Oil of "Petitgrain Portugal" is got from the leaves of the sweet orange tree, generally called "Portugal."

Rosemary grows in fine bushes, wild, on the mountains of Southern France. It is also cultivated as an ornamental plant, and distilled nearly the whole year through; but the best quality is obtained in May. 150 to 200 kilos of leaves yield 1 kilo of oil.

Rose. The culture of roses in the neighbourhood of Grasse has taken an enormous development. The firm of Lautier fils works up nearly 100,000 kilos every year for manufacturing pomades, scented oils, and rose water. 10,000 kilos of roses produce hardly 1 kilo of essential oil. This oil is green, and has greater consistence than the oriental otto. The roses grown here are mostly distilled for the sake of rose water.

Rue (*Ruta graveolens*) grows in abundance in the neighbourhood of Grasse. The leaves require to be handled with the greatest care, or they provoke painful swellings. 150 to 200 kilos produce 1 kilo of oil.

Savin Oil is obtained by distillation of a bush (*Juniperus sabina*), which grows in the southern regions of France; 300 to 400 kilos give 1 kilo of oil.

Sage (*Salvia officinalis*) grows wild, but is cultivated also, in the environs of Grasse. It is distilled in September. About 300 kilos produce 1 kilo of oil.

Thyme, or Serpolet (*Thymus serpyllum*) is distilled in July and August. From 400 to 500 kilos 1 kilo of oil can be got.

Red Thyme (*Thymus vulgaris*) grows wild on the mountains of the Mediterranean coast; it is distilled during nearly the whole year, but chiefly from May to August, when the plants yield the most and finest oil. About 300 kilos are needed for 1 kilo of oil.

White Thyme Oil is the result of rectification of the red oil of thyme.

Verbena is cultivated in the gardens of Grasse and distilled in August.

The following flowers are not distilled, but their perfume is extracted by enfleurage:—

Jasmin flowers are gathered from July to October from a little bush cultivated in the gardens of Grasse. It is very sensitive to temperature and ground, and requires much care and watchfulness. The more the plantations are exposed to the sun the more powerful is the perfume of the flowers.

The Tuberose blooms in the same season. The culture gives a good deal of trouble, as every year, in November, the bulbs must be taken out, to guard them from humidity and cold, and replanted in April. The produce in good years reaches 2500 kilos per hectare.

The Reseda (*Mignonette*) plant is delicate, and the crops fail often in consequence of late colds. Mignonette is sown in December and commences flowering in March. The flowers gathered in March and April give the finest perfume.

The Jonquille blooms in March. The flower, of a fine bright yellow colour and sweet odour, is worked in the same way as the jasmin and tuberose flowers, by the "cold enfleurage process." Tables of glass in wooden frames are spread over with fat and the flowers strewn upon them. These frames are piled up, so as to form columns of about a man's height. The flowers are renewed daily until the fat has taken a sufficient degree of perfume.

The Violet employed in perfumery is the so-called double variety. It is cultivated on a large scale in the shadow of the olive trees which cover the territory of Grasse. The flowers are gathered in February and March. The harvest is subject to climatic influence, and varies much, for while in some years more than 100,000 kilos are brought in, not even the fourth part of that quantity is the result of other crops.

The Lily of the Valley and the Narcissus grow wild in the environs of Grasse. The former is gathered in February and March, and the narcissus in April. The pomades prepared with these flowers are very useful to the manufacturing perfumer.

Cassie is a gold-coloured, sweet-smelling flower, gathered from a small tree (*Acacia Farnesiana*) which adorns, in large quantities, the declivities on the sea-side. The tree begins to give flowers about the end of August, and continues, the weather being favourable, until the end of the year. The operations on this flower conclude the Grasse perfumery season.

On behalf of the North of France, M. Hanart, of Auzin (Département du Nord), asserts the superiority of the essential oils there distilled from labiate plants. But M. Hanart's operations also extend to other orders, for in his case he exhibits a specimen of pure oil of roses, in a bottle of about three ounces capacity, which is said to be the product from about 24 cwts. of petals, or about 12,000 flowers. The soil in one part of the Auzin district is sandy and is said to have been found most suitable to the cultivation of aromatic plants, since, although they attain a less vigorous growth than in richer and moister soil, they are much more aromatic, and the essential oil developed in them is considered to have a more delicate odour.

The cultivation of peppermint and the distillation of the oil is now carried on in the Auzin district to a considerable extent. An acre of land produces annually from three to four tons of the herb. The crop is cut in the full sunshine during the month of May, made up into little shocks, and left on the field several days. After all admixtures of other herbs have been carefully removed the entire plants are packed into the still,—which in M. Hanart's establishment are heated by steam jackets or spirals and are of about 66 gallons capacity,—and distilled as rapidly as possible in order not to acquire a herbaceous taste. Five hundred parts by weight of the herb yield about one part of a colourless or greenish-yellow oil, having a very agreeable piquant odour. This is purified by several washings with cold water and by exposure to the air during some weeks in a cool dark place. After this it is rectified and then kept in bottles, secluded from light and air, for some years before being sent to market. The oil of peppermint so prepared is alleged to successfully rival the English oil both as to quality and price.

The "mélisse citronelle" (*Melissa officinalis*) is distilled here to obtain a water, but this plant yields scarcely any essential oil. On the contrary, the Moldavian balm (*Dracocephalum Moldavicum*) yields about one-eighth per cent. of a strongly aromatic and very agreeable essential oil. This product is said to be hardly known in commerce, that usually sold under the name of "essence de mélisse" being obtained from an Indian species of *Andropogon*.

The case of M. Robertet, of Paris, is not only rendered very attractive, but its interest is increased, by the exhibition with each specimen of essential oil of the part of the plant from which it is produced. Thus, with the oil of neroli are some nice fresh looking orange flowers, with oil of petit grain some orange leaves; and the sources of the oils of lavender, geranium, fennel, rosemary, etc., are similarly illustrated. The lavender shown ("lavande du Piemont") is one with a very small spike, few flowered, and having large rhomboidal bracts. M. Robertet also shows a fine specimen of solidified oil of roses. Messrs. Saujot and Foucher, of Paris, exhibit concrete oil of orris, of a fawn colour. Among other first products for perfumers, scented vaselin is shown by Messrs. Roure-Bertrand fils, of Grasse, and scented paraffin, in large cubes, for the manufacture of pomades, etc., is shown by Messrs. Chardin and Massignon, of Paris.

There are several other French exhibitors in this class, and a great variety of essential oils are shown, but the foregoing will be a sufficient indication of the nature of the display. Of the toilet perfumery, such as soaps, eau de cologne, and other aromatic waters, cosmetics, pomades, and other preparations for the hair, dentifrices, etc., there are upwards of a hundred exhibitors, who well sustain the reputation of the French manufacturers for these articles.

In recent years the manufacture and commerce in the essences adapted for perfumery have attained considerable development in Algeria, chiefly in the province of Algiers; and Blidah, Boufarik, Cheragas, Mostaganem, Bône, and Philippeville are now first-class centres of the industry. Of the plants used those of the orange family are the most important; from these are prepared the essences of petit grain, bigarade, cédrat, portugal and lemon and orange-flower water. Among the other plants cultivated in Algeria for perfumery are the jasmin, cassie, rose, tuberose, verbena, peppermint, etc.; but the plant most largely cultivated is the rose geranium (*Pelargonium roseum*), which grows with marvellous rapidity and yields an essential oil that is said to be much used as a substitute for the high priced oil of roses.

At La Trappe de Staouëli, some little distance from the bay of Sidi Ferruch, the cultivation of the geranium extends over 16 hectares (about 40 acres). Three harvests are gathered every year, and each yields from 170 to 200 kilograms of oil, or equal to from 500 to 600 kilograms per annum. The value of this product never falls below 40 francs the kilogram, the average gross value being therefore from 20,000 to 25,000 francs, or at least £20 per acre. Seven distillatory apparatus are employed in this manufactory.

At Boufarik there is another large manufactory, belonging to Messrs. Chiris and Gros, where the aromatic plants grown on about 300 acres of land

are submitted to distillation in twenty stills that are worked day and night during four months of the year.

Besides these cultivated plants are used the thyme, lavender, wormwood, myrtle, rosemary, fennel, sage, sweet marjoram, and pennyroyal, which grow spontaneously without cultivation.

The greater part of the products manufactured, and a large quantity of geranium flowers, are sent to Grasse; a portion goes to Paris and other French cities, and some reaches Germany and England.

Besides the exhibitors mentioned there are others who display essential oils in the Algerian department, among whom may be mentioned Messrs. Nielli frères, of Philippeville, and M. Parodi. In the case of the latter are specimens of the oils of celery, citron leaves, orange leaves, myrtle, *Lavendula Stœchas* and *L. dentata*, which differ in odour from true lavender. Orange-flower and rose geranium waters are to be seen here in copper vessels, a custom that obtains also in Morocco.*

Of the other French colonies, although most of them exhibit, as has been noticed, raw materials suitable for the preparation of perfumery, the only one in which any manufacturing operations are carried on appears to be New Caledonia. In this island there is a small distillery connected with an agricultural penitentiary, in which the labour of the convicts is utilized in the production of essential oils. Specimens of those from *Andropogon citriodorum*, *Melaleuca viridiflora*, eucalyptus, and a kind of dammar are exhibited.

Tonka beans occur in the French Guiana and Martinique departments; patchouli leaves are shown from Martinique and Réunion; the wild canella (*Laurus cupularis*) from Réunion and French Guiana, the latter sending as well an odoriferous bark from *Humiria balsamifera* and "vanille des bois" (*Vanilla pompona*). Martinique shows also the odorous flowers of *Acacia Farnesiana* and those of *Uvaria longifolia*, and the seeds of *Hibiscus abelmoschus;* also an essence of lemon peel that could be supplied at about three francs the litre. Cochin China exhibits eagle wood (*Aquilaria malaccensis*), from the nodosities that form on the base of the broken branches of which tree is prepared a perfume known in that country as "tram-toc," and fetching 34 francs the kilogram in the Saigon market; also sandal wood (*Santalum album*), vetiver (*Andropogon squarrosus*), and another much esteemed perfume called "tram-huong."

In the British department the exhibition of perfumery takes more the form of articles for the toilet, though some of the exhibitors, for instance, Messrs. Piesse and Lubin and E. Rimmel, are known to carry out distillatory operations on a large scale. Mr. Rimmel exhibits an apparatus for extracting instantaneously the aroma from flowers without distillation, maceration, or enfleurage, apparently by percolation under pressure of a column of liquid. Good selections of essential oils are exhibited by Messrs. Atkinson and Co., Bush and Co., and Burgoyne, Burbidges and Co., and among the other displays worthy of notice are those of the Crown Perfumery Company, Messrs. N. Price and Co., Messrs. Cleaver and Co., and Messrs. Yardley and Co.

Not very many exhibits of perfumery are to be found in the English colonies; in fact they are nearly confined to Victoria and Queensland. An immense number of myrtaceous trees and shrubs, belonging to the genera *Eucalyptus*, *Leptospermum*, and *Melaleuca*, all containing essential oils, flourish throughout Australia; whilst some species of *Acacia* also yield flowers from which perfumes can be obtained. But the distillation of perfumes is at present in a state of infancy even in these colonies. Mr. Bosisto, of Melbourne, exhibits the oils of *Eucalyptus amygdalina odorata*, *Stuartiana*, *obliqua*, *fissilis*, and *sideroxylon*, to illustrate the variety of odours existing in the eucalypti. Besides these he shows an otto of *Melaleuca ericifolia*, a spirit of *Acacia pycnantha*, obtained from the flowers by enfleurage, and oil of peppermint distilled from the herb cultivated in the colony. From Queensland the authorities of the Botanical Gardens send an "essence of verbena," obtained from the scented iron bark, an unnamed species of *Eucalyptus*; essence of jasmin; essence of acacia (*Acacia Farnesiana*); oil of orange from *Citrus aurantium*, and "oil of lemon" from *Eucalyptus citriodora*.

In Austria there is now a considerable production of articles of perfumery, the manufacture of the toilet portion having its principal seat in Vienna, and there are several good exhibits of fancy soaps, among which may be mentioned that of the well-known house of Sarg and Co., of that city. But the essential oils shown come principally from Moravia, where distillation, especially of umbelliferous and composite plants, is carried on to a large extent. Messrs. Klepetar and Co., of Brunn, exhibit the oils of anise, caraway, coriander, fennel, wormwood, millefolium, mustard, tansy, calamus, birch, and juniper, obtained from plants grown in the district. Two kinds of oil of fennel are shown, one called "oleum fœniculi natur.," described as being obtained by redistillation of the crude oil to separate it from the other, "oleum fœniculi stearopt.;" the latter heavier oil is said to correspond in softness of flavour and specific gravity to oil of anise, whilst it is much lower in price. The oleum millefolii is obtained by careful distillation of the flowers of the common yarrow (*Achillea Millefolium*), which grows wild abundantly in Moravia. The product has an intensely blue colour, similar to that of the German oil of chamomile, and is said to be frequently sent into commerce under that name, a fact that finds an explanation in its being much lower in price. The *Acorus calamus* and *Artemisia Absinthium* also grow wild in the Moravian woods, and a large number of poor people find employment in collecting them. The oil of birch is employed among other ways for giving the peculiar odour to Russian leather. The same firm shows the artificial oil of mustard, various compounds for liqueurs, and a series of artificial fruit essences.

Another Moravian firm that exhibits similar products is Messrs. Haas and Rosenfeld, of Gaya, and the figures supplied by them give an indication of the importance of this industry, they having during the year 1877 produced about five tons of oil of anise from native seeds, three and a half tons of oil of fennel, upwards of a ton of oil of caraway, etc. A large quantity of cherry, raspberry, and other juices is also pressed from fruit grown in the neighbouring vineyards. Messrs. Haas and Rosenfeld report that some experiments made with a view of obtaining the essential oils by extraction with carbon bisulphide were unsuccessful. It was found that

* See figure in *Pharm. Journ.* [3], vol. iii., p. 625.

the loss of carbon bisulphide was considerable and that after being once used it could only be employed on the same material afterwards, whilst the yield of oil was diminished and could not be entirely freed from the disagreeable smell of the solvent.

Caraway oil, water, and liqueur are also sent from the Tyrol, where the plant grows wild, by Herr Uberbacher, of Bozen. This exhibitor is one of a class who deal in all kinds of agricultural products. Hence in the same case are to be found mountain honey, of a golden yellow colour; Venetian turpentine, from the *Larix europœa*, clear and almost colourless, said to have a faint lemon odour, bitter taste, and to yield 25 per cent. of oil; pitch; different kinds of sumach and the root bark of the berberis for dyers; and pine pitch, used by the German brewers to pitch the insides of their barrels, and said to be the origin of the peculiar flavour characteristic of some continental beer.

Prague is also a seat of the perfumery industry, and a very good display of raw materials is shown by Herr Demartini, including purified fats, purified wax, poplar buds and an oil obtained from them, and rose water drawn from Bohemian roses.

In the Italian court there are several exhibitors of essential oils from the genus *Citrus*. Messrs. Locaria, of Reggia, Calabria, show oil of bergamot, obtained by hand and by machine pressure and by distillation, and the oils of lemon, portugal, and bitter orange, bigarade, citron, mandarins, and lime. Similar oils are also exhibited by two or three firms from Messina.

There is nothing remarkable in the perfumery shown in the Spanish, Norwegian, Swedish, or Netherlands departments, and very little in that of Russia, the principal products being the oils of anise, wormwood, cumin and mint. But many of the exhibits in the Russian department were still unnumbered and unlabelled, several weeks after the opening of the exhibition, whilst such labels as were to be seen were unintelligible to the majority of the visitors.

In the United States department Messrs. Hotchkiss, of New York, exhibit their oil of peppermint, which has now acquired a considerable reputation, together with the oils of spearmint, wintergreen, tansy, wormwood, and sassafras. Messrs. Fritsche Bros., of New York, also exhibit a "twice rectified" oil of peppermint. Lastly, Messrs. Mackesson and Robbins, of the same city, exhibit the essential oils of peppermint, spearmint, wintergreen, sassafras, chenopodium, tansy, American pennyroyal (*Hedeoma pulegioides*), and erigeron. Another exhibit from the North American continent worth notice is the oil of lignaloe, or "bois de rose," to be seen in the case of Mr. Delpech, of Cuantla, Morelos, Mexico.

FLUID EXTRACTS BY REPERCOLATION.*

BY EDWARD R. SQUIBB, OF BROOKLYN.

(*Continued from page* 186.)

For the purposes of this paper as a model, and to construct the following table, the percolate from the first five percolations of this series was divided into much smaller fractions than is directed in the process or needed in actual practice, leaving for a subsequent table the model for actual practice. The fractions of the first five were somewhere near 2 parts or 2 ounces each, =56·7 grams. It was not easy to get them uniform in weight, and therefore this was not attempted. Each fraction was shaken up and accurately weighed. Then about one cubic centimetre was measured off into a tared shallow watch glass, and quickly weighed to avoid loss by evaporation. These weighed portions were then dried by steam heat until they ceased to lose weight, and the residue carefully weighed. This gave the data for calculating the total residue which each fraction would give if the whole fraction had been evaporated. But a large proportion of this residue was glycerin, and it was sought to get at the extract only. So a cubic centimetre of the menstruum was weighed and evaporated in the same watch glass until it ceased to lose weight under the same conditions, and it was found that the residue weighed 16 per cent. of the weight of the menstruum. This was an unexpected result, for as the menstruum contained 20 per cent. of its weight of glycerin it was to be expected that upon evaporation very nearly this proportion would remain on the watch glass. Therefore the trial was three times repeated, and the mean of the trials was within a very small fraction of 16 per cent., showing that about 4 per cent. of the glycerin went off with the alcohol and water. This gave the remaining element for closely approximating the extract in each fraction by the following formulæ. As the weight of the cubic centimetre taken from each fraction of percolate is to the weight of the residue after evaporation, so is the weight of the entire fraction to the weight of the residue it would leave on evaporation. But had this fraction been menstruum instead of percolate, and been evaporated under the same conditions, it would have given 16 per cent. of its weight of glycerin as a residue. It was therefore assumed (though of course not correctly) that 16 per cent. of the entire fraction was glycerin. Then 16 per cent. of the weight of each fraction was taken and this amount was subtracted from the calculated residue of the fraction, and the remainder was assumed as dry extract of cinchona. Next, as these fractions were not uniform in weight, the assumed extract did not represent a uniform proportion and rate of exhaustion. To show this rate of exhaustion better a second proportion was made to represent it by percentage. As the total weight of the fraction is to the weight of extract obtained from it, so is 100 to the percentage of extract it contained. For example: The first fraction of the table weighed 62·72 grams; one c.c. of this fraction weighed 1·062 gram; this, dried on a watch glass, gave a residue weighing ·488 gram; then, as 1·262 : ·488 : : 62·72 : 28·82. But this 62·72 grams is assumed to give 16 per cent. of its weight of glycerin which does not go off by evaporation or (as 100 : 16 : : 62·72 :) 10·04 grams glycerin: and 28·82 residue less 10·04 grams glycerin leaves 18·78 as the approximate dry extract contained in the fraction of 62·72 grams of percolate. Then if 62·72 percolate give 18·78 extract, 100 percolate would give 29·9 extract, equal the percentage of extract contained in the fraction of percolate.

The remaining column of the table gives the difference in specific gravity, at similar temperatures, between the menstruum and the various fractions of the percolates, and this also illustrates the rate of exhaustion, but in a way much easier of application in practice than that of weighing the extract.

The packing of percolators will vary, even with the greatest care and skill that can be applied, and such variations can never be known without some such investigation and record as given in these tables.

Such variations are commonly the result of too tight packing, so that some portion of the mass is so compact as to make the progress of the liquid through it slower than through other parts, and thus by its slower exhaustion the extract from it is added to the weaker liquor from other parts all the way along through the percolation instead of at the beginning, as is well illustrated in the fourth and fifth percolations of the table, where the percolators were packed too tightly.

In interpreting the results of this table the disturbing effect of the trials of different degrees of moistening and different length of maceration, must be borne in mind as largely concerned in the discordant results. But this discordance fairly shows first the necessity for careful investigations and trials, since otherwise the discords would have escaped observation; and next shows the certainty with which each operation tends to control and correct the results of the preceding one until uniformity be reached. The residues in the percolators were critically examined by tasting, and in none was the exhaustion absolute. As the percolators were emptied the upper eighth would be tasteless as a rule ; then the bitter taste would be perceptible and would gradually increase to the bottom. At three-fourths down it would be very decided, and the remaining fourth would be pretty strongly bitter. The different percolations were only moderately uniform among themselves, and the want of uniformity was mainly in the lower third of the residue. But the residues were much more uniform among themselves than were the proportions of extract obtained, and all were fairly exhausted. The first and sixth percolations gave the most thoroughly exhausted residues, and yet the extract obtained, as shown by the table, was about two to one. This shows in a striking way that the extractive matter is not a measure of the exhaustion as judged by the bitterness of the residue. Therefore, in using the quantity of extract as a guide to exhaustion, if the quality of the extract be not ascertained the condition of the residue must be used as a check upon the extract as a guide.

