lecturer described the several phosphatic manures, and stated their respective degrees of solubility in cold water, or in an extremely weak solution of citric acid—much weaker than the acidity in the juice of the roots of plants, or in soils that are not alkaline. The comparisons showed that the new manure, basic superphosphate, is much more soluble than basic slag in cold water, or in a citric acid solution, and that its proportions of available lime and phosphoric acid are very much greater. Ordinary superphosphate is still more soluble in cold water, and for alkaline soils it is to be preferred to the new manure; but for acid soils the latter can hardly fail to give the better results. The several chemical authorities who took part in the discussion almost unanimously expressed the opinion that basic superphosphate would prove a great acquisition to farmers.

PALAI, OR PALU, WOOD.

Hanwella, March 26.

DEAR SIR.—Referring to Mr. Armitage's letter *re* sawing rate paid for Palai (Tamil, Sinhalese Palu) wood in your paper of the 22nd instant, may I inform you that it is a very tough wood, not inferior to ironwood (Na). A cubic foot of Palu wood is said to weigh 68 lb.; hence it is only used for heavy work, such as bridge construction and for posts in house building. The sawing rates differ according to circumstances and localities. The rates generally paid in the Western Province, for all kinds of hard wood, such as Dunumadala, Galsiyambala, Na, Palu, Munamal, Mee, etc. are between

rupees eight and ten. None of these are used for cabinet purposes except for curiosity, as they are too heavy and apt to crack, being close-grained.—I am, yours faithfully,

A NATIVE.

CEYLON RUBBER.

Kandy, March 27.

SIR,—As of general interest I herein enclose extract from a copy of Messrs. Kramrisch and Company's annual review of the rubber market for the year 1901, received by Government from the Secretary of State for the Colonies.—I am, sir, yours faithfully,

A. PHILIP,

Secretary, P. A.

EXTRACT FROM MESSRS. KRAMRISCH AND COMPANY'S ANNUAL REVIEW OF THE RUBBER MARKET FOR THE YEAR 1901.

"Imports from Ceylon were again insignificant, but whatever small quantity reached this market proved very attractive, as the quality and condition continued to be excellent and many buyers were anxious to secure even the small arrivals, owing to the specially clean condition of this rubber. We confidently expect that, if larger imports could be arranged, a great circle of consumers would come in and pay full prices for these grades, especially if the quality be kept up. It would be advisable to encourage the planters and others interested in this product in giving particular attention to this most valuable rubber. High prices were realised and 3s 9½d was recently paid for fine and 2s 4d for the Negroheads. It is, of course, known that this rubber should practically be of the same kind as the one coming from the State of Amazonas, being grown from para seed."

KIRIMETIANA COCONUTS.

Colombo, April 4th.

DEAR SIR,—Replying to a letter signed "Cobra", under date London, March 7, re Kirimetiana coconut estate, appearing in your issue of 29th ult.—the largest number of trees yet picked from, at any one crop, is 18,380. This includes young trees in bearing with trunks of 4' to 8', of which there are not less than 3,000 to 4,000 on the younger plantations, and amongst the supplies—so that the average from sections of fully matured trees is much larger. Most of the estate is planted 30' apart, which gives 50 trees to the acre, but some small portion is irregularly planted. There are no vacancies.—Yours faithfully,

H. L. D.

[The number of acres being 603, we gather from the above that only about 30 out of 50 trees per acre were picked from at any one crop? It is surely most unusual to plant coco palms 30 feet apart? We had thought few plantations had less than 70 trees to the acre.—ED. T.A.]

CEYLON TEA IN AMERICA.

Kandy, April 7.

SIR,—The accompanying newspaper extracts, received from Mr Wm. Mackenzie, are of considerable interest at present in re-

ference to Ceylon Tea in America and are placed at your disposal accordingly.—Yours faithfully,

A. PHILIP.

Tea merchants say the action of the Ways and Means Committee in retaining tea on the tariff list for another year is outrageous. "The plea that the country is so well stocked with tea that it will take at least a year to work it all off upon the market," declares G T Matthews, a leading New York importer, "is ridiculous. Every one who knows anything about the business is aware that there has not been for many years such a small stock of tea in the country, for the reason that the importers for several months have been expecting that Congress would remove the duty." The Committee made a mistake in discriminating against tea. It is the one commodity that should have been relieved from the tariff burden the first thing. The people have to pay the increased expense.

The market for Indian and Ceylon teas is rather easy. Japan teas are fairly firm. There is still quite a scarcity on the spot in Ceylon greens, and there have been quite a number of inquiries. Owing to the scarcity, however, the inquiry is not as pronounced as it was. The price of Ceylon greens is at least 1c. higher than it was a month ago. There have been a few transactions here in China green teas during the past week, but there is still a pronounced scarcity, although at the price now ruling not many transactions are to be expected.

Worcester, Mass, is taking to the soft drink habit, and the softest drink and the most popular is tea. Dealers say the sale of tea is greater than for years, and in every line connected with drinking and serving tea there is a boom. Tea has become fashionable once more, and that is the reason for its popularity. It is almost a truism to say that fashions move in circles, that, like history, they repeat themselves. The latest turn of the wheel has brought the tea table into vogue, and prospects point to a long reign of the fad. Many housewives have ransacked the garrets and brought out the old tea table, which now stands in an honored place in the drawingroom. The hostess who fails to offer her guests a cup of tea is far from being the real thing, and since the revival of the custom the graceful art of presiding over a tea table is being practiced in many homes. Where Dame Fashion sets the pace all must follow. Physicians try to discourage the practice of tea drinking, claiming that much tea is poison to the system and that digestion suffers in proportion to the amount of the herb consumed. To this the fashionables are returning that the quiet and rest of a short half hour spent over the tea cups late in the afternoon more than

MAKES UP FOR THE DAMAGE

to the system, and that tea properly prepared is not half so harmful as medical men try to make out. In addition to this, they say they are to drink tea as often and as freely as they wish. When fashion and the doctors clash, one party has to go to the wall, and it is not generally fashion. So the tea table and accessories have come back to stay awhile. The woman who owns one of the real old-fashioned Japanese lacquer tea caddies is a queen among her set. The older the better, only it must hold plenty of tea and be air-tight. With the advent of the revived fashion comes a scientific knowledge of properties and constituents of tea and the

fashionables are severe critics of its quality. Instead of discussing the servant girl problem the women talk learnedly of various blends, taking as much interest in the arguments as old clubmen over the virtues of a certain whisky. They can tell to a dot just how much green tea should be mixed with black breakfast tea to produce the desired aroma, and Oolong, Aden and Ceylon are becoming bones of contention as much as women's rights and universal suffrage. Rare old china that has been used for decorative purposes is now being

PUT TO A PRACTICAL USE

in the household. It is correct thing to be able to show a varied assortment of Sevres Chini, and all the other kinds of China, that collectors and amateurs affect. The hall marks of the real articles are being looked up, and if the guest turns up a cup when the lady of the house is not looking, it is to see whether the proper stamps is on the China. Imitations don't go, and the unfortunate one discovered in an attempt to palm off inferior ware is made the topic of the next session from which she is absent. It is not at all the correct thing to show a complete set of any one pattern of varied shapes and sizes are desired, the more varied the better. Old-fashioned brass tea kettle are also in great demand. Many a woman who cast the old kettle aside as being useless, bitterly repents her folly, for the dented and battered old brass is infinitely better style than the newest and most artistic patterns from the shops. Those who have kept their old friends are working up a muscle by polishing their sides to a mirror-like gloss. Useful members of the family who are able to embroider are at work on huge tea cosies for the corner table, and these are being modelled as close to old-fashioned lines as possible. In their construction, old pieces of brocade, fragments of old gowns of fancy silks and satins are utilised and take precedence

OVER NEWER FASHIONS.

The new fad must be in ancient guise to realise its greatest height. The fashion was introduced by one of the fashionable set, who issued invitations to what she called a kettledrum tea. This was really an old-fashioned 5 o'clock tea under an older name. There was some doubt in her mind as to the success of her venture, but to her great satisfaction the kettledrum "went" with a rush. The honored ones were charmed with the arrangements and made mental plans for a repetition of the function at early dates. Since then 5 o'clocks have been the rage, and in the church-going set, where worldly pleasure, is at present set aside, the tea table has provided a relaxation in place of the gayer meetings of a month ago. There are a hundred and one ways of making tea and each has its devotees, Russian tea, German tea, French tea and plain tea are served, and each manner of service finds some one to appreciate it. The old way of taking tea, which has been out of style among fashionable folks for years, is back again, and cream and sugar pitchers and bowls are enthroned. Tea with lemon has not been altogether displaced, but its grip is weakening. Russian tea, a mixture of tea, lemon and Jamaica rum, is one of the really new ideas, and what few

MEN FIND THEIR WAY

to the teas have taken to it with suspicious readiness. If they are allowed to measure out their own proportions they can be persuaded to drink several cups. Houses where Russian tea is served get more men than others, and American men are coming to the belief that the Russians are better fellows than they formerly imagined. The suspicious breath can be easily explained by saying that the owner had just come from Mrs W's afternoon tea. An excuse is sometimes needed in such cases, and by general consent a poor excuse is better than none. There is one essential to a successful tea, no matter in what way the beverage is ultimately served. The tea must be properly prepared in the first place. As well mix a cocktail without bitters as tea without fresh liquor to start with. The accepted mode of making tea is to take fresh cold water and fresh tea. The water is brought to a boil, and while this is going on the maker rinses the tea pot with boiling water, and puts in one big spoonful of dry tea to each cup required. When the water

REACHES THE BOILING POINT

it is poured into the tea pot, allowed to stand four minutes and then is ready to serve. Water that has been boiled and allowed to stand is not good. It must be fresh originally and allowed to come to the boiling point and no further. The recipe is simple, and by following it the best results are obtained. Tea is always prepared within sight of the guests, and for this reason a complete alcohol outfit is required. Instead of having the hot water brought from the kitchen, it is boiled on the tea table, and the transfer from boiler to tea pot is immediate. If a fresh supply of tea is wanted, the process must be repeated entirely. Fresh leaves are never added to those already used, for if the leaves are allowed to stand over five minutes they give out too much tannic acid, which is the hurtful ingredient in their make-up. American women are reverting to the old form of simpler food to accompany tea. The best thing to offer is bread and butter, sliced thin, or a simple sandwich. Afternoon parties had degenerated into a sort of free lunch, where the resources of the hostess were drawn on largely for novelties. This is to be done away with, and the women are heaving a sigh of relief over the reaction.

THE NEEM TREE.

Colombo, April 16.

SIR,—As some of your readers seem interested in the neem tree, called by the Portuguese "Margosa," they may like to know that in India it is revered not only for its medicinal qualities but by reason of its sacred character. It is to the Sivaïtes very much what the bô-tree is to the Buddhists. Twigs of it are generally found in their houses, they like camping in its shade and the delicate blossoms are often seen both at their weddings and funeral ceremonies. Owing probably to its slightly disinfectant properties they also use it largely for the manufacture of the "scrubbing sticks" employed by natives as tooth brushes.—I am, yours truly,
HILTON MERVYN.

THE WALAWE ESTATE COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

DIRECTORS :—Messrs. Edward Elliott, and Edward Rosling.

The Directors herewith submit their Report and Balance Sheet for the year ending 30th September, 1901.

The Working Account, inclusive of R250 deficiency from season ending 30th September, 1900, shows a loss of R2,626'82; and with the liabilities for interest, &c., and cumulative dividend on Preference Shares, it is increased to R4,824'40.

ACREAGE, &c.—The whole acreage of the Estate is 865 acres, of which about 550 have been aswedumised; out of this the area cultivated in the year was 1,054 bushels (twice over), or about 527 acres. An extent of 100 acres has been added since the Estate was taken over by the Company, and more would have been done but for the want of cattle, which are becoming very scarce in view of the extension of cultivation in the neighbourhood.

CROPS, &c.—The Estate share was 5,162 bushels paddy, which realised R7,125 02; and there was a profit of R571'96 on the purchase of seed paddy, making a gross income of R7,696'98 as against R8,419'31 in the previous year. The decrease was due to poor Maba crop. The Yalla was a fair one, and the Directors are glad to say the Maha now being taken is exceedingly good, and the Estate share is likely to realise R4,500 though the area cultivated was about 50 acres less owing to the sufficient supply of buffaloes.

The Provisional Directors, Messrs. Edward Elliott and Edward Rosling, in terms of the Articles of Association, retire from the Board.

The appointment of an Auditor for season 1901 02 rests with the meeting.

EMPIRE TEA COMPANY, LIMITED.

Registered February 26th, with a capital of £50,000 in £1 shares. Object: to plant, manufacture, and deal in any way with tea, coffee, cocoa, and other Eastern and Colonial products; as brokers, importers, commission agents, warehousemen, and wharfingers; to erect machinery, factories, warehouses, &c. The signatories are :—

	Shares.

No initial public issue. The first directors (to be not less than three nor more than five) are to be elected by the subscribers. Qualification, one share. Remuneration to be fixed by the Company.

TALAWAKELE ESTATES COMPANY, LIMITED.

REPORT

to be presented at the fourth ordinary annual general meeting of the Company, to be held at the office of the Company, on Thursday, the 27th March, 1902, at 12 o'clock noon,

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December, 1901, duly audited.

The Mortgage has been reduced to £15,500, by payment of the fourth instalment of £1,500 on 31st December, last, which has been charged against the profit of the year.

The yield of tea and cost of production were almost the same as in previous years and the gross average price obtained for the tea sold in London, though a penny less than that recorded last year, was very similar to that obtained in 1898 and 1899, and may be considered satisfactory.

The expenditure on new clearings, about £325 is charged against Revenue.

STATEMENT SHEWING RESULTS OF WORKING FOR THE FOUR YEARS ENDING 31ST MARCH, 1901.

Season	Acreage Planted	Total Tea Crop.		Yield per Acre.	Sold in London.	Gross Average Price of Tea sold in London.	Cost of Crop per lb. f.o.b. Colombo	Average Rate of Exchange per Rupee.

 (b) 36 acres felled for planting with Tea in 1902.
 (c) 2 acres leased to Messrs. Davidson & Brown.

PORTMORE TEA COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the Fifth Annual Ordinary General Meeting of Shareholders, to be held at 24, Rood Lane, London, E.C., on Wednesday, 26th March, 1902.

The Directors have the pleasure to submit the general balance sheet and profit and loss account for the year ending 31st December, 1901, duly audited. The net amount at credit of profit and loss, after providing for general expenses, income tax, &c., is £4,375 11s 0d, to which should be added balance brought forward from last year, £684 14s 11d, equal £5,060 5s 11d. An interim dividend of 5 per cent. was paid, August 26th, 1901, amounting to, £2,000 0s 0d. It is proposed to pay a final dividend of 7 per cent. (making 12 per cent. in all, free of income tax) which will absorb £2,800 0s 0d, and to carry forward to next year £260 5s 11d equal £5,060 5s 11d.

In presenting their fifth annual report, the Directors have pleasure in recommending a dividend of 12 per cent. for the year ending December 31st, 1901.

The tea crop from the estates has been 226,282 lb., being at the rate of 486 lb. per acre, against 353 lb. per acre last season, the falling-off in quantity being partly accounted for by a certain acreage having been left unplucked during the latter part of the year, in accordance with the scheme for the reduction of output which it is proposed to continue.

The cost of production has been £4,314 19s 4d, being at the rate of 457d per pound, and the crop has netted £9,167 4s 6d, being 972d per pound.

The average price of Ceylon tea sold in London in 1900 was 7·20d, and the Portmore gross average was 10·47d, and while the average price of Ceylon tea for 1901 fell to 6·86d, the Portmore average rose to 10·66d, proving that the quality has been fully maintained.

The average rate of exchange has been 1s 4·32ds, against 1s 4·964ths, last year.

Mr L M Torin retires from the Board by rotation, and being eligible, offers himself for re-election.

The latest reports from the manager in Ceylon shews that estates, buildings and machinery are in good order, and the estates of crop and expenditure give promise of continued good results.

The Directors feel that great credit is due to Mr R C Grant, the manager, and Mr H A Grigg, the superintendent in Ceylon, for the way in which they have cultivated the estates and maintained the high quality of the tea during the past year.

THE CRAIGHEAD TEA COMPANY, LIMITED.

REPORT

to be presented at the fourth ordinary annual general meeting of the Craighead Tea Company, Limited, to be held at the offices of the Company, 12, Fenchurch Street, London, E.C., on Thursday, the 27th March, 1902, at 2-30 p.m.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1901, duly audited.

The mortgage was reduced to £3,150 by the payment of the third instalment of £450 on the 31st December last. This sum is debited to profit and loss account, and is an ample charge for depreciation.

During the year 32 more acres of land have been purchased, the cost of which has been added to capital account.

The total yield, excluding some 20,000 lb. made from purchased leaf, was 431,265 lb. tea, and the gross average price obtained in London was 6·67d per lb. Last year the crop was 395,105 lb. tea, and the gross average was 6·85d per lb.

	£	s.	d.	£	s.	d.
The Net Profit for the year amounted to ..	3,034	9	0			
And the Balance from last year to ..	670	4	6			
						3,704 13 6
Interest on the Mortgage has been paid ...	180	0	0			
The Third Instalment of the Mortgage (£4,500) has been paid ...	450	0	0			
Dividend on the six per cent. Preference Shares for the year has been paid ...	481	16	0

It is proposed—						
To pay a final Dividend of 5 per cent. free of Income Tax, on the Ordinary Shares, which will require ..	1,145	10	0			
And to carry forward the Balance of ..	670	11	1			
						£3,704 13 6

The Directors desire to place on record their appreciation of the efficient management of the estates by Mr Ernest Bertie Hay and his staff.

Mr. Charles Murray Robertson, the Director who retires on this occasion, being eligible, offers himself for re-election.

Mr. J Hamilton Alston, the Auditor, also retires, and offers himself for re-election.

The approximate acreages are as follows as per recent survey:—

	Acres.
Tea.—In bearing ..	834
Tea.—Not in bearing ..	62
Ravines and Waste ..	62
Timber Clearings ..	53
Jungle and Patana ..	31
	1,042 acres.

THE BATTALGALLA ESTATE CO., LTD.

Twelfth annual report to the shareholders:—

The Directors regret that, owing to deficiency in the yield in consequence of unfavourable weather, and the continuance of a depressed range of prices for the produce, the results of the past year have not been satisfactory.

The quantity manufactured has declined from 274,556 lb in 1900 to 218,531 lb last year. The average selling price in London has been 9·34, against 8·38 in 1900, and in Colombo 37·06 cents, against 36 cents the previous year; the total crop averaged a selling price of 7·50d, against 7·85d in 1900.

London sales amounted to 63,232 lb, netting £2,156 16s 4d. and Colombo sales 154,518 lb, realizing net R55,638'87. This compares with 169,285 lb, netting £5,128 12s 1d, and 104,925 lb, realizing net R57,737'95, sold in 1900 in London and Colombo respectively.

Exchange for drafts has averaged 1/4 19-64, against 1/4 7-16 in 1900.

An interim dividend of 5 per cent on the Shares, free of Income Tax, was paid in October last, and the Directors are unable to recommend any further distribution. A balance of £31 16s 3d at credit of Profit and Loss Account is carried forward.

The best thanks of the shareholders are again due to the Estate Superintendent, Mr G C R Norman, as well as to the Colombo Agents, Messrs E Benham & Co, for their valuable services to the Company for the past year.

In accordance with the articles of Association, Mr Adolf Zimmermann retires by rotation, and, being eligible, offers himself for re-election.

THE UNION ESTATE COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

	ACREAGE.				Total Cultivated.	Grass, Jungle & Waste Land.	Total.
	Tea in full bearing.	Tea not in bearing.	Cocoa.	Cardamoms.			
Hayes Group	509	3	—	20	532	1,679	2,211
Dea Ella	243	—	81	—	324	162	486
	752	3	81	20	856	1,841	2,697

The Directors now present to the shareholders the accounts of the Company for the past year.

The crops secured on Dea Ella were 77,336 lb. Tea (including 18,207 lb purchased leaf) 164 cwt Cocoa and small quantities of Coconuts, Arecanuts and Vanilla. The Tea realized 30'69 cents per lb. and the Cocoa R33'15 per cwt, as against 31'44 cents and R44'30 in 1900. The crops from Hayes Group amounted to 273,281 lb. Tea and 1,101 lb. Cardamoms, which realised respectively 30'71 cents and R1'14 per lb. as against 30'75 cents and R1'21 in 1900.

The fall in prices of all the above products is extremely regrettable, and has been unfortunately the experience of many Companies during the past year.

A loss of R6,286'26 was brought forward from 1900 profit and loss account, and this is now reduced to R830'55 by the profits earned in the past year, R5,455'71; it must however be noted that no provision has been made for depreciation. The mortgage of £3,500 bearing interest at 8 per cent, over Hayes Estate, has been paid off and the necessary money borrowed in London at 7 per cent per annum. The Company's Bankers also called for payment of the overdraft, the money for which was provided by Messrs. Whittall & Co., on the security of a mortgage over Dea Ella Estate.

The only Capital expenditure of importance has been the instalments due for the construction of the Hayes Road, which amounted to R7,035'21: there still remains a liability to Government on this account of R9,261'20, which has to be liquidated by half-yearly instalments, the last being due on 30th June, 1903. Contributions to the extent of R1,991'54 paid by this Company in 1896 and 1898 on account of Hean's Land, to ensure the construction of the road, have been refunded by Government in 1902.

The estimate for 1902 is 345,900 lb. Tea, 150 cwt. Cocoa, 20,000 Coconuts and 2,000 lb. Cardamoms, on an expenditure on Working Account of R99,970'22.

In terms of the Articles of Association Mr. G H Aston now retires from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

THE CEYLON TEA AND COCONUT ESTATES COMPANY, LIMITED.

REPORT OF THE DIRECTORS, ACREAGE.

	Acres.
TEA.—In full bearing	410 2 22
Coconuts	559 3 3
Cinnamon	21 2 30
Rubber	40 0 0
Jungle, Patna and Scrub	375 2 38
Total	1,407 1 13 acres.

The Directors have now to submit to the shareholders the accounts for the past year.

THE DIVISION.—The crop secured amounted to 158,963 lb., being 21,037 lb. under the estimate. This is due to the extremely bad season for finishing, and to the continuance of the careful system of plucking,

The cost of laying down the tea in Colombo was 23'31 cents per lb. as compared with 30'47 cents per lb. in 1900, and the nett average price realised was 28'86 cents per lb. against 30'68 cents in 1900. There was no capital expenditure.

COCONUT DIVISION.—The crop gathered was 516,008 nuts, of which 2,430 were sold on the estate at R40 per 1,000 nuts and 4,351 were rejected.

The remainder were made into copra candies 409.2-0.16, and sold at a nett average of R45'58 per candy, as compared with candies 444. 4. 0. 18 in 1900, which realised an average of R44'93 per candy.

The Estimates for the current year are:—Tea, 200,000 lb. against an expenditure on working account of 42,173. Coconuts, 600,000 nuts on an expenditure of R15,569. This crop has already been sold at an advance of R8'50 per candy over last year, Rubber. An expenditure of R750 which possibly will be covered by the yield from trees which are now ready for tapping.

After making the usual provision for depreciation of buildings and machinery, the result of the year's working shews a loss of R3,843'3 as compared with R9,715'92 in 1900.

In terms of the articles of Association, Mr F Crossbie Roles retires from the Board of Directors and is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

THE PUNDALUOYA TEA COMPANY OF CEYLON, LIMITED.

DIRECTORS.—Messrs. Edward Christian, Charles Murray Robertson and Frederick H Christian. AGENTS IN COLOMBO.—Messrs. J M Robertson & Co. AGENTS AND SECRETARIES.—Messrs. Robertson Bois & Co.

Report to be presented at the fifth ordinary annual general meeting of the Company to be held at the office of the Company on Thursday, the 3rd April, 1902, at twelve o'clock noon.

1. The directors now submit their report for the year ending 31st December, 1901, together with the balance sheet and accounts of the Company made up to that date, and duly audited.

The mortgage on Deeside Estate has been reduced to £4,000, by the redemption of £3,618 7s 7d, aid on the 7th May last.

3. The crop gathered off the 1,640 acres of old tea was 679,079 lb., against 697,359 lb. last year, when the weather was unusually favourable. Part of the

new clearing (viz. 137 acres) was plucked for the first time and yielded 13,500 lb. tea; the whole expenditure on new clearings has therefore been charged to revenue. The small yield of about 100 lb. per acre on these clearings largely accounts for the diminished yield per acreage plucked as shown below on para. 4. The reduced profits are due to this smaller yield per acre, to increased expenditure on manuring, plucking and buildings, and to a fall of rather more than $\frac{1}{2}$ d per lb. in the price obtained for the tea.

4. The following statement gives details which may be of interest.

Season.	Acreage Plucked.	Total Tea Crop.	Yield per Acre.	Cost of Crop per lb. f. o. b. Colombo.	Gross Average price obtained per lb Tea.	Average rate of Exchange per Rupee.	Dividend on Ordinary Shares, free of Income Tax.	
	acres.	lb.	lb.	d.	s.	d.	per cts.	
1901	1,777	692,579	390	5.29	8.37	1	43.16	4
1900	1,640	697,359	425	4.86	8.63	1	47.64	6
1899	1,640	644,565	393	4.81	9.23	1	49.32	6
1898	1,640	627,886	383	5.29	9.27	1	43.16	6
1897	1,640	623,699	380	5.22	9.52	1	43.16	6

5. The net profit for the year amounted to £5,831 12 9
To which has to be added Interest 153 10 9
And the balance from last year of 264 15 9

Making a Total of .. £6,249 19 8

The Directors have already paid out of this: Interest for the year upon the Mortgage, less Income Tax £ 297 3 9
Dividend for the year upon the 6 per cent Preference Shares, less Income Tax 1,868 12 6
Income Tax .. 375 8 0
And they propose to deal with the balance as follows:—
To pay a Dividend of 4 per cent, free of Income Tax, on the Ordinary Shares, requiring .. 2,640 0 0
To Transfer to Reserve for Depreciation and General Purposes (increasing this Account to £6,750) ... 750 0 0
And to carry forward the balance of .. 318 15 0

£6,249 19 8

6. The Director retiring on this occasion is Mr Charles Murray Robertson who, being eligible, offers himself for re-election.

7. Mr John Smith, the Auditor, also retires, and offers himself for re-election.—By Order of the Board,
ROBERTSON, BOIS & Co.,
Agents and Secretaries.

SCHEDULE OF THE COMPANY'S ESTATES ON 31ST DECEMBER, 1901.

Estate.	Tea in full and Partial bearing.	Tea not in bearing.	Forest and Patna Land.	Forest and Timber Plantations.	Grass Land, Buildings, and Waste.	Total.
Sheen	609	77	112	45	52	acres
Pundaluoya	462	53	15	29	96	634 do
Wootton	306	8	—	39	25	78 do
Deeside	400	—	10	—	26	456 do
Total	1,777	118	137	113	198	2,343 acres

PLANTING NOTES.

CURE FOR INTERMITTENT FEVER.—Methylarsenate of soda, injected hypodermically in doses of five to ten centigrammes, has proved an excellent specific against intermittent fever in the military Hospital of Constantine, Algeria. Nine cases refractory to quinine were cured by it. The results of the trial were communicated to the Academie of Sciences.—*Globe*, March 21st.

PLANTING PROGRESS ON THE ANAMALAI.—We are glad to have a good account of the young district opened on this S. Indian range in coffee, cardamoms, cacao and tea: all are prospering and promise well: 8 cwt. an acre crop of coffee on an estate under 5 years is spoken of. Cinchona (Ledger) is also being planted interspersed with camphor. There are now 7 resident planters.

COMPANY MEETINGS.—Three Company meetings were held in Colombo today. The shareholders of the Drayton Estates Company have, it will be seen, approved of the sale of Yuillefield estate to Mr Charles Shuttleworth for £9,500. For the further working of the Plumbago Mining Company a sum of R10,000 is required and, unless that is secured by the end of the month, the company will be wound up. We regret to notice that the result of the year's working of the Ceylon Tea and Coconut Estates Company is a loss of R3,843.3.

COCAINE IN BENGAL.—The following notification of the Board of Revenue has been published:—Cocaine having been declared an intoxicating drug under Bengal Government Notification of October 23rd, 1900, and having thereby become an excisable article, the sale of it without a license has become illegal under Section 11, Act VII. (BC) of 1878, and punishable under Section 53 of the said Act. It is now hereby notified for general information that the sales of cocaine will not be allowed at all except for *bona fide* medicinal purposes, and that licences for the sale of it will be given to any persons other than approved druggists and chemists. Druggists and chemists desiring to take out licences should apply to the Collector, who will grant the licences, under certain specified conditions, to duly approved persons and firms. Druggists and chemists will be allowed up to March 1st, 1902, to obtain their licences. After that date the law will be put into operation against druggists and chemists, as well as against any other persons, who may be found selling cocaine without a licence. The West-end of London is evidently not the only place where the cocaine habit predominates.—*Chemist and Druggist*, March 22.

MORE ABOUT RUBBER.

LES PLANTES A CAOUTCHOUC ET LEUR CULTURE, PAR LE PROFESSEUR DR. O. WARBURG. Traduction complétée et annotée par J. Vilbouchevitch.* This translation of Prof. Warburg's able and complete work will be invaluable to those to whom the German volume was a sealed book. The translator prefaces his book by stating that

M. Warburg is one of the most noted of the botanists of the Faculty of Berlin and is also professor of the Course on Colonial Products in that city. He is the head of the *Tropenpflanzer*, a monthly periodical. M. Warburg has also travelled in the tropics, and his work has been written especially for practical men who intend to cultivate rubber. Scientific knowledge has, however, advanced considerably since M. Warburg's volume appeared. Thus, to take only one instance, the Landolphias of Africa, some of which were said to yield good Rubber are now rejected. Again, the statistical portion required revising. "We have, therefore, completed the German text and made several additions culled from the personal experiences of such men as M. M. Chevalier, A. Godefroi Lebœuf, J. Grisard, Dr. Heim, A. Michelin and E. de Wilderman. We have also largely increased the number of illustrations, thanks to the loan of several negatives. Our translation is thoroughly faithful, the author himself having assisted us in some doubtful parts. Thanks to our several additions, &c., this volume contains 300 pages as against 150 pages in the original volume."

M. Warburg in his Preface states that though when he first wrote (1898), most of the Rubber of Commerce was procured from natural forests; yet Rubber was being planted in many directions and the documents about the various kinds suitable for cultivation were scattered in such a multitude of periodicals, &c., that he had set himself to collect and submit to careful criticism and analysis the information thus gained. His statistical Introductory chapter on the production and consumption of rubber shows how world-wide is the problem before us. Thus, his tables show quantities and countries from which rubber is procured and to which it finds its way—also the re-exportation. Some 42 pages are taken up with this. The other chapters are headed as follows:—II. Para Rubber; III. Castilloa; IV. Ceara Rubber Tree; V. Mangabeira Rubber; VI. The African Rubber Plants; VII. Ficus Rubber; VIII. Various Rubber Trees of minor importance; IX. Table of Weights and Monies, Index. 26 illustrations are included and the above chapters occupy about 45 or 50 pages each.

It is impossible to give further details of so complete a work. The book must be possessed by those who make the subject their life work, for it is full of interest; as much practical as scientific.

* Paris: Augustin Challamel, Editeur Rev. Jacob 17, Librairie Marine et Coloniale.

FORESTS AND WATER-SUPPLY.*

(An instance from history)

Everybody has heard of the monks of La Trappe, or Trappists, an order whose vows include a life of silence coupled with 8 hours' hard work daily. The monastery was founded in 1140 by Rotrou II., Count of Perche, after losing his wife and his brother William in the wreck of 'La Blanche nef.' The forests with which it was endowed were kept till the Revolution, when they were confiscated to the State. Under which of the 'rights of man' this course was justified it boots not to enquire.

Whether the Trappists had been abusing their forests is not distinctly explained, but it appears that they had certainly been cutting the coppice portion (the greater part) too young, for at the Reformation of 1665 an edict went out against them. This no doubt emanated from the great Colbert, and ran thus:—"The religious community, the abbot, prior and convent of Notre Dame de la Trappe, &c, are hereby forbidden to cut any of the woods attached to the said abbey before the age of fifteen years, seeing the poverty of the soil. They shall regulate their coupes into fifteen equal fellings, and they shall leave standing at each felling the number of standards required by law; they shall allow one-third of their forest area to grow as high forest on the best soil in proximity to the Abbey itself."

This was duly observed till 1700, when the Abbe de Rance died, after ruling the monastery wisely and well for thirty-seven years. After his death the Trappists thought they would launch out into great ironworks, and the forests had to pay for the disastrous experiment. An old book 'The Life of Dom Pierre, the Dwarf, cleric and former sub-prior of the Abbey of la Trappe,' 1715, states the matter with due appreciation:—"Iron ores have ever been plenty about the Abbey of la Trappe, and many times had the holy father, the late Abbe, been supplicated that he would allow it to be dug out by private persons who desired to establish ironworks. The abbey might expect much profit and no expense. Never would Dom Bouthillier de Rance yield, for he foresaw beneath the promise of large profits the certain ruin of the revenues of his house, coupled with spiritual demoralisation and the relaxation of all the orderly life which he had been at so much pains to institute."

'But hardly was this holy man laid to his rest than Dom Jacques de la Cour, the new Abbe, lent a willing ear to the proposals of certain monks whose vows of solitude, &c, weighed too heavy on their impetuous natures. He took up a contract to run the iron works of la Trappe for thirteen years, and agreed to pay 2,800 livres for every year. Their destruction ran loose in the forests. Nobody knows how wastefully the furnaces swallowed up wood that might have been simply sold to far better effect. The springs soon dried up and the ponds (they had always depended on a series of ponds for water-power) became unable to supply more than six weeks' water for the year. The fires had to go out. The cost of relighting them at intervals was prohibitive. Thus fell to the ground all the ambitious hopes of the new Abbe. La Trappe became desperately indebted, much of its property had to be sold, and the monks were often in absolute want of the necessaries of life.' Dom Jacques de la Cour became naturally Don Jacques de la Sacque, and the ironworks, the monastery, and the forest were involved in a common ruin. So far as the forests are concerned, the State is now working them under a plan of 1894, in three series; a high forest under sixty years' provisional plan, and 2 coppices with standards.

Such is a story that was printed two hundred years ago, long before forest officers and their opponents began to seek for proofs of another disputed matter."

—Indian Forester, March,

* "La Foret de la Trappe," *Revue des Eaux et Forêts* for November 1901.

“THE UTILITY OF ALKALINE PHOSPHATIC MANURES.”

Mr. John Hughes calls our attention to a paper under this heading read by him at a meeting of the Society of Arts on 12th March ult. when Mr. A. D. Hall, Principal of the South-Eastern Agricultural College, occupied the chair. We shall reproduce the essay and discussion in full in our *Tropical Agriculturist*; but meantime may mention that after an animated discussion, in which nearly all the speakers—the Chairman, Messrs. Hermann Voss, John Ruffe, F. J. Lloyd, Dr. S. Rideall, Messrs. Edward Parkard, James Hudson, Dr. Teed and D. A. Louis—spoke of the great value of Mr. Hughes's discovery, the latter in summing up, said:—“He thoroughly believed in superphosphate; but its use ought to be restricted to soils which contained plenty of lime, just as basic slag was confined to soils which were particularly sour, and the new manure to intermediate soils. . . . It is not scientific, it is not economical, that one kind of manure should be sold for application to all kinds of soils—Acid manures may with advantage be applied where there is plenty of lime, and alkaline manures may be more profitably applied where lime is deficient.”

HUMUS AS A PRESERVATIVE AGAINST FROST.

I have just read a French translation, by my old friend, Prof. Henry, of the Nancy Forest School, of Wollny's classic work on the decomposition of organic matter. In it I find the statement that spring and autumn frosts are dangerous on peaty soils, only when the surface of the latter is dry. Wollny gives no illustrations of this law, but I recently observed one in my garden at Cooper's Hill.

Last September, I dug up several rose beds on my lawn and sowed them with grass seed, which has produced a fine crop of young grass. This I carefully watered, and the soil in the beds was well trenched and covered with decomposed leaf mould before the seed was sown. The rest of the lawn has not been trenched, probably for thirty years, and the soil under the grass in it a stiff loam, is now singularly dry for the time of the year. On the morning of Dec. 6th there was a slight frost, 31.0 F being registered six inches above the grass. At 8 a.m. the lawn was white with rime, except on the new grass, which remained green. This must be due to the fact that the moist, well-trenched humus soil under the new grass was able to conduct heat from below and thus kept the air in contact with it above the freezing-point, while the dry, compact loam under the old turf could not supply sufficient heat to the old grass to preserve it from freezing. Dry humus, according to Wollny, has a low specific heat, and is a bad conductor, while wet humus has a high specific heat, and is a good conductor of heat. On another occasion when snow fell, it melted much sooner on the new grass than on the rest of the garden. As a further illustration of Wollny's law I may cite the fact that water is let on to cranberry swamps in Carolina when frost is feared during the blossoming period, and also that in north-West India, on clear evenings when frost is feared, vegetable gardens and sugar-cane plantations are irrigated in order to obviate danger from frost. Kikur (*Acacia arabica*) plantations in the Punjab are also irrigated when frost is feared. It is also well known in Germany that, if a sphagnum peat bog is to be reproduced, a thin layer of peat must be left at the base of the bog after the

upper peat has been removed, and this layer kept carefully under water, as otherwise the drying up and consequent freezing of the peat will kill the moss. Slight frosts are very prejudicial to vegetation in sub-tropical forests, and when frost is imminent, the precaution of trenching the soil, removing weeds and irrigating cultivations is extremely important for young sugar-cane and other crops. W R FISHER, *Cooper's Hill, Dec. 8.*
—*Indian Forester.*

TEA IN NATAL.

20) PER CENT INCREASE IN IMPORTS :
NO EXTENSIONS RECORDED.

The Annual Report of the Durban Chamber of Commerce, shows £37,000 worth of tea imported during 1901 as against £12,000 worth in 1900. On the other hand exports of tea grown in Natal show but a slight increase, under 16 per cent—£15,900 worth in 1901 as against £13,000 worth in 1900. £4,111 worth of tea was sent from Natal into the Transvaal, £1,238 to Orange River Colony, £916 over the East Griqualand border (to the south west) and £143 over the Pondoland border.

We have also the following “tea” paragraph:—

No accurate statistics are available of the area under cultivation or the crop for the season. An estimate, however, has been made that by the end of May the output will be not far short of one and three quarter million pounds weight, say, an advance of 250,000 lb. on that of last year. The chief consumption is within the Colony, but of the exports of 545,647 lb., valued at £22,823, the Cape Colony absorbed 442,000 lb. The area under cultivation may be reckoned as about 4,000 acres.

THE PEARLING INDUSTRY IN NORTH AUSTRALIA.

Representative V. L. Solomon (S.A.) has addressed the following letter to the Prime Minister of the Commonwealth:—“My attention has been drawn by my constituents in the Northern Territory to the position in which some of them are placed owing to the provisions of the Immigration Restriction Act of 1901, which will render it difficult, if not impossible, for those engaged in the pearling industry to procure the necessary labour for manning their boats. The magnitude and importance of this trade will be better understood after a glance at the following figures. The export of shell from Queensland for the year 1900 was 1,250 tons, valued at £123,451; from Western Australia for the same period, 733 tons, valued at £83,423, and pearls valued at £20,000; from the Northern Territory, 175 tons, valued at £22,674, or a total of 2,153 tons of shell and pearls valued in all at £257,553. There are a very large number of boats employing many thousands of hands as divers, crews, &c., in this industry, the whole product of which passes through the hands of European traders at our ports, and the whole of the stores and supplies required by the men are obtained in Australian ports, and contribute customs duty to the Commonwealth revenue

The crew of each boat live on board the boat, visiting the shore only for the purpose of trade, purchasing their stores, and packing their shells for export; and, as their work is in most instances carried on outside of the three-mile limit, none of those dangers which the Immigration Restriction Act is designed to prevent can possibly be anticipated. This question is of such vital importance to a vast number of boat-owners and business people settled in the northern portion of the continent that I feel justified in urging your Government to give it your earliest and most favourable consideration."

Brisbane, March 25.—The Home Secretary has received an important telegram from the Government Resident at Thursday Island bearing on the threatened removal of the headquarters of the pearl shelling industry to Dutch New Guinea on account of the operation of the Immigration Restriction Act. Mr. Mitchell, manager of Messrs. Burn, Philp, and Co., arrived from Dutch New Guinea on Sunday, and reports favourably regarding the Marouky's River. The entrance to the river, he states, is well marked. There is $3\frac{1}{2}$ fathoms of water on the bar, and the river is navigable for 40 miles. He describes the soil as rich with extensive groves of coconuts. The Dutch have built spacious houses and barracks, and have 400 soldiers besides artificers. The community numbers 600, and more are expected shortly. There is a monthly service by steamer from Java. Mr. Kroesen, the President, says the port will be full. "The pearl-shellers here," says the Hon. John Douglas, "are a good deal attracted by the prospects opened out to them, but as yet have made no move." Mr. Douglas's report was confirmed. The Premier regards it as extremely likely that in the present conditions there will be an exodus to Dutch New Guinea. He would not sit quietly down and see this brought about, and it is probable that a direct appeal in connection with the matter will be made to Mr. Chamberlain.—*Adelaide Observer*, March 29.

CRYSTALLINE LIMESTONES OF CEYLON.

[FROM THE ABSTRACT OF PROCEEDINGS OF THE GEOLOGICAL SOCIETY OF LONDON.]

March 12th, 1902.—Sir Archibald Geikie, D.C.L., LL.D., F.R.S., Vice-President, in the Chair.

The Rev. H H WINDWOOD thanked the Chairman for allowing him to introduce the water-colour drawings by his friend, Miss Breton, of some of the grandest canons in North America. The geological accuracy of the drawings might be attributed to the fact that Miss Breton was the daughter of an old Fellow of the Geological Society.

The following communication was read:—

1. 'The Crystalline Limestones of Ceylon.' By Ananda K. Coomaraswamy, Esq., B. Sc., F L S, F G S.

The crystalline rocks of Ceylon may be divided into three series:—

- (1) The Older Gneisses.
- (2) The Crystalline Limestones.
- (3) The Granulites (Charnockite Series)—pyroxene-granulite, leptynite, etc. A local subdivision of this

series is the Point de Galle Group—wollastonite-schapolitegneisses, etc.

The crystalline limestones of Ceylon are intimately associated with the banded pyroxene and acid granulites (Charnockite Series). They form bands with outcrops from a few feet to over a quarter of a mile in width, interbedded with the granulites: The limestones themselves have a banded structure (foliation) parallel to that of the granulites and to the boundaries. This foliation of the limestone depends on variations in structure, amount of accessory mineral, and relative proportion of calcite and dolomite. The grain is coarse, sometimes exceedingly so. Parallel and graphic intergrowths of calcite and dolomite are very characteristic. The most abundant accessory minerals are olivine, phlogopite, pink or violet spinel, diopside, pyrite, and blue apatite; less common are amphiboles, clinohumite, green spinel, etc. The most characteristic contact-minerals are diopside, amphibole, green spinel, and greenish micas; and, rather in the granulite than the limestone, scapolite, phlogopite, diopside, sphene. There occur also in the limestones, nodular mineral aggregates composed of characteristic minerals such as diopside, phlogopite, blue apatite, and spinel.

There are often transitions between the limestones and granulites. In some other cases a zone of green rocks (with diopside, dark mica, amphibole, and green spinel) intervenes. Bands (sills) of granulite of various width, down to less than a foot, may occur in the limestone, and are parallel to the foliation and general strike. They show peripheral transitions to the limestone by incoming of original calcite and the appearance of lime-silicates, or are separated from it by a zone a few inches wide, in which the minerals diopside, amphibole, and green spinel are characteristic.

Some interrupted sills are described, and compared with the interrupted dykes of nepheline-syenite in the crystalline limestones of Alnö, described by Professor Högbon. A sill may thus be continued along the strike as a series of lentilles. Elsewhere quite isolated masses of pyroxene-granulite occur as inclusions in the limestone.

Although the relation of the granulites to the limestones is on the whole intrusive, the two rocks in their present condition are essentially contemporaneous, and seem alike to have consolidated from a molten magma. The calcite occurring in the granulites near the contact has all the appearance of an original mineral. The foliation of the limestones is regarded as a sort of flow-structure, and corresponds with that of the granulites to which it is always parallel. That the foliation does not result from the action of earth movements on a solid rock is shown by this, that the very minerals whose variable distribution is one of its chief causes, have certainly not been affected by deforming earth-movements, nor are they such as to have been produced by these; moreover, in this respect a distinction cannot be made between the limestones and granulites, which would necessarily have suffered alike had they been subjected to deforming strains since the consolidation of the latter. The original nature of the limestones is less evident; they may have been sedimentary or tufaceous, and, if so, subsequently softened and metamorphosed; or possibly *ab initio* truly igneous rocks, and related to the charnockite-magma. Reasons for and against these views are given. The relations between the crystalline limestones and nepheline-

syenites of Alnö have suggested to Prof. Högbom that perhaps the limestone may have been a product of the nepheline-syenite magma there.

The author feels sure that the crystalline limestones of Ceylon have not arisen by the alteration of the basic lime-silicates of the pyroxene-granulites, although Prof. Judd has advanced this theory in connection with the crystalline limestones of Burma, which seem to resemble those of Ceylon in many ways.

DISCUSSION.

Mr. PARKINSON, after expressing his sense of the value of the paper and the care and elaboration with which the details had been worked out, described the contact of granulite and limestone which he had seen near Matala, and remarked that he believed that this section proved, firstly, that the granulite was intrusive, and, secondly, that the intrusion had been attended by absorption of the limestone, which had locally modified greatly the composition of the granulitic magma. As to the original nature of the limestones, he could say nothing; the interrupted sills and isolated masses of the granulite which had been described were very puzzling facts, and he inclined to the opinion that the author's contention that 'the two rocks in their present condition are essentially contemporaneous' was the hypothesis most nearly in accord with the facts.

Mr. HOLLAND thought that the author's self-imposed task of attacking the crystalline problems of Ceylon deserved the highest commendation of the Society, and the additional facts now published formed a great advance on previous work in that area. But he considered that the evidence offered was utterly insufficient to establish the Author's contention that the crystalline limestones had behaved as igneous rocks, and formed part of the magma which gave rise to the associated Charnockite Series. He (the speaker) had described primary and original calcite in a nepheline-syenite from Southern India, as Adams had done for Ontario and Högbom for Alnö; and though he was convinced that calcite might be dissolved without decomposition, and subsequently separated from a nepheline-syenite magma in which there was no free silica and an excess of electropositive alkali, it would be impossible for a limestone and charnockite to come into igneous contact without a chemical reaction which would result in the alteration of both rocks. The phenomena described by the Author were precisely those which would be expected theoretically from the intrusion of a charnockite into a pre-existing limestone. The limestones had been as a whole raised to a high temperature, and (as he had previously suggested from other evidence) had been brought to a condition probably akin to fusion, in which condition there would be a sufficient freedom of molecular movement to account for all their structural peculiarities—the inter-growths of calcite and dolomite, the flow-structures, and the occurrence of large phenocrysts of accessory minerals, which did not indicate an igneous condition any more than the large chistolites of chistolite-slates. The absence of cataclastic structures did not indicate freedom from deformation after solidification, as Adams and Nicholson had proved that marble, under differential pressure and at a temperature no higher than 400° C., could be made to flow like glacial ice without the production of cataclastic structures. The plasticity of the limestone at temperatures well

below the fusing-point of any rock was sufficient to account for the steam-like disposition of the inclusions, as well as the dislocation of the charnockite-sills without internal deformation. In India are seen corresponding contact-phenomena where the charnockites invade aluminous rocks (the khondalites of Walker) and siliceous rocks (quartzites of various kinds), and these, like the limestones, have their nearest chemical equivalents among known sediments. In places these paragneisses and paragneisses predominate over the orthogneisses; while in the south, where denudation has proceeded to greater relative depths, they are subordinated in quantity, and in Ceylon the limestones now exposed are apparently mere inclusions in the Charnockite Series.

Prof. JUDD expressed his gratitude to the Author for bringing forward a description of a district so interesting to geologists. The rocks described were similar to those of Burma, except in the remarkable absence of certain minerals, such as corundum and its derivatives. He found great difficulty, as the author did, in realizing that the charnockites could be intrusive in the limestones. In Burma and Ceylon alike, whatever might be the case in Southern India, the limestones were remarkably subordinate to the silicate rocks, instead of the reverse being the case (as we should expect, if the latter were intrusive in the former). He agreed with the previous speaker as to the difficulty of imagining the limestones to have behaved as igneous rocks, and yet their relations with the igneous rocks were puzzling in the extreme. He referred to the occurrences of Glenelg and Tirez as affording fine illustrations of the part played in such a complex by calciphyres.

Mr. GREENLY remarked that in the Hebridian Gneisses of the North-west of Scotland there was also a great preponderance of igneous over what appeared to be sedimentary material. The Loch Maree Group was now generally regarded as sedimentary, but it was a comparatively narrow zone, while from Loch Maree to Cape Wrath all appeared to be igneous. Limestones were a conspicuous feature of the Loch Maree Group, but they were accompanied by graphite-schists, mica-schists, and other probably sedimentary rocks.

The author, in reply to Mr Holland, said that no doubt in most cases crystallines were a result of the recrystallization of calcareous rocks under pressure; behaviour as a plastic medium did not involve a very high temperature, as had been proved by the work of Adams and Nicholson. But the limestones of Ceylon possessed a number of peculiar characters which, taken together, suggested to him that they had existed in 'a state akin to fusion.' With regard to the interrupted sills, if this phenomenon was due to 'pinching' while both rocks were in a solid state (as Mr Holland had suggested), why did the narrow lime-silicate contact-zones completely surround the lenticles, instead of occurring only on two sides of the granulite, as in the sill itself? Moreover, the accessory minerals in the limestones would show some trace of deformation if such powerful earth-movements had affected their matrix.

In reply to Mr Greenly, the author said that rocks composed mainly of biotite and garnet, which he regarded as of sedimentary origin, were scarce; no rocks with kyanite, andalusite, or sillimanite were known *in situ*. Even if such exist, and are the remains of sedimentary rocks, the igneous rock must greatly exceed

them in amount. No granitic schists had been found. Finally, the author said that he had no wish to lay great stress on his 'igneous' theory, and he regarded the descriptive portion of his papers as of much more importance than the theoretical.

IN THE NORTH :
TRAFFIC FOR THE RAILWAY ;
COTTON—SUGAR—TOBACCO.

The rumoured poor traffic returns from the Jaffna railway section have brought "prophets of evil" once more to the front and one of them has been saying that the man who believes in our great Northern Railway being profitable, may be compared to the sailor who, hearing that parrots lived for a hundred years, bought one in order to test the truth of the statement! For ourselves we shall be much disappointed if at least the Jaffna section of the Railway does not prove profitable, in the face of the dense population of the Peninsula. But, of course, there has hitherto been no experience of how a purely Tamil community—"the Scotchmen of the East"—may care to spend money on railway travelling. In the case of the Sinhalese it has been demonstrated that the villagers almost too freely patronise the comfortable third-class carriages, making this branch the most profitable of passenger traffic. It is, however, too soon to judge of the Jaffna Tamils.

But in any case, the opening of the first section of the Northern railway should direct more attention to the exploiting and utilising of the North-Central country, at least along the railway route. No one expects that trains will run "full up" when the whole line is open to traffic—not even the warmest advocates of the extension without reference to route or gauge; and Sir West Ridgeway will prove himself a far-seeing administrator as well as a vigorous and earnest advocate, if he begins to encourage cultivation by exceptional inducements, if he wishes to see the line become a financial success within the time of his successor. And cotton is one of the products to which both climate and soil over a great part of the route, point as one likely to be successful. Let the Revenue Officers along the line be instructed to start experimental stations, under the guidance of the Director of the Botanical Gardens, and let the best seed available be procured; and that promptly!

This is neither the first, nor the second, time we have counselled the importance of taking time by the forelock, if the Northern Railway is not to prove a burden on the revenue for an inconveniently long period. We should be only too glad if the event convict us of pessimism in expecting an initial loss. There are few, we imagine, who expect the line to do more than pay working expenses for a time;

but even assuming that the Railway may prove financially satisfactory from the start, there would be no harm in the adoption of measures calculated to develop traffic and to promote the prosperity of the country. Admittedly, the population of the interior parts is both scanty and poor, and admittedly the climatic conditions are not such as to attract Europeans; but European capital is essential for operations which would contribute appreciable traffic to the new line. It is in the power of the Government—if not alone, at any rate more quickly and more certainly than private individuals,—to demonstrate the suitability of the country for remunerative cultivation, in order to attract capital. We have before now drawn attention to the probability that part of the country will be found suitable for Sugar, in the opinion of an expert of our acquaintance with large Eastern experience. More recently still we introduced to public notice Mr. MacDougal Gibson who is very hopeful of a great future for the country through Tobacco. And now we desire to emphasise the absolute need of early and thorough experiments with Cotton. At the recent annual general meeting of the Upper India Chamber of Commerce, some facts were brought to light which should receive earnest attention here, and lead to profitable imitation. It was stated that the experimental cultivation of American Cotton at the Cawnpore Agricultural Farm proved that Cotton can be acclimatized in a few years by a system of cultivation which can be adopted by any intelligent ryot, and that the results are a yield five times in weight of that obtained from the local product, and of a fibre suitable for spinning up to 60s instead of 20s. If, as the President stated at that meeting, "a mine of wealth lies literally at the feet of the cultivator" in India, why should it not be so here, too? Let our local Department of Agriculture answer.

—♦—

CEYLON INVESTMENTS.

TEA SHARES AT THE LOWEST POINT YET TOUCHED.

Out of twenty-seven Companies, in the shares of which there have been dealings during the quarter, only six have secured a more favourable price, whilst in the remaining twenty one cases the fall has, in some cases, been serious. It must be remembered, however, that this, the first quarter of the year, with Rupee as with Sterling Companies, is the period for dividend paying and the large drop of Rs 552,720 is partly to be explained by some of the sales having been made after the payment of the dividend; but it is, in any case, decidedly disappointing that the continued favourable state of the tea market has had so little effect upon the quotations. Since last return we have included Rs 5,000 added capital, issued by the Pitakande Company, and Rs 25,000 by the Ratwatte Company. Commercially have, largely by the increase in the quotation for Galle Face shares, recovered from the set-back they experienced last quarter, although "Steams" and "Tees" are still on the down-grade. Hotel shares,

with the exception of the Galle Face, the Kandy, and a small rise in the Nuwara Eliya Hotels have not had a favourable quarter, and indeed, it may be said of the whole state of the share market that the prices for the quarter show that investors are "sitting very tight" indeed. The list of Commercial undertakings has received three additional companies, viz., those of the Kaluganga Navigation Company, the Ceylon Ice and Cold Storage, and the Colombo Brick and Tile Company. We may mention that the share list of the last-named Company was subscribed immediately, an unusually successful flotation, which has no parallel during the past two or three years.

The tables are as follows:—

RUPEE PRODUCE COMPANIES.

RISE AND FALL IN THE FIRST QUARTER 1902.

	Ordinary Capital R	Market Value of Shares.		Rise. or Fall R

—Local "Times,"]

THE BRITISH SOLOMON ISLANDS.

The report of the Resident Commissioner of the British Solomon Islands for the past official year gives the white population of the archipelago on March 31 last as 76, of whom 50 were British. Forty-eight were engaged in trading, prospecting, and pearl-shell diving, 13 were members of the French Mission, and most of the remainder were in Government service or were women and children. For the third year in succession no death was due to attack by natives. The revenue has steadily increased from £957 in 1897-98 to £1,913 last year. Trade also has increased. The exports last year amounted to £28,260

COPRA IS THE CHIEF STAPLE,

and it is likely to go on increasing as the plantations now forming by the whites come into bearing; pearl-shell, ivory nuts, turtle shell, and beche-de-mer are the other exports. The area under cultivation by white owners is increasing annually, and the planting industry is likely to develop rapidly, and should the Commonwealth stop recruiting altogether the supply of labour would be utilised for local requirements. The immediate result of the Queensland labour trade would be a loss of revenue to the islands from the licences granted to labour ships, but this would be met eventually by increased local revenue. There is now regular steam communication with Sydney, but the Commissioner complains that it is not direct, and argues that the growth of the Solomon Islands justifies a direct steamer, and makes the archipelago worth the attention of the Sydney merchants, for the export trade now is larger than that of the New Hebrides or of New Guinea (excluding gold). All the

COPRA IS NOW CONVERTED INTO SOAP AND OIL CAKE

in Sydney itself, and that port must long continue to be the base of the Pacific island trade. The settlement of outstanding land claims also is a matter demanding attention in the interests of progress in the islands,

Before the declaration of the British Protectorate transactions, alleged to have been purchases of land, took place between whites and the natives. In some cases these were reasonable in their nature, and the purchasers have subsequently by occupation acquired what are presumed to be indefeasible titles. In others, however, the claims of the alleged purchasers have been extravagant. Square miles were obtained at a small fraction of a penny per acre, without any inquiry into the title of the vendor, who was frequently the first native met on the beach, and there has been no occupation. Until all the claims have been dealt with, once for all, the agricultural progress of the islands will be retarded.—*London Times*, March 15.

GEM MINING IN CALIFORNIA.

The recent deposit of a specimen of California jade in the park Museum directs attention to California as a field for gem mining, observes the *San Francisco Chronicle*. "Excepting a tourmaline mine in San Diego county, and a turquoise mine near the southern Nevada border, we believe no systematic effort at mining for gems has ever been made here. The pebble beach near Pasadero has yielded at times some valuable stones, but whether they came from the neighbouring formation, or were cast up by the waves from the bottom of the sea, has not been ascertained. Opals have been found on the beach in the neighbourhood of San Diego, and diamonds of good quality have occasionally been picked up in the sluices of some of the placer mines in the northern counties.

"The turquoise and tourmaline deposits are specially valuable. Handsome gems are made from both. The latter is found in the form of variegated crystals, and gems have been produced from them which were splendid imitations of diamonds of the purest water, pigeon-red rubies sapphires, emeralds and pink and yellow topazs. Montana contains large deposits of sapphires of splendid quality, but no deposit of any consequence of that gem has been found in California. It is offset, perhaps, by the turquoise deposits, especially as this stone is now popular. But the California deposit is so large that the market could easily be broken by an excessive output, so the production is regulated to suit the wants of lapidaries and jewellers.

"In Calaveras county there is a mine which is worked expressly for the quartz crystals it contains. These are not exactly gems, but the crystals are so large that enormous ornamental globes of exceptional value are obtainable from them, and these are in high demand. Japan had formerly a monopoly of this business. But the largest quartz crystal ever found is said to have come from this California mine. Another variety of quartz used for gem-making found in this state is chrysoptase, which takes a beautiful polish. Its color is usually a pale apple-green. Some attention is at present being given to the development of this material in this state for gem-making purposes. It is allied to nickel and usually associated with it, and it is believed to be present in the nickel deposits found near Riddles, in southern Oregon. Valuable deposits of it have been found in California recently. But the most valuable of all recent discoveries of precious stone deposits in California is said to be that of the jade, which was lately added to the Park Museum collection. Its quality is of the finest character, and the deposit is said to be large enough to be quarried in blocks big enough for monumental purpose.—*Bradstreets*.

PEARL FISHERIES IN BENGAL.

HANDSOME RETURNS.

Calcutta, April 9.—Some valuable pearls, some of which are being sold for R100 and R600 each, have been obtained at the fisheries on the Ichamati River, where pearl fishing is carried on. The yearly return has been so good that the fishermen have stopped selling fish.—*Madras Mail*, April 10

THE "NEEM" OR "MARGOSA" TREE.

Melia Azadirachta.

A planting correspondent writes:—

"What is neem? Can any of our readers enlighten us as to the identity of the neem leaf, and tell us whether there is any plant allied to the neem indigenous to the Island or cultivated here? An Indian paper has this:—'With regard to the efficacy of neem leaves as a disinfectant, it is interesting to learn that Baroda, which is situated between Borach on one side and Wasad and Nadiad on the other, and where hundreds of people go daily from places infected with plague, is free from the epidemic. In this connexion it is pointed out that until recently there was a special agency employed in Baroda for daily burning, for about an hour, fresh neem leaves for ten days in those houses in which deaths had occurred, no matter from what cause, and also in the neighbouring houses.'"

Our correspondent will no doubt recognise the tree by its other name "Margosa" (Telkohumba of the Sinhalese and Veppamram of the Tamils, we believe). We have a specimen in our garden at Turvet Road, which got so hacked, through native neighbours begging pieces of the bark or branches and leaves (as medicine) that we had to forbid access to it for a time. The tree is common in the Northern forests where Mr. Dyke found it to be indigenous. Balfour's "Cyclopædia" tells us:—

"In appearance the wood is much like mahogany, and is used by the natives for general purposes. Its bark is bitter, is considered a valuable tonic, and has been tried by European physicians with a success nearly equivalent to what might have been expected from cinchona bark. Oil is obtained from the seeds by either expression or boiling, and is much used medicinally. The fruit is not unlike a small French olive in size and appearance. The oil is of a deep yellow colour, has a strong smell and an unpleasant bitter taste; is much esteemed by native doctors as a warm medicine, as an external application in foul ulcers, and as a liniment in rheumatic and spasmodic affections, etc. It is frequently burnt in lamps, and is sold in the bazaar under the name of bitter oil, also black oil. Dr Maxwell found this oil equally efficacious to cod-liver oil in cases of consumption and scrofula. He began with half-ounce doses, morning and evening, which were gradually reduced. Margosa, as well as illipoo oil, mixed with an equal quantity of cold-drawn castor-oil, produces a hard vegetable wax of an agreeable roseate colour. The leaves of the genera *Melia* and *Azadirachta*, dried and kept in books, are much used by the people of India to preserve furs, feathers, books, papers, and clothes that are lodged in trunks, book cases, etc., from the attacks of insects. It is useful to place along with them small packets of camphor, or little cups of camphor dissolved in alcohol."

Dr. Geo. Watt has much to say of the tree, but we need quote only one passage:—

"The *nim* tree is generally supposed by its presence to materially improve the health of a neighbourhood. Believed to be a prophylactic against malarial fever, and even against cholera, it is frequently planted near buildings and villages. Even Europeans believe in this property to some considerable extent, especially in the North-West Provinces and Oudh, and villages surrounded with *nim* trees are frequently cited as proverbially free from fever, when neighbouring villages suffer severely. It is extremely doubtful, however, whether this tree exercises a beneficial effect to a greater extent than any other."

THE SWEET CASSAVA.

According to a communication from the President of the Chamber of Agriculture at Pondicherry, published in the *Journal d'Agriculture Tropicale*, the cultivation of Cassava is an important industry in the whole of Southern India. It is a very remunerative one, with very little risk attaching to it. The variety cultivated in French India is the sweet Cassava, which adapts itself to all varieties of soil, but prefers a sandy, slightly clayish soil to a heavy one. Generally speaking, the cultivation is carried on in land that can be irrigated, and, indeed, it is only in such cases that cultivation can be advantageously carried on at all. The Cassava plant takes ten months to arrive at maturity, and during a period of drought from five to six processes of irrigation every month are necessary. The system of drying the roots to preserve them is not adopted in Pondicherry. Cassava, cultivated under good conditions with good manure, gives from three to four pounds of roots per plant, and is sold at the rate of 60 rupees per candy of 240 kilogs (528 lb.) on the field. The President of the Chamber of Agriculture thinks that, if a factory for the manufacture of "fecula" were installed in Pondicherry, the production would increase so as to supply several millions of tons per annum, as from 2,500 to 3,000 plants can be planted in a hectare (2.47 acres).—*Friend of India*.

PLANTING NOTES.

PHOSPHATES IN TEA SOIL.—Mr. John Hughes bears out, in his letter published elsewhere, the view taken by Mr. Mann and generally established, of the necessity for the presence of phosphates in tea soil, the best tea being richest in phosphoric acid. We have already quoted largely from Mr. Mann's most useful booklet, the tea soils of Assam.

Mexico.—There is a paper in the *Forum*, by Professor Reinsch, entitled "A New Era in Mexico." The article deals with the agricultural and commercial resources of the country, and its value as a field for capital. Mr. Reinsch expects that the next decade will witness great progress in Mexico's industrial life, and thinks that the political and legal conditions of the country give fair security for investors. Most of Mexico's commerce is in the hands of foreigners—Germans, French, and Spanish, while the largest banks are managed by British capitalists. The development of the tropical agricultural belt is one of the great opportunities of the country, land being cheap, and coffee, sugar, and rubber being easily grown. The labour question is the great difficulty, as the natives are shiftless and unintelligent. At present Chinese coolies have to be imported. Mexico, however, is not a land for the investor with small means, as expensive machinery is needed to prepare most of her products for the market.

THE ANNAMALAI PLANTERS—have been favoured with a visit from Lord Amptill, the present Governor, at an early stage of his administration. The bulk of their address to His Excellency, together with the essential portion of the Governor's reply, appear in our daily and T.A.

"CRYSTALLINE LIMESTONES OF CEYLON."—The abstract of what is evidently an able geological paper on the above subject by Mr. A. K. Coomara Swamy, B.Sc., F.L.S., F.G.S., will be found on page 759. It was read before the London Geological Society on March 12th, the veteran Sir Archibald Geikie, F.R.S., being in the chair, while an interesting discussion followed in which Mr. Parkinson (also recently in Ceylon on a geological visit), Mr. Holland, Prof. Judd and Mr. Greenly took part. It is curious and interesting to find comparisons made between our limestones and those near Loch Maree and at other parts of the North-west coast of Scotland.

WATTLE BARK.—South Australian wattle bark has always held a high place in the market for tanning materials. Until prices became greatly reduced some ten years ago, large quantities were stripped and exported. For a long period the industry in South Australia has been depressed, but of late better values have induced greater activity, giving employment to numbers of strippers, and a welcome contribution to the farmers' income and to our staple exports. Plantations have been formed successfully, and more steam grinding mills have been erected, employing many hands. The quantity of bark stripped was 8,330 tons compared with 8,033 tons in the previous year, and 3,131 tons in 1892-3. The quantity exported in 1900 was 8,388 tons, value £63,732; in 1899, 8,953 tons, value £69,955, against 8,206 tons value £62,132, in the previous year. During the decade 1891-1900, shipments amounted to 60,166 tons (the value being £478,433), of which 21,586 tons (valued at £191,237) were exported during the first, and 38,580 tons (value £287,196) during the second five years of the period.—*B. Trade Journal*.

GAME PROTECTION SOCIETY OF CEYLON.—Our columns are largely filled with the annual meeting of this Society at Nowara Eliya last month and it will be seen that the Society is very much alive, although some complaint is made on the score of insufficient monetary support. Mr. Farr's report is a record one and will provide interesting reading to many sportsmen desirous of putting themselves *au fait* with current sport in Ceylon. We are inclined to support the appeal to sportsmen to do their duty by the Society and avoid the lapse of the protection of game entirely into the hands of Government. The announcement is made that a new sanctuary is to be formed in the Puttalam district; news which should be welcome to all huntsmen. One district which needs attention is that of Trincomalee where our military friends do most of their shooting, but unfortunately do not too well consider the claims of the Game Protection Society. It was natural that the shooting of the rogue elephant at the Kraal should not go unnoticed and the secretary, in general terms, condemns the episode; though "inexperienced sportsmen," a somewhat strong term, perhaps, is used to include the gentlemen who undertook the shooting. These are the main points in the report, but it will be seen that a good deal of discussion followed for which we direct our readers elsewhere.

PROSPECT OF PEARL FISHERIES.

It is reassuring to learn that Capt. Donnan with his great experience has found no reason during his recent visit, to alter his expectation of a series of three or four successful Pearl oyster fisheries beginning, say in 1905. Of course, it is impossible to make sure until the oysters are older—indeed until the very season of the fishery—but it is very much in accordance with the past history of our Fisheries that there should now be a successful resumption after so many blank years.

This is, of course, entirely apart from what may come of Professor Herdman's Inquiry and experiments. One proposal arising out of the latter is the transplanting of young oysters from a fully occupied, or even overcrowded Bank, to another Bank not far off where the ground is quite clear. But the difficulties in the way of successful transplanting and culture in this way are we believe, considered by Sir Wm. Twynam and Capt. Donnan to be very great indeed! Still, there can be no harm in a trial, native divers and their boats being utilised. As by 1905, the Colombo Harbor and Dock works should be all completed and with a Port Trust in full sway, the Master Attendant or Port Officer will be one of the busiest officials in the place—not likely to be spared to go after the superintendence of a Pearl Fishery, however important. It may, therefore, be a question to be considered when the day approaches as to whether Capt. Donnan should not be induced to re-visit the East and give two months' special service to the first Pearl Oyster Fishery since 1891?

THE EXPERIMENTAL FARM AND GARDEN AT GANGAROOVA.

We are pleased to learn that this latest experiment on the part of the Government is now fully entered upon. The purchase was effected (through the good offices of Mr. T. H. Huxley) to the satisfaction of all concerned:—the Horsford family, Mr. E. Jeffries (who is shortly leaving the island) and Government. Mr. Herbert Wright, as Assistant to Mr. Willis, has entered on the charge of Gangarooova; and we are glad to learn that this hard-working officer has made a specially good impression on all planters with whom he has come into contact, for his practical good sense, as well as scientific knowledge and personal energy. We trust Gangarooova Experimental Station will prove a great success.

RICE LANDS AS INVESTMENT,

[What do Ceylon experts say to this?—Ed. T.A.]

The splendid crops of the past few years have drawn a considerable amount of attention to the value of rice lands in Texas and Louisiana. Many years ago rice was cultivated on the great prairie stretching between St. Mary and the Texas line; but as it was treated entirely by Oriental methods, the returns were so poor that the crop was considered hardly worthy of attention. In years of drought, especially, the cultivation was

liable to total loss, and after a few dry seasons the area under rice fell to almost insignificant proportions.

Some fifteen years ago farmers from the North-West began to pay more serious attention to rice, and more scientific and modern methods were adopted. Irrigation was properly undertaken and proper plant and machinery erected. The experimental stage has now long been passed, and today there is something like \$20,000,000 invested in the cultivation of 400,000 acres.

Careful comparative tests have proved that a grower can raise a larger yield in Louisiana and Texas than in any other part of the world, even China and Japan, noted as these countries are for rice-growing. It is an actual fact that where the Japanese grower can cultivate half an acre at a cost of from \$10 to \$18 per year, the planter in South-Western Louisiana or Texas can raise a crop of 80 acres at a cost of from \$180 to \$216 per year; consequently, he can raise 160 times the product of a Japanese grower, even though he pays from eighteen to twenty times the amount for labour.

The cost per acre of the various operations connected with the raising of the cereal in Texas has been carefully estimated as follows:—

	Per acre.		Per acre.
Ploughing sod ..	\$2 00	Brought forward	\$8 25
Discing twice ..	1 00	Water ..	6 00
Harrowing twice...	1 00	Cutting ..	2 00
Seeding ..	0 50	Shocking ..	0 50
Constructing levees	0 50	Sacks ..	1 00
Seed ..	3 30	Threshing ..	1 00
Tendering levees	0 25	Hauling to warehouse.	0 50

Carried forward ... \$8.25 \$19.25

An average rice crop produces 10 sacks per acre. A sack contains from 160 lb. to 210 lb., averaging about 180 lb. or about 11 barrels to the acre.

Average market price per barrel .. \$3.25

Eleven barrels, at \$3.25 .. \$35.75

Less cost of production .. \$19.25

Net income per acre .. \$16.50

Assuming the cost of land (improved) at \$30 to \$35 per acre, interest on the investment works out at 50 per cent. The crop is a very certain one, the cereal being easier to raise than oats or wheat. It should also be remembered that the rice itself is but one product of the crop. Taking an average barrel of Texas rice, it is found that it will produce 40 lb. of the highest grade, 25 lb. of head rice (the second quality,) 25 lb. of screenings, and 10 lb. of grain suitable for brewers' use. Every portion of it is available, even the chaff, which is burned as fuel in the mill.—*H and C Mail*, March 28.

BRAZIL AND ITS AGRICULTURAL CRISIS.

The Rev Joseph Orton writes to us from the province of Rio de Janeiro on the subject of British trade in Brazil. We give the following extracts from his letter:—"It is true that at the present time the country is in the throes of the most serious agricultural and commercial crisis it has ever known, due to the fall of prices in the coffee, sugar, and india-rubber markets; but this is a temporary state of things, and the country will soon resume its true nature as an earthly paradise. With this preliminary I will point out three methods by which British trade can benefit itself,

and at the same time be a help to the country :—1. Iron bridge-building.—There is an immense field over nearly the whole of the country for bridges, strong, well-built, safely set, and cheap. A good firm in this line, turning out quickly well-made and cheap work, having its central office in Rio, and houses in the capitals of the different States, would be able to make a good trade. Tropical floods are very disastrous for the wooden bridges commonly in use, and numerous accidents happen through the planks getting rotten. The financial consideration in wooden bridges is that they are cheap. 2. Mineral mining.—At present English mining companies in Brazil confine themselves almost exclusively to that of gold. The country, especially the States of Minas Geraes and Bahia, is, however, so rich in nearly all kinds of minerals, untouched, that there is here a vast field for capital, which, well managed, would bring in good returns. 3. Timber forest exploring.—The three States of Para, Amazonas, and Matto Grosso have thousands of miles of virgin forest timber, for which a market is urgently needed. . . . Since agriculture, sooner or later, will make inroads, and therefore these forests have to come to an end, the best thing to be done is to start companies that could put these timbers on the English market. . . . The three timber-covered States just mentioned have particular advantages for the timber trade, since deep rivers form a complete network all over them, thus obviating heavy road expenses. The lower reaches of the river sides could only be worked six months of the year, owing to floods; but the higher reaches could be worked the whole year.”—*London Times*, March 24.

MINERALS AND OIL IN PERSIA.

On Persian soil there are many undeveloped treasures. There are numerous large petroleum fields in the country, not one of which is worked to any extent, much less in a systematic way. The petroleum fields in the provinces of Nazanderan, Gilon, Chamsee, Kermaun Lauriston, and Arabistan are hardly touched, and render no profits worth mentioning. In those mountainous regions naphtha is also said to exist in considerable quantities. According to Consul-General Hughes experts on this subject believe that the two cities, Sohab and Schuster, would serve best as central stations from which to work the fields. Sohab can easily be connected with the Dijalah River by means of a navigable canal, by a narrow gange railway or by pipe lines, so that the oil could be conveyed *via* the Dijalah and Tigris rivers to Mohammere without heavy freights. From there it would have to be transported by special vessels to India, Egypt, China, and Europe. The natural transportation route from Schuschter is along the course of the River Karun. The environs of Schuschter are particularly rich in petroleum and naphtha. At present nearly all the petroleum consumed in Asia and Africa (particularly in Japan, China, India, and Egypt), is furnished by the wells of Baku and Pennsylvania. Persian Petroleum with less cost for freight could, it is said, doubtless compete successfully in neighbouring countries. The rich Persian coal veins are not properly appreciated. They cover wide regions, and are worked in a very primitive way. There can be no doubt that, if vertical and horizontal shafts were driven into the veins, and the water pumped out, quantities of good coal could be brought to

the surface. The Persians dig unsupported shafts not more than 20 or 30 feet deep, and abandon them as soon as water makes the work difficult, re-opening the vein at another spot. Only the surface coal is utilised. Copper, argentiferous lead, iron ore, arsenic, sulphur, cobalt, antimony, borax, tin and other minerals are also found in large quantities in the Persian mountain districts. All these resources must remain undeveloped so long as Persia possesses no transportation facilities. Even the well-known turquoise pits of Persia, the most important of which are those of Nishapur, in the Province of Khorassan, yield so far very little good material, owing to the fact that they are owned by natives who cannot work them by the modern system.—*Journal of the Society of Arts*, February 7.

THE PAPER MULBERRY IN JAPAN.

The Government of India have made sporadic efforts to cultivate the Paper Mulberry (*Broussonetia papyrifera*) tree in this country without much success, as far as we were aware, from an economic point of view, though the tree has been found to grow well enough in several parts of this country. It may interest our Government officials to know to what varied uses the Japanese put the bark of this plant. We quote below an extract from an informing lecture delivered by Dr. H. Kempe before the Society of Dyers and Colorists, Bradford, last November, and which appears in the *Journal* of that Society for January, 1902. Dr. Kempe said:—

“Permit me to say a few words about Japanese paper in general and about the making of these paper stencils in particular. This wonderful paper with its admirable strength is made of the bast of the Paper Mulberry tree (*Morus papyrifera*), originally a Chinese plant, which is now cultivated all over China and Japan. A mulberry plantation resembles very much a grove of our willow trees, the mulberry having a very short thick stem with many branches. In November, when all the important products, such as tea, rice, beans, etc., have been harvested, the Japanese farmer finds time to cut the branches of the mulberry tree. The first operation is to boil these branches in a weak wood-ash bath in order to loosen the outer layer of bark. After the latter is removed, the bast is peeled off and thoroughly washed by suspending it in the river. The bast is then dried and sold to the papermaker. In our paper mills the pulp is prepared by grinding almost any fibrous material in the beating machine until sufficiently fine, whereby it cannot be avoided that the fibres are cut short. The Japanese, on the contrary, are very particular about treating the mulberry bast in such a way that the fibres retain as much as possible their original length, and this, of course, is the reason for the excellent strength of their paper. The bast is placed on a flat and level granite stone, moistened with water and beaten with wooden hammers until thoroughly fine. The paper is, of course, made by hand, and by shaking the sieve only in one direction, which is almost the rule in Japan, the fibres place themselves nearly parallel. This accounts for the fact that the Japanese paper can only be torn straight in one direction, at the same time possessing a remarkable strength in this direction.

“In China and Japan paper is a far more important and far more generally used article than with us, owing to its superior quality and strength. The Japanese always has a supply of paper sheets in his sleeve pocket. If he has to wipe his nose he does so with a sheet of paper. If he wants a bit of string he twists a strip of paper together. I have had an opportunity in the railway carriage of seeing a Japanese do almost the impossible with a bit of paper string, such as tying up his trunk with the remains of a letter. In Japan, paper not only takes the place of

our window glass, but even of our doors and walls. Considering that the climate in the provinces north of Tokio is colder in winter than in England, and that the Japanese have no stoves, only some burning charcoal in the *hibachi*, a kind of brasier, you will understand how little at home the European traveller feels under such circumstances. I had exactly twelve months ago, when I was in Nagaoka and Nigata, to suffer very much from these primitive arrangements.