The general result, however, as shown by even a glance at the table, a result that could be obtained in no other way, though favourable to repercolation, is unexpectedly unfavourable to the menstruum used because of the overloading and masking effect of the excess of soluble extractive matter in this exceptionally rich, soft, soluble bark. Therefore another percolation, the seventh of this series, was made with another grade of cinchona, using the same weak percolates and menstruum. This cinchona was the poorest in the writer's possession. It is from the *C. officinalis* cultivated in Ceylon, and contains between 4 and 5 per cent. of total alkaloids, of which about three-fourths is quinia. Therefore though still much richer than the U. S. P. yellow cinchona it is much nearer to it than the Java cinchona is. This 8 ounces = 226·7 grams of the new powder was as well exhausted as the other percolations with 1136·33 grams of percolate in 5 portions of about 8 ounces = 226·7 grams each. These portions, by the same calculations, yielded respectively 59·85, 37·26, 22·16, 7·15 and 2·77 grams = 129·19 grams of extract. Of this 102·45 grams was carried forward to it in weak percolates from the sixth percolation of the table. The 8 ounces = 226·7 grams reserved contained 59·85 grams of extract, leaving 4 portions of weak percolate to be carried forward containing (129·19—59·85 =) 69·34 grams of extract. But the extract which appears to have been obtained by this percolation is only (129·19—102·45 =) 26·74 grams and yet the powder was about as well exhausted as any of the previous percolations, and the weak percolates carried forward were much less loaded with extractive.

This improvement of the process by the use of a less exceptional quality of cinchona was, however, still evidently insufficient, and left it still short of the best results. The menstruum was next to be changed, as it plainly needed more alcohol to exolude somc of the extract, and probably less glycerin.

(To be continued.)

THERAPEUTIC VALUE OF THE USE OF ETHER WITH COD-LIVER OIL.

The following extracts from a report made recently by the Committee of Restoratives of the New York Therapeutical Society is quoted by the *Medical Times and Gazette* from the New York Medical Journal :—

"In 1868, Dr. Balthazar Foster read a paper before the medical section of the British Medical Association, on the use of etherized cod-liver oil in phthisis. Referring to the experiments of Claude Bernard, by which it was shown that ether is capable of augmenting the secrction of the pancreas to a remarkable degree, he had reached the conclusion that this discovery opened the way to a great advance in the treatment of phthisis. The defective assimilation of fats being the leading feature in the dyspepsia of phthisis, and this depending upon want of action of the pancreas, it was a clear inference that any agent which would increase the pancreatic secretion would be a valuable adjunct in the treatment of these cases. Moreover, Bernard found that ether promoted absorption independently of the emulsifying action of the pancreatic juice, and thus a double aid was to be expected from its use. Accordingly, Foster administered ether with cod-liver oil to a large number of patients, and preserved careful notes of the results. These results more than justified his expectations, and apparently ought to have led to at least a very general trial of the treatment. But ten years have passed since his paper was published, and only an occasional reference has appeared in the journals, European or American, to this use of ether. Evidently the matter has not been brought sufficiently before the profession, or the success attained by Dr. Foster has not been attained by others. It therefore seemed desirable that more experience upon this point should be accumulated, and accordingly it was selected as one of the subjects for observation by this committee.

"The shortness of the time over which these observations extend does not allow of any conclusion as to the result upon the progress of the disease of this method of administering the oil as compared with others, even in the limited number of cases of which we have reports ; but, so far as the reports go, they have a bearing upon the question of the utility of ether to produce tolerance of the oil, in cases in which the plain oil, or the various emulsions or soaps in common use, cannot be borne. But even in this there is a source of fallacy, which was clearly pointed out by Dr. Squibb at the last meeting of the committee. It is that the intolerance of the oil depends, in many cases, on a slight degree of rancidity, which, in the first place, excites disgust by the offensive taste and smell, producing nausea, if not actual vomiting, and, in the second place, acts as an irritant to the intestinal canal, provoking diarrhœa.

"Now, ether effectually prevents rancidification, and it becomes a question whether, at least in some cases, the good effects of the ether may not be ascribable to this property. That this is not so in every case, however, is shown by the fact that the purest oil, without a trace of rancid taste or odour, is known to have been employed in some of the trials. The report then gives the details of thirty-one cases, and sums up thus:—"In twenty-six of these cases the combination was well borne ; in five of them it was not well borne. In the twenty-six cases in which the oil with the ether was well borne, it is noted in twenty-four cases that either pure oil or an emulsion of oil had been tried, and had disagreed. In one case plain oil was found to agree better than the mixture with ether, and in another case the etherized oil did not answer so well as an emulsion with hypophosphites. The ether was given with the oil in twenty-two cases ; after the oil, fifteen to thirty minutes, in nine cases. Of these nine cases, three had tried unsuccessfully to take the ether *with* the oil, but had exhibited perfect tolerance when the ether was given *after* the oil. The results in this limited number of cases seem to sustain the conclusion of Dr. Foster in a remarkable manner. But it is very important that we should have a large number of cases extended over a longer period of time, and bearing upon the question of the better assimilation of the oil, and therefore of its greater ultimate usefulness, as well as upon its greater

present tolerance. And it is especially important that unsuccessful cases should be reported as invariably and as carefully as those which support the claims of the medicine."

BREWING IN JAPAN.*

BY PROFESSOR R. W. ATKINSON.

At the present time, when the history of the origin and development of the lower forms of life is occupying a great deal of attention, any facts which increase our knowledge of the growth of such bodies should be welcomed. In our breweries the growth of the yeast-ferment is tolerably well understood, or, at least, has been well observed and described. Under ordinary conditions the yeast-fungus exists only in the aquatic form, as it may be termed; and only under special circumstances, and with considerable difficulty in preventing putrefaction, is it enabled to produce spores. The internal substance of the cell becomes differentiated; granulations form and collect round certain points, and these ultimately become invested with a membrane, upon which the spores are ripe. The production of spores is thus unattended with the formation of a mycelium, or if formed, it is so minute as to have been overlooked. This, however, is not a normal process of reproduction: the principal one, and indeed under the usual conditions, the only mode, is by budding.

Those living in Japan, however, have the opportunity of seeing a mode of fermentation which differs in many particulars from that employed in Europe. The subject is now under investigation, and at present I am not able to explain accurately what takes place; but as the process followed is interesting from its novelty, as it appears to consist in the previous practical use of a discovery made, by De Bary, and afterwards confirmed by Rees and by Fitz, that alcoholic fermentation can be effected by the growth of a species of mucor, I am induced to give an account of a visit made, in company with some scientific friends, to the saké breweries, situated about thirty miles away from Tokiô, the capital of Japan.

Saké is the general name given to the alcoholic liquid prepared by the fermentation of rice. There are many varieties of it prepared in different parts of Japan, each receiving some special name, either derived from the district in which it is prepared, or from some fancy of the manufacturer. It is a clear liquid, of a colour varying from the palest yellow to that of the darkest sherry, and containing from twelve to fifteen per cent. by weight of alcohol. There are some special kinds which contain much less alcohol, from four to five per cent., but they do not form the usual drink of the Japanese. It is almost always served hot, being placed in porcelain bottles, which are immersed in hot water, and left there until the whole has attained the proper temperature.

This liquid is prepared on the large scale only in certain parts of the country, the most famous district being that near Ozaka, one of the Treaty ports. It is, however, often prepared on the small scale in private houses. The winter is the only season during which brewing operations are conducted, but this is not because the fermentation temperature is to be kept low, as in the Bavarian method, but, I believe, in order to prevent the action becoming too tumultuous, for the temperature of fermentation is, in reality, even higher than that adopted in England. But, from the fact that the largest breweries are situated nearly 400 miles from Tokiô, and the operations being carried on during a period when the University session is at its height, I have been compelled to confine my inquiries to the smaller breweries at Hachiôji, near this city.

The main room consists of a large wooden building, about 120 feet long by 50 feet broad, and 25 to 30 feet high, running along the middle of which, in the direction of its length, is a platform about 12 feet from the ground, upon which some of the preliminary operations are carried out. Upon this a number of wooden tubs are placed, which serve for the preparation of the ferment, an operation which requires to be repeated several times during the brewing season. On the ground, ranged along the two sides of the building, are large tuns used for the storing of the saké when made, and some of which are also used for the actual processes of fermentation.

The brewing commences with the preparation of the ferment. For this purpose, at the end of the previous brewing season, a quantity of a green mould is produced upon rice by exposing steamed rice mixed with a certain proportion of the ash of some tree, and over which the spores of this fungus have been scattered in a well-closed chamber, which I may term the "fungus chamber." This is a small room about 7 feet high by 6 feet broad and 8 feet long, well lined, and covered with straw and matting, so that its high temperature may be kept up for a considerable time. In this chamber the rice and spores are left for about ten days, the atmosphere being kept quite moist by the vapour given off from the steamed rice, and at the end of that time the grains are found to be covered with a green fungus full of spores, and apparently the same kind as is found growing upon putrefying organic substances. The temperature of the chamber when examined was 25° C., that of the external atmosphere being 13° C. This product is called, in Japanese, *tané* or seed. When prepared at the end of the season it is preserved until the next by being placed in bags, and enclosed in wooden boxes between layers of a mixture of equal parts of lime and wood ashes.

When it is required to commence operations, a similar method is adopted to that just described, that is, a quantity of steamed rice is placed on wooden trays in the "fungus chamber," but not mixed with any wood ashes, and then *tăné* (spores) is scattered over it, and the chamber kept closed for a period varying from two to four days. At the end of this time the rice grains are found to be covered with large quantities of fine hair-like threads, the mycelium of the fungus added. In this state it is called "kōji."

If this were left for a longer period in the fungus chamber, it would produce spores, and the brewer calls it "the friend of tané," but in order to carry on the development of the mycelium most vigorously, it is necessary to use wood ash in addition, which thus seems to act as a fertilizer.

Having thus obtained the "kōji," or mycelium, the brewer uses it for effecting the preparation of his yeast. For this purpose he mixes steamed rice with 30 per cent. of its weight of "kōji" and a sufficient quantity of water to make a thick mud, in small shallow wooden tubs, which are kept on the platform previously mentioned. In these it is frequently stirred and rubbed round with wooden tools, during a period of about ten days, in the course of which the grains of rice appear to be broken down, and the whole assumes a much thinner consistence, while at the same time the liquor becomes decidedly sweet. This is a change which is anything but clear. It would seem that it is connected with the development of an organism derived from the "kōji," as on the small scale I have noticed the production of minute cells, apparently budding; but whether they have any connection with the air-fungus, the mycelium of which covers the rice in "kōji," or whether they have been developed from germs accidentally present in the "kōji," I am not able to say, though I hope that further experiments will make this point clear.

After the end of the ten days this product is mixed with fresh-steamed rice, water, and "kōji," and introduced into larger wooden vessels, in which the mixture is heated by means of closed wooden tubs, containing hot water, and in order to prevent too rapid radiation, the whole is covered with matting. The hot-water tubs are replaced day by day, so that the temperature is kept up for a period varying from eight to thirteen days. The

* Reprinted from *Nature*.

average temperature seems to be about 35° C. (95° F.). During this time there is a continuous development of gas, and a scum gradually forms upon the surface until it has a thickness of a little more than one inch, and, when examined under the miscroscope, presents the usual appearance of brewer's ferment, saccharomyces. At the end of this stage, if the operation has been well conducted. five tastes are to be distinguished: sweet, bitter, astringent, alcoholic, and sour; but of these five, all of which are quite distinct, the bitter, astringent, and sour tastes are most marked. The product of this operation is called "moto," which means "source" or "origin," referring to the fact that it is from this ferment that the saké is subsequently formed. All the previous part of the brewing process has thus had for its object merely the preparation of the yeast, but it is certainly the most interesting, from the obscurity which surrounds it.

The actual fermentation is divided into three stages, called respectively beginning, middle, and end, the proportions of steamed rice and ferment varying slightly in each stage, but giving a final result of 100 parts of steamed rice to 30 parts of ferment. This mixture, together with the proper quantity of water, is placed in one of the large tuns before mentioned and allowed to remain for about fifteen days in all, during which time fermentation actively proceeds, aud the liquid becomes strongly alcoholic, at the end of which time it is drawn off from the grains of rice which have subsided, and introduced into other tuns, where it is allowed to remain to permit the remainder of the rice to be separated. The residue is placed in bags and subjected to pressure in a lever press, the clear liquid which is expressed being added to that which has been clarified. It is now placed in boilers and heated up to about 60° C., after which it is kept in the store vats, carefully sealed up.

The residue left in the press is subjected to a process of distillation in a current of steam, by which a spirit containing about 42 per cent. of alcohol is obtained.

The saké in the store vats contains about 15 per cent. of alcohol, and this fact shows that the fermentation is different to that effected by the *Mucor racemosus*, as described by Fitz. In his experiments he found that the presence of 4½ to 5½ per cent. of alcohol killed the ferment, whilst in the process above described, we find the ferment acting in such a way as to produce 15 per cent. There is, however, nothing improbable in the supposition that different species may possess different degrees of sensitiveness to alcohol, and that the species used here may be less easily affected than the one employed by Fitz.

There are, however, many points about the process which are obscure, and about which I cannot say anything at present, but further experiment will, it is hoped, throw a light upon the obscurity now enveloping the subject. The above account has been given in the hope that it may prove of some interest to those engaged in the study of fermentation, and that it may lead to a more extended examination of the action of various species of fungus upon amylaceous substances.

A FALSE PAREIRA BRAVA.*

BY CHARLES MORRISON, PH.G.

The drug examined was of Brazilian origin, and sent to the United States as true "pareira brava, obtained from *Cissampelos Pareira*;" but it corresponded neither to the description of *Cissampelos* nor of *Chondodendron*. It consisted of the woody stems of a menispermaceous plant, was covered with a grey bark, and the bright yellow wood was formed of more or less eccentric layers of fibro-vascular tissue.

The drug was reduced to fine powder; 12·0 grams of it, exposed to a temperature of 200° F., lost 1·21 gram, equal to 10·1 per cent. Ten grams, dried as above, moistened with alcohol and packed firmly in a conical percolator, required 15½ ounces of alcohol to exhaust it. On again carefully drying, it was found to weigh 9·025 grams, showing the alcohol had taken up ·975 gram. The percolate was evaporated to 2 fluid ounces, and 25 drops of sulphuric acid added; on standing two days it threw down a precipitate of a dark yellow colour, weighing ·3665 gram. The balance of the drug was then exhausted with alcohol in the same manner, and the percolate reduced by evaporation to 3 fluid ounces, to which, while hot, 40 drops of sulphuric acid were added. After two days a large quantity of dark coloured crystals, having a smell very similar to honey, was obtained. The mother-liquor was drained off and the precipitate washed with water acidulated with sulphuric acid, 20 drops to the ounce, until the colouring matter was all removed. The residue was dissolved in hot alcohol, from which it was thrown down, on cooling, in beautiful yellow stellate crystals, which were further purified with the aid of animal charcoal and by recrystallization from alcohol. The crystals resembled those of berberina salt in appearance, and to prove their identity the same tests were applied to both, when it was found that muriate of berberina readily volatilized, while the other product was carbonized and required the addition of nitric acid to make it volatilize readily. The berberina salt does not form a clear solution with ether, but the salt obtained was readily soluble, forming a bright yellow solution. The berberina salt is less soluble in cold water and almost insoluble in ammonia water, while the other is readily soluble. Treating boiling aqueous solution of each with a solution of bichromate of potassium, the product of the false pareira did not show any signs of precipitation until it had stood ten to fifteen minutes after becoming cool, while berberina formed a precipitate before it had become cool, the precipitates in both cases being fine needle-like crystals. On adding a drop of muriatic acid to each of the above precipitates, diffused in water and heating, the solution remained clear after cooling, while berberina threw down a bulky precipitate.

Treating cold aqueous solutions of each with a solution of nitrate of silver in hyposulphite of sodium, the pareira alkaloid was not precipitated, nor was the clear solution changed by heating, while berberina threw down fine light-coloured, needle-like crystals, the clear solution also, being unaffected by heat. To a hot alcoholic solution of each a solution of iodine in iodide of potassium was carefully added; berberina threw down a precipitate of beautiful green spangles, while the other deposited a reddish-brown crystalline precipitate. The dark-brown substance, having a sweet honey-like odour, above referred to, was readily soluble in ether and in hot and cold alcohol; insoluble in petroleum benzin; soluble in caustic potassa, which solution was not precipitated by muriatic or sulphuric acid. The ethereal solution, on evaporation, yielded a powder of a brown colour.

The filtrate from the first precipitate obtained with sulphuric acid gave a precipitate with ammonia water which was not re-dissolved on adding an excess. The sulphuric acid was removed with carbonate of barium; the liquid acidulated with hydrochloric acid and treated with Mayer's test gave a heavy precipitate of a light-yellow colour. The filtrate was rendered alkaline by ammonia, and agitated with ether, but the ether did not take up anything. On treating the precipitate by Mayer's test with an excess of carbonate of potassa, it was turned of a dark dull-red hue, and gave, with a mixture of one part of ether and two of alcohol, a light-yellow solution, from which a slight reaction with Mayer's test was obtained; with solution of iodine in iodide of potassium light-yellow crystals were formed.

It appears from the above that this false pareira brava contains two alkaloids, both of a yellow colour, one of which is similar to berberina, but differs from it in several important reactions.

"VIOLET POWDER."

IN the correspondence that has been carried on during the last three months, the arguments for and against the application of the name "violet powder" to other articles than perfumed starch have been pretty fully urged, and some statements have been put forward which appear to show that the practice is not quite so recent in its origin as might have been supposed. But at the same time the real question at issue has been somewhat obscured by the introduction of considerations that are not altogether to the point, whatever importance they may have independently. In the first place we will refer to the intrinsic merits claimed especially for hydrated calcium sulphate as a dusting powder, and to some extent also for other materials that have been in part substituted for starch. We do not desire to dispute or question in the least the virtues of powdered selenite, or of powdered steatite, or kaolin, or any other powder of the kind, neither do we seek to deprecate or prevent the use of these articles in the place of starch. It would, in fact, be unreasonable to make such an attempt, because it is well known that a substance very similar to two, at least, of the articles above mentioned has long been in favour as an application to excoriated surfaces. We refer to fullers' earth. We are disposed therefore to concede that such articles are not unsuitable for use in the nursery, in the same way as starch powder.

But having done so much we must emphatically declare that we cannot admit this has anything to do with the question, "What is violet powder?" or perhaps rather, "What ought violet powder to be?" The discussion that has taken place clearly brings out the fact that the unavowed substitution of hydrated calcium sulphate, or powdered selenite, for starch, has been heard of with surprise throughout the entire trade, and we may safely add that it has been equally unknown to the public. Those who have sought to justify the practice have not in any instance brought forward reasons for thus applying another substance to a name generally understood to indicate perfumed starch. It is upon this ground solely that we object to the substitution, and in our opinion this objection is not only unanswered but unanswerable.

The term "violet powder" may be in itself vague or even unmeaning, but it has been by long usage so associated with an article consisting essentially of starch, just in the same way that the equally vague and unmeaning term "milk of sulphur," had been associated with another preparation, that it has by this usage acquired a meaning and significance which preclude its application to any other article than perfumed starch. In the same way we have always held that the term "milk of sulphur" should not be applied to the precipitated sulphur of the Pharmacopœia, and that this term should not be interpreted as indicating the latter preparation. Moreover, if powdered selenite be better than starch as a dusting powder why apply to it a name indicating an article inferior to it for that purpose?

On these grounds we dissent from Professor REDWOOD'S suggestion to adopt a new nomenclature for the various kinds of dusting powder, and instead of misapplying or altering the old-established name of "violet powder" are rather disposed to think that the more simple plan would be to adopt the terms "selenite nursery powder" or "steatite nursery "powder," as indicative of the other preparations. These latter would then stand before the public with the recommendation that their greater cheapness or efficacy would entitle them to, and purchasers would have an opportunity of deciding to which they would give a preference.

Apart from the special merits of this question concerning nursery powder, there is a wider and more important consideration to be borne in mind by the pharmacist. He, of all men engaged in trade, should seek to avoid becoming chargeable with countenancing sophistication of any kind or the substitution of one article for another—especially under a familiar designation—without good reason being given for the change and declared without reserve. In some instances substitution of one thing for another may be the result of improved knowledge and justified by the superior qualities of the substitute, as in the case of the mineral fat now proposed as a substitute for wax and animal fat in making ointments, pomade, etc. But in all such instances the change should not be made until the merits of the proposed substitute have been made known, discussed and recognized. We are not aware that this has ever been done in reference to selenite, steatite, or kaolin, as substitutes in part or altogether for the perfumed starch hitherto known by the name of "violet powder," and until those necessary preliminaries have been gone through we must continue to hold, with the majority of our correspondents on this subject, that the sale of these materials under the name of "violet powder" is a practice which should not be countenanced by pharmacists.

We have deferred any remarks on this subject with the object of giving full scope to the discussion, but as that seems to be acquiring a tone of personal criticism we must decline publication of any more

letters on the subject unless they are addressed to those points which we have indicated above as being the essential ones to deal with.

THE RELATIONS OF MEDICINE AND PHARMACY.

We have on many occasions endeavoured to impress upon our readers the desirability of improvement in some of the relations between British pharmacists and medical practitioners, not only for the sake of clearing up doubtful questions, but also with the view of securing a more complete separation of the practice of pharmacy from that of medicine. In this respect our continental colleagues are more happily situated, since they not only know nothing of counter practice, but enjoy the advantage of a strict prohibition of dispensing by medical men. It will no doubt be long ere such a state of things can be generally attained in this country, but it is not the less one that should be sought after by all who desire to advance the position of the British pharmacist.

That we are in the main supported in these views by many active promoters of the general interests of the trade, we have had many opportunities of learning, though various differences of opinion exist as to the mode in which the desired objects are to be brought about. Some advocate conciliatory measures, others defiant litigation, and perhaps the majority are more inclined to let things alone, and indulge in an occasional grumble. In any case there is much reason to believe that some good would be done by a thorough exposition of the facts of the case, showing the advantages to be anticipated from a system more analogous to that prevailing on the Continent as compared with the somewhat confused position of medicine and pharmacy at home.