"If the Japanese or Chinese paper is impregnated with Ye-no-abura, the oil from *Perilla ocymoides*, the Japanese substitute for boiled linseed oil, it becomes perfectly waterproof. It is used for making umbrellas and macintoshes. Perhaps it will interest you to know that during my stay in Japan I never had an umbrella or a macintosh. If it happened that I was caught by a sudden shower, and this happened very frequently indeed, I went into the nearest paper shop and bought a macintosh of oil paper for 2d (8 sen). The same with umbrellas. If the paper is oiled and varnished, then it takes the place of leather; the roofing of the jinrickshas, the little hand carriages, is often made of paper, even the Japanese "tab" for rainy weather, the equivalent for our water boots, are made of paper.

"As the paper for the stencils as used in cotton and muslin printing must stand a good deal of handling, moisture, and chemicals, it is treated specially for this purpose. A very long fibrous paper, made of unbleached mulberry-bast, is impregnated with "shiba," which is an astringent milky extract of the Kaki fruit, *Diospyros kaki*. This extract has the properties of varnish, it dries in the air, stiffens the paper, and makes it very resistant to water.

"The cutting of these stencils is a special industry. It is mostly done by hand; at the most, the stencil cutter prints the outlines on the paper before cutting it."

Dr Kempt called the Paper Mulberry tree *Morus papyrifera*. Its present name is *Broussonetia papyrifera*. It is closely allied to the ordinary Mulberry, and belongs to the Natural Order *Moraceae*. It grows wild in China and Japan and also in many of the islands of the Pacific Ocean, where the natives manufacture a large part of their clothing from its bark. It forms a small tree, attaining about twenty or thirty feet high, with a trunk seldom more than a foot in diameter, and generally branching at a short distance from the ground. The young branches are covered with short soft hairs. The Japanese cultivate this plant very much in the same way that we grow osiers, and they use only the young shoots for the manufacture of paper; these are cut into conveniently sized pieces, and boiled until the bark separates readily from the wood, when it is peeled off and dried for future use. To convert this bark into paper, they proceed in the following manner:—The dried bark is first moistened by soaking for a few hours in water; all superfluous matter is then removed by scraping with a knife, after which the bark is boiled in a ley of wood ashes until its fibres are thoroughly separated, when it is reduced to a pulp by beating with wooden batons; this pulp is then mixed with mucilage and spread upon frames made of rushes. The paper thus made is of a whitey-brown colour, and very strong; it is in common use in Japan. Instead of paper, the natives of the South Sea Islands manufacture from this bark an exceedingly tough cloth, called *tapa* or *kapa* cloth, which they commonly use for clothing, either plain or printed, and dyed of various colors. This cloth is principally made by the women, who adopt the following method of manufacture:—The bark is first softened by being soaked in water for a considerable length of time; it is then placed upon a log of wood and beaten out with a baton until it is of the requisite degree of fineness. The baton is made of very hard wood, and has four flat sides, each of which is sharply ribbed. Two or four women usually work together, and as they keep time in beating, the noise they make is loud and musical. In some islands, however, another and

inferior method is adopted, the bark being placed upon a flat board and scraped with different kinds of sharp-edged shells while kept constantly wet. By employing mucilage obtained from the arrowroot, the natives join pieces of cloth together, and Admiral Sir Everard Howe states that the King of Tongataboo (one of the friendly Islands) had a piece made which was two miles long and 120 feet wide.—*Indian Gardening and Planting.*

EGYPT FIFTY YEARS HENCE.

This was the subject of the lecture which Mr Willecocks gave at the meeting of the Khedivial Geographical Society in the hall of the mixed Tribunals on Saturday afternoon.

The endeavour to pierce the veil which clouds the future is an unsatisfactory task however one may contemplate it. But few of those who listened to Mr Willecocks's glowing description of the Egypt of the future will be alive 50 years hence to bear witness to the value of his predictions, and none we may perhaps say present were so qualified as the lecturer to judge of the possibilities of the country. Mr Willecocks, besides being endowed by nature with a vivid imagination, has an almost unrivalled knowledge of Egypt, and especially of its capabilities under a perfected system of perennial irrigation. Mr Willecocks foresees an Egypt in which

IRRIGATION WORKS

will have been laid out with a most lavish hand. Dams and weirs at the Ripon Falls, where the Nile leaves the Victoria Nyanza Lake, at Fabougo south of Wadelai, at Senaar, at Abou Harez, at a point near Esna, at Kenah, at Sohag, and at the mouth of the Nile, come within the sanguine view of Mr Willecocks's imagination. Apart from these expensive works all the canals which are to provide flush irrigation to the Meroe and Senaar peninsulas, to a district of 150,000 feddans at Kom Ombos, to 400,000 feddans in the Fayoum, have to be constructed. Dykes will be made to provide an escape for excessive floods, and, most expensive of all perhaps, a Ministry of Agriculture with bureaux to deal with forecasting the weather, animal industry, chemistry, soils, forestry, experimental stations, foreign products, foreign markets, pisciculture, statistics. It is true that every new irrigation work pays for itself within a comparatively short number of years, but we cannot seriously consider that the country could possibly digest such an enormous programme within 50 years.

Mr Willecocks foresees the permission of the

TOBACCO CULTIVATION

and draws a striking picture of the fellah discouraging upon the qualities of his home-grown tobacco beneath the shade of his date palms and vines. Khartoum is to be one of the greatest cities of Africa, the centre of trade through which the products of the Meroe and Senaar peninsulas, the New Egypt, will pass by railway. The extensive marshes of the Bahr el Ghazal are to be drained and the White Nile confined within its banks and this large district will be cultivated with rice and the Indian water nut. The rivers will furnish water-power whereby electricity will be furnished to supply power for innumerable factories and for railway locomotion. Those factories, run by the power obtained from the Ripon Falls, will be employed in

GRINDING THE DRIED BANANA

fruit, which forms, according to Mr. Willcocks, a most nutritious diet. The Wady Ryan is to be used as a basin for the escape of an excessive flood and is to become a fashionable inland sea resort. The Nile-bed itself is to be looked after, and by the help of spurs, etc., the river will be navigable from Cairo to Assouan and in Mr. Willcocks's mind, will be covered with the pleasure boats of tourists who will flock to Egypt then as they do to Switzerland now.

—*Egyptian Gazette*, March 17.

PRODUCE AND PLANTING.

The handling and distributing of tea after it is produced, by those who know their business, is, as we have frequently pointed out, more profitable than growing it. The distributing firms play an important part in popularising tea both at home and abroad; and some of them have rendered good service to India and Ceylon in this respect. The wholesale tea trade has become a vastly important business of recent years, and has developed on broader lines since the rise of the Indian and Ceylon tea industries. Some of the old advertising firms of the days of China tea have either dropped out or restricted their operations, while other enterprising people of more recent times have launched out with vigour, and have reason to feel well satisfied with the result. A history of the tea trade to date, with the story of the rise of the large distributing concerns, whose expansion seems to know no limits, would be interesting reading. The Mazawattee Company, with their huge tea and cocoa business, afford a remarkable example of the fruits of judicious enterprise, and there are other firms the history of whose rise and progress borders on the romantic side of things commercial. The successes of the planter on the other hand, at any rate of recent years, do not seem to offer any striking examples of the reward which should attend merit. He suffers both from pin pricks and more poignant wounds, and finds it difficult to develop at all, because if he should do so he will be accused of over-production. He hopes for better days, but doubts if he will ever loom very large in the chronicles of those who write the history of millionaires and how they made their money, except at secondhand.—*Home and Colonial Mail*, March 28.

GREEN TEAS AND—GREEN TEAS.

We are disappointed with Mr. Drummond Deane. It is very natural, and only to be expected, that he should stand up for his own make of "green teas" and the more he tells us about his plans, his new invention and the appreciation felt for his samples or samples made according to his system the better pleased we are. But why in the world he should drag in the "American Commissioner" into a discussion over different makes of green tea, puzzles us in the extreme. We can see no more connection than between the proverbial "Goodwin Sands and Tenterden steeple." Indeed this diversion looks like a "red herring drawn across the scent." As if, conscious of a weak case notwithstanding all he had

written, Mr. Deane in conclusion, wished the planters of Ceylon to understand:—"I and the old school of green tea makers are working according to your official American advices, while the *Observer* is backing-up a new-fangled system which is calculated to discredit your representative in America,—therefore, on the personal question if on no other, I claim your support"! Now any such argument is a simple absurdity. In the first place—though we do not usually reveal secrets of the sanctum—the senior editor (who was the subject of such virulent attacks from the American Commissioner as showed the latter to be unfit for his semi-official position) has not hitherto written on the subject of "green teas" at all. (He has had a very busy three months chiefly with book work, for home as well as local publication.) This may possibly at once dissipate Mr. Drummond Deane's suspicions. But a little reflection should show any impartial reader how utterly far-fetched and ungrounded such suspicions are. Our coadjutor had his information at first hand from Mr. Galt; but he also had it corroborated by the recognised agents of the Planters' Association (the employers and patrons of the Commissioner) and if ever therefore an editor was justified in thinking he was writing for the benefit of the tea-planting industry as a whole, and in accordance with the views of the Commissioner, it must have been in the present case, although, sufficient allowance was not made for the need of continuing the estate manufacture at any rate until it was seen how the superior "greens" meet the requirements of the American trade and what prices they realize. It is a fact that Mr. Wm. Mackenzie advised that Ceylon planters should turn their attention to "green teas" almost from the first day he went to America, though his information was far from being as full on this point as it might have been. Now green teas to suit the people of the United States, we are bound to believe—until the contrary is proved to us—must be teas much more after Mr. Galt's, than Mr. Drummond Deane's, system if we are to accept the local report of experts who have seen and tasted both.

Let us, however, come to closer quarters with Mr. Drummond Deane. By what right, or on what authority, does he assume that the teas made under Mr. Galt's direction—and on the system which will be continued by his trained Chinamen at Ambewatte Mills—*are or need to be artificially colored?* He might just as well assume that teas made on Brunswick, or any other estate, are colored. We of the *Observer* have always dwelt on the supreme importance of Ceylon supplying "pure teas" and what said Messrs. Forbes and Walker in their Report on Mr. Galt's teas:—"the crowning point being their purity and freedom from scum or colouring matter" and the same Broking firm were very careful in their comparison with estate-made greens, thus:—"Green teas now being made in the various factories of Ceylon are generally speaking sound and good, particularly in cup;

but they are undoubtedly at a disadvantage as regards appearance of leaf when compared with China Greens." But says Mr. Drummond Deane, "this is merely the opinion of a Broker, not a Buyer." It is an expert's opinion and we have always thought that buyers paid special attention to such reports. At the same time it may console our correspondent and other critics—who have thought that in making known Mr. Galt's special success (basing our opinion on the expert Broker's report) we were giving an unnecessary advertisement to the new process,—that it is not at all the wish of its promoters to see the ordinary factory preparation of "green tea" cease. On the contrary, we believe, the owners of Ambewatte Mills are considerable purchasers of our ordinary "green teas," the bonus, however, in such cases falling to the estates from which they come. Nor will such teas be shut out from the American—and especially the Canadian market—so long as they can be supplied cheaply. They are most useful for various purposes we are told, chiefly for "mixing"; and in this connection we would ask the "Thirty Committee," if they can say, or can procure the information, as to how much, approximately, of the Ceylon "green tea" shipped last year, got into *direct consumption*? Our object is to get reliable information on all points connected with the subject; but by no means to discourage estates which have been making "Ceylon greens" from continuing their work so long as the bonus is available. The more "greens" of all kinds made, the less leaf there will be for black tea. At the same time there is undoubtedly one risk to be borne in mind, namely, that American buyers may get it into their heads in some cases, that the low-priced "Ceylon greens" which we are told they use chiefly for blending with higher-priced and therefore presumably better teas from China or Japan in order to reduce the price of the latter? are the best we can do in this island in respect of green tea. It is surely an advantage if Mr. Galt and Ambewatte Mills (according to the P. A. Brokers' report) are to show them how mistaken they would be in adopting this opinion?

At the same time, let us do justice to the local enterprise in "greens" so far as it has gone. In our editorial of the 7th instant, a mistake was certainly made when it was stated that "the progress made has been slow and small." Considering the circumstances, the figures work out very satisfactorily on the whole. In 1900, bonus was paid on 472,291 lb.; in 1901 on 1,589,929 lb.; and this year the prospect is of the latter figures being doubled,—indeed at the present moment, it is estimated that 400,030 lb. "greens" per month are being turned out from Estate factories. From the Ambewatte Mills as a present maximum, the outturn could not exceed 2,000,000 lb. a year, and it would make very little difference in the price obtained for this superior kind, if the manufacture of 3,000,000 lb. of ordinary "Ceylon Greens" were stopped, for, the true competition is with Japan and China "Greens." On the

other hand, Mr. Galt believes, if his Ceylon made green teastake as he expects in America—that the Japan trade in this article with the Western Continent will disappear in about six years. No doubt, Mr. Galt includes all the green tea from Ceylon as helping to this end; for, whether for blending or other purposes, there can be no doubt that the produce hitherto shipped has been affecting imports from Japan into Canada as shewn by our correspondent signing "A Friend of all Green Tea," whose letter adds a good deal to our information and offers some needful corrections on our previous remarks without any unworthy insinuation.

To sum up, it seems to us that the great importance of Mr. Galt's improved process is that by its means a green tea is turned out that can obtain a price in the United States sufficient, even with the extra cost, to make it independent of the local bonus; whereas the profit on most of the factory-made teas would seem at present, to be due to that bonus? Of course, so long as a bonus is available, all "green" tea made will be entitled to share in it. Be that as it may, we can see no reason—basing our opinion on the expert report of Messrs Forbes and Walker—to doubt the superiority of Mr Galt's system, and while wishing well to all 'Ceylon green teas' we should be especially proud of a product that is likely to hold its own with the very best make of Japan or China greens.

A FRENCH REVIEW OF THE CEYLON HANDBOOK AND DIRECTORY.

HIGH APPRECIATION OF THE AGRICULTURAL AND PLANTING REVIEW.

From the *Journal D'Agriculture Tropicale* we give a translation of part of a review of our "Handbook," etc., as follows:—

This big volume frightens one by its very richness; it is stuffed full. But once having expressed a reservation as to its overfulness, we do not hesitate to declare that this Ceylon annual is a work of prime value and that it should not be wanting in any Colonial Library.

Leaving aside the Directory and whatever concerns purely local interests, we would emphasize particularly the chapters entitled "Review of the Agricultural and Planting Industries of Ceylon." It occupies with the allied statistics more than 200 pages and deserves the highest praise for the critical spirit, the accuracy and the earnestness or seriousness which characterise the author's work. It is not all at once that one comes to establish such a monument of research and patience. The first review of this kind was published in 1877. Since then the work has been renewed in 1881, 1883, 1885, 1888, 1890, 1891, 1893, 1895, 1898 and finally in May 1901.

* J. Ferguson, Ceylon Handbook and Directory, 1901. In 8° 1780 pages, imprimées en très petits caractères. Chez FERGUSON à Colombo, et chez tous les agents du "Tropical Agriculturist,"

The author gives in succession the history and the statistics of all the great planting industries of the island; he also draws up a summary of all the efforts at introducing new products, attempted whether by private persons or public institutions. Each paragraph closes with a rapid glance at rival countries and their produce or output. One also finds numerous bibliographic indications and suggestions.

In most cases, the documents quoted or referred to, whether in the text or in a note, appeared first in the *Tropical Agriculturist* and Mr. Ferguson never fails to emphasise the fact with legitimate pride. Some of the paragraphs, which thus set forth the planting industries which have made the prosperity of Ceylon, are truly most remarkable; nothing of the kind could possibly be better done. We shall, perhaps, some day be able to give a more complete idea of the way in which Mr. Ferguson publishes in his journal a translation of articles concerning various cultivations of particular interest for the foreigner.

One must also take note of the commercial studies and World's Statistics of the different great agricultural products; this chapter forms a sort of complement to the preceding one; the list of the authorities consulted for the review, quoted on page 184j, gives some idea of the enormous labour involved in collecting all these figures.

The volume contains also, like its predecessor, a list of Ceylon patents (pages 369-372). This will be invaluable for inventors of all countries who have to do with machinery for tea or other tropical products as well as for anyone interested in tools used on plantations.

Between the Tariff of Batta or Allowances to Witnesses and Jurors and the legislation relating to coolies there is an excellent Report on Ceylon Woods and their adaptability for Tea Chests. Also, some hundreds of pages further on, comes a General List of Ceylon Woods, inserted just before a very useful little study on the Coconut Oil Trade from 1860 to 1901.

THE PLANTING INDUSTRY AND THE PEOPLE OF INDIA.

[The following appears in the London *Times* of March 29th.—ED. T.A.]

(To the Editor of the *Times*.)

Sir,—Will you allow me to mention one fact, overlooked by the recent tea-planting deputation to Sir M. Hicks-Beach, that is calculated to give the Government and people of the United Kingdom a greater interest in the planting industry of India and Ceylon than anything hitherto advanced? It is that every acre opened by British capitalists in tea, coffee cacao, &c., means the support, directly or indirectly, of not fewer than five native men, women, and children. Tea alone affords, therefore, a livelihood to between 4½ and 5 millions of the people in India and Ceylon (almost entirely India, because the latter drawn its estate coolies from Southern India). This should afford the best justification for the Viceroy and the Governor of Ceylon deprecating an increase in the tea duty, which would inevitably result in a great many acres being thrown out of cultivation. The Secretary of State

for India and his advisers should specially note this fact.—Truly yours,

J. FERGUSON, of the *Ceylon Observer*
and *Tropical Agriculturist*.

Colombo, March 6.

INDIARUBBER IN NATAL.

ITS CULTIVATION AND PRODUCTION.

BY ANTHONY WILKINSON IN THE "NATAL
AGRICULTURAL JOURNAL."

Some years ago I tried the experiment of planting an acre of "Manihot Glaziovii, or the Ceara rubber tree of South America. Mr. Medley Wood, curator of the Durban Botanic Gardens, was kind enough to furnish me with roots and cuttings of Ceara from trees he had growing in the Gardens, and wished me to try an experiment on a larger scale. I planted an acre of Manihot with coffee plants between. The rubber trees grew well and seeded abundantly, and at four years old, when the trees got to a good size, 4 to 5 inches in diameter, on scoring the bark to extract the rubber, although the rubber was of good quality and very elastic, the collecting or getting of it was slow and costly. Accordingly, I came to the conclusion that the experiment would not pay, unless the trees could be tapped and the juice collected in quantity, as is done in South America, and further that Natal was not sufficiently tropical to make good flow of sap. Coming to these conclusions I cut the trees down, but still the trees come up again from the seeds every year, and grow luxuriantly 5 or 6 feet high in the first year, showing the climate to be suitable for their growth. Among my coffee I have a self-sown Ceara only three years old, and over 20 feet high. The red sandy soil of the coast such as that of Berea, Durban, would be the most suitable. The seeds left to mature do not come up for a year or two. By some, filing is recommended, but this is a tedious process; tapping them with a small hammer until they crack serves as well, and is much quicker. The plan adopted to collect the rubber, with the Ceara rubber trees, is to strip off the thin outer bark, which is like brown paper, and expose the green bark. This inner bark is then scored across with a knife at an angle, and the milky juice or sap then exudes and dries on in an hour or two, and can be peeled off and wound up in balls, but the process is so slow with the coolie women employed at 6d per day that I found it would cost about 5s per pound for the labour of collecting, and the product would be worth only about 2s per pound. Now it strikes me very forcibly that, if a cheaper way of extracting the rubber were adopted, it would pay well. The rubber is there, of good quality, but the question is how to get it out. My idea is this: to plant the trees in rows, 12 or more feet apart, like large hedges, and at two or three years old, when large enough, in the spring or early summer, when the sap is rising, to slash off the small branches and leaves, and crush them in a small steam sugar-mill, and let the juice run into a tank of water. The residue of branches and leaves would then be put into a hydraulic press, with steam outside, and pressed as long as the sap would flow. The rubber juice would coagulate in the water, and rubber raked out and squeezed by hand into balls and dried. By this method the trees would be pollared and dwarfed, and could be cut and trimmed once or

twice a year, as found advisable. It would be necessary to keep the land well-ploughed and scarified between the rows, for all would depend on the cultivation received. The rows, if in hilly land, would require to be run on the level, so as to cultivate cheaply with horses or mules. There are several other plants which would give good rubber, if treated in this manner and well cultivated. The *Beaumontia*, a white-flowering creeper of the order "Apocynaceae," the Borneo rubber creeper, grows well here in Natal, and I have no doubt many native plants would be found to produce good rubber. If this plan of extracting rubber from the plants were found to answer, it would revolutionise the rubber trade in a few years, and rubber could be grown to any extent, like sugar. Moreover, the supply of rubber, owing to the destruction of the trees, is decreasing, whilst the demand for the article, which is now being applied to so many different purposes, is steadily increasing, and therefore there is no fear of the market being over-stocked. India-rubber being so valuable an article, worth £200 to £300 a ton, there is a large margin for profit. For an energetic young man wanting something to do and to try a new industry, I would recommend it, but remember the old American sage's saying: "Be sure you are right, then go ahead." I feel pretty sure there is money in it.

Mr. James Gregson, writing in the same journal with reference to a former and more enthusiastic article, says:—"In 1895 and 1896 I had Natal rubber offered me repeatedly at 1s 8d per lb., but I always thought it too dear at the price. I remember Para rubber going up to 4s 9d per lb. just before the Baring Bank failure; and at that time there was some splendid Madagascar rubber on the market, for which they were asking 3s. per lb., but it would not sell at the figure, although it is the cleanest and strongest rubber next to Para. I have bought flake rubber as low as 6d. per lb. I do not know any African rubber which does not lose from 25 to 30 per cent. in washing and masticating. I have known Mozambique rubber to lose 60 per cent. in washing and masticating, and all African rubbers lose from 25 to 60 per cent. I was never asked above 2s per lb. either in London or Liverpool for Corgo Ball, and it is one of the cleanest and strongest African rubbers known. Let him (the Professor) send a sample to Moseley's of Manchester, or MacLellan's of Glasgow, or W Warner of Tottenham, and they will give its proper market value. Rubber-growing ought to pay in Natal, if kept clean, and not too much sand is put in."—*The India Rubber Trades' Journal*, March 31.

THE MYCOLOGIST'S REPORT FOR 1901: DEVELOPING NEW ORANGES.

AMERICAN EXPERIMENTS.

A large crop of paper bags seems to be the yield of a little tree which stands in the grounds of the Department of Agriculture at Washington. There are about 50 of these bags, each with the neck tied firmly, as close inspection discloses about one of the terminal twigs. The effect, writes a contributor to the "New York Sun," is rather grotesque. The tree is the particular charge of Professor Herbert J Webber, who with his assistant is responsible for its bagging. It is a species of orange tree, the variety having been brought to the United States from China about ten years ago with the idea of using it for hedges. It is evergreen, grows about 30 feet high and has sharp

thorns. The fruit is small and runty, and quite unfit for food. But the fact that it flourishes as far north as Maryland, Kentucky, Indiana and Missouri, gives it a great value to scientists, who are experimenting with a view to securing a more hardy breed of orange.

And this is the explanation of the crop of paper bags. The blossoms of the tree have just been crossed with the St Michael and Signina oranges, which are the standard varieties of sweet Florida fruit. Professor Webber is trying to secure a hybrid which will retain the edible qualities of the sweet Florida orange and at the same time preserve the hardness of the Chinese mother tree. The paper bags are used to protect the flower which has been fertilised with the pollen of the sweet orange. The first step in the operation of cross-fertilisation is the removal of the pollen-bearing stamen from the blossom. This is done with small scissors and pincers. The petals are also removed, leaving the stigma exposed. This is all done before the blossoms are fully opened, for by that time there is danger that bees or other insects might have carried the pollen from some open blossoms and deposited it on the stigma. When the stamen has been completely removed pollen gathered from the blossoms of the trees in the Government green house are shaken lightly upon the prepared flower. Then the bag is tied tightly in place to make sure that no pollen from the same tree becomes mingled with that already used. After the fruit has had time to begin forming the bags are removed and the twig marked with a tag, giving the name of the other parent.—*Melbourne Leader*, April 5.

ELECTRIC-MOTOR TEA-WEIGHING MACHINE.

16 POUNDS A MINUTE.

A novel and intricate apparatus has been installed in the tea warehouse of T H Estabrooks, St. John, N. B. This is nothing less than an automatic weighing machine capable of weighing out 16 separate pounds of tea per minute. It is an ingenious contrivance. From a hopper in the floor above, the tea is conveyed to the machine by a funnel fitted with automatic jaws, which close the moment 1 lb. of tea is deposited on the pair of scales. In the meantime a bag is being pressed up beneath the pan, which revolves, and into this package the tea is dumped, while another pan takes the place of the first (there are two pans). The whole contrivance is run by a small electric motor, and it can be adjusted to any weight and regulated. It is said to be the first machine of its kind in Canada, and was made by Driver, London, England.—*Indian Planters' Gazette*, March 29.

MR. CARRUTHERS ON FUNGAL DISEASES.

It is an evidence of how the work of the Scientific Staff at Peradeniya is growing that the report of the Assistant Director this time, in place of following that of Mr. Willis in a sessional paper, is given publicly separately in one of the circulars issued by the Botanic Gardens. This circular we will, as usual, reproduce in full in our T. A. and need therefore only mention here that Mr. Carruthers supplies a very interesting, as well as adequate, report dealing with Environmental as well as Fungal Diseases, with "Leaf Diseases of Tea," with "Spore Distribution Experiments," gives hints as to "Tea Blight Investigation," "Gray

Blight on Young Shoots," "Root Disease of Tea," "Cacao Canker and other Diseases," "Grevillea Disease,"—for which a special circular is later on to be issued.—"Finger and Toe Disease of Cabbages, etc." "Fungus causing Rotting of Timber," "Fungus on Rubber," [this refers to fungus which grows upon samples of Para Rubber—it does not seem to be of much importance], "Other Diseases of Plants," "'Bluestone' as a Weed-killer," "Grass Seeds for Pastures and Lawns," "Cacao Cuttings," "Measurements of Cacao Pods," with illustrations, which Mr. Carruthers had previously furnished to our monthly; "Selection of Seed in Cacao Planting," "Pollination of Cacao," and "Tours and Planters' Association Meetings." These all show that Mr. Carruthers has a good many subjects under his observation and we may make sure now that no new trouble or what may appear to a planter to be a new disease, will be allowed to escape the notice of the Mycologist. In the matter of greatest importance, diseases affecting tea, Mr. Carruthers reports that tea has been throughout the year 1901 less affected by leaf disease than during 1900.

PLANTING NOTES.

A LUCKY ORCHID PURCHASE.—An orchid grower at Kenilworth has had a piece of good luck. Some time ago he bought for a few shillings from a dealer abroad an orchid in sheath. This turned out to be a rare specimen of the *Odontoglossum Crispum*. He gave it the name of "Mabel Whateley," and the plant gained the award of merit at the last show of the Royal Horticultural Society in London. He has just succeeded in disposing of his treasure for the sum of £220. —*Home paper*, March 11.

THE INDIAN TEA EXPANSION COMMITTEE.—We quote the chief details from this Committee's latest report, which shows that subscriptions and the sale of pice packets continue satisfactory. As compared with 64,327 packets issued in December last, 111,640 packets were issued in January and 135,038 in February. This is a notable increase. Similarly the number of one pie cups of tea sold almost doubled itself within the three months in question. The sale of the pice packets and the brewed tea, we notice, does not yet cover cost, so the working expenses of the Commission have been somewhat increased. The Commissioners, however, hope that these methods will prove a valuable means of fostering the habit of tea drinking amongst the people of India. An outside opinion of the Commission's work that is very encouraging recently appeared in the *British Medical Journal*. "When one comes to consider," says that journal, "the awful death-rate among the Indian poor from such diseases as cholera, bowel complaints, and malignant fevers, all of which owe their origin to the drinking of impure and unboiled water, one is struck with the life-saving prospect of a scheme such as that of popularising the drinking of tea, since tea-making entails water-boiling, and this kills all germs that produce disease."

MALARIAL FEVER.—An Indian contemporary writes:—It is satisfactory to see that the Italian Government and Italian men of science are energetically following up the question of the connexion between mosquito bites and the spread of malaria. They are now specially working at the question of what practical measures can be taken to destroy mosquitoes. It has been discovered that there is a particular aniline dye which, even when very dilute, will kill the larvæ of mosquitoes. There is also a powder made from the flowers of the *Pyrrhtrum Roseum* which is said to be very efficient against mosquitoes when burnt in a room or distributed through the air by means of bellows. Experiments in a slightly different direction have been conducted by Professor Grassi during the past summer, with a view to ascertaining what drugs are most efficient in destroying the malarial poison. He selected one of the most malarious places in Italy—Ostia, at the mouth of Tiber—and administered to a number of persons pills composed of quinine, arsenic, iron, and a further ingredient which is somewhat unscientifically described in the Consular Report as "bitter herbs." The results seem to have been satisfactory, and Dr. Grassi is preparing a full report on them, which will be published in English as well as Italian.

THE TEA INDUSTRY.—Speaking at the *Society of Arts* in a paper by Mr F H Skiine on "Bengal" some interesting remarks were made by Mr. T. Durant Beighton who said that the two subjects on which he wished specially to speak were tea and famine. No doubt the reader of the paper was accurate in saying that Mr W H Verner was the first person to introduce tea into Jalpaiguri, but in justice to himself he (Mr Beighton) wished to say that who when he joined that district of the Duars as Deputy-Commissioner in 1876 the number of tea gardens was only six or seven, but during his incumbency they increased to 50 or 60. The present condition of the industry was very serious. Over-production had glutted the markets of the world, particularly the British markets, and the planters had not the power of combination of which he should like to see them possessed. They should borrow a little of that aptitude from the other side of the Atlantic for the making of trusts. The tea planters of Ceylon and the tea planters of the Tea Association of Calcutta ought to combine and take some steps in the direction of effectively limiting the output especially of low grade teas and of getting rid of some of the evils which undoubtedly now affected the conduct of the business. He wished to enter his emphatic protest against any further burden being put upon tea. Of all the industries which had flourished since our rule had commenced, that of the tea plantations had been upon the whole of the greatest good to the over-weighted population of that country. No doubt, when the gardens were first opened up, there was a certain amount of deadly malaria, but after that he believed there was no healthier occupation or an occupation more conducive to long life and prosperity of the coolie, his wife and family, all of whom found remunerative employment, than employment in tea gardens and tea estates. There was the further great advantage that it removed the population from congested areas and permanently settled them where their labour was required for the development of the country.

THE GAME PROTECTION SOCIETY.

THE REPORT.

In submitting my report for the year 1901, it is expedient that I should notice briefly the work done by the Society during the year. Mr North C Davidson's last annual report, embodying all ordinances, enactments, and proclamations relating to the protection of game in Ceylon, was circulated amongst members of the Society early in 1901, but it fails to record the proceedings of meetings held during the latter portion of the preceding year. Two general and three sub-Committee meetings were held and at these, certain schemes for the better protection of game were discussed and eventually a definite scheme was elaborated and laid before Government. It dealt with that very difficult question, the native trade in deer horns, and recommended that a strict censorship be placed by Government upon this traffic through the officers of the Public Works, the Forest and the Survey Departments, as well as through the Presidents of Gansabhawas, suggesting that all these be armed with the powers of Itinerating Police Magistrates. Government replied on August 14th, 1900, that the suggestions laid before them by the Ceylon Game Protection Society were incapable of being put into practice, at the same time undertaking to carry out a proposal to register and license professional game trackers.

The Society also expressed its approval of the Draft Firearms Ordinance as published in the Government Gazette No. 5649 of 29th September, 1899. The Sub-Committee drafted during the year an appeal to visiting sportsmen, inviting donations to the C. G. P. Society. This was duly circulated through the Government Agents of the various provinces but appears to have been but feebly responded to, and the revenue of the Society from this source may be quoted as too insignificant to be worthy of notice. At a general meeting in June, 1900, the introduction of Indian antelope (Black Buck) was proposed and duly considered, and at a general meeting in July a sum of R1,000 was voted for this purpose.

The Hon. Secretary (Mr Davidson) forthwith put himself into communication with His Excellency the then Governor of Madras who most kindly and liberally offered to the C. G. P. S, a number of antelope from Guindy Park. Numerous suggestions were made as to the best localities to stock with these animals and the hearty co-operation and support of our Government Agents in the North and South was promised. Everything in fact was in train for establishing them in the island, but unfortunately they had to be caught. From correspondence submitted to me this difficulty appeared so great and so likely, in conjunction with the transport of these fragile animals over sea, to be attended with loss and considerable cruelty that upon my assumption of office as Hon. Secretary of this Society I suspended negotiations with Madras. The acclimatisation of game is a costly undertaking, if the efforts made are likely to be crowned with success; and in my opinion the Society is not sufficiently wealthy to expend such a large sum of money in the face of such doubtful results. Previous experimental efforts to introduce feathered games have failed completely, and before any more are undertaken our list of members as well as our annual subscriptions should be doubled. Before closing the *resume* of the year's work, I must allude briefly to a rule that was framed by the Society and put into operation by Government in 1900-1901. This rule prohibits all shooting of deer and sambar in the Hill Reserves above an elevation of 4,000 ft., except by special permission of His Excellency the Governor. The concession was asked for by the Society with the object of protecting sambar in those portions of the Hill reserves where elk-hunting could be indulged in. The subject was freely discussed and it was competent for any member of the Society to oppose the rule or to propose a modification of it. Unfortunately the Province of Uva does not appear to

have been represented at the meetings, or if it was the voice of protest was not raised and the rule passed into practical law. I say "unfortunately" for it has given rise to bitterness on the part of certain Uva members who had been in the habit of shooting red deer and who complain that they are debarred by this rule from a sport they had hitherto enjoyed on their patnas, at elevations exceeding 4,000 feet. The resignation of the Honorary Secretaryship by Mr. N. C Davidson occurred during the year and in January, 1901, I was elected to fill the post. The year 1901 was not remarkable for any great change or improvement in the constitution or scope of the Society. Three general meetings were held in Nuwara Eliya and the Sub-committee had under consideration two important papers from Government, dealing (1) with the Yala Sanctuary and (2) with a proposal to enforce old Forest Laws. The recommendations by the Sub-committee with regard to both these have been approved by the Government. I. In Mr. Horsburgh's report on Sanctuary that gentleman made certain suggestions in paragraphs 24, 25 and 28. These were approved of by the Committee and subsequently adopted by Government. II The application of sub-sections D of section 26 of Ordinance 10 of 1885 was recommended by the Assistant Government Agent of Nuwara Eliya to Reserved Forests and it will probably be put into effect.

SUBSCRIPTIONS AND MEMBERS.—It is a great pleasure to me to be able to report that many subscriptions, which had remained unpaid during the two or three preceding years, were paid up during 1901. A few resignations, hitherto unrecorded, were received from members who had ceased to subscribe for some years and a few members were lost by their leaving the island. It is a matter for regret that the new members who have joined during the year fail to make up the deficiency in numbers due to the causes above-mentioned. It is also regrettable that more pecuniary support is not forthcoming and, if in future years it is found that some of the old sporting centres are played out and barren of game, the younger generation of sportsmen will have only themselves to blame for their apathy of today. Moreover, should the C. G. P. S. lapse and allow its duties and responsibilities to be absorbed by Government, there will be no reasonable ground for surprise if it be found that Government, having paid for the protection of game, shows a disinclination to grant practically unrestricted sporting rights such as we enjoy today. To maintain our position and to ensure a hearing for our suggestions, the Game Protection Society of Ceylon should be a stronger and a more representative body than it is at present. We should not lose sight of the fact that its scope is exceedingly limited and restricted by the laws of the land, and that the power the Society possesses is measured by the length of its purse or in other words by its balance at the bank. To enable us to wield this power effectively, we must devote most of our resources to the payment of game watchers. Under this heading progress is being made and much good is being done in the hills. The destruction of sambar by coolies and by poaching gangs generally has almost ceased. Two watchers, paid by Government at the rate of R15 each per month, are subsidised to the extent of R5 each out of the Society's funds. Two forest peons are also in receipt of the same sum monthly from the same source. In the low country the Yala Sanctuary is watched by night watchers employed by Government and in the proposed new Sanctuary in the Puttalam District four men are to be employed.

The Society pays R30 per month for two watchers in the Meda and Kadawatte Korales under the supervision of the Madawelletenne Ratamahataya. During the year under review a sum of R20 per month was applied for by the Haputale Branch Society and in my opinion this should be disbursed from the Society's funds. I would further suggest that four-fifths of the Uva subscriptions be added to this amount, so that an efficient system of protection

may be established over a wide area of country, extending, if possible, south to Tanamalvila and across to the northern limit of the Yala Sanctuary. This would provide at least a measure of protection to almost the whole of the Uva Province. With a careful selection of watchers and some supervision from the Honorary Secretary of the Haputale branch there is no reason why the Game Centres of Uva should not receive a large measure of protection by these means. The subject of Branch Societies was again brought up at a general meeting held on May 8th 1901 and the distribution of game watchers was discussed. It was eventually resolved that the latter should be postponed until Branch Societies had been formed.

On the 17th October, 1901, the Hon. Secretary of Haputale Branch introduced a resolution against the rule prohibiting all shooting of game over 4,000 feet.

This resolution was eventually withdrawn in favor of an amendment to the effect that it should be permissible to stalk sambar with the rifle where registered packs are limited and at any elevation. It was also resolved at the same time that red deer be removed from the list of protected game. A copy of the above resolution was forwarded to Government by the Hon. Secretary with the expression of a hope that they would be favourably considered. The Hon. the Colonial Secretary replied as follows:—

Colonial Secretary's Office,
Colombo, November 20th, 1901.

Sir,—With reference to your letter of the 30th October, 1901, regarding the shooting of sambar and deer in the Hill Districts above 4,000 feet, I am directed by His Excellency the Governor to explain to you that the "rule" referred to by you is enforced solely by an instruction to the Government Agents to refrain from issuing licenses to shoot game in any district above the elevation referred to.

2. It would be impossible to grant a license in respect of any special class of "game."—I am, sir your obedient servant.

(Signed), A. G. CLAYTON, for Col. Secy.

The Honorary Sec., The Game Protection Society.
BRANCH SOCIETIES.

I regret being unable to report any addition to the number of these during the past year but I do not abandon all hope on this point. Mr. P. R. Shand, the energetic Honorary Secretary of the Nawatapitiya Branch, sends me the names of 16 members who have paid their subscriptions for 1902 and writes hopefully of future support;—

"On information received from our local watcher on 31st October last I wrote to the Government Agent, Kandy, that an elk had been killed at Padupola for a former Aratchchi of that place.

"The Ratamahatmaya of the district was instructed to prosecute and the man was fined R25, which seems little enough as he killed the elk in the close season. The Branch Association or Society started here has brought in a lot of new members. There were 17 on my old list and there are now over 40 on the new one.

P. R. SHAND."

Not having received any financial report for 1901, I am unable to give any information as to what work has been done. In Haputale I cannot help feeling that there is a slightly reviving interest being shewn in the matter of game protection, and it is to be hoped that the Branch Society there will be able to show a good record of work done this time next year. There is ample scope for hearty and undivided efforts.

Since writing the above, I have received from Mr P R Shand a list of members for 1901 and a statement of expenditure for that year.

Mr SHAND proposes handing over to the Parent Society 25 per cent of his total subscriptions and retaining the balance (after providing for last

year's expenses) as a nucleus for further needs and requirements. This arrangement, I think would work quite satisfactorily, provided the estimate of requirements were sent in to the Parent Society in time for the annual meeting in March or April.

It would I think, be only right and proper that the Committee of the Parent Society should pass the estimate and sanction the expenditure.

SANCTUARIES.—During 1901 the Yala Game Sanctuary was visited officially by Mr Hosburgh the Assistant Government-Agent at Hambantota and his very able and exhaustive report was doubtless read by all members of the Society. There are certain paragraphs in that report—viz.: 24, 25, 28—which were suggested by Mr. Hosburgh and which were subsequently approved of by His Excellency the Governor. The two former recommended that houses be provided for the three newly-appointed watchers and the clearing of one of the boundaries. The latter suggested that the country adjacent to Kirindi, Tissa and Palutupane be closed to all non-resident sportsmen. This is a concession that might well form a precedent in the case of other tracts of game country in the island. Through the courtesy of the Hon. Mr Fowler I have recently learned that an efficient water supply has been provided for within the sanctuary and a proper system of patrolling has been established. Game is reported as very plentiful, tame and in good condition. I am also indebted to Mr. H. R. Spence, the Assistant Conservator of Forests, North-Western-Province, for the following information with regard to the proposed new Sanctuary in the Puttalam District of the North-Western-Province. It will consist of all the country lying north of the Kaluoya, some 112,000 acres in extent. It will probably be placed under the charge of the Assistant Conservator of Forests and four watchers who will be paid by Government. All the reports I have received from the Yala Sanctuary clearly set forth the benefits derivable from these protected areas and the Society should now approach Government with a view to obtaining sanction to form sanctuaries of its own. Complaints have reached me from Trincomalee from time to time of a vast amount of poaching and game slaughter in that and adjoining districts both in and out of season, but unfortunately, in spite of the quantity of game killed by the officers of His Majesty's services in that neighbourhood, the C G P Society receives no pecuniary support from that quarter.

DONATIONS.

I am glad to be able to report the receipt of two handsome donations to the Society during the past 12 months: one of £10 from that well-known sportsman and member of this Society, Mr H A Oliver-son; and one of R100 from Sir Edward Kinahan, who has recently been on a shooting trip to the island. Three others of small amounts have been received from Messrs. Jowitt, F R Findlay and H Storey. These donations are encouraging to an Hon. Secretary, and I cannot too heartily express the thanks of the Society for them, nor can I too emphatically commend them to the notice of others. Before closing this paper, I feel it to be my duty as Hon. Secretary to enter a protest on behalf of the Society against the practice of allowing inexperienced sportsmen to destroy elephants that may prove themselves troublesome within the seckade of a Kraal, and the recent instance at Kurunegala em-

phasies the necessity for this in a marked degree. It was not an edifying spectacle for crowds of natives to witness, nor a credit to those engaged in it.

PRODUCE AND PLANTING.

Mr. J. Ferguson of the *Ceylon Observer* writes:—Certainly it is well to rub in the labour view of the question, and the figures given are very much to the point, but presumably Sir M. Hicks-Beach and the majority of thinking people at home are aware that natives are employed in large numbers on Indian and Ceylon tea gardens, and that these will suffer if the industry be restricted. The Secretary of State for India and his advisers can hardly be ignorant of the fact either, although the figures given by Mr. Ferguson may come as a surprise to them. [Our contemporary forgets that the London *Times* editorially asked by what right the Viceroy of India and others interfered in the financial arrangements of the United Kingdom. We think our figures give the best reason and justification.—ED. C. O.]

The annual general meetings of the following tea companies have been held in Colombo and dividends declared: Castlereagh Tea Company of Ceylon, Limited, final dividend of 3 per cent., making 8 per cent. for the year; Drayton (Ceylon) Estates Company, Limited, 5 per cent., making 8 per cent. for the year; Uvakellie Tea Company of Ceylon, Limited, 7 per cent.; Palmerston Tea Company of Ceylon, Limited, 2½ per cent., making 5 per cent. for the year; Yatereria Tea Company of Ceylon, Limited, 20 per cent. Discussing the

INDIAN TEA CROP

for 1901-02, and commenting upon the estimates of the Indian Tea Association, the "Grocer" says: "To form some approximate idea of what was about the quantity of Indian Tea grown in 1901, we must take into account the amounts that were probably raised in the 'private' and other gardens, which, we venture to say, were of too great importance to be entirely ignored. These, it is not unreasonable to assume, could hardly have fallen below 10,000,000 lb of tea, equal to nearly as much as was gathered of the last season's combined crops in the Darjeeling and Terai districts. This quantity, added to that returned for all other centres of tea cultivation in India, would bring the grand total crop for 1901-02 up to 175,263,453 lb, as against 188,937,257 lb (including every kind and place of growth) for 1900-01. Here is plainly shown a difference or deficiency of over 13,703,000 lb in the crop now coming to a finish. Treated another way, by reckoning the yields in regions where precise returns are easily obtainable, the decrease is almost as great, viz., fully 12,413,000 lb. Such an abridgment in the general supply of tea from one particular source in a single season could not fail, as we have seen, to exercise a very favourable influence on the market for importers, raising prices for the common sorts by 21 per lb from the lowest point in their favour. A well-known Mining Lane authority observes that 'the producer has it largely in his power to make or mar.' It is certain, at any rate, that, if growers are again placed in the position they occupied in 1900-01, when they had to force a quantity out of all proportion to consuming possibilities down the throat of the trade they will again feel the inevitable result of transgressing the laws of supply and demand. The heavy extensions carried out about the

middle of last decade are only just coming into full maturity, and under normal weather the approaching crop may easily be got out of hand. Speaking generally, no disturbing feature mar the outlook, if only the market is not over-fed. The use of tea is becoming more and more common throughout the civilised world, and some compensation may here be found for the low prices which have accompanied excessive supplies, and no doubt aided the opening of new markets. The grower has, however, sown freely to his cost; let him now pay attention to the reaping. To judge from Ceylon figures the determination to limit quantity is being well sustained. India should in the coming season see that she also follows a like policy."—*H. & C. Mail*, April 4.

PEPPER IN WYNAAD.

Wynaad, April 15th.—Considerable uneasiness has been felt, during the past year, at the blights which have worked a certain amount of damage amongst the vines in parts of the district, and hitherto no specific prophylactic seems to have been discovered. On the other hand liberal cultivation including the application of plenty of farmyard compost, has been followed by most satisfactory results on the vines raised through fields of Arabica coffee, and on one estate the yield this season where such conditions obtain has been phenomenal, and is estimated at considerably over 12 cwt. of the dried spice per acre. When it is borne in mind that 5 cwt. per acre is deemed a good pepper crop, the above return will appear to be the more striking. On the garden referred to little, if any, disease has shown itself, though the property has been under coffee and pepper for somewhere about 30 and 20 years.—*Madras Mail*.

RHEA FIBRE SYNDICATE.

A Company is being formed under the name of the Bengal Rhea Syndicate Company for the purpose of supplying machinery and aiding the planter in the cultivation of rhea. This beautiful fibre, unlike the aloe, which is grown only for ropage, can be used for a variety of purposes, from the manufacture of a silk pocket handkerchief to a hawser, and as it has been conclusively proved that it can be successfully grown in this district, rhea should have a future before it in Behar. The Syndicate's object is to facilitate the cultivation and manufacture of rhea and, although they are fully engaged for some time to come, applications have been received to extend their terms to a number of other concerns, should the Syndicate decide to increase its capital.—*Indian Planters' Gazette*, April 26.

A POSSIBLE RUBBER YIELDING PLANT.—The Governor of Zanzibar has sent seeds of *Tabernaemontana usambarensis* to the Agri-Horticultural Society of Madras, with a note that the fruit attains the size of an ordinary melon and exudes a juice very much like rubber. Mr. Cavanagh notes that the whole plant appears to contain a great amount of white milky fluid which flows from the slightest bruise on the bark, or from a cracked leaf. About sixty per cent of the seeds have germinated, and are looking strong and healthy.—*Indian Gardening and Planting*, April 17.

ROYAL BOTANIC GARDENS. REPORT FOR 1901.

We are enabled, through the courtesy of the Acting Government Printer, to give the greater part of the Report of the Director and of his Assistants as a *Supplement*, and we need here only call attention to a few salient points. It is satisfactory to learn that last year, so depressing in respect of the price of our staple, was free from any serious epidemic of plant diseases. The success of "camphor" as a minor product,—we hear of distilling being successfully carried on by private parties, notably on a Kotmale estate,—and the discovery that we have indigenous gutta-percha trees, which yield a gutta in fair quantity by simple tapping, which, though not of good quality, may prove commercially valuable, are two very interesting facts. Indiarubber being now an established planting industry within the certain limited area adapted to its cultivation, the export of appreciable quantities, much valued in the London market, has begun and may be expected to increase very steadily. There is also much to encourage the extension of Cinchona planting—which, by the way, must be in districts too high for Rubber—and there is room probably with judicious selection of the land, to add to the area under Cacao; while most certainly more should be done in Pepper. Mr. Carruthers' Report has already been the subject of notice. From the Mycologist's Report, we are glad to see that there is some hope of successfully introducing Sericulture—so frequently the subject of spasmodic experiments in Ceylon—and of getting the Sinhalese to take it up in certain rural districts. And why not also Apiculture?—we would ask Mr. Green, this being another industry well within his province. He will know that we have two honey-making bees peculiar to Ceylon; but we are unaware of any local attempt to domesticate them, though an American Apiculturist (now Professor in the Agricultural Department at Washington) took away colonies of these bees to try in Cyprus and Michigan, with what result we have never definitely heard. Mr. Green's Report shows that he has had a thoroughly busy and useful year. In the opinion of many planters Mr. Herbert Wright, "the Scientific Assistant" is "the coming man," and on the Experimental Station at Gangaroowa, he ought to have abundant scope for useful work that may have important results. His investigations into gutta-yielding trees are likely to add a new export ere long. His Report as Acting Curator also shows much useful work. Mr. Nock has, as usual, a very interesting Report to furnish of the Hakgala Gardens and connected work: 2,000 camphor plants have been distributed and 4,000 more were being got ready to send out. An experiment in growing Mango trees (seeds got from trees growing at 4,200 feet above sea level in Madagascar) at this high elevation will be watched with interest. We are not told much of the subordinate Gardens at Henaratgoda, Anuradhapura and

Badulla—save that the latter is now a great ornament to the town and that Pimento has there fruited well and should be worth a trial as a minor product throughout Uva; while a new Australian fodder grass is also growing well.

THE COST OF PLANTING RUBBER.

Many inquiries are made as to the cost per acre of planting rubber trees, which work, to the uninitiated, doubtless seems a very simple matter. But it is evident, from the printed reports of some of the large plantation companies, that the mere setting out of the young seedlings must represent but a small part of the work necessary in forming a plantation on land just reclaimed from the native forest. Before there can be any planting, must come the establishment of a community of laborers—which does not, of course, exist in a forest-covered region. The work of clearing is no small matter, and this is followed by the planting, continued probably through several years, with simultaneous care of the trees already set out. It seems to be the part of economy to produce on the plantation, as far as possible, crops necessary for the subsistence of the men and animals employed, and not a few companies are engaged also in the cultivation of "side crops" for market, such as will yield an income while the rubber trees are reaching a productive age.

On one plantation in Mexico, a report of which has reached us, although the greater part of the projected rubber planting remains to be done, a village has grown up, with a population varying from 250 to 500, a municipality has been organized and a post office established. There is a company store, carrying a stock of goods valued at \$03,000 Mexican; a meat market, blacksmith's shop, laundry, saw mill, brick-making plant, and lime kiln; and also a school for the children on the plantation and a salaried plantation physician. There is even a police force—paid for, like everything else mentioned above, by the company. It is only by making an outlay for these various purposes that a supply of labor can be insured for the coming years of development which must precede the first yield of cultivated rubber from this plantation. There must be labor for constructing buildings, laying out roads, building numerous small bridges, and for planting the various quick-producing crops—all of which work is carried on while other laborers are clearing land, making rubber nurseries, and transplanting rubber seedlings and caring for them for the first few years. Moreover, some outlay is often necessary for creating means of transportation to the nearest railway or seaport.

Of course the plantation referred to is one of the larger enterprises of this class in Mexico; but even on the small private plantations the owner does not calculate to plant or live by rubber alone. There are, on the small as well as the large estates, many items of outlay beyond the mere setting out of rubber trees, so that the prospective planter who confines his estimates to this one feature alone is likely to be doomed to early disappointment. All of which would indicate that the question so often heard, as to the cost per acre of "planting rubber," is much easier asked than answered.—*India Rubber World*, March 1.

TWO DISEASES OF CACAO TREES.

The occurrence of the disease known as 'thrips' on the cacao trees of Guadeloupe has been reported upon by M. Ang. Eliot, who states that the insects causing the disease is widely distributed among the cacao plantations. The pest was the subject of an article in the *West Indian Bulletin*, Vol. 11. pp. 175-190, where its occurrence in Grenada, St. Vincent, St. Lucia and

Dominica was noted, with a description of its habits and distribution in Grenada. The damage to the cacao tree is sometimes insignificant, sometimes great, according to the climate, conditions, drought and neglect rendering the trees very liable to an attack. Experience shows that, while proper care of the trees will do much to avert the disease, ultimate reliance must be placed on spraying the trees with kerosene emulsion. The insect appears to be closely allied to the 'thrips' affecting cacao in Ceylon, both the Grenada and Ceylon larvae being characterised by a transverse crimson band.

Professor Giard, to whom an insect has been sent, has named it *Thysanus rubrocinctus*, though it has been hitherto regarded as belonging to the genus Heliothrips. The Geographical distribution, as known at present, is Grenada, St. Vincent, St. Lucia, Dominica, Guadeloupe and Ceylon. It is not improbable that the insect will be found to occur in the other parts of the West Indies and South America.

A short time ago, attention was drawn to another disease which attacks cacao trees in Surinam, producing bunches of malformed twigs called 'witch brooms.' In 1900, Professor Bos, of Amsterdam, discovered asci, or fruiting organs, of the *Exoascus* type, on the underside of two rudimentary leaves on the twigs of the 'witch brooms,' from which he concluded that the disease was due to a new fungus, related to those which produce 'witch brooms' in other trees and which he named *Exoascus thebromae*. Professor Went, of the University of Utrecht, has found that in cacao trees containing 'witch brooms' the pods are attacked by a fungus which causes a swelling at the side, and finally produces a worthless, hard and woody pod. He considers that the fungus causing this malformation, may be allied to that which produces the swelling, but since, up to the present, no spores have been observed, the identification of the fungus has been unsuccessful. The planters in Surinam find it advisable to cut out the 'witch brooms' as soon as they are observed. This method is sufficient to keep the disease from making much headway, but, if carried on to a large extent, will undoubtedly impair the productiveness of the trees.—*Imperial Institute Journal* for April.

PLANTING NOTES.

"GREVILLEAS" DOOMED?—What is this news we hear of grevillea trees on estates in Uva dying out from a fungus attacking the roots? Mr. Carruthers has been to see the evil when it was first observed and, we believe, approves of the trees being cut down and dug out. How about grevilleas in other districts—in Dinbula, for instance? We would strongly advise a careful inspection. There is always the danger of such disease spreading. Who can tell us if the "silky oak" (as it is called) is affected in this way in its native home of Queensland?

SALE OF DWARF TREES.—A number of Japanese dwarf trees, and a collection of miniature British and foreign woodland scenes, belonging to Mrs. Ernest Hart, were offered at auction on Thursday by Messrs. Knight, Frank and Rutley, Conduit-street. Several dwarf cedars sold at good prices. One, which was catalogued as 100 years old, with thick twisted trunk and well-balanced branches, fetched £20. A second, also 100 years old, and measuring 22in. in height, was sold for £14 14s. The demand for miniatures was less brisk; the prices obtained ranged from £6 6s to £3 3s. Several lots were purchased on behalf of Royalty.—*Daily Chronicle*.

RUBBER, COFFEE, &c. IN ABYSSINIA.—In the *Century Magazine* for April there is a paper by H. Le Roux which gives a striking picture of Menelik's country. As regards products, here is what is said:—

On the varied levels of the Abyssinian table-land everything may be cultivated in the way of luxurious products—rubber, coffee, cocoa, vanilla, spices, mulberry, etc. As a matter of fact, the combination of a tropical heat and an Alpine altitude, so to speak, produces in Abyssinia climatic conditions which are certainly unique. These different plateaux resemble nothing so much as a series of greenhouses placed one above the other—cold, temperate, and hot. No matter what the altitude, the temperature is remarkably fixed. I was able to live in Abyssinia for six months, under a tent, at an average of sixty-five hundred feet, without ever being inconvenienced by the cold. Wherever I went I met with vineyards and palm trees, growing readily even at an altitude of eight thousand feet. It is true, also, that these unusual conditions have made Abyssinia an inexhaustible coffee-granary. The fact is now established that this precious plant is not only abundant in Abyssinia, but that it is native to this plateau. It was from the Abyssinian province of Kaffa that coffee, hitherto unknown, was first carried into Arabia. This gave it its name. Even nowadays the inhabitants of Kaffa do not take the trouble to cultivate the coffee-plant; they are satisfied to gather coffee wild under the trees—coffee trees of a size so prodigious that the natives cut them down and out of the trunks make boards thick enough to build their houses. The quality of the aroma is so superior that the English decidedly prefer it to the true Arabian Mocha, or, to speak more literally, to all the Red Sea coffee which goes to Mocha and there receives a baptism of good origin. As things now stand all these products are raised by the Abyssinians only in proportion to their limited needs. They are spoiled by this land of unrivalled fertility, which, in certain places, gives as many as four harvests a year. They ask of it merely the cotton necessary to roll themselves in gay-colored coverings which, when they travel, protect them against the night chill. They sow just enough corn, wheat, durra, sorghum, and canary-seed to live on, and they leave the stretches of land that fire or continued occupation have devastated to grow wild as prairie-lands, which serve as pasture for quantities of goats and enormous sheep, whose wool becomes a long, shaggy coat, and especially for fine herds of cows and zebus with humps on their backs which are luscious eating.

The paper closes as follows:—

Emperor Menelik gave the definite pledge of his esteem for Western civilisation in renouncing with iron will the isolation wherein his predecessors had placed all their confidence. In 1892 he addressed to the President of the French Republic a letter drawing up in these terms of his plans of reform: "I wish to open up, to make safe for science, commerce and industry, the routes which lead from Shoa to the rich southern countries." In order to attain such civilised ends, the emperor has given his faithful friends, M. Iig and M. Chefnoux, a grant for all the railroads which, starting from the French harbor of Jibuti, on the Indian Ocean, at the entrance of the Red Sea, must in time unite the rich provinces of the west, the land of gold and coffee, with the shipping-dock where all the vessels of the world will touch. Already the first branch of this railroad, that which connects the harbor of Jibuti with the mountains of Harar, is almost finished; the deserts of Issa and Dankali have been traversed; and the greatest natural difficulties presented by the soil have been overcome.

Some allowance must be made for over-sanguine expectations; but, no doubt, the development of Abyssinia is bound to go ahead.

THE
AGRICULTURAL MAGAZINE,
COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for May:—

Vol. XIII.]

MAY, 1902.

[No. 10.

TWO USEFUL VEGETABLES.

HERE are being introduced into our villages through the School Gardens, two useful and wholesome vegetables which, though common enough in India, are not grown in Ceylon; and as little is

known about them, we append the following notes regarding their uses for the benefit of our readers:—

1. *Rumex Vesicarius*.—Sorrel, Bladder Dock (*Polygonaceæ*). This is an annual monœcious herbaceous plant, 6 to 12 inches high, with succulent leaves and leaf-stalks, inclined to branch moderately, with a characteristic acid sour taste, and a flavour of rhubarb about it.

Watt gives the following note regarding the medicinal properties of the plant:—

"The juice of the plant is considered by natives to be cooling and aperient, and, to a certain extent, diuretic (*Ainslie*). It is used to allay the pains of toothache, and from its astringent properties it is supposed to check nausea. The whole herb is given internally to allay burning at the pit of the stomach and to improve the appetite. Externally a pulp formed of its bruised leaves is applied to the skin to allay the pains of bites of reptiles and the stings of scorpions. The seeds are said to have similar properties, and are besides prescribed roasted in dysentery. The root also is medicinal (*Dymcock*)."

The plant is cultivated as a vegetable almost throughout India, and is used by the natives

both in the raw and cooked state. It is usually grown in patches near wells, and may be procured almost all the year round.

We are inclined to think that the plant will prove of great value to the natives both owing to its manner of growth and its uses. Watt gives the word *Sûri* as its Sinhalese name, but we can find no reference to the plant in any local works on Botany, nor can we give any explanation of the origin of the word *Sûri*. One thing is certain, however, and that is that the plant is not found in use nor under cultivation in the Island.

For native preparations both leaves and stalks are well suited, a vegetable curry made of the latter being particularly tastety. The same parts may also be used to take the place of rhubarb in tarts, as the rhubarb flavour, previously referred to, predominates in the petioles. The leaves themselves go to make a really excellent jam.

The plant in its early stages adopts the rosette form of growth, as in the lettuce, though the leaves always have fairly long petioles—the leaves themselves being somewhat cordate in shape. Later on, as noted above, a system of branching follows, the branches being considerably thicker than the leafstalks and possessing more of the sour taste and rhubarb flavour. When the leaves are cut for use, the plant continues to put out a fresh growth, a characteristic that goes to enhance the value of the plant which may be described as a hardy grower.

Altogether we consider *Rumex vesicarius* a great acquisition, and trust that our village population will take to it without prejudice, and soon

come to recognize its dietic value and medicinal virtues. The plant has not flowered with us yet.

2. *Chenopodium album*.—The white goosefoot (*Chenopodiaceæ*).

The plant is found growing in the tropics at sea-level, as well as in Tibet at a height of 14,000 feet. As seen growing here it reaches a height of about 3 feet before producing its inconspicuous inflorescence.

In India the leaves and twigs are eaten as a pot-herb like spinach, but the plant is there chiefly cultivated for its grain, which is considered better than buckwheat. When cultivated during the rains it is said to attain a height of 6 feet, the seed ripening in India in October. Prof. Church says of the leaves of this plant: They are rich in mineral matters, particularly in potash salts. They likewise contain a considerable amount of albumenoids and of other compounds of nitrogen.

Watt refers thus to the medicinal virtues of this plant:—Said to be used in special diseases, and as a laxative in spleen and bilious disorders (*Atkinson*). It is also given in bile and worms (*Baden-Powell*). It is diobstruent and diuretic.

In the form of the favourite native dish called "mellun" it is very palatable, and would be very welcome in village households. We have no doubt it will be equally suitable for vegetable curry.

The plant is already being grown in School Gardens, and the produce formed one of the vegetables exhibited at the Danowita Village Show held on 22nd March.

OCCASIONAL NOTES.

A Board of Agriculture and Industries has been formed in British Guiana, with the object of facilitating the work of fostering Agricultural industries other than that of Sugar-cane, of extending agricultural instruction to small farmers and settlers on the land, of imparting agricultural instruction through the Primary Schools of the Colony, and generally of developing the agricultural resources of British Guiana.

The consignment of Banana plants referred to in our last issue duly arrived from Queensland, and have already been planted out. It includes two plants of each of the following varieties:—Ladies' fingers, Sugar, Butter, Dacca, Barrego, Cavendish, Moku, Delena.

Professor MacOwan, Government Botanist at the Cape, has been invested with the degree of Doctor of Science by the Cape University. Prof. MacOwan's work in South African botany his of a valuable character, and Prof. Harvey of Kew has borne testimony to this fact by stating that but for Prof. MacOwan's great work at the Cape the "Flora Capensis" would have been miserably incomplete. We offer our hearty congratulations to Dr. MacOwan.

We are glad to find the Agricultural Journal of Cape Colony reprinting the Handbook on Practical Orchard work by Messrs. P. MacOwan and

Eustace Pillans. We formed a very high opinion of this little work when it was first published, and consider it well worth bringing within the reach of all who have anything to do with the cultivation of fruit trees.

The cultivation of Cassava or Manioc (*Manihot utilissima*) is spreading rapidly in Florida and the neighbouring States. One great advantage is that the plant grows in sandy soils unsuited to most crops, and can be fertilized by means of leguminous crops without the aid of other manures. The acre is said to yield 8 tons of roots, and the starch got from it is sold for 2½d. per lb., while it goes six times as far as the best wheat starch at 3d. per lb. As a cattle food it is a great acquisition, making it possible, so it is said, to put on a pound of carcase at the cost of a little over a ½d.

We are glad to learn that Messrs. C. C. Barber's Cocoa (see advertisement on back cover) has "taken" in Australia. It has been accepted by approved Agents in Perth, Sydney, and New South Wales, and its introduction into Queensland and Tasmania has been entrusted to good hands. The first orders received from various quarters have been substantial and promise well for the popularizing of the excellent article turned out by the pioneer firm of Cocoa manufacturers in Ceylon, where Barber's Cocoa is steadily taking the place of the older "brands."

The following Ceylon plants are gall-bearing: *Eugenia Jambolana*, *Areca Catechu*, *Cinnamomum Zeylanicum*, *Pongamia Glabra*, *Terminalia Chebula* and *Acacia Leucophlea*. The fruit of *Terminalia Chebula* and *T. Belerica* constitute the "Gall-nuts" or *Myrobalans* of commerce, valuable in tanning.

A correspondent, writing on 20th March from Adelaide says:—The land is most fertile and the climate, except for two or three months, equal to that of the countries washed by the Mediterranean. During the summer, which we have just passed, the temperature keeps often over 90° F., and sometimes, for a day or so, it goes up as high as 103°; but by the laws of compensation, the Mercury falls to a temperate heat for a day or two after. There is plenty of good land to be got from Government at a rental of 2s. per acre per annum, and twenty years to pay the value in, or on a lease of 999 years at 2s. This is the paradise of the working man. Every man and woman must work, and the dignity of labour is understood here as nowhere else. Farmer and labourer have equal rights, and the man in Parliament is dependent chiefly on the working man for his election. This, in a measure, enables the working man to rule the capitalist and to control the laws of the country.

The sentiments embodied in the article on Town and Country Shows which appeared in the last number of the *Agricultural Magazine* are echoed in the *Cape Agricultural Journal*. Says our contemporary: "Let it be prominently borne in mind that

Agricultural Shows, while run in the interests of the general sight-seeing public, are especially designed to benefit and promote the farming industry. The question is, do the Shows fulfil their object in this direction?" and so on in the same strain.

We read in the report of the Government Agent of the North-Western Province (Mr. L. W. Booth) for last year, that two Cottagers' Shows were held during the year, one at Habarana and the other at Rambewa, where both attendance and exhibits were numerous. The opportunity was taken to distribute seeds to all who cared to take them.

Greatest amount of rainfall registered in any 24 hours on the 29th April, 1902, 5.65 inches.

Recorded by ALEX. PERERA.

COTTON.

Some years ago a good deal of attention was given to the question of Cotton Cultivation in Ceylon, but though a number of small experiments were started at the time, we are not aware that a proper trial under the most favourable conditions was given to the cultivation of the plant. With the opening of the Northern Railway the subject is once more being discussed in view of the possibility of suitable areas being found in the regions through which the new railway runs.

The amount and distribution of rainfall has much to do with successful cotton cultivation, and this fact must be borne in mind in selecting soils. The plant thrives in a very warm atmosphere, provided the latter is moist and that severe drying winds are not prevalent. In the typical cotton climate the mean daily temperature increases from the time of seeding till the plant has reached its greatest vigour and stored up all the reserve food it needs for the production and maturing of fruit. The best type of soil for producing favourable results is a clay loam or

medium heavy sandy loam. The soil should be deep and the sub-soil not heavy and compact. The cotton plant has a well-developed tap-root extending according to the vigour of the plant and the character of the soil, to a depth of three or more feet. The lateral or feeding roots begin usually within three inches of the surface and seldom extend beyond a depth of nine inches. It is a question whether the practice of planting on ridges is as good as working up the land deeply and then sowing the seed on the level ground. The ridge system grew out of the practice of shallow working to a depth of a few inches, though the seed bed is deepened by trowing up the soil till a depth of ten inches or more is obtained. A good seed bed is thus formed it is true, but it will not resist drought as would a level culture accompanied by deep working.

The object of cultivating the land during growth of crop is to prevent loss of moisture in the soil. This is accomplished by maintaining a surface layer one or two inches thick in a thoroughly pulverised condition. At the same time and by the same means weeds and grass are kept down. It is very important that the surface layer of loose soil should be constantly maintained. Especially after rain when the soil tends to settle and form a compact surface, a stirring of the top layer should take place. With the production of crop, cultivation should cease, and the plant helped by reducing water supply by preventing surface evaporation. It is precisely reversing the process desired in the early stages of growth with the object of checking further development of foliage and directing the energies of the plant towards making use of the materials it has already accumulated for the production of fruit.

As regards time of planting &c, local conditions must be consulted before deciding these points, but the object should be as far as possible to secure for the plant an early start and a long season in order to successfully mature its fruit and enable the crop to be gathered in good condition.

On the question of fertilizing or manuring we do not propose to enter, but a good deal of useful information under this head may be derived by a handy pamphlet on "Cotton Culture" published by the German Kali Works for which Messrs. Freudenberg & Co. are the local agents. This publication should prove useful to intending cotton growers as it has proved to us in collating the foregoing information.

We are hopeful of suitable land being found for raising cotton as well as tobacco, which is just at present also being much talked about, in the vast areas now made accessible by the opening of the Northern Railway. With this idea we are making arrangements for trials of suitable varieties of cotton, of which a small supply of seeds has been indented from Egypt.

We have already a local Spinning Company which ought to be some encouragement to intending growers. There is also a Sinhalese pamphlet on Cotton Cultivation compiled by Mr. W. A. de Silva which should serve to bring the subject to the notice of the natives. A revised edition of this pamphlet—brought up to date—and a Tamil translation of the same, might be published with

advantage for free circulation by the authorities interested in the development of a local cotton-growing industry and in the opening up of the areas through which the new railway will run.

TO PRESERVE MANGO CUTTINGS.

In our February number (*vide* first article) we gave some directions for packing Mango cuttings so as to keep them fresh for budding purposes. In the *Agricultural Journal of Natal* for March the following further information on the same subject occurs:—

Mr. H. Knight, according to a recent issue of the "Queenslander," has received a report from the Department of Agriculture (Queensland) with regard to the cuttings of mango he packed at the City Market here on the 7th of September last. There were four tins. In two were eighteen cuttings packed in moist sand; in the other two were six cuttings, packed in coconut fibre, which had been boiled and washed and squeezed dry. One of the big tins was opened on the 15th of October, and it was found that fourteen of the cuttings were dead, two partly alive, and two fairly healthy. The second big tin was opened on the 12th of November. All the cuttings were dead except the largest, which was covered with nodules, but had no appearance of any buds swelling. The first of the small tins was opened on the 12th of November, and all six cuttings were alive, with numerous buds ready to develop or grown out from $\frac{1}{4}$ in. to 2 in. in length, the wood covered with white nodules, and the base of the cuttings well calloused. The last tin was opened on the 19th of December. In this case, also, the whole of the cuttings were alive. They had made shoots of from 2 in. to 4 in long, and all the buds appeared to have developed, though it would have been possible to get adventitious buds from the base of the larger shoots. The base of each cutting was almost completely calloused over. Mr. Benson, who examined the cuttings, states: "I consider the two large tins a failure. Both the small tins were a complete success, and proved conclusively that mango wood can be successfully sent long distances if carefully packed in tight tins filled with coconut fibre, as used by Mr. Knight." Mr. Knight is quite satisfied with the result of his experiments; but he is hopeful, now that he has demonstrated the possibility of keeping mango cuttings alive for a good length of time, that something may be done by the Department of Agriculture in the matter of introducing into Queensland some of the finer classes of the fruit that are grown in the East.

A VALUABLE TIMBER TREE.

The Editor of *Indian Gardening* referring to Mr. Herbert Stone's paper on "The Identification of Timbers" read before the Society of Arts, London, says:—"That our Indian timbers require to be more closely studied is evident. How many people, for instance, know the value of 'Gumbar,' the wood of *Gmelina arborea*, and its peculiarity

of resisting the effects of time, wind and water, and its complete immunity from the attacks of insect pests? Even the voracious white ant will not touch it." The tree known as *Ettlemata* is rather common in Ceylon, and its wood is described by Trimen as "yellowish-white, even-grained, light, strong, tough and durable; an excellent timber." The following note given by Dr. Watt in his Dictionary of Economic Products supplies fuller information regarding this timber which is not known popularly. Colour yellowish, greyish, or reddish-white with a glossy lustre, close and even-grained, soft, strong, does not warp or crack in seasoning, weight from 28 to 35 lbs. per cubic foot, breaking weight of a bar 6 ft. by 2 in. by 2 in., 580 lbs. (according to Baker). It is light, has a good surface, is very durable, is easily worked, and takes paint and varnish readily, and is therefore highly esteemed for planking, furniture, carriages, deck boats, panelling, and ornamental work of all kinds. (Gamble.) Mason states that it is largely employed by the Karens for canoes, and by the Burmans for logs. Owing to its extreme durability, it has been recommended as an excellent timber for making tea boxes, and has also attracted much attention as a very suitable wood for furniture, picture frames and similar work in which shrinking and warping has to be avoided.

Buchanan mentions that it is much employed for making native instruments of music. Roxburgh appears to have first noticed the excellence of the timber. He applied various tests to prove this. In one case he placed an outside plank in the river, a little above low water mark, where the worm is supposed to exert its greatest powers.

After three years in this position it was cut and found to be sound and in every way as perfect throughout as it was when first put into the river. Amongst other things a flood door was made of it to keep the tides out of the Botanic Gardens. Seven years and a half after the door (4 ft. square) was made, it still remained good though exposed to sun and water, while similar doors of teak were much decayed after six years' use.

Dr. Watt mentions that the wood has come prominently into notice and is in considerable demand in Calcutta for furniture making.

We have no doubt that Mr. Frederick Lewis' forthcoming work will contain a reference to this tree, and supply all the information that may be desired from a local point of view.

VETERINARY NOTES.

Experiments are in progress in the treatment of Tetanus by subcutaneous injections of fresh nervous substance. Prof. Shindelka, after having unsuccessfully experimented with rabbit brain tried sheep's brain. The fresh cerebral substance was triturated in a strong proportion of sterilised water and the emulsion injected under the skin. This treatment was applied to eight horses suffering from tetanus, and seven of these recovered; one died on the fourth day. Prof. Shindelka intends to continue his experi-

ments, and as soon as he has tried them on a sufficiently large number of animals will communicate his results.

In spite of the doubt cast by certain practitioners on the efficacy of iodide of potassium, Mr. Hauptmann is firmly convinced of its good effects. He does not favour injection in the udder chiefly owing to the difficulty of managing an antiseptic solution, but recommends administration by the mouth. Injection of an iodide solution into the uterus produced the same good results. Iodide of potassium, according to Mr. Hauptmann, exercises its specific action on milk fever as soon as it reaches the blood current.

Professor Mucki reports good results with the treatment of a severe case of strangles by means of corrosive sublimate. He used the drug intravenously, and first made an injection of 30 grammes of a solution of 1 in 1,000 in the left jugular. On the following day the temperature fell, but the hyperthermia returning two days later, the Professor administered 40, 50, and finally 60 grammes of the same solution daily. In a few days the fever finally disappeared, the local injures improved, and the horse became quite convalescent.

The *Veterinary Journal* for February last contains a reprint of a lecture by Prof. Macqueen in which reference is made to, what we might call for the want of a better word "upishness" of young Veterinary Surgeons. The Professor objects to the insertion of the letters "M.R.C.V.S. L." after a Veterinary Surgeon's name, as suggesting something more than nonsense, and states that the final L. should be dispensed with on the ground of bad taste and of being altogether superfluous. Another thing objected to is the use of the word "Professor." "So far as I am concerned," says Prof. Macqueen, "the name of *Professor* is not pleasing, and I should certainly live quite happily in this world if there was no such title. My conception of a Professor is a man of about 80 years of age, with a head like Lord Kelvin, with flowing locks like those worn by the late Joseph Gangee, a man who has lived through various places in a profession, whose experience is beyond question, and who is entitled to the real dignity of being called a Professor. What would Prof. Macqueen say to the local abuse of the word "Doctor" in describing a Veterinary Surgeon?"

Even the Veterinary profession is threatened with an invasion by the weaker sex. In 1897 a lady sat for and successfully passed the preliminary examination and entered as a student of a Scotch College with a view to being enrolled on the register of the R.C.V.S. She, however, found that the Council declined to admit her to examination. Legal proceedings followed against the R.C.V.S. in the Scottish Courts, but the case was dismissed with costs on the plea that the Scottish Courts had no jurisdiction. So ended

the episode of the lady student. There is said to be only one qualified lady Veterinary student in Europe, viz., Mdle. Kepereaitsch, member of a wealthy Russian family. In America, however, five ladies were enrolled as students in 1897 by the New York Veterinary College. More ladies are seeking admission, with a view it is said of qualifying to treat—*Household Pets!*

AN AGRICULTURAL PAPER.

We give below an Agricultural Examination paper with answers—something for our readers to think about.

Q. Are you aware that plant food exists in the soil in both available and unavailable forms, and that when plants have used up most of the available portion we call the soil "worn out?"

A. Yes. That soils, though unproductive, contain plant food in large quantities, but it is in such condition that plants cannot get it.

Q. Is it true that a soil is capable of being made a laboratory in which changes will take place, and some of this unavailable plant food be made us available?

A. It is only when the soil is in such condition that certain changes can take place, that the unavailable plant food becomes available to the plant.

Q. Are you aware that when the texture of your soil is poor, or, in other words, when your laboratory is out of order, the best manure will not give satisfactory results?

A. The texture or physical condition of the soil is of the first importance. A rock contains plant food, but it will not grow crops because of its physical and chemical condition.

Q. Do you know that heat and air are important agencies in the changes going on in the soil as they are in ordinary fermentation.

A. Chemical changes in the soil cannot take place to the best advantage when air is excluded, or when a favourable temperature cannot be maintained.

Q. Does standing water have a detrimental or beneficial effect on the heat and air, Why?

A. Detrimental because it keeps the temperature low, and at the same time excludes air; while the soil texture is also impaired.

Q. How can you make the soil laboratory do the best work?

A. By making and preserving the best physical conditions possible.

Q. Have you realized what an inch of rainfall means?

A. It means about 113 tons of water supplied the acre.

Q. Are special precautions necessary for preserving the moisture in the soil? Why?

A. Most decidedly. It requires about 300 tons of water to produce one ton of dry matter. A good deal of rain water flows away over the surface of land, and a good deal is evaporated. On this account only a part of the rain is available for

plants; so we must try to save what moisture is already in the soil through previous rains.

Q. How can we make soil moist or keep soil moist?

A. By surface tillage. It keeps a soil moist by preventing it from drying out. When soil is left undisturbed for a long time, and becomes packed down, the moisture in the soil works towards the surface and is evaporated, so passing off into the air. Tillage, or stirring the top layer, make a surface soil mulch through which the soil moisture cannot pass. It is really equivalent to covering the soil with a layer of straw or board. Every cultivator knows how moist it is under a pile of straw which has remained in a place for some time, or under a board. The straw or board does not make the soil moist but prevents it from drying. This is what surface tillage does.

THE ENTOMOLOGY OF THE HOUSE FLY.

The house fly, like the poor, is always with us, and it would be to the advantage of everyone to know all about so familiar an insect, and what its power for good and evil are.

In the *Agricultural Journal of Cape Colony* Mr. Charles Loundsbury contributes, under the head of Entomology, an interesting paper on "the house fly," containing a good deal of information which it is desirable we should add to our knowledge of human things.