Some such considerations as the foregoing appear to have suggested themselves to other minds, according to a circular we have just received, bearing the signatures of Messrs. Broad and Son, Mr. Hampson, and Mr. Gostling, in which it is announced that these gentlemen seek the co-operation of the trade for the purpose of raising a sum of money sufficient to admit of the offer of £200, as a prize for the best essay on the advantages which would result to the public, the medical profession, and to those who practise pharmacy, by the separation of pharmacy from the practice of medicine in this country. The essay is also to give a brief and correct account of the laws and regulations which are in force in other countries where this separation already exists.

The expenses incidental to the initiation of this project have been undertaken by the gentlemen whose names are attached to the circular, and they hope to receive from their brethren a liberal response that will enable them to carry out their idea to a successful issue.

The reasons given for thus calling upon the members of the trade are,—1st, the belief that it is essential for the interests of all concerned, and more especially for those of the public at large, that the practice of pharmacy should be separated from the practice of medicine; 2nd, the belief that the furtherance of this object will be best ensured by the wide diffusion of trustworthy information and by creating an improved public opinion upon the subject. We do not doubt that in this way much good may be done, and are therefore of opinion that the project should meet with cordial support from the trade at large.

Together with the circular is sent a printed form for each intending subscriber to insert the amount he will contribute. The money subscribed is not to be asked for until a sum has been obtained sufficient for the payment of the prize and the publication of one thousand copies of the essay. At the present time, when trade interests are so generally matter of consideration, this project should be especially well received, inasmuch as it is directed towards effecting improvement in relation to that trade interest which is superior to all others.

THE WEIGHTS AND MEASURES ACT, 1878.

It seems probable that by the time the new Weights and Measures Act comes into operation various trades will be agitated by the discovery that their exercise has been made subject to important restrictions. To judge from the tone of some articles that have appeared in the daily papers the provisions of the new Act will give rise to some perplexing questions. As regards the practice of pharmacy, attention was directed to the subject in this Journal, and precautions were taken by the Council of the Pharmaceutical Society to protect the interests of the trade, and a very important amendment was in consequence introduced into the Act. The drug trade, indeed, appears to have been the only one similarly cared for while the Bill was passing through Parliament, and we hear of meetings of other trades being held now to discuss their position under the Act. We purpose, in consideration of the great importance of this Act, giving it in full in an early number of the Journal.

THE COVENTRY AND WARWICKSHIRE PHARMACEUTICAL ASSOCIATION.

This Association, which promises to be a vigorous one, has this week held its first general meeting for the winter session, and on Tuesday, the 22nd inst., a "Students' Section" in connection with it commences operations with a lecture on "Michael "Faraday," to be delivered by the Honorary Secretary, Mr. F. J. Barrett. Arrangements have also been made for the immediate recommencement of the winter classes, particulars respecting which may be had by application to the Honorary Secretary, 75, Hertford Street, Coventry.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The annual meeting of the twenty-ninth session was held at the Royal Institution, Thursday evening, Sept. 26, the President, Mr. T. Fell Abraham, in the chair.

The minutes of the last general meeting were read and confirmed.

Various donations to the library were announced, and votes of thanks awarded the donors.

Messrs. G. O. Chubb, H. Rimmer and A. Watt were unanimously elected members.

Messrs. R. B. Blayney, W. H. Grey, A. E. Jones, J. A. Jones, J. F. Jones, G. Nelmes, A. Olds, J. Wood and J. L. Wright were unanimously elected associates.

The Hon. Secretary, Mr. Thomas Williams, F.C.S., read the following:—

Annual Report.

The Council has the satisfaction, in laying before you its report of the twenty-ninth session, to note that the transactions of your Association show the session now ending to have been one of fair progress.

During the session thirteen members and six associates have been elected; four members and four associates have resigned, and two members have died, leaving the numerical strength of the Association at the present time 149, comprising 17 honorary members, 116 members, and 16 associates.

The attendance of members at the general meetings has considerably improved.

Thirteen papers have been read. The subjects embraced the latest results of research in applied physics, chemistry and pharmacy.

The exhibits of new philosophical instruments, improved chemical apparatus, specimens of drugs and of pharmaceutical preparations, added materially to the attractions of the meetings.

The numerous miscellaneous communications made during the session were highly interesting and much appreciated.

The courses of lectures in Chemistry, by Mr. Thomas Williams, F.C.S., in Botany, by Dr. Shearer, and in Materia Medica, by Dr. Nevins, provided by your Council for pharmaceutical students, were conducted as in the previous session.

The syllabus for the forthcoming Chemistry classes has been distributed, and your Council trusts that the better appreciation of the facilities offered will be shown by an increased attendance.

Several donations of valuable books and pamphlets have been added to the library during the session, and your Council has pleasure in announcing that the binding of twenty-five volumes of journals and periodicals (several missing numbers of which had to be procured) has been accomplished. Some other standard books also have been re-bound.

A better state of efficiency and order is experienced in the library since the addition of the new shelves presented by your President.

The issue of books during the session amounted to 244 volumes; a large number of references were also made.

Your Council has to congratulate you in particular on the improvement your museum has undergone during the recess. Upwards of fifty specimens, illustrative of important chemical manufactures, have been renewed, in addition to the donations of specimens contributed by members during the session.

In compliance with an invitation from the Council of the Literary and Philosophical Society of Liverpool, to consider a proposal for holding an Associated Soirée, the President, Vice-President, Hon. Secretary, and Mr. Edward Davies, F.C.S., were appointed delegates to attend a general committee meeting to confer on the subject, and to report. Your Council having consented to take a part in the soirée, applied to manufacturers of chemicals and to the members of the Association for their assistance, and met with a willing and liberal response on all sides, with the result that the soirée, held at St. George's Hall, was acknowledged by the Committee to owe not a small degree of its success to the assistance afforded by your Association. The lecture on "Spontaneous Combustion," by Mr. Davies, deserves special mention and thanks.

Invitations having been received to send delegates to the British Pharmaceutical Conference, held this year at Dublin, the President, Treasurer, Hon. Secretary, and Mr. A. H. Mason, F.C.S., were appointed to attend.

The ballot at the concluding general meeting for the appointment of President for the thirtieth session, resulted in the election of the retiring President.

The following members of Council retire by rotation and are eligible for re-election:—Messrs. Jones, Mason, Parnell and Woodcock.

Your Treasurer will present a report of the finances of the Association, which shows a credit balance of £7 15*s.* 8*d.*

The Hon. Treasurer, Mr. Robert Sumner, read the financial report, audited by Mr. Edward Davies, F.C.S., and Mr. Michael Conroy, F.C.S., which showed the expenditure during the year had been £54 14*s.* 10*d.*, total receipts £56 10*s.* 6*d.*, and that there was a balance in hand of £7 15*s.* 8*d.*

The Treasurer remarked that the session was commenced with a balance in hand of £6. The balance now resulting was only small, but he felt elated at being able to report the addition, for taking the expenditure towards the improvement of the library into account the condition of the Association and its finances showed a fair progress. He was glad to see the increasing number of associates joining the Association and attending its meetings. They would always find a cordial reception and abundant scope in the proceedings to derive a practical and valuable aid in the prosecution of their studies.

The President moved, "That the reports as read be adopted and, together with the list of members and abstract of proceedings of the past session, be printed and circulated among the members." He reviewed the proceedings at the general meetings and the work performed by the Committee of the library and museum.

The motion was seconded by Mr. Davies and carried unanimously.

Mr. Davies said there had been resolutions passed at different times to have the museum and library re-arranged. Now he was glad to say the task had really been gone into, and members would find the improvements well adapted to their convenience.

Dr. Symes considered the report very satisfactory, and believed the Association to be in a more promising condition than he ever remembered it before. Some time had elapsed since a purchase of new books for the library was last made, and he hoped the funds during the coming session would allow of an addition of some recent standard works. He was very pleased to find the Association so well represented at the Conference held at Dublin. He could not speak too highly of the advantages of that gathering; and being held next year at Sheffield—an easy distance from Liverpool—members would muster there, he hoped, in large numbers.

The meeting then proceeded to the election of four members of Council. Mr. Michael Conroy, F.C.S., Mr. A. H. Mason, F.C.S., Dr. Charles Symes, Ph.D., and Mr. Joseph Woodcock were duly elected.

Mr. Sumner moved "That the best thanks of this meeting be given to the donors to the library and museum, to the authors of papers, and to the exhibitors of apparatus, etc., during the session." Mr. Conroy seconded the motion, and it was carried unanimously.

Dr. Symes moved "That the best thanks of the meeting be given to the officers and council for their services during the past session." The motion was seconded by Mr. E. F. Morton, and carried by acclamation.

The President returned thanks for the council and himself, and the meeting closed.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, October 1, a lecture was delivered in the rooms of the above Association, Halford Street, by Mr. W. J. Harrison, F.G.S., and Curator of the Town Museum. Subject: "Carnivorous Plants." The first part of the lecture was devoted to the food of ordinary plants. The lecturer then described the plants of the order Droseraceæ, giving enlarged drawings upon the black board, and exhibiting several dried specimens. He then called attention to the fact that the spathe of the *Arum maculatum* was so arranged as to catch insects, and said it was a query as to whether the plant obtained nourishment from them. A vote of thanks was given to the lecturer and also to Mr. W. B. Clark, who occupied the chair.

After the lecture the committee made arrangements with Mr. Harrison to take a botany class during the winter, under the Science and Art Department, the class to be held in the Association's rooms, to suit the members.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee, at 17, Bloomsbury Square, London, on Wednesday, October 2, 1878, at 10.15 a.m.

Present—Messrs. Schacht (President), in the chair; Williams (Vice-President), Attfield (Honorary Secretary), Carteighe, Greenish and Symes.

The minutes of the previous meeting were read and confirmed.

Dr. Symes made inquiries respecting the omission, at the annual meeting, of the last subject mentioned in the programme.

The President replied that a member had desired to initiate a discussion on a matter, which though previously published, might elicit interesting remarks. A very large committee meeting had decided that although it had not been the practice at Conference meetings to introduce discussions other than those following original papers, the particular subject referred to might be usefully introduced if there were time after the original papers had all been read, and the title was consequently ordered to be inserted at the end of the programme. There was not time; indeed, as it turned out, the original papers occupied more than the usual time; hence for that reason, and so far as he knew for that reason only, the author at his (the President's) suggestion withdrew the introduction to the discussion.

Several members of the Committee having confirmed the President's statement,

Dr. Symes inquired whether in the first edition of the programme the subject had not been announced as coming on earlier in the day.

The Honorary Secretary produced a copy of the first edition, which showed that the subject was announced at the end of the programme, as ordered by the Committee, and suggested that some one might have been misled into supposing that such a transposition had been effected by seeing a copy of a private proof, which at first contained the titles only in the rotation in which they had been received.

Mr. Greenish inquired what rule was followed respecting papers previously published.

The Honorary Secretary said that on the prefatory pages of the 'Year-Book' it had always been stated, as regarded subjects suggested by the Conference, that any facts discovered during an investigation might at once be communicated to any scientific society or scientific journal, the author being requested in that case to send an abstract or report on the subject to the annual meeting of the Conference.

Applications for grants of money to aid authors to defray the costs of materials in carrying out stated researches were received from Mr. Thresh, Mr. Gerrard with Dr. Senier, and Dr. Wright.

Proposed by Mr. Carteighe, seconded by Mr. Greenish, and carried unanimously:—"That £10 be placed at the disposal of Mr. Thresh for the purchase of materials for 'Analysis of the rhizome of *Zingiber officinalis*, and a comparative examination of gingers of trade."

Proposed by Dr. Symes, seconded by Mr. Greenish, and carried unanimously:—"That £10 be placed at the disposal of Mr. Gerrard and Dr. Senier for the purchase of the drug termed 'Pituri,' and for the materials for its pharmaceutical and chemical examination."

Proposed by Mr. Carteighe, seconded by Dr. Symes, and carried unanimously:—"That a grant of £20 be placed at the disposal of Dr. Wright, towards the costs of the materials for an investigation of the active principle or principles of Japanese aconite, and that a similar sum be granted to Dr. Wright, under similar conditions, for an investigation of the active principles in the leaves and flowers of ordinary aconite."

Correspondence with members at Sheffield, the place of meeting of the Conference in 1879, having been read, a resolution, proposed by Mr. Williams and seconded by Mr. Greenish, was carried unanimously, appointing Mr. W. Ward, F.C.S., of Sheffield, as a vice-president of the Conference, Mr. H. W. Maleham as local secretary, Mr. G. Ellinor as member of the executive committee, and Mr. G. A. Cubley as auditor.

Letters from the editor of the 'Year-Book' and from the printers were read reporting good progress in the preparation for press of the volume for 1878, Mr. Siebold suggesting that in future years some time might be saved if the MS. were sent to the printers as soon as finished, instead of being kept back for presentation at the annual meetings. Resolved:—"That the MS. of the 'Year-Book' be placed in the hands of the secretaries on or before the day of the annual meeting, and that they thereupon immediately summon the 'Year-Book' Committee to consider any matters which may arise respecting publication, etc."

Resolved:—"That the members of the 'Year-Book' Committee appointed last year be re-appointed, with the addition of the President of the Conference."

Resolved:—"That Mr. Siebold be re-appointed editor of the 'Year-Book' on terms similar to those of last year."

Resolved:—"That Professor Attfield be requested to edit the 'Transactions of the Conference.'"

Resolved:—"That the names of the foregoing officers be printed, as usual, on the back of the title-page of the forthcoming 'Year-Book.'"

Professor Attfield reported the secretarial business done since the previous meeting of the Committee.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The first meeting of the second winter session of the above Association was held at its new rooms, 32A, George Street, Hanover Square, on Thursday, October 3. Mr. Wallis, President, in the chair.

The following additional donations were announced:—Messrs. Hearon, Squire and Francis, £3 3*s.* 0*d.*; Messrs. Flood and Co., £2 2*s.* 0*d.*; Messrs. Herrings and Co., £1 1*s.* 0*d.*; Messrs. Wright, Layman and Umney (annual) £1 1*s.* 0*d.*; F. Barron, Esq. (annual) £1 1*s.* 0*d.*

The Chairman then read an inaugural address. After

thanking the members for his election, he gave a history of the rise and progress of the Association, and showed how the objections formerly urged against it were no longer heard. He then touched upon one or two topics of trade interest, especially alluding to the present unrestricted sale of drugs by unqualified persons, and suggested that the sale of articles included in the British Pharmacopœia (subject to certain exceptions) should be a monopoly of the chemist, and for the convenience of the public in places where there was no registered chemist, proposed that a list of all ordinary drugs should be prepared, and one person in each such place (upon proper application) be allowed to retail the same, provided they are supplied to him by a registered chemist and druggist, and that the name of the chemist appear on all labels with which such drugs shall be required to be labelled. After thanking all who had assisted the Association with gifts of money or books, the Chairman concluded by expressing a wish that the opportunities for social recreation and acquisition of scientific knowledge which the Association afforded would prove of lasting pleasure and benefit.

A vote of thanks was awarded Mr. Wallis for his address. Votes of thanks were also awarded to the indefatigable Secretary (Mr. Cardwell), and to the committee charged to select a room. The meeting then broke up.

Parliamentary and Law Proceedings.

The Sale of Poison.

At the Clerkenwell Police Court, on Tuesday, Mr. John Knight, chemist and druggist, 56, Chapel Street, Somers Town, was summoned by Inspector Redstone, of the Y. Division, for having on September 19 sold some prussic acid without having previously entered the name of the purchaser, the quantity and object for which it was sold, in a book, as required by law. Another summons charged him with selling the poison without having labelled the bottle with the name of the poison and also with the word "Poison."

Constable 300 Y. said that on the day in question he was called to 43, Ossulton Street, where he found a person lying dead. He was told that the deceased had taken prussic acid. On the mantel-shelf he found a bottle, which was not labelled. In reply to his question the defendant acknowledged that the bottle witness produced was one in which he had sold some prussic acid, and that he had neglected to label it as required. This was the case on the second summons which was taken first.

Mr. Ricketts argued that there was really no case against the defendant, as the date of the sale had not been proved, while the Act required that it should have been sold within six months.

Mr. Barstow said he should assume that the sale took place within a reasonable time of the occurrence. The defendant would be fined £5 and costs.

Mr. Ricketts asked that a case might be granted, as the matter was of the greatest importance to the trade, and it was defended on principle.

Mr. Barstow acceded to the request.

The other summons was dismissed, on the ground that a person could not be convicted twice for the same offence.

Dispensing Memoranda.

[158]. Vapor Ol. Pini et Tr. Benzoin.—This may be dispensed so as to form a very fair mixture by triturating the ol. pini with the magnes. carb., using the light carbonate as ordered in the Throat Hospital Pharmacopœia, previously made of the consistence of cream with a little of the water, then gradually adding the rest of the water and lastly the tincture. Th. Green.

[160]. Respecting the above query two reasons induced me to ask for opinions through the medium of the *Pharm. Journ.* as to whether a "shake the bottle" label should be attached to a bottle containing the mixture in question or not.

First. The precipitate would be crystalline, and if a little be placed under a quarter-inch objective, it will be found to consist of very little else than crystals of calcium carbonate, and they are liable to produce "irritation of the bowels" (Squire).

Second. The medicine had been previously sent out both with and without direction to shake the bottle.

The rule given in last week's "Month" is a very good one, but we have all heard that there never has been a rule without an exception.

Would the nature of this precipitate justify a dispenser in sending out the mixture with the usual directions? S. F. C. P. thinks it will not.

I may just add that the mixture was for an adult, and that the dose of vin. opii would be two and a half minims twice a day.

Although I mention this I do not wish it to be implied that on account of its being so small it should not be taken into consideration.

J. W. Savage.

---

[160]. It would be erring on the safe side to send out this mixture with a shake label on the bottle. For three of the ingredients, sodæ bicarb., liq. bismuthi, and liquor calcis, are under certain conditions incompatible with each other. If sodæ bicarb. be mixed with liquor calcis, a precipitate of carbonate of lime results, this precipitate is soluble in an excess of liquor bismuthi. Then again liquor bismuthi is precipitated by a large excess of liquor calcis, the precipitate up to a certain point being soluble in the bismuth solution. When this point is reached free ammonia appears, and the bismuth and probably the lime fall out of solution. The mixture may be prepared so as to form a tolerably and perhaps permanently clear solution by dissolving the sodæ bicarb. in the liq. bismuthi, adding the whole of the liq. calcis, and lastly the other ingredients. The balance of power is, however, so even that perhaps a straw might disturb the equilibrium; for if prepared with Schacht's solution the mixture is quite turbid owing to the fact that Schacht's solution contains less ammonio-citrate of bismuth and no nitrate of ammonia to form soluble combinations with the soda and lime.

Th. Green.

---

[161]. By adding a 50% dispensing solution of citrate of iron and quinine gradually to the tr. valer. am., previously diluted with the rest of the water in a bottle sufficiently large, and shaking vigorously, a moderately transparent solution may be effected, containing however a slight precipitate of quinia diffused through it.

T. Green.

---

[163]. Mist. Acaciæ is the old synonym of the Edinburgh Pharmacopœia for Mucilago Acaciæ, B. P., of which "Pulvinus" will find ℥vj sufficient to suspend ℥iss bismuth. subnit.

Sub Umbra Floresco.

---

[163]. I make up mixtures similar to No. 163, of which the following may be taken:—

℞	Bismuth. Trisnit.	℥ij.
	Sodæ Bicarb.	℥iss.
	Mist. G. Acaciæ	℥j.
	Aq. Puræ	ad ℥viij.

M. G. H.

---

[165]. The prescriber evidently omitted the quantity of lap. divin. Squire says, "an eye wash may be made of 2 grains to an ounce;" and if not able to communicate with the prescriber, I should feel justified in using this quantity. K.

[165]. Your correspondent "Major" would not be far out if he dispensed this prescription at the ordinary strength of eye-lotions, gr. ij to iij in ℥j. I may say that lapis divin. is prepared as follows:—

℞ Cupri Sulph.
Potass. Nit.
Aluminis, p. æq.

Fuse together in a crucible.

M.R.C.S., Eng.

---

[165]. In Squire's 'Companion to the British Pharmacopœia' we find among the non-official preparations:—"Lapis Divinus (French, Pierre Divine; Spanish, Pedra Divina), sulphate of copper, nitrate of potash, and alum, of each equal parts, in powder, fused in a glazed earthen crucible, powdered camphor to the extent of $\frac{1}{10}$th part of the whole being added near the end of the process. When cold break in pieces and keep in a closely stoppered bottle. An eye wash may be made of two grains to an ounce of distilled water." "Major," if the prescriber were unknown to and distant from him, would be justified in dispensing the collyrium this strength.

Sub Umbra Floresco.

---

[165]. In answer to "Major," I should dispense the prescription, using 7½ grs. lapis divinus for the ℥iv of rose water. For form of lap. divin. see 'Pereira.'

Manchester. T. F. E.

---

[166]. When inf. rosæ co. is ordered in a prescription written subsequent to the introduction of the B.P. should the old London inf. rosæ co. be used, or inf. rosæ acid. B.P.?

Why do physicians nearly always order an extra quantity of acid. sulph. dil. with inf. rosæ co.? Do they forget that it already contains acid?

S. H. W.

---

[167]. In the following prescription, what should be used for the first and fourth ingredients, neither being official?—

℞	Tr. Guaiaci	℥ij.
	Pot. Iodid.	gr. xxv.
	,, Bicarb.	℥ij.
	Vin. S. Colchici	℥iss.
	Tinct. Opii	℥ij.
	Aquæ	ad ℥iij.

Ft. Mist., cujus capiat coch. mag. unam quarta quaque hora.

K.

---

[168]. Will you or some of your readers kindly favour me with a formula for dispensing a mixture combining quinæ sulph. with liq. ferri dialysati, so as to form a bright mixture that will not deposit in keeping?

Cedric.

---

[169]. Liq. Arsenici Chloridi.—When this is ordered in a preparation, which should be dispensed, the P. L. or the B.P. Liq. Arsenici Hydrochlorici?

Ap Iorwerth.

---

[170]. "Pulv. Aloes," "Ext. Aloes."—When either of these is ordered in a prescription, should that of Socot. or Barbad. be dispensed?

Ext. Aloes, P. L., 1851, is ordered to be made from Socot. aloes, and on that account for ext. aloes I dispense ext. aloes Socot.; and to follow suit, for pulv. aloes I dispense pulv. aloes Socot.

Belfast. P. B.

---

[171]. Acidum Hydrocyanicum Dilutum.—Is it correct to dispense mixtures containing this acid with a "shake the bottle" label? It is a common practice for chemists to do so, but on referring to the B. P. under acid. hydrocyanic. dil., we find that it is "hydrocyanic acid, HCN, dissolved in water and constituting 2 per cent. by weight of the solution;" here we are told that anhydrous prussic acid is dissolved in water to form acid. hydrocyanic. dil., and being quite soluble, there appears to me to be no necessity for a "shake the bottle" label when diluted with more water.

Sub Umbra Floresco.

Notes and Queries.

[523]. Can any reader give me a good recipe for making ginger ale that will not deposit any sediment after being kept a few weeks?

W. Lea.

---

[524]. Will any reader kindly inform me of the best way of preparing pil. aloës ℂ myrrh., in mass, so that it may be kept soft and pliable for some time, and when rolled out will not shrink or wither up, as is the case with the present B.P. preparation?

"Dispenser."

---

[525]. Can any one furnish me with a means of keeping gallic acid in solution for dispensing, say about one in four? Squire's 'Companion' states that acid. gallic. dissolves in eight parts of sp. vin. rect., but that proportion of spirit is too great for the purpose for which it is required.

"Dispenser."

A Correction.

Sir,—In the discussion at the last Council meeting in reference to canvassing, an inaccuracy as to a matter of fact occurs.

At page 264, I am reported to have said "That the Royal Medical Benevolent College at its annual meeting in May last had determined to put a stop to canvassing if possible." This paragraph should read as follows:—"That certain members of the sub-committee, though forbearing to raise the question on that occasion, gave the Council plainly to understand that nothing would restrain their combined action till the abolition of canvassing was secured.

Liverpool, Oct. 8, 1878. John Shaw.

"The New Double Iodide."

Sir,—Fresenius in his work on 'Qualitative Chemical Analysis,' gives a list of nine reagents which precipitate all or nearly all the alkaloids, one of the nine being a solution of iodide of bismuth and potassium.

This solution gives "a flocculent orange precipitate with most alkaloids," quinine among the number, and is prepared as follows:—

"Heat 32 parts of sulphide of bismuth in a combustion tube sealed at one end with 41·5 parts of iodine. Collect the iodide of bismuth in a receiver, purify it by resublimation, heat it with solution of iodide of potassium; filter hot, and add to the solution an equal volume of a cold saturated solution of iodide of potassium."

This double salt, therefore, can hardly be termed "new," except under local restrictions.

T. H. P.

Iodide of Quinine and Bismuth.

Sir,—May I ask the favour of your finding space for the subjoined letters. Fred. W. Fletcher.
73, *Highbury Hill, N.*

"73, *Highbury Hill, N., 3rd October*, 1878.

"Dear Sir,—In the course of some remarks upon the little paper which I read at the B. P. C. meeting at Dublin, you are reported in the *Pharmaceutical Journal* of September 28 as having said that you 'thought this red double salt had been noticed before, and a very close research made upon it by a gentleman in London, whose name you forgot." May I beg the favour of your being so good as to oblige me now with the name of the gentleman you referred to, and also that of the journal in which the research was originally published. I have ransacked all the publications likely to contain it, but without success. The only paper I can find which at all touches upon the subject is one by M. Yvon, *Répertoire de Pharmacie*, vol. ii., p. 335, in which the author discusses the use of iodide of potassium and bismuth as a test for alkaloids.

"Possibly you may have had in your mind a paper which was published in the *British Medical Journal*, 1870, ii., 603, by Drs. Woodman and Tidy, describing the formation of a red precipitate, by the action of iodide of potassium on subnitrate of bismuth. But you will doubtless be able to enlighten me. Yours faithfully,
"*A. W. Gerrard, Esq., F.C.S.* Fred. W. Fletcher.
"*University College Hospital.*"

"*University College Hospital, October 4th*, 1878.

"Dear Sir,—You are quite right in your suggestion that it was the communication of Drs. Woodman and Tidy which crossed my mind at the time you were reading your paper at the B. P. C. meeting at Dublin, and gave rise to my remarks. Yours very truly,
"*To F. W. Fletcher, Esq.*" A. W. Gerrard.

"73, *Highbury Hill, N., October 8th*, 1878.

"Dear Sir,—I am in receipt of your letter of 4th instant.

"You must excuse me for saying that I think the somewhat tardy explanation contained in it would have lost nothing in point of generosity had it been made spontaneously and with a little of that regard to publicity which characterized the remarks which its object is to correct.

"I may add that I have forwarded our correspondence to the Editor of the *Pharmaceutical Journal*. Yours truly,
"*A. W. Gerrard, Esq., F.C.S.*" "Fred. W. Fletcher.

The Admission of English Medicines into France.

Sir,—Your leading article and letter from Mr. Pheasant, chemist, Nice, which appeared in last week's *Pharmaceutical Journal*, regarding the admission of English medicines into France, with lists of preparations refused by the French School of Pharmacy, I am glad to observe. It may interest some of your readers to learn this this difficulty has not altogether been overlooked. While in London, during the last meeting of the Pharmaceutical Society, I first learned something of this case, and shortly afterwards visiting Paris, I had the full particulars from a leading English chemist residing there. On returning, I wrote our senior member of Parliament, Mr. Duncan MacLaren, pointing out the hardship and unfairness of the whole case, and asked his valuable aid in order to have this put right. With his usual zeal and ability, he at once saw Lord Sandon, President of the Board of Trade, who kindly took the subject in hand and had measures taken to bring it under the action of the Foreign Office as the proper quarter to obtain redress from the French authorities. Since then I have lately learnt Lord Salisbury is not neglecting the case, and is making full inquiries into the whole subject in Paris. Whether these will ultimately be satisfactory or not remains to be seen; meanwhile, I have the assurance that full attention is being paid to what interests so many of the British public abroad, as well as our brethren in trade.
45, *Forrest Road, Edinburgh.* James Mackenzie.

Professor Redwood and Violet Powder.

Sir,—I am one of those who admire Professor Redwood for the grace with which he can put antagonists into a corner, but at the same time keep a clear and open space in which to do a little fencing himself. He is doing so now over the violet powder business, and he did the same when the "milk of sulphur" question was on the *tapis*. To say that violet powder may be composed of starch of some kind or other, sulphate of calcium, orris root, and what not, is altogether beside the question.

Is pure selenite violet powder? I deny that it is. The original violet powder contained starch, and orris root simply to give it a perfume, or a drop or two of otto of rose, was all that was added to nursery or violet powder, in days gone by, by honest vendors. The alabaster dodge was not dreamt of, and how Professor Redwood can so accommodate himself to every innovation, and not call a spade a spade, I do not comprehend, and fail to see. Powdered selenite, even with its angularity of particles, may do no harm in some cases; but I deny to Professor Redwood, with all his authority to act as a dictator, the right to say that selenite is, or may be called violet powder. It is a sophistication—one base and mean; one of trade dodgery; and I am sure not an honourable pharmacist in Great Britain will act up to Professor Redwood's suggestion, or obey his advice, or sell alabaster knowingly for pure starch. I tell Professor Redwood selenite is far inferior to starch in allaying irritation, and I pledge my existence that the day will come when such men as Professor Redwood will not advocate even the appearance of adulteration, or, when exposed, smooth it over with all kinds of subterfuges and plausibilities, but put the manly heel of honesty upon all forms of dodgery and chicanery. If Professor Redwood wants alabaster let him have alabaster. If I want starch, or violet powder, give it to me, and supply my patients with it. Let the genuine article, starch, alone be sold, no matter about the price. I think I can imagine with what indignation Professor Redwood would order manufactured butter from his table, and how he would lash any fellow who would have the audacity to cram down his throat the assertion that the spurious article was better than the dairy product.

Now this is just what Professor Redwood is doing. I say it is not what one speaking *ex cathedrâ* should do. There are too many shams and adulteration dodges already; let us expunge them by all means from the nursery, and let it be known that starch, scented or not, is violet or nursery powder, and that it alone should be used. I can remember with what care my own mother used to powder starch (wheat starch) in order to dust a junior brother. No old nurse, to whom I have spoken, ever heard of alabaster as a substitute for starch. If they get it, however, in boxes at the chemists, it is hard for them to know the difference. Only the other day a shrewd old dame called my attention to some "violet" powder, and remarked that it was very heavy. I took a sample home, and found it was selenite. I gave instructions not to buy any more bearing the same brand, and this has been my practice for months. I order the French, or that put up by a few well known London perfumers.

If this plan was carried out by all medical men, the selenite would soon be found relegated to its proper quarter, viz., the builder's store.
Northallerton, Oct. 5, 1878. Henry Brown.

Violet Powder.

Sir,—Will you allow me to supplement Mr. Grecnish's letter by stating that the "time honoured name of violet powder" might, very properly, be altered to violet scented powder, and this powder to mean legally, or otherwise, pure wheaten starch.
Sheerness-on-Sea. John Saffery.

The Scammony Query.

Sir,—I am obliged to F. A. B., but line 10 from bottom, page 278 of the Pharmacopœia, had not escaped my attention. There was a great deal of obscurity and confusion in the B. P. of 1864, when the resin from the root was first introduced.

I had the privilege of attending Professor Bentley's lecture on the "New Preparations of the B.P.," March 23, 1864, and his remarks on scammony, and scammony resin, are reported in the Journal, April 1, 1864, to which I beg to refer; and although most of the doubtful points alluded to were rectified in the 1867 edition, I think the point I drew attention to must have escaped notice.

I read the doubtful line page 278 thus: The resin may

also be prepared in a similar way from scammony, in the event of the root being unobtainable, or too high in price to work commercially.

In 1864 there was very little difference in the price of virgin scammony and resin obtained from the root; but I am informed, that at the present time, the root can be worked at about one fifth the price of natural scammony, so that there is no longer any reason for the doubtful line to be inserted in the next edition of the B.P.

The introduction of the dried root to prepare the resin from, was owing to the adulterations practised abroad on natural scammony, but opinions differ much even now about the resin being equal in every respect to virgin scammony. There can be no doubt, however, that it is much better and more reliable than second or third quality scammony, and it is to be hoped that these will disappear from the market entirely.

Sandown, I. W., GEORGE BROWN.
October 3, 1878.

PATENT MEDICINES AND THE PHARMACY ACT.

Sir,—All your correspondents pretty well agree that our only protection in the patent medicine trade is the extension of the Poisons Act, so as to include all the patents that contain poison,—chlorodyne, cough specifics, etc., to wit. Will you kindly say what is the saving clause that exempts these medicines from the power of the Pharmacy Act? If there is one let us "one and all" use all our powers to get it repealed.

Devonport, September, 25, 1878. SPES ULTIMA.

[*** Section xvi. of the Pharmacy Act, 1868, contains a provision that nothing contained in the previous clauses, which refer to the registration of persons selling poisons by retail, shall apply to the making or dealing in patent medicines.—ED. PH. JOURN.]

THE MEDICINAL PROPERTIES OF ORANGE FLOWER WATER.

Sir,—I chanced to be absent from my place at the Pharmaceutical Conference at the moment when Messrs. Reynolds and Bothamley's interesting paper on orange flower water was read, or I should perhaps have made a few remarks respecting its reputed medicinal properties. I recollect being told many years ago that orange flowers did possess certain sedative and hypnotic virtues, and that in the South of France they were used very commonly to counteract the sleeplessness that tea is apt to cause with nervous persons. This had almost slipped from my memory; but in the spring of the present year I happened to be in Bordeaux, and one evening, accompanied by a friend, strolled into one of the large cafés in the centre of the city. As an experiment we asked for some tea, and they brought us a fairly strong infusion of good tea, sugar, and instead of cream (or its London representative), a little phial of orange flower water with each cup. I have seen, I think, at Nice, dried orange buds sold for mixing with tea leaves for the same purpose. Whether the flavouring of certain teas with orange, by the Chinese, has been originally done with a similar object I do not know. Such an explanation suggests itself, even though now it be nothing more than a fanciful combination of tastes.

HENRY B. BRADY.

LARGE DOSES OF MORPHIA.

Sir,—Seeing in your last impression the report of an adjourned inquest on a person who had died from taking an overdose of morphia, I thought it might be interesting to your readers to know that a customer of mine was in the habit of daily (for some weeks to my knowledge) taking twenty grains of morphiæ acetas in two doses of ten grains each. I must confess that when he asked me to divide the twenty grains into two powders, and then coolly emptied one of them into his mouth, I had in my mind's eye, a coroner's inquest, and all the attendant inconveniences relating thereto, although, I of course, had duly registered the sale of it in my poison book. But as he came in day after day and repeated his order, also swallowing one of the ten grain powders, as he said to save the trouble of carrying it, I naturally was induced to ask him how long he had been in the habit of taking what to most people would have been a fatal dose. He then said, while in India he was suffering from a sharp attack of dysentery and had been ordered the dose I have stated, and that now he could not do without it. Your report does not say how many of the pills were taken by the party who unfortunately became a victim to their agency; be this as it may, it only shows that what one man may swallow with impunity, another, with a less dose, pays the penalty with his life for.

81, *Maldon Road, N.W.* G. H. DUNMORE.

THE RELATIONS OF PHARMACY AND MEDICINE.

Sir,—The chemists who principally offend by prescribing are, as a rule, located in poor neighbourhoods, where it must be remembered surgeons who keep open retails also abound. I suggest that the reason why prescribing is carried on so largely is mainly due to the latter fact. Medical men by dispensing and selling those articles that by right belong to the pharmacist's business, give a cause for encroachment upon their own domain, simply because a chemist cannot clear enough to live upon unless he does prescribe, he has no other alternative; but if all the shops belonging to the medical practitioners were closed, and they were confined to their legitimate profession, then there would be an opportunity for a druggist to obtain a fair existence by his own trade. In my opinion there ought to be some stringent means of prohibiting medical men from dispensing; there seems to me plenty of scope for ability in their own branch, without lowering themselves to compete with tradesmen. It seems most unfair that they should have the power to dispense as well as prescribe. Why cannot the two branches be carried on distinctly? the pharmaceist devoting himself to his duties, and the physician to his; it is a consummation most devoutly to be wished, but unless the higher grade shows the example to the lower, or force creates it, I am afraid it will be a long while coming to pass.

C. H. F.

Sir,—It is clear that next session a Medical Bill will be brought forward which will give chemists and druggists an opportunity of making known their wants and wishes as a branch of the profession. Under these circumstances I beg to suggest that the Council should forthwith publish in the Journal a verbatim report or copy of the proceedings of the trade in 1815 and 1841, under somewhat similar conditions. Such an account is succinctly set forward (by the late Jacob Bell), in the first number of the Journal, but which to the present generation of chemists is unknown. After a careful perusal the trade will be better able to judge of the course that should be taken now. To be successful in defending our legitimate rights and privileges and having our position clearly and definitely set forth, there must be union and co-operation, and I am convinced that the trade at large will rejoice to see the Council take the lead to bring about a better state of things. What we require is to know our real position as regards counter practice and be protected from harassing legislation.

Turnham Green. B. HUMPAGE.

[*** It is intended to carry out our correspondent's suggestion in an early number.—ED. PH. J.]

WATER ANALYSIS.

Sir,—I am sorry to find that Mr. Ekin should have so completely misunderstood the import of my article in your impression of the 21st ult.

With the greatest possible haste I would beg to acquaint Mr. Ekin of the fact that he quite misunderstands me, if he thinks I wish to eclipse, add to, or detract from, in the slightest degree, the present admirable method of water analysis in use amongst scientific chemists and analysts.

If Mr. Ekin would kindly do me the honour to peruse my article with a little more thought, he will doubtless perceive that my sole object is to introduce a test which can be used by an "ordinary inexperienced person."

Simple and admirable as the Wanklyn process is to the scientific chemist, I hardly think it would be found so by a person who possibly may never have heard the name of Wanklyn or Nessler, and it is for the benefit of such persons that my paper was inserted (for "non omnia possumus omnes"). I refer to the majority of druggists in country towns who so often have the question asked, "Is this water good or bad?"

The person who asks may possibly be a good customer to the druggist and still at the same time does not wish to go

to the expense of having the water sent some considerable distance, it may be, to an analyst. Would not a test such as I propose be of use in a case of that kind?

Those waters which contain salts of iron to such an extent as to decolorize my test will be included in the condemnation of Dr. Cornelius Fox, who says that "the presence of 1 grain of iron per gallon is sufficient to justify its rejection." It therefore remains for Mr. Ekin to prove that less than 1 grain per gallon will affect the solution I speak of. I may also say that those instances in which either "nitrites" or "hydrosulphuric acid" exist, uncombined with organic filth to a sufficient extent to destroy the value of my test, are, to say the least, "very rare."

In conclusion, I would respectfully intimate to Mr. Ekin that my paper was not intended for the edification of the professional analyst, and on his part my test yet remains to be proved, in the words of Lycurgus "ου λογῳ αλλ' εργῳ."

High Wycombe, Sept. 28. W. CORDUKES STABLES.

Sir,—In answer to Mr. Stables's invitations for facts relative to the use of potassic permanganate for the detertion of organic impurity in water, I beg to inform him that I have used that reagent for years, and have always found its indications reliable. Of course it must be used with discretion, and in conjunction with with other tests, as salts of iron and nitrites act like organic matter in decomposing it. Iron, contrary to Mr. Ekin's statement, is not a usual constituent of potable waters, and therefore any ordinary inexperienced person might with safety reject a water which more or less rapidly destroyed the colour of the permanganate solution, presuming, of course, that other more complete tests were not to hand.

Mr. Stables will find a number of articles in the *Chemical News* for 1869, from the pen of Dr. R. Angus Smith, on the use of the "chameleon test," as he calls it, in the detection of organic impurity.

I have just completed an examination of a sample of water, in which the indications by the permanganate of the presence of considerable organic matter were fully proved by the confirmatory tests.

Leominster, Sept. 28, 1878. M. J. ELLWOOD.

SQUIRTING CUCUMBER.

Sir,—In your article "The Month" I notice you observe concerning the squirting cucumber, that "fortunately the juice does not appear to have such an irritating effect upon the eye as it does upon the internal mucous membrane of the body." Lest any of your readers should on this observation neglect the necessary precaution, I forward my personal experience in this matter.

One afternoon, when a schoolboy, a companion and myself were amusing ourselves by plucking the pepos and noticing the distance to which the seeds were scattered, when without any warning my companion directed a ripe fruit towards me and gave me the contents directly in one of my eyes, the lid of which became so swollen as to partially close the eye, and the internal inflammation became so great as to obscure my vision for two days. I do not wish to argue from this that the eye is as sensitive to elaterium as the internal mucous membrane of the body, but I should certainly caution your readers from trying the experiment.

H. CUMBER, JUN.

[*** The writer spoke from his own recent experience, but possibly the effects would not be the same in every case.—ED. PH. J.]

THE NEW DISPENSING PRICE LIST.

Sir,—"Tenens" is sorry to see so much criticism with reference to the new dispensing price list in Journal, September 7, p. 200. I am heartily pleased that I am not in the same way of thinking as himself. "Tenens" goes on to say that there are scores of chemists who do not charge any more than the prices quoted by Dr. Williams for dispensing medicines. I am happy to say I am not acquainted with those gentlemen, neither do I wish to know them. There are many M.D.'s who order medicine in a very concentrated form and if the chemist only charges as much for dispensing the prescription as the drugs come to by retailing them over the counter, he is thought to be charging excessively.

He says he might surprise me when he informs me that he dispenses prescriptions for medical men taking large and small bottles together, at the ratio of 5*s.* and 6*s.* per dozen, etc., also sends them out in the bargain. He is quite welcome to do so, but hope I may never be found doing it. If mag. sulph. ℥i and aq. menth. pip. ad ℥viii be ordered, he might charge at that rate. "Tenens" says he moderates his charge when p. p. (poor patient) is written in the corner of a prescription; he must indeed be a very charitable person. I do not think, strictly speaking, the medical man who wrote to the Journal alluded to any class of individuals in his letter, The chemist has a right to grumble when medical men want to dictate to him what he should charge for medicines. I consider it a piece of impertinence; it cannot be done, and the sensible chemist will not be dictated to in that manner.

Wood Green, N. A. F.

DISPENSING PRESCRIPTIONS *versus* PROFIT AND LOSS.

Sir,—Please allow me a few lines in reply to the able letter of Tenens (*Pharm. Journ.*, Sept. 28). We have heard doctors differ, we now see druggists differ (at least, I suppose so, if "Tenens" be a druggist); but if dispenser to the the South Western Æsculapius, I shall be pleased to know. He first expresses righteous disgust that the price bolus, *Pharm. Journ.*, Sept. 7, p. 199 and 200, has not been swallowed. As a rule, druggists do not like physic, and I think next time the S. W. Æsculapius prescribes for druggists tills, he must put in a little syrup, or I feel sure they won't take it. Then poor A. F. seems to have used the word "absurd." Well, I say, the price list was "most absurd." He happened to mention in his letter, Sept. 14, p. 220, his fear the poor druggist would get seedy if he had assistants to pay, dispensing at the new scale of charges. I go further, and say no honest man can employ qualified assistants to dispense prescriptions at 5*s.* and 6*s.* per dozen (errand boy to deliver) unless he intends shortly to make some compromise with his creditors. If "Tenens" agrees so thoroughly with the new price list and directions for druggists (in managing business) he must bear in mind many prescriptions are required by law (when they contain poisons) to be copied, particularly if the poison is mentioned in the 1st schedule of the Pharmacy Act, 1868. I can only say when I was an assistant in some of the best dispensing businesses, we referred daily to old prescription books to dispense prescriptions written, at least, twenty or thirty years before.