Mr. Loundsbury gives us an instance of the ignorance prevailing on such a common subject. He says: I once met a man who was kindly disposed towards the house fly, who confessed to a fondness for its company akin to that felt for the trusting robin red-breast that comes to the door-step at home when snow covers the ground, who was not annoyed when an over-adventurous fly dropped into his coffee, and who never exerted himself to destroy the busy ones which strove to share his sugar. His house was kept scrupulously clean, and flies consequently were not numerous therein, or he might perhaps have held different views concerning these little buzzing guests. He told me he honoured the fly for its intelligence, for its extraordinary vision and the beauty of its complex eye structure, and, most of all, for its peculiar attachment to the habitations of man throughout the wide world. He seemed well acquainted with the creature as a fly and in the house, but, strange to say, he had never probed its earlier history or enquired into its out-door habits; and his respect for the little insect seemed so genuine and unaffected that I forbore from enlightening him. Ignorance to him was indeed bliss. And if any of my readers hold similar views, if they have any affection at all for the house fly and desire to retain it, they had best read no further. My design in penning these notes is to malign the little pest, to lay bare its iniquity, to brand it an abomination of the vilest type, and to instil loathsomeness toward it. I have only one pronounced feeling for the house

fly, and that is of deep disgust. Other creatures there are plenty of an equally offensive production, but the house fly is pre-eminent for habitually insinuating its low-bred filthy self into man's abode, by fouling our food and drink with its dung-stained feet, by soiling our all with its flecks of excrement, scattering germs of foul disease for our injury.

We are reminded of the fact that though we abhor many an insect with little reason, chiefly on sentimental grounds, we are in a great measure indifferent to the filth-bred house fly to common in our dwellings, thronging eating rooms, swarming in baker's shops and meal stalls, and blackening over the baskets of sellers of sweet meats which our children are permitted to eat.

The number of distinct (described) species of flies is said to be 40,000. Of all the number, only about half a dozen habitually enter dwellings, but the most abundant by far is the one species *Musca domestica*—the universal house fly, indeed the "fly."

The only part of the house fly's anatomy worth describing is its mouth. This organ is described as thick throughout, extending down from the head to the ground as the fly stands in feeding, but at other times retracted out of sight. It is expanded at the end and adapted for lapping and sucking, not for piercing.

The house fly is first an elongate white egg, which hatches very quickly, sometimes in less than 8 hours, into a footless white maggot. This grows rapidly, and in about a week in warm weather is about $\frac{3}{8}$ inch in length when it is full grown. The maggot retracts in length, and with hard and darkened surface enters into the quiescent pupa stage. In from 5 to 7 days the fly is developed and set free.

The house fly is an all-the-year pest but is more numerous at certain seasons. The average number of eggs laid by a female is 120 per diem. The mission of the fly is that of a scavenger, and particularly so in its larval stage, but strangely enough though the fly is so common, little of an exact nature is known of its breeding places. Horse dung is believed to be the chief food of the maggots, but the dung of cattle and other animals is also freely resorted to. The maggots, not being hardy, succumb as the food dries out. They appear to thrive in pure horse dung, other forms of ordure being too compact unless broken up or mixed with straw. The ideal breeding place would appear to be manure mixed with bedding and saturated with urine, especially if such a mixture be found in a cool shady place. Badly kept stables are their favourite haunt, and almost all stables serve as breeding places, while places where scavenged rubbish is thrown (such as over-cultivated grass fields) are very suitable. It would be well here to add that kitchen waste so commonly allowed to accumulate near dwellings is well calculated to breed the house fly.

The relation of the house fly to disease and the remedies against the pest will be referred to in our next issue.

(To be concluded.)

THE ADVANTAGES OF MULCHING.

[The appended lecture was delivered by Dr. Lehman, Agricultural Chemist, Mysore, before the United Planters' Association, and clearly explains the advantages of a practice too little adopted in countries subject to drought. The lecture is reproduced in Bulletin No. 2 of the Department of Agriculture Mysore, entitled "Notes on Coffee Cultivation," which in Dr. Lehman strongly recommends mulching instead of digging round the bushes.—*Ed. A.M.*]

The subject is a very large one, but I shall only touch on four of the most important points. These are:—

- (1) The tendency to preserve the soil moisture.
- (2) The tendency to prevent the formation of a crust on the surface.
- (3) The tendency to preserve the soil in a loose and open condition and retarding the growth of weeds.
- (4) Allowing the rain to enter the soil more easily and preventing the surface washing.

The tendency to preserve the soil moisture.—As we all know, the top layers of soil are generally the driest, while those below are gradually increasing in moisture till the level of the sub-soil water is reached. Of course, shortly after rain this order will be partially reversed, but this will only be for a very short time. In mulched soils this is not, however, the case, as Wollney, in his elaborate experiments conducted near Munich, has clearly pointed out. He, for one found that, even after ten days of dry weather, the surface soil, under a mulch of about an inch of coarse, strawy manure, had still considerably more moisture near the surface than at a depth of four feet. Compared with unmulched soil, the differences are also very striking; especially in the first four inches of soil, as it contained 13 per cent more water than that not mulched. At a depth of two feet there were still 2 per cent in favour of the mulched soil and at three feet a little more than 1 per cent. The above is an average of several experiments; and numerous others conducted at different places on different soils and with different mulches gave similar results; boards, stones, straw and leaves were among the mulching materials used. A very loose surface soil also acts as a mulch, but on the one hand, it is not nearly so efficient as leaves and, on the other, it would soon become compact again. Nevertheless, one of the objects of cultivation is to provide this partial and temporary mulch; for in most localities the application of the only other practical mulching materials, *viz.*, straw or leaves, would prove a rather expensive operation. Since part of the object of cultivation is to form a mulch to retain soil moisture, and as a mulch of leaves would perform this object much better than cultivation, mulching may replace part of the cultivation. The more thoroughly we study the subject, the more convinced of this fact will we become. I need not enter into the theories advanced for the facts obtained by experiments notwithstanding that they have been proven beyond a doubt. It is surprising how the soil moisture will vary in adjacent portions of soil only a few feet or a few inches apart. You may have noticed yourselves that under a covering

of leaves only a few feet square the soil may be moist to the very surface, while just beyond this covering the soil is perfectly dry to the touch for perhaps two feet or more from the surface. The shade under which coffee is grown has also a tendency to preserve the soil moisture. But the mulch of leaves from the shade trees will be at least quite as effective in this respect as the trees themselves. I should not like to make any remark which might induce any of you to lessen your shade; but it is just possible that after extensive experiments have been made, it would be found possible to replace part of the shade by a mulch of leaves. As far as soil moisture goes, a mulch and shade trees work in the same direction. Properly speaking, I ought to give a brief account of the functions of the water in the soil to show how far the preservation of soil moisture is an important factor. But as every one knows that a liberal supply of moisture (not stagnant water) is absolutely necessary, I need not speak of it further at present. Of course, it is possible to have too much water in the soil. But as a mulch will in no wise interfere with the drainage, and as the coffee soils do not appear to have an excessive water-holding power, it is not likely that the mulch will retain much of that which would act injuriously to the coffee. But it would tend to keep the water near the surface, where the larger portion of the roots are—at seasons when without it these portions of the soil would be too dry. Of course, experiments will have to prove in how far the wintering of coffee is desirable or necessary, and it will depend upon the results of those whether it would be desirable or not to retain the mulch through the hot and rainless season. Some planters have noticed that coffee does apparently better on stony soil than on adjacent fields which are not stony. It would be premature to say that this was due to the stones on the surface forming a partial mulch. But that stones act similarly to a mulch (though not nearly so effectively) has been proved. And that the crops are sometimes injuriously affected by removing them has also been noted by observant farmers both in England and in Germany.

Preventing the formation of a puddled surface.—The ease with which the surface soil becomes puddled in some parts of the State is very marked. Few of us realize, I believe, what a drawback this really is to plant growth. Frequently you must have noticed that plants are growing very poorly indeed if there is only a thin crust on the surface of the soil. Unfortunately, I do not remember having seen any accurately conducted experiments which would indicate the extent of the injuries done by the crust. But T. B. Terry and other practical agriculturalists claim to have more than doubled some of their crops by always stirring the soil after every shower of rain as soon as it was sufficiently dry, so as to break the crust as soon after it had formed as possible. To do this on any of your estates would be impossible. But a mulch which would break the force of the rain or drip at the surface would prevent this crust formation to a very large extent, if not altogether. The rain water after percolating through the mulch has not sufficient force to move any large

portion of soil particles and deposit them in a compact or puddled condition. One of the principal advantages of surface cultivation during the growing season of plants is doubtlessly to be found in the breaking up of the rain-puddled surface of the soil; and as a mulch will do this effectively it will greatly reduce or entirely replace the cultivation necessary on this score. In addition to surface cultivation there is always a certain amount of deep cultivation necessary. But even this can be reduced more or less by the use of a mulch, as the latter has the tendency to preserve the soil in a loose and open condition. This fact has been proven both by measuring the volume of air contained in a definite volume of mulched and unmulched soil, and by noting the shrinkage taking place in similar samples of soil mulched in various ways and those not protected by such a covering. To quote the figures without a detailed account of the experiments might be misleading. It will be sufficient to mention that in each case the mulch prevented the soil from becoming as compact as it otherwise would have become. In addition to this direct influence a mulch also tends to attract worms, which, by their burrowing, actually loosen the soil and possibly assist in rendering some of the plant food more readily available. Furthermore, any of the mulch decaying supplies the soil with vegetable mould at the surface, the place where it is so much needed. You will have noticed the check that a mulch has on weeds. And it is self-evident that a loose soil with no crust and a moist surface will allow the rain to enter more readily and will suffer less from surface washing.

GENERAL ITEMS.

The neglect of the ground or pea-nut^s in Ceylon is to say the least of it remarkable, seeing that it is well suited to most parts of the Island. In America during a fair year the ground nut crop averages 5,000,000 bushels, and that is only a small proportion of the world's crop of fully 25,000,000. The Americans eat about 4,000,000 bushels of nuts a year, either in candy or the original kernels. The nut is largely used to adulterate Coffee and Cocoa.

Ground-nut oil, which is perhaps the most valuable product of the plant, is of a pale straw colour, very thin, clean and tasteless. It does not become rancid and even improves with

keeping. The yield is variously stated to be from 16 to 30 per cent, the higher quantity being assisted by heat but determined in quality. Its largest use is in adulterating olive oil, while it is also used for sewing machines and small machinery, for soap-making and as a cooking oil, also for burning. The residue or cake is used as a milk-yielding cattle food as well as a manure.

Some time ago attention was drawn to the value of the parched nuts as a diet for consumptive patients. The taste for parched nuts is so universal in America that a ground-nut stand is to be seen at nearly every street corner in the large towns. *The Cape Colony Agricultural Journal*, to which we are indebted for the above notes, makes a plea for the cultivation of the ground-nut along the Eastern Coast lands.

In composition the white of egg consists of proteid matter dissolved in water, while the yolk contains in addition to proteid, fat and coloring matter. The results of analysis are as follows:—
White: 85.7 water, 12.6 proteid, .25 fat and .59 ash.
Yolk: 50.9 water, 16.2 proteid, 31.75 fat, 1.09 ash.
White and Yolk together: 73.7 water, 14.8 proteid, 10.5 fat, 1.0 ash.

A correspondent of the *Natal Agricultural Journal* gives the following recipe which he has found most successful for mange in dogs: Wash the skin first with warm water and soap (whale oil or Carbolic is preferable). Then apply 4 oz. of whale oil, 1 drachm of creosote, 1 oz. sulphur. Grind the sulphur into a little oil and creosote and then gradually add the rest of the tar and oil. Rub thoroughly into the skin.

Pergularia odoratissima, known among the Chinese as the "Night-Scented Orchid" is what is called the "tonkin creeper" in Ceylon. It is, of course, not an orchid, but a member of the order Asclepiadaceae. The flower is a great favourite among older members of the Ceylonese population, and is often placed among articles of clothing owing to the scent it imparts. An attar is said to be extracted from the blossoms. The fruit is incorrectly supposed by some to be the scented bean called "Tonka" or "Tonga" which is borne by *Dipteryx odorata*, a leguminous plant and the seed of which is used to scent snuff and communicate a pleasant odour to clothing.

COLOMBO, JUNE 2ND, 1902.

No 12.

ANNUAL REPORT OF THE CEYLON GOVERNMENT MYCOLOGIST AND ASSISTANT DIRECTOR, 1901.

FUNGAL DISEASE.

THE past year has been, from a meteorological point of view, rather less favourable to the growth of fungi than is usual in Ceylon. The number of days and hours during which the atmosphere was laden with moisture has been fewer, and the dry and sunny hours more, in

nearly all districts than in most previous years. In addition, a good deal of preventive and sanitary work has been done in various districts, and this has lessened the number of spore-producing areas to some extent.

In regard to blights and diseases of staple products of the Island, we are at least in as good a position, if not better, than in January, 1901. Tea diseases have not wrought much havoc, though both leaf and root diseases have still to be seriously reckoned with. In cacao the stem and fruit canker are on the decrease, and will continue to be so, if cacao planters do not slacken their measures against this serious disease.

Some three hundred inquiries have been received during the year, chiefly dealing with diseases in tea, cacao, coconuts, cardamoms, shade and timber trees, and other estate cultivations, but a few referring to horticultural plants.

The work of diagnosing the diseases attacking specimens sent, and by so doing being in a position to recommend preventive or curative measures, is greatly helped by an adequate quantity of material being submitted for examination, and also when any facts which

may bear on the disease are sent with the specimens. A single leaf or too have on occasions been received, with a request for report as to the cause of its abnormal appearance, and recommendations as to treatment, with no other information.

The task is then somewhat similar to that of a doctor called upon to examine a portion of a dead or dying man without any facts about the case, and asked to recommend a course of treatment for this and other similar cases. It will greatly help, in a not always simple task, if as much material can be sent as convenient; if a leaf disease, then all stages of the blighted appearance on old and young leaves, if possible not quite dried up. For sending by post, a small tin box, such as a cigarette or tobacco box, answers the purpose well. Notes as to the time when the disease was first noticed; if tea, how long from pruning, whether on all the plants or only some, whether on all leaves or only some; the conditions present, favourable or otherwise, such as drought, cold, or excess of rain—all these are of much value in forming an opinion as to the causes of disease.

ENVIRONMENTAL DISEASES.

Many of the specimens sent for report are found on microscopic examination to contain no parasitic fungi or other organisms, and to be affected by what are purely *environmental* diseases, *i. e.*, due to the presence of physical conditions, such as drought, excess of water, absence of nutrition in the soil, powerful and continuous wind, lightning, and other such causes. In these cases, when the tissues have been found to be free from the presence of any parasitic organism and show no signs of having been attacked by any insect or other animal, an investigation of the conditions under which the plant has been living is needful, in order to find out the why and wherefore of the evil.

Two cases of tea struck by lightning were examined, and from the facts observed by the planters sending them, and the appearance under the microscope of both stem and leaves, there was no doubt that the injury was due to the passage of an electric current along the ground occupied by the roots of the plants. I have investigated a similar case in England, of elms in Leicestershire struck by lightning, where the shrubs and other plants near the elm trees were damaged along the track of the current.

In the Ceylon case a *Grevillea* tree was struck and the tea bushes immediately surrounding were damaged. In such cases of accidental injury it is possible by the help of some cattle or other suitable manure to prevent the plants dying, if they are observed and treated soon after the shock.

It is often not easy to say definitely that the lack of health of a plant is due to environmental causes, especially without careful observations of the circumstances of the case, but these are evils that the planter knows well and knows the way to cure—by removing the conditions. In my experience the planter generally does recognize environmental diseases, though, as is only to be expected, he is inclined to attribute the first effects of certain root diseases which are caused by fungi to such causes. If, however, bushes in nearly similar conditions, and apparently originally as vigorous, are "shuck," some root disease of a fungal nature may legitimately be suspected. In any case of doubt the roots should be examined, and if a fungus is found, or if signs of it are seen, such as discolouration and decay of the root tissues, the whole should be destroyed by burning, and the soil around limed.

The planter who will suffer least from diseases in his cultivations must exercise the same observation and use the same care to keep his plants in health as he does for his horse or his dog. Without a knowledge of the anatomy and physiology of animals, he is yet able to prevent and cure many of the diseases of his domestic animals, and so in the case of his plants; whatever kind they are he may use preventive and curative means as soon as he notices any disease affecting his estate.

LEAF DISEASES OF TEA.

Tea has been throughout the year less affected than last year by leaf diseases. In the case of Gray Blight (*Pestalozzia Guenipi*), it has been sent to me from almost every tea district in the Island, and therefore seems to have spread across wide areas. Though I have since my arrival in the Island examined an immense number of diseased leaves from jungle and other plants said to be affected by this leaf disease, I have in no case found the fungus to be growing on any other plant. In many cases badly affected tea is surrounded on one or more sides by jungle or scrub and though vast numbers of spores must have lit upon the leaves of plants growing there, no blighted leaves with this particular fungus have been found.

An interesting case of the method of distribution of spores was observed on an estate in a wet district. On the windward side of a narrow strip of jungle, at the brow of a hill, was a badly blighted field of tea; a road some 20 or 30 feet wide had been cut through the jungle, and on the leeward side was a field of tea, only blighted on the bushes which were opposite the opening through the wood. This points to the protection of tea in some cases by means of wind or other belts of trees. The whole question of spore distribution is one of rather a complex nature; it is however one of great importance from an economic point of view, and the experiments initiated during the year with a view of gaining a definite knowledge of conditions under which spores are distributed will, it is to be hoped, lead to measures likely to prevent or hinder the spreading of the spores of leaf diseases.

SPORE-DISTRIBUTION EXPERIMENTS.

The experimental "tabernacles," which are built of jute hessian and are 45 feet long by 8 feet broad, enclosing thirty tea bushes in two rows of fifteen, are

9 feet high, and are placed at right angles to the prevailing winds in certain selected districts at various elevations and climates. They are open to the sky, and the tea in the enclosure is as nearly as possible under the same conditions as that outside. The observations already made in the tabernacle where the tea has already begun to bear leaves have yielded valuable information, and when the whole of these enclosures at varying heights and climates are under observation many data of importance will be gained.

All the tea both in the tabernacle and the surrounding field is pruned and when the field has come into bearing all leaves on bushes inside the enclosure and around it which show any sign of disease are examined microscopically and the disease determined. The outbreak of disease on either side of the tabernacle is also observed and recorded in the same way. By thus observing at close and regular intervals the same thirty bushes a knowledge is gained of the behaviour of different bushes to disease. One question of much interest as regards tea with Gray Blight and other leaf diseases, viz., whether the weakly bushes are more or less liable to attack than more vigorous plants, and as to how they re-act to the disease, can here be studied carefully. The data are to be collected at the different stations by the superintendents of the estates selected and the leaves forwarded to me for examination. I also hope to personally inspect them at certain intervals. These gentlemen have most kindly taken a great interest in the investigation, and their valuable help in this matter will, I hope, be repaid by an advance in our knowledge of the whole question. The following is the schedule to be returned after each plucking, which will explain to those interested the *modus operandi* of the investigation:—

TEA BLIGHT INVESTIGATION.

The Mycologist, while wishing to reduce the amount of trouble taken by each observer, will be glad to receive as complete answer as possible. If the terms suggested in the footnotes only are used the comparison of the observations at the different stations will be simplified. When convenient the returns should be sent to Peradeniya next day, so that the diseased leaves can be examined with little delay. All the diseased leaves should be sent, unless too bulky, when they should be weighed and the weight sent, with as many of the leaves as possible.

The tabernacle should be kept closed and only the Kangany or Cooly who is to pluck the bushes admitted.

GRAY BLIGHT ON YOUNG SHOOTS.

As was mentioned in my last annual report, a circumstance with regard to Gray Blight, which calls for attention, has been again more than once brought to my notice. It is the fact that the fungus grows in some leaves so vigorously that it penetrates back through the leaf-stalk to the young shoot. In these cases it is able to grow longer than it can do in the leaf, which usually falls off the bush when entirely killed by the fungus and consequently it is on these older parts that I have at last discovered the perfect

fruiting form of the fungus or ascigerous state. This form I am investigating, and it will form the subject of a paper of a more technical character than is suitable in these Circulars. From a planting point of view this discovery is most interesting, as it points to one method this fungus has of perpetuating itself. All such cases, which can be seen by the discolouration of the young shoots and the absence on them of any flush, should be treated by pruning these young shoots back and burning the prunings. A case has occurred of the Gray Blight fungus attacking the youngest beds over a whole field and reducing the yield to a grievous extent. I cannot say whether in the cases I have examined the buds were "banji" by which I mean buds the growth of which has been checked, or whether they were attacked when in their earliest stages.

If the buds are "banji" they may have been on the bush for sometime—long enough for the growth of the fungus as it generally occurs; and further it is probable that the presence of the fungus in the buds may itself have produced a "banji." This phase of the Gray Blight fungus is, however, still being investigated and I may hope to learn more of its nature on visiting the area affected and noticing the conditions prevalent there.

The efforts of the Gray Blight fungus in this direction to decrease the output of tea should be carefully watched and by pruning lightly below the infected places, stopped before it becomes at all common.

ROOT DISEASE OF TEA.

A Disease which is more difficult to fight, and which has more disastrous effects in the places where it occurs, is the root disease of tea, which is to be found in many districts, more especially those at higher elevations, where the disintegration of dead vegetable matter is slower than in the low-country.

This is caused by a fungus, most probably *Rosellinia radiciperda*, Massee though in almost all cases there are not present the fruiting parts of the fungus, by which alone it can be certainly identified.

The mycelium of the fungus commonly called "White Root-rot," can be noticed as white thread-like strands, easily seen with the naked eye. When it has permeated the root entirely, it often assumes a fan-like shape covering the surface of the root, and can be easily detected on scraping away the dirt and the outer surface of the root. The majority of known fungi are saprophytic, *i.e.*, living on dead and decaying substances; others are parasitic, *i.e.*, growing on the living tissues of plants or animals. In some cases fungi have the power to exist in both these ways, and the tea root disease fungus is one of this latter kind. It begins its life as a saprophyte on any dead timber of a suitable kind. The softer and more spongy roots of trees like *Symplocos*, when the tree is cut down, are an ideal home for this fungus.

I have found it growing on various jungle roots,—in most cases it is not easy when the tree has been cut down for sometime to certainly determine the species of the root,—on buried logs, and prunings of all sizes, even no thicker than a slate pencil.

Having grown for some time on these dead hosts, when moisture is present it spreads out in different directions until it encounters another piece of suitable food. Unfortunately for the cultivation of tea it has acquired the liking for the living roots of tea bushes. The mycelium can grow to a considerable distance through the soil if damp until it reaches the next piece of nutritive material. I have observed a strand of mycelium $8\frac{1}{2}$ inches in length which had apparently no intermediate host in its growth from a piece of dead *Symplocos* root to a young root of tea. It must be borne in mind that the presence of moisture is necessary for the growth of this fungus, and also that when it first reaches and attacks the root of living tea the injurious effect to the plant is not noticeable.

From a large series of observations I believe that in the case of vigorous tea a bush may be affected for two years or longer without succumbing. The tea bush is a hardy plant and makes a good fight against such an

enemy, but it is hardly possible that if once the fungus has got a foothold on its roots it can ever throw it off. I have seen this fungus killing out gradually some of the finest tea bushes in a field, and it will generally be seen that when one bush is badly affected and almost dead, some of the surrounding bushes are unhealthy and show signs of suffering, though in a less degree, from the same evil.

The remedies which should be employed to prevent spread of this disease are simple, and where carried out thoroughly have in all cases lessened and should eventually drive out the fungus.

The cutting of drains not less than two feet deep by one broad has the double effect of removing moisture from the soil and isolating the patches of disease, as the fungus mycelium cannot pass over a space of one foot, and if these are kept free from decaying matter, it will be stopped in its progress.

The burying of prunings in infected areas is dangerous and should be discontinued, as by this means the fungus has no other food than the roots of the tea and may be starved out.

The use of lime is undoubtedly a deterrent to the progress of the fungus, but since it is not possible to effect the application of lime so that it is in contact everywhere with the mycelium of the fungus, it is not always successful. I have been told by a careful observer that he has noticed a piece of lime round which the strands of this fungus were wrapped, and I am at present experimenting on the action of various proportions of lime in cultures of this mycelium.

All bushes which are killed should be carefully dug out, leaving none of the root if possible. The hole should be exposed to the air if the weather is fairly dry, and before filling in an application of lime should be made.

The ditches or drains should be dug around a larger area than is observed to be diseased, as some of the surrounding bushes may have the fungus in their roots though not noticeably diseased.

It may be noted as an encouraging feature in the case of this fungus that it rarely produces its spores underground, and seldom reaches the surface, and therefore almost its sole means of spreading itself is by the running through the soil of its mycelium or vegetative portion.

CACAO CANKER AND OTHER DISEASE.

Passing from tea to other cultivated plants, a leaf disease of the coconut palm has been studied, which bears a close resemblance to Gray Blight in tea, though it is undoubtedly distinct, and does, happily, not do very much damage to this valuable products.

The canker of cocoa has been somewhat fully dealt with in a Circular discussing the whole question, and it may be mentioned here only briefly. No new phases in the workings of this disease have been found, and the cures and prevention where used have continued to repay those carefully carrying them out. It is still a subject for regret that larger areas are untreated, and that in these places the fungus prospers and spreads both on pod and tree.

It may be that this report will reach some cacao planters who may not have read the circular "Cacao Canker in Ceylon," published in October last, and for these it will be well to repeat the summary of measures which are, I think, very generally considered as effective:—

"*Prevention.*—Regulate the shade so that the sun and air can reach all parts of the cacao trees, and keep the cacao from being so close as by its own leaves to densely shade the ground.

"Prevent dampness by surface draining, especially in low hollows.

"Allow suckers to grow on all trees that show any sign of disease.

"Burn all dead cacao trees and branches.

"Burn all discoloured pod husks from whatever cause they are discoloured. If this is not possible bury with lime."

"Bury all pods under at least two inches of soil with a sprinkling of lime.

"*Cure.*—Cut out all diseased patches on bark or branches, removing also a wide margin—not less than two inches—of apparently healthy bark, and burn all the pieces removed.

"If this method is too expensive or too drastic, shave lightly over the diseased areas and around them, and burn the shavings. This latter treatment is not so effective as cutting out. Such work should be done vigorously in the dry weather, when the results are vastly better.

"Keep a gang of expert coolies continually on the look out for new canker patches, and have these parts removed before they spread far or produce their spores.

"Notice any dead cacao trees or branches on neighbouring small holdings, and endeavour to get these removed and burnt.

"These sanitary measures should be carried out on all estates, even where the canker is very rare, and the personal oversight of the superintendent seems to be the only way to prevent small patches of disease being missed in going round. It is much better to take a longer time in going round the estate and have the work thoroughly done than to cover large areas and overlook some canker."

Another disease of cacao of which the nature is not yet exactly known, has been observed and investigated. This is a condition of small and unripe fruits, which is characterized by the unusual flexibility of the pods, giving them when handled the feeling as if made of indiarubber. Pods when in this condition are said to never attain full maturity, and, as a rule wither up and are of no use. I have not been able to find in any typical pods of this character any mycelium of a fungus or injury by insect and it is probable that this is another of the environmental diseases, the cause or causes of which are not yet apparent. That the fruits are fertilized seems proved, an examination of many showing a normal embryo. The loss by this "going off" of a proportion of the pods is important. This condition must not be confused with the drying up of very small pods, which is referred to later, and which at present seems to be due to different causes.

GREVILLEA DISEASE.

A disease of *Grevillea robusta* very prevalent in certain districts is at present occupying my attention. This is a canker which, though it grows upon the roots of the *Grevillea* tree as well as the stem, seems in most cases to originate on the stem, usually near the base. The external signs are a darkening of the bark accompanied, as a rule, with an exudation of gum at various points. Some trees are being treated experimentally, and the fungus is being cultivated, and its effect on the tree examined, some healthy trees being inoculated for this purpose. A Circular will be issued and preventive measures recommended when the facts desired are obtained.

Meanwhile it is important that a look out should be kept for this disease of a most valuable shade and timber tree. All specimens which seem to agree with this short description should be noted, and I will be glad to be informed of their existence and any facts bearing on the case.

FINGER AND TOE DISEASE OF CABBAGES, &c.

Passing from diseases of our extensively grown plants to those of others, the most important is *Plasmiodiophora Brassicæ*, Wor., which has been found in more than one place on cabbages and turnips; it is due to a fungus which attacks the roots and shows itself in malformation of the root, lack of vigour, and subsequently in the death of the whole plant. This disease has been known in Europe for more than a hundred years, and in England is called "Finger and toe," "Club-root, Clubbing," and "Anbury." On the Continent the popular names also have reference to the shape of the root, which resembles fingers and toes. These malformations are due to the irritation or stimulus of a fungus which belongs to the group of Myxomycetes, or

"Slime fungi," a most interesting group botanically but not so important economically, since hardly any of them are parasitic, *i.e.*, disease-producing, or other plants. This slime fungus is so called because it has no outward shape, like the majority of the fungi, but consists of a mass of plasmodium or jelly-like material which makes its way from cell to cell of the root and absorbs the contents of each.

After consuming all the food it can find it forms its spores—which are the reproductive bodies and may be considered as seeds—and these can remain for some time without sprouting. In Europe they carry the fungus over the winter and germinate in the spring. When conditions are favourable, these resting spores germinate and throw out a jelly-like material, which it comes in contact with the young root of a cabbage, turnip, or similar plant penetrates into it and produce the "finger-and-toe" disease.

There are two recognized methods of fighting this disease. The first is to starve out the fungus, and this is done by taking advantage of the fact that *Plasmiodiophora Brassicæ* only grows on cruciferous plants, *i.e.*, plants of the cabbage order. By not growing such plants as cabbage, kale, turnip, kohlrabi, and substituting crops of potato, lettuce, beans, peas, &c., the fungus can obtain no food, and will consequently in a few years be entirely exterminated. The other one known is lime, and this is only a partial remedy. It has been found that acids favour the development of the "finger-and-toe" fungus and alkalis retard it. Thus, a dressing of lime in a garden or field affected by this disease is of value, though not a certain preventive. It is to be hoped that these measures, preferably the former, may be taken wherever this evil is present in Ceylon, so that this disease may not get a foothold in this Island, such as it has in Europe, where it annually causes great losses to root crops and other plants.

FUNGI CAUSING ROTTING OF TIMBER.

Two other fungi have been studied both of economic interest, though not growing on living plants. The first is a species of *Polyporeæ* growing upon beams used for building purposes and causing "dry-rot," the name of which until the cultures have grown sufficiently to produce fruit cannot be given. Some experiments are being made with substances suited to preserve wood from the attacks of this fungus, and also with some different woods in use for building in Ceylon, as to their liability to attack. Some woods are by their structure less easily attacked by this fungus and it is well that the exact amount of immunity they possess should be known.

FUNGUS ON RUBBER.

Another is a fungus which grows upon samples of rubber, those examined begin from *Hevea Brasiliensis*, Para rubber; it was growing more abundantly upon these samples which had been precipitated with acetic acid, than on the untreated rubber, but this point will be experimented on. The fungus is a species of *Syncephalis*, and causes characteristic red markings in the sample, though not destroying its translucency. Whether the growth of this fungus on the rubber affects the market price, I have yet to learn.

OTHER DISEASES OF PLANTS.

The following plants, in addition to those previously mentioned, have been received as diseased; where the fungus causing the disease or growing on the plant has been identified it is mentioned. In other cases the material did not afford means of identification:—

- Dillenia retusa*, *Thumb.* *Marasmius sarmmentosus*, *Fr.*
- Michelia Champaca*, *L.* (*Sapu*). *Polyporus sanguineus*, *Fr.*
- Garcinia Xanthochymus* *Hk. f.* (*Cochin Goraka*). *Strigula Complanata*, *Fee.*
- Oxalis corniculata*, *L.*
- Mangifera indica*, *L.* (*Mango*). *Fusicidium*, *sp.*
- Crotolaria*, *sp.*
- Desmodium cajansfolium*, *DC.* *Peronospora*, *sp.*
- Phaseolus vulgaris*, *L.*

Erythrina nimbrosa, H.B.K. (Bois immortelle)
Sparassus, *sp.*
Acacia decurrens, Willd.
Rosa indica, L. *Phragmidium devastatrix*, Sor.
Eucalyptus, *sp.* (Gum tree). *Rosellinia radiciperda*,
Mass.
Pennisetum indica, L. *Corticium*, *sp.*
Quisqualis cœrulea, L. (Passion-flower). *Cystopus*,
sp.
Cucumis sativus, L. *Cucumber*. *Peronospora*, *sp.*
Daucus Carota, L. *Carrot*.
Coffea liberica L. *Cladosporium herbarum*, *Pers.*
Rhododendron sinensis, *Sor.*
Mimnosus hexandra, *Roxb.*
Piper nigrum (Black pepper). *Coleroa*, *sp.*
Acalypha indica, L.
Agathis obtusa, *Lindl.* *Strigula complanata*, *Fee*
Musa paradisiaca, L. (Plantain).
Karatas *sp.* *Pythium de Banyanum*, *Hesse*.
Elettaria Cardamomum, *Baton.* (Cardamom).
Areca Catechu, L. (Arecaut palm). *Physcia*
speciosa, *Fr.*
Corypha umbraculifera L. (Talipot palm). *Sphaeria*,
sp.
Borassus flabelliformis, L. (Palmyra palm) *Sphaeria*
sp.
Caladium bicolor, *Vent.* *Diachocœa elegans*, *Fr.*
Panicum sanguinale, L. *Ustilago*, *sp.*
Setaria glauca Beauv *Claviceps*, *sp.*
Andropogon, *sp.* *Epichloe typhina*, *Tul.*
Eleusine ægyptiaca, *Pers.* *Ustilago*, *sp.*
Adiantum Capillus-Veneris, L. (Maiden-hair fern)
Cystopus, *sp.*

Some other plants and parts of plants were received which the senders did not know the name of, and which did not afford sufficient material for naming.

"BLUESTONE" AS A WEED KILLER.

Other botanical matters not relating to fungi or plant diseases have occupied my attention during the past year. The question of the use of "Bluestone," Copper Sulphate, in stopping the growth of weeds like oxalis, has been investigated, but the experiments showed little or no effect. The undoubted value of this substance in getting rid of charlock from wheat fields in England, without damaging the crop, suggested this experiment, which will be continued under different conditions until it can be definitely stated that it has no useful effect, or its value proved.

GRASS SEEDS FOR PASTURES AND LAWNS.

An examination of the seed used in laying down a large area of grass at a high elevation has been made. Four different samples of the mixture, which was obtained from a leading English seed merchant, were analyzed and the proportions of each of the different grass and clover seeds in the mixture determined. By enclosing a portion of this land and allowing the plants to flower, which has been sown down for some time, and observing the plants forming the herbage, an interesting record will be obtained as to the grasses and clovers which have grown and prospered, and those that have failed to come up at all. In this way we shall arrive at a conclusion as to what European grasses, clovers, and other herbage and lawn plants are suited to the hill country. I shall be glad to receive samples from any one who is laying down European seeds, to analyze and give advice as to the value of seeds for the purpose. The practice of buying mixtures is, however, to be deprecated; it is much better to get from the seedsman the required quantities of named seeds and mix them when bought.

CACAO CUTTINGS.

Cacao and its improvement has not been lost sight of. In the first place, though my own experiments in obtaining new plants from cuttings have not proved successful either in the open or under glass, Mr. Herbert Wright, the Scientific Assistant and Acting Curator of the Gardens, has achieved the re-

quired result, and has succeeded in rearing a plant from a cutting. The conditions which seem to have helped in this case are a sandy soil and an abundant and constant supply of water at the roots. It will be well if this is noted by cacao planters, so that they may be helped in their experiments in this direction. It need hardly be stated how valuable it will be if we can arrive at an easy method of striking cacao cuttings, as by this means we can perpetuate the characters of a specially valuable tree.

MEASUREMENTS OF CACAO PODS.

The measurements of fruits have been continued with a view to arriving at a decision as to whether any external characters of the pod can be used for selection of seed. The same results which were recorded last year, and later in a short note in "Tropical Agriculturist" for April, 1901, have been arrived at, viz, that the external shape and size of the fruit affords no criterion as to the commercial value of the seed within, and may often be a most misleading character. The pods examined—more than 1,000 in all—were of all kinds and varieties and on different estates. They were all measured accurately, both lengthways and around the thickest part, and weighed; then they were opened and the number and weight of the seeds and the weight of the fruit wall recorded. The diagrams, produced first in the *Tropical Agriculturist* show more clearly than any explanation the absence of relation between external characters of the fruit and weight of seed.

SELECTION OF SEED IN CACAO PLANTING

The natural method of selection of seed pods with our present knowledge of cacao is to select from a parent possessing the qualities wanted. A heavy cropper, i.e., a habitual heavy cropper, not an occasional big yield, a hardy plant, these are the things to be looked for in selection, if we are to improve our Ceylon cacao. No fruit tree gives better promise, and the wonders which have been achieved in improvement of the European and American fruits are an example to encourage in this direction. An experimental plot which was mentioned in last year's report, in which were planted seeds from a tree which has borne for six years an average of 434 ripe pods, has been preserved and tended, and the plants from this bed will be planted out and carefully watched with a view to their possessing a great deal or in part this heavy cropping character of the parent tree.

POLLINATION OF CACAO.

The pollination of cacao has been again worked at though unfortunately pressure of other matters prevented much time being devoted to this interesting question. That the heavy cropping qualities of some of our Ceylon trees is due to the more effective pollination and fertilization is more than probable, and therefore a knowledge as to the method of pollination will perhaps help us in finding what conditions are most favourable to the setting of a large quantity of pods. So far as my researches in this field go, I have only discovered one animal, an aphid (*Aphides Ceylonica Theacola*, Baxton.) which was carrying pollen grains. This insect I found in considerable numbers in buds and young flowers, and several of them had pollen grains of the cacao adhering to their bodies and limbs. During the next flowering season I hope to carry out an exhaustive series of experiments with regard to the pollination of cacao. Some remarks on this matter in my last annual report were misunderstood, and in letters to the daily papers it was thought that I was attempting some method of artificial pollination. The structure of the cacao flower and other things render this impracticable. In this connection it may be mentioned that inquiries are still made to me about the structure of the cacao flower, owing to an erroneous statement as to "male and female" flowers being at one time published. The flowers of cacao are all truly hermaphrodite, i.e., having both stamen (male) and pistil (female). I have in an examination

of a very large number of flowers, while working at the fertilization, never found any abortion of organs. Cacao seed has been sent to distant parts of the British Empire with a view to discovering the length of time that the seed will retain its vitality under varying conditions. It is important to know the best method of sending seeds or young plants from a distance.

TOURS AND PLANTERS' ASSOCIATION MEETINGS.

During the year I have visited many planting districts, including Badulla, Passara, Monaragala, Dikoya, Matale, Deltota, Dunbarra, Ambagamuwa, and the low-country, where experiments and investigations have been made and material collected for laboratory work. I have also attended Planters' Association meetings at various centres, where diseases of plants and cognate matters have been discussed and explanations given on various technical points. It is a pleasure to record my thanks to many planters for valuable help in investigation of plant diseases and other matters.

J. B. CARRUHIERS,
Government Mycologist and

Assistant Director of the Royal Botanic Gardens,
Peradeniya, January, 1902.

PINEAPPLES, ORANGES, CASSAVA, MANGOES, &c.

REPORT ON THE CULTIVATION OF
PINEAPPLES AND OTHER PRODUCTS OF
FLORIDA.

By ROBERT THOMSON.

(Formerly Superintendent of the Botanic Gardens of the
Government of Jamaica, now Adviser
to Messrs. Elder Dempster & Co. on
the cultivation of Fruit and
other products.)

(Concluded.)

ORANGES.

I visited according to arrangements made at Washington a great Orange nursery at Glen. St Mary, about 80 miles from Jacksonville. Many millions of plants have been propagated here. There are here about half a million plants comprising all the best varieties of Citrus fruits. The proprietor is a well known expert. Orange cultivation prior to the great freeze of 1895, was the greatest industry of Florida, it was the chief "wealth producer" extending over an immense area to the south of Jacksonville. Previous to that great disaster that ruined thousands of families, this region was extolled as the most congenial in Florida for Oranges, for it is recognised by most leading growers that the further north even to "danger point" they grow the more luscious is the fruit. The tallies with our cultivation on the hills. Another frost 2 years ago destroyed the groves connected with this nursery, the trees being frozen to the ground. Thousands of groves were also destroyed by that morning's frost over hundreds of miles of land. Many of the growers are now planting further south in order to escape the frosts. Since last frozen the trees have sprung anew from the bases of the trunks and they now present a splendid appearance having attained a height of seven or eight feet. Several stems are allowed to grow from the base,—most luxuriant stems, branches and foliage. Next year innumerable trees are expected to yield considerable crops. Only a few severe freezes have occurred in about 60 years.

In this extensive nursery thousands of small plants budded two years ago yield from 20 to 40 fruits each. I suggested that many hundreds of small trees could be grown to the acre for early cropping. These precocious trees are budded on citrus trifoliolate stock. Peaches, peaches and plums are commonly cultivated

side by side with the orange. Many of the groves in the great orange region of Orlando that were less severely injured by frost are now in a flourishing condition, far finer trees than any in Jamaica. This is another example of the capability of a sandy soil, in which they are made to flourish by constant care and fertilizers. At this nursery I witnessed a new departure in orange cultivation. A considerable number of plants are under experimental treatment for the Department of Agriculture at Washington, plants that were hybridized a few years ago. There are at least 50 very distinct forms, distinguishable by foliage, etc. These are about 8 feet high, and some of them are likely to fruit next year for the first time. At Miami a few hundred miles further south I also saw duplicates of these new forms at the Government Experiment Station, but much smaller plants. Varieties that will endure more frost as well as superior in point of quality are anticipated from these hybridized types. In the orange plantation connected with this nursery my attention was directed to great piles of logs between some of the wide rows of trees. I was surprised to learn that these piles are placed in summer in readiness for the winter frost. When the temperature falls seriously the huge piles of wood are set on fire to repel the frost by means of smoke, this in the open air. The result is usually satisfactory. Orange groves I noted everywhere are peculiarly sensitive to bad cultivation, that is by allowing weeds to grow, by withholding fertilizers, by insufficient cultivation. Whenever neglected, they languish. The ownership of a ten acre grove has been and is still locked forward to as ample to provide all the comforts of a well-to-do family. Each tree is highly prized, for on arriving at maturity it is valued at from \$15 to \$25. "In an Orange Grove 8 to 10 years old \$1,000 per acre has often been realized." Ordinary manure is deprecated "the benefits of barn manure in an average grove are in serious question. The fruits produced by nitrogen from this source are as above stated usually large, coarse, thick skinned, with abundant rag and of inferior flavour." My attention was repeatedly called to the notorious manner in which oranges are packed in Jamaica. Frequently trained packers have been selected in Orlando, sent a few days journey to New York or Baltimore at great expense and besides paid \$2 a day to rehandle orange shipments from Jamaica, that is to size, pick and repack in boxes for distribution. Orange growers and dealers freely express their surprise at this incredible example of Jamaican incompetency. For be it remembered that the splendid quality of the fruit itself is depreciated. "Fruit which is well known by a brand will often sell readily and quickly for 50 per cent more than other fruit equally as good, but not known to be so by the buyer." Orange and Grape Fruit groves are being largely planted in the vicinity of Miami. Plants three years old budded on small lemon stock yield 100 fruit. The size and luxuriance of the foliage is remarkable. Several of the most successful growers informed me that they did not know 10 years ago the difference between an oak and an orange tree. With determined energy and enthusiasm they have become noted cultivators. Before the 1895 freeze five million crates of oranges were shipped from Florida valued at about fifteen millions dollars. After this freeze the number of crates fell to 100,000. Last year it increased to 750,000 and next season double the latter number are expected. California produces six million crates. In a conservatory at Washington the most famous of all orange trees was pointed out to me, the original plant of the navel variety from which by propagation about half of the orange crop of California has originated. Californians commonly salute this wonderful tree.

Since my return from Florida I have visited the parish of Manchester the chief centre of orange production in Jamaica, more than half of all that are shipped coming from here. One firm alone collects

and ships about 100,000 barrels a year. Great benefit has accrued to Jamaica by the naturalization of plants introduced hundreds of years ago. Thus Logwood and Oranges have spontaneously overrun hundreds of miles of the Island and the former has long been established as one of the staple products. The spontaneous diffusion of a species of plant affords abundant proof of the eligibility of the environments in which it grows. Innumerable orange trees are thus widely disseminated in Manchester. Intermingled with other forest trees they have been subjected to severe condition of existence. Thus they present a dwarf stunted aspect. Practically the only attempt at cultivation has been to destroy the native trees by which they are surrounded with the result that small crops are obtainable. From these semi-wild trees thus reclaimed from the forest the average yield is less than half a-barrel each. A little attention is sometimes bestowed upon groups of trees. For instance, trees occur on the settlers' coffee fields which have to be regularly weeded. Here they occasionally yield several barrels each and they present a distinctly improved appearance. One of the settlers pointed out a considerable group of trees he obtained on land he purchased. A few years ago his first crop was sold for 3s, the following year he had 6 barrels and in the two subsequent years 14 and 62 barrels respectively. The trees are very unequally distributed; in many places from 20 to 60 may be counted on an acre—occupying but a small portion thereof. Commonly from 6 to 12 of these dwarf trees are crowded in a space equal to that allotted to a single tree in Florida. The Manchester oranges are excellent in point in quality. They are sold at 2s. per barrel of about 40 fruits. If they were carefully handled, sized, etc., and packed in boxes the value would be greatly enhanced. It is interesting to note that several gentlemen in this parish are initiating the cultivation of budded trees with very promising results. I strongly recommend medium sized wild trees as the best stock for budding purposes. This can be done on a large scale. The cultivation of Coffee in Manchester is a large industry among the small settlers. The profit realizable can hardly exceed £2 per acre. If the same cultural attention were paid to the cultivation of oranges the returns would be surprising. Instead of an acre, containing irregular groups of desolate orange trees aggregating some 30 to 60, from which 20 barrels may be obtained, 150 of these small trees could be established per acre by the simple process of transplantation. By higher cultivation than that applied to Coffee 300 barrels of oranges would be assured per acre. On the lines I have propounded orange cultivation is capable of becoming one of the great industries of the Island. There are numerous decayed or worn out trees that should be destroyed and replaced by healthy medium-sized trees. Better to cut the transplanted trees well back to induce new and vigorous growth. In the delightful climate of the Port Royal Mountains this tree yields the very best possible fruit. Thousands of acres could be cultivated in lieu of thousands of trees as at present. The moderate application of fertilizers would ensure splendid returns when the soil is not sufficiently rich, this applies to all parts of the Island. All the conditions referred to emphasize our pre-eminent orange growing capabilities, capabilities such as throw into the shade all Florida that culminated with returns valued at 15 million dollars. Our illimitable resources await enterprising Englishmen to embark in orange growing. Limes grow with perfect success, double the size of those that grow on the keys of Florida. On rocky land hundreds of thousands of lime trees could be established at a trifling cost.

CASSAVA CULTIVATION.

It is an interesting fact that Orlando (in Florida) the home of the pineapple shed system of cultivation, is indebted to Jamaica for an important industry. About three years ago an American tourist in Jamaica, Mr.

Perkins, was struck with the value of cassava as a starch-yielding plant. On his return to Florida he organized a company and erected a great factory at Lake Mary, 18 miles from Orlando, for the manufacture of cassava starch. I visited the factory at the end of June and was kindly permitted to see through it, the managers taking a great interest in Jamaica. One thousand acres of cassava are cultivated in the vicinity hundreds of acres of which by gentlemen connected with the factory. There are fields of one hundred acres each which I had the pleasure of inspecting. Within 60 miles of the factory the managers purchase the tubers delivered at railway stations at \$5 per ton, and the culture is extending rapidly. This factory crushes 40 to 50 tons of tubers daily during the cropping season of 4 months. The average crop per acre is 9 tons. This plant grows remarkably well on the all present sandy soil. On the day of my visit to a 100 acres field fertilizers were applied to the field, to the value of \$500. I pointed out that larger returns would be obtained from a better soil, in fact double the crop. The yield of starch from the tuber is from 17 to 20 per cent. It is also noteworthy that the manufacture of tapioca and dextrine from cassava are to be taken up with the least possible delay. The coloured labourers employed in this cultivation are paid \$1 a day. From the planting to harvest seven months are requisite. On account of the winter frosts the seed (stem cuttings) has to be buried in the sand for several months. Great piles of them are thus covered during the winter. The cost of preparing the land for this cultivation is \$40 per acre. This for digging up the Palmetto roots which cover the land. I quote the following from a Savannah Newspaper of June, 29th, 1901, relative to this cassava factory: "Brunswick's Board of Trade held an interesting meeting to-day to hear an informal address from President Perkins of the Florida Starch Factory, and for a lengthy session President Perkins entertained a large attendance. President Perkins is en route to the North, where he will study the needs of various cotton factories in their use of starch, and will still further adapt his factory to the manufacture of products suited to them. At present his firm has about \$100,000 invested in the development of the cassava industry and the enlargement of their plant is one of the near by plans." During my sojourn in Florida, I collected other valuable information regarding cassava as an article of food for cattle, etc. Indeed Florida is determined to make cassava a leading staple product. The matter is discussed everywhere. From the report of the professor at the Florida Agricultural Experimental Station I make the following extracts "With all the facts procurable, and with the experience not only of myself, but many practical farmers to support the opinion, I have reached the conclusion that, all things considered, cassava comes nearer furnishing the Florida farmer with a more universally profitable crop than any other which he can grow on equally large areas. It can be utilized in more ways, can be sold in more different forms, can be more chiefly converted into staple and finished products and can be produced for a smaller part of its selling price than any other crop. It is unquestionably true that cassava, all things considered, comes nearer supplying a perfect ration for farm stock than any other concentrated food produced upon Florida farms. Every beef animal in Florida can be put in the condition of western stall-fed cattle by the simple use of cassava at a mere fraction of the cost to the corn feeders of the west. An acre yielding 40 bushels of corn would at this rate produce 1,187 pounds of starch, while an acre of cassava producing 6 tons would yield 2,400 pounds of starch. It thus appears that cassava is to-day the cheapest known source of starch, costing at present market values of raw material only about one fourth as much as its nearest competitor. Not only therefore does the high yield of starch in cassava place it prominently before manufacturers as a probable new material for the great glucose industry, at present practically dependent upon corn, but more.

over cassava contains two other constituents worthy of consideration in this connection, namely, its 3 per cent. of sugar, against the 0.4 per cent. in corn and 1.68 per cent. of fibre, as compared with 2.20 per cent of corn.

"Manufacturers are now considering the importance of these facts, and there is good reason for expecting the erection of at least two gluco factories in the near future, which will depend upon cassava for their raw material." The same authority says in another report: "The actual profit on the feeding of the cassava steers was 48.42 per cent on the investment. The cotton seed steers returned a profit of 37.43 per cent, and the corn fed steers 14.98 per cent. The difference between lots 1 and 2 is decidedly apparent and shews cassava to be very materially the cheapest and best ration which can be used for fattening purposes. The most astonishing fact, however, is the very great difference demonstrated between the cost and the results of feeding corn and feeding cassava, the difference being almost two-thirds in favour of the latter. Cassava proves itself a most superior beef fattening food. The cost of live weight beef produced by feeding cassava is 1.1 cents per pound, and in 75 days a profit of 59.10 per cent was made by fattening beef upon cassava." The Tampa Herald says "The one thing necessary to secure for Florida an immigration that will convert our pine woods into paying farms, is the discovery and fixed establishment of a money crop; a staple that can be produced on every farm in the state, and which will always bring cash to the farmer in profitable volume so that he can every year have some surplus money to put in the Bank; unless he should prefer to enlarge or improve his farm. Now the Herald believes that this crop can be established by the cultivation of Velvet Beans, and Cassava, and the conversion of them into beef and pork. After all is said and done, meat is the great backbone of the North West, where more good money is made than anywhere else. Let the farmers and owners of lands demonstrate this fact, and they can sell every acre of their holdings to men that will push the stock business. We will have as many people as the land can hold. We will have a village with churches and school in every township. We will have a wealthy and powerful State. We can have it is our firm belief." In addition to the importance of cassava from the foregoing points of view I have the pleasure to state that I directed the attention of the Secretary of State for India four years ago to the utilisation of new varieties of this plant, (the bitter and sweet varieties have been known in one or two localities of India for hundreds of years) among the inhabitants of famine-stricken regions there. I pointed out that the cassava is peculiarly drought resisting, flourishing as it does in arid regions, as well as in humid regions. Thus about 14 inches of rainfall secures abundant crops, whereas for rice cultivation from 50 to 60 inches are requisite. I also pointed out that some of the varieties when cooked as Irish potatoes, rival that edible in point of palatableness. My lectures on this subject have been published in India. A few months ago, I received instructions to furnish two Agricultural Departments in India with these special varieties for experimental cultivation. I have obtained these varieties from Colombia from sections of it, one thousand miles apart. During my residence in that Republic, many years ago, I detected the merits of some of these varieties. Thus co-incidental with the intimation to hand of the great economic importance of one or two varieties of cassava in America, the acquisition of some 23 additional varieties is most opportune. Several of these are exceedingly rich in starch. And I have just despatched to Bombay and Punjab all the varieties. I am forming a nursery of them here, so that vast numbers of cuttings will be available soon. I purpose establishing a plot of each variety, with a view to determine their merits here. I am also forwarding immediately to the Agricultural Department at Washington the entire collection, also of the bitter cassava which is much richer in starch than the one under cultivation for Florida. I am for-

warding a supply for extensive propagation. Millions will soon be disseminated over Florida. Two varieties the "Bitter" and the "Sweet" have been cultivated here from time immemorial; they are also spread throughout the West Indies. Starch is made from the former for household purposes; from the latter cassava cakes are made and frequently the roots are cooked and eaten by the peasantry though the variety is inferior. Small patches are grown everywhere by the peasantry. The total aggregate may be 100 acres, consequently seed cuttings may be obtained for thousands of acres for immediate cultivation. Doubtless twenty thousand tons of root could be produced within a year. The cultivation is exceedingly simple; it thrives under the most diverse conditions of climate, on the Liguanea and other dry plains, on rocky hill sides, as well as on humid plains and hills wherever the soil is friable or gravelly. To obtain large crops it must be planted annually; it may be planted twice a year in Jamaica; the roots or tubers can be dried to keep for scintime; thus the weight is greatly reduced for transport to be brought from distant parts to a factory. I have mentioned that the factory at Orlando is in operation only four months a year. In Jamaica a factory can be kept going most of the year. It is impossible to exaggerate the importance of a great cassava industry in Jamaica. As a matter of fact an acre of it is worth more than an acre of sugar cane. We have cheap labour compared with Florida. The land is sufficiently rich without artificial fertilisers. A peasant can cultivate a few acres, each yielding at least ten tons at \$5 per ton; this is \$50 per acre. A factory here would confer immense benefit on the community.

MANGOES, &c.

Palm Beach is perhaps the most famous Winter Resort in the world. At one of Mr. Flagler's Hotels 400 rooms are added annually. The tropical aspect of the grounds is extremely grand; great avenues of palms, miles in length and forests of palms. The coconut plays an important part; thousands of them commonly 30 feet high are transplanted to command effect. Many other tropical plants are displayed here. There are also hundreds of acres of pineapples and the shed system is strongly advocated. One of the finest plantations is that of Mr. Mattham, and he has several hybrid forms from Washington. Mango and Avocado trees abound here; Mango fruit is extremely popular; hundreds of thousands are eagerly bought at about \$7 per thousand. In the city of Key West the consumption is very large and its popularity is extending northwards, where in the near future it will doubtless become a staple fruit. My programme from Washington included a visit to a noted Mango grower, Professor Gale. He was delighted to show what he has done. Great Indian grafted trees as well as our no. 11 variety are propagated far more successfully than is the case in the west Indies,—by budding, grafting, and inarching. It affords me great pleasure to report that I obtained from the Director of Botanical Gardens at Washington six plants of a new variety of Banana; it is described amongst bananas as "the best fruit of any." My attention will be directed to its propagation with the least possible delay

EUPHORBIACEOUS PLANTS.

The veteran Director of the Botanical Garden, Mr. Smith, whom I have known for 25 years, suggested to me on my way to Florida, to consider and form an opinion, on the practicability, of cultivating Euphorbiaceous plants in this region. I therefore have the pleasure to submit a few remarks. In addition to the characteristic sandy soil of the east coast, another soil rich in humus abounds near Miami, vast areas of it, namely Everglade land. Heretofore nearly all experiments with tropical fruit cultivation have been conducted on the sandy soil, where sub-tropical fruits mingle with purely tropical fruits. In this region frost is practically unknown, coco-nuts thirty years old flourish here, large mango trees, avocado pears with large trunks, some of which must be over twenty years

old, rose apple, tamarind, guava, cotton tree, naseberry (sapodilla), ponciana regia, and many tropical palms. This affords substantial evidence of the capabilities of soil and climate. The widely dispersed pine forests cover great tracts; oaks are scrubby. In this region, therefore, many tropical as well as sub-tropical forms flourish, forms that withstand the reduced temperature of the cool season. At the same time the sub-tropical conditions are typical, for oranges, grape fruit trees, &c., grow with remarkable vigour. I have had a wide experience in the cultivation of valuable economic plants at altitudes ranging from the sea level up to 10,000 feet in the tropics. In this connection, near the equator it is interesting to observe that at an elevation of 6,000 feet mangoes, avocado pears grow side by side with exceedingly fine oranges, just as they do in Florida. At this elevation in the Colombian Andes up to 8,000 feet one of the most important species of rubber is indigenous, I started the cultivation of a plantation of this tree in its native habitat. This plantation was abandoned at the time extensive Cinchona plantations were abandoned. The rubber tree grew with great rapidity, twenty feet high in three years. It is a very distinct form of *Sapium biglandulosum*. More than a year ago I had the pleasure to direct the attention of the secretary of Agriculture to this important plant. I now beg to say that I have carefully considered at the suggestion of Mr. Smith of the Botanical Garden, the conditions at Miami compared with those on the Andes at 6,000 feet. In the forest at this elevation Oak tree abound; there are several species of coniferous trees. Close to Miami I found many indigenous species belonging to natural orders that grow at 6,000 and 8,000 feet in the Colombian Andes, for instance, many forms of Rubiaceae a characteristic order at this elevation (amongst Urticaceae I detected at Miami a congener of Ramie with a beautiful fibre) These analogous conditions couple with the fact that Oranges, &c., flourish at the same elevation at which this rubber tree grows led me to the conclusion that the conditions presented near Miami on the beautiful lands of the Everglades distinctly point to the practicability of growing successfully this species of rubber thereat. Where this tree grows the rainfall is more than one hundred inches a year; it delights in water at the roots when thoroughly drained. Hence irrigation from the beautiful Miami River could be made subservient.

Halfway Tree, August 27th, 1901.

—Board of Agriculture, Jamaica.

THE *HæVIA* "PARA," INDIAN RUBBER:

ORIGIN OF THE INTRODUCTION AND CULTIVATION OF THE TREE.

BY H. A. WICKHAM*

Although advertisements for sale of the seed of Para rubber (*Hævia*) at so much a thousand have now been commonly seen for some time past in all the planting journals in Ceylon and the East, it is not generally known that to the initiation of the Government of India is due the fact that they are within the reach of the planting community at all. Any planter who has had practical experience with the seed of this tree will understand the difficulty which had to be encountered in getting the original stock plants established in the Eastern tropics at such distance from their primitive home in the highland forests of the valley of the Amazon.

In the first instance, so far back as the seventies, the initiation of the Government of India in backing liberally the recommendation of Sir Joseph Hooker enabled me to seize an opportunity, singularly occurring for specially chartering a steamship which happened to be up the Amazon River at the exact time of the fall of the ripe seed in the rubber forest. Had this not been so, I should never have been able to accomplish the feat of securing the large original stock from an only seed so prone to quickly lose vitality.

Just now there seems to be a disposition in some quarters to deprecate the efforts made by the Indian Government as bearing on the method best for the cultivation of the *Hævia*. This seems to be exceedingly short-sighted and ill-advised. As a matter of fact, in the hands of the Government of India, through their forestry officers, all such experimental planting or cultivation cannot be calculated to be other than object lessons of the greatest value to practical planters in all the equatorial colonies, in that it will furnish them with authoritative data (especially the *Hævia*) of a nature to be depended upon.

The true "Para," Indian rubber (*Hævia*) is to be found growing naturally within the immense forest-covered area of the valley of the Amazon and in the tributary rivers, including the head streams of the Orinoco. I found it abundant high up on the Orinoco, above the junction of the Guaviare (the latter stream by right, indeed, should be styled the head stream of the Orinoco). It is plentiful on the banks of the Cassiquiare—that curious bifurcation by which the Orinoco gives of a stream to the Rio Negro, and so converts Guayana into an immense island. I also found it growing in the interior betwixt the Tapajos and the Xingu. The rivers from which the largest supply is drawn now by traders are the Purus and the Madeira. In its native forests it grows dispersed among the other forest trees, two or three trees rarely being found in juxtaposition. In appearance the *Hævia* is a handsome tree, with straight cylindrical trunk—differing wholly from the Ule—the Indian rubber tree (Castilloa) seen in Moskito and Nicaragua to South Mexico. The wood is soft and perishable. The bark, as in the great majority of tropical trees, is not very thick, and is of a grey colour on the surface, but when scraped, approaches the appearance and colour of a light bay horse's coat. This cleaning has to be done, as in moister regions the bark is thickly coated with growths of moss, ferns, and orchids. The seeds grow, three together, in a sort of hard pod. This pod, becoming heated by the sun, bursts when it is ripe with a sharp popping sound, and scatters the seed for a considerable distance around the tree. The seed is exceedingly oily, and the oil extracted therefrom, closely resembling linseed oil, is a valuable product. The range of temperature in the *Hævia* forest is between 70deg. and 90deg. throughout the year. Rainfall varies considerably in different districts where *Hævia* are found, some districts being nicely divided into wet and dry seasons, each of about six months' duration, while in others it rains more or less the year round. In such districts it is more difficult to collect the caoutchouc profitably, as if the stem of the tree is very wet when it is worked, the latex, or rubber-milk, spreads over the surface of the bark, and is in large part lost. From what has been said it may be seen that the main part of the Indian rubber must be collected during the dry season, although "siringaros," who live near their "siringals," or rubber walks, improve their opportunity by tapping their trees whenever fine days occur during the rainy season. But the trees are doubtless better for a half-yearly rest.

When the native bunter has discovered for himself a district of the forest in which "siringa" trees are sufficiently numerous and near together he first connects them together by cutting a "picado," or path, with his bush knife. Having thus discovered their relative bearing, he next straightens and clears out his paths, endeavouring at the same time to

*Planter, and some time Commissioner for the introduction of the *Hævia* (Para) Indian rubber for the Government of India, and inspector of forests.—B.H.

take in as many trees as possible in each path, and to make all the paths converge to a certain spot, where he puts up his "barrica," or curing station. This done, and having collected a supply of the old nuts of the *inaja* (*Maximiliana regia*) or similar oily palm nuts, he is ready to commence operations on the first fine day. There is some diversity in the manner of taking the rubber *latex* in the Amazon Valley. In some districts they prepare long strips from the inner pith of the foot-stalk of the leaf of the *inaja* or of the *bacaba* palm. These are tacked obliquely round the stem of the trees, with sharpened pieces split out of hard covering of the same leaf stalks. These strips, being smeared on the inside with wet clay, form a channel for collecting and conducting the *latex* milk into the cup placed to receive it. In the other method, which I consider the better, the cups are put on in a ring round the trunk, usually a span apart. Three cuts about 1½ in. long are made in the bark with a small axe. In this way the number of cups is proportioned to the size of the tree. Tin cups are used. They are made slightly concave on one side in order to fit the convexity of the tree trunk. They are attached to the tree by the use of a piece of the ball of kneaded clay, which each collector carries in his bag. The tapping always begins as soon as there is light enough in the forest path to see by. One man is usually apportioned to each path, containing say, 100 trees. When he has cupped his trees he sits down at the end of the path for half an hour or so, but as soon as he sees that the tree last tapped has ceased to drip the milk, he starts at a trot on the back track, detaching and emptying the cups into his calabash as quickly as possible. Speed throughout is a great object, as the milk *latex* speedily coagulates, and then can only be sold on the market for an inferior price, as *serwambi*, as compared to that obtained for that which has been smoke-cured. When the men arrive at the central hut from their different converging paths they each empty their quantum of the *latex* taken for the morning's work into one of the large Indian native earthenware pans, usually used as a receptacle. Care is taken to squeeze out with the hands all of the already coagulated crnd-like masses. These are thrown on one side to be made up into balls. Earthen pots in form of miniature kilns are placed over small fires, and the "siringero" sits down to the really tedious part of his business. He drops a handful or so of the oily palm nuts down the narrow neck of the kiln, and forthwith arises a dense smoke. Taking a wooden mould—like an ace of spades in form—and holding it over the pan, he pours some of the *latex* over it in a thin film keeping it turned, so that it shall not run off before he succeeds in setting it to an even surface, which it soon does as it is passed backward and forward through the column of smoke. This is continued, one coating after another, until he has finished the day's supply of rubber-milk. He then sticks his mould up in the thatch of the roof of the shed for the repetition of the process next day, and until he finds the thickness of the *biscuit* makes the mould unwieldy to handle, when it is cut down one side, slipped off, and stored. This is the native method, which can without doubt be improved upon under conditions of systematic cultivation.

But as all the stock of plants or seed available for the planting and cultivation of this tree in the Eastern tropics are and will be derived from direct lineal descendants of some or other of those 7,000 odd originally introduced by me at the instance of the Government of India in 1876-77, it may be well if it be recollected that their exact place of origin was in 3deg. of south latitude, and to remember their natural conditions there. This the more so since a very general error seems to have obtained that swampy or wet lands are the fitting locality for the *Hevia*. This would seem to have arisen in that the "explorer" of a few years' ex-

perience would have some of these trees pointed out to him (naturally in answer to enquiries) growing scattered along the wet margins in going up the lower Amazon or tributaries, whereas the true forests of the "Para" Indian rubber tree lie back on the highlands, and those commonly seen by the enquiring traveller are but ill-grown trees which have sprung up from seeds brought down by freshets from the interior.

As a matter of fact, the whole of the *Hevia* which I procured for the Government of India were the produce of large-grown trees in the forest covering the broad plateaux dividing the Tapajos from the Madeira rivers. The soil of these well-drained, wide-extending, forest-covered tablelands is a stiff soil, not remarkably rich, but deep and uniform in character. The *Hevia* found growing in these unbroken forests rival all but the largest of the trees therein, attaining to a circumference of 10 ft. to 12 ft. in the bole. These forest plains, having all the character of widespread tablelands, occupy the space betwixt the great arterial river systems of the Amazon, and present an esorped face, which follows, at greater or less distance, and abuts steeply on the *igapo* or *bagas*—*i.e.*, the marginal river plains—subject to inundation by the annual rise of the great river. So thorough is the drainage of this highland that the people who annually penetrate into these forests for the season's working of the rubber have to utilise certain *lianas* (water-bearing vines) for their water supply, since none is to be obtained by surface-well-sinking, in spite of the heavy rainfall during great part of the year.

The *Hevia* is much more amenable, better adapted for systematic cultivation, planting, and working than any other of the rubber-yielding trees with which I am acquainted—for instance, the *Ficus elastica* of the Eastern tropics or the *Ficus regia* of New Guinea, and probably of Malaya; the various species of jungle rubber vines of the East and of New Guinea and tropical Africa; and, to a less degree, the *Castilloa* and *Ceara* of tropical America. The remarkably shapely cylindrical form of the lower trunk (the workable part of the tree) from the ground upward renders it singularly adapted to regular extraction of the rubber *latex*, and although the *latex* of the *Hevia* does not appear to lend itself to the process of separation by centrifugal separating machines, as do the *Castilloas* of Guatemala and Southern Mexico, the "Para" rubber, produced by a simple smoke process which has been devised, always commands the best market price.

In New Guinea I was in 1894 first to discover a vine growing in the forest there which produces a very fine quality of Indian rubber. There is also a large forest tree, native of these forests, (a species of *ficus*) which yields a good class of rubber in quantity. None of these, however, being so suited (so amenable) to cultivation in plantation as the "Para," it is much to be recommended that cultivation of the *Hevia* be encouraged in that late and undeveloped possession of the British Empire. Now that it has been established in the East, there should be no great difficulty in bringing it down from Singapore; and I have myself seen large tracts of forest and jungle land in New Guinea which are admirably adapted for the planting of this, the premier rubber-producing tree.

The conditions required for the successful and profitable cultivation Para (*Hevia*) Indian rubber are in my opinion, that it be regarded as a plantation—a cultivated product—rather than as one to be planted with view of being widely disseminated, under canopy, of an area covered by primitive standing forest. This opinion, formed at the time of the original introduction of the *Hevia* to cultivation at the instance of the Government of India in 1876, has been strengthened by subsequent years of planting experience; and I am convinced that any advice for the setting out of the *Hevia* rubber-tree as a self-disseminating forest product—*i.e.*, planting it out under canopy through wide areas of existing forests or jungle—will be

found to be founded on fallacy. The *Havia* has no light-winged seed, as mahogany and others. On the contrary, although the seed is scattered to some extent around the parent tree by the bursting of the ripe trifoliate pod, it should be remembered that the seed is in form an exceedingly heavy and oily nut, and falls thickly in a circumscribed area. Even there it is exceedingly attractive to every four-footed creature of the jungle, who devour it greedily. In its own forests it owes its preservation only, as I think, to the fact that very venomous and large snakes, the *saracucu*, are in the habit of lying in wait about the base of these trees in seeding time, and so ward off to a great degree the agents, Indian rabbits, and other rodents. Forest deer, also, in my experience, are very destructive to the young plants. In any case I have found that *Havia* take at least three times as long to come to productive size grown under forest shade as under plantation cultivation free from top shade. Lateral shade to the extent required, at first, for formation of a straight trunk form is readily got by allowing intermediate "second growth" to come up between the young *Havia*. For myself, I have known these trees, when grown in the open, seed abundantly in three years, whereas they would have taken 10 to 12 to do so in the shade of the woods. It is therefore recommended that *Havia* should be systematically grown in cultivated plantation. For spacing distance I advise the half chain (33ft. by 33ft.) diagonal, as giving more root scope. This gives 40 trees to the acre. Besides being a good distance, the half chain is of practical advantage in marking off forest land, as by opening lines with the prismatic compass or theodolite, the man following can plant the seed to stake as the chain is drawn over the lines. As soon as the young trees attain proper trunk form the more light and air they are given, and the cleaner they are kept, the stouter and quicker will be their growth, and in the fourth to fifth year they would be in condition to yield to a first tapping for rubber latex—say, by using two cups taking on an average a pound (1lb.) of rubber during the drier season of that period. The empty tins used for "preserved milk" answer admirably for this purpose, as they are of about the right size, and being made of thin tin readily bend to the shape of the tree trunk. The operation if carefully done will not arrest the growth of the tree. It is rather shown from experience that accumulation of the latex in the bark of the trunk of the trees is augmented thereby. For purpose of extraction there has yet, as I think, been no better instrument devised than the ordinary carpenter's chisel, carefully used with a light mallet. The cuts (three oblique cuts one above another, should be clean cut, and should not penetrate into the wood of the tree. Caution should be exercised in this respect, as if the wood is injured certain species of boring beetles attack the tree. The spacing should be about a span apart, one circle round the trunk of the tree beginning at the ground surface for each day's tapping; and so giving an increased number of cups in use as the tree grows in circumference, with proportionate increase in yield of the latex.

One advantage of the close system of cultivation recommended, besides greater economy in working is that centrally-placed curing stations can be secured. This is necessary in order that the latex may be quickly treated, so soon as it is taken from the trees, or much of it will become coagulated before it could be subjected to the smoke-curing process, and so lose the higher market value.

The *Havia* is naturally a large tree, under favourable conditions attaining a girth of 12ft. in the bole. To stint it in matter of root space or scope will be found to be false economy. I would, therefore, strongly deprecate closer planting than that recommended—half chain (33ft. by 33ft.), 40 to the acre. Planted and cultivated at this distance, and giving say, 5lb. of rubber per tree at 3s. only per pound, it would yield at the rate of some £30 per acre for sale

of rubber alone, apart from value of the seed crop, to be converted into oil worth £25 to £30 per ton.—*The Contract Journal*, Jan. 8, 1902.

COFFEE CULTIVATION.

The Cultivation of Coffee throughout the world is the subject of an interesting geographical study, illustrated by maps, by M. H. Lecomte, in *La Géographie* June 1901. The subject is treated in three sections: the geography of the natural species of Coffee; the distribution of coffee-growing throughout the world; and the consumption of coffee in various countries.

The coffee-plant belongs to the genus *Coffea*, of the family Rubiaceæ. The latter, which is the fourth in the numerical importance of its species, is distributed chiefly in the warm regions, and no travelling botanist can fail to remark the great abundance of the Rubiaceæ in tropical forests. This family is, on the other hand, poorly represented in temperate lands; although it includes, in all, more than 300 genera and 4,000 species, there are no more than 6 genera and 60 species in France, and only 14 species in Belgium. The tropical flora is incomparably richer in the Rubiaceæ; indeed, it would be easy to show that the family is one of the most extended in tropical regions. Oscar Drude states that 75 per cent. of its species are tropical and affect especially the hot, damp forests. Of 712 species of the Congo Free State, described by Durand and Schinz, the Rubiaceæ come first with 75 species, the Leguminosæ second with 73, then the Compositæ with 64, and the Labiata with 33. This family includes a considerable number of useful plants, e.g. *Cinchona*, *Cephalis*, *Ipecacuanha*, *Rubia tinctorum*, *Uncaria Gambir*, etc.

The species which is most cultivated is *Coffea arabica* L. Notwithstanding the general opinion, it is improbable that the shrub is a native of Arabia, where it has never been found wild; it has, on the other hand, been long known in Abyssinia, where it is called *Boun*. The Abbe Raynal thinks that it is a native of Abyssinia, and that it was carried into Arabia by Ethiopian conquerors; and Charles-Jacques Poncet, who travelled in Ethiopia in the years 1698, 1699, and 1700, reports the cultivation of coffee in that country.

This is not the only species which is native to Africa; a large number are known both on the east and west coasts. On the west coast there are 22 species. The indigenous species of Asia are all mountain plants.

Of the numerous species of coffee the *arabica* is the only one largely cultivated, though recently one or two other species have been grown to a small extent; but all the species which can be utilised belong to that region in Africa between 15° N, and 15° S, latitude. The Asiatic varieties have no commercial value, and in America where it is so much grown it is not indigenous.

Till the beginning of the eighteenth century Arabia held a monopoly in the cultivation of coffee. It was shipped to Europe direct from Arabia by the cape, or was purchased in Egypt, whither it had been brought across the Red Sea. Attempts to grow it from the bean were so unsuccessful that it was supposed that the Arabians soaked the beans in boiling water or dried them in hot furnaces. At the end of the seventh century however, the beans germinated perfectly at Batavia, so that to the Dutch belong the honour of first acclimatising the coffee plant outside Arabia.

The Governor of Batavia sent a plant to Amsterdam and a specimen was brought to France by Lieutenant de Ressons. It was placed in the *Jardin des Plantes* at Paris and bore flowers and fruit, but did not live long. In 1714 the magistrates of Amsterdam gave a new plant to Louis xiv., and it was sent to the royal garden in Paris. From this coffee plant sprang those which were transplanted and have multiplied in the French colonies. The first attempt at acclimatisation was made at Martinique in 1716, but this was a

failure. In 1723, however, Captain de Clieux, who was voyaging to Martinique, was intrusted with a plant. The story of his devotion has often been told: the passage was long and perilous, and fresh water became scarce. De Clieux, who was impressed with the importance of his commission, and anxious to secure a new source of wealth for his country, shared his meagre supply of water with the precious shrub, which, thanks to his care, reached Martinique in good condition. At the first harvest it yielded two pounds of beans; these were distributed over the Island, and in February 1726 there were nine trees twenty months old, 2,000 smaller ones, and many more just above ground. An unfortunate event hastened the development of coffee culture. Till then the chief industry of the country consisted of cocoa plantations, but a severe earthquake, in 1727, destroyed the plantations, and the colonists in future grew coffee instead of cocoa. Soon Martinique produced more coffee than could be consumed in France.

From Martinique the coffee plant was carried to the other Antilles, and to Central and South America; and now, after less than two hundred years, the countries of America and especially Brazil, are the chief producers. In Java, where the first attempts at acclimatisation were made about two centuries ago, the development of the industry has not been great; Arabia, which used to supply Europe, now produces a very small quantity; and Martinique at present produces scarcely enough for home consumption, and Brazil, where cultivation was insignificant a hundred years ago, is now the great producer.

Numerous and very various are the circumstances which determine the principal subjects of cultivation in any country. The full study of these conditions is of great interest, but only a few of them can be mentioned, such as climate, character, and fertility of soil, means of communication, cost and quality of labour, the history of colonisation, the influence of governments, the taxes in the lands of production, and the tariffs, in those of consumption.

As regards the New World, one may say roughly that coffee is cultivated between the tropics; but not all sections of this vast region are equally suitable for it. In the east there are no important plantations near the Equator; in the west on the contrary, there are very extensive plantations in the state of Ecuador, for the high mountain chain makes it possible to cultivate at a considerable altitude and also prevents that dry season which occurs in all mountainless equatorial regions. This is certainly the reason for the success of coffee growing in Ecuador; for close to the sea, where the annual rainfall is very small, it is not possible to grow it. The same may be said of the coast of Peru.

Brazil is the choice country for growing coffee. Till the beginning of last century Brazil did not grow much, but now it produces three fifths of the coffee which finds its way to the markets of the world. At first the plantations were confined to the province of Rio, then they stretched north to the province of Spirito Santo, latterly they have been extending south into San Paulo and even into Minas Geraes. Some of the plantations are enormous. There is one, thirty kilometres from Ribeiro Preto, which covers 6,000 hectares and contains 4,700,000 coffee bushes. 8,000 Italians are employed to work it. It is estimated that in the year 1900-1901 Brazil will have exported 9,000,000 bags of coffee.

Coffee is also grown and exported by Dutch Guiana, Venezuela, Colombia, and all the states of Central America; Cuba, Jamaica, Porto Rico, and Martinique, all produce a little, but not so much as formerly. In Africa, coffee is grown principally in Abyssinia and the Congo State. The industry has also spread to many of the islands in the Indian and Pacific Oceans.