Well, we were advised not to copy prescriptions. Does it save time to scamp things? I know not. But the old adage says, "Lazy people take the most pains." I conclude by saying I believe every labourer is worthy of his hire.

W. N. G. LANCE, M.P.S.

207, *Copenhagen St., London.*

DANGEROUS DOSES AND DIFFICULT PROBLEMS.

Sir,—Mr. Greenish was quite right in calling further attention to the subject of his letter if only for eliciting the opinions of pharmacists as a body, and proving to the medical profession that they are equal to the emergencies and responsibilities for which their education is supposed to fit them.

The prescription was certainly an unusual one and no doubt was intended for a special purpose. If "Beta" had referred to standard works of reference such as Pereira or Neligan, he would have found that the dose of cantharides was quite below the maximum, and he should not have hesitated to dispense the prescription.

As regards dispensing the one hundred pills, he might or might not have done so, at the same time intimating to his customer that the medicine was of such a character as not to justify its continuance longer than the time prescribed for without again consulting his medical man. Every dispenser knows how courteously such suggestions are received, and doubtless the one above would have commanded the approval both of the patient and the medical man.

It was quite beyond the sphere of "Beta" to dilate upon the probability of strangury or irritation of the bladder, symptoms treated very lightly by Mr. Henry Brown, but capable of producing in the mind of the sufferer anything but a charitable remembrance of medical man and chemist, who by a timely caution might have spared him the suffering. The conduct of "Beta" in absolutely refusing to dispense the prescription, was highly to be condemned, and it is only

charitable to assume that it was due to youth and inexperience and a temporary absence of a senior referee; under such circumstances I commend his caution.

Darlington. JAS. SWENDON.

Sir,—I certainly think with Mr. Henry Brown that the chemist was not justified in refusing to dispense the prescription to which he refers.

In the 'Handy-Book of Forensic Medicine,' by Drs. Woodman and Tidy, p. 538, the question is asked "What may be regarded as a medicinal dose" (of cantharides)? The authors reply, "Thomson says I to 3 grains of the powder; Pereira 1 to 2 grains of the powder and 10 minims increased to ℥j of the tincture; Garrod 5 to 30 minims of the tincture; whilst the late Dr. Dyce states that he was in the habit of giving 10 grains of the powder as a medicinal dose." So small a dose as one and a third grains of the powder could only have excited alarm in a pharmacist who was imperfectly acquainted with his toxicology. I should as a physician very much object to have all my doses limited within the range of the Pharmacopœia; probably I have seen the best results obtained in some forms of erysipelas by heroic doses of tincture and perchloride of iron, I have known ℥ij to even ℥iij given as a dose, ℥iss to ℥ij in the 24 hours. The syrup of iodide of iron is dosed as from 20 to 60 minims. I never give even young children less than ℥ss to ℥j and find smaller doses ineffectual. Of the powdered ergot (fresh) I always adminster ℥j for a dose, which is double the maximum dose of the B.P. Experience has taught me that I cannot depend on the result I want if I keep within the Pharmacopœia limit in a great number of other cases. Am I then to be hampered and defeated in these cases because a pharmacist, whose knowledge of the action of medicaments can scarcely be derived from experience, but is almost always obtained from books, chooses to take his stand on the hard and fast line of the Pharmacopœia, which he will not allow me to overstep? I deliberately say the posology of the Pharmacopœia is nothing to me; I refuse to be guided by it where my experience as a medical practitioner teaches me better.

What! because the maximum dose of syrup of lemon and orange is there given as ℥ij, am I to have my prescription for 20 or 30 or even 40 grain doses of quinine (as I have known given) refused to be dispensed, that same authority limiting the dose to 5 grains?

I think it is always a duty we owe to the dispenser to indicate by our initials in the margin against any unusual dose such as I had indicated, but having done so and thereby taken all responsibility upon ourselves, I hold that a pharmacist within the bounds of a medicinal dose ought to dispense our prescriptions without question.

EDWARD BERDOE, L.R.C.P., M.R.C S., L.S.A.

56, *Victoria Park Road, E.*

Sir,—I venture to think that your correspondence on "Dangerous Doses and Difficult Problems" is a matter of so much importance to the physician, as well as to his patient, that it ought to receive a fair and impartial discussion.

A few weeks since I prescribed for my patient what in my practice was an ordinary dose of the solution of atropine (three drops), and I was certainly very much surprised to find that the pharmacist refused to make up the draught, stating as his reason that the dose was excessive. I am frequently in the habit of prescribing large doses of the rarer alkaloids, which of course necessitates my confining my business to one compounder in order to avoid inconvenience similar to that I have just stated. I may say that I now adopt the method of writing doubtful doses in full and underlined.

THOMAS STRETCH DOWSE, M.D.

2, *Old Burlington St., S.W.*

Sir,—There can be little doubt that the above subject is of immense importance alike to the pharmacist and the medical practitioner.

Some of us who have had to do with "hospital dispensing" are not so easily startled by doses exceeding the Pharmacopœia maximum as those who have not been engaged in that work, and who are accustomed to the more quiet routine of smaller towns and country practice; nevertheless these difficulties do arise and cause much perplexity as well as trouble to the dispenser.

The writer well remembers in his earlier dispensing days having a prescription handed to him to dispense, as follows: ext. cannabis. indicæ, ft. pil. nocte maneque sumend. gr. v. It was written by an eminent physician some two miles from the house where it was presented; nothwithstanding, it caused many doubts and surmises, till at length it was submitted to another eminent member of the faculty who pronounced it an excessive dose and advised it not being dispensed.

The writer was then deputed to wait on the physician, in order to ascertain his real intention. He stated that in India he had often prescribed 10 grains. On the suggestion that there may be a possible difference in the preparation as well as between an Indian and an English constitution it was finally altered to 2 grains for each dose, and as such dispensed.

In more recent times, the following passed through the hands of the writer—

℞. Ol. Crotonis. . . . . ♏xij
Syrupi . . . . . ℥j

Statim sumend. et repet. post horas 4, si opus sit.

In this case, consultation with the prescriber elicited the fact that one minim dose of ol. crotonis was intended, the syrup was therefore increased to ℥iss, and the dose a teaspoonful.

Other facts could be supplied, but these suffice to show the necessity for watchful care on the part of the dispenser, and the anxiety caused through actual errors occasionally creeping in, together with the difference of opinion in regard to doses which does exist amongst some of the faculty and the consequent difficulty which sometimes arises as to whether the dose is intentional or in error.

Under these circumstances we consider ourselves perfectly justified in asking those prescribers who use and intend doses so largely in excess of our maximum Pharmacopœia standard, that they give to us some plain mark of their intention, that we may be assured the quantity ordered is not in error, but has (by the indication) the professional sanction of the writer, and thus remove the onus of responsibility from the shoulders of the dispenser to that of the prescriber.

The supply of concentrated medicines, such as liquor strychniæ, liquor arsenicalis, etc., is not to the point in this discussion. No chemist would refuse to supply such when the proper directions were given (he may have his own opinion about the expediency of prescribing such). But should the dose ordered be an excessive one, the prescriber need not be surprised if he heard from the dispenser in reference to the matter.

In case of accident under such circumstances the responsibility would be medical, not pharmaceutical.

Brighton, Oct. 1, 1878. G. G. HORNSBY.

NOTE ON PEPTONE.

BY STEPHEN DARBY.

Peptone, which belongs to the group of proteine bodies, is specially distinguished from other members of this class by its ready solubility in water, and not undergoing coagulation when the solution is boiled; but it would perhaps be more conclusive to name, in addition to these, the diffusive property it possesses, for Schmidt has shown that albumen when freed from saline matters by dialysis no longer undergoes coagulation on heating.

With one slight exception, all members of the proteine group are convertible into peptone; this change may be effected in several ways, but by far the most ready one for obtaining peptone is digestion with acidified pepsin solution.

Such conversion of proteine bodies into peptone is possibly not direct, or, if it be so, other substances, intermediate in their properties are formed with it, but these pass eventually, by sufficient digestion, into the condition of true peptone. It is so with the proteine bodies which Meissner distinguishes as para-, meta-, and dia-peptone.

On true peptone the acidified pepsin solution, or artificial gastric juice, exerts no further action even with long continued digestion; differing in this respect from pancreatic secretion, by which peptone is quickly split up; yielding other and crystalloid products.

Peptone is freely soluble in water, and dissolves also in moderately strong alcohol. Its aqueous solution is not affected by boiling unless this be very prolonged. It dialyses readily, possessing a high diffusibility.

Aqueous solution of peptone yields insoluble compounds with mercuric chloride (the precipitate being readily soluble in sodium chloride solution), and lead acetate with ammonia or basic lead acetate; but no precipitate is caused either by neutral metallic salts, acids, or alkalies; nor does ferrocyanide of potassium with acetic acid cause any turbidness. Alcohol in very considerable excess causes its precipitation, and this is more readily effected by admixture of ether with the alcohol. When a small quantity of cupric sulphate is added to a solution of peptone with caustic alkali, the brilliant rose colour produced is very noticeable as compared with the violet or purple tint yielded by a solution of unchanged proteid.

The ultimate constituents of peptone on analysis seem to agree pretty nearly in their proportions with those of the protein substance from which it is obtained, there is, however, a somewhat diminished percentage of carbon and nitrogen, and a triflingly increased percentage of hydrogen. This has led to the conclusion that the difference is due to hydration of the original proteid, and similar to the change which takes place when grape sugar is prepared from starch. This theory of hydration would appear to have received actual confirmation from the experiments of Dr. Henniger who has resolved peptone into a species of syntonine by a process of de-hydration.

On heating a mixture of fibrine-peptone and *acetic anhydride*, he finds acetic acid is formed, together with a substance which dissolves in hot water, and, when the aqueous solution is reduced to only a slightly acid condition, by means of dialysis, yields a precipitate with either potash, nitric acid, or ferrocyanide of potassium, whilst the solution is also rendered turbid by heating. These experiments I have not as yet had an opportunity of repeating.

Attention is called to Henniger's results at page 222 of the current Journal, under the interesting notice of the collection at Paris.

Professor Bamberger, of Vienna, has employed peptone as a vehicle for mercurial subcutaneous injection, but its real value is due to peculiar nutrient qualities.

The value of peptone as a means of nutrition has been strongly denied by some physiologists who maintained that only the unaltered albumen was capable of being assimilated and of replacing tissue waste; moreover that peptone, being effete matter, incapable of becoming absorbed into the animal economy, was at once ejected in the form of secondary products.

That such views are erroneous has been conclusively shown by many carefully conducted experiments, notably those published by Professor Maly, of Gratz, in 1875. It is true that for some years prior to this date peptone, as peptonized flesh, had been already extensively employed in this country as an aliment, and no doubt existed in the minds of English physiologists and physicians as to the nutrient value of peptone; but the experiments of Maly (and others subsequently) prove incontestibly that with food containing no other nitrogenized constituent than peptone, not only is health maintained but an increased bodily weight is gained beyond that yielded with an equal amount of ordinary food containing a similar proportion of unchanged proteid; whilst if peptone were effete and not available for nutrition the animal must of necessity have steadily lost weight and died from starvation.

This slight recapitulation of the characteristics of peptone may perhaps be of some little interest, not only on account of its nutrient value in cases of suspended digestive power, but because with the altered mode of life necessitated by an advancing state of refinement peptonized food can scarcely fail to become an important article of diet in the future.

THE PARIS EXHIBITION.

(*Continued from page* 286.)

Chemical Manufactures.—Crude Materials used or applicable in the Arts.

The science of chemistry has made such immense strides during recent years, and its application in the arts has now become so universal, that the task of defining the limits of the class of chemical products for occasions like the present exhibition is one of some difficulty, and this fact will account for the appearance of some articles in it that at first sight strike the observer—especially in the French court—as being very incongruous. The plan followed appears to have been to include within the class five groups of manufactures in which operations based upon the principles of chemical science play an important part. These are (1) the manufacture of chemical products, in the ordinary acceptation of the term; (2) the production of pigments; (3) varnish, glue and size making; (4) the fat and oil industries, including candle and soap making; and (5) pharmaceutical products. The last-mentioned group has been dealt with in the previous portion of this report.

In considering the crude materials used in the

chemical manufactures as thus defined sulphur and its compounds must be allowed the precedence, since it has been well remarked that the amount of this element used is an indication of the progress of the whole chemical industry. Turning then to the Italian court specimens of native sulphur are to be found there in abundance, but the absence of methodical arrangement made the tardy appearance of a catalogue of this department doubly inconvenient. Some fine specimens from the solfatara of Naples, the sulphur works of Venice, and from the Romagna are, however, specially noticeable. The Cesena Sulphur Company also shows good specimens of sulphur ore and the products of the first melting. Spain exhibits natural and bituminous sulphur from Almeria and Albacete, and from other districts specimens of refined sulphur that have probably been obtained from pyrites. Native sulphur is also shown from Russia, Corfu in Greece, Japan, China, Guatemala, and from La Soufrière, or the "Sulphur Mine," a volcanic range of mountains in Guadeloupe. The Government of Venezuela exhibits sulphur obtained from a thermal spring at San Diego. Some very handsome crystallized refined sulphur is shown by Messrs. Boude and Son, of Marseilles, under the name of "soufre candi," which appears like a mass of yellow coral. With this also are specimens of roll sulphur, "flowers of sulphur," block and powdered sulphur,—the powder being specially prepared for the dusting of vines. M. Cros, of Narbonne, and M. Renard, both exhibit fine specimens of native sulphur, quite transparent, and products similar to those just mentioned. Sulphur is also exhibited by Messrs. Chambers, of London.

Several improvements upon the old methods of extracting the sulphur from the ore by melting it in kilns and stacks have been suggested during the last few years. Among these are the use of heated air that has been deprived of oxygen, and that of steam under a pressure of three to five atmospheres. Steam is used in the Russian mine at Czarkowy; but in Italy the scarcity of fuel has hindered the adoption of the methods, and the plan by which a portion of the sulphur is used as a source of heat still generally obtains there. Another method that has been suggested is to dissolve the sulphur out of the ore with carbon bisulphide. The amount of sulphur obtained annually in Sicily alone is estimated at 200,000 tons, or four times the quantity produced forty years ago.

Pyrites is exhibited from various sources. France herself has large beds in the Rhone and Gard departments. Spain sends pyrites, mostly cuprous, from several localities in the provinces of Huelva, Seville, and Almeria, and the mineral is also exhibited from Mertola in Portugal, and Helgeland and Trondhjem, in Norway. Other specimens are shown from Victoria, the Isles of St. Pierre and Miquelon, Newfoundland, where pyrites is said to be very abundant, and from Japan. In working pyrites for sulphur it is usual to heat the mineral in retorts only sufficiently to drive off about one third of the sulphur it contains and then to burn the residue, the sulphurous oxide thus produced being deprived of its oxygen by passing it over heated carbonaceous materials or by reaction with sulphuretted hydrogen. The sulphides of the alkalies and alkaline earths have the same property, and Dr. Hofmann has recently introduced a continuous method in which sulphide of calcium being heated in the current of sulphurous oxide deprives it of its oxygen and is converted into sulphate, from which the sulphide is afterwards regenerated.

The utilization of soda waste as a source of sulphur has made great advances during recent years, Mond's process being largely adopted in France. According to this the soda waste in the lixivation tanks is partially oxidized by passing through it a current of air, and the hyposulphites and polysulphides thus formed are decomposed with hydrochloric acid. The Société anonyme de Sambre et Meuse exhibits a beautiful hollow sphere of crystallized sulphur, alleged to contain not more than 0·02 per cent. of impurity, which has been thus obtained from the soda waste of its factory. Mr. Mactear's process of recovering sulphur from alkali waste has also been adopted in many places in this country and France, but especially in connection with the famous St. Rollox works in Glasgow, where it has been the means of abating the nuisance so long complained of by the inhabitants of Glasgow, caused by the drainage from the immense heaps of waste flowing into the Kelvin and Clyde. The process consists practically in heating the yellow liquor obtained by collecting the drainage from the soda waste with sulphurous oxide and hydrochloric acid, the resulting products being sulphur and calcium chloride. At the present time upwards of two thousand tons of sulphur per annum are profitably recovered from the St. Rollox waste by this process, and the plant is being largely extended. This sulphur is produced as "rock," "roll," and "precipitated sulphur for vine dressing," and a magnificent block of crystals, more than 2½ feet high, is exhibited, together with other specimens, by Mr. Mactear, in the cases of Messrs. C. Tennant and Co.

Chilian caliche is now the source of nearly all the cubic nitre met with, as well as of much potassium saltpetre and iodine. This mineral contains generally from 45 to 55 per cent. of nitrate of soda, and a full description of the district and conditions in which it occurs has appeared in a recent number of the *Pharmaceutical Journal*.* Some potassium nitrate is exported from Chili, where it is obtained as a by-product in the refining of the sodium nitrate, but it is also now produced on a large scale at Simmering, near Vienna, and other places, by heating together strong solutions of sodium nitrate and potassiuu chloride, the salts obtained from Chili and Stassfurt respectively being used. Very few specimens, if any, however, of these products are shown, but native saltpetre occurs in the Guatemala, Peru and San Salvador departments. Neither are any specimens noticeable of natural saltpetre from Hungary or India, and no doubt these industries are much affected by their South American competitor. Attention is called in the special official catalogue to the presence in Algeria of numerous saltpetre beds which are worked by the natives, who are also said to be familiar with the process of developing this salt artificially in saltpetre plantations. Potassium nitrate is exhibited by M. Lefebvre, of Corbehem, apparently as a product obtained in working up beet molasses.

Indeed the by-products in the manufacture of sugar from beets are made to yield a variety of substances and are assuming considerable importance. In the case of Messrs. Dècle and Co., of Rocourt, alcohol and different salts obtained from this source

* Vol. ix., p. 27.

are shown. The percentage composition of the "saline de mélasse" is given as—potassium carbonate, 46·89; sodium carbonate, 14·78; potassium chloride, 15·70; potassium sulphate, 2·31; insoluble substance, 15·02; water, 5·30. M. Vincent, of Paris, shows a series of methylamines and other products, obtained from beet waste, and in the next case the utilization of the by-products of alcohol distillation is illustrated by M. Poiron. Allied to these may be mentioned wine residues and argol, and a considerable number of specimens of tartar have been sent from Fehértemplon, in Hungary, and from Italy. Cream of tartar from the leaves, flowers and fruit of the *Myrtus communis* is also exhibited. From Italy, too, come some specimens of citrate of lime, whilst lemon juice is exhibited by Messrs. Mulaton and Co., of Lyons.

Suint is another source of potassium salts, and this manufacture is carried on by M. Rogelet, of Paris, who exhibits a series of substances obtained from it, including "pâté de suint" and "salin de suint." In the Victoria, Algerian and other courts are numerous samples of wool "in grease." Victoria also shows crude potash obtained from various species of *Acacia*, *Bursera*, and *Eucalyptus*, etc. Other colonies exhibit similar products, but their importance is now vastly diminished by the discovery of the Stassfurt beds, which unfortunately are not represented in the present exhibition.

Seaweed is another important source of potassium salts and iodine, and it forms the crude material of an important series of products obtained from it by destructive distillation that are exhibited by the North British Chemical Company. The seaweed used by this company is obtained on the shores of the Hebrides, where it is collected during the winter. Another very interesting case illustrative of this industry is that of Messrs. Pellieux and Mazé-Launay, of Kerhuon, France, which contains specimens of various seaweeds and the kelp and iodine yielded by them. The information as to the raw materials used in the French iodine industry furnished by this firm is worth quoting with greater fulness than is possible in this report; but it may be referred to again on a future occasion.

Of the four or five hundred kinds of seaweeds that are met with on the west coast of France, only about a dozen species are, from their size and abundance, worth collection for this purpose: these are *Fucus vesiculosus*, *F. nodosus*, *F. serratus*, *Halidrys siliquosa*, *Himanthalia lorea*, *Laminaria bulbosa*, *L. saccharina*, *L. digitata*, vars. *stenoloba* and *stenophylla*, and *Alaria esculenta*. Each of these has its habitat at a definite depth below the surface of the water, and with the exception of *L. bulbosa*, which as collected off the Finistère coast is nearly devoid of iodine, these algæ are superposed in the inverse order of their richness in iodine. Taking *L. digitata*, var. *stenophylla*, as the standard for 100, the following table represents the average relative richness of the other kinds:—

Laminaria digitata, *stenoloba*, new frond	122·89
" " " stalk	109·33
" " " old frond	58·03
" " " entire plant	66·16
L. digitata, *stenophylla*, entire plant	100·00
L. saccharina, entire plant	45·08
Fucus vesiculosus, *F. nodosus*, *F. serratus*, and *Halidrys siliquosa* (average)	12·14
Alaria esculenta	10·84
L. bulbosa	7·83

The richness in iodine of a species, however, varies with the place and conditions of its growth; as a rule, rapidity of growth is adverse to richness in iodine. Temperature, therefore, plays an important part in the assimilation of iodine by seaweeds; those growing on the coasts of Ireland and Scotland yield more than those growing on the coast on Brittany, and even on the coast of France the *L. digitata* from Finistère contains nearly six times as much iodine as the same species from Noirmontier a couple of degrees further south. The richness in iodine will also vary as much as 40 per cent. in the same plant, according to the part of the plant, its age and the season, the maximum richness being attained in the winter and the minimum yield corresponding with the months of June, July and August. Thus in *L. digitata*, var. *stenoloba*, taking the quantity in the new frond as 100, that in the old frond still attached to it would be represented by 47·22 and the stalk by 88·97.

The following table, showing the yield of kelp and iodine by different kinds of seaweed, is based upon a number of laboratory experiments, but of course such favourable results are not attained in manufacturing operations.

	Seaweed required for 1000 parts of kelp.	Soluble matter per 1000 parts of kelp.	Iodine per 1000 parts of seaweed.	Iodine per 1000 parts of kelp.
Laminaria digitata, *stenoloba*—				
New fronds	18,752	582	1·224	22·952
Stalks	16,988	527	1·089	18·500
Old fronds	16,166	502	0·578	9·344
Entire plants	20,095	765	0·606	12·177
L. digitata, *stenophylla*	20,255	714	0·996	20·174
L. saccharina	18,906	711	0·448	8·470
Alaria esculenta	21,080	700	0·108	2·277
Fucus vesiculosus, *F. nodosus*, *F. serratus*, *Halidrys siliquosa* (average)	16,456	507	0·121	1·991
Himanthalia lorea	16,401	720	0·087	1·443
Laminaria bulbosa	21,565	738	0·077	1·660

The fresh seaweed gathered from the place of its growth is considered by Messrs. Pellieux and Mazé-Launay to be the most valuable, as the drift seaweed always becomes rapidly impoverished in iodine by the action of the sea water; after two days it will not contain more than 59 per cent. of the iodine present in it at the time it became detached, and after ten days only about 7 per cent. will remain. On the east coast of Finistère about 1000 or 1200 boats are employed in the collection, the men being provided with long staves with which to detach the weeds from their place of growth. Another considerable cause of loss of iodine is the exposure of the seaweed to wind and rain during the drying for the ordinary operation of kelp burning. The way in which Messrs. Pellieux and Mazé-Launay claim to have overcome this evil will be best described when referring to the iodine manufacture.

Kelp from seaweed is also exhibited in the Venezuelan department by the "gouverneur du territoire colon," and barilla is exhibited from Atacama, in Bolivia.

The *salines* of France, notwithstanding the temporary depression caused by the discoveries at

Stassfurt, now send a large quantity of products into the market, and soda salts as well as the chlorides of potassium and magnesium from this source are shown in the French court. The most important French salt marshes worked are in the departments of the Bouches-du-Rhône, Landes, Charente-Inférieure, and Loire-Inférieure and the Ile de Ré. The salt beds are in the Meurthe-et-Moselle and Doubs departments. In 1876 the home consumption of common salt in France upon which duty was paid amounted to about 300,000 tons, and the exports to about 180,000 tons. Besides these quantities, about 150,000 tons, for which duty is not paid, are used annually in agriculture and the chemical works. The Algerian colony is remarkably rich in salt lakes, which dry up in summer and are then worked by the natives; also in salt springs, and beds of rock salt. In the sub-district of Bougie there are three masses of rock salt, which yield on an average 90 per cent. of chloride of sodium. Products are also exhibited from the salines in the province of Guadalajara, Spain, Aveiro, in Portugal, Salsomaggiore, in Italy, Cagliari, in the island of Sardinia, and in the English court, by Mr. Corbett, from the brine springs at Stoke Prior, Worcestershire.

In the Italian court are to be seen specimens of boracic acid from the *fumaroles* of Tuscany, together with borate of soda, whilst some fine borate of lime is exhibited from Bolivia.

Among the aluminous minerals shown may be mentioned alunites from Civita Vecchia and the Tolfa mines in Italy; bauxite from Herault in France and Willersdorf in Austria, and "alumino-ferrous lignites" from the Aisne and Oise departments. Denmark sends some cryolite from the mines near Ivigtut, in Greenland, which yield about 5000 tons per annum. This is, however, principally used up near Copenhagen for the sake of the soda it contains, it being decomposed by means of incandescent lime. Native alum is shown from Guatemala and Venezuela. Bauxite and kaolin are exhibited from French Guiana, and Guadeloupe sends a specimen of trachite which by the action of sulphurous vapours has been converted into alunite. Kaolin is also exhibited from St. Austell, in Cornwall, and from Spain.

Native phosphate of lime from the province of Cáceres, in Spain, is shown by several exhibitors. It is also to be seen in the Norwegian court from Christiania, and in the Canadian court from the province of Ontario. Messrs. Packard and Co., of Ipswich, exhibit in the French court, as well as in the Agricultural section of the English court, specimens of natural phosphates from various geological formations, together with Suffolk coprolites.

Numerous specimens of calamine are shown in the Spanish court, from the provinces of Navarre, Santander, Teruel, and Almeria. Here also are antimony and manganese ores, from Huelva, Teruel, and Gerona; cinnabar and mercury from Almeria and the Asturian mines; and sulphate of baryta from Almeria and Valencia. Cinnabar and mercury are also exhibited in the Italian court; cinnabar, ethiop's mineral and quicksilver in the Austrian court from the mines in Idria; native cinnabar, and quicksilver extracted from it, in the Queensland and in the Japanese courts. Sulphide of antimony is sent from Portugal and antimony ore from Italy. Some fine star antimony is exhibited by Messrs. Bright Bros., of Melbourne, and antimony ores are displayed by the Costerfield (Victoria) Gold and Antimony Mining Company. Regulus of antimony and block antimony are exhibited by the Queensland government, and antimony and antimony ore are both to be found in the Japan court. In the Swedish court there is a fine show of nickel in cubes, powder and fragments. Nor should some splendid specimens of plumbago and plumbago crucibles, exhibited by the Canadian Plumbago Company, be overlooked. Plumbago is also shown in the Queensland department. But to attempt to give a mere list of the collections of minerals—especially fine in the English and French colonial and the Spanish courts—would extend far beyond the limits of this report, and the enumeration must be limited mainly to those that find their application in the manufactures exhibited.

Bituminous shale is the representative of an important class of products to which reference will have to be made. The celebrated Boghead mineral is exhibited in the case of Messrs. Young and Co., of the Bathgate works, and the Oakbank Oil Company, of Glasgow, show the shale used by them. Shale and its manufactured products also occur in the case of M. Voiret, of Ménat, who puts forward a carbonized shale as a substitute for animal charcoal. Ozokerite, mineral wax, or ceresin, is well represented in the Austrian court, being obtained principally from the mines in Gallicia, in which district, too, a considerable petroleum industry exists. In its crude form ozokerite appears generally in large compact brown homogeneous masses, but it sometimes occurs in shallow veins in gypsum, slaty schist, and clay, giving them a marbled appearance that is well illustrated in some of the specimens shown. Ozokerite is also exhibited from Russia, where it occurs in the Caucasus, and the "ceresin" and its manufactured products shown in the Italian court are from this source. Petroleums of different shades from black to almost colourless are sent from the Bakow factory on the shores of the Caspian.

Beeswax is exhibited from different sources, but probably the most numerous specimens are in the French, Portuguese, and Algerian courts. In the colony the Kabyles are the principal raisers of bees, some of them possessing as many as 800 or 900 hives, each of which will yield upwards of a pound of wax of good quality. In 1876 Algeria exported more than eighty tons of bees wax, of the value of about £10,000. Apiculture is carried on also to a considerable extent in the centre and south of France, where in 1874 there were nearly 2,000,000 hives, producing about 1000 tons of honey and 2500 tons of wax, and the number is now estimated at 2,500,000. M. Laverdure, of Montauban, exhibits wax in "bread," and purified. There is also in this case a curious specimen of black comb, or *rayon*, said to be from the "ruches des montagnes." Some good specimens of bleached wax are to be seen in the Netherlands department, in the case of Mr. Bressers, of Tilbourg. Two or three varieties of wax are also to be found in the Indian, Gaboon, Cochin China, Guatemala, San Salvador and Guadeloupe courts; that from Guatemala, and probably those from the other South American countries, being the product of the genus *Melipona*.

The number of oleaginous materials exhibited, available for soap and candle making and similar manufactures, is legion. Among those from the vegetable kingdom, shown in the group of cases of the Marseilles soap makers, are the ground nut,

rape seed, colza seed, poppy seed (white from India and black from the north of France), sesame, linseed, hempseed, nuts of *Jatropha Curcas*, palmiste nuts, and the seeds of illipe (*Bassia longifolia*) and *Trichilia emetica*. The first place must be conceded to olive oil, of which there are upwards of three hundred exhibitors in the Spanish court alone and nearly as many from Portugal and Italy; but of course the greater part of the specimens of this oil shown are intended for alimentary purposes, and it will be better therefore to deal with it under that head.

In France the field poppy (*Papaver Rhœas*) is cultivated in Artois and Picardy, and the seeds are pressed on the spot for their oil, which is known as "white oil." The colza, rape, hemp and linseed are also obtained from home grown plants. Another plant cultivated in France for the sake of its oleaginous seeds, which are reddish brown and rather larger than poppy seeds, is the *Camelina sativa*. The ground nut (*Arachis hypogœa*) is pressed principally at Marseilles, Bordeaux, Nantes, and Dunkirk, the nuts coming from the west coast of Africa. Some idea of the importance of this industry in France may be formed by the following figures which give the production in 1875:—hempseed oil, 1800 tons and 4200 tons of cake; linseed oil, 3000 tons and 5800 tons of cake; colza oil, 43,000 tons and 71,000 tons of cake; poppy, rape, and camelina oils, together, 10,500 tons and 16,500 tons of cake.

The flax plant is also largely cultivated in Algeria and the export of linseed from that colony probably amounts to upwards of 5000 tons annually. There are also a large number of samples of linseed in the Portuguese court. The seed when expressed with heat yields 22 per cent. of oil, the Sicilian variety being the richest in oil. Colza seed yields from 30 to 32 per cent. of oil. The castor oil plant grows vigorously in Algeria, yielding in its second year about two pounds, and in its fifth or sixth year six or seven pounds of seeds. The seeds of *Ricinus communis* yield 30 per cent. of oil, and those of *Ricinus spectabilis* as much as 52 per cent. The seeds of *Arachis hypogœa*, when pressed without heat in a hydraulic press, yield a clear and very fluid oil, which is edible when fresh, but is especially used in the manufacture of soap. Sesame seeds yield in three expressions from 5 to $7\frac{1}{2}$ per cent. of a fine oil, which has a considerable reputation in the East as an absorbent of the odorous principle of flowers. There are also several specimens of sesame and ground nut oil to be seen in the Chinese court.

The treatment of animal fats for soap-making is illustrated in the case of Messrs. Arlot and Co., of Aubervilliers, who utilize, among other things, the fat of the refuse flesh obtained by scraping bones. Products from butchers' refuse are also shown by Messrs. Souffrice and Co., of St. Denis. In the Forestry department are a considerable number of animal fats, as well as vegetable oils, and M. Derin exhibits an apparatus for filtering animal fats. But a more important piece of apparatus is to be seen in the case of Madame Deiss and Sons, in the original invention for the extraction of the fat from animal refuse, bones, oil cake, cotton seeds, greasy rags, or other materials by carbon bisulphide. There are also some very good specimens of colza and linseed oils in the Netherlands department where, too, the extraction of fats by carbon bisulphide is illustrated by the house of Hartogh and Co. In the Uruguay court there are numerous specimens of animal fats and other by-products in the manufacture of extract of meat, as well as some soaps prepared in Uruguay from fat residues.

But a glance at the French colonial courts reveals the fact that all the oleaginous materials available are far from being in use. French Guiana, the Gaboon, Senegal and French India are particularly rich in this respect, and in French Guiana and the Gaboon especially, an immense quantity of oil seeds are wasted annually because there is no demand for them. Most of the better known oil seeds are represented, together with specimens of the oil obtained.; but there are a large number of others, concerning which very little is known, and it is to be regretted that in most cases no indication is given of the nature of the product or the quantities of the raw material that could be supplied. The following are a few that may be particularized:—

Aleurites triloba, or candle-nut tree (Euphorbiaceæ).—The kernels of the seeds, or "*noix de bancoule*," yield to pressure 56 or 57 per cent. of a limpid oil, which only requires a single filtration to render it fit for burning, and is said to be superior for use in lighthouses to colza oil. When boiled, this oil makes a good siccative for paint and is suitable for the varnish manufacture, while from its capability of drying in the interval between two tides it has been used for painting ship's bottoms. The oil is also used to some extent by artists. The oil cake furnishes a good manure, containing 9 per cent. of nitrogen, 4 per cent. of phosphoric acid, potash, magnesia and carbonate of lime. When eaten fresh the kernels are apt to produce purging and colic, but it is said that this may be avoided by carefully removing the embryo. The seeds and oil are exhibited from Guiana, the Ile de la Réunion, Tahiti, and New Caledonia, where the plant is reported to be very abundant.

Arachis hypogœa (Papilionaceæ).—The ground nut has assumed a considerable importance during recent years in Senegal and its dependencies, where thirty thousand tons are now produced annually. The nuts most esteemed, because of the thinness of their shells and superior yield, come from the Galam district. When pressed cold the oil is edible, but the ordinary oil is used in soap making and lighting. The nuts and oil are also shown from Pondicherry and New Caledonia.

Anacardium occidentale (Anacardiaceæ). — The kernels of the seed (commonly known as the cashew nut) yield 40·5 per cent. of oil, and the pericarp 29·5 per cent. of an acrid oil. The nuts, kernels and oils are exhibited by M. Castaing, of Pondicherry.

Azadirachta Indica (Meliaceæ).—The seeds and oil, used for lighting purposes, are exhibited by M. Castaing, of Pondicherry.

Bassia Djavé and *B. Noungou* (Sapotaceæ).—The former species is said to yield 56 per cent. of oil, the specimen exhibited in the Gaboon department being of a dirty white colour; the oil from the latter is pure white. Seeds and oil from *B. longifolia* are shown from Pondicherry and the oil is said to be much esteemed for soap making.

Bertholletia excelsa (Lecythidaceæ). — The brazil nut is exhibited from French Guiana as yielding 66 per cent. of oil, but probably it would hardly be available for such a purpose considering its value on the dessert table.

Calophyllum inophyllum (Clusiaceæ).—Nuts and

oil shown from Cochin China, Tahiti, and New Caledonia.

Carapa Guianensis (Meliaceæ). — Seeds and oil shown from French Guiana and Senegal. In the former country the fall of the seeds commences in February and continues during four or five months: this is the principal harvest, during which the soil is covered in some places with a layer of seeds three or four inches in depth. Another less abundant harvest occurs in October and the seeds are said then to yield a thick oil well suited for soap making. In consequence of the necessity of pressing the seeds on the spot an immense quantity is wasted every year.

Caryocar butyrosum (Rhizobolaceæ).—Seeds and "butter" from French Guiana.

Cocos nucifera (Palmaceæ).—The nuts and oil from the cocoa nut palm are shown from Pondicherry and Mayotte, and the nuts from French Guiana, Martinique and Senegal. The dried kernels yield 69 per cent. of oil and the fresh ones 42 per cent.

Citrullus vulgaris (Cucurbitaceæ).—Seeds, from Senegal.

Couepia dulcis (Chrysobalanaceæ).—Seeds, from French Guiana.

Coula edulis (Olacaceæ).—The seeds, an abundance of which could be collected in the Gaboon, yield 32 per cent of an edible oil.

Curcas purgans (Euphorbiaceæ).—The white kernels yield a good oil for lighting. Seeds are exhibited from the Gaboon, Senegambia (where they are very abundant), French Guiana, Réunion, and Pondicherry. The cake forms a manure, and is said to cause rabbits to disappear from places where it is employed.

Dryabalanops sp. (Dipteraceæ).—Attention is specially called in the Gaboon department to the seeds of an undetermined species of *Dryabalanops*, which yield 61 per cent. of fat that does not melt below 70° C.

Elæis Guineensis (Palmaceæ).—The outer rind of the fruit of the oil palm yields about 71 per cent. of oil suitable for saponification, and the kernels 47 per cent. of a white fat adapted for making the finer soaps. The nuts are exhibited from the Gaboon, whence a much larger quantity could be supplied, Senegambia, the Gold Coast, and French Guiana.

Gossypium barbadense, from Guadeloupe ; *G. acuminatum* and *G. vitifolium*, from India (Malvaceæ). — Cotton seed oil, used for soap-making and lighting.

Guizotia oleifera.—The seeds, which yield the ram-til oil of India, are exhibited from Assinie and Grand Bassa, on the Gold Coast.

Helianthus annuus (Compositæ).—Sunflower seeds, from Pondicherry.

Hibiscus cannabinus and *H. populneus* (Malvaceæ). —Seeds, from Pondicherry.

Irvingia Barteri (Burseraceæ).—The seeds bruised and submitted to a gentle heat form "dika," or "Gaboon chocolate." The percentage composition of dika is, water, 5 ; protein, 9·5 ; fat, 65·5 ; starch, 10 ; cellulose, 3·0 ; gum, 2·6 ; and inorganic substances, 4·4. Dika fat resembles cacao butter, and melts at 40° C. The seeds are exhibited from the Gaboon, and special attention is called to the fat in the official catalogue as suitable for fine soap making.

Lecythis Ollaria, or "monkey pots," *L. Zabucajo*, or "sapucaia nuts," and *L. grandiflora* (Lecythidaceæ). —The fruits and seeds are exhibited as oleaginous materials from French Guiana.

Melia Azedarach (Meliaceæ).—The seeds yield 50 per cent. of oil suitable for soap making. India.

Moringa pterygosperma (Moringaceæ).—The seeds, which yield an oil used by watchmakers, are exhibited from Senegal and Guadeloupe, Some undetermined seeds, about 2 in. by 2½ in., shown in the Gaboon department under the name "m'pôga," appear to yield an abundance of a very fluid oil that might also be useful as a watch oil.

Myristica spp. (Myristicaceæ).—The seeds of *M. longifolia*, yielding 54 per cent. of oil and those of *M. Angolensis*, yielding 72 per cent., are very abundant in the Gaboon, where with other oil seeds they are said to be wasted for want of a useful application for them.

Omphalia diandra (Euphorbiaceæ).—The seeds yield 61 per cent. of a fine machine oil. From French Guiana.

Pentadesma butyracea (Clusiaceæ).—This tree, the "butter and tallow tree" of Sierra Leone, grows abundantly at the bottom of the estuary of the Gaboon, and it is said that at times considerable quantities of the nuts are found on both banks of that river "transformed into fatty acid."

Ricinus spp. (Euphorbiaceæ).—The seeds of various species are exhibited from Guiana, Guatemala, Martinique, Guadeloupe, the Gaboon and India, including *R. communis*, *R. sinensis*, *R. spectabilis*, *R. sanguineus*, *R. lividus*, *R. rutilans*, and *R. americanus*.

Salvia Chio (Labiatæ).—The mucilaginous seeds of this species of sage are exhibited from Guatemala, and are said to yield a siccative oil superior to linseed oil.

Sapindus Saponaria (Sapindaceæ).—The oleaginous seeds and saponaceous rind are exhibited from Guiana, Martinique and Guadeloupe.

Sesame indicum and *S. orientale* (Bignoniaceæ).— Sesame seeds—red, white and black—yielding 50 to 54 per cent. of oil, constitute one of the principal branches of commerce at Pondicherry. They are also exhibited from Upper Senegal, but the cultivation there, which had attained considerable proportions, has been nearly abandoned in consequence of war.

Sterculia sp. (Sterculiaceæ).—The seeds of an unnamed species, yielding 62 per cent. of oil, exhibited from the Gaboon.

Terminalia Catappa (Combretaceæ).—The seeds, which resemble almonds in shape, are said to yield an oil comparable to that of sweet almonds. They are exhibited from Martinique, Réunion and Pondicherry.

Virola sebifera (Myristicaceæ).—This tree is very abundant in French Guiana. The seeds when bruised and pressed yield 26 per cent. of an odorous fat, suitable for making fine toilet soaps.

In the Cochin China court is exhibited a specimen of vegetable wax, extracted by boiling and pressing the seeds of an unnamed species of *Buchanania*. The trees are said to be abundant in the colony, and for the most part unworked. In the Guatemala court are exhibited crude vegetable wax, from *Myrica cerifera*, and vegetable tallow, from *M. sebifera*.

Of the crude materials for varnish making there are several displays in connection with the manufactured article, but very much the finest collection is to be seen in the English court, in the case of

Messrs. Gidney, Clark and Co., of West Ham Abbey, London. One enormous block of Kauri resin is shown that weighs about 2 cwt., and some of the specimens of copals are extraordinarily clean and clear. Success in varnish making is very dependent upon a judicious selection of the resins, or "gums," as they are technically called, of which our knowledge at present is very imperfect. Some interesting information respecting the fossil, semi-fossil, and other resins most in use is given in a pamphlet issued by this firm, from which a few details may be quoted.

Sierra Leone Copal an almost white exceedingly elastic resin, is shipped from Sierra Leone, but has no other connection with that port. It is principally obtained from the beds of the Malacourie, Pongos, Nunez, and other neighbouring rivers, being washed down by the rains from the mountain slopes in a "cindery" condition, and collected by the natives, who subject it to a rude washing. Its probable source is the *Guibourtia Copallifera*. The proper manipulation of this particular gum is said to be the foundation of all fine varnishes.

It is used principally in conjunction with "Animi, or Anime," a very hard, true fossil resin, having the highest melting points of all the varnish "gums." This is found on the east coast of Africa, and shipped from the island of Zanzibar. According to Stanley it is dug from the earth, being originally derived, it is supposed, from the *Trachylobium Mosambicense*, though it is doubtful whether the trees of this species now produce this particular resin. A very inferior kind is shipped from the island of Madagascar, and also from the Mauritius, but these are principally re-exported to the Continent and America, being unsuited for the English maker.