The countries where most is grown are between the tropics, but not close to the equator. The New world holds the first place, actually producing five-sixth of

the world's supply, and this accounts for the influence of the American harvest on the price of coffee. Since 1895 the price has been going down steadily, because of the enormous Brazilian crops. These, however, come from the virgin soil of the province of San Paulo, and its productiveness is bound to diminish unless the planters enrich the soil, which they can scarcely afford to do at present prices.

It is difficult to estimate the amount of coffee used in the countries where it is grown, but very easy to arrive at figures for non-producing countries. France uses about 1'82 kilog. per head per annum, England '39, Belgium 3'45, Russian 1'15, Italy 1'42, United States 3'95. Several facts are worth noticing in this connection. Northern European countries drink a great deal more coffee than Southern European. In all countries where the consumption is important it increases rapidly each year. The small amount used in England is counterbalanced by the large consumption of tea. The use of coffee is steadily increasing from year to year, and the increase would be still more marked if both coffee and sugar could be imported duty free; but the influence of tariffs must not be over-estimated, for the duty paid in France only amounts to two centimes on every cup. The fact that more coffee is used in France than in Spain, and more in Sweden than in France seems to indicate a decided climatic influence on the use of such beverages as tea and coffee.—*Scottish Geographical Magazine*.

FIBRES:

RHEA FIBRE CULTIVATION IN CHINA AND INDIA.

INDIA NOT A FAVOURABLE FIELD.

The writer has had considerable opportunities of investigating this rather vexed question in both countries, combined with some practical experience, and in the former country, under the auspices of the Chinese Government.

As various schemes are being continually brought before investors in this country, and considerable sums of money lost in attempts to bring them to a practical conclusion, to which in former times the Indian Government have on more than one occasion lent financial encouragement, the information the writer has gained may possibly be of some interest to the planting and commercial community.

First, investigations were made in India as to whether the extended area of cultivable land available, through the completion of the various Government irrigation schemes, such as the Periyar, would afford any opportunities or advantages to the people in the introduction of rhea cultivation.

The experience of the authorities, however was that all land as it became available under these schemes, and was thrown open to cultivators, was easily disposed of to native buyers for rice, etc., cultivation. So long therefore as land continues to be eagerly taken up for the production of food stuffs, there would apparently be no public object gained in replacing their production by fibre cultivation, unless the latter could be sandwiched in as a rotation crop. Rhea not being an annual but a permanent crop, and not succeeding in flooded land such as rice districts, it is therefore not available for that purpose as jute would be.

Generally the conclusions so far come to, do not establish that India in any part, is in any sense a favourable field for the introduction of the industry.

There is no doubt that China is at present the only country of production in commercial bulk, and it remained therefore to be seen whether investigation into the conditions of successful cultivation in that country would throw light upon, and explain the reasons for, its non-commercial success in India, and elsewhere.

The production in the provinces of Hupeh Hunan, and Szechuen is very large. For manufacture into the finest classes of goods, much of it is shipped to

Canton, Swatow, and other Chinese ports, and the whole production is practically consumed internally, the small export to Europe being of no account. The fibre fulfils all the purposes in China that flax does in England. Clothes for summer wear, shoe, thread, fishing nets, bow strings, twine, rope, and sail cordage, etc., etc.

Investigations into, and practical experience of the Chinese methods of cultivation, revealed much that was useful and instructive, and practically, the writer thinks, explains the whole position, and not favourably possibly to the introduction of the industry in India or the Colonies, under European supervision in large blocks, *i. e.*, on the estate system.

The fibre is undoubtedly indigenous in China, growing as a weed along the roadsides, and in the crevices of the City Walls, therefore, even the delicate seed must find a congenial home and survive the winter, which is sometimes as severe as in England, but of course the commercial yield is from cultivation solely. Now in India, it is difficult to produce from seed with the greatest care, and where the plant has been imported into a new district, the seed absolutely will not germinate, presumably from the absence of a fertilizing agency.

The experience of cultivation in India, was that taking freshly felled forest land with rich alluvial soil, the plant gave luxuriant crops of great height for about 15 months, gradually declining, and the ground was then so completely exhausted, that weeds would hardly grow.

The plant of course is purely a surface feeder. In a short time the roots meet, and become a solid block, and although of course all experiments in digging, root pruning, and turning up the soil were exhausted, and are practised, the plant being a permanent one and not an annual, it is not really possible to give the plant fresh turned soil in an efficient way after each crop, without taking the whole plantation up, which, of course would involve interruption to growth, for the best commercial crops are not really gained until the second year. The writer believes the experience of other planters has been the same, not only in India, but other places, and such manuring as is within the average range of an Indian planter, say once a year even, including replacing stems and leaves, did not put the land into condition again or produce any commercial results, even such manuring as that would probably be impossible in large blocks.

How then do the Chinese continue to produce successive commercial crops? In China every particle of human excrement inclusive of the cities is conserved and put on the land, and there is little doubt that if we ever interfered with their system, by our sanitary regulations, we should probably ruin the country. The liquid manure collected in tanks, after a sufficient time to a low fermentation is brought down to the river and shipped in junks by contractors who supply the farmers; the solids are deposited on the river banks, turned over, mixed, tempered, fermented and then similarly dealt with. It is all applied to the land in the liquid form and the Chinese will not use animal manure in preference, or on the same level, on the ground of want of strength.

The China Grass receives two applications of the strongest liquid manure *each* crop, starting from the time of planting, first immediately after cutting crop, and the second in ten days, and a plantation is calculated to last about ten years, the roots being cut from time to time. Even with all these advantages, while the results are successful and commercial, there are no points to give away as regards the value and length of the crop.

This it appears is how the exhaustion of the land is got over, and successive crops maintained, and it would appear, therefore, to be idle for anyone to embark in any cultivation schemes, except they can find at least equally favourable conditions as the Chinese possess, *i. e.*, they must be prepared to manure richly twice in each crop. This condition does not appear likely to fall in with large blocks under European ownership and

supervision, although reference may be made to the possibility of artificial fertilizers, the result would be exceedingly dubious, if only on account of their slow assimilation, in a necessarily quick growing crop and of finding the right one, combining all the necessary elements in a form that can be at once drawn upon by the plant.

The statistics and estimates of yields, etc., which often occupy so important a place in prospectuses seem to be really of very little importance. The land responds exactly in proportion to the generosity of treatment it receives, yield is heavy or light in proportion. There is no difficulty in getting a remunerative yield, given the necessary conditions. However rich any available site of virgin forest soil may be to start with that practically only governs the situation for the first period of 15 months. When in any case manuring must begin on the Chinese system, and the real question is always the average yield over, say 10 years. Sites therefore are not of premier importance.

The only point of importance or improvement the writer could see that could be added to Chinese methods, is that they do not trouble to irrigate. Thus on a dry season, they often lose the best growing time, *viz.*, the hot weather, and a short length crop follows, This is well known on the market.

There are, however, some other very important details to be learned from the Chinese. The writer has seen in European hands, the crop laboriously gathered by cutting each stem with a knife, with much injury to the young shoots that are to form the next crop. The bulky result containing only 3 to 5 per cent. Fibre is then bundled and carried off the field to the factory, decorticated by machine or hand, and the refuse, stems, etc., actually carried back and spread over the land.

The Chinaman knows better, and does not cut the crop at all. He simply snaps the stem near the root whereupon the fibre opens of itself at the break into two ribbons, inserts his fingers, runs them up, and with a slight pull decortication and cutting are done at one operation, actually taking less time, than mere cutting would do, and leaving each stem and its leaves on the ground in their own place. Thus the whole cumbersome foreign method and its immense cost and extra labour is disposed of at one stroke.

It is evident therefore that decortivating machines have no place, and are absolutely superfluous, because the stems would have to be cut, if they were used, and this, together with the handling the bulky crops of stems on and off the field that has been the bugbear of all European devised scheme, are difficulties that really never existed if an investigation of existing method in China had been made.

The operation above mentioned of course gives ribbons with the brown pellicle on, and where these have to be cleaned, which with modern degumming processes is not at all always essential, the Chinese method has been again grossly exaggerated in difficulty and cost, I have seen descriptions stating that each ribbon was tied to a book and tediously scraped with a knife, the work being only one pound daily. As a matter of fact the Chinese cleaner has a knife sharpened like the blade of a trowel, which he holds in the palm of the right hand, on his thumb attached to a ring he slips a small piece of bamboo, he then takes a *handful* of ribbons (green) in the left hand, and draws them rapidly between the knife edge and bamboo, then reverses and cleans the hold end. The whole thing is exceedingly simple, quick and easy, and the average work tested is 10 lb. cleaned dry fibre per man per day, and as it is really done either in spare time or by the women and children, of no cost as regards any competition by decortivating machines.

In any case if decortivating machines were used the cultivation difficulty being first got over, it would obviously be more economical to decorticate the stripped ribbons in the machine for the purpose of cleaning (gathered in the Chinese way) than the bulk of stems, with the carrying off and on the field

Three crops are taken in the year, the time for growth and maturity being about the same as in India, viz., about six to seven weeks.

The writer does not go into the question of yield, which appears satisfactory because the matter seems more to turn upon the other points mentioned.

The native yarn is spun without any twist, which gives it great covering power in the cloth, that is the cloth will be 30-40 closer, or less threadbare, than if made from machine-spun yarn of the same weight, and being spun in the gum, it is perfectly smooth and hairless, without any expense in finishing machinery as is required in machine-made yarn and cloth. The hard grass is wetted, and then shredded into the requisite size, the lengths being joined by a dexterous twist of the fingers, as the thread is wound on a reel continuously. Yarns of astonishing regularity and fineness, are thus produced, and the operation is surprising in its dexterity and result.

It may be interesting also to mention that the Chinese are extending the cultivation of jute, and with the immense area of rich alluvial soil they possess in the great river basins, and their powers of cheap production, India may shortly be seriously threatened in this industry.—*South of India Observer.*

THE ORANGE.

At a recent meeting of the Renmark Agricultural Bureau Mr. C. R. Rose read a paper on "The Orange" to the following effect:—

The orange is of comparatively modern introduction in horticulture. It is not mentioned in the Scriptures, nor by Herodotus, who lived five centuries before Christ, and who wrote a list of fruits then known, nor by Virgil, who wrote much about such matters 100 years before the Christian era. The orange came originally from the south of China, Burmah, and India. It is found growing wild in the jungles in various parts of India. The Arabs introduced the orange to their country, and thence it got to Syria and Southern Europe. This was probably the bitter orange. The sweet variety was brought to Europe about the fourteenth century by merchants of Genoa or Portugal. Thence the tree was passed by the Spaniards and Portuguese to the Azores and other parts of the "New World," and found congenial conditions. Mexico, Florida, California, proved to be highly suitable. The St. Michael orange originated in the Azores; the Pernambuco and Bahia, (or Navel) were both named after provinces in Brazil. The orange is now found growing in nearly every country where there is enough sunlight and absence of severe frosts. The orange tree seems to thrive in many different kinds of soil. In the Azores the soil is intensely volcanic, which is highly suitable, but in Renmark the tree grows on sand and on stiff clay with equally good results, but the growth is more rampant on the sand, so that it may be fairly concluded that as long as there is sufficient nourishment and moisture in the soil, combined with proper drainage, the orange will do well. The essential in nourishment are chiefly potash, nitrogen, lime, and phosphoric acid, together with several other substances in small quantities, which are almost universally distributed in all soils. Even when all the necessary constituents of plant food are originally present in the soil some or all of them will in time become more or less deficient when crops of any kind are grown without restoration by means of fertilizers. The farmer's land is not racked by crops all the year through, but the orangery is making calls on the soil during the whole time. It is a mistake to starve fruit trees, but the application of manures on too liberal a scale will produce a rank growth of wood with little or no fruit, or there may be an excessive crop of undersized oranges. The first defect is due to too much nitrogen, the other to an excess of phosphoric acid and lime. A moderate dressing with fertilizers each year is better than one heavy application every three years. If a tree has sparse and few leaves, and

there is no lack of moisture, we may reasonably conclude that nitrogen is lacking in the soil, but if there is vigorous growth and little fruit it is probable that lime and phosphoric acid are needed. Drainage is necessary where there is an excess of water, but with the scanty rainfall and regular irrigation at Renmark the danger is reduced to a minimum, the ground should be kept damp, but never swampy. In winter the soil must be kept moist, as at that time the trees are maturing a crop and forming buds which are to supply the crop of the succeeding year. Moisture in winter prevents the tree suffering from the effects of frost. Renmark settlers cannot wait long enough to propagate trees, so they must procure them ready for planting out from the nurseries, and they must carefully guard against the introduction of Icerya purchasi and other insect pests as well as fungus diseases. There should be a law against the introduction of diseased trees as well as against diseased fruit. There are about twenty-five species of fungus diseases, and very many kinds of borers, scales, beetles, caterpillars, and other insect pests affecting fruit trees and vines in Australasia, but very few or none of them at present are found at Renmark. We owe it as a duty to ourselves and our neighbours to maintain a vigilant lookout for the first appearance of any pest or disease, and should such appear to use the most vigorous and effective means to at once suppress it. The essayist here drew attention to a pamphlet issued by the Agricultural Department of New South Wales dealing with such pests and diseases and the remedies to be adopted. He might also have quoted a similar pamphlet issued by the Central Agriculture Bureau of South Australia some time ago. He objected to the cyanide of potassium treatment for insect pests, because the cyanide gas is very poisonous to human beings, and because the application must be made when the sunlight is strong, but both objections are untenable in the face of the great efficacy of the treatment, and the fact that arsenates are constantly used with safety although very poisonous.—Gen. Secretary.] Newly-planted orange trees must be sheltered, the soil must be constantly maintained in a free and open condition by the use of the hoe, especially beneath the branches of the trees, where there is a favorite breeding harbour for grubs and all sorts of insect pests. In regard to pruning the orange tree should be in a solid compact mass, like a well-built haystack. To attain this allow the tree to grow in the centre, and at the same time shorten the lateral branches. The fruit should be gathered with great care to avoid bruising. In August, 1895, the writer planted 600 orange trees, and now the average height is 10 feet., girth round the branches 30 feet., the butts at 1 foot, from the ground average 15 ft. These are Washington navelles, Seletta tree, six years old, which produced 500 oranges. The fruit from this orangery has taken eight first prizes at shows in Adelaide, Mildura, and Renmark. Much damage is done to Renmark fruit by exposing the cases on open trucks, covered with a tarpaulin, between Morgan and Adelaide, when the shade temperature reaches 100 deg, or more. Some effort should be made to secure an alteration in this respect.

Discussion took place upon the best kind of stock to bud or graft the orange upon, but no conclusion arrived at. Re-fumigation Mr. Rose said the cost of fumigation with hydrocyanic acid gas is very small after the first cost of tents, and that fumigation kills every insect on the tree, whilst spraying always misses a number of them.—*Adelaide Observer.*

RUBBER CULTIVATION IN VERA CRUZ.

TO THE EDITOR OF THE "INDIA-RUBBER AND GUTTA-PERCHA JOURNAL."

DEAR SIR,—I will in this letter confine myself to the work in the nursery. After the woods are burnt off, the best location for a nursery should be selected,

if possible somewhere near to the centre of the land to be planted, as rubber plants, if well grown, are very bulky.

The selection having been made, begin by gathering up all the unburnt logs, place into piles and burn. Then dig the whole location over with mattocks or pickaxes, about one foot deep, taking out all small trees less than 6 inches thick; pile all this on one side of the nursery, as it will be too green to burn. Now go to work with a good stump puller, and pull out all the stumps that the machine can handle without breaking it, or the wire cable. Very often it will be well to help the puller by cutting the roots of some of the largest of the stumps. As soon as they are pulled out, all the earth between the roots should be dug out with mattocks, so as to allow the stumps to dry as soon as possible, when they can be burnt or removed to one side.

As soon as the stumps are all removed, go to work and rake up all the chips, clean, carry them away, then level off the ground, because pulling the stumps make very large holes; now plough the ground about 6 inches deep, then harrow with a good heavy harrow and cross harrow, and if the clods are rather large go over the ground with a roller. Now the land is in good shape to begin work in a workmanlike manner. First lay out two roads, one across the centre, the other at right angles; now the nursery is in four parts, and ready for the seed.

It is of the greatest importance that the seed is of the very best. Last year we purchased seed from an American, as well as from some native planters. Of course, we marked the different seed, or rather the location, but, to our sorrow, that was not at all necessary, as the seed from the American planter germinated at least 95 per cent., while the other germinated about 25 per cent., and very poor plants at that. So the first thing to do is to be certain that the seed is from a reliable person, then go ahead,

Get good hard wood pegs 2 feet long, pointed at one end; now stretch your line across the upper end of one of the quarters, close to the road, which should be 4 feet wide; now with a rule measure 2 feet from the starting point, drive your peg, and so on at every 2 feet, until the whole is marked out; then go the opposite side and do the same, beginning near the centre line and running full across the same piece of the nursery, and, of course, exactly opposite to the first line of pegs. All the rest of the nursery is to be done in the same manner. Now run lines of very stout cord from peg to peg across the quarter to be planted. Open out the lines with a rake and just 1 inch deep, drop in the seed as soon after the lines are opened as it is possible, so as to save the moisture; drop in the seed just 2 inches apart, and cover at once, using the back of the rake for this operation. I have been particular in describing the work in the nursery because the nursery is the foundation of the plantation. Any slipshod methods tolerated in the nursery will for ever show in the plantation.

I prefer to make the lines 2 feet apart for the reason that a small cultivator can be used between the lines for keeping the weeds down while the plants are very young, after they have grown 1 foot high one hand weeding will be all that is necessary. Some planters may think that 2 feet apart is not enough, but they should remember that we are not after primary branches, or secondary ones, all we want in the young rubber plant is a good straight stem. In coffee, for instance, we take the crop from the branches, but rubber is taken from the

trunk of the tree; besides, all branches of the rubber fall off until the tree is at least 12 or more feet high.

The nursery, as I have said above, is the most important part of the plantation; so I will close with the promise that in my next letter I will treat on pitting digging the plants trimming, carrying to the field, distributing and planting. This latter requires great attention. For instance, we are to plant out 1,500,000 rubber plants in the coming season in a given number of days; so we have to find out how many holes a man can make in a day, how many plants a man can dig and trim in a day, how many he can carry out to the field, how many boys will be required to distribute the plants in front of the planters, and how many plants a man can properly plant in one day; this being done, the question of getting the men to do this amount of work in a given number of days has to be thought out.

Rubber planted out quick after the beginning of the rains shows up the best, and with fewer vacancies than those planted later. Of our last season's planting, those plants put out at the beginning of the rains show up very much better than those planted last, although we were only 28 days planting 340,000 plants.-- Yours truly,

JAS. MAUNDER.

THREE WAYS OF FEEDING MILK TO CALVES.

Twenty head of grade Shorthorn and Hereford calves were purchased by the Kansas Experiment Station in the spring of 1900 and divided into two lots. One lot was fed on sterilized creamery skim-milk, with a grain ration composed of equal parts of corn and Kafir-corn meal, with all the alfalfa hay they would eat. The second lot was fed the same as the first, except that fresh whole milk was used instead of skim-milk. In addition to these two lots the station secured the privilege of weighing 22 head of high-grade Hereford calves which were running with their dams in a pasture near the Experiment Station.

RESULTS WITH SKIM-MILK.—For the 22 weeks under experiment the 10 calves consumed 24,736 pounds of skim-milk, 1,430 pounds of corn chop, 1,430 pounds of Kafir-corn meal, and 641 pounds of alfalfa hay. The total gain was 2,331 pounds, or a daily average of 1.51 pounds per head. Figuring skim milk at 15 cents (7½d.) per 100, grain at 50 cents (2s. 1d.) per 100 pounds, and hay at \$4 (16s. 8d.) per ton, the total feed cost of raising these calves was \$52.68 (£10 19s. 6d.), or \$5.27 (£1 1s. 11½d.) per head. The feed cost for each 100 pounds of gain was \$2.26 9s. 5d.)

Cows that are milked will produce larger yields than when suckling calves. According to the average yield at this station, 10 cows (one for each calf) produced 55,540 pounds of milk, testing 3.93 per cent. butter fat. With butter fat at 15½ cents, (7½d.) per pound, this would amount to \$338.52 (£70 10s. 6d.) The value of the skim-milk not needed by the calves would raise this to \$374.24 (£72. 19s. 4d.) Deduct from this the value of the feed consumed by the calves, and there remains \$321.56 (£66 19s. 10d.), or \$32.15 (£6 13s. 11½d.) per calf to pay for the expense of milking, feeding the calves, and hauling the milk to the creamery. At 12½ cents (6½d.) per hour this expense need not be one-half of the above sum, leaving \$15 (£3 2s.

6d.) to \$16 (£3 6s. 8d.) clear profit for each calf raised on skim-milk.

RESULTS WITH WHOLE MILK.—During 22 weeks these 10 calves consumed 23,287 pounds of fresh milk, 8,355 pounds of corn chop, 835 pounds of Kafir-corn meal, and 835 pounds of alfalfa hay. The total gain was 2,878 pounds, or a daily average of 1.95 pounds per head. (Charging butter fat at creamery prices, the feed cost of raising these calves amounts to \$157.19 (£32 14s. 11½d.), or \$15.72 (£3 5s. 6d.) per head. The feed cost for each 100 pounds of gain amounts to \$5.46 (£1 2s. 9d.).

RESULTS WITH CALVES NURSED BY THE COWS.—On May 28, 1900, 22 calves that were running with their dams averaged 174 pounds. On October 15 these same calves averaged 422 pounds, or an average daily gain per head of 1.77 pounds. The only expense attached to raising these calves was the keep of the cows, which was estimated by the owner to be \$12 (£2 10s.) per head. Multiplying the average daily gain of these calves by 154, the number of days in previous experiment, gives a total gain of 272 pounds per head. With \$12 (£2. 10s.) as the cost of raising the calf each 150 pounds of gain cost \$4.41 (18s. 4½d.).

RESULTS IN FEED LOT AFTER WEANING.—In the fall all these calves were placed in the feed lot, where they were pushed for baby beef. During the seven months under experiment the skim-milk calves gained 440 pounds per head, the whole milk calves 405 pounds per head, and the calves nursed by the cows 422 pounds per head.

This experiment shows that the feed cost of raising a good skim-milk calf need not exceed \$5.25 (£ 1 1s. 10½d.), in contrast to 15.75 (£3 5s. 7½d.) for a whole-milk calf, and \$8 (£1. 13s. 4d. for one nursed by the dam. The skim-milk calf becomes accustomed to eating both grain and roughness early in life, is handled enough to be gentle, and when transferred to the feed lot is ready to make rapid and economical gains. D. H. OTIS, Experiment Station, Manhattan, Kan.—*Journal of the Department of Agriculture of Western Australia.*

CULTIVATION OF SUNFLOWERS.

The first year of the twentieth century closed with a curious sale, on the Baltic, of a cargo of sunflower seeds, which changed hands at £11 5s. per ton. Though a small trade has been done in sunflower seeds for close on 200 years, this transaction was the first in which a whole cargo—300 tons from Odessa—was dealt with. In Russia, where the cultivation of the sunflower and the manufacture of oil from its seed is conducted on a large scale, the Grandi Flora is the variety grown. The species rises in a slender stalk of 5ft. high, producing one monster head, the average yield being as much as fifty bushels of seed to the acre. So rich is it in oil that that quantity of seed will yield fifty gallons of oil; while the refuse of the seed, after this quantity of oil has been expressed, weighs 1,500 lbs. when made into cattle cakes. Few people in England who grow the sunflower for ornament have any idea of its usefulness. It is among neglected crops in which there is money, as is shown by the price paid a few days ago. Besides the seed, every other portion of the plant can be utilized. The leaves furnish an excellent fodder; while in Russia the stalks are rized as fuel, and their ashes, which contain 10

per cent. of potash, are readily sold at soapmakers. Naturally, in Russia the chief virtue of the sunflower lies in oil contained in its seed. The oil is of a clear, pale yellow colour, almost inodorous and of an agreeable, mild taste, so that it is in great request as a table article. Why sunflowers are not cultivated on an extensive scale in England, it is difficult to say. Poultry and cattle like the seed either in its natural state or crushed and made into cakes. No plant produces such fine honey and wax; when the flower is in bloom the bees abound in it.—*Journal of the Department of Agriculture of Western Australia.*

PLANTING NOTES.

BUREAU OF PLANT INDUSTRY.—This is a section of the U.S. Department of Agriculture, organised in July 1901, and devoted to the investigation of vegetable physiology and pathology, botanical investigations and experiments, the study of grass and forage plants of pomology, of seed and plant introduction and other matters relating to horticulture and agriculture. Some idea of what our American kinsfolk are doing may be obtained by stating that the bureau consists of a chief, Prof. Galloway, and no fewer than twenty-five assistants, comprising pathologists, botanists, physiologists, a "cerealist," a Tobacco expert, a mycologist, and a chemist.—*Gardeners' Chronicle.*

THE ROTHAMSTED EXPERIMENTS.—The Lawes Agricultural Trnst Committee at a recent meeting appointed Mr. A. D. Hall, M.A., principal of the Agricultural College, Wye, to succeed the late Sir HENRY GILBERT, F.R.S., as the Director of the Rothamsted Experimental Station. Principal HALL, who received his training at Oxford, and has since distinguished himself by his successful development of Wye College as a centre of agricultural education, will thus carry on the historic experiments that were jointly conducted by Sir J. B. LAWES and Sir HENRY GILBERT for over half a century at Rothamsted, and it is anticipated that not only will the continuity of the work of the past be maintained, but that the progress of science will be advanced in new directions at this national centre of agricultural research.—*Times.*

A GIANTIC GRASS SEED.—At the meeting of the Linnean Society on Thursday, March 20, Dr. OTTO STAFF exhibited several seeds of *Melocanna bambusoides*, a species of Bamboo, which completely upset the popular idea of grass seed dimensions, the giants of which are presumed to be represented by pedigree Wheat and Maize, in which latter the huge mass of seeds constitutes, it is true, a very substantial fruitage, the actual seeds, however, are comparatively small. In *Melocanna*, on the other hand, in lieu of a spike arm or cylindrical mass of associated small seeds, we have solitary ones, measuring no less than 5 inches in height, by 3 in diameter, a massive pear-shaped body, the size and form of which are as utterly different from our usual idea of a grass seed as can well be conceived. By what evolutionary process this huge solitary fruit has been arrived at, is not clear, but as might be expected, the great store of nutriment embodied in so large a fruit favours the development of the associated embryo plant to such an extent, that the first product of germination is a robust growth, which practically secures establishment and continued existence. The single seed is thus fully as efficacious, if not more so, in securing reproduction, than a very large number of small ones, and by its greater individual vigour, would probably have an infinitely better chance of survival in a dense, growing Bamboo jungle, where small weakly seedlings would be utterly incapable of reaching the light. This, indeed, is probably the key to its genesis.—*Gardeners' Chronicle.*

TEMPLESTOWE ESTATE CO., OF CEYLON.

The following is the report of the directors, prepared for presentation to the annual meeting of this Co. in the office of Messrs J M Robertson & Co. :-

The Directors have the pleasure to submit their reports and accounts for the year ending 31st Dec 1901. The Crop amounted to 207,173 lb which was short of the Estimate by 17,827 lb. The shortage occurred during the latter half of the season when the weather was most unfavourable for flushing. 7,711 lb clean cinchona bark were also harvested.

The Tea cost 27.57 cents per lb and netted 38.11 cents, (including tea unsold but estimated) against 37 cents last year, which is not unsatisfactory, considering the low prices ruling for the period under review. The Superintendent deserves much credit for the way in which he has worked the Estate and kept the tea up to a very steady standard of quality.

The Acreage of the Estate now consists of :-

479½	acres	Tea 5 years old and upwards.
14½	do	4 do
70½	do	3 do
6	do	2 do
110	do	Forest. do
342½	do	Chena and Patra.

1023

The profit on the year's working amounts to R18,033.30 including the balance brought forward from last season and after paying interest on the loan of £1,500. Out of this an interim dividend of 3 per cent has been paid on the Preference Shares, absorbing R3,258 and the amount available for distribution is therefore R14,775.30.

The Directors recommend that this sum be disposed of as follows :-

By the payment of a final Dividend of 3 per cent on the Preference Shares, absorbing	R3,258.00
By the payment of a Dividend of 3 per cent on the Ordinary Shares, absorbing	R4,926.00
By transferring to Depreciation account	R5,000.00
By carrying forward the balance of	R1,591.30
	R14,775.30

Mr H G Bois, who was appointed a Director in place of Mr F W Bois who has left the island, retires in accordance with the Articles of Association but, being eligible, offers himself for re-election.

It will also be necessary to appoint an Auditor for 1902.

KANDYAN HILLS COMPANY, LIMITED.

THE REPORT.

ACREAGE STATEMENT.

Tea in full bearing	410	acres
Not in full bearing under one year	23	..
Cocoa	90	..
Reserve and Forest Land	787	..

Total ... 1,310 acres

The Directors beg to present their Report for the season ended 31st December, 1901, together with a statement of the accounts, duly audited, for the same period.

The Tea Crop secured, including bought leaf and Tea made for others, amounted to 200,858 lb. The Cocoa Crop amounted to cwts, 131-1.25 and Croton Seed cwts, 2.3-14. The made Tea gathered from the Estate itself was 175,200, as against an estimate of 200,000 lb, whilst the bought leaf represented 1,600 lb and Tea made for others 24,103 lb, making the total of 200,858 lb.

102

The total cost of production, including Manuring, was 25.20 cts. per lb. made Tea.

The surplus at credit of Working account represents R11,261.59 which, together with R1,414.38 brought forward from Crop season 1900, makes a total of R12,675.97. After paying Interest and other charges and providing a sum of R3,000 for depreciation, there remains a balance of R208.82, which the Directors recommend should be carried forward to the new year.

The new season's estimate of Expenditure is based on a Crop of 200,000 lb. of made Tea at a cost of 22.92 per lb. (including R3,160 to be spent on manuring) and 130 cwts. Cocoa costing R3,760.

Mr. A Collingwood Small, who has taken up the visiting of the Company from the commencement of this season, in his report dated 18th February, writes hopefully of prospects. Pruning during 1902 is well distributed, which should prevent the Factory at times being overcrowded, and therefore tend to the making of a better and more uniform style, the latter a matter to be aimed at with Tea at this elevation. Mr. Small also mentions that he hopes there will be a saving on the estimated cost of production.

Mr. W Shakespeare retires from the Board by rotation, but is eligible for re-election.

The appointment of an Auditor rests with the meeting.

YATIYANTOTA, CEYLON TEA COMPANY, LIMITED.

DIRECTORS.—A Thomson Esq., Chairman, Charles Young Esq, J M Skinner Esq.
MANAGING AGENTS.—Messrs. Whittall & Company, Colombo.

SECRETARY AND OFFICERS.—T. A. Williams, 27, Mincing Lane, London, E.C.

REPORT OF THE DIRECTORS

The following is a comparative statement of the past three years' working :-

Year.	Average Plucked mature and in partial bearing.	Crop secured from Company's Estates.	Average yield per acre plucked.	Average Rate of Exchange per Rupee.	Cost of Crop per lb.	Net Average Sale Price per lb.
1899	2,376	1,343,387	565	1s 4 5-16d	3'48d	5'68d
1900	2,854	1,470,590	515	1s 4 7-32d	3'40d	4'56d
1901	2,970	1,261,484	425	1s 4 7-32d	3'83d	5'10d

to be submitted at the fifth annual general meeting of shareholders to be held at the London Commercial Sale Rooms, 30 to 34, Mincing Lane, London, E.C, on Thursday, the 10th April, 1902, at 12 noon.

The Directors now beg to submit the duly audited accounts of the Company for the year ended 31st December, 1901, and they regret being unable to place before the Shareholders a more satisfactory statement.

The bearing area, of all ages, was 2,970 acres from which crops amounting to 1,261,484 lb. were secured, and, in addition, 4,338 lb. were made from purchased leaf. Of the total, 626,087 lb. were sold in Colombo, and 639,735 lb. were shipped to London, the net average realised for the whole being 5'10d per lb.

Including purchased leaf, the average cost, for (or delivered to buyers in Colombo), was 3'83d per lb. The average rate of exchange for the year was 1s 4 7-32d per rupee.

The Crop of last year was much smaller than that of 1900, due partly to an alteration in the system of plucking, and partly to the season having been a less forcing one. As a result the Teas produced have shown considerable improvement in quality, but, owing to excessive stocks of Tea in bond in London, the increase in the average price secured has not

been commensurate with the improvement in quality. A further extent of young Tea came into the plucking area during the past year; all young and weak fields have been very lightly treated, and this has contributed to the lowering of the average yield per bearing acre.

The net profit for the year amounts to £5,962 3 8

To which has to be added
Balance from 1900 Account. £2,349 15 3
Less Bad Debt (Ceylon) now
written off .. 289 13 6

2,060 1 9

Together .. 8,022 5 5

Dividends have been paid as follows:—

On the Preference Shares at
6 per cent per annum—
On 1st July, 1901, and 1st
January, 1902 ..

2,700 0 0

Leaving now to be dealt with ... £5,322 5 5

This the Directors propose to appropriate as follows:—

(1) In payment of a Dividend on the ordinary shares of 2½ per cent (free of Income Tax) for the year 1901 .. 2,250 0 0

(2) In writing off Cost of Properties, including Depreciation of Machinery and Buildings ... 1,000 0 0

(3) In carrying forward to 1902 the balance of .. 2,072 5 5

£5,322 5 5

The following are details of the acreage of the different properties as on 1st January, 1902:—

ACREAGE UNDER TEA.

Estate.	Bearing.			Total.	Forest Reserves, &c.	Total Acreage.
	Bearing.	Partial Bearing.	Not Bearing.			
Polatagama ..	791	—	59	841	201	1,042
Weoya and New Polatagama ..	632	95	—	727	345	1,072
Walpola ...	871	—	—	871	145	1,016
Rondura ...	506	87	8	601	629	1,230
	2,800	182	58	3,040	1,320	4,360

The Company's properties are well equipped with buildings and machinery, and are generally in good heart and condition. The Directors trust, in view of the steadily increasing demand for British-grown teas, that a return to a profitable level of market values may soon be experienced. Mr W J Smith having retired from the Board, the Directors appointed Mr John McLInnes Skinner to fill the vacancy, and the appointment will be submitted for confirmation by the Shareholders. In terms of the Articles of Association, Mr A Thomson retires from the Board, and, being eligible, offers himself for re-election. Messrs. Cape and Dalgleish, C.A. offer themselves for re-election as Auditors of the Company.—By order of the Board, T. A. WILLIAMS, Secretary.

27, Mincing Lane, London, E.C., 2nd April, 1902.

GENERAL CEYLON TEA ESTATES, LIMITED.

REPORT OF THE DIRECTORS

and accounts to December 31st, 1901, to be submitted at the 5th annual general meeting of shareholders, to be held at Cannon Street Hotel on Monday, the 14th April, 1902, at 12 o'clock noon.

The Directors beg to submit herewith the accounts of the Company and their report for the year ending

December 31st 1901, showing a profit of £11,737 8s 0d.

After allowance for debenture interest and other charges, there remains a sum of £3,717 15s 11d at the credit of profit and loss, to which has been added a balance of £493 8s 11d brought forward from the previous year, making a total of £4,210 19s 10d out of which the Directors have written off a sum of £2,000 on account of depreciation of plant and machinery and propose to carry forward the balance of £2,210 19s 10d.

The crops from the Company's estates amounted to 2,371,738 lb. Tea, exclusive of bought leaf, against an estimate of 2,614,000 lb tea, 2,133 bushels of coffee, and 262 cwt. of cocoa.

The tea cost, sold in London, 5-03d., and realised 6-04d. per lb. The exchange for the year averaged 1s. 4 17-64d.

The yield per acre was 433 lb over the fields in full bearing, after allowing 200 lb per acre for the partial bearing fields.

The present cultivated acreage is as follows:—

Tea in bearing ..	5,139	Acres.
Tea in partial bearing ..	297	do
Not in bearing ..	163	do
Cocoa ..	126	do
Coffee ..	118	do

Total cultivated area 5,843 Acres.

The decrease in the expenditure, as compared with the previous season, is largely due to the temporary suspension of manuring operations for a portion of the year.

The position of affairs during the year decided the Directors that this curtailing of expenditure was prudent, but they are satisfied that manuring can now be resumed.

The statistical position of the tea industry has become sounder during the year, but the present level of prices is still unsatisfactory.

Mr James Sinclair, the Director retiring by rotation, being eligible, offers himself for re-election.

Messrs. Boards, Paterson & Co., the Auditors to the Company, retire, and, being eligible, offer themselves for re-election.

NAHALMA TEA ESTATE CO., LTD

REPORT OF THE DIRECTORS

to be presented to the shareholders at the eighth annual ordinary general meeting to be held on Wednesday, 9th April, 1902, at the office of the Company, 39, Victoria Street, Westminster, at 12 o'clock noon.

The Directors beg to submit their report, together with the general balance sheet and profit and loss account, for the twelve months ending 31st December, 1901, duly audited with results, before paying debenture interest, interest on deposits, and Directors' fees, in a profit of (after making provision for bad debts incurred on estate prior to 1st October, 1901) £29 13s 1d. But after allowing for—interest of various instalments on prior line 6 per cent., Mortgage debentures from dates of payment to 31st December last, not payable till 30th June, 1902, £23 8s 4d.; debenture interest to 31st December, 1901 (not paid) £540; interest on deposit loans (not paid) £18 17s 4d.; Directors' fees (not paid) £100; debit balance from 1900, £423 19s 1d there will be a balance at debit of profit and loss account to be carried forward to next year of £1,076 11s 8d.—£1,106 4s 9d.

The crop obtained was 135,268 lb, as against an estimate of 266,000 lb.. The shortage was due in a measure to climatic conditions prevailing generally throughout the Kelani Valley.

The acreage of the Company's properties on 31st December last remained unaltered, at—tea in full bearing, 446 acres; jungle, 246 acres; total 692 acres.

A change in the superintendents of the estate was made on 1st October last, since which date the estate

has shown better results, which the Directors confidently hope will be continued.

The crop for the season 1902 is estimated at 210,000 lb.

Mr John Abernethy, the Director, retiring by rotation, being eligible, offers himself for re-election.

Messrs. Fox Sissons & Co., Auditors to the Company, offer themselves for re-election.

PANAWAL TEA COMPANY, LIMITED.
REPORT OF THE DIRECTORS

to be presented to the shareholders at the tenth annual ordinary general meeting, to be held on Tuesday, 8th April, 1902, at the office of the Company, 39, Victoria Street, Westminster, S.W.

The Directors beg to submit the general balance sheet and profit and loss account for the year ending 31st December, 1901, duly audited:—The net amount at credit of profit and loss account, including balance brought forward at 31st December, 1900, after providing for general expenses, Directors' and Auditors' fees £943 13s 10d. Dividends on the 7 per cent. cumulative preference shares were paid for 1901, in full, amounting to £371. It is proposed to pay a dividend of 8 per cent on the ordinary shares for the year ending 31st December, 1901, free of income tax, which will absorb £510. Leaving a balance to be carried forward to next season of £62 13s 10d.—Total £943 13s 10d.

The Directors recommend the distribution of a dividend at the rate of 3 per cent. on the ordinary shares of the Company for the year ending 31st December, 1901.

The Directors have still to report upon the very unsatisfactory state of the tea growing industry. Prices during the early part of the season were abnormally low, and the rise that took place later appears only to have stimulated free plucking where possible, and this has tended to reduce prices again later.

No alteration has taken place during the last twelve months in the acreage of the Company's properties, which stood:—

On 31st December last.	
Tea in full bearing	... 590
Jungle	.. 341½

931½ Acres.

The weather during the season was against free growth in the Kelani Valley. The crop realized for 1901 was 273,322 lb. as against an estimate of 335,000 lb. and a revised estimate of 295,000 lb. The yield in 1900 was 339,550 lb.

The visiting Agent (Mr F J Clements) reported the properties at the date of his last visit as being in satisfactory order.

The Honourable Norman Macleod Sinclair, the Director, retiring by rotation, being eligible, offers himself for re-election.

Messrs. Fox, Sissons & Co., Auditors to the Company, offer themselves for re-election.

TYSPANTEA TEA COMPANY, LTD.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December 1901, duly audited.

The total yield was 277,773 lb. Tea against 280,000 lb. estimated and 252,373 lb. obtained last year, and in view of the generally unfavourable season this may be considered satisfactory.

The average price realised per lb. Tea was 5.66d. nett against 5.72d. nett last year.

The expenditure includes the cost of new machinery about £440, and upkeep of new clearings about £142, charged against revenue. The factory is now fully equipped, and for some time to come only repairs should be necessary.

The present season's crop is estimated at 285,000 lb. Tea.

Exchange averaged 1s 4½d per rupee against 1s 4 5-16d last year.

The Net Profit for the year, after payment of the Interest on Debentures, is .. £986 10 4

To which has to be added the balance brought forward from last year of ... 176 7 3
— £1,162 17 7

The Directors have already paid out of this an Interim Dividend of 2 per cent., free of Income Tax .. 360 0 0

Income Tax .. 60 7 9

And it is proposed:—

To pay a final Dividend of 4 per cent. free of Income Tax, making 6 per cent. for the year .. 720 0 0
And to carry forward .. 22 9 10

£1,162 17 7

Mr. Edward Dumaresq Thomas, the retiring Director, offers himself for re-election.

The Auditor, Mr. J Hamilton Alston, also offers himself for re-election.

The acreage of the Estates is as follows:—

Tea in bearing	693 acres.
Tea in partial bearing	47 do.
Tea planted in 1897	10 do.
Do 1898	28 do.
Do 1899	4 do.
Do 1901	18 do.

Jungle, Timber, } 168 do.
Waste, &c. }

968 acres.

AUGUSTA TEA ESTATES CO., LTD.

FIFTH ANNUAL REPORT.

The Directors beg to submit the Audited Accounts for the year closing 31st December, 1901.

The quantity of tea manufactured has been 125,971 lb. which has brought an average price of 6.36d per lb. gross, the cost of production having been 23.12 cents., or equivalent to about 4½d per lb. in London. The average rate of exchange has been 1s 4 11-32d.

The result of the year's working has been satisfactory, and the Directors are able to write off an adequate amount for depreciation.

The profit and loss account shows that, after writing off £232 10s from Factory and Machinery account, there is left a sum of £223 11s 7d at credit, and out of this the preference dividend for the year has been paid and the balance carried forward to next account.

By the Articles of Association, Mr Edward H Hancock retires and, being eligible, offers himself for re-election.

The Auditors, Messrs Singleton, Fabian & Co., also offer themselves for re-election.

CHARLES A. REISS and THOMAS J. LAWRENCE,
Directors, ALBIN B. TOMKINS, Secretary.
London, 17th March, 1902.

LINDULA TEA COMPANY, LTD.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1901, duly audited.

The total crop was 171,311 lb. tea, against 185,000 lb. estimated, and 185,634 lb. obtained last season. The falling-off in yield is chiefly attributable to the unfavourable flushing weather during the latter half of the year. The crop was at the rate of 535 lb. per acre, and cost 27 cents per lb., free on board at Colombo, and the gross average price of the 166,050 lb. sold in London was 8½d against 8½d for 174,820 lb sold last year. The current season's estimate is 175,000 lb. tea.

Drafts were negotiated at an average rate of 1s 4½d against 1s 4 9-32d last year.

The Nett Profit for the year amounts to ..	£1,722 18 9	
And the Balance from last year to ..	217 0 10	
Making a total of ..	£1,939 19 7	

The Directors have already paid out of this, Dividends on the 6 per cent Preference Shares for the year ending 31st Dec., 1901	£780 0 0
Interim Dividend on the Ordinary Shares of 2½ per cent free of Income Tax ..	650 0 0
Income Tax ..	83 12 10

And it is Proposed:—	
To pay a Final Dividend of 1½ per cent free of Income Tax on the Ordinary Shares, making 4 per cent for the year ..	390 0 0
And to carry forward the balance of ..	36 6 9
	£1,939 19 7

The Director retiring on this occasion is Mr Edward Dumaresq Thomas, and, being eligible, he offers himself for re-election.

The Auditor, Mr J Hamilton Alston, also offers himself for re-election.—By Order of the Board,
ROBERTSON, BOIS & Co., Agents and Secretaries.

GENERAL CEYLON TEA ESTATES, LIMITED.

The following is from the report of directors, to be submitted at the fifth annual general meeting of shareholders, to be held on Monday next:—

The directors beg to submit herewith the accounts of the company and their report for the year ending December 31, 1901, showing a profit of £11,737 8s. After allowance for debenture interest and other charges, there remains a sum of £3,717 15s 11d at the credit of profit and loss, to which has been added a balance of £493 3s 11d brought forward from the previous year, making a total of £4,210 19s 10d, out of which the directors have written off a sum of £2,000 on account of depreciation of plant and machinery, and propose to carry forward the balance of £2,210 19s 10d. The crops from the company's estates amounted to 2,371,738 lb tea, exclusive of bought leaf, against an estimate of 2,614,000 lb tea, 2,133 bushels of coffee, and 262 cwt of cocoa. The tea cost, sold in London, 5'03d, and realised 6'04d per lb. The exchange for the year averaged 1s 4 17-64d. The yield per acre was 433 lb over the fields in full bearing, after allowing 200 lb per acre for the partially bearing fields. The present cultivated acreage is as follows: Tea in bearing, 5,139; tea in partial bearing, 297; not in bearing, 163; cocoa, 126; coffee, 118; total cultivated area, 5,843 acres. The decrease in the expenditure, as compared with the previous season, is largely due to the temporary suspension of manuring operations for a portion of the year. The position of affairs during the year decided the directors that this curtailing of expenditure was prudent, but they are satisfied that manuring can now be resumed. The statistical position of the tea industry has become sounder during the year, but the present level of prices is still unsatisfactory.

Mr James Sinclair, the director retiring by rotation, being eligible, offers himself for re-election—*H. and C. Mail*, April 11th.

STANDARD TEA COMPANY OF CEYLON, LIMITED.

The following is from the eleventh report of the directors to the shareholders, to be submitted at the general meeting, to be held on Wednesday, 23rd inst:—

The directors submit statement of accounts to December 31, 1901. The profit and loss account shows a profit on the working of the estates in Ceylon of £10,980 19s 8d, which, with the amount brought forward from last year, less interest and home charges, shows a sum of £10,183 11s 8d available for division. In August, 1901, the directors, under the powers entrusted to them, distributed an interim dividend for the six months ending June 30, 1901, of 5 per cent. (10 per cent per annum), absorbing £2,975. They now recommend a dividend at the rate of 10 per cent (making 15 per cent for the year) absorbing £5,950; and the carrying forward to the next year £1,258 11s 8d. The coffee crop was 24 cwt; it realised about £95. The tea crop was 1,105,996 lb, against 1,129,753 lb in 1900. The average exchange for the company as drawers in Colombo was 1s 4 5-32d, against 1s 4 7-32d in 1901, and 1s 4 9-32d in 1899. Prices for Ceylon teas were again generally lower this last season. Of the company's teas produced during 1901, those from the St Leonard's factory sold at about 1½d per lb lower price than 1900 teas; those from Gordon, 1d per lb lower; those from Gouravilla, at about the same average price. The company's properties at the close of 1901 were 3,466 acres, with 2,188 acres of tea considered in full bearing, viz:—In Uda Pussellawa—St Leonards and Coneygar, 902 acres, 530 acres tea bearing; Liddesdale, 814 acres, 200 acres tea bearing; Eskdale, 240 acres, 227 acres tea bearing; Gordon, 386 acres, 304 acres tea bearing; Tulloes, 4.9 acres, 275 acres tea bearing; in Up. Ma-keliya—Gouravilla and Up. Cruden, 705 acres, 652 acres tea bearing. There are also 293 acres tea in partial bearing, and some 28 acres in addition planted with tea. Mr Norman W Grieve, the Director, who retires by rotation, being eligible, offers himself for re-election.—*H & C Mail*, April 11.

BALMORAL (CEYLON) ESTATES COMPANY, LTD.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1901, duly audited.

The total yield of tea was 595,197 lb., against 563,556 lb. last year, being at the rate of 616 lb. per acre all round; the cost of production, exclusive of capital expenditure, was 24½ cents per lb., free on board at Colombo, and the Gross average price obtained was 8.53d per lb., against 8.86d per lb. last year—Sandringham teas averaging 8.28d, and Clydesdale 8.78d per lb. Exchange have averaged throughout the year 1s 4 3-16d against 1s 4½d last year.

Two Oil Engines have been erected in the Clydesdale Factory, and the cost of them, £498 3s 4d., is charged to capital account. All other expenditure having been charged against revenue, the Directors do not consider it necessary to set aside any specific sum for depreciation.

The Net Profit for the year amounts to ..	£7,782	4	2
And the Balance from last year to ..	22	17	4

Making a total of .. £3,505 1 6

The Directors have already paid out of this, Dividends on the 6 per cent Preference Shares for the year ending 31st December, 1900 ..	£1,800	0	0
---	--------	---	---

EASTERN PRODUCE AND ESTATES COMPANY, LIMITED.

REPORT.

To be presented at the Fifteenth Ordinary General Meeting, to be held at Winchester House, Old Broad Street, at 12 o'clock noon, on the 30th April, 1902.

The Directors submit Report and Balance Sheet for the year ending 31st December, 1901.

The profit for the year is £20,439 9s 2d, which, added to £7,242 6s 9d, balance from last account, amounts to £27,681 15 11.

From this has to be deducted:—Interest on Debentures £3,600; Debentures for £7,500 drawn and paid off, with bonus of 6 per cent, on 31st December, 1901, £7,875; Interim Dividends of 2½ per cent. on Preferred and 1½ per cent. on Ordinary Share Capital, paid 4th November, 1901, £3,746 19s.—Total £15,221 19s; Leaving a balance of £12,459 16s 11d, which it is proposed to apportion as follows:—Final Dividends on the Preferred Shares of 2½ per cent, making 5 per cent for the year, and on the Ordinary Shares of 1¼ per cent, making 3 per cent, for the year £5,238 4d; Balance to be carried forward as provision for retirement of Debentures in the current year £7,221 12s 11d.—Grand Total £12,459 16s 11d.

The Debenture debt which stood on 31st December, 1900, at £80,000, has been reduced by the payment of £7,500 out of profits, and now stand at £72,500.

As shown in the schedule below, the Company on 31st December last, had 11,028 acres under Tea cultivation, of which 10,491 were over four years old.

The yield of Tea in 1901 was 3,830,383 lb, the average gross sale price being 6 61d., as compared with 6 51d. in 1900. The short yield as compared with the previous year is due to the unfavourable weather that generally prevailed combined with a

more careful system of plucking. The enhanced price obtained for the 1901 crop may be considered satisfactory in view of the fact that the Ceylon average price shows no improvement on the corresponding period for 1900.

The average rate of exchange was 1s. 4 11-32d., as compared with 1s. 4 7-16d. in 1900.

Accompanying this Report will be found a copy of Special Resolutions to be proposed at an Extraordinary General Meeting to be held at the close of the General Meeting on the 30th instant. It will be remembered that the formation of this Company was of an exceptional character, and the Articles of Association did not include all the powers usually inserted. It is now considered desirable to supply this omission so that the Directors may be free to act as and when called upon in the interests of the Company in relation to the matters indicated in the Resolutions in question.

In accordance with the Articles of Association, two of the Directors, Mr. R. A. Cameron and Mr G A Talbot, retire from office, and, being eligible, offer themselves for re-election.

The retiring Auditors, Messrs Welton Jones & Co., offer themselves for re-election. RALPH A CAMERON, Chairman and Managing Director, 41, Eastcheap, E.C., 11th April 1902.

SCHEDULE OF THE COMPANY'S ESTATES AT 31ST DEC. 1901.

Arapolakande, Asgeria and Bulatwatte, Colonna, Condegalla, Doombagastalawa, Dromoland, Hope, Ingurugalla and Berrewella, Kirrimettia, Kumara, dola, Kubukkau, Labookellie, Meddecoombra, Norwood, Rothschild, Sogama, Vellai oya and Dandukelawa and Wevekellie.

Under Tea.—11,028 acres; Cocoa 593 acres; Cardamoms, Cinchona, Rubber and Sundries 327 acres; Forest, Grass and uncultivated Land 4,642 acres.—Total 16,590 acres.

CEYLON TEA PLANTATIONS CO, LTD.

Report of the Directors to be submitted at the Fifteenth Annual Ordinary General Meeting of Shareholders, to be held at the office of the Company on Monday, 28th April, 1902.

The Directors have the pleasure to submit the general balance sheet and profit and loss account for the year ending 31st December, 1901, duly audited.

The net amount at credit of Profit and Loss Account, including Balance brought forward at 31st December, 1900, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is ..	£	s.	d.
	44,044	11	6

Dividends on the 7 per cent Preference Shares were paid for 1901 (less Income Tax) amounting to ..	£	s.	d.
	5,356	7	3

An Interim Dividend of 7 per cent on the Ordinary Shares was paid 29th October, 1901, amounting to ..	11,716	12	0
---	--------	----	---

It is proposed to pay a final Dividend of 8 per cent on the Ordinary Shares (making 15 per cent in all, free of Income Tax) which will absorb ..	13,390	8	0
To write off for Depreciation ..	5,000	0	0
And to carry forward to next year a balance of ..	8,581	4	3
	£41,044	11	6

The unfavorable condition of affairs in the Tea-Growing industry, which had to be recorded for the year 1900, was, your Directors regret to say, continued during the past year.

It is, however, a matter for satisfaction that the profits of the Company enable the Directors to recommend the payment of a dividend of 15 percent, free of income tax, for the fifteenth consecutive year to the ordinary shareholders; to set aside £5,000 for Depreciation, and to carry forward the sum of £8,581 4s 3d.

Owing to finer plucking on some of our estates, but mainly due to most unfavorable weather, the crop from the Company's tea proprietors showed a diminution of yield per acre of 12 percent as compared with the previous year, the output being 463 lb. per acre as against 526 lb in 1900.

The following shows the quantity of tea accounted for in the profit and loss statement :—

Estate Tea.	Bought Tea.	Leaf Tea.	Manufac-tured for others.	Total.
lb.	lb.	lb.	lb.	lb.
3,957,335	421,960	301,445		4,680,740

The average gross price for the tea sold in London and elsewhere, including bought leaf, was 7 1/4d per lb. compared with 7 1/5d the previous year, and the rate of exchange 1/4 15-64 as against 1/4 19-64 in 1900.

The coconut crop was 1,401,768 nuts. Owing to the improved state of the market, and the favourable condition of the properties for an increasing yield, the future prospects are encouraging for this product.

The year under review has been a trying one for those working tea properties in Ceylon, and the services of the Company's Staff deserve the appreciation of the Shareholders for the results obtained.

Under Clause No. 69 of the Articles of Association, Mr. H K Rutherford retires on this occasion from the Board and, being eligible, offers himself for re-election.

The Auditors, Messrs. Harper Brothers, Chartered Accountants, also retire from office, and offer themselves for re-election.—By order of the Board,

WM. JOHNSTON, Secretary.

London, 19th April 1902,

AVERAGES OF TEA ESTATES AT 31ST DEC. 1901.

Estates.	Districts.	Tea in bearing 1901.	Tea not in bearing.	Jungle and Timber Clearings.	Patana and Waste.	Total Acreages.

VELLIKELLIE TEA COMPANY OF CEYLON, LTD.

Your Directors have the pleasure to submit their Report and Balance-sheet for the year ending 31st December, 1901, duly audited.

The crop amounted to 275,549 lb tea, which cost 26'90 cents per lb free on board at Colombo, and the average price obtained for the 251,699 lb sold in London was 8.03 per lb. Last year the crop amounted to 233,785 lbs, costing 29.95 cents per lb f.o.b., and the average price for the 209,880 lb sold in London was 9 3/4d per lb. The crop for 1902 is estimated at 280,000 lb tea.

Owing to the fall in the price obtained for the tea, it will be seen that, in spite of the increased yield, the profits are much the same as last year, and the Directors recommend the payment of the same dividend.

An installation of fans in the factory is now complete, and the cost of this, some £207, has been charged against the current season's expenditure.

The rate at which Drafts were negotiated was 1s 4 3/16d, against 1s 4 1/4d per rupee last year.

The Net Profit for the year amounts to	2,241	10	6
And the Balance from last year to	108	13	4
Making a total of	2,350	3	10

The Directors have already paid out of this dividends on the 6% Preference shares for the year ending 31st December, 1900.. £285 0 0

Interim Dividend on the ordinary shares of 3% free of income tax	1,057	10	0
Income tax	89	4	8

AND IT IS PROPOSED :—			
To provide a dividend of 2% free of Income Tax on the Ordinary Shares, making 5% for the year	705	0	0
And to carry forward the balance of	213	9	2
	2,350	3	10

The Director retiring on this occasion is Mr. Percy Lawrence Johnson, and, being eligible, he offers himself for re-election.

The Auditor, Mr. J Hamilton Alston, also offers himself for re-election.

NUWARA ELIYA TEA ESTATES COMPANY, LIMITED.

Report of the Directors—to be presented to the sixth annual general meeting of shareholders, to be held on Wednesday, the 30th day of April, 1902, at Winchester House, Old Broad Street, London, E.C., at 12 o'clock noon.

The Directors beg to submit the duly Audited Accounts of the Company to 31st December, 1901.

The Crop Account shows a profit from the working of the Estates of £15,297 4s 1d.

The Profit and Loss Account, including the sum brought forward from last year, and the payment of Debenture Interest, Income Tax, &c., shows a credit of £15,791 11s 6d, from which £2,000 has been written off as Depreciation, leaving available for distribution

£13,791 11 6
An Interim Dividend of 3 per cent, free of Income Tax, was paid on 23rd October, 1901, absorbing ... £6,000 0 0

It is now proposed to pay a final dividend of 3 per cent, free of Income Tax, making 6 per cent for the year, which will absorb a further ... 6,000 0 0

12,000 0 0

And to carry forward the balance of ... £1,791 11 6

The Directors regret the falling-off in returns as compared with last season, in view of which they have considered it unnecessary to charge against the past year's profits the Capital Account outlay on additions to buildings and machinery, but ample provision for depreciation has been charged in the accounts.

The Crop of Tea from the Company's Estates was 1,225,614 lbs., as compared with 1,458,911 lbs. in 1900. The shortfall is attributable partly to less favourable weather, and partly to the adoption of a system of finer plucking, resulting in enhanced cost of production.

The average rate of Exchange for the year was 1s. 4½d. per Rupee, and the cost of the crop, free on board steamer, or delivered to buyers in Colombo, was 5'53d. per lb. The average nett price realized was 8'48½d., as against 8'66d. in 1900.

The following table shows the results of the working of the different Estates for the past year :-

Estate.	Percentage in bearing in 1901.		Tea Crop.		Average yield per bearing acre.		Nett price realized per lb. Tea.		Profit per bearing acre.	
	Full.	Partial.	lbs.	lbs. d.	lbs.	d.	£	s.	d.	
Park ..	212	22	147,852	560	8'45	7	16	7		
Portswood..	322	30	186,790	530	7'95	4	6	1		
Naseby ..	178	20	97,964	500	9'13	6	10	1		
Pedro ..	370	118	261,223	535	8'44	7	4	5		
Concordia..	288	152	198,395	440	9'05	6	18	3		
Court Lodge	366	—	155,264	424	8'47	5	19	2		
Hethersett	375	25	178,126	445	8'16	4	7	7		
	2,139	367	1,225,614	485	8'48	4	6	2	1	

The yield from Tea in full bearing was 532 lb per acre, and that from Tea in partial bearing 262 lb per acre, as compared with 644 lb and 371 lb respectively in the previous year.

As on 1st January, 1902, the acreages of the Company's properties stand as under :-

Tea in full bearing	..	2,132
do do leased lands	..	98
do partial bearing	..	350
do not yet in bearing	..	22
Total land under cultivation with	—	—
Tea		2,602
Jungle, Patna and Scrub, and Fuel Trees, &c.		410
		3,042

The Estates continue in excellent condition as regards cultivation, and the Directors are satisfied

with the general working of the properties during the past year.

The retiring Directors are Mr. C A W Cameron and Mr H St. J O Thompson, who, being eligible, offer themselves for re-election.

Messrs. Cooper Brothers & Co., Chartered Accountants, offer themselves for re-election as Auditors of the Company.—By order of the Directors,

FRIEZE, SANDS & Co., Secretaries,
London, 18th April, 1902.

PRODUCE AND PLANTING.

THE TENSION AS REGARDS THE BUDGET

IS OVER, and so far as tea is concerned producers have reason to be thankful. Not only has the Chancellor of the Exchequer declined to avail himself of Sir Robert Giffen's hint, by abstaining from adding to the duty, but he has expressed himself in terms of sympathy with tea planters. His reference to tea will be very acceptable. He said, in the course of his speech on Monday night: "Then, Sir, I come to tea. Well, I have listened to the pitiful cry of our fellow-subjects, the tea-producers in India and Ceylon, and, bearing in mind that tea, which is almost a necessary of life (hear, hear), is already taxed to as much as 75 per cent of its average value, I confess I should be sorry to increase that tax." This is all that could be desired under the exceptional circumstances, for no reduction on the duty was to be looked for, and it is something to the good to learn that, at a time when so much money has to be raised, the Chancellor of the Exchequer admits that tea is a "necessary of life," and that he would be sorry to tax an article of produce already bearing an impost equal to 75 per cent of its average value.

TEA-GROWING OPERATIONS IN SOUTH CAROLINA continue to excite a great deal of interest. The British Consul at Charleston makes reference in his annual report to the experiments in tea culture at the South Carolina Government tea farm. While it is probable, he says, that these experiments will be carried on for several years more, with different qualities under widely differing conditions, the most important facts relative to American tea culture have already been demonstrated. Among other things it has been proved that a number of kinds of tea from different countries—Japan, China, Siam, and Formosa—can be grown with profit, and that several other varieties have been found unprofitable in a commercial way. Future experiments will probably continue along this line with a view of getting the greatest productiveness from the tea plant in the shortest time. Another important point ascertained is that the tea bush can survive very cold weather. While it is undoubtedly better that it should be grown where the mercury does not go below 25 deg. Fahr., yet in the frost of two winters ago the tea gardens were subjected to a temperature below zero and suffered little injury therefrom. In the East, where tea grows naturally, the rainfall is from two to three times as much as in Carolina during the summer, which deficiency has been compensated for in the Carolina gardens by a system of irrigation. The careful labour needed in picking the delicate leaf has been provided by giving special school advantages to all the little negroes living in the vicinity who are willing to avail themselves of them, and these children are, during school hours, instructed in tea-picking, and during the tea-

gathering season they are given remunerative work. The most common objection that has been raised to the establishment of an American tea industry has been the difference in the price of labour in America and in the East, but with a full appreciation of its force as applied to poorer grades, there seems to exist a good profit in the production of those higher grades in whose cultivation cheap labour plays a minor part. And in addition the home tea production has this further advantage, that the final drying of the leaf need not be carried to the same extreme degree of heat, whereby a sacrifice of much that is agreeable and beneficial in the flavour is entailed. As we have pointed out before, and as the British Consul thinks possible, if the American Government were to place an import duty on tea, and the home-grown tea industry were to make rapid progress when so fostered, the Indian and Ceylon tea imports to the United States would be affected; but that is in the far future. Meantime we learn from New York that with the passage of the War Tax Repeal Bill the tea market shows signs of renewed activity, and in favour of this it may be noted that the stock of tea is small.—*H. and C. Mail*, April 18.

MOSQUITOES AND MALARIA IN ITALY.

A CONSULAR REPORT.

The British Consul remarks in his Report on the Trade for South Italy for 1901:—

The subject of mosquitoes and malaria, which was mentioned in the Report from this Consulate (No. 2,550, Annual Series), is still attracting considerable attention in Italy, and more especially in this District where a large area is subject to malaria. Next to Sardinia, the Province of Basilicata is the largest malarious tract in Italy, and therefore the most interested in the extermination of the disease. The most fatal season occurs in the months of August and September, but the further we go South the longer does the dangerous season continue, so that in Basilicata security can rarely be enjoyed or reckoned upon until the month of October is past.

MOSQUITOES GO BY TRAIN.

Mosquitoes dislike wind and when it is high they take refuge where they can. Hence they are not transported by wind as has been often supposed but they move from place to place on or about men and animals and any baggage which attracts them, a fact which explains isolated cases and epidemics which have occurred in places distant alike from marshes and stagnant water. Some interesting cases of fever, owing to this cause, occurred at the station of Termini near Rome, the cases having probably originated from mosquitoes conveyed by the Terracina train which crosses the most deadly part of the Pontine marshes.

AN ANILINE DYE EFFICACIOUS.

There is a special aniline dye which when diluted, even to the extent of 0.00031 per mile, is said to kill the larvæ. The well-known pastilles and powder, similar to ordinary insect powder, which can either be burnt or distributed by means of bellows, may also be mentioned. This powder is made of the flowers of the *pyrethrum roseum*, a herb extensively grown on the Dalmatian coast, the cultivation of which is being tried near Ceprano a town in this district about half-way between Naples and Rome. It is found that valerian root, powdered and mixed with the other, renders it more efficacious.

THE DIFFICULTY ABOUT DRUGS.

Experiments have been made in the past summer by Professor Grassi to combat the malady by the use of drugs. In this he has obtained a great measure of success, but here again the expense of the drugs and the difficulty of getting the large quantity necessary, taken at regular times, will form an insuperable difficulty in the case of the peasants. Having selected one of the most malarious places in Italy, Ostia at the mouth of the Tiber, Professor Grassi and his staff have administered six pills a day to adults and a proportionate dose to children, the pills being composed of a compound called "Esanofele," a harmless drug composed of quinine, arsenic, iron and bitter herbs. Which salt of quinine or iron, and the proportions used of each of them, has not yet been disclosed, but Dr Grassi, in his recent work (which is in course of translation into English), speaks most highly of the results and the tabulated statistics of the Ostia treatment appear very favourable, though these are too long and too complicated for reproduction here.—*Madras Mail*, April 23.

PLANTING NOTES.

THE UNION ESTATE COMPANY OF CEYLON—is certainly one of the unfortunate ones—no dividend for five years and the prospect is not brilliant, apparently, unless there is a determination to abandon any non-paying fields or products and to stick to what we heard long ago described as the really very fine Hayes property. At the same time, the Directors deserve credit for giving up half their fees while no dividend is declared;—but why not mention this in the Report? It is certainly a fact of special interest to shareholders and well-deserving of a sentence, apart from what may be shown in the accounts. The continuation of our full report will be found elsewhere: the "hecking" was unusually long drawn out.

ARSENIC AND TREACLE.—It is good news that the ravages of locusts can be controlled, if not checked, by means of arsenic and treacle. In Natal, we read, that the locust plague is now easily controlled by this simple means. It would be interesting to know how the remedy can be applied over an extensive area. Coconut planters may do well to try them for beetles; and why not for porcupines? The latter pest renders coconut cultivation almost impracticable in parts of the island. The Pallegama Grant suffered severely from porcupines; estates in the Kurunegala-Puttalam districts are said to have been badly smitten by them; in the Southern Province, the extension of Cinnamon cultivation is explained by the difficulty of growing coconuts owing to the destructiveness of porcupines; and even from the Kelani Valley we hear of immense damage done to promising plantations by their fondness for stems just as they begin to show above ground. We should like to hear from some of our more experienced planters, European and Ceylonese, as to the best means of checking the depredations of porcupines—apart from catching them at mischief and then blowing them up!

UGAR PLANTING IN THE STRAITS: AND THE STRAITS' GOVERNOR.

We have had the pleasure of a call recently from Mr. J. Turner, administrator and attorney of the Penang Sugar Estates Co., who was homeward-bound with his family on six months' leave. Mr. Turner visited Ceylon on his way out after his last furlough early in 1900 and had a look at the country as far north as Anuradhapura. He did not think it suitable for sugar-growing as far as he saw; but, on hearing that further north paddy was plentifully grown, Mr. Turner agreed that sugar might there be profitably cultivated while the quantity of irrigation required (the same kind of soil being suitable for sugar that was used for paddy) would vary to a great extent with the quality of the soil and the rainfall. The rainfall on the Penang Estates was on an average 90 to 100 inches per annum. Since Mr. Turner was in Colombo last, the land either planted or taken up for planting by the Penang Sugar Estates Company has more than doubled the Company's property, no less than 9,000 acres being now opened. The estates are worked by a staff of 50 Europeans—"mostly Scotchmen!" Mr. Turner told us--and, though these are comparatively free from tropical affections, several qualified doctors are employed by the Company to keep the native workers in health as far as possible; as many as 150 natives have succumbed from cholera alone. Mr. Turner was able to renew acquaintance today with Mr. in Thurn, calling upon him at the Colonial Secretary's Office—in a far more responsible post than when he knew the latter as the able and scientifically gifted curator of the Demerara Museum.

From Mr. Turner we were further interested to hear of the impression Mr. Taylor had made at the Straits—namely that of an exceedingly hard-working and thorough official, almost too much so for that Colony, and determined to possess a complete acquaintance with the details of all business in his hands. Upon Sir Frank Swettenham, Mr. Turner was loud in praise. He regards this Governor as one who will be "heard of" in years to come with a fame greater than any, based merely on his Colonial Governorships. Sir Frank has, says Mr. Turner, *made* the Malay States; he has opened railways and constructed roads out of revenue derived from the country itself, in a most skilful manner. He has all the gifts and capacity of a progressive colonial statesman, who understands the conditions of growth in comparatively young settlements such as the Straits or Colonial infants-in-arms, nearly such as the Malay States. As such he has proved a welcome addition to the Straits, as one not bound to oppose anything in the nature of progress and even wise enough to overrule local conservatism in the larger and future interests of his charge. Mr. Turner regarded his advocacy of Mr. Matthews' scheme for the improved harbour accommodation at Singapore as a remarkably powerful and intelligent piece of work, and the passing of it by the Legislative Council, in the face of strong mercantile

opposition, as an achievement that redounds to the credit of his personal force as well as governing sagacity. Long may Sir Frank be spared to rule the Straits—is the wish we may offer from a flourishing neighbouring Colony, equally blessed with an able Governor who should be "heard of" in days to come—as long as he continues to see and provide for its needs and development as he does today.

LORD LAMINGTON ON QUEENSLAND.

On March 11th, 1902, the Right Hon. Lord Lamington, G.C.M.G., read a paper on "Notes on Queensland."

The Right Hon. the Earl of Onslow, G.C.M.G., a Vice-President of the Institute, presided.

All friends of Queensland have cause for some satisfaction in the facilities which now exist for obtaining information, supported by statistics and figures, relative to the country's progress, as well as interesting accounts of its early history and physical features. And if this circumstance has made it difficult for me to produce in my "Notes on Queensland" matter which is new to you, and, at the same time, free from the embarrassment of political topics (just recently so very much to the fore), it is, at all events, pleasant to know that the many gaps I have left may be filled at larger sources of information. Among these sources I would especially mention General Sir Henry Norman's Paper read before the Manchester Geographical Society in 1896, Sir Horace Tozer's address of three years ago to the Fellows of this Institute*—an address, it will be agreed, that left scarcely a phase of human interest untouched, and publications issued under the auspices of the Government, entitled "A Queen Colony," and "The Official Year Book," give a most complete account of the resources and history of Queensland.

The point that first occurs to my mind is the distress that Queensland has suffered, and—according to the most recent news—is, unfortunately, still suffering, through the long period of

DROUGHT.

I hear it is especially severe in the Central and Western districts. According to most people, it is the longest on record. Yet it is somewhat misleading to speak of Queensland as being drought-stricken; the country is one of large areas, and things are rarely ever so bad or ever so good as represented by a general statement. Thus, in October, 1900, I travelled in North-West Queensland, and even in some of the worst of the drought-stricken country I came across districts that fared well. This was owing to their being in the track of some thunderstorms, which, as a rule, follow one another over a particular line of country. But even these smiles of nature are often unreliable. For example, paddocks may be seen with good grass which remains uneaten through the absence of water for the stock to drink. And it is in these cases that artesian wells are of such benefit. On the other hand, a creek may be flowing "a banker," and not a blade of grass in the vicinity. This may occur in the case of a regularly flowing river, as the Gregory, but more often is simply due to thunderstorms that have fallen higher up the river

* Proceedings of the Royal Colonial Institute, vol. xxx. p. 74.

basin. Four years ago I saw an instance when I went on an official tour to Thargomindah and South-West Queensland, accompanied by Sir Horace Fozer. I had continued the journey further to the south-west to see the devastation caused by the rabbits. We were camped on Bulloo Downs, and from the heavy thunderclouds, looking like massive black blocks, I anticipated a drenching night. My companions, however, said it would not rain, and they were right. Never a drop fell in our vicinity, and the heat was intense, but the clouds had burst further north, and, on returning to Thargomindah, our buggy horses were all but swimming where creeks had to be crossed. Even at that date the drought was severe, yet in those places where the heavy thunderstorms had fallen the country's remarkable recuperative powers became apparent, luxuriant grass springing up where, but a few days before, there had been the barest ground. Considering the heavy losses that the pastoral interest has suffered during these last years, it is to be hoped that the Government, as the State landlord, will be lenient as regards the payment of rent and the renewal of leases. It is as much the moral duty of the State and to its interest to be lenient to distressed tenants as it is the duty of a private landlord. The question of the

ARTESIAN WATER SUPPLY

has been recently ventilated both by Dr. R Logan Jack and Mr. W Gibbons Cox. Only those who have seen the limitless areas of parched ground, and houses and townships dependent on the storage of water drained from the roof into circular corrugated iron tanks that burn to the touch in the fierce sunlight, can at all adequately appreciate these copious discharges of subterranean water. Mr. Gibbons Cox has emphasised the value of the water for the irrigation and growing of crops. No doubt the water varies much in temperature and in analysis from the different bores, but I know of no instance, as yet, where after two or three years it has not been found adaptable for this purpose owing to the accumulation of mineral deposit. This does not, however, prove that some of the bores, particularly those that are more shallow, might not be free from this defect. On the other hand, the Government Hydraulic Engineer is not optimistic at present as regards the cultivation of crops by this water, and says it is totally inadequate for the irrigation of grass lands on a large scale, though, of course, of inestimable value for watering stock. On the western border of the Gregory River near Camooweal the country has a limestone formation, and on Rocklands station windmills pump water out of ordinary wells. Though situated on the watershed of the Gregory River that flows north, this subterranean water is believed to drain into the Georgina; flowing south. Incidentally I may mention that this part of the country is in places honeycombed by caves that give no sign of their existence till the observer is close upon them, their entrances being flush with the surface of the land. Further north there are curious limestone rocks, which in one instance almost block one small valley, standing in long parallel rows, and, being grooved horizontally by intersecting lines, they give an impression of walking along the passages of a ruined Cyclopean temple.

By way of further confirming my opening remark on the misconception conveyed by the general use of the term drought-stricken, and in

contradistinction to this experience of these years of drought when the pastoral and mining interests have so suffered, farming has thriven, sufficient rain having fallen in this more restricted area. In the vicinity of the Russell river the rainfall last year exceeded 246 inches. If at present there is but little

AGRICULTURE

on the western plains, it is not the case on the Darling Downs and on the coastlands, which are rapidly being broken up. Where, five years ago, I shot quail with a lot a house in sight, is studded today with small farms. Passing along in the train the 20 or 30 feet of rich black soil can be seen in the creeks cut deep through the fertile plains. Land that was worth about 1s an acre per annum for grazing sheep, when under lucerne or other green crop, may be reckoned as bringing in about £1 a year. Such were the figures supplied to me by a squatter who had broken up some thousands of acres. Then there are the farms on the chocolate-coloured volcanic soils of the ranges; these vie with the others in fertility, but the scrub, that is, the jungle, has first to be cleared, and in places they suffer from the soil being washed away off the steep slopes by the torrential rains. Below the range the soil is equally rich, but somewhat stiffer to work, preferred by some, however, on account of the more certain rainfall. On the whole, I regard farming in Queensland as a prosperous industry; no doubt there are some drawbacks, and nature provides many plagues, but by contrast with farming here, I should say there was a far larger margin of profit to be gained by the man who, aided by his family, is willing to work. This is particularly true of the dairying interest, which even during the few years I was there not only developed largely, but made vast improvement in the quality of its products. And it must be remembered that the actual necessities of life are few and easily supplied. Meat is cheap, only light clothing is required, fuel is to be had for the cutting, and for nine months of the year anyone could live comfortably under canvas. Before leaving this part of my subject I should like to briefly notice a pestilence which is, most unfortunately, to be reckoned as a serious evil to the pastoral industry. I refer to

RABBITS.

From what I last heard, it is to be feared they are working north and east. I found difficulty in obtaining reliable information. In Brisbane, for instance, I was most authoritatively assured before setting out on my journey to the south-west that I should see no rabbits. At first this appeared quite correct, but at length we saw a few on Dynevor Downs. As a matter of fact, they were numerous, but owing to the great scarcity of herbage they were scattered in all directions. At any rate, they do sufficient harm to make it worth while to keep on a single run, two or more carts employed in spreading poison. It must be remembered that some stations in those districts have only about ten cattle to the square mile; hence there must be very little spare food. But on Bulloo Downs there could be no question about the existence of rabbits. The land literally swarmed with them, especially to the south of a cleft rabbit-proof fence. They were living on bushes barked five or six feet high, and were anything but plump. As for rabbits climbing, I may say that I do not be-

lieve they have, up to the present, developed any fresh powers in that direction. To scramble up amongst the thick branches of a bush, as they manage to do up a dry stone dyke in this country, is the full limit of their capability so far as my own observation goes.

Let me now refer

THE GENERAL SCENERY OF THE COUNTRY.

I fancy a stranger's conception of an Australian landscape would be a vista of rolling plains, relieved by sparse green trees of a painfully uniform description. As contrasted with this country, it is quite true, there is a monotony of feature and colour. The close observer, however, will notice distinctions in the vegetation even of the western country, and more pronounced variations from the configuration and vegetation of the eastern. The open plains, with the curiously marked ridges, as if once ploughed, intersected by the stony volcanic open forest ridges, form the characteristics of the Downs. Towards the west these give way to a more park-like country with clumps of the soft grey-green of the brigalow scrub. Further west still there is the cypress pine and mulga. Accompanying these are the gidya (which smells so unpleasantly before and after rain), the bumble orange, lavender bush, sandalwood, glosse box, cinnamon, and countless others. One notable feature about these trees and bushes in that stock in time of drought, when the saltbush and the Mitchell grass are no more, eagerly eat them. It is not until one goes north and reaches the central district that the true open country is seen, entirely devoid of trees. The coast, again, is very dissimilar and the open forest country, being better watered, grows timber much bigger than in the west, whilst on the ranges the scrub land resembles a dense jungle full of vines, creepers, lawyer cane, palms, and gigantic timber.