Kowrie, or Kauri, is a semi-fossil resin, the produce of the *Dammara Australis*, a large coniferous tree, and is found solely in the English colony of New Zealand, imbedded in considerable quantities in the earth, sometimes in remarkably large pieces It is sorted into qualities in the colony, carefully cleaned and scraped by the natives, and shipped. direct to London, and thence, as with Madagascar and Mauritius animi, re-exported to America and the Continent. Although, on account of its easy manipulation larger quantities of this resin are used than of any other kind, it is not to be compared with the two resins previously described, for producing durable varnish. The declared deliveries of kauri resin from the public warehouses of London during 1877 amounted to 1522 tons, while the declared deliveries of all the animi and copal sorts together did not exceed 800 tons.

Benguela Copal of a whitish colour, with a blackish coating, and Angola Copal, of a reddish or creamy colour with a bright red coat, are both found in the interior of Africa, but the exact sources are not known further than that the natives bring them down with ivory, gold dust, etc., to barter on the coast. They are named from the port or part of the coast where the shipment takes place. They are fossil resins and from their dusty and dirty nature both are evidently found imbedded in the earth. Being poor, weak, and unreliable gums, they are very sparingly used by English makers.

Accra and Lisbon Copals, both of the copal or hard nature, are similarly clouded in African mystery as regards source of supply and the trees that produce them. Probably they are the produce of a species of *Guibourtia*, but beyond being resins occasionally used they have little or no value as standard varnish "gums" in England.

Manilla Copal derives its name from Manilla, in the Philippine islands. Its true botanical source is unknown, but probably it is from a species of *Trachylobium*. It is not a fossil resin, but the natural exudation concreting on the bark of contemporary trees, whence it is collected every season by the natives. There are two varieties of this resin, hard and soft manilla: the latter has the lowest melting point and market value of the varnish "gums" and much resembles rosin in its nature and results. Though considerable quantities are imported into England it is nearly all re-exported to foreign countries.

Dammar is the clear resinous exudation of the *Dammara orientalis*. It is extremely soft and easy to dissolve and is used in the manufacture of the white paper varnishes. The finer qualities are shipped from Batavia, and the inferior from Singapore.

Amber is a fossil gum found on the shores of the Baltic and some Russian lakes; it is exported also from Japan. It is used occasionally in the manufacture of varnish and amber oils.

Mastic is an exudation from the *Pistacia Lentiscus*. It is principally exported from the island of Chios, and is an expensive resin used in the manufacture of mastic varnish.

Beside these, which are the principal resins used in the manufacture of oil varnishes, this firm exhibits specimens of Pebble Copal, from the west coast of Africa, resembling small pebble stones, a form resulting from the abrasion consequent on the fragments being washed down by the rapid mountain torrents; and also benzoin, sandarach, and shellac, which are used solely in the manufacture of spirit varnishes.

The firm of Wilkinson, Heywood and Clark, of London, too, shows a number of these resins and gum-resins, together with about seventy different essential oils obtained from them by destructive distillation. They also show solutions of copal, animi and kauri resins, in eucalyptus oil. Hydrated oxide of iron is used by this firm instead of the more expensive ferrocyanides as a pigment for black varnishes.

Among other crude materials that are shown may be mentioned various dye woods; gas residues; bones, as a source of gelatine, animal black, gelatine and phosphate manures; fish skins and rabbit skins, as sources of gelatine; and blood, fish's spawn from Sweden, and hens' eggs from different places, as sources of albumen. But it is left for our American cousins to startle the shade of the late Professor Graham with "crystallized eggs," which are—or are not—to be found in the case of the United States Egg Desiccating Company of New York.

(*To be continued.*)

PREPARATION OF PERMANENT RENNET-ESSENCE.*

BY H. SOXHLET.

For the preparation of concentrated solutions, only dried calves' stomachs are suitable, and those which have been blown out with air and dried as quickly as possible are

* (*Dingl. polyt. J.*, ccxxviii, 341–349). From the *Journal of the Chemical Society*, October, 1878.

best. The small stomachs of the youngest animals are richest in ferment. Fresh stomachs are useless for preparing a concentrated essence, as they yield a thick jelly which, by filtering, gives only a small quantity of liquid. Concentrated extract prepared from stomachs after fourteen days is light yellow in colour, whilst that prepared after six to eight months' storage of the stomachs is dark brown. This results from slight decay of the stomach, and as the colour does not affect the usefulness of the product, it is advisable to use stomachs which have been stored for at least three months. The portion of the stomach without folds, the Portio pylorica, is cut away as it is poor in ferment.

Acid liquids are usually employed for extracting, as they seem to produce richer solutions, but this is only because they act more quickly at first than water alone. Hydrochloric acid containing 0·1 and 0·2 per cent. of acid in two days gave extracts twice as rich in ferment as an aqueous one; but after eight days all three solutions were equally strong. A little thymol was added to prevent decomposition during the experiment. When the temperature is raised to 30–35°, water acts more rapidly than the acid, and the solution is richer than that produced by acid at the ordinary temperature.

Attempts were made to produce concentrated solutions by means of dilute acids, but without success. A 0·3 per cent. solution of salicylic acid gave a liquid which was quite fresh after twelve months, but after only two months its activity had fallen off to the extent of one-half.

A series of experiments made with solutions of common salt containing from 2 to 26 per cent. shows that solutions containing 3 to 6 per cent. of salt yield the liquids richest in ferment and capable of the highest degree of concentration.

This property of dilute salt solutions depends on the fact made known by Graham, that common salt is a very easily diffusible substance. Organic acids in combination with common salt are no better extraction agents than the salt alone. 5 per cent. solutions of sodium or potassium sulphate are less efficacious than the same strength of salt solution. Potassium chlorate behaves in much the same manner as common salt; an excess of the potassium chlorate, however, neither acts as efficiently as a precipitating agent, nor as a preventive of decomposition.

60 to 80 grams of calf's stomach steeped for five days in 1 litre of a 5 per cent. solution of common salt at ordinary temperatures, yield a solution of which 1 vol. will coagulate 10,000 vols. of new milk at a temperature of 35° in forty minutes. If the filtered solution is treated with 60 to 90 grams more of stomach a solution of double strength is obtained; another repetition gives a solution three times the strength of the orignal one.

To prevent decomposition, about 0·3 per cent. of thymol may be added to the concentrated rennet extract solution. Possibly a slight taste due to this may be detected in the finest cheese, but for the same reason oil of cloves is much more objectionable. Boric acid is on all accounts the best antiseptic to employ, and solutions to which it has been added may be kept in covered vessels for months.

All extract solutions lose strength on keeping; during the first two months the solution may become 30 per cent. weaker, then the strength remains nearly constant for eight months in the case of a solution of 1 : 18,000. Alcohol is almost as good an antiseptic as boric acid, if the solution be preserved in well-stoppered flasks.

Detailed experiments are given, showing that the time required to coagulate milk is inversely proportional to the strength of the extract solution. From this the strength of a solution can be determined by adding 1 c.c. to 1 litre of milk at 35°, and noting the time required to coagulate the milk; this time multiplied by 10 gives the time for the proportion 1 : 10,000.

THE PRESENCE OF OZONE IN VEGETABLE TISSUES.

Under the title "A New Point of Resemblance in the Respiration of Plants and Animals," Dr. James Jamieson, of Melbourne, Victoria, publishes some interesting observations which seem to point to the formation of ozone in the process of vegetable respiration. The points which he considers to have been established are these:—(1). That the oxygen, inhaled by plants as well as by animals, enters first into some form of loose combination whereby it is ozonized or rendered active; and (2). That plants contain a substance, other than chlorophyll, which has some important points of analogy with the hæmoglobin of animals, acting like it as an ozone transferrer. He thinks, however, that it cannot yet be regarded as more than fair presumption that this substance is that with which oxygen becomes loosely combined. The test employed by Dr. Jamieson is the deep blue colour produced in a mixture of tincture of guaiacum and peroxide of hydrogen by a minute trace of blood or hæmoglobin. The experiments were made chiefly on fruits of different sorts, especially apples and pears, though what is true of them holds good of most other fresh vegetable structures and expressed juices. If a drop of tincture of guaiacum be allowed to fall on a freshly cut surface of an apple or pear which has not been too long gathered and is not decayed, it will generally be found that a blue colour is quickly struck. Here we have the recognized reaction characteristic of the presence of ozone. The rapidity and intensity of the reaction will be found to vary with different articles or different specimens of the same article; and they may fail altogether, as in very watery fruits, such as some grapes; though even with these the guaiacum reaction may be perceptible in a green berry from the same bunch. The reaction was not observed with the soft pulpy fruits which decay quickly, such as the strawberry or peach. When fruits have been long kept, the ozone reaction becomes gradually weaker, the power of inhaling oxygen being lost and the amount stored up gradually consumed. It may still be detected when the fruit has become overripe, and has entered on the stage of incipient decay, disappearing entirely when actual rottenness sets in. When fruits, etc., are cooked, either with moist or dry heat, both this substance and the active oxygen are destroyed, no blue colour being produced by guaiacum alone or on the addition of peroxide of hydrogen. Dr. Jamieson adduces reasons for concluding, (1), that the agent which produces these reactions is not merely ordinary oxygen absorbed and dissolved in the vegetable juice; (2), that it is not newly-formed oxygen separated by the chlorophyll; (3), that it is not probable that it is actually dissolved ozone; and he considers the only remaining explanation to be that the oxygen is in the form of a loose combination, as it is in the blood, and therefore capable of being slowly given off in a very active form to combine definitely with oxidizable substances. Dr. Jamieson has come to no definite conclusion with regard to the substance with which the oxygen is temporarily combined; but he considers it certain that in fresh fruits and other vegetable substances there is an element which is possessed of the same ozone transferring property as hæmoglobin. It certainly is not chlorophyll, because it exists abundantly in the interior portions of fruits, and in many other structures, such as the potato, turnip, etc., which never contain chlorophyll. It is probably intimately associated with the vascular tissue, since the ozone reaction, as well as the ozone transferring function, is most marked and persistent in fruits near the core, where the vessels from the stalk are more abundant than in the outer more purely cellular parts. In conclusion he considers it possible that the substance is in some way attached to the small granules termed by Sachs aleurone-grains, which are, according to him, mainly proteinaceous; since the coloration sometimes appears most intense at the spots where these are abundant.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 19, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ORANGE QUININE WINE.

A CORRESPONDENT in the North of England informs us that he has had a visit from the Excise officer in reference to the sale of this preparation which has so often been the subject of inquiry. The impression of our correspondent was that some new regulations had recently been introduced necessitating the taking out of a sweets licence by chemists and druggists who sell quinine wine, and as we were not acquainted with that circumstance we have made inquiries at the Inland Revenue Office.

We find that there is not any change in the regulations of the Excise Department respecting the sale of quinine wine, and although the subject was mentioned in a general order issued last June, this was done only with the object of directing attention to the requirements of the Excise. The matter is one of such general interest that it seems desirable to recapitulate for the information of our readers the details of the Excise regulations.

Orange quinine wine containing sulphate of quinine in the proportion of one grain of quinine in every ounce of the wine is a preparation agreeing with the directions of the British Pharmacopœia, and for that reason it is regarded by the Excise Department as a medicine, the sale of which without a licence should not be objected to. A preparation of this strength is moreover considered as being no longer fit to be used as a beverage, which is an additional reason for allowing its unrestricted sale.

So far the statement of the regulations contained in the recent general order agrees with the information given in October, 1872, and published at that time in the *Pharmaceutical Journal*, to the effect that no licence was required for the sale of quinine wine if made according to the recipe in the British Pharmacopœia, and not sold as a proprietary or patent medicine.

The latter exception appears to have been understood by some to mean that when quinine wine of any strength is sold as a proprietary medicine it must have affixed to the bottle the ordinary patent medicine stamp, and that if the seller held an ordinary patent medicine licence nothing further was necessary.

This, however, would seem to have been a misunderstanding, and in the recent general order it is stated that if any druggist sell quinine wine of the Pharmacopœia strength as a proprietary medicine he must affix the proper stamp to each bottle, and hold a patent medicine licence. But if any such medicated wine not containing one grain of quinine to the ounce be sold, labelled as a medicine or not, the usual sweets licence and magisterial certificate will be necessary.

It is on this latter point that it is supposed an innovation has been introduced by the Excise Department, and in a circular of a quinine wine maker it has been stated that such is the case. We are, however, informed by the authorities at Somerset House that the requirement of a sweets licence for the sale of quinine wine containing less than one grain of quinine to the ounce of wine has always been in force, and it is only in consequence of finding that quinine wine containing less than that proportion of quinine has been sold that attention has been directed to the subject in the recent general order.

As regards the sale of such wine containing less than the Pharmacopœia proportion of quinine, the general order directs that should it appear to be recommended instead of ordinary wine, or to be drunk in quantities inconsistent with the fact of its containing the required proportion of quinine, samples are to be sent to the laboratory at Somerset House for analysis and the facts are to be reported to the Board of Inland Revenue with a view to prosecution.

We have deemed it requisite to place this information before our readers in order that they may be upon their guard and to make them acquainted with the actual state of the law. That there is some need for this being done appears from the fact that we are informed one quinine wine maker is taking back all the wine his agents have in stock for the purpose of making it up to the proper strength.

So far as the action of the Excise Department is concerned we understand that the object is merely to warn chemists and druggists of what is required, and we learn that the communications made by the excise officers were of a similar friendly nature. There does not appear, therefore, to be any ground for alarm or for the supposition that there is any intention to take unfair advantage of the sellers of quinine wine.

The one thing essential for keeping quite clear of the excise restrictions is to make sure that the wine contains the proper proportion of quinine and then it can be sold without a sweets licence. If quinine wine of full strength be sold as a proprietary article the usual patent medicine stamp must be affixed to each bottle.

When wine containing a smaller proportion of quinine is sold in any way a sweets licence is requisite, while if it be sold as a proprietary article a patent medicine stamp will be required as well as the sweets licence.

VIOLET POWDER.

In justice to Professor Redwood we are constrained to insert the letter in which he repudiates the charge implied in Mr. Brown's letter, that he desires to countenance any kind of substitution of one article for another. We do so the more readily, also, because Professor Redwood's disavowal of such an intention is important in regard to the general merits of this subject. Unfortunately the violet powder discussion has been somewhat complicated by the introduction of two distinct lines of argument that have been confounded together. Professor Redwood and others defend the sale and use of powdered selenite as a dusting powder because they consider that it is a harmless and appropriate material for that purpose. Others condemn the sale of this article under the name of "violet powder," because they consider that name to have been so specially appropriated to perfumed starch as to render inadmissible the secret substitution of any other material in place of starch and under that name.

There is a very wide difference between these two positions, and even if the harmlessness and fitness of powdered selenite as a dusting powder were fully established it would not follow that it should be sold as "violet powder," nor could the advocates of its use be charged with countenancing its substitution for starch under that name. The only difficulty there is arises from the want of a name that will be as acceptable to the habits of the persons who use dusting powder as the term "violet powder" has been. This difficulty is one that must, we think, be encountered and overcome as best it may be by making known the merits of powdered selenite, and any disadvantage that may attach to the adoption of the article by the public must be charged to the omission of that step at an earlier period.

Adopting Professor Redwood's statement that powdered selenite has long been extensively used as being unquestionably correct, it would seem that there is good ground for the opinion that it is at least not an inappropriate article for the purpose it has been applied to in place of starch. That being the case there is equal reason to believe that if it had been originally introduced as "Blank's improved dusting powder," its own intrinsic merits would have secured its recognition, and we should not have had the disagreeable disclosure that some "violet powder" was, not what almost the whole of the trade thought it was and what the public had been in the habit of using, but an entirely different thing.

Whatever may be the merits of powdered selenite, and however much they may be proved by the fact of its extensive use for some years past, they were not made known until quite recently, and both those who have sold it and those who have used it as "violet powder" have had no chance of deciding for themselves whether the article they sold or used was to be perfumed starch or not. This is the objectionable circumstance, and it is one that demands the provision of a suitable remedy by those who offer the article to the public.

CHEMISTS' [ASSISTANTS' ASSOCIATION.

On Wednesday, Oct. 23, at 8.30 p.m., Mr. Branson will read a paper on the "Chemistry of Aloes," at the rooms of the above Association, 32a, George Street, Hanover Square.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London on Wednesday, October 16, 1878, the Report of the College of Preceptors on the examination held on October 1, was received.

One hundred and ninety-five candidates had presented themselves for examination, of whom *one hundred and three* had failed. The following *ninety-two* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students :—

(Arranged Alphabetically).

Anderson, James Grant	Aberdeen.
Ashfield, Armishaw	Stratford-on-Avon.
Barford, Herbert William	Stamford.
Barlow. George Robert	Congleton.
Batchelor, Charles	Southsea.
Beaton, Hugh	Woodside.
Bell, Jacob	Hexham.
Bells, James	Dumfries.
Bisset, William Henry	Aberdeen.
Bond, Frederick Joseph	London.
Bostock, John William	Ashton-under-Lyne.
Buckley, William	Oldham.
Calhaem, Richard Edmund	Bristol.
Carr, Percy	Sheffield.
Chapman, Robert	Banff.
Chubb, Emanuel	London.
Coull, George	Edinburgh.
Crompton, William	Bury.
Davies, David	Lampeter.
Drury, George John	Scarborough.
Drysdale, William	Glasgow.
Dugan, Alexander F.	Aberdeen.
Eeles, Joseph Walter	Woolwich.
Ellis, Austin	Shipley.
Fairweather, Ernest Barratt	Tavistock.
Gould, William E.	Birmingham.
Greensill, Francis William	Blakenhall.
Hardie, John	Dundee.
Harry, Samuel Rhys	Swansea.
Hart, Frederick Charles	Tongham.
Hayter, Charles Robert	Hayward's Heath.
Henderson, Alexander	Cupar Fife.
Heyes, Harry	Bolton.
Horne, Charles	Stourbridge.
Kay, John Allison	Elgin.
Kenway, Douglas Maitland	Birkenhead.
Kingan, David	Dumfries.
Koster, Jacob Willem	London.
Lacy, Herbert	London.
Linnell, George	Bickley.
Lynn, John Robert	Stroxton, Grantham.
McGregor, Thomas George	Dingwall.
Marris, Henry Joseph G.	London.
Martin, Stephen Luther	Llanelly.
Meadley, Arthur Lawrence	Birmingham.
Miles, Derwent Maurice	Bicester.
Millhouse, Edward	Grantham.
Monk, John Thomas	London.
Morrison, Charles Orr	Sheffield.
Mungle, James	Edinburgh.
Munro, James Mitchell	Aberdeen.
Nicholls, Charles	Wellington,Somerset
Parish, William	Cleator Moor.
Parry, Joseph	Towyn.
Pearson, Walter	Manchester.
Pickles, Walter	London.
Powrie, Percy Chamberlain	Mossel Bay.
Pyle, Robert	Morpeth.
Rees, Richard	Neath.

Rhoden, Samuel Thornton .....Sheffield.
Richardson, John .....Mansfield.
Rouw, Robert Wynne.....Ruthin.
Rowland, Thomas William.....Epping.
Russell, John William.....Dundee.
Shacklock, P. J. .....Littleworth.
Smales, Alfred John.....Darlington.
Smith, Alfred Bowman .....Lexden.
Stark, Ernest Annan .....Birmingham.
Stephenson, Sydney.....Sheffield.
Stuart, Findlay.....Dumbarton.
Style, Frederick William.....Havant.
Taylor, Percy William .....Leamington.
Thom, John .....Forfar.
Thomson, Isaac William .....Edinburgh.
Thwaites, Frederick.....Bishop Auckland.
Tomlison, James Stevenson ...Preston.
Turner, Charles Wall .....Bath.
Urwick, William .....London.
Wade, Albert Holland .....Kingston-on-Thames
Wakefield, John Henry .....Dudley.
Walker, William .....Aberdeen.
Waller, Ernest George .....London.
Watson, David Sydney .....London.
Watson, William .....Aberdeen.
Whitford, William .....London.
Wight, James Andrew.....Settle.
Williams, William .....Bath.
Wilson, Henry .....Newark.
Wilson, Richard .....Kidderminster.
Winters, Charles Thomas .....Drax; near Selby.
Wright, William Charles .....Stockport.
Wylde, Samuel Roe.....Macclesfield.

The following is a list of the centres at which the examination was held, showing the number of candidates examined at each centre and the result :—

	Candidates.				Candidates.		
	Examined.	Passed.	Failed.		Examined.	Passed.	Failed.
Aberdeen	13	9	4	Lancaster	1	1	0
Birmingham	12	9	3	Leeds	7	2	5
Brighton	3	1	2	Lincoln	3	2	1
Bristol	6	4	2	Liverpool	7	2	5
Cambridge	5	0	5	London	33	17	16
Cardiff	3	1	2	Manchester	18	9	9
Carlisle	6	3	3	Newcastle-on-T.	5	2	3
Carmarthen	7	3	4	Norwich	2	0	2
Carnarvon	2	0	2	Nottingham	8	2	6
Cheltenham	2	0	2	Oxford	1	1	0
Darlington	3	2	1	Peterborough	2	1	1
Dundee	7	3	4	Sheffield	8	5	3
Exeter	2	1	1	Shrewsbury	2	1	1
Edinburgh	11	4	7	Southampton	5	3	2
Glasgow	3	2	1	Truro	1	0	1
Guernsey	1	0	1	Worcester	2	0	2
Inverness	2	1	1	York	2	1	1

The questions for Examination were as follows :—

FIRST OR PRELIMINARY EXAMINATION.

October 1*st*, 1878.