THE BUNYA PINE

I make special mention of, as it is, I believe, peculiar to Queensland, and even there grows only in a limited area. With leaves not unlike those of an ordinary araucaria, the stem cleans itself of branches, and as it grows old presents a noble appearance, rising perhaps 200 feet, with its vast symmetrical bole-crowned by a mushroom-shaped top of deep green foliage. The huge heavy cones contain a seed or nut that tastes like a chestnut. When ripe, natives for hundreds of miles flock to the Bunya Mountains to feast on these seeds, and so rich is the food that they—the natives—become fat and sleek. On the eastern slope of the Main Range the streams and rivers are usually flowing with clear water, through wooded hills, to where the Pacific rolls ceaselessly on the white sands of the coast. Here the most striking features are the isolated peaks of the Glasshouse Mountains, so named by Captain Cook, from their glossy appearance. Further north Mount Larambe stands out in bold relief. The Barrier Reef protects the shores of Central and Northern Queensland. Some day this will be recognised as an ideal yachting-ground. The numerous uninhabited islands, of almost every conceivable shape, clothed in scrub, scented shrubs, and deep grass—the intricate channels running between, and affording splendid scope for the skill of the navigator—these must before long compel grateful recognition from those in search of change and pleasure. Central and Northern Queensland has a coast line usually bold and rugged. Its dangers are only too evident in the many remains of wrecks which

occurred before the coast was properly lighted. In places where the ranges recede from the shore, there are strips of fertile plain and sugar-growing country. Elsewhere clear mountain streams resembling those in the Highlands of Scotland, only with brighter water, flow invitingly. The Whit Sunday, Molle and Albany Passages are well-known for their beauty. The deep channel allows of the steamer passing close along the wooded shores. But the Hinchinbrook Passage of shallower depth is the most picturesque. The rocky peak of the island is over 3,000 feet. High palms and tropical vegetation fringe the base to the water's edge. On the mainland, the mountains tower yet higher in a series of pinnacles. Mourilyan Harbour, Cairns, and Cooktown are all attractive, and Port Douglas is of especial charm. Certainly, I enjoyed nothing more than yachting along these shores, visiting the little-known Barrier Reef islands. This pleasant experience I was enabled to have by the consideration of the Queensland Government. And now let me add a short notice on

THE BIRD-LIFE OF AUSTRALIA.

On the coast country there are to be found many varieties of parrots, cockatoos, the bird-magpies, larks, pigeons and innumerable other species. Nothing could be more melodious than the note of the bell-bird in the thick recesses of the scrub, or more curious to hear than the sharp note of the whip-bird—nothing prettier to see than the black and yellow of the regent-bird, or the claret and black of the rifle-bird. On the western plains flocks of pink galas may be seen whirling in the air. Cockatoos, both black and white, parrots, doves, kingfishers, in addition to the larger forms of bird-life, are also in plenty. Ducks, plain and scrub turkeys, pigeons, quail and snipe are almost the only edible wild birds.

I mention the bird-life to contradict the statement sometimes made that it is scarce in Australia; it is certainly not in Queensland. I might add, too, that the Queensland scrub, I have been informed, is excessively rich in the number and variety of botanical specimens.

Turning now to the consideration of the life of

MANKIND

in Queensland, I think the aboriginal population has first claim on our attention. When brought into contact with civilisation they generally deteriorate. I observed many fine types of robust manhood among them, especially such as lived their natural life, uncontaminated by the evil influences of civilisation. They have great muscular strength and activity, are fast runners and high jumpers. As a race, they are very callous to pain. In their tribal conflicts the most severe wounds would be treated with indifference. One mode of punishment is for two or three men to thrust a spear through the body, and I have heard of a native walking sixty miles with a spear through him before he could get help to pull it out. Their intelligence always impressed me, as did their quickness of comprehension. In the back blocks they usually work as stockmen on the runs, and one most capable and successful manager told me he preferred to employ black boys, both on account of their intelligence and reliability. In a mission school at Mapeon I was told the children were quite as intelligent as white children. It is apparent, therefore, that their inferiority, as a people, is not so great as is usually represented. Perhaps, too, the improvement is

more marked as one goes north. To reflect on the swift disappearance of their former thousands is somewhat terrible—in fact appalling. Except in the N. W. and in the Cape York Peninsula, their camps are few and but sparsely occupied. Drink, opium, and disease have mainly contributed to their disappearance, and deeds of violence have not been altogether wanting. Had large reserves been established in the first instance, missionaries and education might have developed a moral spirit that would have combated more successfully the worst influences of civilisation. I do not pretend that the race would have been perpetuated indefinitely, but at least its existence would have been prolonged. They have undoubtedly suffered at the hands of our race, and I never could learn for certain of a single authenticated case where the wild blacks injured a white man or his property without some provocation having been given previously by a white man, or occasionally by one of the new-comers through ignorance giving offence by a neglect of their superstitions. From their inability to differentiate between one white and another, the provocation may have been given by a very different party to the one upon whom revenge was inflicted, and, perhaps, at a date long anterior, whereas the oldest residents have told me sad tales of the punishment and cruelties inflicted when a murder had been committed by

THE NATIVES.

Here I may quote the experience of Mr. Petrie. He settled at North Pine about forty-two years ago and can remember seeing tribal fights take place where now the Brisbane Exhibition building stands. Some white settlers had made complaints of natives who were in hundreds about the place. He was, however, considerate to them, and, as a result, never lost a single bullock. He would leave them in charge of his house, and never missed even an ounce of tobacco. They would bring him presents, as they did to anyone who treated them with any consideration, and, furthermore, their conduct towards shipwrecked people was generally good. The two most frequent causes of trouble were the taking of black women by the settlers, and in the spearing of cattle by the blacks. The former incident invariably led to the trouble, and in connection with the second, it must be remembered that the natives were largely deprived of their means of subsistence by pastoral and mining occupation, and hunting, in consequence, almost ceased because of its difficulties. What were the blacks to do? Surely they had a claim for protection, and not to run the risk of being dispersed and shot. At no time are they liked on a run, as the cattle get frightened by their appearance amongst them. "It is impossible," as a judge said in a summing-up, "to overcome racial prejudices where juries of another colour are employed." I hope matters are now on a different footing. I am proud to think that the first real remedial measure was passed during my term of office. Sir Horace Tozer was then Home Secretary. His strenuous and humane endeavours to bring about happier relations are, I am glad to say, being vigorously maintained by his successor, the Hon. J. F. G. Foxton. The continuance of Sir Horace's policy is especially noticeable in the Acts prohibiting the sale of drink and opium to aboriginals and half-castes. Doubtless these are provisions very hard to enforce in dealing with semi-civilised nations. Again, as

part of the general scheme of improvement, protectors have been appointed to exercise supervision. One of these, Dr. Roth, has been specially selected for his interest in native life and his ability to administer medical treatment in cases of disease. I may say here that a native believes that sickness or death is always due to the operations of some foe, and has no idea that they could possibly result from physical causes, and does not therefore understand taking any steps to guard against illness. But perhaps the most beneficial feature of these Acts is to be found in their causing the natives to be regarded as fellow-creatures worthy of help, rather than troublesome beings whose presence was unwelcome and irksome. Greater precautions, too, have been taken against cruel and unfair treatment where natives engage to serve on the pearl or lêche-de-mer fishing boats. These were grievously necessary. It must be remembered that the pioneers of civilisation are not always given to sentiment.

The Missions that have started are meeting with considerable success. The children afford the best, if not only, chance of obtaining permanent good results. The great obstacle to improvement in the adult consists in the lack of any appreciation of wants beyond those of bodily gratification for the moment. The perfect communism that prevails is chiefly responsible for this characteristic. Everything a man possesses, or may earn, is at once shared by all other members of the family or tribe, old and young. The chief incentive to work is thereby removed. Mr. Hey, the missionary in charge of Mapoon, quoted to me how a native came to him who had earned two bags of flour as wages. He shared one with the rest of the tribe, but saved the other by handing it over to the custody of the missionary who, from time to time, doled the flour out as required. But as each dole had to be shared with his friends and relatives the poor native merely became a philanthropist on a sort of instalment system, and failed utterly as a domestic economist. Perhaps the only sense of property is to be found in respect of their weapons and dogs. The absence of this sense might, I believe, be traced to the want of any religious faith. They receive no guide to present conduct by looking to the future or hereafter. The present day is the only consideration, without the slightest regard to the next. In a greater or lesser degree I believe this to be a great factor in the disappearance of a race.

To turn to topics more associated with

THE NEWCOMERS

is now our business. Outside of political questions, I suppose, there is none of greater interest than of climate. Indeed, it has, in the last few months, assumed the aspect of a political question in itself. I always endeavoured to learn what doctors and others possessed of experience thought upon this point. Naturally, there was some divergence of opinion, but, on the whole, it was corroborative. I will make a general deduction, but allowance must be made for the vast area of country and consequent local variations. To begin with, the death-rate of Brisbane in 1899 was 10.90 per 1,000—the lowest for any of the Australian capitals. For the year 1900 the death-rate of Brisbane was 14.99 per 1,000, and for the colony of Queensland 11.72 per 1,000. The higher rate of Brisbane is due partly to the more crowded con-

ditions of life, and also to the unhealthy lives drawn there for treatment, but the average rate of 11.96 for the quinquennial period 1896-1900 compares very favourably with the other Australian Colonies. These figures are omitting consideration of the coloured races. As regards Southern Queensland, there can be little, if any, doubt of its healthy character, especially to the west of the main range. Although there is rarely the extreme heat that is experienced in Southern Australia, it may be contended that some people feel the summers long and hot. Many, therefore, like to go to the south for a change, but equally, people in this country like to go to the Rivera or Egypt, and yet the cold here could not be described as unbearable or rigorous, as in the Arctic. These remarks apply also to Central Queensland, only in rather a greater degree. In Northern Queensland and to the north of Townsville, it would hardly be denied that continuous residence in the coast country *does* have a relaxing effect, and that there the white race could not retain its vigour and robustness. Once on the high ranges parallel with, and not far from the coast, I believe living to be quite as healthy as in any other part. One morning at Herberton my thermometer was down below freezing-point at my bedstead. Here (and this remark applies to the greater portion of Queensland) the air is wonderfully light and refreshing. Possibly, there is some connection between this atmospheric condition and the great rarity of sunstroke, for the head covering of the men in the bush always seemed a very moderate protection. To summarise, I believe that man can engage in almost any kind of labour, except such forms as cane-trashing and cutting, in the tropical regions without deterioration. But the female portion of the community must not be forgotten. The more active the life so much the less does a woman suffer from the heat. From what doctors and others have told me, without, I think, a dissenting opinion, on the tropical coastlands or in the gulf-country white women cannot, as a rule, bring up families without injury to health. On the other hand, it must be remembered that, if the climate in these small portions of the country has a deleterious effect for some, many have come to Queensland to save their lives, and this the dry air of the Downs and western plains especially has done for them. Though it is too early to judge with certainty, one may reasonably assume that, with a climate very different from what obtains here, there will in time be some variation in stock, and the race may become of slighter build, but wiry. On the whole

QUEENSLAND MAY BE PROUD OF ITS CLIMATE

when contrasted with other places of equal latitude elsewhere. With the exceptions before mentioned, the whole of the work is done by the white man. Townsville is, essentially, an Anglo-Saxon town. Yet it is of the same latitude that passes through Mauritius, the heart of Madagascar, Beira, Matabeleland, and, to the east, Fiji, South Sea Islands, Chili, Bolivia, and well to the north of Rio Janeiro, in all of which places labour is carried on by coloured natives or half-breeds. In making this comparison, let it be remembered that Townsville is only in the south-eastern corner of Northern Queensland, and that Croydon, Cooktown, and other places are nearer the Equator, and yet the mining and other work is

done there by white men. Whilst on this topic I may allude to a habit closely connected with the health of a country. I mean the drinking of spirituous liquors. From my own observation and from the information of others, I may say that, whilst it is usually said that habits of drinking are rife, it is certainly not the case, especially amongst the younger generation who are noticeably abstemious. This must, of necessity, have a beneficial effect on the health of the population. I believe any drinking that may have existed is chiefly due, in the first place, to the pernicious habit of "shouting." Those in the higher ranks of life should now be able to meet without it being thought necessary to treat all around them, and it should not be considered mean for a man to order only what he wants for himself. Another evil is to be found in the bad quality of liquor sold in the back blocks.

I was much struck by the number of hospitals scattered throughout the country. Till recently, in this land, where we are now, hospitals were almost unknown outside the large towns. But in the most thinly populated parts of Queensland a home for the sick and injured is within reasonable distance, considering the vastness of the territory. Great pride is taken in the maintenance of these hospitals, and money is rarely asked for in vain. These are managed by the subscribers, and the State contributes £2 for every £1 locally raised. With one exception they always seemed most carefully and excellently managed, and Lady Lamington, who has interested herself in this subject, would testify to their being at least equal, if not superior, to the country hospitals she has seen over here. The best site in the town or township is well-nigh always occupied by the hospital or by a Roman Catholic Institution.

As regards the general advancement, Queensland moves of course on similar principles to those of the rest of Australia, and it is curious to note the divergent lines of development followed by the two great branches of the British race. In the United States of America

INDIVIDUALISM HAS HAD FULL PLAY.

A man there is self-reliant, and ever believes he will himself make his way. In Australia the Government and the laws are looked to in every department of activity for support, direct or indirect, and the laws passed are usually opposed, as much as possible, to the accumulation of capital in the hands of the employer. This policy may procure a more dead level of the diffusion of wealth, and ensure the happiness of the greater number, to a wider extent, than that sudden creation and disappearance of fortunes in the United States, but it necessarily checks that great amount of enterprise, development of resources, and increase of wealth that so prominently characterises the progress of the latter. Another minor comparison I used to note, and the difference is, perhaps, due to the same causes. This consists in the essentially peaceful character of Australian development. As a nation, it is, of course, without parallel. No country has ever attained such prosperity unchallenged by any foe from within or without. But in private individual life the inhabitants, too, themselves, except when the great rush was made at the discovery of the goldfields, have always quietly pursued their way, and weapons of offence have been unknown; whereas in some of the American States, if not today, at any rate till quite recently, a revolver or a bowie-knife was an essential part of a man's every-day attire,

Coming to a general review of Queensland, I should first of all like to mention the fact that throughout the rivalry of the different States it was always conceded, by the southern States, that Queensland was destined to become the richest and most prosperous in Australia. It has such an enormous variety of sources of wealth; its agricultural products alone would take long to enumerate, drawn as they are from the subtropical and tropical zones. In public, and privately to me, has this often been allowed; and I believe that the future will prove the estimate to be a true one. For my part (and here again I have had the support of outside opinion), I believe its Governments have always been amongst the most patriotic and far-sighted—in other words, the most statesmanlike. I think it proved not only by internal policy, but external as well. As regards the former, the civil administration is on a better basis than can be said of some of the other States. And in my opinion the officials are better instructed. I could give an instance of this from events which occurred after the declaration of the Commonwealth. Sir Samuel Griffith, the present Lieut. Governor and Chief Justice of Queensland, is, to a large extent, responsible for this satisfactory position, as also for the codification of the criminal law. The Government accounts are well kept, and, thanks to a prudent measure passed by Sir Hugh Nelson, the surplus of any one year is automatically handed over for the discharge of public debt. Thus, it is the wish of every Treasurer to pay every account possible before striking his annual balance on June 30, and not to allow an accumulation of arrears by parading a large surplus as regards external affairs. Successive Prime Ministers have invariably shown themselves large-minded in dealing with British New Guinea, and Governors have never lacked support in carrying out their policy despite its complex system of administration, even though, now and again, there has been some little pressure applied to exploit the possession more in the interest of the white man than that of its own inhabitants. The recruiting of the Kanaka labourers has been carried out with the greatest humanity. As I have already stated, Acts have been passed to improve the condition of the aborigines. Adhesion was given to the treaty with Japan, by which the influx of Japanese is placed under control. In this matter Queensland stood alone amongst the States, as I believe she alone, despite the financial depression, has not reduced the salary of the Governor under the Federation. Her regard for her position as a State entity would not risk the decline that might result from reducing the position of its head. She was the first of all the Colonies to offer troops for service in South Africa before the war broke out. She has a system of local government; this decentralisation of business and handing over responsibility to local authorities must tend to a truer appreciation and recognition for the proper supervision of the duties of the government of a country. The admirable lighting of its coast for 1,200 miles is most creditable for a population now, today, only numbering half a million. She was always foremost in maintaining the Federal Council, in erecting Federal forts, and in maintaining and supplying Federal garrisons. She was urgent, too, in the matter of the Pacific cable, and, perhaps, though a small point, I cannot better prove what I mean by the broad and statesmanlike attitude of Queensland than by men-

tioning that she alone of the Australian States gave £1,000 to the cost of the Antarctic Expedition, though, presumably, the State least directly interested.

These considerations make one's sympathies the keener for Queensland under its present disagreeable circumstances. The uncertainty of the operation of the Federal tariff hampers its trade. Without discussing the merits or demerits of the Kanaka question, it is hard that, at a time when nature has sorely troubled the country by lack of rain, a prosperous industry should be threatened with extinction. At least such is the opinion of those who have given their labour and money to it. Even if their fears are exaggerated, one can feel for the men who have developed, and so have the real stake in, the country, whilst we can feel for the Government who have aided them in their enterprise, and on whom these anxious fears must react in the sense of a threatened loss of security for capital, and in a diminution of revenue. Queensland went grudgingly into Federation, knowing her conditions and characteristics were unlike the rest of Australia, and might not be recognised. It must be unpleasant for the responsible authorities to find their fears were to a certain extent justified.

Before I conclude, I must refer to what, to me, as the constitutional chief of the State, was the most agreeable feature—viz., the deep-rooted attachment that is entertained to the Sovereign of this Empire—H.M. the King. I used often to marvel, when visiting some distant lonely settlement, to find how fervent was the loyalty, even amongst people that one would suppose so remotely situated as to lose a sense of such ties. What a wonderful work has been accomplished by one remarkable personality! I speak of our late Queen. How her bright shining goodness and sense of responsibility have gained an influence, widespread and deep, in these hearts and minds—an influence strengthened by the recent journey of Their Royal Highnesses, the Prince and Princess of Wales, which is well known to have been sanctioned by Her late Majesty! Being privileged to remain in Queensland in order to receive Their Royal Highnesses, I know something of the impression created by their visit, when they showed such pleasure in becoming acquainted with as many people as time would allow, and in informing themselves of everything that concerned the commerce, politics, and life of the great dependency. The fruits of these inquiries we have seen in the remarkable speech of H.R.H. the Prince of Wales at the Guildhall, a speech that is often referred to and quoted.

Before I sit down let me repeat my opening observation with regard to a general account of Queensland. Nothing of the kind has been attempted here. I have merely touched upon some matters that often engaged my attention during the happy years that Lady Lamington and myself spent in a country to which our thoughts often revert, and toward which the best wishes of our hearts will ever go forth.

*The Paper was illustrated by a series of
Lantern Views.*

The CHAIRMAN (The Earl of Onslow, G.C.M.G.):—I am sorry I must leave now, in order to catch a train, but Lord Brassey, formerly Governor of Victoria, has kindly consented to take my place.

The CHAIRMAN (Lord Brassey, K.C.B.):—I will now conclude the proceedings in the usual way by tendering on your behalf a most hearty vote of

thanks to Lord Lamington for his interesting paper. Everybody who has spoken—and we have had many interesting speeches—has highly and most justly praised the paper. Allusions have been made to one or two points which are not dealt with in the paper. They were not dealt with for the obvious reason that they were controversial, and those of us who have been Constitutional Governors in Australia have been trained to know our duty in the avoidance of matters of controversy. I desire to associate myself in the fullest sense with all that Lord Lamington has said, of regard and appreciation of Australia and its people. We sometimes exchanged visits. On more than one occasion I had the pleasure of travelling in Queensland and of voyaging along its beautiful coast. I have undying recollections of the Hinchinbrook Passage, and my visit extended to the extreme point of Thursday Island. Many of my Victorian subjects were deeply interested in Queensland properties, and I admired greatly the spirit of enterprise with which they endeavoured to develop their resources. Nothing which science could do to cope with the difficulties which climatic conditions too often present to enterprising settlers was left undone. We can only hope that they and all those interested in Queensland may meet with the reward they deserve. Some speakers have been able to present a most encouraging picture of Queensland, which I hope will attract youthful enterprise and benefit that State.

LORD LAMINGTON, GCMG:—I wish to acknowledge with extreme gratitude the kind references made to my paper. I only wish it had been more complete, but I thought on an occasion like this it was best to take only certain topics for treatment. As to the subject of industries, which I regret I have omitted, I may say that for a new country they are very considerable, and I may mention that Maryborough has perhaps the largest and most complete iron works in all Australia. As to the sugar question, I cannot help thinking there is perhaps a little excess of fear, for if Kanakas are not obtainable there may be found some other form of labour to be engaged on the sugar-cane fields, which will be able to afford the planters the means of producing sugar in the future as in the past. I understand that coolies are proceeding in large numbers up north. I should not like to dispel the pleasing illusions which Sir Arthur Hodgson has indulged in respect to the cattle camp provided for the inspection of Their Royal Highnesses. I listened with interest to Dr. Jack's statement with regard to Mr. Kennedy, and I regret to hear that the authenticity of the treacherous conduct he described can be established. But I adhere to the opinion that in earlier times it ought to have been the business of the responsible authority to see that there was some reserve or that something was done to endeavour to prevent the two races coming in conflict one with another. I will conclude by expressing my admiration for the great earnestness of the Australian character. I noted, so far as my own experience went, that whatever they took up they endeavoured to carry through. Whether in sport or in business, they are thoroughly in earnest, and in whatever they engage their methods are thorough. I will ask you to join in giving a hearty vote of thanks to our Chairman, Lord

Onslow. I regret that he has been compelled to leave, but we are grateful for his presence so long as he was here, because a man engaged as Under-Secretary for the Colonies has not many leisure evenings. We are deeply indebted to our friend, Lord Brassey, for taking his place. Lord Brassey and I often came together when he was Governor of Victoria. He by no means restricted his interests to that prosperous State, but made himself thoroughly acquainted with the rest of Australia. He was most intent always on the duties of his position, and I regard it as an honour that we have had his presence on this occasion.

THE BALATA OF VENEZUELA.

An extraordinary yield of Venezuelan balata (a species of *guita-percha*) is recorded in the journal "El Guaynes," of Uputa in that republic. During the twelve months ending with October last, according to that paper, 1,840,000 kilograms (equal to 4,048,000 pounds) of balata were shipped from the ports of San Felix and Guri, in the territory of Yuruary, to Ciudad Bolivar. The district lies south of the Orinoco and east of its tributary, the Caroni, besides which the region is drained in part by the Yuruary and Imataeca rivers. This balata paid a tax to the State of Bolivar equal to about 4 cents gold per kilogram (the rate has since been doubled), and two cents to the national treasury of Venezuela. Besides, there were 772 dols. collected in company taxes, fees, etc. The total public revenue from Balata was 11,425,60 dols. The export value of the balata, according to our contemporary, was equivalent on an average to 38 cents gold per pound, bringing the total value for twelve months up to 1,538,200 dols.—*Indiarubber Trades' Journal*, March 31,

RUBY DEVELOPMENT CO., LIMITED.

(73,081).—Registered March 13, with capital £4,000, in £1 shares, to adopt an agreement with R Oblatt and L and N Karpf, to acquire patents, inventions, licences and information relating to the re-construction of rubies, to re-construct work, to sell, purchase and deal with rubies and precious metals and to carry on the business of jewellers, goldsmiths, silversmiths, etc. No initial public issue. The number of Directors is not to be less than 4 or more than 6; the first are L Karpf, N Karpf, R Oblatt and A Raphael. The three first-named are agent; qualification £250. Registered office, 67, Banner Street, Finsbury, E.C.—*Investors' Guardian* March 29.

A CHINESE EXTRACT OF TEA.

At a meeting of the Pharmaceutical Society of Great Britain, held on the 15th ult., Dr Augustine Henry, who was described by the President of the Society as "the greatest living authority in Chinese drugs" delivered a lecture on that subject. In a report of the lecture the *Chemist and Druggist* says that a sample of *Extract of Tea* made in the office of the Prefect at Szmao and used only by the Dowager-Empress, to whom it is sent as tribute, was shown. It is in the form of a yellowish-brown powder, and contains 6 per cent. of caffeine and 12 per cent of tannin,

WILD COFFEE IN CENTRAL AFRICA.

AN APPARENT HYBRID.

Beyond the Lusambo on the shores of the Sankuru grows a very wild interesting kind of *Coffea* tree, which is apparently new. It exists also, it is said, in abundance on the left bank of the Lomani, west of the Ganda. It is a small tree three to five yards high with branches spreading out often over the streams with fine leaves larger than those of the Liberian Coffee, and small flowers, smaller than those of the Arabian variety. The berries are of medium size, the seeds rather small and regular and have a very delicate aroma. Coffee of this kind that had been gathered towards Ganda tastes excellent. This coffee is said to abound in the woods on the left bank of the Lomani, and is even cultivated in certain villages. This variety has been cultivated, first by the Arabs, and then by M. Gillain at Lusambo station, where there is about five hundred trees. In the same plantation there were some Liberian coffee trees planted at the same time, but which had not developed so well as this wild kind. This is attributed to the nature of the soil of Lusambo: a silicious earth, rich in vegetable soil for twenty or thirty centimetres down. In such land one must give up Liberian in favour of the new kind, accustomed to grow on the sandy soils so common in the basins of the upper Kassai, Sankuru and the Lomani. This coffee seems to have a great future before it, especially after the southern portion of the great forests is opened up to cultivation.

ANOTHER VARIETY.

In an island of the Lualaba, above Wabundu, grows, in a wild state, a kind of coffee much like the Arabian. It is also found opposite Coquilhatville and on the banks of the Uelle and the Ubangi. It forms a shrub 6 to 13 feet high, with narrow leaves, small elongated beans, rather small berries of rather irregular shape owing to there being often three berries in a bean. The colour of the berry is grey, and there is so little aroma that many berries are required to produce a fair cup of coffee.

A TRUE LIBERIAN.

At Wanik Kukula, there is in the forest another kind of wild coffee whose reputation has no longer to be made: Liberian coffee living in the forest under the shade of great trees. There are trees in flower 30 to 40 feet high, the trunks of which measured 15 to 25 centimetres in diameter 3 feet from the ground. They bore branches only at the summit of the stems, which is explained by the struggle for light of the denizens of the forest. The seeds are a little smaller than those of the cultivated Liberian trees. In every point the wild and the cultivated Liberian resemble one another, and in a plantation of 5 to 6 hundred trees near by it was not possible to distinguish them. The trees belonged to some Arab Chiefs to whom the Commandant Lothaire had advised as to the cultivation of wild coffee and had given seeds of the cultivated variety.

THREE DISTINCT KINDS.

We must note then the existence, in their wild state, of three different kinds of coffee in the Congo State, and two of these have a great economic importance. For if equatorial Africa is the home of these precious plants, there is no doubt that they may be cultivated there with success. To satisfy oneself, it is sufficient to visit the plantations of Wabundu, and especially those of Stanley Falls. At the latter Station, 400 trees were planted in 1899 on the recent deposits of the left bank of the river. They are very fine and covered with berries; one of these trees was photographed after it had been stripped. The fruits weighed 21 kilog. (47 lb.) which corresponds to about 3 kilo. of coffee (7 lb.). After the Arab campaign, coffee planting was resumed vigorously under the direction of M Rom. Last year there were more than 5,500 plants over a year old and growing vigorously.—*Madras Mail*, April 26.

MR. JOHN HUGHES AND BASIC SUPERPHOSPHATE.

Basic superphosphate is a manure prepared by mixing superphosphate with slaked lime, and is distinctly alkaline, combining the solubility of superphosphate with the alkaline nature of slag. It is particularly adapted for clayey, gravelly, sandy, granitic, or peaty soils, and in general for all soils having less than 1 per cent of lime. It is in the form of a dry powder easily applied. According to the inventor, Mr. John Hughes, it is intended to take an intermediate position between slag and superphosphate, and results in the field last season confirm those of the laboratory.—*Globe*, April 18.

THE CULTIVATION OF TEA IN LOWER BURMA

has disappeared. The late D. Mountjoy cultivated it successfully in the Akyab district for many years. He commenced in 1862 and gained a prize for the excellent quality of his tea at the Calcutta Agricultural Exhibition in 1863-64. In 1876-77 the outturn of tea in the Akyab district amounted to 25,374 lb. According to the *Rangoon Times* no tea has been grown in Lower Burma for some time past, though the returns for Upper Burma last year show 249 acres under tea in the Katha district, and 1,167 acres in the Upper Chindwin.—*Indian Planter's Gazette*, April 26.

GROWING TOMATOES.—Most Growers of tomatoes for sale or export aim at producing very large smooth fruit. That the smooth variety is preferred to the wrinkle kind is evident from the fact that the public, as a rule, do not care for the latter and that a better price can be obtained for the former. But abnormally large tomatoes are a mistake. As a general rule, the public prefer a moderate size. The housewife does not like getting two or three fruits to the lb. because there is often much wasted in the large sizes. From 2 to 3 inches in diameter is quite large enough, and such tomatoes will always command a better price than the very large ones, which are more useful to the cook for "fancy work" than for general purposes.—*Queensland Agricultural Journal* for March.

PESTS AND DISEASES.—Caterpillars, slugs, flies, locusts, birds, worms, scale insects, fungoid diseases of various sorts, will all attack your garden in their turn, and they must be destroyed as soon as they appear, or there will be very little pocket-money. What is the best way of fighting them all? In a small garden you can do a great deal by picking off the caterpillars, but the slugs (*vaginula* particularly) are night intruders, and these may be destroyed by the use of the powder of tobacco refuse. A dusting of this is fatal to them. Then there are sprays which will destroy both insect parasites and fungous diseases. Whale oil soap, 1 lb to 2 gallons of warm water, applied when cold, is an excellent spray. Paris green and Bordeaux mixture will also help. If taken in time most of the enemies of the vegetable garden can be destroyed by proper appliances. Study the writings of scientific vegetable gardeners, and make use of the remedies suggested by them and you will find that you will be successful with your garden, and still have plenty of time to do chores on the farm.—*Queensland Agricultural Journal* for March.

THE CEYLON TEA SALES OF LAST YEAR.

DECREASE IN AVERAGE AND OUTPUT; BOTH LOCALLY AND AT HOME.

It is interesting to compare the results of the local (Colombo) Tea Sales for 1901, as compiled for our contemporary the other day and quoted elsewhere, with the Tea Memoranda and London Sales of 1901, reported by Messrs. Wilson Smithett & Co. which we published last month. It will have been observed that the London average for 1901 is nearly a half-penny less than for 1900, notwithstanding the finer "plucking" observed at this end and the poor season which so largely aided reduction of crop. Looking over estates, we observe that in some of the high districts the falling-off is more than $\frac{1}{2}$ d. For St. Leonards, for instance, it is $\frac{3}{4}$ d; but then it gave a larger yield by 90,000 lb. last year, but the Mining Lane Brokers remark generally on a falling off in Udapussellawa teas, perhaps due to an unfavourable season. Badulla is a half-penny better; but the outturn was less by 130,000 lb.—possibly in a great degree through less leaf being bought. Again Talawakelle average is down $\frac{3}{4}$ d, but with more tea by 40,000 lb. It is, however, impossible to institute fair comparisons all round, without knowing whether any of the tea from particular estates is sold in Colombo. Possibly 1901 may have seen some sold locally that in the previous year went to London, and *vice versa*.

Turning to the local Sales of 1901, we note that the high districts have shown a similar falling off in the local sales, which inevitably reflect the home market to a large extent. Naseby, it is true, is actually 7 cents above its figure for 1900; but Monkswood shows a drop of 1 cent, St. John's 2 cents, High Forest 13 cents (a big drop from the first place it held last year with the 59 cents that Naseby holds this year), Dunbar, Dunkeld, Queensland and Tonacombe 2 cents, Mocha 7 cents and Maha Uva 3 cents. A rise is shown by only two estates, beside Naseby, out of 25 high-grown; we refer to Glasgow (1 cent) and Malvern (4 cents). Glasgow showed the large output of 333,500 lb. at an average of 46 cents and Malvern 54,000, at 37 cents. Turning to low-grown tea we see that here also only three estates among the best show an increased average:—Weoya (by 4 cents), Glencorse (1 cent) and Polatagama 2 cents; their outputs were, respectively, 134,000 lb., 148,000 lb. and 280,000 lb. The output of Naseby we should mention, seeing how its result stands out amongst the rest, was a medium one, 87,000 lb., in proportion to the other totals, though this means a yield of 550 lb. per acre. The biggest yields have for

the most part been obtained by estates showing an average of 31 cents and over. But they are all surpassed by two: Yata-deria (415,000 lb.) and Kurulugalla (655,000 lb.) with averages of 39 and 25 cents respectively; below the 31 cents average the next highest is Rayigam (290,000 lb.) with average 28 cents. Above 30 cents we find the yields as follows:—

	Yield.	Average.
Yagan	... 333,000 lb	32 cents
High Forest	... 371,000 "	46 "
Glasgow	... 333,500 "	46 "
Pallagodda	... 325,000 "	32 "
Agra Ouvah	... 324,000 "	47 "
Marlborough	... 323,500 "	38 "
Chesterford	... 312,300 "	31 "

The output for the whole year is very slightly less than in 1900—a decrease by a fraction per cent, namely by 97,065 lb. on 38,442,926, but the average shows $1\frac{1}{2}$ cents decrease; this is not so bad as the drop of very nearly 4 cents that came about in 1900; but it is bad enough, seeing how low the average has sunk in the past 10 years. We give in conclusion, the annual totals sold in Colombo and averages obtained, for the past ten years as follows:—

ANNUAL TOTAL AND AVERAGE.		
	lbs.	Cents.
1891	... 9,573,611	... 41
1892	... 11,578,869	... 41

VEGETABLE PRODUCTS IN MINCING LANE.

At this time of the year, when the British public generally is more or less interesting itself in the Chancellor of the Exchequer's Budget, our thoughts run over a wide range of commercial products, or likely sources of taxation that may, possibly suggest themselves to the resourceful and fertile mind of the Chancellor, and that will not press too heavily on any class of the community in particular. In doing this we cannot help being struck with the prominent part the vegetable kingdom plays in the realisation of revenue. A glance even at the Customs Tariff of the United Kingdom which, of course, is a list of those articles which are already liable to duty, proves the truth of this statement, not only with regard to the number of vegetable products in comparison with those from other sources, but also to the absence of many other well-known substances of equal or even more importance, and which would probably yield large sums, were a slight duty chargeable. Tobacco, Tea, and Sugar are, as everybody knows, fruitful sources of revenue which, though the rates upon each may be varied, will, like the income tax, probably never be surrendered. Probably, however, there are comparatively few people who have any idea of the important position fruits and flowers under different forms hold in the Customs tariff, and the unequal manner under which they are taxed; thus, while dried Currants pay only two shillings per cwt., Raisins are charged seven shillings—very unequal rates for two varieties of the Grape, the presence or absence of "stones" or seeds in the fruit apparently making all the difference, and yet not entirely so, for the Sultana (a stoneless Grape) is classified as a Raisin, while some of the very large Currants now often seen in the market are sometimes a puzzle even to the Customs authorities, who have to decide whether they should be classified as Currants or Raisins. Figs and Fig-cake, Plums, and Prunes are chargeable with the same rate as Raisins; while canned

and bottled fruits preserved in thin syrup pay one shilling per cwt., the same preserved in thick syrup have to pay two shillings more, or three shillings per cwt. Crystallised fruits are distinguished from others by a higher rate, namely 4s 2d per cwt. Ginger preserved in syrup or sngar is charged three shillings per cwt., while preserved Tamarinds pay only one shilling.

Flowers occur in the Customs tariff in one form only, and this not in a fresh or dried state, but in the condition of sweetmeat, namely, the crystallised flowers of the Violet, Rose, Orange, and which are charged at the same rate as crystallised fruits, namely, 4s 2d per cwt.

If the Chancellor of the Exchequer were to take a walk through the several brokers' show-rooms in Mincing Lane, he would, no doubt, become imbued with new ideas of taxation; at any rate a glance down the reports of the London market in that busy corner of the great city is a lesson of much interest and great educational value, for it is chiefly in these reports that we first find references to products new to commerce—things that are sent into market at first in small quantities to test their suitability as marketable articles, and their prospect of finding purchasers. Products of this kind of any real value seldom make their way with any flourish of trumpets, but become quietly established, the demand increasing as their properties become known.

The case, is, perhaps, rather different with regard to medicinal products. Any new discovery in this direction has of late years been made the cause of many much-advertised quack medicines, though some of them have proved of value, and have found a place in the *Pharmacopœia*, such as Coca (*Erythroxylon coca*), and Cascara Sagrada (*Rhamnus Purshiana*), and others. In the Mincing Lane classification of products, it is sometimes difficult to find any special article; for instance, one unacquainted with the ways of product brokers would scarcely expect to find Chillies classed with spices, but in such company they are always placed, though the principal use of the Chilli is as a condiment, either for making cayenne pepper or for mixing with pickles. Very large quantities of these pungent fruits now come into English commerce, and it is said that the increased demand is to some extent due to the use of much larger quantities than has hitherto been the case in the West of England pilehard prescribing trade though there is also a fairly good demand for them in medicine.

The geographical range of commercial Chillies has of late years become much wider than formerly, for, beside the regular source from India, we receive Chillies of good quality and very bright appearance from Nyassaland, Sierra Leone, and Zanzibar; and more recently from Japan. The botanical source of the African Chillies is attributed to *Capsicum minimum*, and though the general appearance of the Japanese form is very similar, it is usually somewhat larger and has less pungency; and it has been suggested that it may be a small form of *C. annuum*. The market value of Chillies varies from 38s per cwt for ordinary mixed Zanzibar to 52s for good red Nyassaland fruits, but these prices are affected by the ebb and flow of supply and demand.

Speaking of spices, one would rather expect to find Vanilla under this head, but so important is this valuable product in the Mincing Lane trade that it is not only placed under a separate head-

ing in the market reports, but the samples themselves are always shown in a separate show-room, and indeed in a distinct building.

The extension of the cultivation of Vanilla, not only in new plantations, but also in entirely new countries, is sufficient proof of its constant demand, and of its value as a profitable crop; and this notwithstanding the continued manufacture and use of artificial vanilline. The following facts on the present condition of the trade in Vanilla are gathered from our well-informed contemporary, the *Chemist and Druggist*, who, in reporting on the Vanilla sales at the end of last month, says that the supply brought forward was the heaviest on record and attracted a much larger attendance of buyers than usual. There was, however, a good demand and practically the whole quantity offered, about 2,800 tons, was sold. Long lengths, being scarce, brought good prices while medium lengths, also sold, were pods from 8 to 8½ inches long, and of good chocolate colour and fetched 22s 6d per lb; 7½ to 8 inches, 19s 6d to 21s 6d; and so on in proportion, for it must be remembered that Vanilla pods are classified in the market and valued according to their length, plumpness, and colour. Thus, at the same sale the lowest grade of dry, brown pods realised only from 4s to 11s 6d per lb.

Referring to the condition and prospects of Vanilla cultivation in the Seychelles, Messrs. Brookes & Green, the well-known brokers, state that the Seychelles crop for 1901, shipped from August to December, totalled fully double the heaviest quantity exported from the island in any previous season, it being estimated at about 80 tons. The feature of this season's supply of Vanilla from the Seychelles is the unprecedented large proportion of short beans. Medium to good size quality measure from 6 to 8 inches, but the consignments landed in London during the past three months have contained about 75 per cent of very short beans, ranging from 3 to 5 inches. The result has been that, whilst long-length quality has fairly maintained previous values, the short measurements show a reduction of about 50 per cent. To obtain good plump pods, it is incumbent for planters to see that early in the season the young shoots are thinned by picking out a quantity of surplus sprouts; in the present case it would seem as though nearly all had been allowed to grow. This view is somewhat confirmed by recent reports from the Seychelles, which advise that the flowering for the next crop is small—possibly due to the weakening of the vines last year; indeed, some of the older plants are reported as seriously exhausted—a very natural result if the above surmise is true.

The warning here given, though not expressed in gardening terms, will be understood by those who cultivate the plant for profit, and who will, no doubt, benefit by the hints. As an illustration of the quantity of Vanilla sometimes shipped in one consignment, it may be stated that in November last one shipment from the Seychelles amounted to 21,267 kilos, of which 12,385 kilos went to Marseilles, and 8,881 kilos to London. The exports from Tahiti during 1900 amounted to 162,636 lb., of the value of £32,132—no small sum to be added to the finances of the island.

Chillies and Vanilla, to which we have referred, are only two items in the immense returns that flow into and are distributed from the great city markets included under the generic name of Mincing Lane. At another time I hope to refer

to other products of equal value and interest. JOHN R. JACKSON, Lympstone, Devon.—*Gardeners' Chronicle*, March 22.

WORLD'S PRODUCTION AND CONSUMPTION OF COFFEE.

The French Consul in Brazil, in a report on the state of trade in that country, states that there is an over-production of coffee throughout the world, and that in Brazil there is a tendency to restrict the area of cultivation. He says that in the year from July 1, 1900, to June 30, 1901, the total production of coffee throughout the world was 15,460,000 bags of 132lb. each, and that of this quantity 11,500,000 bags were grown in Brazil, 1,150,000 in Guatemala, Costa Rica, Mexico, and Nicaragua, 1,050,000 in Venezuela, Colombia, Ecuador, and Peru, 480,000 in the Dutch Indies, 450,000 in Hayti, 315,000 in British India and Ceylon, 200,000 in Puerto Rico and Jamaica, and 90,000 in Padang. He estimates the consumption at 14,117,620 bags, leaving an excess of production at 1,342,380 bags.—*London Times*, April 7.

SUGAR CULTIVATION IN FIJI.

An important feature in the sugar industry of Fiji is the cultivation of cane by Indian coolies who have completed their term of indenture. At Rewa they cultivated, during 1900, 1,077 acres, producing 18,399 tons of cane, valued at £9,473. At Navua they cultivated during the same period, 1,921 acres, producing 24,087 tons of cane, valued at £12,516. During the last three years Government has acquired, under the Settlements Fund, certain blocks of land, aggregating 6,790 acres, which have been divided into small holdings, and considerable areas have now been leased at a nominal rent to Indian immigrants whose terms of indenture have expired with a view to inducing them to remain in the country. The annual rental at present obtained from the blocks leased aggregate £234.—*H. and C. Mail*, April 11.

WILD ANIMALS IN MADRAS.

The number of wild animals destroyed in this Presidency during 1900-01 was 1,015, or 41 more than in the previous year. Of tigers killed there were 105, or 16 less than in the previous year, but of panthers, leopards, and cheetahs killed there were 829 accounted for, or 55 more than in the previous year. As usual, Ganjam and Vizagapatam contributed the largest number of animals killed, the figures being 209 and 257 respectively. The rewards disbursed during the year amounted to R20,761, against R19,548 in the previous year. The loss of human life caused by wild animals was as high as 203. It was heaviest in Vizagapatam, where 71 persons were killed. The number of cattle killed was 15,197, the heaviest mortality being in South Canara (4,623).—*M. Mail*.

PLUMBAGO MINING IN CEYLON.

As we mentioned in our last issue Capt. Tregay, the well known mining expert, leaves Ceylon by the mail steamer "Orizaba" on Thursday after 4½ years' residence in Ceylon, having been here since 1897 and spent most of his time on Monerakande whilst also visiting various parts of the island for plumbago mining purposes. "I have had considerable experience in mining generally" said he to our

representative, "and my opinion most decidedly is that there is a good deal of money to be made out of plumbago, if sufficient funds are provided for deep mining. The fact of the matter is that I am going home now with the object of floating one or two companies to take the matter in hand. Most of the surface plumbago has already been exploited and what we want to do is to mine deeper with proper appliances. The deeper the mining, the better the quality and therefore the better the price. High prices, of course, always stimulate prospecting and this was overdone during the boom 3 or 4 years ago. The present prices are sufficient to encourage prospecting on legitimate lines. There is not much new ground to open up but there is plenty of ore below present workings which can be reached with proper appliances to go to great depths. What I mean by proper appliances is superior pumping and hauling machinery; nothing else is required but good management. Most decidedly I believe there is money to be made out of plumbago, if it is properly worked. All you want is a proper system of working and there does not seem to be any system whatever in the native way of working. You want really to get down to the primary rock. What I say is that you may get plumbago at practically an unlimited depth. The greater the depth the better the price. There is a large export from Ceylon just now, but honestly I believe it is from stock and that the production is not keeping pace with the consumption."

PROFESSOR HERDMAN'S RESEARCHES.

(To the Editor of the *Daily Post*.)

Sir,—The enclosed letter from Professor Herdman reaches me abroad, hence delay in transmission. Although more specially intended for his biological friends, it is of such interest as to deserve the wider publicity through your columns, and forms the fourth of the series.

The experiment of the drift bottles, thrown overboard *en route* down Channel as a clue to currents, has proved even more successful than anticipated and form a most valuable sequel to previous experiments made in the Irish Sea.—Yours, &c.,

ISAAC C. THOMPSON.

Mentone, April 3rd, 1902.

S.S. "Lady Havelock," off Chilavaturai Pearl Fisheries, Gulf of Manaar, Feb. 28th, 1902.

My Dear Thompson,—I have just heard from our Fisheries Department at University College of the success of the drift-bottle experiment which we started the night we left Liverpool. Perhaps Mr. Johnstone has given you later information than I have, but within a month from the time they were set free 120 out of the 200 drifters had been returned, and they were practically unanimous as to the story they told about the currents.

Mr. Hornell and I have now been here about six weeks, and have finished the first part of our work, which was a general survey of the marine zoology of the Ceylon coast, and have started the second part—viz. a detailed study of the pearl oyster banks in the Gulf of Manaar. For this work we have our dredging steamer the "Lady Havelock," a smaller steamer the "Serendib," and two large sailing barques, on one

of which we have laboratory and tanks, while the other accommodates the divers and other natives. With the numerous native and ship's boats added, we make a flotilla such as, the Inspector of Fisheries tells me, has never before been seen in this out-of-the-way place.

The general marine fauna here is very rich, and we get up, either by means of the divers or by dredging, new and interesting specimens every day including many cases of commensalism and of protective colouration. We are also getting a good many new facts about the pearl oyster which will, I hope, enable us to make a useful report. But I don't intend to tell you anything about our oyster work except in most general terms, as we shall not come to any conclusions until we have all the facts before us. With our numerous divers and facilities for dredging and trawling we are making a most thorough examination of the ground, and as you know well, in a biological problem of this kind, the whole of the rest of the fauna—both bottom and surface—may have to be taken into account. We are, of course, taking frequent tow-nettings at different depths and times of the day, and I am trusting to you to work the Copepoda out for me, which will be a help in determining the food necessary for the oyster, as we find some Copepoda in its stomach. There are a great many water snakes here. It is striking to find animals like these of terrestrial origin so far out at sea as we do. We have caught and dissected a considerable number. They have been said by the divers to eat the pearl oysters, but we can find no evidence of that from their stomachs. Their food, so far as we have seen, is entirely small fishes. Part of my work is to report upon the most suitable spot for a small biological station. This has necessitated visits to several little-known parts of the coast. Between two trips lately I had a couple of days to spare, which enabled me, along with Mr. Willis, Director of the Botanic Gardens, to go up Adam's Peak, a very interesting climb. We were on the top on the night of full-moon, and found about 500 pilgrims worshipping at the shrine of the sacred footstep—a motley crowd. We had a perfect sunrise, and the famous shadow of the Peak was well shown.

We have seen no sharks yet at the pearl fishery, although they generally make their appearance. The divers wear charms to protect them, and they also have a shark-charmer, who plays a pipe to keep them away. There is likewise a Goddess of the Pearl Banks who has to be propitiated. She was formerly in prehistoric times an Amazonian Queen of the Cingalese who took such an interest in the pearl fishery that she sat all day on the northern end of Karativue Island, watching the divers. Now Karativue is at present at least twenty miles to the south of the pearl banks, which must be discouraging to the believer unless the Queen had remarkable eyesight; but there is a shoal upon which we have been dredging and which extends from the end of Karativue up to within a mile of where we have found the pearl oysters, and it is highly probable that that shoal was formerly part of the island—which establishes at least the possibility of the ancient story. The Queen like the northern part of her island is now beneath the waves and the pearl divers believe that she is still watching them. I hope that this will reach you in time to give my remembrances to the biologists at the April meeting of the Society, and I hope to be with you at the May meeting.—Yours ever.

W. A. HERDMAN.

THE RENOVATION OF TEA ESTATES,

(By an old Planter.)

Although a considerable number of gardens in the Surma Valley have covered their expenses and declared dividends, the ruins carried forward indicate that dependence upon accommodation, either from banks or agency houses, has still been resorted to for tiding over the unproductive months; thus very few proper-

ties at the present time of writing are unencumbered with debt, and recent accounts show that over a very large area the first flush has well nigh been annihilated by hailstorms of unprecedented violence. Considering the overstocks that must be locked up in the Continent, and the dwindling down of the shortage to less than one-fourth of what it was estimated to be in August last, the ripping visitation may be regarded as a blessing in disguise; for there is reason to believe reduction in output has not been so loyally observed as those who professed to have adopted it wished their neighbors to believe,—the statistics proving the allegation. * * * The lighter soil in Sylhet and Cachar is exhausted, and though persistence in keeping up estates which yield but meagre returns (that cannot really be considered legitimate profits) may suit the views of certain interested parties who alone benefit, the hopes of shareholders grow fainter every successive season. * * *

The chief need of the tea plant is ammonia, which by enriching the sap gives extra strength to the leaf, which sales show the Surma Valley teas are deficient in; phosphates develop wood and fruit, corresponding to bone and muscle, but as the ordinary run of our plants are tolerably well supplied in this respect, when not knotted and gnarled by the now fortunately obsolete system of pruning; the bone meal vendee does not contain a sufficient proportion of ammonia to bring our leaf up to the mark; an undue amount of the alkali would prove detrimental, but 25 per cent. is certainly required, so that agents might well put themselves in communication with the local gas works upon the subject. Were it feasible we are inclined to recommend one-fourth ammonia, one-fourth fine-ground bone dust two-fourths compost of well-dried weeds, dead leaves and other vegetable matter, or wheel soil procurable from such places as are inundated by mountain streams. The proper shape of the renovating pits will suggest themselves to most people, which may be wedge-like, the base being toward the root of the plant, such with the contents well stamped down as much as possible, to prevent evaporation of more volatile gas would have a lasting effect over three or four years, while simple top dressing, even when forked in, wastes its constituents up on the empty air. * * * More remunerative prices must be obtained, for the cost of production has reached its limits; and the carryings forward are neither sufficient to meet cold weather expenses nor clear off any appreciable amount of the debt the majority of plantations are labouring under, still less yield any return to the investors. Mr Mann's whole attention should be directed to the subject of manure; we do not require analysis of soils, which everyone knows have long since parted with whatever productive properties they may have at the outset possessed. Few, even if they have the land, can afford the expense of extensions, which will return nothing for four years, and a good number by ill-advised relinquishments have brought their whole available area under plant. The only hope therefore lies in renovation; the alternative we need not dwell upon. Rule of thumb planting must now give way to systematic gardening, which ultra-conservative orchard owners have at length realized in England. This, combined with curtailment in production, may yet bring the Surma teas up to the 9d., otherwise estates must be thrown up. For though many of the adjuncts or substitutes to tea, suggested *ad nauseam*, promise better results, it has to be remembered that these will not thrive upon exhausted soil, though there are a number of people who in discussing this matter are wont to express a different opinion.—*Indian Planters' Gazette*, April 19.

TOBACCO IN CENTRAL AFRICA.

As the writer was anxious to know definitely whether tobacco should be fermented or not before exporting, the small sample submitted was unfermented.

The report is as follows:—"In the present condition of the sample of Zomba-grown tobacco, it is quite impossible to denote for what it is suitable. There is little or no flavour of tobacco in it, and evidently it has not been properly fermented.

We presume this is the result of the first attempt to grow tobacco for the London Market and from the general appearance we should think that, with proper expert supervision, a merchantable article could be produced.

The tobacco should be fermented before it is packed."

From the report it would appear that all that is now required to place a good tobacco on the London Market is expert supervision. This is undoubtedly where the whole tobacco question hinges. It has been the critical point in tobacco-growing in other countries as well as B C A, and expert curers have been obtained from America to manipulate the tobacco for the London Market; but can B C A go in for expert curers? From enquiries made in America it is ascertained that the salary of an expert curer for B C A would be over £1,000 per year. It is almost impossible to think of an expert curer being obtained for B. C. A. until a big business is done in tobacco-growing; then, the community might combine for the services of an expert.

The time is scarcely ripe to engage an expert at present, owing to the small quantity of tobacco grown, and the industry being only in the initial stage of development.

Under the present circumstances it may appear disappointing, and to some perhaps a waste of time and labour to grow tobacco; still it would be a great mistake that there should be any hesitation to cultivate such a valuable product because of the difficulty met with in its curing.

It certainly is a delicate matter to manipulate tobacco to its proper condition, but it is within the range of all to do it; and, considering the suitability of the climate, the cheapness of labour, and the great demand for B C A tobacco in Southern Rhodesia and South African markets, the curing of the crop should be persevered in until a commercial article of good quality can be produced.

Since the receipt of the London Chamber of Commerce Report, about half (nearly 250 lb) of the tobacco grown at Zomba last season has been experimentally fermented, and from the experience thus gained it is hoped that some progress may be made towards successful curing. The bulk now made up is of leaves that were first cut from the stalk, and dried in an ordinary grass shed. A second quantity now being fermented is of leaves that were dried on the stalk, in a grass shed with free circulation of air.

It is too early to say anything definite regarding the quality of the first experiment, but the result is certainly encouraging. It has shown where mistakes occurred in the manipulation, from the time of cutting in the field.

A special highly graduated Hygrometer has now been received for the purpose of fire (flue) curing.

Should anyone be desirous of curing their crop in this manner, every assistance will be given them from this office as far as it is possible.

POULTRY CULTURE IN FRANCE. ARTIFICIAL INCUBATION ON A BIG SCALE.

In the last report of Consul-General Inglis, of Paris, an interesting account is given of the

method adopted in France in poultry culture, and a description of the artificial incubation which has for many years past been conducted on a large scale, particularly at Gambais, near Hondan, on the Paris-Granville line, about 31 miles from the capital. At this place there is a practical school of aviculture, which was instituted in 1883 by a decree of the Minister of Agriculture, and it is in the centre of the poultry-farming industry, Hondan itself being renowned for its breed of fowls, the favourite description being Hondans, Crèveccœur La Flèche, and Faverolles. The Bresse, another breed—a cross between the Andalusian and common fowl—is bred extensively about Bourg, and gives the renowned "Poularde de Bresse." The School of Aviculture at Gambais enjoys a high reputation, and pupils of either sex are received. Candidates must not be under the age of 15, and must have received a certain amount of general instruction, such as would entitle them to a certificate from the primary schools. The terms are £14 for a three months' course, including tuition, board, and lodging. On leaving the school, pupils who have shown capacity to act as instructors in aviculture, received a certificate of competency, which, it is said, enables them without difficulty to obtain employment in this line of industry. In connection with the system of artificial incubation which is practised at the school, it may be said that the incubators and other appliances are more or less the invention of the original founders. Heat, moisture, and aeration are the principal factors in the process of incubation. The heat is now arranged so as to come from above, and, being thus directed on the entire surface of the drawers in which the eggs are arranged, is more evenly distributed, and it is claimed that the eggs, by receiving the warmth from above, are in this respect in the same condition as if under the hen. Regular aeration is obtained by pipes running along each side of the apparatus, and an outlet at the same time secured for the carbonic acid disengaged by the embryos. The requisite degree of moisture is ensured by taking advantage of the difference between the temperature of the drawers and that of the surrounding atmosphere, the two currents being brought into contact by the lateral pipes already referred to; a moist vapour is the result, similar to that observable on the windows of a room in winter.

THE NEW HYDRO-INCUBATOR

used is capable of accommodating from 200 to 500 eggs, the price of the apparatus ranging from £6 to £12, the latter including drying-box. Heating is now effected by a small briquette of compressed brick dust, which burns slowly from 12 to 14 hours, according to dimensions. To heat an incubator of 250 eggs it is said that three-fourths of a briquette, costing 1½d, is sufficient for 12 hours. The danger of fire inseparable from the use of a lamp is thus eliminated, since the briquette is placed out of harm's way in a specially-arranged chamber. An incubator of 60 eggs requires about 20 briquettes, one of 130 eggs 25, of 250 eggs say 35. The eggs having been placed in the incubator in the morning, the drawers are not opened until the evening, and then only for three or four minutes; the next morning the temperature is taken, the drawers are removed, and the door is then closed; the eggs are turned over and their places changed, so that the eggs which were in the centre are now at the sides of the drawers; they are thus made to

occupy alternately the warmer and cooler parts of the apparatus, and are never twice in succession in the same place or on the same side. An ingenious contrivance has been devised for effecting this operation, which, however, does not appear to require any great expenditure of time, as it is said that as many as 290 eggs can be turned in five minutes, or in ten minutes by an inexperienced hand. After the lapse of ten more minutes the eggs are returned to their places, having been out a sufficient time, if it is summer, for aeration and cooling; the water is then re-heated, or the briquette replaced in the apparatus; the whole then remains undisturbed until 7 p.m.; the doors are, however, opened at 1.30 p.m., and the eggs are gently fanned so as to renovate the air, thus also imitating the hen flapping her wings; at 7 p.m. the temperature is taken, to see if any water has to be drawn off and replaced by a further supply. The eggs are then once more turned and their places changed, as in the morning, and the whole is at once closed. Such is the procedure during the whole period of incubation. To recapitulate:—(1) Temperature 39° to 42° (Centigrade) during the course of incubation; (2) re-arrangement of the eggs, as described, morning and evening; (3) maintenance of the temperature by the addition of boiling water, or of the briquette, and (4) testing the eggs. With regard to the last item, it is estimated that in dealing with a large number of eggs,

SOME 20 TO 50 PER CENT. ARE STERILE,

hence the necessity of testing. This is done on the fifth day (120 hours), a special lamp tester being employed for that purpose, for the operation must be performed in a darkened room. In this case, the light is placed at a height of about five feet, the egg being held with the fingers of the right hand, the large end uppermost, while the left placed over the egg acts as a shade. A practised eye can then readily distinguish the fertile egg. After 120 hours in the incubator, if fertile, the yolk is seen to be dilated, forming a semi-circle shaded at the base. The embryo is seen in the centre, and resembles somewhat a spider, the legs of which are represented by the blood vessels, now plainly apparent in proximity to the embryo, and increasing in distinctness as they approach the perimeter of the egg. If the embryo is alive, it oscillates from right to left, from the bottom upwards, every time the egg is moved. If on the other hand it is without life, the vessels are dull and ill-defined, and the embryo will be seen clinging to the sides, and remains motionless, having the appearance of a spot of ink. Before being placed in the incubator, eggs are also tested as to freshness. The air chamber is barely visible on the first day, but goes on increasing in dimensions. Eggs should not be more than a week old. They are collected in boxes with partitions, so that each egg is in a separate compartment and cannot receive a shock or get cracked. They are then placed in a box and covered with bran or dry sawdust. Shaking caused by conveyance in carts or by railway is prejudicial; it cannot, however, always be avoided and in these cases the eggs are laid on grain, in a cool, dry place, for 24 to 36 hours. Fertile eggs cannot be recognised until after five days' incubation. The 21st day having been reached, the drawers of the incubator are opened at 7 a.m. and the tempera-

ture noted as usual; the chirping of the young brood will now probably be audible. Eggs not hatched out are, however, turned as usual, any shells showing signs of perforation being placed with the perforated side uppermost, so that the young chickens may more readily breathe. Chickens already hatched out are now transferred to the drying box. At noon the incubator is again opened, and the operation proceeded with as before, the chickens being covered with a soft woolen cloth in summer, and with a small eider down in winter; the more numerous the brood the less susceptible will they be to cold. The young birds are never helped out of the eggs, except perhaps when one adheres only by a few strands of membrane. If the chicken is assisted to emerge from the shell there is every danger of the blood vessels being lacerated and the loss of a single drop of blood at this stage is, it is said, sufficient to cause the death of the chicken in from three to four days. The drying-box is prepared with a layer of soft straw or hay, barley straw being preferred; 40 to 50 chickens are placed in it and covered as already described. The next day they are brought out into the open compartment; but at this stage no food is given. After being out for from five to ten minutes they are restored to the box, to be taken out again two hours later. This time they are given a few crumbs of very dry bread. After a day in the drying-box, they are transferred to the artificial mother or breeder; two of these suffice for some 450 chickens. During the first week they receive constant attention; on the third or fourth day they are given some liberty, being let out into an enclosed space a few yards square, but the moment they show signs of chilliness they are driven back under the protection of the breeder. The food during this early period consists of a paste made of barley meal and milk, sufficiently consistent to adhere to the wooden bitlet employed for that purpose. Instead of waiting, as is usual in the Bresse and Maine, until the birds are from six to eight months old, at Gambais the operation of fattening for the table begins as soon as the pullets have reached the age of three-and-a-half months. Cages containing fifty birds are arranged along the walls of the building devoted to this purpose, which is kept warm in winter, and, as far as possible, cool in summer. The floor of these cages is covered with a thick layer of straw, which is renewed every morning. Three meals are given every day for a fortnight. The first consists of a lukewarm liquid mash, composed of barley meal and water; the second is the same; but for the third the mash is made with milk or "petit lait." The latter is the milk running from cheese in process of manufacture, and fetched in barrels from the manufactories. At the end of a fortnight the fat begins to make its appearance. In order to give the finishing touch, a small quantity of lard is now given to each bird at each meal. This is continued for four or five days, when the bird will be so fat that, if the *végine* were maintained for two days more, it would inevitably succumb. If it is sought to attain the extreme limit of perfection, for the last three days eggs are added to the mash in sufficient quantity for each bird to have at least one per day. The food is given by means of a funnel specially made for the purpose. Two persons, it is said, can thus dispose of sixty fowls in an hour, one in a minute.—*Journal of the Society of Arts*, April 11,

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1903, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from sea level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February; also plants.

Coffee Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel, and Ornamental Trees, Trees for Roadsides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee Cacao, Cardamom, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

WILLIAM, HENARATGODA, CEYLON.
Liber's, A.I. and A.B.C. Codes used,

J. P. WILLIAM & BROTHERS,
Tropical Seed Merchants,
HENARATGODA, CEYLON.

To the Editor.

TEA IN AUSTRALIA :

CUSTOMS INSPECTION AND "COOLIE" VERSUS
WHITE MAN'S PACKING.

Melbourne, April 9.

DEAR SIR,—Since writing to you last I have been able to ascertain that the supervision of tea at the Customs will be much the same. The Health Officer still exercises the same power, but unless tea is absolutely unfit for human consumption, I believe, the quality passed may be very low. The prominent aspect of the subject, in fact, seems to be the prevailing impression that an inferior description of tea will now be foisted on Australia. It is therefore for Ceylon to look to what tea is sent here, and be careful never to have her name associated with any of the scandals which are predicted to crop up at the Customs here ere long as stocks diminish. You are doing well in urging this, in season and out of season, particularly at present, as I have noted that *Ceylon* is chiefly aimed at, in a mass of letters which have been appearing in the local press, in regard to what they call "the grave injustice done to Australian tea packers and blenders by the cancellation of the duty on packet tea."

The Labor members are much blamed for their oversight, in what was undoubtedly *their* move, and though I do not think you need anticipate any alteration of the *free* decision in regard to *bulk teas* in the Senate, I am so imbued with the feeling that the Barton Government is under the thumb of the Labor Party that, if the packet people once get the Ear of Trades Hall, "Coolie packed tea" will soon cease to be on the free list. I enclose you some letters and send papers on this and other political aspects.—Yours faithfully,
ONLOOKER.

The Australian tea importers find their interests have received little consideration at the hands of the representatives in the Federal Parliament. The abolition of the duty places them in a very uncertain position, whilst it entails a heavy loss on their duty-paid stocks. One section of the tea trade will benefit materially, and that is the retailer. Possibly the consumer may get a tea better by 1d per lb. for his 1/3 or 1/ today, but an additional 2d per lb. profit goes into the pockets of the distributor, which is very much to his liking, notwithstanding all Mr Watson's talk. Neither that gentleman nor his friends know much of the trade, and in their efforts to get a free breakfast table have played into the hands of a small section of the community, which will absorb almost the entire remission in duty. The tea packers are in a worse position. All the rubbish which is packed in Ceylon and Indian markets, to which attention was called some time back, will now find its way to Australia, and the coolie will oust the local white packer from his employment and thus fill the ranks of the unemployed. The Labour leader in the end will probably be cursed by those whom he thought he was serving. Packet tea should by all means be dutiable, and it is

regrettable that Ministers did not recognise the urgency of the situation with as much readiness as they have shown in other directions by bringing down recommittals for favored industries.

TEA IN PACKETS.

From time to time the grave injustice done to Australian tea packers and blenders by the cancellation of the duty on packet as well as bulk tea has been pointed out in "The Age," yet singularly enough none of the supporters of local labour has stirred a finger to place a small protective duty on the former, made up by coolie labour and packed in wrappers, &c., which have no duty. The question of packet tea must be kept altogether apart from bulk tea, which the House has in its wisdom or otherwise made free. The total quantity of tea imported into Australia annually is estimated at over 30,000,000 lb., and of this quantity it is computed that more than 20,000,000 lb. are sold in 1/2 lb. to 12 lb. packets, employing local labour. The result of the Federal Government's decision has been to endanger this industry, and coolie-packed teas are being ordered freely. Under the proposed tariff a protective difference of 1d per lb. was made between duty on bulk and packet teas. The trade in Melbourne, Sydney, Adelaide and Queensland are all protesting against the action of the Government, the Melbourne petition reading thus:—

Melbourne, 10th April, 1902.—In drawing attention to our cause, we wish to give assurance that the question of whether tea ought to be free or bear a duty does not form one of the points of our contention. Until recently the different tariffs existing in the various colonies served to make these markets so small that they acted to some extent as a protection to the local tea packers against aggressive competition from the employers of Asiatic labor, but latterly even then it was becoming apparent to us that the cheap black labour must in the end beat us out. With the inauguration of the Federal tariff, our market became one easier for our opponents to work; and we fear, unless some assistance is given us, the disadvantages under which we labour will compel us to remove our packing operation to where we can take advantage of this cheap labour. At the present time there are here representatives from Ceylon canvassing for orders, and using as their main argument that they can undersell locally-packed teas, because of the advantages they have of cheap labour, and that they avoid payment of duty on the materials used in the containers. We pay white men's wages, which is estimated to be about 1/ to every penny that colored labour costs for similar services. In addition to this almost every article we use in our business of tea packing is subject to an import duty, whilst those who compete against us have no such handicap. Wrapping paper, twine, printed matter, timber for cases, weighing machines, scales, dynamos, gas engines, blending machinery, starch for paste making, &c., are subject to duty, and these are the principal items in use. We therefore feel justified in asking that some counter-vailing duty be imposed on all packages of 12 lb. and under containing tea.

CACAO IN THE WEST INDIES: THE
WITHERING OF YOUNG PODS.

Trinidad, B.W.I., 9th April, 1902.

SIR,—I noted in your January issue that the author of the article on cacao diseases said that information on the withering of young pods would be acceptable. I gathered some such information some time ago in response to questions which I sent to several planters and managers

in the colony, being anxious to know why there was so much waste of plant energy and to find a remedy. I send herewith four sets of answers and also the list of questions put.

No. 1 is a Manager in Tobago, a neighbouring island, famous for the richness of its soil, and that may account partly for the small percentage given in answer 2.

I regret to notice so little reciprocity between those who live on the estates and those who work from a scientific point of view for the benefit of the former class. Hoping I am not intruding on your valuable space.—I remain, yours faithfully,
W. L. (CURATOR.)

CACAO.

1. What difference is there between Cacao Trees (a) under dense shade; (b) under normal shade (c) under no shade?
And how is the crop, the number of flowers, the growth, and the amount of disease—especially the drying up of young pods—affected by the above conditions?
2. About how many per cent of young pods wither or dry up on healthy full-bearing trees?
3. Is there a distinct difference in such percentage from trees on poor soil and those on rich soil?
4. Do young pods usually dry up in bunches, *i.e.* all on one cushion?
5. Do all young pods except one or two sometimes dry up on one cushion and those remaining become good mature pods?
6. Where only one, two or three young pods appear on one cushion, do these usually develop into good pods?
7. Are some parts of the tree more subject to pods drying up than other parts?
8. In what way is the drying up of young pods affected by the weather? And is there more drying up of young pods in or just after an abnormally wet season or an abnormally dry one?

ANSWERS TO QUESTIONS ON CACAO.

- 1.—(a)—Under dense shade pods rot from too much moisture; (b) under normal shade the largest percentage come to perfection; (c) under no shade—except in sheltered valleys—pods wither and dry up.
- 2.—About 12 per cent of pods dry up.
- 3.—Decidedly in favour of rich soil.
- 4.—No.
- 5.—If carefully thinned, those remaining come to maturity.
- 6.—Yes, and this is what is most desired by the cacao planter.
- 7.—Yes, trees not pruned early into shape will bear those pods on the superfluous branches.
- 8.—Pods do not dry up in ordinary weather, but a heavy downfall of rain has a destructive effect on flowering trees, and very young pods. Under the most favourable situation and cultivation, those dry pods will be seen.

The answers to these questions depend largely on climate, soil, and district or situation.

- 1.—(a)—Cacao trees under dense shade generally grow to be long and thin, and they are more likely than otherwise to be affected by disease. During wet weather lots of flowers come out and pods form, but they get rotten and wither. (b) Under normal shade, such as Immortal trees at 36 feet apart on the Vega, the trees are in their glory, they will grow uniform and healthy. (b) They will give their full crop of 15 fanegas (average) per thousand according to season. (c) Under no shade, the crop is practically nothing during a dry year. During the wet months the trees throw out promising young shoots, but during the dry months these seem to burn and dry up.
- 2.—Fully 95 per cent wither. When it is taken into account that even on estates yielding 10 bags (of 165 b each) per thousand trees, the average yield per

tree is 20 to 23 good pods, it is plain that an enormous number must wither.

3.—Little difference, because trees on poor soil throw out fewer flowers than those on rich soil.

4. 5 and 6. One, two, three or more pods often come to maturity on one cushion, which originally had many more young pods, which withered before maturing. In many instances, however, all the young pods on a cushion will dry up.

7. Given a healthy tree, properly pruned, there is no part of that tree more subject to pods drying than other parts.

8. A prolonged season of drought after a season of rain causes a very large percentage of young pods to dry up. Also if after dry weather we experience heavy and continued rains, the young pods seem to become, as we say, "seized" and rotten. On the flats or lowlands more pods wither after an abnormally wet season than after a dry one, but in the hilly and undulating districts many more wither after an abnormally dry season than after a wet one.

1. (a) Slow growth; very small crop; nearly all flowers and young pods die; few flowers; disease frequent. (b) Quick growth; crop large and regular as a rule; flowers plentiful; disease not frequent. (c) Slow growth; very small crop; few flowers; flowers and young pods destroyed by exposure; disease not frequent.

2. About 80 per cent.
3. The percentage must be much the same, as trees on poor soil have proportionately fewer young pods.

4. Yes.
5. Yes.
6. Yes.
7. I do not think so.

8. The drying up of young pods is equally affected by excess of damp or heat and also by high winds, but if the land is hilly it is not affected to any great extent by either excess.

1. (a) Trees appear healthy, but develop very little fruit. (b) Trees put out more blossom and develop a higher percentage of fruit. (c) Under no shade, or on poor dry soil, it would be impossible to grow a tree to bear fruit; on good soil in deep gullies or ravines a fair crop could be obtained without shade.

2. At least 25 to 35 per cent.
3. Percentage higher on poor soil.
4. No, the weakest ones throughout the trees dry up.
5. Yes.
6. Yes.
7. The lower parts of old trees and the upper parts of young ones.

8. Both extremes favour the drying up of young pods. As alternate showers and sunshine seem to be most favourable I prefer very wet weather to very dry, for in the latter, not only do young pods dry up, but those approaching maturity fail to ripen properly.

TEA IN THE UNITED STATES: WILD SPECULATION.

Fairfield, Lindula, April 15.

DEAR SIR,—I think the enclosed cutting from an American paper will amuse some of your readers. Who can Harold Weddle be?

The Dr. Shepard mentioned must be a *very* sanguine man—in addition to being "an enthusiast and benefactor."

Of course, we poor planters have not the advantage of possessing "Dragon's food" jät tea; but many of us own China tea of similar sorts and we will kindly supply the worthy Doctor with an unlimited amount of seed from the same and will label it "Dragon's food" or anything else; or I fancy he could save himself the trouble of opening land in Carolina by purchasing the source of wealth as

above here—and—when he is tired of losing money over the “benefactor” business—he could start an oil factory to work off surplus seed.—Yours faithfully, T. M.

TEA CULTIVATION IN SOUTH CAROLINA.

Harold Weddle of London, Eng., visited a number of South Texas points last week on a tour of inspection to determine the adaptability of the soil for tea growing. He is largely engaged in tea culture in Ceylon and India. Through the experiments made in South Carolina he recently became interested in America as a possible tea-growing country. Speaking of the experiments in South Carolina, he said:

“An invitation was recently extended me to visit Pinehurst tea estate at Summerville, S C, by Dr Chas. Shepard, the proprietor, who is experimenting with the possibility of tea culture with the aid of the United States Government Department of Agriculture. Summerville is situated 22 miles from Charleston, S C, a most delightful spot surrounded with lofty pine trees. The soil is admirably adapted for tea growing, being rich and loamy. Dr Shepard has found that tea can be grown in America, but admits that better results could be obtained further south, where more even temperature predominates, less disposed to sudden changes, and where the thermometer does not reach below 25 degrees Fahrenheit. Pinehurst is divided into several sections of tea growing, owing to experiments in the seed obtained from India, Ceylon, China and Japan, both hybrid and indigenous. The best results so far obtained are from Darjeeling seed, a hill region of India. But excellent results have been obtained from seed which the United States government procured from a celebrated tea estate in China, known as Dragon's food, where the tea is never exported, being entirely consumed by wealthy Chinese. The tea bushes are grown to a height of about four feet and are vigorously pruned and all the soil is sub-drained. Dr Shepard is an enthusiast and benefactor to his countrymen in undertaking so thorough a research in tea cultivation. His motives are purely for the advancement of scientific discovery, without pecuniary gain to himself. And the United States department of Agriculture, Realising this, offers every possible aid to facilitate him in furthering the industry.

“The main difficulty now that is to be overcome, to bring the cost of production on a basis of competition to meet foreign grown tea, is labour, as the heathen and Hindoos receive wages about equal to 8 cents per diem. However, Dr Shepard has partly overcome this obstacle by the employment of several negro children, who live with their parents on the tea estate. The children are educated and fed, which in turn is another step towards the solution of the negro problem. The children are taught to pluck the leaf and in many ways are well adapted in the tea fields.

“No expense has been spared at Pinehurst in adopting modern machinery for driving and preparing the leaf after it is picked. Having imported from England the very best tea machinery in use in India and Ceylon, Dr Shepard has recently completed a machine of his own invention, whereby green tea can be made without the handling as in vogue in China. Its simplicity appears at once to those understanding the manufacture of tea. There is absolutely no sense in artificially coloring tea green, as it comes from

China and Japan. The flavor can be obtained naturally with the aid of Dr Shepard's machine.

“The cultivation of tea is undoubtedly feasible in America and, if carried out on a large scale and the expense of labor saved, there is no reason to doubt that in course of time it would become a great and paying industry. One of the important facts is that the tea plant lives longer than a human being and can be gathered from when over 100 years old. We begin to gather the leaf at five years old, but Dr Shepard told me that he had so cultivated and grown it that he gathered the leaf, and it was good, after one year.”

CEYLON GREEN TEA—GOOD PROSPECT BEFORE ALL KINDS:—No. 1.

April 16th, 1902.

DEAR SIR,—I want to put before you some facts which go to show that Ceylon Green Teas, as made in estate factories last year and now, are appreciated on their own merits in Canada and even in the States. I rather think, for one thing, that Mr. Lipton's representative could tell you that they are pushing and selling successfully the present make of green tea in the States. As you doubtless know, the tea business of the States is in the hands chiefly of four or five large and very wealthy importing firms who have their agencies in China and Japan, and a good deal of money sunk in these; hence the difficulty in getting in either our black or green teas.

Then during the past month advices have been received from Japan, both independent statements, one private, the other taken from an official report, thus,—“Japan teas are also exported to Canada, but there, I hear, they are being rapidly supplanted by Ceylon produce.” “The position of the Japan tea trade in Canada is unsatisfactory in the extreme. The trade in the finer grades of Japan tea has been to a great extent supplanted in Canada by the Ceylon product, and the only demand that exists for Japan leaf is for the commoner descriptions which can be sold at low prices and which are largely used for mixing purposes.” “In Canada, however, the Japan tea trade is certainly suffering from the competition of Ceylon teas, and it is probable that, except in the lower grades of Japans, used chiefly for mixing purposes, the Ceylon product will eventually supplant the Japan growths.” Export from Yokohama to Canada 1899 7,193,776 lb.; 1901 5,623,366 lb.

In the States they do pay higher prices, and here no doubt Mr. Galt's tea will meet with a ready sale, and if the difference in price paid for these teas and the present Ceylon green is considerable, no doubt they will find many imitators; but their success yet remains to be seen. My own opinion is that there is an opening for both varieties, and you may have overlooked the statement made by Mr. Bois at the Chamber of Commerce meeting on the 25th March quoting from a letter he had received from Japan “the taste in the U.S. is gradually undergoing a change, and the demand for a *pure uncoloured tea is on the increase*. Therefore o

the tea now shipped about 1-3rd is now what it professes to be—pure *uncoloured* Japan teas.

I make a quotation from your columns:—"India has just been advised that a proper green tea should be made there, and not a tea such as Ceylon makes, which is neither 'fish, flesh or good red herring.'" This, no doubt, refers to your Calcutta telegram of the 4th in which Ceylon is stated to be producing a "namuna" tea; in this your correspondent erred. No "namuna" tea has been made here. This is a black tea, with an out-turn somewhat similar to an oolong un-scented, and a tea of this description, might be made, so Mr. Foley says, and pushed in Persia, to replace a similarly made tea, obtained from Java.

Is the Ceylon green neither fish, flesh nor good red herring? Possibly not; but this type *is* being made in India, it is finding a good sale in Russia, was approved of in Calcutta when tasted by the Afghan envoy and suite, obtained highest recognition at the Chicago Exhibition in 1893, and has met with satisfactory success in Canada. 'Japan greens' is a misnomer, they are known in the American market as "Japans," and are many-hued, black, brown and various shades of green, grey, blue, &c, Ceylon greens, although uncoloured, are green and become greener the more they are handled.

I see that the Anglo-American Direct Tea Trading Company is stated to do already the largest Indian and Ceylon business in America, and I wish them success in their new venture; but surely nothing should be done at this moment to check the output of the present article, which appears to be steadily making its way, if the price paid is any criterion. Low country green selling at the present moment at 34 cents and 35 cents average or two or three cents higher than they would get for their leaf made into black tea. I think the future outlook for our greens promising. They are being taken in Russia and other countries beside America, and we know that the supply from Japan is steadily falling off, and likely to continue; labour there is going up in price, and already costs over a shilling a day, or more than double ours. Their tea has also been falling off in quality as well as quantity,—I am, truly yours,

A FRIEND OF ALL GREEN TEA.

No. 11:—GREEN TEAS—AND GREEN TEAS.

Stagbrook Group, Peermaad,
Travancore, S. India.

13th April, 1902.

SIR,—Being, of course, greatly interested in Green Tea manufacture, I have read your recent editorials on the subject with interest. That Mr. Galt's experiments in "finishing off" (rather than manufacturing) Ceylon-made greens are so successful, from Messrs. Forbes and Walker's point of view, is certainly encouraging; but a broker is not necessarily a buyer. I had only recently before me samples of Green tea made, I believe, by a Chinaman in a Kangra Valley garden, and though the prices obtained made one's mouth water, viz., R1—2 as; 12 annas and 10 annas per pound, it apparently did not pay, as the

manager wrote to me with a view to adopting what I may call my "Ceylon system." The extra cost of panning and coloring made teas must be considerable from my observation of the process in Japan; and it is more than doubtful at present if a compensating higher rate will be given for appearance by our American buyers. As Mr. Galt is aware some of the highest-priced Japan teas are "uncolored" basket fired, and also the coloring is only resorted to by foreign buyers after the teas have reached the Treaty Ports. The finest teas are those made up into very thin squills which, though feasible with "China" leaf, would not be feasible with our large indigenous or Hybrid teas unless the bud and first leaf were plucked separately, a process entailing much extra cost.

I venture to express the opinion that (while it is very desirable to take greater care to obtain a good twist and appearance than is frequently the case), carefully made Ceylons, such as some samples of Dewalakande estate, which I had sent me by Mr Larkin from Toronto, are good enough in appearance for any market; and will push their own way on their intrinsic merit without any artificial aid from "coloring matter"—some teas answering to this description I sold in bond in New York at 22 dollar cents last year. Do I understand you to say that the teas Messrs Forbes and Walker refer to are manufactured in Colombo or are they manufactured upcountry and then manipulated in Colombo? I have great hopes that the machine I am about to place on the market will make the matter of "twist" and appearance a very much simpler one than at present; but meanwhile it will be interesting to know the average cost of production on the "Ceylon" system after adding on the Colombo factory charges, and to also get some idea of the trifling extra capital required to enable one to copy Mr Galt's (or rather the Japanese) system of panning and coloring as done in Colombo, without which we are apparently to be shut out of the American market. I fear much that a "dig" at the Ceylon Commissioner had more to do with the articles under comment than a sincere opinion that Ceylon and India should make the retrograde movement of "coloring" their teas.—Yours faithfully,

H D DEANE.

P.S.—It must be remembered Ceylon-made Green Teas took a first award at the Chicago Exhibition without the aid of coloring matter, and I may add that Messrs Frame, Alston and Arbutnot, of 21, Mincing Lane, and 132, Front Street, New York, writing me on 20th March last say they have just heard from their *Toronto friends* who had just inspected my samples, sent to Messrs P Larkin & Co., the Indian Tea Association, Calcutta, and the Planters' Association of Ceylon, "and consider the quality and manufacture to be both first class."

THE NEEM OR MARGOSA TREE: NO I.

Jaffna, April 22.

DEAR SIR,—As the information given in your valuable paper concerning the neem tree was interesting to some of your readers, I beg to add the following remarks. The tree is indigenous to Jaffna and the northern forests, and is extremely common here. It is known in Tamil by the name of *vembu* or *veppamaram*. Its uses are numerous and

it is worth special mention, at a time when so much is said about malaria and mosquitoes, that the smoke of the husk or shell of the seed is particularly odious to these unwelcome insects. The shell is put into a pot or chatty and allowed to smoke in a room during the mosquito season, and it is believed to be effective in keeping away these insects so long as any trace of the smoke is left. Cattle are made to inhale this smoke in some diseases. It may also be mentioned that the gum which exudes from the tree when the bark is hacked is the best paste that could be obtained locally. Enough has been said about the medicinal properties of the leaves, bark, and oil, and it is unnecessary for me to revert to it again further than to say that the leaves and twigs are believed to have a magical effect in the hands of the class of native physicians or devil-drivers who administer gentle blows with a bunch of them on the affected parts in cases of sprains, swellings, or snake-bites—or all over the body, in cases of so called possession of devils.—Yours truly,

A. N.

II.

Kayts, May 1st.

DEAR SIR,—The leaves of the *vembu* tree serve as disinfectants during the time of small-pox and other epidemics. The bark is a febrifuge like the cinchona bark. The twigs are used as toothbrushes in the mornings, the bitter taste promoting appetite. The discovery of cinchona in America has to a considerable extent diminished the value of the *vembu* or *margosa* tree.

M. T.

RAINBOW TROUT BREEDING IN CEYLON: SOME UNMISTAK- ABLE SIGNS.

Bogawantalawa, April 27.

SIR,—It will, I am sure, interest all fishermen and naturalists in Ceylon and India to know that the Rainbow trout (*salmo irridens*) is breeding freely in our upland streams.

On Friday and Saturday last Mr. W. A. Sparling and myself spent several hours in carefully inspecting two streams which were stocked less than two years ago with Rainbow Trout fry and it is no exaggeration to say that we saw *hundreds* of fry and fish in all stages of growth, from one inch in length to the size of a large minnow.

They were in shoals and in parties of four and five and appeared to be remarkably strong, healthy and wary, taking cover with marvellous rapidity when disturbed. I may state for the information of the sceptical that the streams referred to contain no other fish of any kind or description.

It having now been established beyond any doubt that the Rainbow Trout is breeding in Ceylon, I would suggest that all members of the Ceylon Fishing Club cease forthwith to kill any more of these fish for the space of at least 12 months. Otherwise, we are undoubtedly killing the proverbial goose. Judging from the size of the young fish I saw (from $1\frac{1}{4}$ inch to $3\frac{1}{2}$ inch), I should say

that they were hatched from ova deposited between October 1st and January 31st.—I am, yours faithfully,

THOS. FARR.

PLANTING NOTES.

RUBBER.—We are indebted to a Colombo merchant for a copy of the elaborate Annual Review of the Rubber Market—covering three pages of foolscap—of Messrs. Kranovisch & Co. of Liverpool and London. We shall reproduce it in full in our *Tropical Agriculturist*, as interesting in itself to all rubber planters and merchants and handy for reference.

LORD LAMINGTON ON QUEENSLAND.—Apart from the interest felt in Queensland as partially a semi-tropical planting country, a paper by Lord Lamington (owing to rumours connected with his name) is bound to meet with due local attention. The paper he read before the Royal Colonial Institute recently is reprinted on page 813.

TEMPLESTOWE ESTATE COMPANY.—The property owned by this Company has been very well worked during the past year, as is testified to in the report which we publish elsewhere. The crop was nearly 18,000 lb. under the estimate, but there was an advance of 1.11 cents in the price obtained and the profit was such as to admit of a dividend of 3 per cent on the ordinary shares, the transference of R5,000 to the depreciation account and the carrying forward of R1,591 30.

PEARL-FISHING EXPERIMENTS.—As oysters differ among themselves, so do pearl-yielding oysters. We suppose that oysters which are valuable for their shells seldom have pearls comparable to those which our local fisheries yield. Now that experiments are being made with the bi-valve which has contributed handsomely, though erratically, in recent times to our exchequer, it may be well if the experiments can be extended to cover oysters within easy reach of the island. We read in an Indian paper that "it is not generally known that pearl-fishing is carried on annually in the Ichamutty river near Bongong. A correspondent states that this year the pearl-fishers have been unusually fortunate. Among the pearls obtained are some exceptionally good ones, which have sold for as much as R400 and R600 each."

RAINBOW TROUT BREEDING IN CEYLON.—All members of the Ceylon Fishing Club, as well as any anglers in the island who have not joined the Club, will read with especial interest Mr. Farr's letter elsewhere. It leaves little doubt of the hope which has gradually been growing into a belief that trout have begun to breed in Ceylon. Even now, however, we know there are some who will not credit the signs put forward—unless Mr. Farr's letter converts them out of hand. If they can account for the latest facts on opposing theories of their own, we shall be glad to hear from them as the subject is one of the utmost interest, while the introduction of trout ova and the hatchery experiments at Nuwara Eliya still continue in full swing.

CEYLON TEA IN BOSTON.

The Ceylon tea estate proprietor who, having sent some of his own tea to a friend in Boston, received the information in reply that "Ceylon tea was unknown there," once again sends us an extract from a letter he has had by way of rejoinder to the letter of Mr. MacGuane of the Salada Tea Company. The Bostonian resident who, we need scarcely say, has "no axe to grind" and probably never heard of the Ceylon-American Commissioner or Messrs. Larkin & Co., not being in tea, writes to the estate proprietor as follows:—

"Boston, March 19.—I must try and give you some answer to the 'Salada' Tea Manager's letter of December 30th, 1901, which you sent me. It is amusing to see how ruffled he is over my remarks. I still stick to it that Ceylon tea is *not known* in Boston. Mr. McGuane and I happen to be referring to entirely different sets of Bostonians. I referred to the upper classes who reside on the Back Bay and who would never, for a moment expect to lunch or dine at the Crawford-Woodcock, Marston's, Crosby's or Cottrell's restaurants. These are frequented by business men, shop girls and country people. The Lennox Hotel, I did mention in my letter. It is the only first-class hotel Mr. McGuane has mentioned in his letter. The Thorndike is a family hotel—that is, people live there in suites, all the winter, like many others of its kind, but we would not think of going to lunch there. By first-class hotels I mean such as would be starred in 'Baedeker.' The Touraine is perhaps, the most noted first-class hotel, in Boston I, have myself asked for Ceylon tea there, when lunching with friends, and have been told that they did not serve it. At the clubs too, such as the Somerset, the Union and the University, where ladies whose husbands are members can lunch and dine Ceylon tea is not on the menus. These clubs—especially the first two—are the social clubs of Boston, and membership in either carries with it, admission as guests to the social clubs of London, etc. I think I have said enough so far to convince you that Mr. McGuane and I are talking of entirely different sets of Bostonians. He apparently does not know my set, and I certainly do not know his. So with regard to the tea room. The locality he suggests would be patronised by people who would dine at Crosby's or Martin's. The locality I suggested would be patronised in the afternoon by Back Bay people. Society people do not shop down town (Washington Temple and Winter Streets) in the afternoon. The shopping is all done in the morning—after which lunch is had either at home, or at one of the clubs, or the Touraine. What is wanted in Boston, from *my* standpoint, is a nice tea room where ladies and gentlemen could go after a concert, or a visit to the picture galleries, or a walk or a drive. Tea at Marston's and such like places is served in *thick* semi-porcelain cups, such as one would see in Glasgow at 'Lockhart's' dining rooms—not in dainty china cups with nice spoons and knives. At a recent 'fair' I sold Ceylon tea (*not* the 'Salada' brand, whatever that may be) and I have had dozens of enquiries since from my own personal friends as to where they could get more! One lady to whom I gave some of the tea you sent me—two years ago—asked me the other day if I would tell her what tea it was, as she could

not get it and had even sent to New York for tea at \$5 (20) a pound, hoping it might be as good. But I have said enough. My letter to you was written entirely in the interests of Ceylon tea. I still stick to it that the article 'Ceylon Tea' is not known well in Boston—whatever the special brand called 'Salada' may be. A thousand or more such signs as 'Salada' does *not* advertise CEYLON-TEA pure and simple—but a special brand of a special company. It is like advertising Lipton's tea—which may be a blend of every tea in the world and not necessarily *Pure Ceylon Tea*. I hope this will explain matters.

To turn to another subject, Prince Henry's visit was quite amusing. Boston looked lovely in a fresh mantle of snow with clear bright skies overhead. He passed our house, driving at a tremendous pace and accompanied by the most awfully mounted cavalry I have ever seen. I suppose it was hard riding in the snow at such a pace, but the men kept falling off their horses and rode like potato sacks. It was a humiliating exhibition, and the Prince remarked to Admiral Bob Evans, who was with him, that men who rode like that in Germany were arrested! I was very fortunate in getting a ticket of admission to Sanders' Theatre in Cambridge, where Prince Henry had his LL.D. degree given him. I was right in the middle of the third front row, so I saw him very well. He is a very handsome man, over six feet in height, and absolutely thorough-bred looking."

In regard to the "tea" reply, our friend ("Estate Proprietor") writes:—

"I'm bound to say it is a high-flying defence: has an atmosphere which is death to anything but 'blue blood' and is redolent of the "hub of the universe"! Personally it is the horny-handed toiler, that I would like to see attracted to Ceylon tea, who would take to it and come again, albeit to have it the vogue in Society circles would mean a good deal too, for its being in the fashion would in time filter from the classes to the masses who quickly follow suit.—especially in America, where one man is as good as another."

We think the "Thirty Committee" will admit there is enough useful information in the above correspondence to justify its publication. Evidently there are attractions in "pure Ceylon Tea" which ought to make it a profitable article of sale among the better classes in Boston and why not of other New England towns, not to speak of New York, Philadelphia and Chicago. Meantime, enterprising Mr. Wm. Saunders and his supporters might do worse than arrange for a "Tea-room" to sell and serve pure Ceylon Tea in the West end of Boston, U. S. A.

THE PARASITIC ORIGIN OF PEARLS.

We have already mentioned the observations of Dubois and other French investigators on the parasitic origin of pearls. At a recent meeting of the Zoological Society of London, Dr H L Jameson said the pearls of the mussel were caused by the larva of a parasite allied to the liver-fluke. The larva is encysted in the mantle of the mussel, and if it dies is calcified, thus forming the core of a pearl. There is hope of producing pearls artificially by their means.—*Globe*, April 11.

TEA CROPS AND PROSPECTS IN
INDIA AND CEYLON:
IS THE MAXIMUM OUTFURN OF TEA
CLOSE AT HAND?
CONSENSUS OF OPINION AS TO "A
GOOD TIME COMING."

We are surprised that in their interesting review of the Indian Tea Market for 1901-2 (which we reproduce elsewhere), Messrs. Carritt & Co. do not dwell more clearly on the risk arising from an unusually large crop during season 1902-3, owing first to the extensive area planted in 1898 now coming into bearing and, secondly, to the unlikelihood of a second unfavourable season in regard to weather. Leading Calcutta-merchants in December last made special mention to us of the above risk, adding that, if 1902 were once rounded off without any serious blow to tea, they had the utmost confidence in the future of the industry. There have been no plantings of any serious consequence since 1898 and probably in India, as in Ceylon, the very maximum of crop outturn is close at hand. As regards young tea coming into full bearing, Messrs. Carritt & Co. seem, indeed, to think the period is passed; but they must have overlooked the figures of 1898 and their relation to the present season. They say:—"the coming season can be viewed with confidence so long as the outturn continues "on a moderate scale," and they are inclined to think that "scarcity of labour" may counterbalance any climatic advantage. We shall see. But we trust in any case that careful "plucking" will distinguish the majority of Indian gardens, so as to prevent a disastrously large export to the London market during 1902-3.

Turning to Ceylon, it is becoming increasingly evident that our export of black tea to London will be moderate this year. Still more, the opinion is gaining ground that we have probably seen our maximum total export of tea in the 148 million lb. sent away in 1900. The limit of "ten years" given by Mr. Robert Porter for average tea gardens in Ceylon—including the many formed out of old coffee plantations—beyond which their crop outturn cannot be maintained without the application of manure, is, we find, generally accepted; and what with the abandonment of unprofitable fields here and there, the general cessation of planting beyond small clearings few and far between,—we cannot see how Ceylon can send away more than between 140 and 150 millions of lb. of tea during each of the next two or three years. Considering, therefore, the natural expansion of consumption in the larger consuming countries, the good prospect of gaining ground for British grown teas on the Continent of Europe, especially in Russia; the favourable future before "green teas," particularly in America; the likelihood of the Imperial war-tax being taken off tea in 1903, or at latest in 1904; and, though last, not least, the prospect of the spread of a taste for tea among many millions who can afford to drink it, in India,

—we certainly agree that there must be "a good time coming" for planters both here and in the Indian districts, who are favoured with fertile gardens, or who can keep their gardens in good heart by judicious cultivation, including the application of suitable fertilisers.

To back our opinion we may quote the following sentences from the letter of an authority who has a wide practical knowledge of what tea is doing both in Ceylon and India. He writes, after a tour of inspection through certain local districts:—"Properties generally seem to be flushing well; but this is the season for flush, and exports are still $4\frac{1}{2}$ million lb. behind those of last year; and yet Ceylon was plucking fine last year during this period." As regards the outlook generally the same writer says:—"My opinion about tea in general is that it is bound to turn the corner before long (though it may take longer than was expected) and that, if cultivation of estates is maintained—so that the bushes do not go back, and yields consequently decrease,—tea properties will yet pay as well as ever they did in the past, even in the low-country and at medium elevations."—So mote it be!

CEYLON TEN IN CANADA.

GREEN TEAS NOT PERFECT: PINE-
WOOD TEA-CHESTS INJURIOUS.

We have had placed at our disposal, and have much pleasure in publishing, the following extract of a letter received by a leading Colombo firm from a large tea importer in Montreal, which will interest a large section of our readers, while it scarcely needs any special comment at our hands. The letter speaks for itself and with no uncertain voice:—

"In reply to your enquiry *re* the prospect of Ceylon and Indian teas with the Canadian market, I may tell you my own opinion, which is, that they have a good prospect in blacks as much as Japan has in its green. They try quite hard to compete with us in green tea recently, but unless they *make still further improvements*, I do not think they can ever displace us from the market. There are many defects on their part if I point out, but it is needless to tell you about its make, etc., except something wherewith you are interested directly.—It may be interesting to you to know that I have seen many packages of Ceylon tea which are not of Momi wood, but of Pine; the latter, in my opinion, is not from Japan and resembles very much Chinese Pine. As you have some idea of tea, you should know that boxes for tea made out of Pine-wood, either from Japan or elsewhere, cannot be good for tea, and I am greatly surprised to see the Ceylon merchants (who are so earnest in pushing their tea and affecting all kinds of improvements) use boxes made of Pine. Perhaps China Pine is cheaper, but cheap things always come out dearer in the end."

We may add that the writer is the Representative of the Japan Central Tea Traders' Association, and the above is interesting as giving an idea of the view taken by our competitors as to the success of our competition with them in the Canadian market.

BANDARAPOLA CEYLON COMPANY, LIMITED.

REPORT OF THE DIRECTORS

To be presented to the Shareholders at their 9th annual ordinary meeting to be held at the office of the Company, 16, Philpot Lane, London, E.C., on Wednesday, 7th May, 1902, at 12 noon.

The Directors have pleasure in submitting to the Shareholders the Accounts and Balance Sheet for the year ending 31st December, 1901, with Auditor's certificate attached.

After payment of Debenture Interest and all other charges, the net profits for the year amount to £2,223 19s 9d, which with £407 18s 4d, brought forward from previous accounts, gives a total to be dealt with of—£2,631 18s 1d. It is proposed to pay a Dividend for the year, of 6 per cent. (tree of Income Tax) absorbing £1,260. To write off Estates Account £500. To write off for depreciation on Buildings and Machinery 10 per cent on £5,265 11s 2d.—£526 11s 2d. £2,286 11s 2d. Leaving a balance to carry forward of £345 6s 11d.

The crops secured during the season amounted to 468,901 lb Tea (including 18,892 lb from purchased leaf) and 303 cwts. 0 qrs. 18 lb Cocoa, against 487,432 lb. Tea, and 267 cwts. 1 qr. 13 lb Cocoa during the previous year.

The average yield per acre was 575 lb of Tea, against 612 lb per acre during 1900, this shortage being chiefly due to finer plucking, while the prices realized were 33 cents per lb for the Teas sold in the Colombo market, and 6'254d in London against 5'512d last year.

The average rate of exchange was 1/4 3/4ths per rupee.

The acreage of the Company's holdings has not been altered during the year, and remains as stated in last Report, viz:—

Tea in bearing	782 acres
Tea not in bearing	6 „
Cocoa in bearing	224 „
Grass, Ravines, &c. ...	12 „
Reserve, Jungle, &c. ..	525 „

Total acreage ... 1,549 acres

The Visiting Agent, Mr Joseph Fraser, reports that the general appearance of the estate is most satisfactory, showing a remarkable absence of insect and fungoid pests, and the Board take this opportunity of expressing their appreciation of the services of their Manager, Mr James Anderson.

Of the Debenture Issue £2,100 matured for payment on 1st January, 1902, of which £1,850 was renewed for three years, and £250 for five years at 5 per cent interest per annum.

In accordance with the Articles of Association Sir George A Pilkington retires from the Board, and, being eligible, offers himself for re-election.

Mr John Dalgleish, C.A., also offers himself for re-election as Auditor. G W PAINE, Chairman.
16, Philpot Lane, London, E.C., 22nd April, 1902

GALAH A CEYLON TEA ESTATES AND AGENCY COMPANY, LIMITED.

REPORT OF THE DIRECTORS

to be submitted to the shareholders at the fifth annual ordinary general meeting to be held at 30, Mincing Lane, E.C., on Thursday, 8th May:—

The Directors have pleasure in submitting their report, also statements of accounts duly audited for the period of 12 months ending 31st December last. The gross profit for the season after providing £100 for depreciation on machinery, &c., is £10,357 8s 2d; add balance of last account £100 14s 8d; equal £10,468 2s 10d; from this has to be deducted interest on £55,000, debentures at five per cent per annum £3,750 dividend on £60,000, preference shares at 6 per cent per annum £3,600; London charges—fees to Trustees, Directors and Auditors £550, interest on loan £660 8s. 5d., income tax, Insurance, &c., £248 1s 10d

7d leaving a balance of £2,659 12s 10d, which the Directors appropriate as follows:—transfer to reserve £1,000 dividend proposed, three per cent on £50,000 ordinary shares, £1,500, balance to carry forward, £159 12s 10d; equal to £2,659 12s 10d.

The tea crop during the season, including 48,053 lb from bought leaf, amounted to 1,217,329 lb, and the cardamom crop was 16,973 lb.

Notwithstanding that the crop was considerably below the estimate, owing to the unfavourable weather which prevailed all over the Island of Ceylon last year, and to the finer plucking adopted on the estates, the net profits would have permitted of a dividend of six per cent. being paid on the ordinary shares for the year, but the Directors, following out their policy have written off £100 for depreciation on machinery, transferred £1,000 to the reserve, bringing that Fund up to £6,700, and recommend a dividend of three per cent, on the ordinary shares for the year.

The Directors are glad to say that the standard of quality of the Company's teas has been fully kept up and they meet with continued favour.

The factory machinery and all buildings are being well maintained and the estates are in the highest state of cultivation.

On the 31st December last the Company had under cultivation in tea 2,867 acres, and in cardamoms 235 acres and the following is a schedule of the acreages of the Company's estates:—

	Tea		Cardamoms.	Timber.	Patna, etc.	Total.
	3 years and over.	Under 3 years.				
Dunally and North						
Vedehette	404	—	49	—	269	722
Galaha	618	—	61	42	58	779
Goorokelle	872	—	—	—	563	1435
Kitoolmoola	342	—	46	17	25	420
Mausakelle	258	5	—	—	397	660
Vedehettes, East and West	368	—	79	69	324	840
	2862	5	235	128	1636	4866

Mr C E Straehan now retires from the Board, and, being eligible, offers himself for re-election.

The appointment of Auditors rests with the shareholders, and Messrs. Fuller, Wise, and Fisher offer themselves for re-election.

BURNSIDE TEA COMPANY OF CEYLON LIMITED.

REPORT OF THE DIRECTORS

To be presented to the Shareholders at their sixth annual ordinary meeting to be held at the office of the Company 16, Philpot Lane, London, E.C., on Wednesday, 7th May 1902, at 2 30 p.m.

The Directors beg to submit to the Shareholders the Report and accounts of the Company, duly audited, for the year ending 31st December, 1901.

The total crop from the four estates was 353,284 lb. Tea against 402,113 lb for last year and 9 maunds of Tea Seed were obtained and sold as compared with 5 1/2 maunds in 1900.

For the deficiency in crop of 48,829 lbs., Wattagalla Estate is mainly responsible, and the present Manager considers that the shortage is fully accounted for by the fact that a large area fell due for pruning in the middle of the year, in addition to which somewhat finer plucking was resorted to over all the estates.

Mr. Thomas Smith, our Visiting Agent, in his report of his visits towards the end of January to Burnside, Heeloya and Wattagalla states that through all the old fields of Tea there is no falling-off in the appearance or condition of the bushes, and that

he considers the Tea shows a good growth, as healthy appearance, and is just as capable of giving good crops as it ever was, and both Mr. Smith and Mr. Porter report favourably of the condition of the Estate and prospects of crop at Midlothian.

The average price obtained in London for the Burnside Group was 6'047d per lb., and in Ceylon 32½ cents, while the corresponding averages for Midlothian were 7'108d per lb., and 37½ cents respectively. The average rate of Exchange was 1/4 25/64ths per rupee.

The shortfall in crops and the extremely poor price obtained during the first six months of the year account for the unfortunatè position shewn by the attached Balance Sheet, and the Directors regret that to the loss carried forward from last year a further deficit of £742 10s 6d has to be added, making the amount at debit of Profit and Loss Account £1,067 5s and 10d.

The Directors have to report that the Debentures which matured on the 1st January last have been renewed as follows, bearing interest at six per cent per annum :—

For three years	...	£5,250
For five years	...	9,150
		£14,400

The latest Reports from all the Company's Estates speak favourably of their condition and of the crop prospects, the total amount of tea made up to the end of March shewing a considerable increase on last year's figures.

In accordance with the Articles of the Association Mr G W Paine retires from the Board, and being eligible, offers himself for re-election.

Messrs Cape & Dalgleish, O.A., also offer themselves for re-election as Auditors. By order of the Board, LYALL, ANDERSON & Co., Agents and Secretaries.
16, Philpot Lane, London, E C, 23rd April 1902.

EDERAPOLLA TEA CO. OF CEYLON LTD.

REPORT OF THE DIRECTORS.

To be presented to the Shareholders at their sixth ordinary general meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Monday, 5th May, 1902, at 12 noon.

The Directors beg to submit to the Shareholders the Report and Accounts of the Company, duly audited, for the year ending 31st December, 1901.

Inclusive of 22,017 lb. made from bought leaf, the total out-turn of Tea from the three Factories amounted to 508,058 lb., showing a decrease of 46,372 lb. compared with last season; a deficiency chiefly due to more careful plucking throughout the year.

The average price realised was 6'186d per lb. as against 5'803d per lb. last year, and the average rate of Exchange was 1/4 3/8ths, compared with 1/4 27/64ths for 1901.

The net profit for the year amounts to £1,336 9s 7d, which, with £421 15s 1d brought forward from last year, gives £1,758 4s 8d to be now dealt with, and this it is proposed to apportion as follows:—

Amount as above	£1,758 4 8
To Dividend of 5 per cent. (free of Income Tax)	...	£1,275 0 0	
To write off Estate Account..		300 0 0	
		1,575 0 0	
To carry forward to next Account	...	£183 4 8	

It is hoped that Mr Porter, who has been in Ceylon for the past three months, will have returned in time to be present at the General Meeting now called, so that the Shareholders can obtain from him the latest information as to the condition and prospects of the

Company's Properties, the detailed acreage of which, as on 1st January last, is now given:—

	Tea in full bearing.	Ten in partial bearing.	Paddy Field.	Jungle.	Petna and Scrub.	Cardamoms not in bearing.	Total.
Adross	258	15	42½		8½		324
Ederapolla	381	143	7	68	44		648
St Helens	255				34½	13½	303
Totals	894	163	7	110½	87	13½	1,275

In accordance with the Articles of Association, Mr J M Macmartin retires from the Board at this time, and being eligible, offers himself for re-election.

Messrs. Cape and Dalgleish, O.A., also offer themselves for re-election as Auditors.

G. W. PAINE, Chairman,
16, Philpot Lane, London, E.C., 21st April, 1902.

HIGHLAND TEA COMPANY OF CEYLON.

REPORT OF THE DIRECTORS,

To be presented to the Shareholders at their sixth annual ordinary meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Tuesday, 6th May, 1902, at 10-30 a.m.

The Directors have pleasure in submitting to the Shareholders the Balance-sheet and Accounts for the year to 31st December, 1901, with Auditors' Certificate attached.

The net profits for the year amount to £1,499 3s 6d, to which has to be added £105 10s 3d. brought forward from previous accounts, giving a total to be dealt with of £1,604 13s 9d., and this amount it is proposed to apportion as follows:—

Amount as above £1,041 13 9; An Interim Dividend of 2 per cent. (free of Income Tax) paid in September, absorb £640 0 0; It is now proposed to pay a final dividend at the same rate, making 4 per cent. for the year (free of Income Tax) £640 0 0; To write off Estates Account £250 0 0. Total £1,530 0 0. Leaving a balance to carry forward £74 13 9.

The results for last year are disappointing, showing, as they do, a considerable shrinkage from the profits of previous seasons. The factors which have brought about the shortage in question are twofold, viz., the depressed state of tea market, especially during the early part of the year, and the shortness of crop owing to the unfavourable climatic conditions in Ceylon.

The total crops secured for the year from Chrystlers Farm and Glenorchy estate amounted to 241,481 lb. against 262,510 lb., the average yield over all being 413 lb. made tea per acre against 448 lb., in the previous season, while the average price realized in London was 7½d., against 8d. per lb.

During the later months of the year your Directors have been selling the Tea from Glenorchy estate in the Colombo market, the average price realized there being 45 cents per lb., which compares favourably with the prices previously obtained in London.

The average rate of exchange was 1/4 11/64ths as compared with 1/4 19/64ths at which the previous accounts were made up.

Mr. R Porter, now on his way from Ceylon, paid visits recently to both estates and reports that he found them in excellent order.

In accordance with the Articles of Association, Mr. George G Anderson retires from the Board, and, being eligible, offers himself for re-election.

Messrs. Cape & Dalgleish, O.A., also offer themselves for re-election as Auditors.

By order of the Board, LYALL, ANDERSON & Co.,
Agents and Secretaries.

16, Philpot Lane, London, E.C., 23rd April, 1902

KELANI VALLEY TEA ASSOCIATION, LIMITED.

REPORT OF THE DIRECTORS

To be presented to the shareholders at their sixteenth ordinary general meeting to be held at the Office of the Company, on Monday, 5th May, 1902, at 2 p.m.

The Directors beg to submit to the shareholders the report and accounts of the Company, duly audited, for the year ending 31st December, 1901.

The crops from the Company's four estates amounted to 549,906 lb. against 662,248 lb. in 1900; the average price realised was 6 206d against 5 794d, and the average rate of exchange is 43d as compared with 1s 4 27-64 in the previous year.

The shortfall in the crop compared with 1900 is partly due to more careful plucking which was adopted at the beginning of the year, but it is also traceable, to a large extent, to the adverse climatic conditions that prevailed during the latter part of the year.

Although the prices obtained in the later months were fairly satisfactory, the average price for 1901 is very little above that for 1900, as the rates that ruled during the first six months were very low.

The net profit for the year amounts to £612 12s 5d, which, with £456 15s brought forward from 1900, makes £1,069 7s 5d now available. Out of this sum the Directors propose to write 5 per cent off on buildings and machinery, which will absorb £638 2s 11d, leaving £431 4s 6d to be carried forward to next season's account.

Debentures to the extent of £7,400 matured during the year, and have been renewed for three or five years at 5 per cent per annum.

Owing to continued absence from London, Mr L F Davies found it impossible to attend the Board Meetings, and he therefore tendered his resignation, which was accepted with much regret.

In accordance with the Articles of Association, the Board have elected Mr John Wallace Stocks, who is duly qualified, to fill the vacancy thus created.

In accordance with the Articles of Association, Mr G W Paine retires from the Board, and, being eligible, offers himself for re-election.

Mr J B Laurie, C. A., also offers himself for re-election as Auditor.

C. W. PAINE, Chairman.

16, Philpot Lane, London, E.C., 21st April, 1902.

POONAGALLA VALLEY CEYLON CO., LTD.

REPORT OF THE BOARD OF DIRECTORS

To be presented to the shareholders at their sixth annual ordinary meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Tuesday, the 6th May, 1902, at 2 p.m.

The Directors beg to submit the report and Accounts of the Company, duly audited, for the year ending 31st December, 1901.

The total crop of tea amounted to 396,593 lb. showing a decrease compared with that of last season of 84,293 lb. the result, to a certain extent, of finer plucking, but chiefly caused by the severe drought experienced in June, July, and August, and to very high cold winds during the latter months of the year.

This serious shortfall, coupled with the very poor prices realized during the first six months of the past year, is accountable for the unfortunate result of the year's working, the loss shewn having been incurred during the half-year ending 30th June. The estates are in good heart and condition, and, given reasonable weather and a fair market, it is hoped that the year now entered upon will end much more satisfactorily.

The Balance Sheet herewith shews that the loss on the year's working amounts to £1,233 19s 11d; and, deducting therefrom £216 2s 8d brought forward

from last year, the debit of Profit and Loss Account stands at £1,017 17s 3d.

The following figures are given for comparison:—

	1901.	1900.
Total Tea Crop secured	396,593 lb	480,886 lb
Total Coffee Crop secured	147½ bushels	231 bushels
Average Price realised for Tea—		
Sold in London	7d per lb	5 44d per lb
Sold in Ceylon	36 cents	—
Total Rainfall	69 64 inches	1080 7 inches
Average rate of Exchange	1/43ths	1/4 13-32nds

On the 30th September, at 3 a.m., during the prevalence of a very heavy south-westerly gale, the new Withering House at Poonagalla took fire, and, but for the presence of mind and hard work on the part of the Tea-maker, watchman, and coolies, before the Manager could arrive, the main Factory building would have been destroyed.

The building and contents were fully insured, and the Company will suffer but little pecuniary loss.

The re-erection of the Withering House was immediately taken in hand and is now almost complete.

During the year 25 acres in the Jungle strip at Lunugalla have been planted with cardamoms, which promise well, and the Visiting Agent recommends a further 20 acres being sotedrated during the present season.

Your Directors have to announce that, in order to provide further necessary capital, the Chairman has had to advance £7,000 on second debenture bonds for four years, bearing interest at 6 per cent per annum.

In accordance with the articles of Association, Mr Robert Porter retires from the Board, and, being eligible, offers himself for re-election.

Messrs. Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.—By Order of the Board,

LYALL ANDERSON & Co.,
Agents and Secretaries.

16, Philpot Lane, London, E.C. 21st April, 1902.

THE SUNNYGAMA (CEYLON) TEA ESTATES COMPANY, LIMITED.

THE REPORT OF THE DIRECTORS

to be submitted to the shareholders at the general meeting to be held on Wednesday, 30th April, 1902, at 11 a.m. at No. 34, Great St. Helen's, London, E.C.,

The Directors herewith submit their Ninth Annual Report, together with statement of accounts and balance sheet for the year ending 31st Dec., 1901.

The profit and loss account (including £107 9s 6d carried forward from last year) shows a credit balance of £1,928 0s 9d, after paying interest on the debentures to 1st January, 1902, which the Directors propose to apply as follows:—To pay a balance dividend of 3 per cent on the preference shares for the year ended 31st December, 1900, £1450; to pay a dividend of 6 per cent on the preference shares for the whole year 1901, £900; total £1,350; carrying forward the balance, viz, £578 0s 9d, total £1,928 0s 9d.

The following figures show the result of the year's working:—

SUNNYCROFT ESTATE.—Crop—641,673 lb tea at an average net price of about 5 9-16d realised £14,871 4s 8d, interest on account £76 16s 3d, total £14,948 0s 11d. Expenditure—Cost of cultivation, shipping, etc., £11,301 15s 8d, profit £3,646 5s 3d.

PAMBAGAMA ESTATE.—Crop—276,861 lb tea at an average net price about 4 15-16d realised £5,713 9s 8d, 9,615 lb tea sold in Ceylon, realizing R1,642 at Exchange of 1/4, £109 9s 4d, total £5,822 19s 0d. Expenditure—Cost of cultivation, shipping, etc., £6,195 16s 8d, interest on account, £8 9s 8d, total £6,204 6s 4d, loss £381 7s 4d, net profit £3,264 17s 11d.

The total crops amounted to 928,149 lb, against an estimate of 1,080,000 lb given in the last Report, the reduction being caused by the finer plucking then referred to. This, together with the better market has led to improved prices, the gross average price of

Sunnycroft being about 6½d per lb against 6d last year, and Pambagama about 5½d against 4½d. The latter estate costs more to work than the former, and the tea is not quite so good, but the quality is improving, and it is hoped Pambagama will show a better result in the next annual report.

Estimates for the current year provide for crops and expenditure (Ceylon) as follows:

	Crop. lb	Expenditure. R.	Cost per lb. F.O.B. 23 cents.
Sunnycroft ..	780,000	180,834	23 cents.
Pambagama ..	335,000	83,800	25 "
	1,115,000	264,634	2373 cents.

On the above basis the cost laid down in London at the current rate of Exchange will be about 4½d. per lb. In addition provision has to be made to the extent of R1,500 on each estate, for planting shade rubber trees, and, in the case of Pambagama, R500 for improving the coolie lines, which may be regarded as capital expenditure.

The amount spent on buildings and machinery, &c., has been £2,767 2s. 4d., which has been met without having recourse to an issue of debentures referred to in the last report.

Both estates are now provided with adequate buildings and machinery, and are reported upon as in good order and condition. No further extensions are contemplated at present. The total area is as follows:—

	Planted.	Reserve.	Total.
Sunnycroft ..	1,145	668	1,813 acres
Pambagama ..	607	371	978 "

Mr J B Keith, one of your Directors, retires by rotation, and does not seek re-election. Mr W R Arbuthnot, jr., will be proposed to take his place on the Board.

Messrs. Durry, Thurgood & Co, the Auditors of the Company, also retire, and again offer their services.

THE KANDAPOLLA TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the general meeting to be held on Wednesday, the 30th April, 1902, at noon, at the offices of the Company.

The Directors submit the statement of accounts to 31st December, 1901.

The Profit and Loss Account shows a profit on the working of the estates of £2,644 14s 4d; interest, £14 10s 6d; doubtful coast advances recovered, £5 13s 0d; transfer fees £0 10s 0d; brought forward from last year, £586 13s 7d.—£3,252 1s 5d.

The Directors have paid the interest on the debentures, viz., £1,570; dividend on the preference shares to the 30th June, 1900, £939; home charges, as per account, £147 1s 9d; leaving a balance to be disposed of of £595 19s 8d.—£3,252 1s 5d.

The Directors propose to place to the depreciation of machinery account, £250; carrying forward the balance, £345 19s 8d.—£595 19s 8d.

The estimates for the year were based upon a yield of 497,000 lbs. The crop resulted in a total of 411,682 lbs., a falling-off of 85,318 lbs., and, as compared with the preceding year, the decrease is 72,697 lbs.

During the year some 150 acres have been manured, chiefly with non-stimulating chemical manures. The cost of this is included in the current expenditure.

The cost of production averages 37·10 cents per lb of made tea. The amount realised by sale works out at 46·25 cents gross, the profit being 9·15 cents per lb., as compared with 13·20 in 1900, and 14·20 in 1899.

The estimates for the current year are based upon a normal yield, and on a system of medium to fine plucking.

The labour supply and coast advances are in a sound position on all the properties.

The buildings and machinery are generally in good order and repair, but as the engine on Kandapolla,

which has now been running for many years without a stop, is showing signs of wearing out, your Directors have approved the erection of two oil engines of 9-h.p. each, which are now in working order. A considerable saving in the cost of fuel will probably result from this, firewood being a very expensive item at the present time. Should the yield on Devonford increase during the year, as anticipated, it will be necessary to erect a new roller.

£250 has been set aside this year towards the provision of this new machinery.

The yield for the year was lower than was expected, especially during the months of November and December, owing to unfavourable weather, whilst the market price for fine and medium teas, such as are produced upon the Company's properties, was lower than in any previous year.

The following is the total acreage of tea, &c., and crop secured for 1901:—

Estates.	Forest, Waste,		
	Tea Acreage.	&c. Acres.	Tea Crop lb.
Kandapolla (Group) ...	369	17	159,206
Protoft (Group) ..	478	177	121,211
Erroll ...	215	24	68,971
Devonford ..	245	42	62,204
	1,307	260	411,682

Mr J H Alexander, the Director, who retires by rotation, does not offer himself for re-election in consequence of frequent absences from London.

The appointment of Auditors rests with the shareholders.

THE DIMBULA VALLEY (CEYLON) TEA CO., LIMITED.

DIRECTORS' REPORT

To be submitted to the Shareholders at the sixth annual ordinary General Meeting, to be held at the Cannon Street Hotel, on Thursday, 24th April, 1902, at 12 o'clock noon.

The Directors beg to submit the General Balance Sheet and Profit and Loss Account for the twelve months ending 31st December last.

After bringing forward £1,973 10s 6d from last account, and providing for general expenses, London Office expenses, Superintendents' commissions, and £500 for depreciation, the nett amount at credit of Profit and Loss Account for the year ending 31st December last is £15,474 3s 8d.

Dividends aggregating 6 per cent., less Income Tax, have been paid for the 12 months ending 31st March on the Preference Shares, amounting to ..£ 3,440 2 6

An Interim dividend of 4 per cent., less Income Tax, on the Ordinary Shares has been paid, and amounted to .. 4,586 12 0

It is proposed to pay a final dividend of 4 per cent. on the Ordinary Shares, making 8 per cent. for the year, and which will amount to .. 4,586 12 0

It is proposed to carry to Reserve Fund a sum of .. 2,000 0 0

(Making the total at Reserve £5,000).

Leaving to be carried forward .. 860 17 8

£15,474 3 8

The crop amounted to 1,193,357 lb. to 31st December, against, for the previous twelve months 1,091,963 lb.

The Directors recommend a final dividend of 4 per cent. on the Ordinary Shares, making 8 per cent. for the year.

The cost of cultivation and placing the crop on board ship was 26·18 cents, against 26·97 cents the previous nine months.

The total crop, including 46 cwt. coffee, realised £36,262 19s 11d nett, equivalent to a gross average for the tea, of 811d per lb., against 8'93d last year and 9'0d for the previous season.

Mr Keith F Arbuthnot has been re-appointed to the Board of Directors.

Mr W Forbes Laurie retires by rotation, but being eligible, offers himself for re-election.

Messrs. Singleton, Fabian & Co, the Auditors to the Company, retire, and, being eligible, offer themselves for re-election.

JAMES SINCLAIR, Managing Director; ROWE, WHITE & Co., Secretaries.

April 14th, 1902.

THE ALLIANCE TEA COMPANY OF CEYLON, LTD.

REPORT OF THE DIRECTORS

to be submitted at the annual ordinary general meeting of shareholders, to be held at the Company's Office, 9, Fenchurch Avenue, London, E.C., on Friday, 9th May, 1902, at 11'30 a.m.

The Directors have pleasure in submitting the balance sheet and profit and loss account for the year ending 31st December, 1901.

The Net Profit, after payment of Debenture and other Interest for the year, amounts to ..	£4,868 16 10
To which has to be added the Balance brought forward from 1900	1,272 10 1
	£6,141 6 11

An Interim Dividend of 3 per cent was paid on the 26th September, 1901, absorbing £1,957 16s; and the Directors now propose to deal with the balance as follows:—(1) In writing off from cost of properties as depreciation of machinery, &c. £1,000; (2) In payment of a final dividend (free of Income Tax) of 3 per cent (making 6 per cent for the year) £1,957 16s; (3) In carrying forward to next year the balance of £1,225 14s 11d. Total £6,141 6s 11d.

The following table gives the acreages and results for the year:

Estate.	Acreage in full and partial bearing.	Tea Crop, lb.	Yield per acre.	Cost of Crop per lb in cent.	Net price realised per lb. in price.	Working Profit.
Aberdeen	361	101,537	281	29'85	4'79	12 2 0
Calsay	365	172,604	473	30'30	6'79	1,355 7 3
Dunkeld	517	184,883	358	31'14	5'92	685 14 2
Luccombe	542	173,751	321	29'80	5'42	470 0 3
Thornfield and Gleneagles	457	257,604	564	26'47	7'25	3,185 8 3
Uda Radella	413	196,482	476	28'88	8'20	2,863 12 2
	2,655	1,086,861	409	29'16	6'60	£8,592 4 1

The results from Thornfield, Gleneagles and Uda Radella are very satisfactory, but the Working Profits of Aberdeen and Dunkeld estates show a considerable decline owing to the reduced tea crops.

The total acreage of the estates on 1st January, 1902, was as follows:—

Estates.	Acreage under Tea.			Forest Reserves, &c.	Total Acreage.	
	In full bearing.	In partial bearing.	Not in bearing.			
Aberdeen	347	14	—	361	119	480
Calsay	352	13	10	375	12	387
Dunkeld	517	—	—	517	79	596
Luccombe	542	—	—	542	208	750
Thornfield and Gleneagles	457	—	7	464	48	512
Uda Radella	405	8	62	475	80	555
Kehelgama	—	—	—	—	322	322
	2,620	35	79	2,734	868	3,602

In accordance with the Articles of the Association, Mr. R. S. Corbett retires from the Board at this meeting, and, being eligible, offers himself for re-election.

Messrs. W B Peat & Co. also offer themselves for re-appointment as Auditors to the Company.—By order of the Board,

W. H. BARTLETT, Secretary

London, 28th April, 1902.

THE RAGALLA TEA ESTATES LTD.

REPORT OF THE DIRECTORS

to be submitted to the shareholders at the seventh annual ordinary general meeting, to be held at 80, Mincing Lane, E.C., on Monday, 5th May, 1902, at 12 o'clock noon.

The directors beg to submit their report and also statement of accounts duly audited, for the period of twelve months ending 31st December last—

Showing a net profit for that period, after writing off £200 for depreciation of	£3,828 19 4
Add the balance of last account	152 8 4
	£3,981 7 8

Out of which the following dividends have been paid:—

1901, 1st July—Preference Shares	£1,050 0 0
1902, 1st Jan. do.	1,050 0 0
	2,100 0 0
	1,881 7 8

From which the Directors recommend a dividend of 4½ per cent on the ordinary shares, free of income tax ..

1,755 0 0

Leaving a balance to carry forward of .. £126 7 8
The tea crop for the season amounted to 648,442 lb., against the estimate of 750,000 lb., and the shortage of 102,000 lb. was owing to the unfavourable weather that prevailed during the greater part of the year, and also to the finer plucking adopted on the estates. The net average price of the tea was 6'97d. per lb.

The crop for the present season is estimated at 745,000 lb., which should be fully realised.

The Directors are pleased to say that progress is being made with the Railway to the Udapussellawa district. The Government have acquired from the Company the necessary lands for the terminal station, and it is expected the line will be open for traffic some time next year.

The following are the acreages of the Company's estates:—

Name.	Tea.	Coffee.	Timber	Patna, &c.	Total.
Ragalla and Halgran Oya	911	—	177	302	1390
Kelburne	730	10	177	64	981
	1641	10	354	366	2371

Under Clause 97 of the Articles of Association Mr. C. E. Strachan retires from the Board, and being eligible offers himself for re-election.

The appointment of Auditors rests with the Shareholders, and Messrs. Fuller, Wise and Fisher offer themselves for re-election.

C. E. STRACHAN, M. P. EVANS, *Directors.*

M. P. EVANS & Co., *Secretaries.*

London, April 23rd 1902.

SCOTTISH CEYLON TEA CO, LTD.

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the Shareholders at their thirteenth annual ordinary meeting, to be held at the Office of the Company, 16 Philpot Lane, London, E.C., on Monday, 12th May, 1902, at 12 o'clock noon. The Directors have pleasure in submitting to the Shareholders the Accounts and Balance Sheet for the year ending 31st December, 1901, with Auditor's Certificate attached. The net profits for the year amount to £4,154 5s 11d, to which has to be added £413 13s 5d brought forward from last Accounts, giving a total to be dealt with of £4,567 19s 4d, and this it is proposed to apportion as follows:—Amount as above £4,567 19s 4d; To interim Dividend on the Ordinary Shares of 3½ per cent (free of Income Tax) paid in September, 1901 £1,435; To Dividend on the 7 per cent, Preference Shares paid September, 1901, and March, 1902 £630; To Final Dividend on the Ordinary Shares of 4½ per cent (free of Income Tax), making 8 per cent for the year £1,845; To write off the Capital Expenditure incurred during 1901 £429 9s 3d; To carry forward to next Accounts £228 10s 1d.—Total, £4,567 19s 4d.

The results for the season are disappointing, the shortage as compared with previous accounts being due principally to continued unsatisfactory markets.

The adoption of a system of finer plucking on the Company's estates has also occasioned a considerable shrinkage in the crop of tea secured, which amounted to 795,098 lb, against 899,806 lb in 1900.

In addition to the above, 63,583 lb of tea were manufactured for others, thus giving a total output from the Company's factories of 858,681 lb for the season.

The average yield per acre was 466 lb, against 523 lb. The rate of exchange was 1s 4½d, against 1s 4 27-64d, and the prices realised in London and Colombo respectively for the Company's tea averaged 7-08d and 80½ cents, against 6-94d and 80½ cents for the previous year.

The cinchona bark harvested during the year amounted to 45,108 lb.

The Company's acreage remains unaltered at a total of 1,963 acres, of which 1,720 acres are under tea cultivation.

The periodical reports from Mr. Kerr, the Ceylon Manager, continue to be of a satisfactory nature, and the Directors take this opportunity of acknowledging the services of the Company's staff, both in Ceylon and London.

In accordance with the Articles of Association, Mr. R. W. Forbes retires from the Board, and, being eligible, offers himself for re-election.

Mr. James B. Laurie, C.A., also offers himself for re-election as Auditor.—H. L. FORBES, *Chairman.*

London, 30th April, 1902.

THE IMPERIAL CEYLON TEA ESTATES, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the annual ordinary general meeting of shareholders to be held at the Company's Offices, 9, Fenchurch Avenue, London, E. C., on Friday, the 9th May, 1902, at 3 p.m.

The Directors now beg to submit the balance sheet and profit and loss account for the year ending 31st December, 1901.

The Nett Profit, after payment of Debenture and other Interest for the year, amounts to .. £4,062 11 11
To which has to be added the balance brought forward from 1900 .. 234 17 4

£4,297 9 3

This the Directors propose to deal with as follows:—(1) In writing off from cost of properties, as depreciation of Machinery, &c, £500; (2) In payment of a dividend of 3 per cent (free of Income Tax) on the paid-up share capital of the Company £2,700; (3) In carrying forward to next year the balance of £1,097 9s 3d. Total £4,297 9s 3d.

The following table gives the acreage, and results for the year:—

Estate.	Acreage in full and partial bearing.	Tea Crop, lb.	Yield per Acre.	Cost of Crop per lb. in cents.	Nett price realised per lb., in pence.	Working Profit.
Binoya	526	192,285	366	23-22	5-75	1,059 11 9
Edinburgh	362	211,257	584	27-85	7-60	3,489 13 11
Friedland	161	50,240	312	34-92	7-56	399 14 10
Mottingham	221	101,700	460	28-97	5-52	352 0 7
St. Vigeans	185	66,314	358	33-84	6-62	315 16 8
	1,455	621,796	427	29-36	6-58	5,616 17 9
Non- pareil	175	19,985	—	—	—	loss 332 6 3
	1,630	647,742	427	29-36	6-58	£5,284 11 6

The result of the season's operations compares favourably with the previous year, and is largely due to the greatly increased profit from Edinburgh estate. Binoya has also done well, whilst the deficiency arising from the working of Nonpareil is much less.

The total acreage of the estates as on 1st January, 1902, was as follows:—

Estate.	Acreage under Tea.					Forest, Reserves, &c.	Total Acreage.
	Tea in full bearing.	Tea in partial bearing.	Tea not in bearing.	Total.	Coffee and Cardamoms.		
Binoya	441	85	—	526	—	403	929
Edinburgh	362	—	48	410	—	40	450
Friedland	161	—	—	161	—	2	163
Mottingham	212	9	—	221	—	37	258
St. Vigeans	185	—	—	185	—	—	185
Nonpareil	50	125	134	309	44	196	549
	1,411	219	182	1,812	44	678	2,534

In accordance with the Articles of Association Mr. W. Megginson retires from the Board at this meeting, and, being eligible, offers himself for re-election.

Messrs. W. B. Peat & Co., also offer themselves for re-appointment as Auditors to the Company.—By order of the Board,

W. H. BARTLETT, *Secretary.*

London, 29th April, 1902.

RANGALLA TEA CO. OF CEYLON.

REPORT OF THE DIRECTORS

for the year ending 31st December, 1901, to be submitted at the annual general meeting of Share-

holders, to be held at the Offices of the Company, on Thursday, 8th May, 1902, at 12 o'clock noon.

The Directors beg to submit the Balance Sheet and Profit and Loss Account for the year 1901.

The net profit for the year amounts to	...	£1,668	15	9
To which has to be added the balance brought forward from 1900	..	412	12	7
		£2,081	8	4

An Interim Dividend of 2 per cent was paid on 19th September, 1901, absorbing £440: And the Directors now propose to deal with the balance as follows:—
 1. In writing off from cost of Properties, as Depreciation of Machinery, &c. £1,000, 2. In payment of Final Dividend (free of Income Tax) of 2 per cent (making 4 per cent for the year) £440; 3. In carrying forward the balance of £201 8 4. Total £2,081 8 4. per lb. of 6·49 pence, as against the cost of 5d., or 28·53 cents per lb. f.o.b. Colombo. Exchange for the Company's drafts during the year has averaged 1s. 4 17-32 d. as against the exchange for 1900 of 1s. 4 39-64 d.

The following table gives the acreage of the estates for the last five years:—

	1897.	1898.	1899.	1900.	1901.
Tea in full bearing ..	591½	591½	591½	673	673
Tea in partial bearing ..	63	90	90	22	43
Tea not in bearing ..	61½	34½	34½	21	—
Cardamoms ..	56	56	56	46	36
„ not in bearing ..	—	10	14	38	38
Grass and Fuel Timber ..	25	25	25	25	10
Forest and Waste Land ..	444	434	430	416	441
	1,241	1,241	1,241	1,241	1,241

The following is a Statement of the Tea and Cardamom Crops, with the yield of Tea per Acre for the same period:—

	Tea lbs.	Cardamoms lbs.	Yield of Tea per Acre lbs.
1897 ...	212,555	8,291	360
1898 ...	206,620	4,026	349
1899 ...	211,361	4,211	357
1900 ..	218,572	1,828	325
1901 ...	230,002	3,119	342

The Estimates for the current year are, with purchased leaf, 265,000 lbs., and 3,000 lbs. Cardamoms, which, with 30,000 lbs. Tea to be manufactured for a neighbouring estate, will give the Factory about 300,000 lbs. Tea to deal with during 1902.

Mr Young has just returned from Ceylon, and reports favourably on the Company's properties. The plants are looking healthy and in good heart, whilst the Factory is ample for all requirements, and well equipped with machinery. Another roller may be necessary towards the end of the year if the output of Tea comes up to expectations.

Mr. William Keswick, M.P., retires from the Board, in accordance with the Articles of Association, and, being eligible, offers himself for re-election.

The Auditors, Messrs W B PEAT & Co., also offer themselves for re-appointment. By order of the Board, London, April 30th. W. H. BARTLETT, Secretary.

SPRING VALLEY COFFEE COMPANY, LIMITED.

Directors.—Messrs Alfred Brown, (Managing Director) Leon Famin, P C Oswald, J G Wardrop, Secretary.—J Alec Roberts, Offices,—5, Dowgate Hill, London, E.C.

REPORT.—To be presented to the Thirty-eight Ordinary General Meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Thursday, the 15th day of May, 1902, at 12·30 o'clock p.m.

The following Annual Accounts are now presented to the Shareholders, viz.:—Balance Sheet made up to 21st December, 1901 Profit and Loss Account for the year ended 31st December, 1901.

The crop of Tea for the past season amounted to 612,026 lb, and this, together with 5,816 lb brought from neighbouring estates and manufactured at Spring Valley, sold for £18,525 8s 3d.

The crop from the few remaining Coffee trees amounted to 47 cwt 2 qrs 3 lb, and realised £184 6s 0d, being at the rate of 77s 7d per cwt, against 68s 2d obtained for the 1900 crop. Coffee sold in Ceylon to the value of £37 12s 0d.

The total proceeds from the sales of produce amounted to £18,747 16s 3d, and expenditure in Ceylon and London to £16,915 9s 4d, leaving a profit on the year's working of £1 832 6s 11d. To this profit has to be added a sum of £627 18s 2d, brought forward from last Account, and after debiting £90 1s 6d for Income Tax and £900 for Dividend on the Preference Share Capital for the 12 months ended 31st December, 1901, there remains a balance of £1,470 3s 7d to be now dealt with.

The Directors recommended the payment of a Dividend of 1½ per cent on the Ordinary Capital, which will absorb £1,200 of the above sum, and that the balance of £270 3s 7d be carried forward to next year.

The weather during the past year was not favourable to flush, and the crop only reached a yield of 408 lb of made tea per acre against 452 lb previously. The cost of production was consequently higher, being 29 cents f.o.b. Colombo, which compares with 26·28 cents for the year 1900.

The unfavourable season and also finer plucking on many Estates resulted, however, in shorter crops both from Ceylon and India and a better price was secured for our produce, the average being 7·19 pence against 6·81 pence for the preceding year.

Cultivation and manufacturing appliances on the property have been well maintained and crop is at present coming in freely.

The future depends upon market conditions, and these should improve, as while consumption continues to increase both at home and abroad, further planting of tea on a large scale has ceased.

The area of the estate as on 31st December, 1901, was as follows:—

	TEA.	
5 years old and over	..	1,521 acres
Planted Nov./Dec.	..	1897 194 do
Do	..	1898 196 do
Do	..	1901 10 do
Total under Tea	..	1,921 do
Total under Fuel	..	163 do
Forest, &c.	..	257 do
Oolanakande Estate	..	365 do

Total Area .. 2,705 acres

Mr J G Wardrop, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election. Messrs Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By Order, J. ALEC ROBERTS, Secretary. London, 5th May 1902.

PACIFIC PHOSPHATE COMPANY.

Pacific Phosphate Company, Ltd. (73,481).—Registered April 18th, with capital £250,000 in £1 shares (125,000 preference) to adopt an agreement with the Pacific Islands Company, Ltd, to prospect, search, examine and explore any territories for phosphate, guano, carbonate of lime, phosphate of lime, nitrate, alumina, oxide of iron and similar substances or products and other

fertilising deposits and substances and to carry on the business of miners, refiners, distillers, manufacturers, exporters and importers of and dealers in such substances as aforesaid and any chemical or other preparation, whether liquid or solid. The subscribers are:—

	Shares.
E T Church, 2, Kepler Road, Clapham, S W, clk	1
J A Fuller, 50, Chatterton Road, N, clk...	1
E S Harper, 76, Oliphant St, Queen's Park W, clk	1
H W Brown, 63, Mackenzie Road, Beckenham, clk	1
A S Cohen, 18, Compayne Gardens, S Hampstead, solr	1

G Troughton, 54, Marville Road, Fulham, S W, clk	1

Minimum cash subscription 25 per cent of any shares first offered to the public. The first directors (to be not less than 3 nor more than 10) are to be appointed by the subscribers; qualification £250; remuneration as fixed by the company. Registered by Ashurst and Co, 17, Throgmorton Avenue, E C.—*Investors' Guardian*, April 26.

PLANTING NOTES.

TEA-PACKET WORK IN AUSTRALIA—we learn from Mr. Edward Drummond, of one well-known Melbourne tea firm, Drummed Brothers, can be done in Australia about as cheaply as in Ceylon. It is not because the labour per hour is as cheap, but because the white labour works so much faster and more continuously than black.

BRITISH CENTRAL AFRICA.—In our daily and *T.A.* will be found our latest notes from British Central Africa, which have taken two months to reach us. Though the country has not been progressing but rather the reverse, the last year or two, the advent of the railway brings a brighter prospect and it is hoped to develop the neighbouring markets to the south, for B.C.A. products—coffee, rubber and ivory.

THE NUWARA ELIYA TEA ESTATES COMPANY'S REPORT—is an interesting document. Beside 6 per cent being paid, nearly £1,800 is carried forward, and the Directors and Superintendents are to be congratulated. Of the estates Hethersett has the biggest planted acreage (370); while Pedro (488) has the largest total, and total crop, 261,223 lb. Park (560 lb.) gave the top yield per acre; Naseby, 9-13d gave the top nett price per lb.; and Park, £7 16 7d gave most profit per acre.

PEARLS AND PEARL OYSTERS.—We draw attention to the interesting contribution given under this heading from the pen of Dr. Andrew Wilson on another page. The theory started by Dr. Jameson may turn out to be of considerable practical importance in connection with Dr. Herdman's investigation, and we have no doubt the discovery will come under the attention of the latter distinguished scientist while he is in England.

BALATA.—In the annual report of British Guiana it is shown that the production of balata has risen from 237,824 lb of a value of £12,231, in 1899 to 1900, to a total of 425,371 lb of a value of £19,535, in 1900 to 1901. A large tract of virgin bullet tree forest were discovered and the industry is in a very healthy condition at present.—*India Rubber Journal*, April 28.

THE TEA CROP FROM THE FAR EAST.—Mr. Tchokoff, in the address we reproduce elsewhere from our contemporary, indicates that that the tea crop at Hankow will not be any bigger this year—unless the reduction of the export duty is going to have any effect. Further we publish news today of recent injury as to the Japan tea crop. If all this proves true, it should go to assist Ceylon and India with what is more than likely to be a bigger output in 1902 than in 1901.

THE REDUCTION IN CHINA'S TEA DUTY—by 3d per lb.—is the result of the Commissioners' memorial to the Throne, regarding which *The Times'* Shanghai correspondent wired on April 19th, a message we quoted two days ago. The export duty at present is, we believe, 2½ taels per picul—or 7s 3d per 133½ lb—which works out at rather less than 3d per pound. The reduction therefore leaves the tax barely 1d per pound. This should assist the China tea exports—which sank by 72,204 and 13,373 piculs, in black and green respectively, in 1900 from the exports of 1899.

RATE OF GROWTH OF SAL (AND OTHERS).—The THINNED AND UNTHINNED AREA TREES figures which Mr Dickinson was kind enough to communicate in the December number are, I think, likely, in their bare nakedness, to lead many people astray, and for that reason I should have been glad if Mr Dickinson had explained just what value he himself puts upon them. The correctness of the measurements is not in dispute, but their application. Personally, I rejoice that various considerations “make it impossible to thin such forests at an early age.” Nobody doubts the greater rapidity with which girth is acquired by isolated or semi-isolated trees as compared with stems grown in close canopy. The volume per tree is also no doubt greater for a smaller number of trees. I am also aware that the total soil production has been alleged to increase by means of thinnings. But here I begin to boggle, and I refuse decidedly to take the jump that leads to open crops from their youth up. Open crops mean grass on the ground. Grass in sal forest is proof positive of a lot of sunlight wasted. How can the soil production then be said to increase? In any case, youth is the period for the upward struggle. *Tall and upright* should be our watchwords. When we have got the maximum possible of length and straightness it will be time to go in for girth, but not before. Not knowing the plots, I cannot discuss the figures; but, in any case, I am not prepared to accept the rates of growth deduced as in the least representative of the difference between an unthinned crop and one thinned with due caution. The very constitution of a selection forest is opposed to correct results, such a forest be in more or less in a chronic thinned condition. One-aged crops are the only ones capable of giving true results in regard to effects of thinning

F. GLADOWE.

CARRITT & CO'S INDIAN TEA
MARKET REVIEW.
SEASON 1901-1902.

Calcutta, April 1902.

The season has closed with an actual crop of 175½ millions, of which 153 millions have been exported to the United Kingdom; the corresponding figures for last year were 187½ and 161 millions respectively.

The shortage in outturn, as compared with last year, has amounted to about 12 millions; Assam made 2¾ millions, Cachar 4½ millions, and Sylhet 4¼ less; other minor districts also contributed to the shortage. The Dooars' crop weighed out about ½ million more than last year; this is accounted for by the recent extensions coming into full bearing; on last year's area of mature tea this district would have been appreciably behind in outturn. The yield from Darjeeling was practically the same as last year.

The quality of the crop, as a whole, has been good and above the average. Assam sent excellent teas forward up to September when quality fell away, and the concluding week's manufacture was disappointing, there being a very noticeable dearth of true autumn-flavoured tea. Cachar and Sylhet have supplied clean useful types, and the teas have shown a marked improvement, both in respect of appearance and liquor. The Darjeeling crop has been fully average, the proportion of really fine tea has, perhaps, been smaller than usual, but on the other hand there has been less of the thin pointless types. Dooars and Terai, especially the former district, have sent forward particularly good crops; they have been the best seen for a number of years.

A few Nilgiri teas have found their way to this market, and we believe sellers have been well satisfied with the result of their venture. There is always a demand here for these types, particularly the higher quality kinds, and there is room for freer supplies. An invoice from "Daverashola" was very well received towards the close of the season.

The market features of the past year have been the higher range of prices at which low grades have been selling, and the proportionately low level of value of all teas above this category, but more especially the higher grades; the one movement is collateral with the other, and is attributable to a smaller supply of common tea.

The past year will be remembered as one of unusual importance in the history of the industry; twelve months ago the effects of an over-abundant supply of indifferent tea were being keenly felt and prospects for the approaching season were anything but bright. The position at the moment is very different, nevertheless the crisis through which the industry has been passing cannot be regarded as over. The improved conditions and outlook are solely attributable to the production of a smaller and better quality crop brought about by a more careful system of plucking and considerably assisted by climatic influences.

Growers are to be congratulated upon their determination and self-restraint shown in the matter of curtailing supplies and improving quality. During the early months of the season there was much to dishearten them; it was an exceptionally late opening, and outturns fell appallingly behind the average for a number of

years. In addition to this the markets took some time to respond and no compensating advance in prices was immediately seen.

It was not until the season had well advanced that tea hardened in value, but with a consistent shortage in supplies this movement became accentuated and the average level of value of Indian tea is now about ½d. better than at this time last year.

It cannot, however, be said that the working of the past season shows uniformly better results to producers than last year. The course of the markets has not treated individual interests alike; generally speaking, advantages have been counteracted by drawbacks and no real benefit has yet been gained. Low grade teas have advanced in value, but gardens producing them lost most heavily in outturn; the value of medium grades upward has not risen to any appreciable extent, but though short crops have been made they have not weighed so heavily in the balance. The advance in value has been chiefly confined to the lower grades, and Assam gardens particularly may be disappointed with the comparatively small recovery in prices so far shown.

The tendency, however, is in the right direction. There is very clear evidence of prosperous times ahead and not so far distant. The action of growers during the past season has undoubtedly averted a crisis in the industry; they now find themselves in a stronger position at the close of a single season, with a brighter outlook for the future before them, so long as they persevere in their determination to curtail outturn and improve quality. It is interesting and instructive to go into figures and get some idea of what the conditions might have been, had the industry failed to recognise its serious position before a start was made on the past year's crop. Owing to the absence of outturn and export figures of the crop from Southern India, it is difficult to compile an absolutely accurate estimate, but a very fair idea can nevertheless be formed from details at hand. It is probable that, had similar conditions of weather and manufacture existed in 1901-1902 as in 1900-1901, the quantity to be accounted for through Calcutta would have totalled 192½ millions, of which about 166½ millions would have been shipped to the United Kingdom. This heavy crop would have had much the same effect on prices as in 1900. By reason of unfavourable weather, however, and more careful plucking, the actual crop and shipments to the United Kingdom have been reduced to the much more moderate limits of 175½ millions and 153 millions respectively.

From now onwards the industry should realise the vital importance of keeping the crop within reasonable bounds, and particularly during the ensuing two to three years, as the period is now being passed when large extensions, made a few years ago, come into full bearing. Weather was abnormal last year, and played a very important part in levelling down supplies, and it cannot be expected to have the same influence for some time. The position must therefore be met by strict adherence to careful plucking. The producer has recovered considerable strength during the past twelve months and he will continue to do so, provided the markets are fed judiciously; breathing time will be given to enable demand to come abreast of supply and it will not be long before "Tea" will offer as sound an investment as can be found. The past two

years have furnished excellent examples of opposite workings. Season 1900-1901 with its heavy crop of indifferent quality gave a result little short of a crisis, the market became clogged and prices tumbled away below bedrock level; the evils continued their effects into season 1901-1902, but were counteracted by smaller supplies and improved quality, and before many weeks had passed there were signs of recovery which have since developed into a quotable advance in the average price of all tea. The coming season can be viewed with confidence so long as the outturn continues on a moderate scale. Although weather is not likely to tend to check supplies, its place will be taken by scarcity of labour which is now occupying the serious attention of producers. The flow of labour from the recruiting districts has been seriously checked, chiefly by recent Government restrictions; and the difficulty in obtaining coolies is, perhaps, greater than had ever before been experienced: it is doubtful if gardens have secured half their additional requirements for their labour force, and this will undoubtedly have its effect on outturn. Circumstances are all in favour of a moderate output; the past year's experience has infused a determination amongst growers to continue on last season's lines, and the labour difficulty, and abandonment of non-remunerative areas, which is considerable, will have a material effect in curtailing the supply.

The conclusions which may reasonably be drawn are that the approaching year's crop will again be a moderate one, and no large increase on last year's export is likely to take place, while a very much greater off-take by new outlets may be anticipated if the local market is more liberally supplied.

In our last annual review we remarked as follows:

"As regards the outlook and prospects for the future it may be said that the position is almost entirely dependent upon the attitude of growers during the coming season. The remedies for dealing with the present depression are in their hands, and they have only to make it evident that they are determined to curtail outturn, improve the standard of quality and devote more attention to the demands for new outlets to bring about more prosperous times."

It has been seen that endeavours to reduce supply and improve quality have been, with the assistance of weather, successful; but no headway, however, has been made towards fostering the demands for outside markets. Only 46½ millions have been sold in Calcutta during the past year, which shows a falling-off of 3¼ millions in the supply to this market; a short crop in some measure accounts for this, but not entirely and, it is once more apparent that the importance of studying the requirements of new outlets is not yet realised. For some years past we have urged the necessity of a free supply to Calcutta, and at the conclusion of each season have shown the strength of outside demands, their relation to the supply and the disappointment that must eventually follow a continued disregard of them. The season just closed indicates that Indian tea has lost ground in the markets of the world outside the United Kingdom; from year to year they have increased their trade, until in 1900-1901 they absorbed half the offerings in Calcutta, and there is no doubt that further expansion would follow an increasing supply; on the other hand, a retrograde movement must occur if the course of supply becomes underfed.

This is what has really happened during the last twelve months. Calcutta sales have shown a falling-off of 3¼ millions, and outside trade shows 4½ millions decrease. There are now no obstacles in the way of extending our connection with foreign markets; shipping facilities to all parts of the world have marvellously improved of late and the only explanation lies in the reduction of supply on the Calcutta market. The various demands for tea, however, exists and are increasing rapidly, but Ceylon is reaping all the benefit; she is not only getting the increase but is also cutting very seriously into our trade by reason of the better handling of her crop.

In contrasting the two markets last year we remarked:—"As Ceylon increases her business with new markets, so in like proportion is the supply and selection in that market increased by producers. Why should India continue to do the exact opposite?"

The following is an interesting comparison of the two markets:

	CEYLON.		
	Total Crop. millions.	Offered in Colombo. millions.	Shipped to outside markets. millions.
1901	146½	51	40
1900	148½	48	34½
1899	130	38½	25½
1898	119¾	36	23¾
1897	116	33¾	17
1896	108	32	14½

	INDIA.		
	Total Crop. millions.	Offered in Calcutta. millions.	Shipped to outside markets. millions.
1901	175½	46½	20½
1900	178½	50	25
1899	174¾	50	22
1898	154	49	17½
1897	148½	46	13
1896	135½	47½	13

In the six years it will be seen that Ceylon's outside trade shows an increase of 25½ millions, and her off-rings to meet it have increased 19 millions without a pause from year to year.

During the same period India's outside trade has increased 7½ millions; her offerings, however, have been irregular, and for three consecutive years were stationary while last year they were actually 1½ millions less than five seasons ago when the total crop was 40 millions lighter. The whole of the increase in the crop from India from year to year has been forced on the London market, and no portion of it has been seen in Calcutta. Ceylon shows a very different record in 1899 and in 1900 her crop increased 18½ millions, but only 10 millions of it went to London, the remaining 8½ millions being offered in Colombo. In 1901 her crop was less than the previous year, yet she recognised the advantages in obtaining on the local market and gave it 3 millions more.

Comparing the two centres again, Colombo placed 44½ per cent of its supply in new markets in 1896, and nearly 80 per cent in 1901; while Calcutta figures are 27 per cent and 44¾ per cent respectively.

The indications last year correspond to those in 1896 and 1897 and are unmistakable; supplies showed a decrease in all three years, and exports were either less or could make no headway.

Ceylon has therefore gone ahead so rapidly that her local offerings last year were nearly 5 millions more than Calcutta and she has diverted from London just about double as much as India; she thus

feeds and fosters her new outlets carefully and in doing so affords relief to London, providing for a reasonable supply and a healthy tone to that market. She is a long way ahead of us. In 1900 her offerings were 2 millions less than Calcutta, while in 1901 they were nearly 5 millions more.

The distribution of the crop from Calcutta compares with recent years as follows:—

	1901-1902. millions.	1900-1901. millions.
To United Kingdom	153	161
To Colonies	8½	10½
To America	2½	4½
To other outside markets	10	10
	1899-1900. millions.	1898-1899. millions.
To United Kingdom	149½	133½
To Colonies	8½	6½
To America	6	3½
To other outside markets	7½	8½

The disappointing figures have been explained. Russia has now made Calcutta a regular market for obtaining its supplies. It is capable of drawing large and increasing quantities and is one of the best fields for an extending trade.

The quantity taken by outside markets from Calcutta sales has amounted to 20½ millions which is equal to 44½ per cent of the total offerings. Last year the proportion was 50 per cent., and the year before 44 per cent. Comparative details are as follows:—

	1901- 1902. mills.	1900- 1900. mills.	1899- 1900. mills.	1898- 1899. mills.
Total quantity sold in Calcutta	46½	49½	50	49
Percentage of above exported to Colonies	.. 18½%	21¼%	16½%	13½%
Percentage of above exported to America	.. 4½%	9%	12%	6¾%
Percentage of above exported to other outside markets	.. 21½%	20%	15½%	17%

The Port Commissioners have now before them a scheme for improving the present facilities for handling tea in Calcutta, whereby the work can not only be considerably accelerated, but a material reduction in charges is also expected, and a better preservation of the condition of packages. Such improvements are needed more especially in respect of arrangements for ensuring greater expedition in the simultaneous handling of incoming and outgoing teas; the present system necessitates numerous handlings, and at times an exceptional strain is placed on the existing available resources of the warehouse.

The transfer of warehousing accommodation from the centre to the outskirts of the city, however, may interfere with the expeditious working of Calcutta sale teas unless reliable provision is made for continued and easy access to the warehouse, and it is to be hoped this important matter will receive careful consideration for otherwise the working will not be successful.

The following is an extract from a circular having reference to this matter:

“The Port Commissioners have now under consideration a comprehensive scheme for the provision of suitable berths at the docks, to which the inland vessels would proceed direct on their arrival in Calcutta and discharge their cargoes by means of special appliances into a warehouse, where the tea

might be stored whether for sale in Calcutta or London. Consignments when ready would be passed on from this warehouse direct to the berths of ocean steamers. The object of the scheme is to give despatch and at the same time reduce the handlings, thus cheapening the cost and avoiding the damage and waste, which must be sustained when such articles as chests of tea are subjected to repeated removals. The new tea warehouse would be equally accessible to the railways. The handling of tea from the time it left the Inland vessel or railway wagon, until it was in the Ocean steamer's hold would be reduced to a minimum, whether it was tea for sale in Calcutta or London. As the handling of Calcutta and London teas, under the proposed scheme, would practically be the same, there would always be the option of selling the tea without extra expense, in whichever market suited best for the time being. The present tea warehouse would be used for other purposes. Should the scheme go through, arrangements would be made for conveying by train once or twice a day the representatives of the Tea Brokers and Agents to the Docks.”

The duty question has once more engaged the attention of the trade, but, although it has been responsible for disappointing markets, it has fortunately not been productive of such serious disorganisation as attended the scares of the last two years. Strong representations have been made to the Governments, and it is fervently hoped they have been successful in convincing the powers that be that tea has reached the utmost limit of taxation. Even as it now stands, the impost of 6d per lb is comparatively unfair, and a further increase would invoke a strong feeling of iniquitous legislation, while so many other products remain unburdened. A further increase in duty could not be borne, it would come as a fatal blow to the industry, and at a time when, through its own endeavours, it was overcoming difficulties and a more hopeful future might reasonably be anticipated.

The past year has seen a definite start made in endeavouring to increase the consumption of tea in India. Messrs. Andrew Yule and Company have been appointed Commissioners, and considerable assistance has been given in contributions of cash and tea by the Indian Tea Association and the producing community. The object of the scheme is to put supplies of sound honest tea within easy reach of all classes, and at the same time to relieve the markets of an appreciable portion of the yearly supply. It is unusually comprehensive and every possible outlet in the Empire is being energetically tapped. The Advisory Committee and Commissioners are to be congratulated upon the excellent results already shown. The movement has been in existence but a few months and up to the present about 6½ lakhs of pice packets of dry leaf and 1½ lakhs of cups of brewed leaf have been turned over. The total quantity distributed in various ways is about 2,500 chests. This progress is doubtless beyond expectation, and as the scheme is being thoroughly worked through the proper channels its success seems assured and the offtake through this source, will soon afford material relief to the markets. It is to be hoped the Commission will be loyally supported by producers, as they undoubtedly should, so that the good start made may be carried through to a successful issue. A memorial, praying for the sanction of an export duty on all Indian tea, has

been presented to His Excellency the Viceroy and his reply is anxiously awaited. The export duty or cess is asked for at the rate of one-fourth of a pie per pound, the infinitesimal equivalent in sterling being one-twelfth part of a farthing. On the total export, however, this assumes the very considerable proportions of about 2½ lakhs of rupees, or nearly £17,000 sterling. It is desired to utilise this amount for the purpose of increasing the consumption of Indian tea in India and other countries outside the United Kingdom. The memorial is a fully presentative one, being signed by those interested in almost 400,000 acres, and it is to be hoped His Excellency's reply will be favourable. The cess will correspond to that which has been in existence in Ceylon for about eight years.

The foregoing remarks will help to convey some impression in regard to the coming year's outlook which is again chiefly dependent upon the policy of growers, but unlike last year they can count upon freer working markets in all parts, occasioned by more or less moderate stocks, and no locking up of capital in London to any great extent. Home stocks appear somewhat heavy on paper, but last year's figures were exclusive of the heavy clearances from bond made in anticipation of the Budget, which were held by dealers and occupied their attention for many months. The present position, however, should not be regarded as any inducement to free plucking and increasing of supply: such action would be extremely unwise and the industry would immediately lose all the advantage gained during the past twelve months.—*Indian Gardening and Planting*, April 24.

TRADE AND NAVIGATION OF BRITISH INDIA.

FOR THE 12 MONTHS, 1st APRIL 1901
TO 31st MARCH 1902.

TOTAL TRADE TEN TIMES THAT OF
CEYLON.

LARGE EXPORT OF PEPPER, CHILLIES
AND GINGER TO THE VALUE OF 7½
MILLION RUPEES.

COFFEE KEEPING UP;—FALLING-OFF
IN EXPORT OF RUBBER.

On 20th instant we received from the Government of India, its full Customs Accounts for the year ended less than two months ago. This is expeditious work. The grand total for the Import trade is ... R1,011,189,172 and Export trade ... 1,325,565,619.

Grand total ... R2,336,754,791

But the above includes gold and silver imported (over R196,000,000) and exported (over R84,000,900)—and deducting these, the total of "Merchandise" was as follows:—

	R.
Imports ...	814,705,376
Exports ...	1,208,336,706
Total ...	R2,023,042,082

It is interesting to compare our Ceylon figures with the above:

	R.
Imports (without Specie) 1901 ...	104,050,030
Exports " " ...	85,977,410
Total ...	R190,027,440

So that our annual Ceylon trade is less than one-tenth that of India. This is a wonderfully good comparison however, when the population and size of this little island are contrasted with that of the big continent. One curious point is the preponderance of value in Exports in the case of India, while the reverse is found in Ceylon. We suspect the Customs valuations for Exports are more liberal in India than here; for, of course, the rates applied here are nominal and below real values. At the same time, Ceylon is still to some extent, though slightly now, a distributor of imports, and therefore gets more than she consumes.

Among interesting details is the fact that India imported 12½ millions coconuts last "year" against 17½ in 1900-1. Of betel-nuts she took 9½ million lb. in 1901-2 from Ceylon valued at R1,517,521. The Straits gave India seven times this quantity; but the value is less than three times. Can the Ceylon betel-nut be worth more than twice that of the Straits, although the very name "Penang" means the home of the betel-nut? Who will clear up the mystery.—Of Cloves, Pepper and other Spices, India also imports, but only to a fraction of her exports. Here is a grand show in this department (in which Ceylon is far behind, even in supplying its own wants):—

	1901-02	1901-02
SPICES—	lb.	R.
Cardamoms ...	144,792	225,493
Chillies ...	9,806,416	958,719
Ginger ...	5,758,616	1,302,323
Pepper ...	13,589,172	4,801,554
Other sorts ...	514,814	120,180
Total ...	29,813,810	7,408,269

We may as well also give the full official return for tea exports:—

	1901-02	1901-02
TEA—	lb.	R.
To United Kingdom ...	159,014,075	73,905,206
„ Russia ...	1,624,580	537,496
„ Canada ...	1,059,483	412,125
„ United States ...	1,080,293	385,736
„ China—		
Hongkong ...	1,111,192	418,767
Treaty Ports ...	225,452	48,939
„ Persia ...	2,530,546	1,141,549
„ Turkey in Asia ...	2,626,130	1,008,133
„ Australia ...	8,575,036	2,913,010
„ Other Countries ..	1,838,145	723,932
Total ...	179,684,932	81,494,893

Tea showed 175,038,127 lb. exported in 1899-1900; and 190,305,490 in 1900-01.

It is interesting to note how wonderfully well the export of coffee keeps up:—255,042 cwt. in 1901-2 (of which curiously enough 100,777 cwt. went to France) against 246,431 in 1900-01; and 281,533 in 1899-1900. Cinchona Bark, Caoutchuc (Rubber) and

Tea Seed go steadily down, however, in the exports:—

	1899-1900	1900-01	1901-02
Cinchona Bark, lb.	3,290,236	2,753,858	1,917,250
Rubber, cwt.	8,169	7,698	4,136
Tea Seed, cwt.	1,659	1,121	647

We may add that Cardamoms which were shipped last year to 144,792 lb. gave 191,120 lb. in exports in 1899-1900; but only 123,254 lb. in 1900-1901. The fact is that the Presidency towns offer a splendid consuming market for Cardamoms and all Spices and it is a wonder any are shipped to Europe.

NEW COMPANY: TO DISTRIBUTE TROPICAL PRODUCTS.

ASSURANCE TRADING Co., LTD. (73,408).—Registered April 12th, with capital £50,000, in 49,500 ordinary shares of £1 each and 10,000 finders' shares of 1s each, to carry on by wholesale and retail the business of tea, coffee, cocoa and chocolate dealers and blenders, general grocers, provision merchants, dealers in foodstuffs, distributors of gifts, bonuses and benefits to customers, planters and growers of tea, coffee, rice, cocoa, cinchona, tobacco, indigo or other produce, farmers, graziers, cattle dealers, millers, storekeepers and general merchants. The subscribers are:

	Shares	Ord. Frnds'
H F de Trafford, Hill Crest, Market Harborough, Bart. ...	4,050	1,000
H M Stourton, Manor House, Banbury, gentleman ...		1,000

P L D Perry, 57, Whitefriargate, Hull, manager ..		2,666

No initial public issue. The number of directors is not to be less than 3 nor more than 7; the subscribers are to appoint the first; qualification 250; remuneration according to profits (minimum £100 each per annum and £50 extra for the chairman.) Registered by W Webb & Co., 23, Queen Victoria Street, E.C.—*Investors' Guardian*, April 19th.

LUMINOUS TRAPS FOR INSECTS.

(From a correspondent.)

Le Phare Agricole "Meduse"—described and figured on the separate slip—would be the most convenient form for use in Ceylon. I have been using one (obtained through Mr. E B Creasy) for the last month. It is very simple and effective. I have proved it to be an excellent moth trap; but it has failed in the case of *Helopeltis* and *Shotbole Borer*, which pests do not appear to be responsive to the attractions of light. It ought to be possible to import these machines at a small cost. Cheapness is a *sine qua non*, if they are to come into general use on estates. For—to produce any practical result—a number of the lamps must be employed simultaneously, in different parts of the affected fields.

"COFFEE" TOBACCO: NOT OBNOXIOUS.

M Baral, a Frenchman, finds by experiments that while cigarettes made with tobacco are noxious to men and animals, those made with leaves of the coffee plant are inoffensive. Perhaps an English investigator will follow up the clue. What with American "combinés" and cheap Virginia cigarettes there is ample room for a wholesome rival of tobacco.—*Globe*.

BRITISH NORTH BORNEO TOBACCO.

We are informed officially that, at the sale of 19,337 bales of Sumatra and British North Borneo tobacco, which was held at Amsterdam on the 8th instant, a parcel of 1,348 bales of North Borneo tobacco, grown by the New Darvel Bay Tobacco Company, fetched the highest average price—viz., 5s. per lb. for the lot, over £50,000.—*London Times*, April 10th.

RUBBER PLANTING IN MEXICO.

The president of the Tehuantepec Rubber Culture Co.—Mr H W Bennett—writing from their plantations, says: "Over 600 acres of and, which, six months ago, was heavy virgin forest, has been cleared and partially planted. With a large force of laborers employed, it is expected that this area will be more than doubled by the month of June, when all new clearings will be burned over, staked and planted (with the early July rains) with selected stock from our own nurseries. The soil is so exceedingly rich that it will readily support a much larger number of trees per acre than contemplated by our proposal to investors, and it is the purpose of the management to largely increase the number of trees to be planted, with the idea of cutting out (for profit) whenever the growth shall become too dense. This process is considered advisable, if for no other reason than to furnish proper shade for the trees which will later form the permanent plantation."—*India-rubber World*, April 1.

WILL OF MR. GEO. WHITE.

The estate of the late Mr. George Thomas White of Malvern House, Kenley, and of the firm of Messrs. George White and Co., 31, Fenchurch Street, E C, tea brokers, who died at the Mandeville Hotel on March 5, aged sixty-two years, has been valued at £29,194 11s 7d gross, and £28,423 5s 4d nett.—*H & C Mail*, May 2.

TROUT IN CEYLON.—We give some interesting particulars elsewhere regarding the trout fry at the Nuwara Eliya Hatcheries, and simultaneously Mr. John Fraser's letter, in search of truth and showing unreadiness to be convinced too easily that trout are breeding in Ceylon, is to hand. It is certainly a question that should be authoritatively settled by more than mere observation of the contents of streams; expert investigation is desirable. "A. J. M." unfortunately has gone a-coronating to Alexandra Park, or his assistance in identification of local-bred trout (whatever his gift be in this direction as regards authorities) might have been of some immediate service.

CEYLON TEA: MONTHLY SHIPMENTS TO UNITED KINGDOM AND ESTIMATE.

Estimate for	May 1902—	10½ to 11 mil. lb.
Total Shipments	Do 1902—	9½ mil. lb.
Do	Do 1901—	9,804,879 lb.
Do	Do 1900—	10,570,836 lb.
[ESTIMATE for June 1902—	12½ to 13 million lb.]	

THE DEAF HEAR.—No. 479 of the *Illustrated World* of 624, Chiswick High Road, London, W., England contains a description of a remarkable Cure for Deafness and Head Noises which may be carried out at the patient's home, and which is said to be a certain cure. This number will be sent free to any deaf persons sending their address to the Editor.

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce.)

EXPORTS

Colombo, May 26th, 1902.

CEYLON EXPORTS AND DISTRIBUTION FOR SEASONS 1901 AND 1902.

CARDAMOMS:—			
All round parcel, well bleached per lb.	R1 05		
Do. dull medium do.	R0 85		
Special assortment, 0 and 1 only do.	R1 20		
Seeds do.	R1 00		
CINCHONA BARK:—			
Per unit of Sulphate of Quinine 9c—1½ to 3 per cent.			
CINNAMON:—			
Ordinary assortment per lb.	53c.		
Nos. 1 and 2 only per lb.	58c.		
Nos. 3 and 4 only per lb.	47c.		
CINNAMON CHIPS:—			
Per candy of 560 lb	R72 50		
COCOA:—			
Finest estate red; unpicked per cwt	R40 00		
Medium do do do	R36 00		
Bright native unpicked and undried	R37 00		
Ordinary do do do	R25 00		
COCONUTS—(husked).			
Selected per thousand	R56 00		
Ordinary "	R46 00		
Small "	R39 00		
COCONUT CAKE—			
Poonac in robins f. o. b. per ton	R30 00		
Do in bags	none.		
COCONUT (Desiccated).			
Assorted all grades per lb	21c		
COCONUT OIL—			
Dealers' Oil per cwt	R19 25.		
Coconut Oil in ordinary packages f. o. b. per ton	R425 00.		
	—Sellers at the higher figure.		
COFFEE.—			
Plantation Estate Parchment on the spot per bus.	R11 00		
Plantation Estate Coffee f. o. b. (ready) per cwt.—	None.		
Native Coffee, f.o.b per cwt.—	None.		
CITRONELLA OIL—			
Ready do per lb.	45c

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for June :—

Vol. XIII.]

JUNE, 1902.

[No. 12.

VARIATION IN THE COMPOSITION OF COW'S MILK.

HE variation in the quality of milk has perplexed many a dairyman. As a rule variation below the higher stand is attributed to adulteration; and while it is certain that the instability of the standard is taken advantage of by the unscrupulous dealer in milk, the honest man is often unjustly blamed for what he cannot help, through the vagaries of his milking stock.

Those who are interested in this subject and are desirous of informing themselves, instead of dogmatising in their ignorance, should carefully read the article by Mr. Herbert Ingle, F.I.C., of the Yorkshire College, Leeds, who takes up no less than thirty pages of the latest number of the *Transactions of the Highland and Agricultural Society of Scotland* in detailing the results of investigations into the inconsistent results as to the quality of milk under regulated treatment and feeding of cows.

The various points which were carefully considered in the investigation were (1) determination of fat, (2) determination of specific gravity, (3) period of lactation, (4) season of the year, (5) time and manner of milking, and (6) the effect of food.

The records given are interesting to those who have the care of milch cattle, but it suffices us to reproduce the general conclusions to be drawn from the results brought out by the practical investigation into the subject.

1. The percentage of fat in the milk of individual cows is liable to enormous variation from time to time, from causes which are unknown.

2. Morning milk is much poorer in result than evening milk, though slightly richer in solids not fat and more abundant. This statement applies to cases where the night interval is much longer than the day.

3. The percentages of fat and solids not fat in milk tend to diminish for two or three months after calving, and then steadily increase as lactation advances.

4. Foods rich in albuminoids seem to improve both the yield of milk and the proportions of fat and solids not fat, at least for a time, while large quantities of carbohydrates, though slightly increasing the yield, appear to diminish its quality.

5. The mixed morning milk of a herd may often fall below 3 per cent of fat in the late summer or autumn, if the milking be performed at the usual unequal intervals.

While the variations referred to under the heads 2, 3 and 4 are thus accountable and to some extent controllable, that referred to as being due to unknown causes must remain a very unsatisfactory element in the dairy industry. With this variation in the percentage of fat, will vary the specific gravity of milk, and to depend upon the lactometer as a gauge of the purity must lead to very erroneous conclusions.

It is to be hoped, however, in the interests of all concerned in the production of pure milk, that the mystery will be soon unravelled and the unknown causes that are responsible for sometimes lowering the quality of milk will, with the help of science, be eventually made known.

Recorded by ALEX. PERERA.

OCCASIONAL NOTES.

We publish in this issue an account of the cultivation of ground-nuts, of which a small crop has just been taken at the Stock Garden, from whence the seeds will be distributed to School Gardens. As we stated in our last issue it is surprising how little this plant is cultivated in the Island, in spite of its being so valuable a product for dietetic and other points of view.

About the middle of May we had the opportunity of inspecting the mangosteen plantation on Mr. J. Dassanayake's property at Bellana, where the mangosteen tree flourishes as luxuriantly as we have seen it do anywhere. At the time of our visit the trees were heavily laden with crop just coming into maturity.

We were struck a few days ago by the peculiar odour of chlorine gas in the gardens of the School of Agriculture, and were reminded of the fact that we had the same experience last year, as far as we remember about the same time. We have failed to connect the odour with some form of vegetation in the neighbourhood, but it may be that it comes from some neighbouring garden, as it seems to be brought by the wind at intervals. There is no reason for believing that the smell is due to decomposition. Have any of our readers had a similar experience, or do they know of any flowers emitting the peculiar odour referred to?

Of the fruits that are well suited to the very sandy soil of the "Cinnamon Gardens" of Colombo are the custard apple and the pine. A plantation of the latter has been bearing very

well all through May, and there will be more fruit to gather in June. The custard apple trees are just now in heavy bearing, and always bear good crops. The trees have been given a small dressing of rape manure which we have found good for all fruits. The great trouble with custard apples is to keep the fruit from being attacked by squirrels. Apparently nothing will force the orange into bearing in such a soil. Trees growing in the clay soils of the Matale district are worth looking at about this time.

SERICULTURE AN INDUSTRY FOR
THE NATIVES OF CEYLON.

As long ago as August, 1896, a correspondent writing to the *Agricultural Magazine* made the following allusion to this subject:—It must be admitted that we have very few industries in the Island capable of giving employment to the native agriculturist, and especially to the members of his family during the time they have little work in the paddy fields. The Sinhalese cultivator is accused of apathy and gross laziness, but the average tillers of the soil cannot be expected to possess the knowledge and resources necessary for experiments in connection with new industries with a view to their adoption. No one will, however deny, that when he knows of an industry that is likely to bring him an income and will not interfere either with the cultivation of his field or with his liberty as a proprietor, he is not only ready to adopt it, but is capable of carrying on the work with success. Under these circumstances it surely behoves those who have the welfare of the country at heart to experiment in connection with and popularise such industries as will give employment to and draw forth the latent energies and capacity of a large number of the rural population. The improvement of the villagers' condition cannot be effected by the introduction of any industries which require large capital, and which will necessarily involve factory work and coolly labour. These will benefit the larger capitalists, but the material and moral welfare of the agricultural masses can only be improved by providing them with work that will not necessitate the sacrifice of their independence or the neglect of their holdings, however insignificant these may be. They must be encouraged to depend on themselves and work for themselves and not to work for others to the neglect of their land; and they must not be encouraged to congregate in manufacturing centres where with busy surroundings they begin to feel discontented, a condition which leads to much trouble. Under these circumstances the importance of home industries cannot be over-valued. Sericulture or the rearing of silkworms may prove to be one of the industries adapted to the peculiar circumstances of the villagers. We say "may" because there are industries which though they appear likely to be suitable will eventually be found to contain some element which makes it impossible for the people to carry it on with success. This point can only be satisfactorily settled by one or more experiments, and there is no reason why such a trial should not be undertaken in Ceylon.

The history of the various attempts that have been made to establish the silk industry in Ceylon is thus summarised by the Editor of the Ceylon Handbook and Directory:—

There is a spot on the banks of the Kelani river 3 or 4 miles above the Bridge of Boats *en route* to Hanwella called "Orta Seda" (Sin. *Sedawatta*) or Silk Garden, where the Portuguese are believed to have fed silkworms. The Dutch unsuccessfully attempted to propagate the Silkworm plant (mulberry) trees, and produce Silk at Jaffna. (See Tennent, vol. I, page 265.) Tennent also notices the presence of the Tusser silkworm which feeds on the country almond (*Terminalia Catappa*) and the very common *Palma Christi* or castor-oil plant; but nothing has been done with the Tusser to make it a commercial success. In the British period Bennett takes credit for introducing the white and digitated mulberry (as well as the opium poppy), and on 21st September, 1829, a Government regulation was passed to encourage the growth of "silk and opium" among other agricultural produce. He thought the Northern Province eminently adapted for the silkworm and mulberry plant, being the least humid part of the island; as Tennent thought it best adapted for the Tusser silk and castor-oil plant. Bennett gives instructions (page 217) for the formation of mulberry nurseries, and he quite hoped to see silk a staple of the north of Ceylon. He proposed shading the mulberry plant with plantains and afterwards to grow an undercrop of Indigo. Latterly, experiments with the true silkworm have been tried more than once, more particularly by a coffee planter in Haputale, on whose produce a favourable report was received, but the difficulty of securing careful skilled labour and the injurious effects of thunderstorms on the silkworms prevented the continuance of the experiment. Sir Wm. Gregory took a great interest in the Silk-growing, as in all other experiments with new products. In 1872 he reported that the "mulberry tree grows quickly and vigorously in Ceylon, and the worms are reported to be hardy and to thrive well, but the difficulty was to find patient and skilled hands to wind the silk." Accordingly he recommended the dried cocoon to be sent to Europe to be spun, but the cost of female labour in England is another difficulty. Sir Wm. Gregory introduced and distributed Japanese silkworm eggs in Ceylon. The late Mr. Bury of Golconda, Haputale, Father Palla at Galle and Mr. P.N. Braine in the Central and North-Western Provinces among others, took a special interest in silkworms, and, for a time, had a fair measure of success, also Mr. C. Ralston White in Haputale West and Mr. R. Frazer of Wariapolla. The Matale Agricultural Association (in July 1888) took steps at the instance of Mr. E. Gordon Reeves to endeavour to establish Sericulture among the natives of the district. A good plan would be to establish groves of mulberry trees and a silkworm hut near every vernacular school as one means of technical instruction. It would be well if the Ceylon Government could offer a sufficient bonus for the production of an appreciable quantity of this and other new products which only require a good start to take root in the island, develop and prosper.

We have referred to this subject and summarised the information regarding sericulture in Ceylon, as it is now proposed by Mr. E. E. Green, the Government Entomologist, to make a fresh attempt to popularise silkworm rearing among our village population through the School Gardens that have lately been established. The proposal has the approval of the Director of Public Instruction, and already the Superintendent of School Gardens has made a start with the distribution of mulberry cuttings to school teachers. Thus the wish of our correspondent of 1896 and the suggestion of the Editor of the Ceylon Handbook and Directory will be given effect to, with what result remains to be seen, but with an already existing agency for the fostering of the industry, and under the advice of an expert in Mr. E. E. Green, the attempt to popularize sericulture as a home industry for the village population starts under fair auspices.

A FINE GAUVA.

Some time ago the *Bulletin of the Botanical Department of Trinidad* described under the above heading a variety of the gauva found growing in the suburbs of Port of Spain and known as the red or Cayenne gauva. The fruit is oval in shape and of an average size of 3½ in. in its longest and 2½ in. in its shortest diameter. It has fewer seeds than the ordinary kinds, and is filled with semi-solid red pulp in the interior. For making the celebrated Gauva Jelly of the West Indies it deserves to be widely cultivated. The weight of an average specimen is .35 lb., thus taking seldom more than three fruits to the pound. The flavour is said to be excellent.

We are glad to state that we have received through the courtesy by Mr. T. H. Hart of the Botanic Department of Trinidad a packet of the seed of this gauva, and in writing Mr. Hart says: "I trust you may be successful in raising plants, as it is a variety well worth growing."

A NEW MANURE.

Mr. John Hughes, in a paper read before the Society of Arts made the following important statement:—"The time has come," he said, "when manures should be adapted to the soil, rather than that the soil should adapt itself to the manure. Obviously soils differing so much in their chemical composition and physical character as chalk and clay, peat and sand, granite and gravel, require different manures in the same way as they require different cultivation and different kinds of crops. It is not scientific, it is not economical, and it cannot be to the advantage of the farmer, that one kind of manure should be sold for application to all kinds of soils."

Such a pronouncement on the subject of manuring by a chemist who has had ample opportunity of judging of the value of manures and their effect on soil, deserves to be carefully considered by us. In this country, the practice of employing chemical fertilizers is of recent date, and where here has been little opportunity for growers to

acquaint themselves with the character and action of special manures in their various forms, there would naturally be a tendency to a careless use of them, careless in the sense that their use is not based upon a definite knowledge of the substances employed. A perusal of Mr. Hughes' paper and the discussion that followed thereon will show how, even in England, the question of economical manuring is still far from settled.

Mr. F. J. Lloyd, another authority on chemical questions, speaking at the same meeting gave it as his opinion that the time had come when some authoritative body should lay down a definite standard which could be accepted universally as a means of estimating the available food in both a soil and a manure—a statement that still further proves the unsatisfactory character of our knowledge of the relation of manures to soils.

One inference to be drawn from the paper under review is that an alkaline phosphatic manure is under ordinary circumstances the most economic, for while superphosphate is suited only to soils which contain plenty of lime, basic slag is best restricted to soils which are particularly sour.

The question will be asked, what is alkaline or basic superphosphate? This is the new manure which Mr. Hughes may be said to have "discovered." The following extract from his paper will give our readers a fair idea of the fertilizer:—

It occurred, to the author, after careful consideration in the autumn of 1900, that a new and useful manure could be produced by the careful admixture in suitable proportions of ordinary acid superphosphate with finely ground or slaked lime.

After making numerous trial mixture the most suitable proportions were decided upon, and a manure was produced which possessed a distinctly alkaline or basic character, and at the same time supplied from 25 to 27 per cent of phosphate of lime in a form readily soluble in the standard solution (1 in 1,000) of citric acid.

The manure so produced was appropriately called basic superphosphate, because it combined the alkaline nature of slag with the well-known solubility of superphosphate.

The mechanical condition is superior both to that of basic slag and superphosphate. Compared with the former it is much more bulky and lighter in weight, so that if equal weights be placed in two glass tubes about 1 foot long, basic superphosphate will be found to occupy a space of 11 inches as compared with only 4½ inches occupied by basic slag, the relation in round numbers being as 100 to 40.

Compared with superphosphate the new material is very much drier, containing only 4 to 5 per cent of moisture instead of the 14 to 18 per cent usually found in commercial superphosphate.

Being in a finely ground dry powder of light weight and bulky nature, greater uniformity and more perfect distribution can be obtained than is possible with basic slag, which when sown by hand is apt to drop between the fingers before complete delivery can be effected.

The general composition of basic superphosphate may be gathered from the following analysis:—

COMPOSITION OF BASIC SUPERPHOSPHATE.	
Moisture (lost at 212° F.) 4.15
Combined water and loss on ignition	12.86
*Phosphoric acid (total) 13.60
Lime 35.15
Sulphuric acid 28.50
Oxides of iron, alumina, magnesia, &c.	2.34
Insoluble siliceous matters 3.40
	Total
	..100.00

*Equal to phosphate of lime 29.68

The manure usually contains from 33 to 35 per cent of total lime, so that in this respect basic superphosphate supplies fully 10 per cent more lime than ordinary acid superphosphate.

Basic superphosphate can be applied, indeed has been applied in the season of 1901, with great advantage on soils deficient in lime, such as sand, gravel, granite, peat and clay.

Briefly, it may be stated that all soils containing less than one per cent of lime will be greatly benefited by the application of basic superphosphate instead of slag or ordinary superphosphate.

It is of practical importance to state that, though originally invented to supplement the deficient solubility of slag, which is fully recognised by those interested in its sale (they therefore recommend its application during the winter months), it has been found by actual field results that the new manure is superior also to superphosphate on soils deficient in lime.

For a further account of the new manure and results of trials made with it we must refer our readers to Mr. Hughes' paper. There is no doubt that a useful fertilizer has been brought to light, and that through it the problem of how to secure the most economic results in the use of phosphates has in a measure been solved. It has been long recognised that the action of these manures is to a great extent dependent on and controlled by the presence and proportion of lime in the soil. But lime, as we know, is very liable to leave the surface soil, and as Mr. Hughes points out it would be far more expensive to supply sufficient lime to a soil that lacks lime so that every square inch should contain enough of it to neutralise any acid brought in contact with it. The adding of about 20 per cent of lime to the superphosphate, sufficient to neutralise all the acid and produce slight excess in order to give it a distinctly acid character, does everything that is required to be done.

THE CULTIVATION OF THE GROUND NUT.

The pea, earth, or ground nut (*Arachis Hypogaea*) is an annual of the leguminous order, or pea tribe of plants. Before it blooms it generally assumes an upright habit, usually attaining a height of about one foot; but when the flowers appear the plant falls over, and makes its subsequent growth in a procumbent position. The leaves are abruptly pinnate, bearing two pairs of leaflets without any tendril; stipules elongated and adnate to the leaf-stalks.

The flowers are yellow, and are arranged five to seven together in the axils of the leaves. These are succeeded by pods about 1½ inches long, and contain two, and sometimes three, seeds, seventy-five of which weigh 1 oz. The most remarkable feature of the plant is that it thrusts its fruit into the ground to effect its maturation. This peculiarity, however, is not confined to this genus of plants, but exists likewise in an allied genus (*Peanutia subterranea*, Thours.), commonly known as the Bombara ground-nut. This plant is a native of Madagascar and various parts of Africa, and has been grown successfully in this country, but it will be more fully noticed in a separate article.

The pea-nut is a native of the West Indies and West Africa, but it is now cultivated extensively in many of the warmer parts of the earth for the sake of its seeds. There are two well-marked varieties of the plant, the difference between them being that one has a small pod and the other a large one. Its cultivation is withal so simple, and as it only occupies the land for about five months of the year, the produce can soon be turned to profitable account. Taking into consideration the quantity of pea-nuts that are consumed in the Colony, it would take the produce of many acres to supply the annual demands. The chief commercial value of this plant, however, is the valuable oil that can be expressed from its seeds.

Professor Church, (to whom we are also indebted for the engraving of the plant), gives the following analysis of the Pea-nuts:—

Composition of Pea-nuts.

	In 100 parts.	In 1 lb.
Water	... 7.5 ...	1 oz. 87 grs.

It will be seen by the foregoing analysis that the pea-nuts contain 50 per cent of their weight in oil. This excellent result must not be expected, however, as a general thing, for the yield varies in nuts that are grown on different soils, and it will be safe to put it down at a lower figure. The oil is thin, of a clear, pale, straw colour, somewhat resembling poppy and the finer kinds of olive oil. It will not become rancid, and it is said to be improved with age. In commerce it is known as "nut oil," and it is said, on good authority that olive oil is not only adulterated with it, but that this nut-oil is "often substituted for it." It is a valuable oil as a lubricant for delicate machinery, and as it does not clog the bearings, it possesses great advantages over many other kinds of oil. The oil is extracted from the pea-nuts by two processes—one of them by simple pressure, and the other by the application of heat. Whilst a greater percentage of oil can be obtained by the application of heat, that obtained by the simple pressure process is more valuable as a commercial article. After the greater part of the oil has been extracted from the pea-nuts by pressure, the residue, or cake, can be used for feeding cattle, and it is considered very fattening. Moreover, it can be used as a fertiliser for sugar-cane lands, and also for other crops that are exhaustive to the soil,

Besides the valuable products already mentioned, the pea-nut has many other important economic uses. Owing to the fact, however, that the nuts contain such a large percentage of oil in a fresh state, they require a considerable admixture of starchy food in order to render them easy of digestion. Enormous quantities of parched pea-nuts, however, are consumed nearly all over the world, more particularly in America, and they are far from being unknown in this country, for boys may often be seen eating them, although they are sometimes inferior to what they would be if grown and parched in the Colony. I read a short time ago where one American writer of authority stated that the manufacture of chocolate cakes out of pea-nuts alone, and without a particle of cocoa, is an immense and profitable manufacture in the States. Although so much has been said about this valuable economic plant, its uses are not nearly exhausted. As a green crop it makes valuable forage, and after the pea-nuts are picked off the dried stems, the latter make valuable fodder, which herbivora of all kinds are remarkably fond of, and they are said to be very fattening.

The soil best suited to the growth of the pea-nut.—

The soil best suited to the growth of this plant is of a light sandy nature, or one inclined that way. It is important that the surface soil should be loose, so that the young pods have no difficulty in pushing their way into the ground to effect maturation. After a suitable piece of ground has been chosen it should be thoroughly cleaned of all weeds and rubbish, and ploughed with a light one-horse plough to a depth not exceeding 6 inches. If it is not naturally fertile, some manure should be applied. If well rotted farm-yard manure is not available, then those commercial manures should be applied that are rich in phosphates. Superphosphate of lime is considered an excellent manure to apply to the land where this crop is grown. The advantage of shallow cultivation will be apparent when it is explained that after the embryo nuts are fertilised, the stalks they are attached to will continue to push themselves into the ground until a firm bed is reached for the nuts to mature on. When the pea-nuts are matured as near to the surface of the soil as is practicable, the harvest operations are not nearly so laborious, because the produce is more easy to bring to the surface, and a less number of nuts will be likely to be left in the ground. If the soil can be left in a rough ploughed condition for a month or so previous to planting, so much the better—the sun and air will get into it and sweeten it. If weeds should spring up, however, the scarifier should be put over the land to kill them. The scarifier should be freely used on the land a few days previous to planting, so that it will be in the best possible tilth to receive the seed, and be cleaned thoroughly free from weeds.

The rows should be 3 feet apart, and the seeds sown 18 inches apart in the rows. This will allow the land to be easily worked with a horse and light plough or scarifier. It will take 25 lb. of seed to plant an acre. Like many other kinds of seed that contain a large percentage of oil, the pea-nut soon loses its germinating power, even when kept under the best of circumstances. The first

requisite for a good crop of pea-nuts is good seed. In countries where the crop is grown on commercial lines the selection of seed is a most important matter. They are all carefully shelled and hand-picked, and only the plump, perfect ones with unbroken skins, being kept for sowing. If this matter is not carefully attended to, there will be a great many blank places in the field. A few years ago pea-nuts were planted by hand, but it was a very tedious and laborious process. Of late years, however, a simple but effective mechanical contrivance has been brought into use, which deposits pea-nuts at regular distances in the rows and covers them carefully over. With the aid of one of these machines a man can plant about 7 acres per day. It is advisable to sow a few extra seeds in some portion of the field to provide plants for any blanks that may occur. It will also be necessary to keep a close watch on the field until the seedlings are well above ground, for many birds and small animals are so fond of pea-nuts that if the fields are unprotected there would be many blanks to fill up. The young plants will begin to appear above ground in about ten days or a fortnight, according to the state of the weather. When the plants have appeared above ground they are a very pretty sight, and look very much like a lot of young red clover plants, as we see them in spring time in the old country.

When the crop shows signs of ripening, the pods will turn brown. As soon as they have arrived at that stage they must be lifted, or they will get discoloured. If this should take place, their value as a commercial article will be depreciated. If only a few rods of ground are under cultivation, the pea-nuts may be lifted with a fork, but where there are several acres the operation is best done with a plough. This should be run under each row, which will sever the main root of the plant, and will leave the plants and pods on the surface. After they have laid on the ground and become partly dried, they should be stacked in the field to complete the operation. This is usually done in the following way:—Select some stout stakes, about 8 feet high, sharpen one end, and drive them into the ground about 18 inches. See that they are left in a perfectly upright position, at right angles. Nail cross pieces of wood, about 3 feet long, beginning at 2 feet from the bottom and continuing at every 2 feet until the top of the stake is reached. With a fork gather up the plants, and put as many on each stake as it will comfortably hold. If showery weather should ensue before the pea-nuts are sufficiently dry it will be advisable to put a cap of hay or straw on each stake to throw the rain off. After they have become sufficiently dry, the pods may either be picked off in the field or the stacks stored in a barn for the pods to be picked off at some future time. The picking is the most tedious process of all, for it has to be done with hand labour. If an efficient but simple machine could be invented to strip off the pods without injuring them it would not only facilitate getting the produce to market, but it would prove of inestimable value to farmers in sparsely-populated districts, where it is often a difficulty to get labour of any kind to perform what work there is to be done.

As many as 115 bushels of pea-nuts have been harvested from an acre. This, however, is an exceptional case, and the average yield must be put down at a much lower figure. About 25 or 30 bushels are considered a fair crop.—*Agricultural Gazette of N. S. Wales.*

SHADE FOR YOUNG TREES.

To the Editor of the "Agricultural Magazine."

DEAR SIR,—In a state of nature young trees grow for a considerable time under shade, and this fact would lead one to ask the question whether shade might not be advisedly supplied to cultivated trees such as the coconut during the early stages of growth—shade for roots as well as foliage. This might be considered rather a fantastic idea by many, but it may be worth looking into.

In the young stage the parts of the tree—stem, leaves and roots—are in a more or less immature and tender condition, at least they have not become "hardened" with increased vigour to the extent that trees of some age have done. Under such circumstances some means of protection against the effects of extreme or varying temperatures may be admitted to be likely to act beneficially. Some fast growing tree of the leguminous order (as likely to add fertility to the soil) such as the *Erythrina*s would naturally be thought of in this connection, if remunerative catch-crops (such as cassava in Ceylon or plantain—the favourite shade tree of the West Indies) are to be discarded as likely to impoverish the soil and as providing insufficiently high and yet broken shade.

In very dry situations shade during the early years of growth, as preserving the soil moisture and protecting the foliage, would enable the plants to make an earlier start and more rapid growth than if no shade were provided.

I have heard of a case where coconuts failed to grow till the lantana scrub was provided, when they came up and flourished into a valuable plantation.

Bare land exposed to a fierce tropical sun is hardly the best condition of soil for young growing plants. Just now much attention is being paid to mulching which is highly recommended by competent authorities in coffee cultivation. In the case of the coconut it is only reasonable to expect some protection for the soil and the roots that in the early stages have not penetrated to any extent into the lower moisture-holding strata.

Weeds, small and great, are generally looked upon as robbers of the soil, but that can only be when they are allowed to flourish and are then pulled up and conveyed off the land. In the case of short-lived delicate plants such as are grown in market gardens the utilization of weeds to any advantage is impracticable, but this is not the case in the permanent cultivation of large trees. Here weeds cannot retard the growth of the crop to an appreciable extent—if at all—while there would be no loss (rather gain) of fertility, provided that they were not carried off the land. The only

requisite would be to keep the weeds within reasonable bounds.

I have seen young trees parched and struggling on a dry soil during the hot weather, while others of the same age were green and flourishing amid *lantana* scrub. This was in the Chilaw district.

I have also seen full-grown trees looking decidedly cool and comfortable with a dense undergrowth of leguminous weeds in the Kurunegala district.

I should like to have the views of experienced planters on these points:—(1) Whether they approve of keeping young coconut palms for a few years amid low jungles but protected from over-crowding by creepers, &c., in order to provide shade and conserve the soil moisture, or whether they would recommend planting leguminous shade trees (*Erythrina*) to be gradually removed later on. (2) Whether they approve of keeping an undergrowth of weeds (preferably leguminous) in old plantations. If not, what objections they have in the carrying out of these suggestions.

Yours truly,

C. P.

[Here are a few interesting points for some of our subscribers (and among them are many experienced coconut planters) to attack during a leisure hour.

Clean cultivation our correspondent is no doubt ready to admit is a *sine qua non* under certain circumstances, but he evidently desires to have the views of experienced hands on the departure he proposes in the special case of coconuts and other large trees. A gentleman who possesses a large plantation of mangosteens whispered it to us as a secret that it is kindness (in the shape of too much attention) that kills the young mangosteen: and he showed us some hardy plants which looked double their age, flourishing as he said "in the jungle." Those thinking over the question of growing under shade will be interested in the first article in the May *Tropical Agriculturist*, where an account of the successful cultivation of pine-apples under shade is given.—ED. A.M.]

THE ENTOMOLOGY OF THE HOUSE FLY.

(Continued.)

Many of the habits of the fly are painfully familiar to all of us. Its discordant buzzing, its exasperating persistency in returning again and again to our sensitive bald spots, setting our nerves on edge with the tickling of its feet and the rasping of its proboscis and its headlong floundering into the milk jug and coffee cup; likewise its habit, so distressing to the careful housewife, of marking its path, especially on newly-polished mirrors, with little dots of brown-black excrement, are well known to almost everybody. If the fly was a cleanly insect, the importance of these associations with man and man's belongings would be limited by the temporary annoyance caused. But the house fly is far from cleanly. It breeds in dung and returns

to dung to lay its eggs, it flits direct from suppurating sores on the skin of animals to regale itself on our perspiration; it visits sterces, and then, perhaps, the milk pail.

Numerous diseases, some of them most serious in character, may result from the visits of the fly to our food and our persons, for it oft brings with it virulent germs from the faecal or putrid matter which it has visited. It has been demonstrated that the fly can contract plague from feeding on animals that have died of this disease, and that, having contracted plague, it may live for several days and finally fall or drop dead on to food, meanwhile having been depositing excrement laden with virulent bacilli. It is firmly believed by medical men in India that cholera is very frequently transmitted by the house fly. Tuberculosis bacilli are taken up by it through feeding, as it often does, on the sputum of consumptive persons, and these germs are given off in the excreta. The excreta of flies that had been fed on infective sputum, when injected into rabbits, has given rise to tuberculosis. But of all diseases that it may transmit, typhoid or enteric fever probably ranks first in importance. The dejections of persons infected with this disease, it has been stated on the best of authority, harbour the causal organism not only during the period of actual illness, but for some days before and for some time after apparently complete recovery. The fly becomes contaminated by alighting on dejections that have not been properly disinfected, and then may carry the germs into surrounding households. The bacilli multiply rapidly in milk, and how easily can a fly render a whole pailful poisonous by falling into it or even simply sipping it! In cities and towns with good sewerage systems and well-enforced sanitary regulations, the carriage of typhoid by the fly is doubtless exceptional, but in concentration and army camps it is presumed to be very common.

Not only may the fly convey infectious diseases, but, it is asserted, some of the worm parasites that afflict humanity as well. The eggs of the tape worm and of the tiny thread or pin worm were found to pass unaltered through "flies" (presumably house flies) by an Italian investigator; and an American zoologist found that fly maggots (of genus *Musca*, species not stated) will devour the common round worm, and that the eggs of the worm are passed off alive in the excreta of the winged adults. The excreta may be dropped on the food and the contained eggs carried into the intestines, where they can develop. It is probable that the life circle of the worm normally depends upon such an extraordinary sequence of happenings for its completion, but as the eggs are almost numberless the survival of the species can safely rest on very slim chances of one egg, or indeed of any one egg if a thousand becoming lodged in the intestine.

The fly evil can be abated to some extent by preventives against multiplication. The thorough cleansing of stable floors even once a week, and the keeping of manure in pits from which flies cannot escape or spreading it on the land where it will dry out quickly are practical measures of high

value to which effect may be given. The maggots swarm in floor crevices and in corners of stalls where dung collects, and thence the necessity of thoroughly cleansing the floor.

To minimise disease transmission human excrement should never be left exposed, and indeed should be at once disinfected. Where sanitary measures are in force covers should be provided for buckets.

Small mesh nettings at the windows and doors are little seen, though in America dwellings are thus protected. Incidentally the screens afford relief from mosquitoes and lessen the dust. The nettings (generally coloured) admit air freely but break the light, so that though a person within can see out clearly one without can see in only dimly.

The value of sticky fly papers, the best of which is that styled "Tanglefoot," of sticky fly strings, of poisoned fly paper, and of wire fly traps are well understood by most housekeepers. All these devices for reducing the number of flies have their disadvantages, yet with due regard to circumstances they are all highly commendable. Sticky fly paper is the least objectionable, despite the buzzing of the victims and the risk of catching one's clothing. Poisoned paper is somewhat dangerous where inquisitive children and pets are about, and besides, it is rather disagreeable to have dead flies dropping into everything. The art of driving flies out of a room seems almost unknown by the majority of Colonials, but driving them out is one of the best ways of getting rid of them. The room to be cleared is darkened except at one partially opened door or window, and the flies are "shooed" with a whisk or cloth to this exit; they move readily towards the light when disturbed, but some skill and patience is required to get them all to leave. Even without more trouble than simply darkening the room and leaving a lighted exit, many of the flies within will pass out; it is a good practice to thus treat dining-rooms between meals.

Pyrethrum powder, otherwise known as insect powder, Persian powder, Dalmatian powder, and most familiarly as Keating's powder, is excellent for use against flies. Some people like to blow an ounce or two with a powder bellows into the closed room at night, others to burn a little on coals or in a roll of twisted paper, but the first method involves a layer of dust and the second a peculiar odour that remains for days, while both necessitate the sweeping up of the stupefied victims in the early morning. The neatest way to use it, I think, is to dust it liberally on the window ledges and sills, the windows being closed. When the other sources of light are shut off the flies sooner or later seek the windows and one by one are overcome by the volatile oil of the powder and drop senseless. In the writer's house, the fly is kept almost completely suppressed by darkening the rooms on the days that flies most commonly seek to enter, dull days when rain threatens, by keeping food under cover as much as possible, and by keeping the dining-room, kitchen and pantry dark at all times when not in use, together with the exertions of madam with her butterfly net. Thanks to these measures, it is seldom that a dozen flies can be found in the whole house even in the height of fly season and when the dwellings of

neighbours swarm with the nasty pest. Catching the fly with a butterfly net may seem a childish measure, but it is really a quick way of clearing a room by one who knows how and has a wide deep net.

There is a section of the public of late years who believe that every insect has sufficient natural enemies to hold it in close check, and that insects are only pests through reason of having been separated from one or more of these enemies. I should like to hear one of these people apply his theory to the house fly. It is an insect that seems to be known throughout the world and to pester man everywhere. Natural enemies it has to be sure, but who thinks of these in connection with its abundance? Aside from climatic conditions, the factor of overwhelming importance governing its numbers is not parasites or predaceous enemies, but the question of food supply. Furnish it with an abundance of suitable manure to breed in, and its natural enemies, as far as I can see, have no appreciable effect on it. I greatly fear it is the food supply factor and not the absence of the "proper enemy" that accounts for the pestiferousness of many insects that attack farm and orchard crops. The house fly is preyed on by various small animals as toads and some lizards, and every child knows how some spiders ensnare them. A certain species of long-legged centipede, *Scutigera forceps*, an uncanny creature one sometimes sees scurrying over the walls at midnight, is credited with being an enemy of some importance. So is a tiny red mite, like a small tick, that infests the body of the fly. Then hymenopterous parasites and predaceous beetles are recorded to destroy the maggots; and, lastly, a fungus disease accounts for many of the adults. Specimens which have succumbed to the disease are often to be seen adhering to window glass, surrounded by a halo of white fungus filaments. All over the world the house enemies of the fly seem to be the same.

The remarks here made apply to our species of house fly (*M. domestica*), but half-a-dozen kinds of flies have the habit of intruding themselves into dwellings. In general what has been said as to remedies applies equally to the others. Most of them, like the house fly, are creatures of filth, but as they are far less abundant indoors they are correspondingly less dangerous to health. Dr. Howard recently had collections of flies caught for him in dining-rooms and kitchens in different parts of the United States, and of the 2,300 specimens he received, 98% proved to be the true house fly. Next to the house fly a species called the stable fly (*Stomoxys calcitrans*) is reported to be most abundant in houses in the United States. This fly would be mistaken for the house fly by ninety-nine people out of a hundred, but it is distinct and has a hard-pointed proboscis for piercing the skin instead of the broad-tipped, fleshy retractile one.

In closing, let me urge you to always remember that everywhere the common house fly is a creature of foul and filthy habits and one liable to bring misery, disease and even death to your household. Therefore, spare not a little trouble to make its existence a hard one on your premises.—*Cape Agricultural Journal.*

PLANT LIFE.

[A SERIES OF SIMPLE LECTURES INTENDED FOR
A CLASS OF JUNIOR STUDENTS.]

LECTURE V.

Let us now enquire what plants take up from the soil by way of food. To begin with, we must recognise that the food of plants as taken up from the soil consist of more or less soluble compounds spoken of as salts. There are compounds produced by the action of an acid (such as nitric acid) upon a base (such as potash). In this way we get salts such as nitrate of potash, or as it is better known "Saltpetre." This last mentioned salt is one of a class of similar compounds (salts) which, as I have already stated, form the food of plants. Some of these salts though present as a rule only to a small extent are essential to the life of the plant; others which are generally met within the soil are not indispensable though useful to plants. Those which are essential are the salts of potash, magnesia, lime, iron, and in addition phosphorus and sulphur. These which are useful though not indispensable are the salts of soda, silica, manganese, together with chlorine and occasionally other ingredients. What salts these substances form will of course depend upon the acid with which it combines, whether nitric acid, sulphuric acid, or any other acid. Thus we will get nitrates, sulphates, and so on. To attempt a fuller explanation of this part of the subject will be going too much into chemistry, which at present we must avoid. What I have told you will, I think, suffice to make you understand the nature of the food taken by plants from the soil. The most important of the salts referred to above are the nitrates, because they supply what we may say is more important than any other of the elements of plant food, viz., nitrogen. If you ask why certain elements are essential as plant food, I can only say that it has been proved by actual experiment that plants will not grow and flourish without them. The exact place which they fill in the plant economy is difficult to make out, though some scientific men appear to have found that they are required for certain ends. For instance, nitrogen, we are told is an essential constituent of protoplasm (that is the *living* part of plants), and since without nitrogen there can be no protoplasm, without protoplasm there can be no plant. Potash is said to be necessary for the full assimilation of the carbon, which, we have seen, is derived from the air in the form of carbonic acid gas. Recent experiments also tend to shew that without potash no starch can be formed, and starch, you should know, is of primary importance in the nutrition of plants.

Both sulphur and phosphorus are found associated with protoplasm. Phosphorus is believed to be needful in the formation of the pollen or fertilizing powder in the flower, and in the ripening of seeds.

Iron is essential to the formation of leaf-green or chlorophyll, which is essential to the production of starch.

Though the precise function of lime is not known, it is of the greatest importance at least in keeping up the supply of the other essential ingredients. The substances already mentioned and others not alluded to, though not directly concerned in nutrition, yet are so indirectly, by causing change in the soil, by rendering some matters soluble and capable of absorption by the plant, by storing up and preventing the waste of ingredients useful as plant food, and so on. But we are again going rather outside the scope of our subject.

Plants are known to take their food in certain proportions, and cannot be induced to favour a particular substance, because it is supplied or is present in the soil in large quantity. This would seem to indicate the existence of a power of selection as regards food, but is explainable by the varying absorptive capacity of plants; so that by virtue of such varying absorptive and digestive powers, plants take what they want and when they want it, and are not induced to take more by additional supplies.

GENERAL ITEMS.

According to the *Jamaica Agricultural Society's Journal* there is no difference whatever between the two pines known as smooth Cayenne and Giant Kew. A variety, apparently a new one, as being unknown in Jamaica, that should be worth cultivating is the "white Guatemala spineless," thus described by Mr. J. C. Harvey who says that it was introduced into Mexico from Guatemala. It is absolutely smooth and has much the appearance of smooth Cayenne, that is to say the plant. The latter has a few short spines at the end of every leaf and the flesh is yellow; this new pine has absolutely no spines whatever and the flesh is almost snow white—sweet but with a slightly sub-acid yet not stinging taste. The fruit is smooth and not conical—in fact perfect in form—and reaches with practically no cultivation 7 lbs. The core is never woody, and as it keeps well should prove a good market pine. The plant seems to be particularly adapted to heavy soils and damp situations.

In some of the largest and most successful pine apple plantations in Florida, the soil is almost a pure sand containing as much as 99 % silica. It is said to be a mystery how pines grow in such a soil and yet they do grow. At the School of Agriculture, where the soil is particularly sandy, the pine apples have been doing very well, and all through May bore a good crop of fruit.

The Paris Exhibition, where Ceylon made such a good show, has for one thing benefitted the tea industry in the Island, for the custom of "five o'clock Ceylon tea" appears to be spreading in the French capital. It is to be hoped that advantage will be taken of the St. Louis Worlds' Fair to make a thorough representation of our products with a view to educating the great American nation to an appreciation of what is "made in Ceylon."

Says the *Agricultural Journal and Mining Record*:—"The object of an Agricultural Show is the thoroughly practical one of improving agriculture and live-stock of the country. It would be a regrettable circumstance if this fact were ever to be overlooked in the slightest degree."

There are still among practical foresters those who do not admit that the destruction of forests diminishes the rainfall. Two instances lately brought up are the cases of Tripoli, once a fertile

country now desolate owing to the destruction of the forests which resulted in the disappearance of water, and of the forests of La Trappe by the denudation of which the springs and the ponds fed by them dried up.

Some interesting specimens of grafting showed before the Prussian Horticultural Society proved that the graft had exercised a more or less marked influence on the stock—an effect the opposite of what is usual.

ROYAL BOTANIC GARDENS.

EXTRACTS FROM THE REPORT OF THE DIRECTOR FOR 1901.

I.—GENERAL.

THE organization of the Department upon modern lines has continued, and is becoming fairly complete in the case of two of the three main subdivisions which are proposed, the Scientific and the Botanic and Horticultural Gardens Divisions. The third, or Division of Experimental Gardens, is as yet only under consideration, but it is hoped that it may soon be organized. The Scientific Division, which includes the Director, Mycologist, Entomologist, Chemist, and Assistant, is charged with the scientific investigation of the flora of Ceylon, both indigenous and introduced, with special reference to the economic uses of the plants and the diseases that attack them. The work of this division includes the upkeep and working of the laboratories, library, herbarium, and museum, tours in the Island for the study of plants, cultivations, and diseases, the giving of advice and assistance in all such matters to officials and cultivators, personally and by letter, and, most important of all, the continual carrying on of researches upon the physiology and pathology of plants, their structure, distribution, and other subjects. Successful practical applications of science must be based upon thorough scientific investigations; such work is laborious and needs long periods of time, and it is of the greatest importance that the scientific officers should have the greater portion of their time at their disposal for such work. The appointments of the Entomologist and Mycologist in particular have met with much appreciation, and their help is so constantly sought that a very great part of their time is taken up with personal visits, interviews, and correspondence. In the past year a great amount of work has been carried out by these officers, whose reports are given below, and the result of their work is becoming clearly apparent in the greater freedom from disease of many districts and estates. The Colony has on the whole been free from any very serious epidemics of disease during the year, and the agricultural public has become much more alive to the advantage of keeping a sharp look out for the first appearance of disease and of immediate treatment thereof.

The Director and Chemist have completed an investigation into camphor and have published results, showing a fair possibility of this product proving remunerative as a cultivation in Ceylon. It has already been tried on several estates, and if it prove successful will add another to the few minor products that are as yet cultivated in the tea districts. Investigations of citronella oil, indiarubber, and other products have been continued. The good results of similar work in past years are now becoming apparent in the increasing export of, and the high prices obtained for, indiarubber and coca, both originally introduced by this Department, and which may now be looked upon as new minor industries in Ceylon.

The Assistant has continued his researches into the mode of formation of ebony, calamander, and similar timbers, and into the important problem of the formation of rings in tropical timbers. He has also explored the guttapercha-yielding districts of the south-west, and investigated our local gutta-producing trees. Some of these have been found to yield a gutta in fair quantity by simple tapping, without its being necessary to sacrifice the tree. The gutta is not of good quality, but it is not improbable that it may prove commercially valuable.

The Director has completed the investigation of the flora of the Maldive Islands, including the cultivated plants. The results have been published in the new scientific journal, the "Annals of the

Says the *Agricultural Journal and Mining Record*:—"The object of an Agricultural Show is the thoroughly practical one of improving agriculture and live-stock of the country. It would be a regrettable circumstance if this fact were ever to be overlooked in the slightest degree."

The good results of similar work in past years are now becoming apparent in the increasing export of, and the high prices obtained for, indiarubber and coca, both originally introduced by this Department, and which may now be looked upon as new minor industries in Ceylon.

The Assistant has continued his researches into the mode of formation of ebony, calamander, and similar timbers, and into the important problem of the formation of rings in tropical timbers. He has also explored the guttapercha-yielding districts of the south-west, and investigated our local gutta-producing trees. Some of these have been found to yield a gutta in fair quantity by simple tapping, without its being necessary to sacrifice the tree. The gutta is not of good quality, but it is not improbable that it may prove commercially valuable.

The Director has completed the investigation of the flora of the Maldive Islands, including the cultivated plants. The results have been published in the new scientific journal, the "Annals of the

Royal Botanic Gardens, Peradeniya," of which two numbers have been issued during the year, containing several papers by members of the staff and one by a visitor, who worked for some time in the Peradeniya laboratory. Several scientific workers from abroad have used the laboratories and other facilities now available here, which are becoming widely known. A small branch laboratory has been constructed at Hakgala, with sleeping and living accommodation attached to it, thus rendering that garden of much greater value than hitherto.

Several numbers of the "Circular" have been published during the year, and appear to have met with much appreciation. The circulation of this little periodical continues to increase; it is sent to local subscribers at the lowest possible rate, merely sufficient being charged to cover postage (50 cents for twenty numbers). The articles in this journal are popularly written, and do not overlap those in the "Annals."

In view of the extension of the work of the Department, and the increasing interest manifested in "new" products and in scientific methods of cultivation and preparation of economic products, a re-organization of the Economic Museum at Peradeniya has been commenced, and at the same time an attempt is being made to collect and classify all available information about the existing or possible economic products of Ceylon; the great masses of letters, cuttings, notes, references to books, &c., which have accumulated at Peradeniya during the past century are being arranged in files of a somewhat new design, which will be kept in a public consulting room at the museum, and the specimens in the museum are being renewed and re-arranged in accordance with the files, so that inquirers may be able to obtain all available information about products in which they are interested with the least possible trouble to themselves and to the staff of the Department. At the same time a *résumé* of the chief facts of importance about all known economic products of the Island, native, cultivated, or imported, is being put together in book form, and is now in course of publication in the form of supplements to the "Annals." It is hoped that in this way a reliable work of reference may be completed within two or three years, which may prove valuable to planters, officials, and others interested in the products of the Island. The first chapter, dealing with gums, resins, indiarubber, &c., is now almost completed, and part of it has already appeared in print with the second number of the "Annals." The local annual subscription of Rs. 2.50 also covers the supplements.

The second division of the Department (Botanical and Horticultural Gardens) includes the five gardens in different parts of the Island, and it has lately been decided by Government to open a sixth very small garden in the new park at Nuwara Eliya, with the view of trying what can be done on the peculiar soil of that place. The main duty of this division is to introduce and cultivate a few specimens of every possible kind of plant that may prove of use or interest, and to provide beautiful gardens for the pleasure and instruction of the public. At the same time it provides instruction and advice on horticultural matters, and supplies seeds and plants to the public in small quantity. It is no part of the duty of a botanic garden to make large scale trials of economic plants or to supply large quantities of seeds or plants. This is the work of an experimental garden, and hitherto such an institution has been wanting in Ceylon, but negotiations have been in progress during 1901 with the object of providing such a garden, where experiments may be tried on a commercial scale with staples or with plants which may become staples. Such experiments may include not merely the cultivation of considerable areas of one plant, but the trial of manures, different modes of cultivation and treatment for disease, modes of preparation of products for market, and their actual sale upon the open market. Such an institution may serve as an object lesson, and supply when necessary large quantities of seeds or plants, besides testing the commercial possibilities of different cultivations. It may also undertake the very desirable work of breeding new and improved races and varieties of cultivated plants.

Office work continues to increase, and the correspondence with planters and others is becoming very heavy. Working rooms have been provided for the Entomologist and Mycologist by the alterations of the godowns under the library suggested in last report. The library has been largely added to by purchase, gift, and exchange, and is steadily becoming a really good working collection.

An Ordinance (No. 5 of 1901) has been passed enabling the Government to take any necessary steps, such as fumigation, quarantine, or exclusion, to prevent the introduction of disease into the Island with plants from abroad. The import of cacao plants from the Dutch Indies has already been prohibited under this law.

A system of small gardens at village schools having been inaugurated by the Department of Public Instruction, this Department has supplied large quantities of seeds and plants of the best useful kinds for distribution to the schools. Good results in the introduction of new cultivations and increased interest in agricultural progress may be hoped for from this work.

The total cost of the Department, including special votes, has been Rs. 72,087, against Rs. 71,740 last year. The receipts from sales, though the number of purchasers has increased, show a fall from Rs. 4,658 to Rs. 3,741, owing to the cessation of the demand for rubber seed.

2.—NOTES ON ECONOMIC PRODUCTS, &C.

Hitherto the notes given annually under this head have been somewhat irregularly arranged, the more important products being treated first. Commencing with the present year the various products will be dealt with according to the different classes to which they belong, following the scheme of classification adopted in the Handbook of Economic Products of Ceylon now in course of issue.

Class I: Gums, Resins, Caoutchoucs, Guttas, &c.—An investigation into the gums and resins produced by the wild plants of Ceylon has been started, with the view of finding out which are of value for local use as substitutes for imported articles. It seems improbable that any of our local products of this kind are good enough or cheap enough for export.

Indiarubber may now be regarded as established as a minor product in the low-country, and an export of appreciable quantities of Hevea or Para rubber has begun: 66 cwt., valued at Rs. 11,986, were exported in 1901 to England. Being carefully prepared, this rubber is of excellent quality, and has sold for prices much exceeding those of the best Para rubber sold on the same market from wild sources. On one occasion 4s. 1½d. per lb. was received for "good biscuit," against 3s. 9½d. for "best Para." A recent market report says: "Ceylon sells with eager competition. The rubber is much liked, and in large quantities would bring high prices." Extension of planting continues in suitable districts, and probably 3,000 acres are now in rubber. In most cases the rubber is mixed with tea and planted by roads and ravines, and perhaps this is for most estates the most satisfactory method of planting under present circumstances.

There has been no demand for, or planting of, guttapercha during the year. At the instance of the Forest Department Mr. Wright was deputed to explore the forests of the low-country of the south-west and test the gutta-yielding trees there found. His report below gives a brief statement of work done, and full details will be published after receipt of analyses and valuations.

Camphor has been a good deal planted during the year, the chief check being the difficulty of getting good seed, there being no local supply as yet. A Circular has been issued by the Department showing, as the result of some years' experiments, that the tree can be successfully cultivated in many parts of the Island, and that the twigs and leaves yield about 1 per cent. of camphor by a simple process of distillation, a yield which offers a prospect of proving remunerative. The great risk attending this cultivation is that the high price is due to the action of the Japanese monopoly, and that if Ceylon became a serious competitor, the monopolists could probably lower the price enormously by allowing large harvests for a few years. Hence the cultivation of camphor is not to be recommended as the main industry for any estate, but only as a minor industry.

Class II.: Oils.—The export of cocoanut oil rose from 443,959 cwt. in 1900 to 453,531 in 1901, and that of copra from 362,467 to 439,865 cwt. At the same time there has been a considerable rise in the market value of both these articles, due to short crops in other countries.

The export of citronella oil has also increased from 1,409,058 lb. to 1,430,168 lb., but has not reached the figures of 1899. The investigation of the oils, mentioned in last report, has continued, but is not yet complete. The industry is in a very depressed state, owing to overproduction and adulteration, the latter being so bad that even good local oils do not obtain the value that is really due to them. Prices have reached a very low ebb, 9½ to 10d. per lb., and land is going out of cultivation in the grass. On the other hand, the new Java oil, mentioned last year, is selling in increasing quantities at high prices (often 1s. 4d.). It is not in reality so superior to the best Ceylon oils as the price would indicate, but it is not adulterated, and has no bad reputation to contend against.

Of other oils, the export of cinnamon oil has slightly increased, from 72,904 oz. in 1900 to 73,493 oz., but has not yet reached the figures of past years. Trial plantations of castor oil have been made by various planters during the year; the plant grows well here, and there seems no reason why Ceylon should not export this oil as well as India.

Class III.: Dyes and Tanning Substances.—The export of sapanwood has been 7,180 cwt. Planting of *Acacia decurrens* continues in the higher districts.

Class IV.: Fibres.—There has been a slight decrease in the total export of coir, our chief fibre, the figures being rope 13,030, yarn 75,788, fibre 122,526 cwt., as against 12,572, 87,415, and 115,090 cwt. in 1900. Of palmira and kitul fibres, the export has been 12,353 cwt. and 2,541 cwt. No interest has been taken in other fibres. Sisal hemp is being taken up in India, and the available stock of plants last year was mostly sold to planters there.

Class V.: Drugs.—An investigation of the native drugs of Ceylon is being set on foot, and plots of all possible species are being laid out at Peradeniya (see Mr. Wright's report).

“Of cinchona, the export has materially increased, almost reaching the figures of 1899. Increased interest has been shown in matters relating to this cultivation, and seed has been purchased from abroad and planted in various districts. There is reason to hope that by the planting of improved varieties, and by the practice of grafting of better kinds on poor stocks, this product may again become of importance in Ceylon.” (J. B. Carruthers.)

There has been an appreciable export of coca leaves, which have sold on the London market at 1s. to 2s. 2d. per lb., a price equal to that of the South American kinds.

Class VI.: Foods and Edible Products.—Of rice and dry grains there is nothing of special interest to report. The export of coconuts has decreased, having been 14,850,781 nuts, as against 14,995,909 in 1900; that of desiccated coconut has increased from 13,604,913 lb. to 14,055,493 lb. Tapioca or cassava cultivation continues to spread in the low-country as a minor and catch crop, but no tapioca is made from the tubers, which are eaten like yams. Fruit trees continue to sell steadily from the gardens, but there is but small sign of any attempt to cultivate fruit on any large scale for market, if the long-established industries of coconuts and plantains be left out of consideration. The vegetable gardens of Nuwara Eliya have been much troubled with finger and toe disease.

The export of tea seems at last to be reaching its maximum, and shows a slight decrease on the figures of 1900, viz., 145,188,244 lb., against 148,431,639 lb. Part of the decrease is, however, made up by the export of 1,110,774 lb. of green tea, most of which went to America. The export to Russia and Australia has increased, that of black tea to America decreased, but the decrease is more than made up by the green tea. The year has been one of depression, but prospects of the industry are more favourable, the export to England having been 8 million lb. less, and the stock of Ceylon tea there having been considerably reduced. The average price is the lowest as yet recorded, 6·86d., against 7·20d in 1900, but towards the end of the year prices were considerably improved. The industry has not suffered from any very serious outbreaks of disease, and planting has not extended. The remarks made last year on the general prospects of tea in Ceylon continue to hold.

Coffee exports show a further fall from 10,777 to 9,722 cwt. Experiments on grafting coffee are in progress in the gardens (see report of Acting Curator).

“Cacao exports show a very large increase on the figures for 1900, being 49,459 cwt. against 33,476. This, as was foretold in last report, is due to some extent to the lateness of the crop of last year, some of which is credited to 1901, but is also largely due to the energetic measures being taken in combating the canker, and especially in reducing the number of diseased pods, the quantity of ‘black cacao’ having been reduced in some instances by 75 per cent. The prices obtained for cacao, even the best qualities, have been much below those of last year; this is perhaps more due to the conditions of the home market than to any difference in quality of the product, but the increasing proportion of Forastero kinds may have something to do with it. The fall of price should spur planters to consider the questions of cultivation of more productive trees, and the selection of seeds for planting. The canker has, as a rule, been seriously attacked on approved methods, and a marked decrease in the number of diseased trees is apparent. There are, however, many estates where no hindrance is put in the way of the invading fungus.” (J. B. Carruthers.)

Of spices there is little to record. The cultivation of cardamoms is extending, and the export has increased from 537,455 to 559,704 lb. Pepper shows signs of extension of cultivation, and it should at least be possible to dispense with the present large import of this spice. Exports of cinnamon show a rise in bales, a fall in chips, the figures for 1900 being 2,678,111 and 1,863,406 lb., and those for the last year 2,756,270 and 1,516,083 lb. respectively. The “wild cinnamon” again shows an enormous fall to 8,581 lb. bales and 5,066 lb. chips. Vanilla planting has slightly extended. Tobacco cultivation continues to extend in the North and also in the Dumbara district. Of fodder plants there is little to report. An experiment with Swedes is described in Mr. Nock’s report. The much-vaunted grass *Paspalum dilatatum* is being tried in many districts, and a report will be issued later as to its success.

Class VII.: Timber, &c.—Mr. Wright’s work on the ebonies, &c., is described in his report below.

Ornamental Plants.—Cannas and the small white variegated caladiums have been largely in demand through the year.

ENTOMOLOGIST'S REPORT.

DURING the past year the usual work of correspondence, research, and experiment has been carried on. Local correspondence shows an increasing interest in, and appreciation of, the work and aims of the Department. In addition to advice to local planters, letters of inquiry and specimens for report have been repeatedly received from Southern India, especially since the much-to-be-regretted death of Mr. Lionel de Niceville, the talented Entomologist lately attached to the Indian Museum. Owing to the scarcity of students in this particular branch, considerable collections of "scale insects" (*Coccidæ*) have been received from foreign countries for determination.

In January an extended tour was made through the Maskeliya, Dikoya, Bogavantalawa, and Balangoda districts, during which I had an opportunity of investigating on the spot several prominent insect pests, notably the "Tea Tortrix" (*Capua coffearia*, Nietn.), and a kind of "white ant" (*Termes* sp.) that has been doing considerable injury to otherwise healthy tea plants. Meetings of the local branches of the Planters' Association in the same districts were attended, at which information on economic entomology was given and discussion invited.

In March a trip to Jaffna, occupying two weeks, was made in company with Dr. Holtermann, a distinguished scientific visitor. The principal object of this tour was to investigate the insect pests of such native-grown products as tobacco, gingelly, palmirah, and the various grains. These crops were found to be remarkably free from attack this year, though several serious pests have been previously reported from the Northern Provinces.

The Gampola district was visited in July, where the "Shot-hole borer" (*Xyleborus fornicatus*)—a serious enemy of the tea plant—was made the special subject of investigation.

In the same month the Rangala district was visited for the purpose of studying a pest of the cardamom plant.

In August a special visit was made to Colombo, at the request of the Municipal Council, to study the habits of the "Lake fly" (*Chironomus* sp.), a pest that has attracted much attention in the neighbourhood of the Colombo lake. These flies do not cause any actual injury, but make themselves objectionable by their habit of swarming into the bungalows at night (attracted by the lights), invading the food, and immolating themselves in the lamps in enormous numbers. The complete life-history of the insect was discovered, and an exhaustive report made advising the best means of removing the nuisance.

A tour in the Kelani Valley was planned for November in connection with the so-called "Mosquito blight" of tea (*Helopeltis antonii*). But this visit was postponed until the conditions should be more favourable for study.

Experiments are being conducted, with satisfactory results, to ascertain the connection between attacks of tea-mites and pruning. These experiments tend to show that injury from these pests may be very largely avoided by regulating the time of pruning, but a longer period is required to obtain accurate data.

Experiments are also being conducted with a view to the efficient destruction of "white ants" (termites). Various means have been tried, but nothing promises such complete success as bisulphide of carbon, which proved absolutely fatal to these pests in the limited experiments that I was able to make. The difficulty is that at present, owing to the exceedingly inflammable nature of the gases given off by the bisulphide, the shipping companies refuse to carry the compound, and it appears impossible to obtain it in any quantity in Ceylon. With the advent of special steamers for the transport of explosives, this difficulty should eventually be removed.

The question of quarantine continues to receive attention. All Wardian cases received at the Botanical Gardens are promptly fumigated with hydrocyanic acid gas before the contained plants are distributed. The Legislative Council has now passed an Ordinance providing for the effective treatment of all imported plants, and a fumigatorium is being erected for the purpose in Colombo. It is hoped that imported fruit (a fertile source of introduction of noxious insects) will be subjected to similar treatment. The same Ordinance empowers the Government to absolutely prohibit the importation of proclaimed plants from countries known to be subject to specially dangerous pests of such plants.

Sericulture would appear to be an industry particularly suited to the natives of Ceylon. Efforts are being made to introduce a good stock of silkworm, and if the results are satisfactory, it is hoped that the Sinhalese may be induced to interest themselves in the cultivation of silk.

Circulars dealing with the *Helopeltis* insect and the "Mosquito-Malaria" question have been issued from the Department.

Fuller particulars of the miscellaneous work of the division of entomology will be published shortly in the form of a Circular.

SCIENTIFIC ASSISTANT'S REPORT.

DURING the past year my time has been spent investigating several branches of economic botany and for convenience the report is arranged under separate headings.

Ebony.—The work on Ceylon species of *Diospyros* has been continued, and I have now succeeded in obtaining samples of every species known in this Island, together with material from India, Ceylon, Malaya, Australia, and the Andaman Islands. A comparative account of the value of ebony from all countries is being prepared, and to ensure completeness I shall be very grateful if any one interested will forward specimens of any species of ebony whenever possible. In Ceylon, by direct observation in the forest, two species have been found, which, though ordinarily regarded as of little value, are capable of producing an ebony which certainly comes second to calamander in point of beauty and hardness. These species (*D. oocarpa*, Thw., and *D. affinis*, Thw.) are not found in the wet zones, but occur, often in abundance, in the intermediate and dry zones of Ceylon.

The greater part of my work has, however, been spent in the forests of the wet zone, and here I have been able to find abundance of calamander trees in flower and fruit, together with quantities of material of several of our rarest species. One species of ebony (*D. oppositifolia*, Thw.) is limited to the upper part of a hill in the Southern Province, and the timber from it was associated by our botanists with that of calamander. I regret that such is not the case, the timber being, when freshly felled, of a dirty white colour and the centre of the stem invariably hollow. Furthermore, the abundance of parenchyma, the presence of wide medullary rays, and the large-lumined water-conducting elements which characterize this species prove it to be of poor value when compared with other *Diospyros* timbers.

Seeds of every Ceylon species have been obtained, propagation by layering and cuttings has been effected, and we have now a representative collection of the Ceylon *Diospyros* growing in these gardens.

The flowers, hitherto regarded as mainly dioecious (*i.e.*, male and female on different trees) have been studied from fresh material in the forest, and in this branch of work many interesting facts of purely systematic value have been obtained. Though in Ceylon we have only twenty species of *Diospyros*, yet at least nine of them show a departure from the dioecious condition. Some are monoecious only, others monoecious or dioecious, and others are dioecious or polygamous. The complicated relations determined for the different species show how inadequate an account may be which is based on examination of herbarium material alone, and the necessity to work out questions concerning the morphology of the flower in the forests.

Many flowers and fruits have been found which are new to science, but an account of them, together with remarks on the evolution of sex in Ceylon species of *Diospyros*, will be published elsewhere.

Guttapercha.—On the suggestion of the Director, an investigation into the yield of guttapercha from Ceylon species of *Palaquium* was instituted. This work has been done almost entirely in the forests of the wet zone, and up to the present some eight species of *Sapotaceæ* have been experimented with.

The results from two species of *Palaquium*, *viz.*, *P. petiolare*, Engl., and *P. grande*, Engl., have been satisfactory. The yield of guttapercha from these species exceeded all expectations, since in point of quantity it was in excess of the latex yield from Para rubber trees in Ceylon. Furthermore, there is no necessity to fell the tree as is done in Malaya, and though they are of slow growth, they constantly bear abundance of fruit.

Samples of the guttapercha have been prepared in various ways, and should the analytical reports upon them prove encouraging, there will be no difficulty in collecting several hundreds of seeds and seedlings from the districts investigated.

Seeds of many other sapotaceous plants have been received from all parts of the world, and a comparative account of the nature and development of the laticiferous system in them is now being arranged.

Medicinal Plants.—A revised account of the medicinal plants now growing in Ceylon is being prepared. Large experimental plots have been started, and an analysis is being made of the occurrence, quantity, and nature of the chemical bodies to which the medicinal properties are due.

General.—An analysis of the tea plant is being made in conjunction with Mr. Kelway Bamburgh and the results obtained, particularly with reference to the occurrence and quantity of the enzyme, tannin, and starch, the value of certain tests, and the relation of percentage of enzyme to flavour, will soon be placed before the planting community.

Other subjects, such as the comparative value of Ceylon timbers, nitrogen nodules on *Entolas scandens*, observations on *Dracaena reflexa*, cleistogamy in *Ruellia tuberosa*, the botany of Hinidukanda, and the development of sandalwood trees, have received much attention during the past year.

EXTRACTS FROM THE REPORT OF THE ACTING CURATOR, PERADENIYA GARDEN.

Cultivation and Experiments.—In this department the main part of the skilled and cooly labour has been used. Large plots of ornamental plants such as cannas, roses, and palms, economic plants such as species of *Crotalaria* now used so extensively as a nitrogenous manure for tea in Ceylon, Para and Ceara rubber, ebonies, guttaperchas, durians, and mangosteens, have been commenced in order to keep up the supply to the public.

Large medicinal plots have been started behind the cattle shed and near the kitchen garden, primarily with the object of making a representative collection of all the more valuable Ceylon species, and secondly, to supply the general public with quantities of especially valuable species. There has been a fair demand for *Brucea Sumatrana*, *Wrightia zeylanica*, and *Ixora coccinea* during the year.

A plot behind the Curator's office has been allotted for the experimental cultivation of fourteen kinds of cocoanut presented to the gardens by W. H. Wright, Esq., Mirigama. In this collection it is satisfactory to note that many of the nuts, particularly the Siam, Maldivé, and King varieties, have already begun to sprout. This is a valuable contribution to the garden, and every care is being taken to rear healthy plants.

Experimental cultivations have been established for sandalwood trees. Pot and plot experiments are being carried on in all conditions of soil. We hope to settle whether they are ever parasitic, and the best conditions for development.

Grafting, Layering, and Cuttings.—The Java method of grafting has been used in many of our experiments. "The scion is cut from green wood, and the notch is cut in green wood of the stock. The scion is cut about half inch below the leaves with long cuts on both sides to a long V-shaped apex. A corresponding notch is made in the stock, starting between two leaves. The leaves of the scion and of stock are removed at and just below the graft. The graft is then tightly bound with wax and bark, and a small glass test tube is placed over the whole to keep the air damp, &c." An improvement has been made in this experiment, which enables us to maintain an equable temperature and humidity in the region of the graft.

Coffee.—In the grafting experiments with coffee, I have been principally concerned in determining the ease with which one kind can be grafted on to another. We have tried Arabian, Liberian, *Stenophylla*, and hybrid coffees with one another, sometimes having the stock an established tree, at other times in bamboo pots. The best results have been obtained with Arabian stock and Liberian scion, and with these reversed.

Mangoes.—Grafting in mangoes is invariably easily accomplished. The Jaffna mango has been grafted on to rupee and honey mangoes, and many others distinguished by the native names, *kohu-amba*, *girawe-amba*, *me-amba*, can be grafted easily with one another.

Oranges.—In this division the mandarin has been successfully grafted on to *Citrus indica* and *C. Limonellus*, and the latter on to the mandarin. We are hopeful that good results may yet be obtained in this direction, and experiments will be repeatedly made during the rainy seasons.

Nutmegs.—In order to try and reduce the number of males in plants exported from the gardens, a considerable number of saplings have been grafted by approach. Propagation by layering, leading to an increase of the female trees, has been tried, with some success; in these experiments only 10 per cent. of the layerings rooted, but a considerable increase can be assured by more careful work. We have repeatedly tried grafting female on male trees and *vice versa*, but so far have no good results to report. In two cases only were we successful in grafting trees in bearing on to sapling stocks: this was by the "approach" method, and not by fitting scion into incision of stock.

Mangosteen.—Successful experiments have been made in layering, but the grafting of the mangosteen on to the Cochin *goraka* is not so easy a matter. We have reason to expect that good results can be obtained by grafting these by approach in the sapling stage, and for this purpose the whole of the year's seed supply of mangosteens has been reserved.

Cacao.—We have been successful in grafting one variety on to another in about 30 per cent. of the experiments. In layering and reproduction from cuttings much labour has been spent. The only successful cuttings have been in soil which is very sandy, practically free from all leaf mould, and supplied with running water at irregular intervals. In one set of cuttings only those situated along the course of a small stream, and therefore subject to occasional miniature floods, were successful. This is an important point to note. The cuttings were taken at all ages, but only the woody ones about as thick as a man's finger were of any use. Young twigs with young and mature leaves were tried in pots of sand covered with glass bell jars, but gave no successful results.

Attempts were made to reproduce the slowest growing of our tropical trees from cuttings, and we are able to report good results in species of *Diospyros*. A large number of *Amherstia nobilis* trees have been layered, but as yet nothing definite can be stated. If we can successfully reproduce this plant it will be a public boon, as its gorgeous flowers render it one of the most beautiful of ornamental trees.* Reproduction of roses by inverting the cuttings and using the heat of the sun's rays as the source of "bottom heat" have been partially successful.

Fruit Trees.—The past year has been very good. The only fruit-bearing tree of the mangosteen in these gardens gave excellent results, no less than 627 fruits being obtained from it during August and September. As previously mentioned, the whole of the seed supply from this tree has been reserved for grafting experiments.

The mangoes were, as usual, a great success, thousands of fruits having been collected during the season. The same can be said of the Cochin *goraka* and the *Rambutans*.

The durians have this year yielded an abundance of fruit. The trees alongside the river drive near the laboratory gave the best results, five of them giving no less than 243 large ripe fruits. The fruits were sold at from 25 cents to Re. 1 each, and the saplings, four or more of which can be obtained from every fruit, realize 25 cents each. It is conceivable that a few acres of the above fruit trees in bearing might turn out very profitable, since they will thrive on poor soils without much attention.

A plant of the "Cannon Ball tree" was planted by T. R. H. The Duke and Duchess of Cornwall and York near the laboratory, and is growing vigorously.

Visitors.—The gardens were visited on 14th April by T. R. H. The Duke and Duchess of Cornwall and York and suite. A memorial tree was planted by them in the Great Circle, near the laboratory. Tea was provided in a pandal erected upon the Great Lawn, and an exhibition of elephants bathing in the river concluded the afternoon. The number of foreign visitors during the past year (2,293) shows a slight decrease on that for 1900.

Weather.—The heaviest rainfalls were during the months of April, June, and November, it being 12.03, 14.27, and 18.59 inches respectively. The month of February was the driest in the year, rain falling on four days only, and totalling up to 1.73 inch. The month of December was remarkable for great wind velocity, and a small rainfall of only 4.72 inches. The total year's rainfall is small compared with that of 1900. The following is the year's rainfall with the average of each month for the last eighteen years:—

Months.	1901.			Average for last Eighteen Years.		
	Inches.	Days.		Inches.	Days.	
January	2.00	7	...	2.88	6.16	...
February	1.73	4	...	1.62	3.80	...
March	2.19	9	...	4.65	8.44	...
April	12.03	18	...	9.75	14.03	...
May	3.87	10	...	6.75	11.55	...
June	14.27	25	...	10.45	20.33	...
July	7.83	25	...	7.43	13.03	...
August	7.07	20	...	6.19	17.06	...
September	3.30	12	...	6.51	15.08	...

HERBERT WRIGHT.

EXTRACTS FROM THE REPORT OF THE SUPERINTENDENT, HAKGALA GARDEN.

A batch of camphor seeds were sown at the end of February, and 5,000 plants were raised from them. The seeds took from two to three months to germinate. Of the camphor cuttings mentioned in last year's report, I regret to state that only about 10 per cent. struck root. As plants can be so easily raised from seeds or layers, it is a waste of time and labour to raise them from cuttings, as the process is difficult and costly.

* Since writing the above I have examined several plants and am able to report that several of the layers have rooted.—H. W.

The English laurel has now become established in the gardens, and 200 cuttings and 56 layers have been put down in the nurseries, and all look well.

The available stocks for grafting were very poor this year, but some scions of apples and plums have been grafted on to the best of them.

As will be seen below, a great deal of work was done in the nursery during the year in the way of propagating and distributing plants. The number of economic and ornamental trees, fruit trees, and general garden plants distributed during the year was 22,405, besides 1,420 cuttings and 67 packets of seeds. The number of plants—chiefly conifers and ornamental trees and shrubs—that were propagated and supplied gratis to the Board of Improvement, Nuwara Eliya, was no less than 12,668, and 620 were supplied for the grounds at the Diyatalawa Camp.

Borders and Shrubberies, Improvements, &c.—118,523 plants of ornamental trees and shrubs, herbaceous plants, and general garden plants and bulbs were set out during the year in the upkeep of the gardens, the majority, as usual, being showy annuals and edging plants.

Much damage was done in various parts of the gardens by the high winds in June and July, and a good deal of labour was employed in cutting up fallen trees and clearing away *débris*.

The filling in of the lower side of the drive opposite the lower lakelet was completed in January, and 230 square yards of turf was laid down there, which now forms a belt of nice green lawn.

Some improvements were made at the back of the Picnic Arbour. The ground was dug up under the acacia trees and 195 square yards of turf laid down.

A new border, 48 feet long, has been made on the north-east side of the eucalyptus clump and planted with various kinds of liliaceous plants.

The patana around the new laboratory was cleared of undergrowth and weeds, a new 4-foot wide path 234 ft. long was made leading to this building, and 98 square yards of turf was laid on the banks in front.

Fifty large plants of *Cupressus macrocarpa* were planted in the land between the fernery and old eucalyptus plantation. Two hundred assorted plants that have become too large for the nursery were also planted out in this land.

The forest track leading from the upper part of the gardens to the large pool under the Hakgala rock has been cleared for a distance of 762 yards, so that it can be used with ease for bringing out posts, fence sticks, and other forest produce frequently required in the gardens.

Classified Herbaceous Garden.—The bank on the east side of this garden, which was broken away by the heavy rains in March, has been rebuilt and turfed.

Rose Garden and Rose Borders.—The rose plants in the several borders flowered very well at the beginning of the year, producing some really fine blooms, but those in the rose garden proper have not done at all well. These latter were all pruned, lifted, and re-planted during July and August. Although some plants have answered to this treatment, the majority have not improved, and I am afraid they will never do any good again. A fresh stock from Europe is now required to replace them.

Flower Garden and Flowers.—No alterations or additions were made in the flower garden, but the usual display of flowers was maintained. The flowers in the beds and borders in other parts of the gardens made a good show from January until the end of May and again in August and September.

A plant of *Magnolia grandiflora* flowered well during November and December. Several of its handsome pure white flowers measured over 10 inches in diameter.

Calophyllum Walkeri, the "Kina Tree" of the Sinhalese.—It may be interesting to state that thousands of these trees flowered most profusely during the first three months of the year. The masses of white flowers in all the forests in this locality were very noticeable.

Casuarina Plantation.—The plantation of *Casuarina montana* has continued to thrive during the year. A small strip of land at the bottom, and another at the top has been cleared and planted with 275 more plants.

Villebrunia Integrifolia.—The cinchona planted on the plot of land cleared last year below the amphor plantation was all destroyed by sambur deer. This land has now been planted with *Villebrunia integrifolia*, an indigenous plant said to yield an excellent fibre.

Quercus Cerris, "Turkey Oak."—A piece of land above, and to the west of, the *Casuarina* plantation has been cleared up and planted with 1,000 plants of the Turkey oak. This piece of land is good, well sheltered, and it is presumed that this species of oak will do well in it.

Camphor.—The plants in the small plantation have continued to grow well. Several batches of specimens of the leaves and twigs have been forwarded to Mr. Bamber for further experiment in distillation. Six samples of the soil they are growing in were supplied to him for analysis in August, and

the very interesting results are published in the Royal Botanic Gardens Circular No 24 published in November. Many inquiries have been made about camphor cultivation during the year, and all have received attention. 2,000 plants have been distributed, and we now have about 4,000 more ready for sending out.

Mana Grass.—Four bundles, 40 lb. each, of this grass, from four different localities, have been supplied Mr. Bamber for distillation.

Ferns.—Six plants of the indigenous tree fern *Alsophila crinita*, with stems 5 to 6 feet long, were despatched in March for the Botanic Gardens at Munich. Large quantities of maiden hair plants and several thousands of fern fronds were supplied to Queen's House and to the King's Pavilion for decorations during the Royal visit in April.

New Cart Road to Ambawela Railway Station.—This road is now completed. We sent the first cart through on the 11th February. It is only 7 miles by this road to Ambawela station, against 9 miles to Nanu-oya. On the return journey there is only about $1\frac{1}{2}$ mile of uphill, instead of 4 miles as is the case from Nanu-oya.

Fruit Trees.—Seeds of a good mango were received from the Director of Agriculture, Madagascar, in May, and fourteen plants have been raised from them. These seeds were from trees growing at an elevation of 4,200 feet, and it is thought that they will produce plants that would fruit at the higher elevations in this Island.

Three dozen assorted fruit tree plants were received in July, through the Director, from Australia, but I regret to report that two-thirds of them were quite dead on arrival. Of the remainder, all the figs and a few oranges revived, and are now doing well.

Paspalum Dilatatum.—A small plot of this fodder was sown in the nursery and has grown well. All stock eat it greedily, and it promises to become a very useful addition to the fodders of the up-country districts.

Swedes.—An ounce of seeds of a variety called "Defiance" was sown on the 23rd July on a piece of land 48 square yards. They came up well, and were carefully cultivated, and grew splendidly. The crop was taken up on the 9th December— $4\frac{1}{2}$ months from the time of sowing—the yield being 280 lb., or at the rate of $12\frac{1}{2}$ tons to the acre. The largest weighed 8 lb., and measured 24 inches in circumference. The six heaviest weighed 30 lb., the twelve heaviest 52 lb., and the twenty-five heaviest 91 lb. These roots, which are easily produced, possess grand feeding qualities, and if our local butchers would only feed their cattle on them for a month or two before slaughtering, the quality and flavour of the Ceylon beef would be very much improved.

Oxalis.—This pest has continued to spread. The nature of its growth makes it a most difficult plant to eradicate. Nothing but picking out by the hand and burning the tubers seems to have any effect on it. 68½ bushels have been picked out of the nursery and borders during the year. This represents 300 to 400 days' labour.

A weed killer was tried on a small patch, but it simply killed the foliage, and after a few weeks the bulbs grew with renewed vigour. It has now got such a hold of the gardens that, unless some enemy or disease can be introduced to destroy it, it will be impossible to keep it down.

Barbed Wire Fence.—A special vote was granted for wire fencing, and a barbed wire fence has been fixed all round the inner boundary, enclosing about 46 acres. This fence is made of five strands of 4-point barbed wire, fixed on posts 9 feet apart and 5 feet 6 inches high, the total length being 2,062 yards.

A belt of land 24 feet wide has been cleared all round the inner side and planted up with 6,000 plants of the following trees:—*Acacia decurrens*, *Acacia melanoxylon*, *Frenela rhomboidea*, and *Cupressus macrocarpa*, the latter being planted 50 feet apart with the view of their growing into large timber trees. Seven gates have been fixed at convenient points, and galvanized wire netting has been purchased for fixing along the upper boundary on the forest side in the hope of keeping out small wild animals, such as mouse-deer, porcupines, hares, &c.

Water Service.—A special vote was made to the Public Works Department to bring a supply of water to the gardens. This has been accomplished by damming a permanent stream at Sita Eliya, from which 2-inch piping has been laid, leading the water into the old reservoir in the upper part of the gardens, the distance being about $1\frac{1}{2}$ mile. This supplies a long-felt want, and when the proposed connections are made with the bungalow, laboratory, Foreman's quarters, nurseries, and other parts of the gardens, it will be a great boon, and will greatly facilitate the cultivation and general work of the gardens.

The following table shows the monthly rainfall and averages from July, 1883, to the end of 1901 and the number of days on which rain fell during the 20 years 1882 to 1901, inclusive :—

The greatest pressure of the wind during the year was 6·840 lb. per square foot on the 5th June, equalling a velocity of 36 miles an hour, against the same pressure on the 12th June last year.

The mean daily horizontal movement of the air for the year was 84·85 miles, against 90·88 miles of the year before.

The windiest month was again June, with a mean daily horizontal movement of 185·60 miles, against 223·30 miles of the same month last year.

The calmest month this year was January, with a mean of 25·14 miles, against 25·50 miles in February of the year before.

The highest temperature of the sun's rays was 131·0 on the 28th May, against 129·0 on the 1st and 21st and 25th May last year.

The lowest on grass was 33·0 on the 27th January.

* Rainfall of half year.

† Average of 18 years January to June, and 19 years July to December.

‡ Average of 20 years.

§ Average of 18 years.

The mean amount of cloud was 6·8, against 6·5 of that of the year before.

The cloudiest month was January, with a mean of 8·0, against 8·1 in November of last year.

The brightest months were March and May, with a mean of 6·0, against February and March of the year before, with a mean of 4·5 each.

W. NOCK.

HENARATGODA GARDEN.

THE late Conductor having resigned during the year, Mr. W. Perera, First Foreman at Peradeniya, was appointed in his place. A complete overhaul and re-organization of the garden is now being carried out. The main road has been gravelled and ditched, new walks opened, many new flower beds planted, and the general condition of the garden improved. Several experimental plots of rubber, tea, &c., now no longer needed, have been cleared to make room for trials of other things. It is intended in 1902 to catalogue the entire garden, and to plant several new experimental plots. 210 visitors, other than parties, visited the garden in 1901. The rainfall for the year has been—

	Inches.	Days.		Inches.	Days.
January	8·54	13	July	9·25	15
February	5·79	11	August	1·80	12
March	5·07	14	September	2·37	10
April	10·88	18	October	11·23	11
May	10·94	19	November	19·51	20
June	15·66	27	December	3·69	6

Total, 104·73 inches on 176 days, against 100·83 inches on 177 days in 1900.

The average for the eleven years 1891–1901 is 100·37 inches on 163 days.

ANURADHAPURA GARDEN.

THE garden has been kept in good order. Watering in the long dry season consumes a large part of the labour, and a better water supply would be a great boon. The flower beds have been very effective in display, and many so-called English flowers have done well.

Fruit trees continue to be distributed in the district by the aid of the Government Agent, and 336 have been issued in this way during the year.

BADULLA GARDEN.

THE Conductor having been promoted to Hakgala during the year has been succeeded by Mr. D. T. de Alwis from Peradeniya. The garden has been kept in good order, and is now a great ornament to the town. New cooly lines and plant sheds are much needed.

Pimento has fruited well, and should be worth trial in Uva. *Paspalum dilatatum*, the new Australian fodder grass, has also grown well.

AUGUST, 1901.

THE SINHALESE LANGUAGE: ITS ORIGIN AND STRUCTURE.*

A REVIEW.

(Communicated.)

WHERE THE SINHALESE CAME FROM AND HOW THEY GOT THEIR LANGUAGE.

Some years ago the late Dr. Rost, Librarian of the India Office, in writing to a friend of the writer, remarked on the growing interest manifested by European scholars in the language and literature of Ceylon and lamented the want of facilities afforded to the Continental student in procuring books published in this island. That this interest in the subject has grown with years and has borne good fruit appears from an elaborate treatise just published in Germany by the Erlangen Professor of Sanskrit.

Dr. Geiger, who spent some time in Ceylon collecting materials for his great work, has clearly indicated the exact place that Sinhalese occupies in the family of languages, its near kinship to Mahrathi; and has ascertained its original home to have been in the North-West Provinces. Before the Professor came into the field, the ethnological questions regarding the origin of the Sinhalese had long since been settled and the verdict of the historical scholar that they are an Aryan people has been strangely confirmed by the philological student. Though the history and origin of the Sinhalese people have long been examined carefully by Orientalists at home and abroad, the subject of their language had not received that critical attention which it deserved. But we may no longer complain; light has burst from two opposite quarters, from the East and West, when it was least expected. Simultaneous with the publication of Prof. Geiger's work in Germany, there is published in Ceylon an interesting brochure, with the title of the heading of this article, by that veteran Sinhalese scholar, Mr. W P Ranasinghe. Both students have had the courage to grapple with a subject, which

has for a long time baffled Orientalists, owing to its intricacy, and although working independently they have arrived at practically the same conclusions. It is foreign to my purpose to notice at length the work of the German *savant*, and I shall turn with interest to the no less important contribution by the Sinhalese scholar.

Mr. Ranasinghe, in his preface, after reviewing the efforts hitherto made to show the affinity of the Sinhalese language to Sanskrit, Pali, and Hindi, says:—"But no effort has been made in either of these treatises to set forth the various changes which words have undergone in their passage from Sanskrit, Pali, and the Prakrits into Sinhalese; much less to account for such changes. I have attempted to show the changes, and to find reasons for most of the changes which these words have undergone. While engaged in this task I found that there was a certain uniformity in the way these changes had taken place, and that they are regulated by certain fixed principles. I have sought to deduce these underlying principles and have set them forth as rules, supporting my position in each case by several examples. I have also not thought it foreign to my purpose to print the Indo-Aryan equivalents side by side with their Sinhalese cognates, so that the reader may see at a glance how nearly related Sinhalese stands to the Sanskritic dialects of Modern India."

Mr Ranasinghe has here given us an insight as to the method of his work, and the difficulty of his task can only be realised by those who have attempted any similar work. The author can fairly claim the credit of having made the "first attempt to reduce the intricate subject of Sinhalese word-formation into scientific form" and the success he has achieved is as much due to his energy as to his intimate knowledge of the Sinhalese language and the heterogeneous elements which go to the composition of it.

The book contains four chapters, the first two of which include letter-press dealing with the origin of the Sinhalese language, whence it is derived, and the nature of the characters in which it is written. The interesting problem, as to what language Prince Wijaya and his war-band spoke, is here discussed, and for the first time a satisfactory solution is offered. "The language of

* The Sinhalese Language: Its Origin and Structure, London. Luzac & Co. 1s 6d; Colombo Rl.

Wijaya and his followers," summarises Mr. Ranasinghe, "could not have been Pali, as that language is now known to us, but it must have been Prakrit or corrupt Pali, which, Professor Max Müller says, was the parent of all the Aryan vernaculars of India, and this supposition is confirmed by the fact that the early rock inscriptions in Ceylon are in a corrupt Prakrit."—p 3. Another misapprehension which the book will remove is in regard to the term Ehu, whose derivation has baffled some older scholars who considered it to be a special poetical dialect of the Sinhalese. In the first page of his book Mr. Ranasinghe shows the word Ehu to be no other than a different form or derivative of the term Sinhala. Professor R C Childers first pointed this out some years ago in a paper contributed to the Royal Asiatic Society of Great Britain and Ireland, and Mr. Ranasinghe has further traced the derivation of the term. As regards the form of the Sinhalese letters the author says that "an examination of the. Iát characters, in which the ancient rock inscriptions of Ceylon are inscribed, with their development from time to time, will clearly shew that the modern Sinhalese letters are evolved from them, and those letters that are not found in the inscriptions and peculiar to Sanskrit are taken from the Dewa Nagara."

The book is an excellent production of the kind and by its publication Mr Ranasinghe has rendered a great service to Philological Science. The work when complete—for it is only the first part that is out—should go a great way to supply what is so much needed: a Historical Grammar of the Sinhalese Language, a volume to occupy the place so admirably filled in England by Dr Morris's Grammar. It may be added that the book is very neatly and carefully got-up by the Government Printer, and I have succeeded in detecting only one typographical error, *e.g.*, the title of ch : II. for ch : III. at the head of the latter chapter which has not been noted in the "errata" column.—LIBRA.

THE GEOLOGY OF CEYLON.

We omitted yesterday to call attention to the able review by Mr. A. K. Coomaraswamy—now in the island—of a learned paper by a German scientist on the geology of Ceylon, or rather on the department affecting our plumbago deposits and granulitic rocks. Professor Weinschenk arrives at conclusions as to the geological sequence of events in Ceylon, which are no doubt satisfactory to his fellow-scientists but which we confess are rather puzzling to our ordinary non-scientific lay mind. Mr. Coomaraswamy would be doing a service if he interpreted the learned German's conclusions into language that might be "understood of the common people", and still more, if he would show us how far progress has been made in explaining two of the most mysterious rocks in our earth's crust, which are abundant in Ceylon, namely, laterite or cabook and graphite or plumbago. Where the iron of the one came from and the carbon of the other, we have always understood that even the most accomplished geologists would be chary of dogmatically affirming. About low-level laterite something may be said; but gneiss and other rocks passing into laterite on the top of

a hill is another question. Equally difficult is it to say whether graphite was deposited from water or solidified from gas. We would like to know if the German Professor explains why the mineral should have so strong an affinity to quartz, or is this still amongst the as yet unsolved problems of the science of Geology? We would again press for the Geological Survey so long promised and talked of, to take up the work systematically for the island as a whole, and we trust to see Mr. Coomaraswamy's services retained and utilised by the Government when that Survey actually begins.

[Extracted from the GEOLOGICAL MAGAZINE, Decade IV, Vol. VIII, No. 442, p, 175, April, 1901.]

E. Weinschenk. Zur Kenntniss der Graphitlagerstätten. III. Die Graphitlagerstätten der Insel Ceylon. Abh. k. bay. akad. Wiss. Cl. II, Bd. xxi, Abth. 11; München, 1900.

Professor Weinschenk has examined a series of rock and vein specimens from the graphite mines of Ragedara, Ampe, Pushena, and Humbuluwa, in Ceylon, collected by Dr Grunling. He discusses the nature of the granulitic rocks and the mode of occurrence and origin of the graphite.

A general petrographical description of the granulitic rocks is given, illustrated by three plates of microphotographs. Massive habit, granulitic structure, and variable chemical composition are characteristic. Except in the more basic varieties, intergrowths of two feldspars are very noticeable. The granulitic rocks include a continuous series ranging from aplites (weiss-steine) to pyroxenepлагioclase rocks (trapp-granuliten) and even pyroxenites. A rather oily lustre and greenish colour are very characteristic features. The constituent minerals are in a remarkably fresh condition, except in the immediate neighbourhood of the graphite veins. It is interesting to note that Professor Weinschenk does not mention any pleochroic monoclinic pyroxene.

There are certain other rocks in Ceylon which include coarse-grained dolomites and 'cipolins', containing blue apatite and contact mineral such as forsterite, chondrodite, phlogopite and spinel, and also the peculiar andaluste, sillimanite, and corundum bearing rocks described by Lacroix.

The granulitic rocks show no trace of the operation of dynamic causes; they are regarded as an eruptive mass which may form a single unit or be compound in character. The occurrence of coarse crystalline dolomites in the midst of the granulitic series seems to show that different eruptive units are separated by contact rocks. The existence of still younger eruptive masses of granite has not yet been demonstrated, for the few rocks as yet described from Ceylon as granite are rather varieties of the granulitic series.

Professor Weinschenk compares the Saxon and Ceylon granulites, thinking with Naumann that the former are truly eruptive rocks. Had the Ceylon rocks been studied before those of Saxony this view would have been more widely held. They differ from the Saxon rocks chiefly in their non-schistose character and coarser grain. Lehmann regarded the peculiarities of the Saxon granulites as the result of dynamo-metamorphism. He regarded the micropertithitic intergrowths of two feldspars as the result of such a process, but as these are

characteristic of quite unaltered rocks in Ceylon they may also be original in the Saxon rocks. The absence of sericite in the latter presents a difficulty to those who favour the dynamo-metamorphic view. Lehmann supposed that its place was taken by biotite, but this mineral is not infrequently an original constituent in Ceylon rocks. Garnets are characteristic of typical granulites, and their presence is the result of chemical peculiarities in the magma or peculiar physical conditions obtaining at the time of its consolidation. The chemical composition of Ceylon and Saxon granulites resembles those of truly igneous rocks. Perhaps in Saxony we are dealing only with the outer margin of an eruptive mass intruded into surrounding schistose rocks, while in Ceylon the heart of the eruptive mass is exposed. In both cases there has been extensive magmatic differentiation, and this may be considered characteristic of granulites in general.

It is only in immediate contact with the graphite veins that the granulite matrix is chemically altered and finally impregnated with graphite. Fragments of rocks included in the veins are also specially affected. In altered rocks the feldspars are largely changed to nontronite, a feature associated with the occurrence of graphite in the Passau district also. The pyroxenes change to a fine scaly material with aggregate polarisation. Mica and garnet alter less readily. Impregnation with rutile and titanite is characteristic, as in the Bavaria-Bohemian area. Beside the rock fragments, pieces of various minerals occur in the veins—quartz, pyrite, orthoclase, micropertite, apatite, biotite, augite—the formation of these being previous to that of the graphite; while calcite, and sometimes biotite, seem to have been deposited contemporaneously.

In the Passau district (Bavaria) the formation of nontronite and impregnation with graphite affect the whole schistose complex, while in Ceylon the graphite occurs in veins. This difference depends chiefly on the harder and more massive character of the Ceylon rocks. In Ceylon, Siberia and Cumberland the graphite occurs in veins; in Passau and Ticonderoga (U. S. A.) in veins and beds; in Bohemia in beds: these differences depend on the varied character of the matrix and not on different modes of origin of the graphite. Emanations of carbon monoxide, with or without cyanogen-bearing compounds, may have given rise to the graphite veins; while the introduction of iron oxide and manganese peroxide in their neighbourhood may argue that metal carbonyls were also present.

Finally Professor Weinschenck would suppose the following to have been the sequence of events in Ceylon:—A fluid magma intruded into beds of unknown age consolidated as a peculiar 'schlierig' rock, while contact-metamorphic structures were developed in surrounding beds. Contraction-joints developed on cooling, allowed the formation of pegmatites, including pure quartz veins to some extent. But, contemporaneously with the formation of the pegmatite, there were emanations of carbon monoxide and cyanogen-bearing compounds, which followed the same paths as the pegmatites and then gave rise to the graphite veins. The system of veins traversing the whole massif played in latter mountain movements the rôle of buffer, the soft yielding mineral absorbing the mechanical effects, and thus the Ceylon granulites remained unaltered by dynamic changes.

I have attempted in this review merely to give an abstract of Professor Weinschenck's views as expressed in his important paper.

A. K. COOMARA-SWAMY.

VISIT TO A CINGALESE INSANE ASYLUM.

BY A NURSE GLOBE-TROTTER.

Seven o'clock in the morning according to English ideas of time is a most unsuitable hour at which to visit a public institution. In Ceylon a before-breakfast round of a hospital or asylum is quite "the thing." Later on, the stifling heat makes up-and-down-stair visitation a penance and weariness to the flesh. Unlike most tropical institutions, which are commonly built on one floor, bungalow fashion, the huge insane Asylum at Colombo possesses many stairs and an upper storey.

Accordingly, at 7 a.m. punctually, after a drive through the lovely Cinnamon Gardens, which are the joy of generations of globe-trotters, one of the highest officials of Ceylon and I explored the wilderness of tropical trees, flowers and gorgeous blossoms, in which the vast insane Asylum of Colombo, containing some 1,200 patients, stands. The patients, like ourselves, had taken an early cup of tea and bread and butter, the more substantial breakfast which we subsequently saw in process of being cooked is served at about 10 a.m. It was the Europeans who taught the Cingalese to drink tea, a habit which has now become inveterate and exaggerated in native family life.

The asylum household had been up and busy for about a couple of hours before our arrival, groups of semi-safe patients were scattered under the shade of the trees, for even at this early hour the sun was sufficiently strong to make a shelter from its rays both grateful and comforting.

They were squatting native fashion on the grass, chattering, crying and laughing in turns. Most of the men were smoking; some were dressed in the Cingalese "half petticoat," wearing turbans made from several yards of linen wound about their heads; others were garbed coolly fashion in a single wide loin cloth.

A DRAWBACK TO GOOD NURSING.

The native ideal of bliss is to squat eternally—and talk eternally. Before visiting the East I had accepted the "grave quiet Oriental" of literature as a gospel truth, but as a matter of fact neither the man nor the woman of the East ever stops talking. They stay awake most of the night, because the day has not been long enough to give them time to say all they want to. And if by some chance sleep overcomes a native he still goes on talking. This incessant chatter is a terrible drawback to good nursing, both in Ceylon and India. For the nurse finds it a most difficult matter to obtain absolute quiet for her patient, either in the daytime or the still small hours of nights. The punkah puller's wife and family cannot be prevented from camping out with him day and night, so as to form a cheery conversation party. The incessant prayer of a patient in the East is for one hour's real rest. For if the humans can be silenced by superhuman effort, threats and fines, the flying foxes, monkeys, jackals, and crows all have their noisy innings till a sick man's nerves grow raw with noise.

AMUSEMENTS.

The amusements of a Cingalese Asylum are few and far between. Natives play very few games, though they are incessant dice-throwers and

gamblers. Amusements such as are common in the home asylums would not be a success if they were introduced in the East. None of the inmates would know what to make of a piano. The only form of music appreciated by the Cingalese is that resulting from the tom-tom and a gruesome imitation of a bagpipe. All other harmonies would be regarded as weary, stale, and unprofitable. Since the beating of tom-toms could hardly be permitted for the sake of the sanity of doctors and nurses—the routine seemed somewhat dull from the European standpoint. But the native does not find it so.

THE NURSING STAFF.

The matron and all the head nurses are Burghers, which means that they are of Dutch extraction with a more less commingling of native blood. The Burgher of Ceylon corresponds to the Eurasian of India. There is a large staff of Cingalese attendants in addition, who do duty of a non-nursing kind. The patient help to cook, do most of the domestic housework, keep the grounds in order, saw and assist the native and quite sane cooks. Some of the patients, recognising the important official who accompanied me, removed the cloth from their shoulders, this being the highest mark of respect to his superiors that a native can show.

HOMICIDAL PATIENTS.

Many of the patients are homicidal, but the medical superintendent told us that epilepsy and epileptiform varieties of insanity are not nearly as common in Ceylon as at home. An old lady was pointed out to us whose greatest boast and pride in life rests in the fact that she cut her husband literally and truly into tiny shreds. She looked very crude and primitive, as most of the Cingalese do, but there was nothing markedly ferocious about her appearance. Among the other patients she is a kind of heroine from the complete and unusual nature of her crime. The Cingalese temperament is rarely violent or cruel, though it is treacherous to a degree. It is a somewhat curious fact that the insane male natives we saw looked far more manly and decided than sane Cingalese men usually do. For it is a proverbial truth that the average Cingalese man looks "rather more like a woman than a real woman does." It was very touching to see an old insane native woman bestowing such tender care on her blind, insane, and grown-up daughter, whom she tends and watches and cares for as though she were an infant. Maternal devotion is characteristic of the natives of Ceylon, and cruelty or even mild unkindness to children is very rare in the island.

COOKING AND THE DIET.

The kitchen presented a novel scene. All the cooking—and capital cooking, too—is done picnic

fashion, by means of a few smouldering logs and primitive saucepans. An old man patient—and we were relieved to hear that he was not classed with the homicides—was brandishing a big knife and shredding some fifty fresh half-coconuts for use in the breakfast curry. After the nut is cut in fine shreds, it is rolled with the most crude kind of native rolling pin, before it is added to the curry pot. Other patients were busily slicing the Bombay duck and somewhat "high" salted fish, without which and some twenty other odd vegetable and pickled compounds the native curry of the country would not be considered complete. Nice-looking rice "hoppers" were in process of preparation, the rice previously boiled being mixed with coconut oil into a consistent mass and fried in small portions, like pancake or fritters. It takes a native to swallow, enjoy, and digest the strong rancid coconut oil which enters so largely into Cingalese cookery. Some of the patients were lepers, for leprosy is not yet compulsorily segregated in Ceylon. Many have become insane through immoderate drinking of the strong and deadly arrack spirit or toddy which the native distills so cleverly from coconut flowers. Indeed, he is very skilful at extracting strong drinks from almost any tree.

GOVERNING BY KINDNESS.

The cubic space for each patient, judged by the British point of view, is enormous, but, of course, more air space is needed in the tropics. Very little restraint is used, and a strong effort is made to govern by kindness and moral suasion rather than by a show of force. The patients appeared to be devoted to their doctors, some of whom are English, while others are "Burghers," who have mostly taken their medical degrees at Edinburgh. One old man, who was rather a bad case, hearing of our contemplated visit, determined to honour the occasion by gathering the most gaudy and resplendent tropical blossoms from the grounds. In the absence of flower vases he had filled two pairs of shoes, borrowed for that purpose from a European source, since the native wears only the hardened skin shoes wherewith nature endows him. Bright with tropical blossoms most tastefully arranged, four shoes stood ranged outside his cell door, and he proudly did the honours of the flower show. He had calculated on a money result—and he got it. It is impossible to visit and study the workings of this huge Insane Asylum of Colombo without being impressed with its admirable methods. Indeed, the Asylum ranks high in the estimation of all who are familiar with it, and it is popularly allowed to be "a credit to Ceylon."—"Hospital" Nursing Mirror.

Total Exports from 1st Jan to 31st Dec. 1901	145188244	148481639	1110774	9631	91	9722	601089	510462	49459	559704	2756270	1516083	8581	5066	453531	443950	439865	14055493	204356	14850781	453267	389350	13030	75788	122826	10259	7180	12353	2541	1430168	73493

It has been ascertained by reference to the Customs Returns and from other sources that a quantity of tea included by us previously in our U. K. Shipment was actually in course of transhipment to America and Canada, also that a quantity of tea described previously as for China was actually intended for Western America. The figures have been adjusted as far as possible. It should further be noted that for good reasons the Russian figures have been altered. Out of the large quantity of the teas appearing as for China, the bulk eventually finds its way to Russia (in Europe and Asia) in the form of Brick Tea.

The Planters' Association of Ceylon, KANDY.

FORTY-EIGHTH ANNUAL REPORT. FOR THE YEAR ENDING 17TH FEBRUARY, 1902.

The forty-eighth Annual Report of the Planters' Association of Ceylon which your Committee presents to-day records a further period of work accomplished in the interests of the Planting Enterprise, and Agriculture generally. It reviews briefly the operations of your Committee and indicates some salient features while bringing various matters of a more general character under notice.

PLANTING PRODUCTS.

TEA.

Partly owing to finer plucking but chiefly on account of unfavourable climatic conditions the total shipments of tea for 1901 fell short of those for the previous year by 8,243,895. Outside markets however, took an increase of 5,019,599 lbs., leaving a total shortage of 8,262,794 lbs. sent to the United Kingdom.

As of considerable interest for perusal, reference, and comparison from time to time, a few quotations from the leading London and Local Tea Circulars are herein placed on record with acknowledgments, and thanks to the compilers.

The packages printed for Public Sale in the past three years at London stood as follows:—

Table showing tea packages printed for Public Sale in the past three years at London.

In consequence of the inferiority of the 1900 crop, due to heavy frosts and coarse pluckings generally, prices at this time twelve months since (December, 1900) were at an abnormally low level for ordinary to fair kinds, clean Pekoe Soucheongs selling at 4d. per lb., or 2d. per lb. under the quotation of the same period of the former year.

Owing to the measures taken, quality was considerably improved, and the Teas, especially common and medium descriptions, were better than for several previous seasons.

QUOTATIONS.

Table of quotations for various tea types like Pekoe, Orange Pekoe, Broken Pekoe, etc., for the years 1901 and 1900.

LONDON TEA RETURNS.

Table showing London Tea Returns for Imports and Deliveries for the years 1901 and 1900.

Table showing Stock at 31st December for the years 1901 and 1900.

Monthly shipments from Ceylon to the United Kingdom during the past five years.

Table showing monthly shipments from Ceylon to the United Kingdom from 1901 to 1897.

Production.—Exports from India and Ceylon in 1900 totalled 384,000,000 lbs., while the world's consumption was only 314,000,000 lbs., resulting in a surplus of 20,000,000 lbs.

Table showing production and consumption of tea in 1900, comparing India and Ceylon.

While the Consumption at home and abroad was about:— India ... lbs. 184,000,000 against lbs. 170,000,000 last year. Ceylon ... lbs. 15,000,000 against lbs. 14,000,000 last year.

The surplus is thus partially worked off. Exports from China have been considerably below last year's, which may further divert foreign demand towards British grown teas.

CONSUMPTION.—Home consumption appears to expand in spite of the higher duty, which has mainly been paid by Producers. Duty payments (estimating December) amount to 255,000,000 lbs. against 249,792,086 lbs. last year, and 242,580,819 in 1899.

COARSE PLUCKING was mainly instrumental in reducing the lower grades to almost nominal values, and proved disastrous to many estates. Manuring, which was perhaps overdone in 1900, has not this year been so freely resorted to.

FROM COLOMBO REPORT: THE TOTAL EXPORTS FOR 1901 WERE 146,726,066 lbs. against 148,569,477 lbs. in 1900 distributed as under.

Table showing tea distribution from 1st January to 31st December, 1901, categorized by destination like United Kingdom, Russia, Other countries in Europe, America, etc.

The following show an increase over 1900.—Australia, Austria, Africa, China, Germany, Holland, Italy, Mauritius, Russia and Singapore, while America, Belgium, France, India, Malta, Spain, Sweden, Turkey and the United Kingdom show a decrease. The figures for America, however, are somewhat misleading, as a considerable quantity of tea has been shipped there via London and China.

Ceylon showed an absence of the coarse Teas noticeable last year, and quality in consequence was better, and about equal to that of recent years. Average for Teas sold on garden account, 6.86d., against 7.20d. in 1900.

Green Tea.—Some attempt has been made to capture the markets for Green Tea, especially in America.

Duty payments in 1901 indicate a normal increase in Home Consumption, the quantity consumed per head of population amounting to lbs. 6.17, against lbs. 6.11 in 1900, and lbs. 5.98 in 1899. The use of China Tea was extremely limited. Re-exports of Indian and Ceylon Tea showed a marked increase.

In Appendix C. will be found further Statistics relating to Ceylon Tea in London.

TEA BLIGHTS.

By far the greater portion of the Tea Districts have been wonderfully free from blights and pests of all description, and wherever cultivation has been carefully carried out grey blight has been practically absent. The most important during the year has been a serious attack of shot bore in one District, whilst the caterpillar of one or more of the Tortricæ has given a good deal of trouble in another.

TEA INDUSTRY AND OVERPRODUCTION.

During the year an effort was made, in conjunction with India, to curtail the excessive production of tea, and after various schemes had been considered it was decided to ask proprietors to reduce the estimated crop by 10% either by resting a portion of the acreage, finer plucking or by making the surplus into Green Tea. This scheme though approved of in India failed to receive a sufficient amount of support in Ceylon.

INCREASE OF THE LEVY ENACTED TOWARDS INCREASING THE CONSUMPTION OF CEYLON TEA IN FOREIGN LANDS.

The following Minute and Resolution having been passed at a meeting of the "Thirty Committee" held on the 14th September, 1901, were submitted for the consideration of the Planters' Association of Ceylon:—Read Report of the Colombo Members of the "Thirty Committee", in conference with others interested in the American and Continental tea trade.

Your Committee having considered the abovementioned Report and opinion, passed the following Resolution:—That the Committee of the Planters' Association are convinced that an increase in the cess is a pressing necessity.

OFFICIAL ESTIMATE OF TEA CROP FOR 1901 AND 1902.

It having been decided not to make public an official estimate of the Tea Crop for 1901 in February, it was not until May that the Committee confirmed the original estimate of the Tea Crop for export during 1901 at 140,000,000 lbs. as follows:—

Table showing official estimate of tea crop for 1901 and 1902, categorized by destination like United Kingdom, Australia, Russia, America, etc.

Your Committee estimates the Tea Crop for Export during the year 1902, at 154,000,000 lbs. As regards the distribution of the Crop the following is submitted:—Russia 11,000,000 lbs., Australia 21,500,000 lbs., America 6,000,000 lbs., other countries 7,000,000 lbs., leaving for the United Kingdom 108,000,000 lbs.

CACAO.

The crop for the past year, (1901), 47,471 cwts. is the largest on record, and as a careful examination of the increase of acreage does not lead to the conclusion that this is to any appreciable extent caused by new land coming into bearing, it may be assumed that the increase is due largely to the recovery of estates from the attacks of canker and other pests and that agriculturally cocoa is in a sounder position than it has been for some years. Forastero continues to supersede the red cocoa, and it is possible that it is due to this change in the character of cocoa exported that the market for Ceylon is in its present disorganized condition.

The demand for the red cocoa of Ceylon was always of a limited description and the price depended on the sample being free from dark coloured beans. Very little Ceylon cocoa is now free from these, and as a result it has been hard to sale. At the same time it is probable that as the Forastero increases in Ceylon, that it will no longer command fancy prices, but will sell on a par with good West Indian and with equal readiness. The statistical and the stocks are smaller than they have been for some years. Locally cacao stealing continues, and whilst acknowledging the efforts of officials to suppress this evil, it is now apparent that special legislation is necessary. Special outbreaks of crime are met with special legislation in all countries and the coffee stealing ordinance of the same description is now required to suppress cocoa stealing. As the law at present stands, to obtain a conviction eye witnesses of the actual theft are a necessity, and many convictions therefore fail when there is no real doubt of guilt.

The following statistics are taken from Messrs. Wilson, Smithett & Co.'s London circular.

Table showing statistics for Cacao from 1901 to 1895, categorized by origin like Trinidad, Grenada, Other British possessions, Ceylon and Java.

Table showing Guayaquil, Bahia (Brazil), African, Other Foreign for the years 1901, 1900, and 1899.

Table showing Total Stock all growths for London, Havre, Liverpool for the years 1901, 1900, and 1899.

Table showing Year's Imports—London, Deliveries—London, Havre for the years 1900, 1899, and 1898.

Table showing Some Comparative Prices for Guayaquil, Summer Arriba, Winter, Machala and Caracas for the years 1902, 1901, and 1900.

Table showing Some Comparative Prices for Guayaquil, Summer Arriba, Winter, Machala and Caracas for the years 1899 and 1898.

CARDAMOMS.

The area under this cultivation has been very largely increased during the past two years both here and in India. The exports for the year ending 31st December, 1901, show the heaviest on record, being 559,704 lbs. against 587,456 lbs. in 1900. Prices both in the London and local markets have fallen considerably in the past year in consequence of the heavy exports. With a still further large increase in acreage shortly coming into bearing from European estates and from native gardens recently planted in almost every village in the Kandyana Province the tendency must be to increase the exports to such an extent that the supply will probably exceed the demand and the market will likely fall below remunerative prices.

The following statement submitted by leading London Brokers shows the movements during the last twelve months as compared with the five previous years:—

Table showing Stock 31st December, Imported in year, Delivered for the years 1901, 1900, 1899, 1898, 1897, 1896.

COCONUTS.

The quantities of the different products of the coconut palm exported in 1901 show conclusively that, taking the island all over, there was no falling off in production, but rather a slight increase. Oil, Copra, Poonac, Desiccated nuts, all show an increase. The figures for oil and coconuts were the highest on record, save on two occasions; poonac has only once been higher, coconuts were exceeded by only about 150,000 last year; and the quantity of Desiccated Coconuts the largest ever exported. Copra rope and fibre were the largest for 8 years past (for particulars see Chamber of Commerce Price Current Appendix), so that the industry in all its branches may be said to have well maintained its position. It is difficult to say what has caused the recent great rise in the price of oil and especially of Copra; the rise in the price of nuts was greatest in the districts with cheapest access to the Metropolis, and in localities where there were desiccating Mills, which competed keenly with the Copra driers. Supplies, compared with other years, were not short, so outside influences must be sought for, and these were probably many. The war in the Philippines, restricting the export of Copra Ac., reported decrease in the crop in the Straits Settlements; possibly a shortage in the export of palm oil from Africa; and your Committee hopes, the discovery of new uses for the Coconut. Whatever the causes they contributed to raise the price of oil from Rs. 18 to Rs. 20 per cwt. and of Copra from Rs. 16 to Rs. 64 per Candy of 580 lbs., other products of the palm sharing more or less in the high prices. Such prices were never known before in the history of the industry, and fill there is further information as to the real causes operating to produce them, it is not possible to say whether they may be expected to continue. The Coconut industry is at present on a very firm footing, and the acreage of new land planted of late is not such as to, in the near future, materially affect it. The trees continue free of any serious pest, the "Kurumimia", their worst enemy, being easily controlled. Altogether the outlook for owners of Coconut property seems bright.

RUBBER.

This product is receiving more attention; it is being steadily planted up both in the low country and also on estates situated at medium elevation. The yield and quality of rubber obtained from the Para variety growing in the Kalutara district has been very satisfactory, some of the rubber realising 4s. 2d. a lb. Steps are being taken to import the seeds and plants of the best varieties of Castanea into the Island.

TOTAL EXPORTS FROM CEYLON DURING THE YEAR 1901

Your Committee as usual invites attention to Appendix A. hereto annexed for official statements of Exports from Ceylon during 1901, for which your thanks are again due to the Hon'ble Mr. W. H. Jackson. The return is useful for reference and comparison with similar data made up to the same period by the Ceylon Chamber of Commerce, which follows as Appendix B.

RAILWAY EXTENSION AND IRRIGATION WORKS.

In view of the discussion that took place at the General Meeting of your Association on the 5th December, 1899, in considering the Secretary of State's Despatch No. 222 relating to the surplus balances of Revenue, attention is herein drawn to Sessional Paper XXXI, 1901, despatches relating to Expenditure on Railway Expenditure and Irrigation Works which will be included in the Book of Proceedings for future reference. With special reference to progress made in Railway Extensions the latest available authoritative information is the following from the Address of His Excellency the Governor on opening the present Session of the Legislative Council:— "The Railways under construction are the Northern, the Kelani Valley, and that from Nann-oya to Nuwara Eliya and onwards to the Hill Districts of Uda Passellawa. The cost of these Railways is estimated at Rs. 11,029,876, Rs. 4,084,780, and Rs. 1,801,851, respectively. On the Northern Railway, which like the Uda Passellawa Railway is under the charge of Mr. Oliver, the expenditure at the end of July amounted to Rs. 3,200,000. At both ends substantial progress has been made. On the first forty miles at the southern end the works are in hand, including nearly all the bridges and culverts on the first twenty miles. The rails are laid for ten miles, and there is a large quantity of bridge, permanent way, and other material on the ground. On forty miles of the northern end from Kankasanturai the work is well forward; the rails are laid for twenty miles, nearly to Chuyakachcheri. At Anuradhapura also, on five miles on either side work is begun. Labour has been fairly plentiful. Work on the Uda Passellawa Railway is in progress on the Crown lands through which the line runs, and the acquisition of the private lands required is now proceeding. On the Kelani Valley Railway (48 1/2 miles) land has been acquired up to 45) miles, and the

earthwork has been completed up to 31 miles, and is being vigorously carried on between 31 and 43 miles. Of the major bridges, the masonry of three spans of 60 feet has been completed, and the masonry of three spans of 100 feet and of two spans of 60 feet is in progress. The Kirillapane bridge (which is to consist of one span of 100 feet and one span of 60 feet) and the Sitawaka bridge (which will consist of four spans of 75 feet) are advancing towards completion; the masonry of 185 bridges and culverts has been completed, and the masonry of 94 bridges and culverts is in progress.

By the courtesy of Government your Committee has been favoured with a copy of Report from the Chief Resident Engineer, Kelani Valley Railway, showing the progress of the construction of the Kelani Valley Railway up to the end of December 1901—Maradana Junction to Yatiyantota, Length 48 1/2 miles, Gauge 2 feet 6 inches, and it may therefore be of interest to add that land for the Railway has been acquired up to 46 miles 11 chains, while the earth work in formation of banks and cuttings has been completed up to Avisawella Station (86 miles), and is in progress between 86 miles and 46 miles 11 chains. The Kirillapane Canal Bridge, the Bada Amuna Ela Bridge and the Maha Oya Bridge have been completed. The masonry of the Wak Oya Bridge has been completed, as also for the Heen Ela Bridge. The work in connection with other bridges is being pushed forward. In the forty-fifth Annual Report for the year ending 17th February 1899, your Committee placed on record an expression of the cordial thanks of the Planters' Association to His Excellency the Governor for the steps he had taken in the matter of the Kelani Valley Railway Extension, and in watching with keen interest the development of the policy of progress, it is matter of congratulation to know that His Majesty has been pleased to approve of the extension of His Excellency's term of office as Governor of Ceylon until October 1903, before which time it is certain the construction of the proposed Railway will have greatly advanced, thereby demonstrating that the period of the Governor's rule has witnessed progressive policy on wise and liberal lines.

CEYLON GOVERNMENT RAILWAY.

In connection with the Ceylon Government Railway your Committee welcomes the change in management and looks forward to early improvement and reform as so persistently asked for in the past.

INCIDENCE OF TAXATION.

Government having been unable to comply with your request for a reduction of Railway Rates, the appointment of a Commission on the incidence of taxation was asked for, and it is satisfactory to report that the Commission will ere long begin its labours.

GOVERNMENT CONTRIBUTION TO TEA FUND.

At the Annual General Meeting on the 17th February, 1901, a resolution was passed inviting Government to give practical effect to expressions of concern for the welfare of the Ceylon Tea enterprise in connection with the further exploitation of Ceylon Tea at various exhibitions by contributing to the Ceylon Tea (New Markets) Fund from general revenue during 1901; a sum equal to the amount collected during 1900 under Ordinance No. 4 of 1894 for increasing the consumption of Ceylon Tea in foreign lands. The application was formulated on the precedent of what has been termed the grant-in-aid system which has from time to time been applied in connection with planting and native interests with much benefit in other matters. The arguments adduced in support of the resolution were that owing to the serious fall in the price paid for Ceylon Tea the planting industry was in a critical position, a proportion of estates having been even worked at a loss, so that proprietors were not in a position to easily find the necessary further sums for required increased expenditure recommended by the "Thirty Committee". It is admitted that the prosperity of the industry and of Ceylon generally depends largely on increased demand for Ceylon Tea from foreign markets, and that it is desirable that the "Thirty Committee" should be placed in a position more extensively to make known Ceylon Tea throughout the world. The question was ably brought before the Legislative Council by your Representative there, but as he failed to receive that support which your Association fully expected the proposition was negatived.

LABOUR SUPPLY.

As usual your Committee appends abstracts of the Official Returns of arrivals and departures of coolies during the years 1899, 1900, 1901.

Table showing Labour Supply (Arrivals and Departures of coolies) for the years 1899, 1900, and 1901, categorized by month.

Table showing Labour Supply (Arrivals and Departures of coolies) for the years 1900, 1901, and 1902, categorized by month.

Table showing Labour Supply (Arrivals and Departures of coolies) for the years 1901, 1902, and 1903, categorized by month.

LABOUR FEDERATION OF CEYLON.

In connection with the Labour Federation the following Resolution was recently brought under the notice of your Committee at the instance of the Dinbulla Association:— "That this Association considers the present law regarding bolting coolies to be inadequate, and requests the Labour Federation Committee to consider the advisability of making the employment by any superintendent or gangany knowingly of a cooly who has not legally ceased to belong to another estate, an offence punishable by law."

A sub-Committee was appointed to consider the Resolution and to report generally on the present state of the Labour question. CENSUS 1901.

According to Sessional Paper XXI, 1901: "The fourth decennial Census of Ceylon was taken on the night of 1st March 1901. The previous enumerations of which there is record were those of 1824, 1871, 1881 and 1891." The result is herein given for future guidance and reference. Your Committee and the Office bearers of District Associations co-operated all in their power as regards Estate Labours.

The Population of Ceylon at the Census of March 1, 1901, in the various Provinces, Districts, and Chief Headmen's Divisions of the Island, compared with the Population at the Censuses of 1881 and 1891 for the Local Areas of 1901.

Population estimated by the Census, Military Shipping, and Processes of War.				The Estate Population.

KEEPING OUT THE PLAGUE.
Your Committee would again, in continuation of the observations made in last Annual Report, congratulate the Planting Community and the whole Colony upon the fact that under Divine Providence Plague has for another year been kept from the Island. The thanks of the inhabitants are due to His Excellency, to the Plague Committee, and to the Port of Colombo Sanitary Officers for vigorous and effective action.

TATAPARA DEPOT FOR COOLIES AND RAGAMA CAMP: SCHEME FOR REGISTRATION BROUGHT INTO OPERATION FROM OCTOBER 1st 1901.
It will be remembered that your Committee brought under notice in last Annual Report the proposed Scheme for the Registration of all estates employing Tamil labour by giving to each a distinguishing letter and number which would serve as an abbreviated and unmistakable address. The scheme has been satisfactorily launched and has received the cordial co-operation and support of the community. In reference to the tin ticket system it would be well not to lose sight of the vital reasons for the scheme. It was found that many coolies reached Tatapara without the necessary funds for maintenance in the depot while waiting for a passage or for remittance from Ceylon and such coolies had to remain outside in a more or less impoverished state. The result was that the environment of the depot became unsanitary with the risk at any time of an epidemic which the authorities might control with difficulty. Some alterations appeared to be advisable and necessary in the circumstances, but until some means were found to identify a particular coolie through the name of the estate to which he was attaching himself the difficulty was to be overcome was not apparent, as it might become imperative to send back indigent coolies in large numbers from Tatapara to the villages from which the coolies had arrived. The new scheme provides a means of identification, and Government has approved and accepted it taking over the work of it in a liberal spirit. The risk of losing advances or coolies has not increased in any way, but the Planting Community will now, if desired by individual planters, know that when a coolie reaches Tatapara Depot cost advances and the coolies are as safe as if they were at a Railway Station in Ceylon. The scheme protects the coolie from blackmailing and extortion, so prevalent at Tatapara and Trincomalee. To insure the success of the scheme it is essential that the Government Railway should issue cheap tickets to coolies only who have tin tickets under the scheme, though at the request of your Association Government has agreed to defer this restriction until the scheme has been in actual working for a period of three months, that is from 1st April 1902. To recapitulate the use of the tin tickets is primarily because they afford a means of identification of the coolies returning from the coast at Tatapara. The tin tickets will probably prove advantageous to the Superintendent of Estates, because by having a consecutive number on the tickets it can be entered against the name of the recipient in a check roll, while each coolie going to the coast should have a tin ticket and a consecutive number should have a certain number of tin tickets with him to issue to recruited labourers. One ticket will only pay one coolie. The coolie who recovers the ticket or tickets becomes responsible for any claims against such tickets, but such claims would merely represent part of cost advances to the coolie. Your Committee does not anticipate trouble or loss from forged tickets, but the matter is one that can only be tested by experience. Any coolie having a tin ticket—forged or otherwise—will be detected at the nearest Railway Station, to the estate referred to. In most cases the coolie can be met, and in the majority of other cases he comes over again with a responsible company who will see him on to the estate or who would send him an estate tin ticket. There appears to be no sufficient inducement for forgery, as a bona fide estate labourer would always be able to secure one, whereas the coolie seeking one for other purposes would hardly secure a forged ticket only to find himself delivered at a Railway Station many miles from his intended destination.

In appendix D will be found the latest information and regulations with reference to the working of the scheme.

POST AND TELEGRAPH.

The representations made by the District Association the Postmaster General was addressed regarding the advisability of advancing as District Letters ordinary covers bearing a 2 cent stamp, and it is satisfactory to be able to report that the necessary authority to allow of the 2 cent per cover rate District Letters was obtained. The various forms relating to the new stamp, the printing of the postpaid covers and letters in different quantities to suit purposes. The desired improvement will doubtless be found both useful and economical.

PROVINCIAL AND DISTRICT ROAD COMMITTEES.

In connection with the proceedings of the Provincial and District Road Committees, Central Province, during the past year, printed lists of the Minor Roads in the districts have been tabulated and will continue to be found useful, as also similar information in reference to the Postboxes open or otherwise available for the use of travellers. Your Committee has further endeavoured to obtain through the various District Associations a return of grant-in-aid roads in the various districts and these will be fully communicated to you. The important proposal made in paragraph 25 of the memorandum of the law as to the application of section 1 of the District Roads Ordinance to estate roads and also to the use of Government land for the construction of public roads towards which a Government contribution of certain roads, has also been brought and will be proposed in the Legislative Council, but the proposals are in the hands of the Government and will be fully communicated to you in due season.

PUBLIC WORKS.

In the annual report of your Committee for the year ending 17th February 1901 reference was made under this head to the work of the new survey which included the Northern, Uda Pass, Uva and Kelani Valley Railways, and Irrigation Schemes, which were estimated to cost Rs. 20,540,000, half of the whole estimated cost amounting to Rs. 10,270,000, half of which was to be provided by loan and half from the surplus Revenue of past and future years, and it was shown that at that time, the cost of the Irrigation works of Rs. 20,000 per annum, a sum of Rs. 2,000,000 remained to be provided out of revenue.

under the supervision of these local bodies, whose interest it is to ensure economy. It is understood that an Ordinance is being drafted to give effect to the above recommendations. The proposal to take over the Grant-in-aid Roads will be referred, it is anticipated, to the Commission on the incidence of Taxation.

REDUCTION OF BRITISH TEA DUTY.

In addition to the representation of your Association forwarded through Government to the Secretary of State for the Colonies urging a reduction, at as early a date as is compatible with the financial needs of the Empire of the Import Duty on Tea in Great Britain, His Excellency the Governor also telegraphed that the Ceylon Government desired to impress on His Majesty's Government the disastrous consequences which a further increase of duty on tea might entail on the chief industry of this loyal Colony. A reply was duly received that the Governor's despatch and telegram had been laid before the Chancellor of the Exchequer, while later on it was announced that though the duty would not be reduced at present it would not be increased meanwhile. Your Committee would again record the gratitude of the Association for the action taken by His Excellency in the matter.

CUSTOMS DUTY UPON COLONIAL PRODUCE ENTERING FRANCE FROM COUNTRIES WHICH DO NOT ENJOY MOST FAVOURED NATION TREATMENT.

At the close of last year the Ceylon Association in London was asked to watch the further developments in the matter of the proposed increased Customs Duty upon Colonial Produce entering France from countries which do not enjoy Most Favoured Nation Treatment with a view to any further action. In conjunction with the Ceylon Chamber of Commerce a second memorial to the Secretary of State was forwarded in September, 1901, again drawing attention to the law passed by the French Government on 24th February, 1900, that altered Customs Duty upon Colonial Produce entering France from countries which do not enjoy Most Favoured Nation Treatment, pointing out the serious effect which the final passing of such a law would have upon British Colonial Products and particularly upon Tea, Coffee, Chocolate and Spices exported from India, Ceylon, the British West Indies, and the British East and West Coast of Africa. The prayer of the memorial had in view the securing a postponement of the new duties, at all events to the extreme limit allowed by article 6 of the law so as to avert if possible should the British Government be unsuccessful in obtaining for its Colonies Most Favoured Nation Treatment an exceedingly severe blow to British Colonial trade with France. Your Committee is glad to learn that the French Law referred to of 24th February, 1900, will again be suspended for a year, so that the duties during that time will remain as they now are and there will be no increase of the present duties on Ceylon Tea.

DUTY ON TEA IN AUSTRALIA.

It will be in the recollection of members that a proposal was made to levy a duty of 2d. per lb. plus 20 per cent *ad valorem* Duty on Tea within the Commonwealth of Australia and that prompt action was taken in the matter both by His Excellency the Governor and the Ceylon Chamber of Commerce to insure reconsideration. The thanks of your Association are herein rendered and the following resolution was transmitted to the Chamber:—
"That the Committee of the Planters' Association cordially approves of the action taken by the Chamber of Commerce in approaching the Federal Parliament of Australia with a view to re-adjustment of the duty proposed on tea, and endorses the arguments brought forward by that body that the imposition of an *ad valorem* duty is seriously detrimental to the interests of capital employed in the tea industry of Ceylon and India, placing as it does a premium upon cheap China teas." In the result the composite duty on Tea was abolished in favor of a fixed duty on Tea of 8d. per lb. bulk and 4d. per lb. packets.

RUBBER PLANTING IN BURMAH.

Your Committee having received information that the Government of India was taking steps to develop the cultivation on a large scale of Rubber producing trees in Burmah, notably the Para Rubber Tree *Hevea brasiliensis*, Moll, Arg., in the Tenasserim division of Burmah, resolved to bring the question under the consideration of His Majesty's Government. In a memorial to the Secretary of State on the subject it was pointed out (I) that an authoritative statement that the Government of India had no intention of placing Rubber on the London market nor competing with private enterprise by large operations would tend to remove any cause for alarm, and (II) that there appeared to be no necessity for an extensive experimental cultivation of five thousand acres because the successful planting of Para Rubber in suitable climates is already assured. Your Committee regrets to report that the reply received must be considered distinctly disappointing in as much as it exhibits a want of sympathy with the legitimate claims of private enterprise to due consideration and an assurance as desiderated.

PERIODICAL TOURS OF SCIENTIFIC OFFICERS, AND CONNECTED MATTERS.

Your Committee has pleasure in again bringing under notice the periodical tours of scientific officers of the staff at the Royal Botanical Gardens, Peradeniya, and to the interesting papers read at various District Association meetings during the year as well as to the discussions that took place. The idea continues to recommend itself as a happy one which it is hoped will continue to expand, thus bringing scientific research and practical working in agricultural operations into yet closer touch with the best results.

ANALYSIS OF MANURE.

ORDINANCE No. 12 OF 1901. AN ORDINANCE FOR REGULATING THE SALE OF MANURES OR FERTILIZERS OF THE SOIL.
Your Committee is glad to be able to direct attention to the Ordinance above mentioned which may be cited as the Fertilizers Ordinance 1901 which came into operation on the 1st of January, 1902. The regulations under section 9 of the Ordinance made by the Governor with the advice of the Executive Council were published for general information in the "Ceylon Government Gazette" No. 5816 of November 6th, 1901, and copies were circulated to the various District Associations. They relate chiefly to the proceedings and regulations with general directions as regards samples of the fertilizers. Your Committee has lately, on the invitation of His Excellency, submitted for approval the name of Mr. Elwyn Barber as analyst under section 5 of the Ordinance No. 12 of 1901.

VISITORS TO HOSPITALS AND DISPENSARIES IN THE PLANTING DISTRICTS.

Without anything special to mention your Committee is glad to know that these appointments continue to prove useful and beneficial. Quoting from His Excellency's address on opening the session of the Legislative Council for 1901, your Committee records with satisfaction the following sentence:—"Many necessary advances have been made during the year to dispensaries and hospitals, and it is expected that the new hospitals for Matarata, Pussellawa and Dimbala and the Infectious Diseases Hospital at Nuwara Eliya will be finished by the end of the year."

PLANTERS' WARD AT THE GENERAL HOSPITAL, COLOMBO, AND AT THE BAKER WARD, NUWARA ELIYA.

Your Committee would convey an expression of thanks to the Principal Civil Medical Officer and through him to those immediately in charge of the wards, for the attention and care bestowed upon Planters in these wards during the past year. The following is the Official Return of Planters who availed of the Planters' Ward, Colombo, and the Baker Ward, Nuwara Eliya, during the year 1901:—

Hospital Ward.	Number remained on 31st Dec. 1901.	No. admitted during 1901.	No. discharged.	No. remaining on 31st Dec. 1901.
Planters' Ward, Colombo	4	43	47	4
Baker Ward, Nuwara Eliya	1	15	14	1
Total	5	58	61	5

PUBLIC WORKS.

In the annual report of your Committee for the year ending 17th February 1901 reference was made under this head to the work of the new survey which included the Northern, Uda Pass, Uva and Kelani Valley Railways, and Irrigation Schemes, which were estimated to cost Rs. 20,540,000, half of the whole estimated cost amounting to Rs. 10,270,000, half of which was to be provided by loan and half from the surplus Revenue of past and future years, and it was shown that at that time, the cost of the Irrigation works of Rs. 20,000 per annum, a sum of Rs. 2,000,000 remained to be provided out of revenue.

This sum has now been provided, as the following quotation from His Excellency the Governor's address to the Legislative Council at the opening of the Session of 1901/02 on the 18th October, 1901, will show:—"Last year I drew attention to the large liabilities which we had incurred on account of the very extensive scheme of Railway and Irrigation Extension sanctioned by the Secretary of State, of which the cost was estimated at Rs. 20,640,000. Of this amount, one-half was to be met from borrowed money and one-half from past and future savings from General Revenue. I then expressed the hope that the whole of this liability—[I mean the sum of Rs. 10,320,000 to be found out of revenue—] would be discharged in 1902 or perhaps in 1903. My anticipation has been more than realized, for the correspondence with the Secretary of State, which will be submitted to you, will show that the balance can be met out of the surplus for 1900, and accordingly that the liability is fully discharged. You are now free from debt on this account and the surplus of this and succeeding years will again be at your disposal. I congratulate you on this happy issue of a vexatious controversy. It dissipates many gloomy anticipations and justifies the views and arguments with which I commended to you this great policy of progress." During the year the Commission on the cost of Public Works continued its sittings and its report has been published as sessional paper No. XXXIII, 1901. A good deal of valuable information has been made, most of which have met with the Governor's approval, and will be acted on. One important recommendation was that the grant-in-aid principle should be extended to a cheaper class of roads than had been permitted under the old ordinance, and it is understood that an ordinance to carry out this recommendation is now under consideration. The subject of the taking over of grant-in-aid roads as main roads has not been lost sight of, but as it is to be referred for the consideration of the Commission on the Incidence of Taxation nothing further can be done until that Commission commences its sittings. The expenditure on Public Works extraordinary was considerably cut down when it became apparent that the revenue of 1901 was likely to show a falling off, and by the omission of certain works not of a very urgent nature only about Rs. 1,765,000 will have been spent out of the estimated Expenditure of Rs. 1,850,120. For the new year the estimate of expenditure on Public Works extraordinary is Rs. 1,847,072, and on annually recurrent works Rs. 2,043,815. This is exclusive of the expenditure by the Irrigation Department which is now in full swing and has an estimated expenditure of Rs. 1,240,187 principally chargeable to surplus funds.

REDUCTION OF TELEGRAM CHARGES BETWEEN THE UNITED KINGDOM AND THE EAST.

In continuation of the paragraph in last year's Report it is interesting to note that a reduction is now definitely spoken of from 4s. 2d. to 2s. 6d. per word on cable rates to the East and that effect may shortly be given to this new departure in the right direction.

CEYLON PLANTERS' RIFLE CORPS.

Adverting to the paragraph in last Annual Report recording the establishment of a Rifle Corps your Committee congratulates all concerned on the progress since made and places as appendix F hereto for perusal and reference the latest authoritative information regarding the corps as to regimental organization and equipment.

CEYLON CONTINGENT OF MOUNTED INFANTRY.

It will be remembered that His Excellency the Governor remarked in addressing the Legislative Council:—"From our small European population we raised a contingent of 180 young men, well mounted and fully equipped, to represent the Crown Colonies among the armed levies which the self-governing Colonies were despatching to the seat of war. Our contingent—too few in numbers—has been cruelly decimated by disease, but those who remain have been in the forefront of the fighting and we have the testimony of the Commander-in-Chief, spontaneously offered, that they have rendered excellent service."

In addition to and in continuation of other references in previous Annual Reports your Committee has the honor to record that during the Royal visit to Kandy in April, 1901, His Royal Highness the Duke of Cornwall presented the King's Colour now domiciled in the Victoria Commemoration Buildings to the Officer Commanding the Ceylon Mounted Infantry and distributed Medals to the Members of the Ceylon Contingent who had returned to the Island. The words of the Prince were:—"A very pleasant duty has been deputed to me by the King. It is to present His Majesty's Colour to the Ceylon Mounted Infantry and to confer the South African War Medal upon those of the Regiment who have taken part in that campaign. I confide to your keeping this Colour, not only as a record of past services but as an emblem of loyalty and patriotism, round which you may rally whenever the occasion shall arise to afford your services to the defence of the interests of the Empire. I regret that as hostilities yet continue, many of your comrades cannot be present here today. There are some who, alas, can only be here in memory. We heartily sympathize with all who mourn for dear ones such as Lieut. Thomas, one of three brothers belonging to an old and respected planter family, and others who laid down their lives or sacrificed their health in following the call of duty. I take the opportunity of acknowledging the valuable services rendered by the planters. They not only sent a large number of Volunteers to the Front but formed themselves into a Rifle Corps, which I am glad to say is represented here today, for the protection of your own shores against a possible foe."

CEYLON ASSOCIATION IN LONDON.

During the year the action of the Ceylon Association in London in correspondence with your Association has been alike practical and beneficial. Your Committee rests assured that cordial co-operation and a good understanding will always be maintained if possible on both sides and that in this as in other matters conspicuous regard will be rendered to the motto "Unitas Salus Nostra" in the interests of all in any way connected with the great Agricultural enterprise of Ceylon.

REPRESENTATIVE IN THE LEGISLATIVE COUNCIL.

To the Hon. Mr. J. N. Campbell an expression of the cordial thanks of your Association is again conveyed for his watchful and greatly appreciated services as Planting Representative in the Legislative Council during the past year.

DISTRICT ASSOCIATIONS.

There are now, your Committee is glad to report, twenty-six District Associations as compared with ten District Associations during the year ending 17th February, 1892. In no mere form of words an expression of thanks is herein tendered to the Officers and members for willing co-operation and courteous attention to the various demands made during the year in connection with planting and connected matters.

BAKER MEMORIAL.

In the Annual Report for the year ending 17th February, 1897 and 1898 respectively, reference was made to the munificent gift by the late Mrs. Baker of the Planters' Ward at Nuwara Eliya and to the proposed Window in Holy Trinity College, Nuwara Eliya, to perpetuate her memory, it is satisfactory therefore at length to be able to report that the work has now been completed. The three lights in the East Window of the Church representing the Annunciation, the visit of the wise men and the raising of Jarius' daughter are those on which the subscribers' money has been expended amounting to Rs. 1,503.95 inclusive of Erection and also the Enlarged Photograph of Mrs. Baker placed in the Victoria Commemoration Buildings, Kandy.

PLANTERS' BENEVOLENT FUND.

ESTABLISHED TO COMMEMORATE THE JUBILEE OF HER MOST EXCELLENT QUEEN VICTORIA 1837—1887.

Though the aggregate of Donations and subscriptions collected by the Honorary Treasurer of the Fund during the year 1901 is less than usual, amounting to Rs. 112.27 and Rs. 2640.00 respectively, this is largely accounted for by those who are "Patrons" annually and by the removal or decrease of old subscribers, while Donations naturally are more or less exceptional and can hardly be looked upon as a steady factor in calculating annual revenue. During the year 1900 a considerable sum was collected as arrears of subscriptions for previous years which thus increased the total for that period of twelve months. When these incidents and adjustments are looked into it appears that the position of the fund has been maintained notwithstanding the fact that in view of the times and the many demands made on planters no special

effect was given to the general recommendation of the subscribers, that an application be sent direct to the members of the Planters' Association of Ceylon on a form to be drawn up. The disbursements from the "Fund" in the form of grants to those in need of assistance have aggregated Rs. 1926.18 during 1901 while the interest on investments amounted to Rs. 1829.80 Indian Government 3½ per cent paper was purchased during the year to the value of Rs. 8,000.00, other investments remaining as before. Your Committee would again cordially commend the Planters' Benevolent Fund to all Planters and would invite every one either by annual subscription or donation to co-operate in building up the Fund so as to permit of its beneficent action being kept up and extended in the future.

VISIT OF THEIR ROYAL HIGHNESSES THE DUKE AND DUCHESS OF CORNWALL AND YORK IN APRIL, 1901.

An event unique in the History of Ceylon—and not Ceylon alone but also His Majesty's Dominions beyond the seas—has to be recorded in the auspicious and ever welcome visit of Their Royal Highnesses the Duke and Duchess of Cornwall and York, now Prince and Princess of Wales. It will be remembered that Their Royal Highnesses broke their journey and visited Kandy en route, as the Princess said, "To preside at the first representative assembly of the Australian Commonwealth," and there can be little doubt, as has been well remarked, that one result of the Prince's journey will be to systematise and make more businesslike the bonds uniting the Empire. An Address of Welcome on behalf of the Association was presented to His Royal Highness at the King's Pavilion, Kandy, on the 18th April to which the Duke graciously replied. The Address was placed in a beautiful Casket of Ivory set with Ceylon gems of value, and it is hoped may be regarded as a Memento of the visit to Ceylon by the Prince and Princess in years to come. From the Duke's eloquent words then spoken the following might be engraved as alike of admonition, encouragement, and aspiration:—"I feel sure you are fully alive to the necessity in these days of keen competition of maintaining the same high standard of skill and energy for keeping and extending the position you have secured. I much regret that at the present time your prospects are not so bright as usual. I earnestly trust that this depression is but temporary; and I shall watch with interest for an early revival of prosperity, which you so well deserve. I thank you for the language in which you refer to the important mission with which I have been entrusted by my dear father, and for your wishes that it may serve to knit even closer the ties of affection which bind together the Empire over which His Majesty rules. I shall not fail to convey to him your expressions of loyalty and attachment to his throne and person, and of your reverence for the memory of our late beloved and universally mourned Sovereign."

GEORGE WALL REFERENCE LIBRARY AND TOWER.

The thanks of your Association is herein recorded to Government, kindred Institutions and other donors for valued contributions to the Reference Library in the past year. It is well remembered how small was the beginning made twenty years ago as mentioned in the Annual Report for the year ending 17th February 1882 in the direction of a more convenient arrangement of a few books then belonging to the Association and a more comfortable Reference Reading Room, for publications, Reports and Newspapers. Your Committee is glad to again report progress and that the Collection now styled "The George Wall Reference Library and Tower," is firmly established and is likely to increase in usefulness, interest and importance hereafter.

OBITUARY.

To the Roll of deceased Members of the Planting Community has to be added with much regret the following:—W. Beattie, C. C. Bell; Alexander T. Brown; John Cameron; Wm. D. Evans; P. O. B. Horsford; Wm. Keith; H. P. Marshall; T. J. Martin; A. Orchard; T. N. Orchard; A. A. Pillans; J. M. Smith; L. C. White; W. Boyd; A. H. Hopkinson; F. D. Lloyd; Fred. Pulley; H. P. Shakerley; John Stuart; A. H. Bisset; J. B. S. D'Aguiar; Stanley Ross; C. Campion; Jas. G. Macfarlane; Norman Smellie; E. Kensington; Geo. S. Duff; H. B. Carrick; Wm. Robb; J. Hodgson; W. Sandys; Thomas; W. J. S. Scott; P. B. Whitaker; E. Kensington.

FINANCES.

In laying on the table the Accounts of your Association for the year made up to 31st January, 1902, it is satisfactory to state that the balance remaining at credit is Rs. 3,186.20. The record of the year has been one of investigation, development and progress. Interest in the work of the Planters' Association continues to increase, while the value of its organization to producers has been again apparent and it is believed appreciated. It is certain that in the future the extended usefulness and operations of your Association will be further demonstrated, and your Committee in resigning office would urge on Proprietors and all interested in the agricultural prosperity of Ceylon the importance of prominent and practical support with cordial consideration at all times to proposals submitted having in view the advancement and continued prosperity on the great planting enterprise.

APPENDIX A.

General Export from the Island of Ceylon in the year 1901.

H. M. Customs, Colombo, 20th January, 1902. W. H. JACKSON, Principal Collector.

REPORT OF THE THIRTY COMMITTEE.

Report of the "Thirty Committee" appointed to administer the proceeds of the Export Duty on Tea, levied under Ordinance No. 4 of 1894 for increasing the consumption of Ceylon Tea in foreign lands for the year 1901.

MEMBERS OF THE "THIRTY COMMITTEE," 1901.

The following is the list of the "Thirty Committee" at 31st December, 1901. Messrs. James Westland, J. A. Burmester, A. C. Kingsford, J. B. Coles, Hon. Mr. J. N. Campbell, Geo. Kent Deaker, Alex. Wardrop, Wm. Saunders, R. A. Galton, H. O. Hoesason, Gordon Pyper, W. D. Bosanquet, T. C. Huxley, Wm. Forsythe, A. Philip, J. P. E. Ryan, Joseph Fraser, W. B. Tatham, E. D. Harrison, R. S. Duff, Tyler, W. D. Gibbon, Edward Rosling, Oliver Collett, Keith Rollo, Geo. Hathorn, G. F. Trull, R. S. Temple, Hon. Mr. W. Henry Figg, Duncan Skrine, Stanley Bois.

For part of the year Messrs. H. A. Tittle and E. H. Hutchinson were members.

FINANCES.
The total collections paid into the Ceylon Tea (New Markets) Fund on account of the Export Duty on Tea from January 1901 to 31st December 1901 amounted to Rs. 292,542 29. The balance in the Bank brought forward from 1900 was Rs. 82,000 98. The usual summary of accounts for the half-yearly periods ending 30th June 1901, and 31st December 1901, with various connected statements of Charges and Discharges are appended.

MINUTES OF PROCEEDINGS.
The Minutes of Proceedings of the Meetings of the "Thirty Committee" have been as usual forwarded to Government for information and guidance after confirmation.

GOVERNOR IN EXECUTIVE COUNCIL.
The approval of the Governor in Executive Council was obtained to the following appropriations of the proceeds of the levy as from time to time desired and determined by the "Thirty Committee" during the year.

- Credit opened for—
- 1.—Representative in America. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 3rd February 1901, for advertising Ceylon tea in America during 1901, £8,000 sterling at exchange 1/4 per rupee ... Rs. 120,000 00
 - 2.—Ceylon tea on the Continent of Europe. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 10th January, 1901, for the purpose of payments under the scheme ... " 20,000 00
 - 3.—Ceylon Green Teas 1900-1901 scheme. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 18th February, 1901, for the purpose of payments under the scheme ... " 30,000 00
 - 4.—Ceylon Green Teas 1900-1901 scheme 5 cents basis. Amount sanctioned by the Governor in Executive Council per letter dated 4th June, 1901, (vide also resolution of the "Thirty Committee" 14th July and 15th September, 1900) ... " 20,000 00
 - 5.—Amount sanctioned by the Governor in Executive Council per letter dated 30th September, 1901) ... " 80,000 00
- In connection with the grant fixed at five cents per lb. for the second million pounds in terms of the resolution passed by the "Thirty Committee" on the 14th July, 1901 ...

The Grand total of Rs. 1,708,041 91 has been levied since 1895 as under.

30th June, 1895	Rs. 142,874 64

REPRESENTATIVE IN AMERICA.
The Remittances made to Mr. Wm. Mackenzie from 1st January 1900, to 31st December, 1901, were as under.

	£	Rs.
February 18th to Remitted to Mr. Mackenzie	2,000	29,767 44
April 9th do.	2,000	30,058 71
June 13th do.	2,000	30,000 00
September 25th do.	1,500	22,588 23
December 11th do.	2,000	30,000 00
1901		
February 25th do.	1,000	15,000 00
May 14th do.	1,000	15,029 85
May 28th do.	1,000	15,058 82
July 19th do.	1,000	15,058 82
September 9th do.	1,000	15,000 00
October 4th do.	1,000	15,000 00
November 12th do.	1,000	15,000 00
December 23rd do.	1,000	15,000 00
		Rs. 262,561 87

Up to 31st December, 1899, the amount remitted to Mr. Wm. Mackenzie for pushing, advertising and making known Ceylon tea in America aggregated Rs. 811,862 11, making a grand total of Rs. 1,081,862 11 placed at the disposal of the Representative in America from 1891 onwards. As regards the results of the Campaign opinions may doubtless differ, but as affording useful data in the matter the following is quoted from recent remarks of leading London brokers under date 29th November, 1901.

There has been considerable progress in the quantity of Indian and Ceylon tea taken in North America during the last nine months, as compared with the same period of 1900, the increase amounting to nearly 40%. Re-exports from this country have also materially increased.

It is noteworthy that 1,276,868 lbs. of all tea were sent from America to this country between 1st January and 27th November, but there is reason to believe that much of this was China tea, while a portion of the tea sent from Ceylon to China may possibly have been for the Russian Market, although the majority has doubtless gone to America.