(*Time allowed: Three hours for the three subjects.*)

I. LATIN.

1. Translate into English the following passages :—

Gallis magno ad pugnam erat impedimento, quod, pluribus eorum scutis uno ictu pilorum transfixis et colligatis, cum ferrum se inflexisset, neque evellere, neque, sinistra impedita, satis commode pugnare poterant ; multi ut, diu jactato brachio, præoptarent scutum manu emittere, et nudo corpore pugnare.

Cognito Cæsaris adventu, Ariovistus legatos ad eum mittit: quod antea de colloquio postulasset, id per se fieri licere, quoniam propius accessisset : seque id sine periculo facere posse existimare.

Nonnulli etiam Cæsari renuntiabant, cum castra moveri ac signa ferri jussisset, non fore dicto audientes milites, nec propter timorem signa laturos.

2. Decline throughout *scutis, ictu, corpore, timorem, legatos.*

3. Give the present, perfect, supine, and infinitive of *transfixis, colligatis, emittere, ferri, accessisset.*

4. Explain in each case the use of the infinitive mood, *fieri, licere, facere, posse, existimare*, in the second of the above passages.

5. Translate into Latin :—All who were present began to seek aid from Cæsar. Ariovistus spoke much about his own merit. Ariovistus led his forces past Cæsar's camp.

II. ARITHMETIC.

(The working of these examples, as well as the answers, must be written out in full.)

6. A mixture is made of 6 gals. of spirits at 12*s.* 6*d.* per gal., 4 gals. at 18*s.* 9*d.*, and 10 gals. at 22*s.* 8*d.*; what is the value of a gallon of it?

7. Simplify $(3\frac{2}{3}+4\frac{3}{4}+4\frac{4}{5}-5\frac{5}{6})\times\frac{60}{4\,43}$.

8. Find the value of ·6 of £1 + ·25 of 5*s.* 4*d.* + 3·75 of a crown.

9. If 30 cwt. are carried 15 miles for £5 8*s.* 9*d.*, how far ought 80 cwt. to be carried for £29 ?

10. What is the length of the "metre" in inches? Define the terms "gramme" and "litre." How many grammes will a litre of distilled water weigh ?

III. ENGLISH.

11. Name the Relative Pronouns. Explain the differences to be observed in their use.

12. Write out the present indefinite and the past indefinite, indicative and conditional, of *strike.*

13. Give the number of the verb, when the subject consists of (*a*) two singular nouns connected by *and*, (*b*) two singular nouns connected by *or.*

14. Parse :—

"But yesterday, the word of Cæsar might
Have stood against the world."

15. Write a short essay on one of the following subjects :—Photography, the Forms of Water, Coal-gas, Self-culture, Thrift.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first general meeting of the thirtieth session was held at the Royal Institution, Thursday evening, September 10th, the President, Mr. T. Fell Abraham, in the chair. The minutes of the previous meeting were read and confirmed.

The Secretary announced the officers, viz., T. Fell Abraham, President; Charles Symes, Ph.D., Vice-President; Robert Sumner, Hon. Treasurer; Thomas Williams, F.C.S., Hon. Secretary.

Messrs. Charles Field, junior, C. J. McAllister, William Ockleston, and E. C. Smith were unanimously elected members.

The President announced that a conversazione would be held on November 7th, and invited any members who were willing to give their assistance to communicate as soon as possible with the Secretary or himself.

Dr. Symes called the attention of members and associates present to the chemical class of the school of pharmacy now being commenced by Mr. Thomas Williams, F.C.S., at his laboratory in Lord Street, the number of students attending being very small, and he (Dr. Symes) was very desirous to see it larger. The mistake he believed to be committed by a number of young men was that they study for examination and put off this even till the

eleventh hour. He admitted that a young man was entitled to a fair amount of recreation, but from the time he entered a pharmacy as an apprentice, he should commence his studies with the object of fitting himself for his duties in life. The classes were instituted with a view of assisting in such education, and he felt most anxious that young men should embrace the opportunities offered. If the place or hour of meeting was inconvenient to the majority Mr. Williams had offered to make any change, and in conjunction with the Council would as far as possible meet their requirements. The President had offered a prize of one guinea to the first, and half a guinea to the second in the class, so that altogether it was to be hoped that an augmentation of members would be realized.

The President then read his

Inaugural Address.

Gentlemen,—When, a year ago, I for the first time occupied this chair, I looked forward to the session then opening with feelings of apprehension, and to the end of it as a time of relief.

However, with your indulgence and kindly help the reality has proved to be more agreeable than I could have anticipated. We have had a session which, whether judged by the quality of the papers and other communications, or by the interest taken as indicated by the attendance at the meetings, has been fully up to the average of former years.

On a recent occasion I briefly referred to the fact that all the papers read had been from members of our Association. This is in one sense a source of satisfaction as showing a considerable amount of self-contained activity. We must not forget, however, that in former years the Association has frequently had the pleasure of receiving most valuable and interesting communications from gentlemen engaged in chemical pursuits, and not within its roll of members. There are many of these gentlemen with whom my avocations do not bring me into contact. I would therefore strongly urge on such of you as are acquainted with the class of gentlemen to whom I have referred, that you should, as opportunity offers, bring before them the claims and objects of our society, and thereby not only promote its interests, but also a feeling of fellowship amongst the scientific chemists of the district. We must take care that we do not gradually lapse into a merely pharmaceutical association. Though founded principally by pharmacists, and though our members, many of them, are engaged in pharmacy, I am happy to say that we have still amongst us a considerable number of professional and manufacturing chemists. To some of these gentlemen we are much indebted for their valuable aid in the past, and while I trust that they will continue their co-operation in the future, I would appeal to those who have not hitherto rendered us much active assistance, whether they cannot, without any serious self-sacrifice, do something to help on the cause for which our Association exists.

As a pharmacist, addressing a society composed largely of pharmacists, I may, I trust, be excused for referring to matters which can hardly be of much interest at present to persons not themselves of our own calling.

For some months past a legal battle has been carried on between the Chemists and Druggists' Trade Association and the Society of Apothecaries. The cause in dispute is what is called "counter prescribing." I should perhaps apologize for introducing such a subject on the present occasion, but I believe that the question not only concerns many members of this Association, but also the general public. The latter knows little about the law of the matter, and less of what would be the probable result of a decision of the extreme character which alone would satisfy some persons. To defend the practice of medicine or surgery by chemists would be very far from my wish. A chemist who, without a proper medical and surgical training, induces persons to commit the care of their health into his hands, is guilty of a misrepresentation, which I can hardly characterize as less than fraudulent. But to say that a pharmacist, knowing the nature and properties of his wares, shall not recommend them for use in the cases for which they are specially intended, is to deny to him the right which is common to all others.

I believe I am correct in saying that the outside public prescribe far more medicine than all the doctors and druggists together. What is more natural than that, when a man has derived benefit from the use of a particular preparation or drug, he should suggest its use to a friend, whose symptoms are apparently like his own? Such recommendations may very often be useless or even hurtful, but would any one suggest that they should be prohibited? Many little ailments, too trifling to warrant a man in spending a guinea, or half a guinea, or even half a crown, in addition to the loss of time involved in a visit to a doctor, but which at the same time are very annoying and even painful, are relieved by some simple remedy suggested by a druggist. No one is defrauded or injured. The druggist earns an honest sixpence or shilling and his customer is relieved or cured. Or suppose an individual receives a slight wound and is in the same unfortunate position as your president, namely, minus a wife; what is more natural or proper than that he should run to a druggist who has sponge, lint, and plaster at hand, rather than to a draper, or possibly some one would suggest, a butcher?

Take another case: A man has a sore throat; unless it be very bad or he be rich he will get an astringent gargle, or lozenge, or application from a druggist. Is it not better that he should do so than that he should go about grunting for a week, an annoyance to himself and every one he comes near?

I make these observations because I am convinced that if in these matters the rein be drawn too tightly, the effect will be, not to drive people to the medical men, but to give an immense impetus to the trade in proprietary articles, popularly but very absurdly called patent medicines. I hope I shall not be misunderstood. I would not defend a chemist or druggist who treats serious cases, or even cases in which the symptoms,—though not then serious may be premonitory of something serious. The man who so acts not only wrongs his customer, but wrongs the professional class whose members have devoted their talents and money to acquiring the knowledge necessary for the treatment of diseases.

Pharmacists have little to fear. So long, and in so far, as they supply a public want, the law will not, and even if it would, cannot, prevent the public from availing itself of their services. Some temporary inconvenience may arise from an extreme legal decision, but in the long run the public requirements must and will be respected.

The past year has been prolific in scientific novelties. The liquefaction of the so-called "permanent gases," the practical development of the telephone, the production of the phonograph and microphone, have succeeded one another with bewildering rapidity. The extreme simplicity of the means by which the marvellous results attained with these three new scientific toys (I fear they have hardly yet got beyond that stage of their existence) is such that one's mind almost refuses to accept as statements of sober fact the accounts concerning them. The great difficulty hitherto found in the practical working of the telephone in noisy places, seems in a fair way of being removed by the agency of the microphone. Who knows but that some day the much vexed question of parliamentary reporting may be settled in a manner satisfactory to all parties except the gentlemen of the press, and perhaps Major O'Gorman, by the introduction into the precincts of the chair of a set of phonographs.

The adulteration question still occupies a large share of public attention. Prejudice and ignorance, extending even to those classes where such ignorance and prejudice would hardly be expected to exist, have much to answer for. Magisterial ignorance has frequently branded as a rogue the baker, who using a small and totally non-inju-

rious quantity of alum to his flour, has thereby enabled the poor to have a bread better, independently of its improved appearance, than they otherwise could obtain at the same price. In other cases where absolutely no alum had been added, an incompetent or rash analyst, not making an adequate allowance for the alumina almost unavoidably present in some flour, has set down all above his arbitrary percentage as being due to alum present as an adulterant. Sundry milk of sulphur and violet powder prosecutions may also be cited as instances of serious injury being done to innocent tradesmen.

When the dealer is sufficiently wealthy or spirited to challenge the dictum of the analyst by the production of professional evidence in his defence, he frequently fails, because it seems as if the magistrates, some of them at all events, in common with many newspapers, proceed on the assumption that every tradesman is a rogue until he is proved to be otherwise.

I had the pleasure the other day at the Pharmaceutical Conference of listening to a moderate and sensible paper on the adulteration of drugs by Professor Tichborne. The newspapers, totally misapprehending the aim and nature of the writer's statements, forthwith announce that Professor Tichborne had declared that in his opinion the Adulteration Act, as far as drugs were concerned, was almost a complete failure, and that serious adulteration was still very extensively met with; the fact being that he declared nothing of the sort. Again, because an obscure person calling himself, or at all events styled by the papers, a "wholesale druggist," by some extraordinary and hitherto unexplained blunder mixed arsenic in a batch of violet powder,—the newspapers write hundreds of articles—in which it is assumed that such admixture is intentional and is almost universal.

The other day a batch of dealers were summoned and actually heavily fined because they sold so-called soda water which did not contain soda, whereas it is a fact that the public does not want, and any one who asked for a bottle of soda water and was served with, the pharmacopœial preparation, would denounce it as "soap suds" and take care not to invest in a similar manner again.

Such instances as I have ventured to adduce (and they might easily be multiplied) have several most mischievous results. They bring into hatred and contempt the Adulteration Act, and in a secondary degree the law and its administration. A still more serious evil for the public is that these proceedings tend to drive honourable and high-principled men out of all such trades as are liable to be affected in the manner described.

These results are of course general, affecting the whole community. The special hardship inflicted by such unjust decisions is in itself a thing very grevious and much to be deplored. Such scandals, for they are nothing else, are sure to exist under present arrangements at all events for some considerable time to come. I hope I shall not be considered presumptuous if I venture to suggest that there should be appointed a small number, it need be very small, of analytical referees or assessors, whose duty it should be to assist, by their technical and scientific knowledge, in all cases of appeals from the decisions of the primary tribunals. Their functions would be analogous to those of the nautical assessors who now assist, by their practical knowledge and experience, in the settlement of inquiries into the causes of casualties to shipping.

At present if the accused party feels that justice has not been done him, he is practically at liberty to appeal, though I am not sure that a magistrate is bound to grant leave for an appeal. But an appeal to quarter sessions is not only expensive, but the result may be no more satisfactory than the original decision, and in several cases, we know very well, has not been so. It might be provided that in cases of appeal, where the appellant demanded that the analytical assessor should be called in, he, the appellant, in case the original decision were confirmed, should be required to pay the specified fee of the assessor. Of course it would only be reasonable that an exactly similar appeal should be allowed to the prosecution.

But to turn to matters of more scientific interest. A new artificial oil of bitter almond, has been prepared in Germany from toluol and is declared absolutely identical in its characters with the natural product which has been deprived of its hydrocyanic acid.

A new method has been described for the production of artificial volatile oil of mustard. Another triumph of chemistry in realms where not many years since it was believed that natural processes were unapproachable, is the discovery that isatin, a substance capable of conversion into indigo, may be obtained by the oxidation of amido-oxindol by either nitric acid or the perchlorides of iron or copper. Indigo artificially prepared is, I believe, at present only a chemical curiosity, but its production as an article of commerce is doubtless only a question of time.

With such discoveries as these it is natural that we should look forward hopefully for the time, when many of the organic principles now obtainable at great cost and in small quantities, may be produced for us by the chemist in a state of absolute purity at lower prices and in any required quantity.

To the list of alkaloids and active principles must now be added gelsemia, from *Gelseminum sempervirens*; cyclamia or arthanatin, from *Cyclamen Europæum*, said to be similar to curarin and a remedy for tetanus; sicopirin, from the Brazilian tree *Bowditchia Major*, which is used in syphilis and cutaneous diseases; capsaicin, from Cayenne fruits; heliotropine, from *Heliotropium Europœa*; ditain, used as quinine, from *Echites scholaris*; emodin, from *Rhamnus frangula*; timbonin, from *Paullinia pennata*, a plant closely allied to that yielding guarana. As the name capsicin has for years been applied to an oleo-resin and also to crystalline substances obtainable from Cayenne, but neither of which can be recognized as its active principle, I may explain that the substance now referred to, the name given to which is almost identical, may, from its properties and physiological action, be fairly considered as the active principle of cayenne.

The method of preparation briefly stated is a follows:—Dissolve the ethereal extract of the fruit in boiling caustic, dilute with water and precipitate with barium chloride wash and dry the precipitate, dissolve in ether, evaporate to dryness: product is capsicol. Capsaicin is obtained thence by dissolving in almond oil, separation with proof spirit, evaporation, solution in dilute caustic potash, and finally, treatment with dilute ammonia, from which the capsaicin is deposited in the form of pearly white crystals.

Gelsemia, which, according to Professor Sonnenschein, is identical with æsculin, is prepared from the alcoholic tincture. This is treated with acetate of lead, the lead precipitated with sulphuretted hydrogen. The mixture is shaken with ether and an excess of caustic potash added. The precipitate is dissolved in hydrochloric acid, precipitated with caustic potash, and the gelsemia separated by ether which is evaporated off.

Chloroform as an anæsthetic is again attacked and threatened with extinction. Time will show whether the new candidate for public favour will be more successful than its predecessor. Hydrobromic ether, the composition of which is represented by the formula C_2H_5Br, in some respects resembles chloroform. Like it, it is colourless, transparent, of a pleasant odour, sparingly soluble in water, freely in alcohol and ether, and of a very high specific gravity. Several methods for its preparation are given, but I will not trouble you with the details. They will be found fully described in the *Pharmaceutical Journal* for March 9. Perhaps I am too conservative, but the dismal failures that many much vaunted improvements—tetrachloride of carbon, for instance—have turned out to be, when tried by disinterested and not rashly sanguine experimenters, make me very cautious of accepting the glowing accounts put forth concerning new remedies and appliances.

In these days, when it is so fashionable to denounce the use of all alcoholic beverages, malt liquors not excepted, it is rather curious to note that a series of experiments, carefully and scientifically conducted, have shown that all malt liquors to a greater or less extent possess a solvent action on bread and other starchy foods, and that the beneficial action of the various "malt foods" and "extracts" is really due to a principle, common also to both beer and porter, but present in much greater quantity in the former class of preparations.

This conclusion has been arrived at as the result of a large number of experiments, conducted with praiseworthy perseverance, by Mr. Coleman, F.I.C., and described at length in the *Chemical News* for May 3. Having heard of some cases in which considerable benefit had followed the use of a preparation imported from Germany now in considerable quantities, and known as Hoff's malt extract, Mr. Coleman set to work to ascertain if possible, the *modus operandi* of the remedy. Analysis showed that in alcoholic strength the preparation differed little from ordinary porter, and also that the total quantity of solids was pretty much the same. It was therefore fair to assume that the good effects following its use were not to be attributed to its alcoholic strength. Experiments of a comparative nature were then commenced and for a long time with entirely negative results. It was found that if bread, potatoes, and other starchy foods were digested at blood heat with equal quantities of various ales, porters, and Hoff's malt extract, the quantities dissolved varied to but a small extent. It then occurred to Mr. Coleman to try similar experiments with the solutions rendered faintly alkaline, thus more nearly resembling the conditions actually existing in nature, where the food is acted upon by the pancreatic secretion, which is distinctly alkaline. The results then were totally different. It was found, for instance, that while Hoff's liquid dissolved 60 per cent. of a starch food, Burton ale only 15 per cent., London porter, 40 per cent., Wrexham ale, 26 per cent. I have commenced a series of similar experiments with some of the other malted foods offered for sale, and hope to have the pleasure of laying the results befere you at an early date. Mr. Coleman's investigations afford a scientific confirmation of the popular belief in the flesh forming virtues of malt liquors, more particularly porter.

At the risk of being charged with telling stale news, I may refer to the discovery of the new metals, neptunium, obtained from columbite, lavœsium, which has been found in iron pyrites and other minerals, gallium in zinc blende, davyum in platinum ores. The last named was detected in the separation of two other rare metals, rhodium and iridium, from the residues of some platinum ores. The weight of the ingot obtained was only some four grains, and yet the discoverer, Sergius Kern, of St. Petersburg, prepared, and treated with reagents, a chloride, sulphide, sulphate, nitrate, sulphocyanide, and double chlorides with sodium and potassium. As far as at present appears there is not much reason to suppose that the discovery will ever become of much practical importance, as the quantity present in the only ore, and that a rare one, in which it has been found is only about one part in three thousand.

Lavœsium is a metal of silvery white colour, malleable and fusible, forming colourless salts. M. Prat describes it as extensively distributed, and especially amongst iron pyrites, but in minute quantities.

Gallium is a metal which in some of its properties strongly resembles mercury. It is liquid at a temperature above about 86° Fahr., oxidizing very slightly on exposure to the air. Below that temperature under favourable conditions it crystallizes. In the solid state it is hard, malleable and flexible. At about its melting point it may be attached to glass, forming a mirror, from which the heat of warm water removes it in the form of small pellicles which may be united together by pressure. Heated to redness in air it does not volatilize, and if on platinum forms with that metal an alloy insoluble in hydrochloric acid but soluble in aqua regia. Like davyum, the extreme state of dilution of the occurrence in nature of this metal leads one to fear that it will continue to be, as now, but a chemical curiosity.

As I write, news comes that Mr. Edison, the inventor of the phonograph, has discovered the means of dividing a powerful electric current into an almost indefinite number of parts. If this be true, the problem of electric illumination is practically solved, as hitherto the enormous expense, which really in the main arose from the enormous waste, involved in the application of the light, has been an insuperable obstacle to its practical introduction.

And now, gentlemen, I fear I have occupied too much of your time, and will conclude by thanking you for your attention and expressing a hope that the session on which we are entering may be one of satisfactory progress.

Mr. A. H. Mason, F.C.S., said that he felt he was reciprocating the feelings of the whole of the members present in asking them to accord a very hearty vote of thanks to the President for his thoroughly practical and admirable address. He had alluded to topics of interest to all the members present. It was a privilege to be permitted to criticize any address from the chair to the Association without showing any want of courtesy. As the President would be well aware, he was strongly prejudiced against subjects of a definite trade nature being brought forward at these meetings, and he therefore thought the legal aspect of counter prescribing was one which did not immediately concern the scientific bearing of the society, and certainly one in which the public were not to be educated from the President's chair. The President had stated that the telephone was merely a toy, but if he would walk down to Hanover Street, he would soon be convinced of its practical utility, as two were constantly in use there with most advantageous results. Respecting Professor Tichborne's paper on Adulteration read at Dublin, he was rather surprised to hear the President speak so highly of it, as his impression of the paper referred to was that it was one of a most sensational character, and one which justified the remarks made upon it by the medical press, he (Professor Tichborne) most distinctly stating that the working of the Adulteration Acts was an utter failure, and had it not been for the strong protest of Mr. Umney the public might have been lead to believe that the statements made by Professor Tichborne were facts. Respecting the application of hydrobromic ether as a substitute for chloroform, he was aware some medical men used it, but it was found to be so uncontrollable that he thought there was no probability of its taking the place of chloroform, as there was considerably more danger attending its administration. Respecting the prosecutions for the sale of soda water he took it that the intention of the authorities was to insist upon the public being supplied with what they asked for. It would be quite possible to supply a water containing carbonate of soda; thus the necessity for the public to ask for what they want by the right name. Respecting referees, the authorities at Somerset House had appointed analysts there, to whom samples could be sent for a final report, and in case this was not found satisfactory, the Institute of Chemistry, which had been recently formed in London, would probably provide such a final court of appeal as the President suggested.

Dr. Symes said he had great pleasure in seconding the vote of thanks to the President for his able address. He would remark that the Association was primarily a pharmaceutical one, and the term Chemists' Association when first adopted implied this. Still they were highly pleased to have the support of scientific chemists. He could scarcely agree with the President that the telephone was a mere toy, as for nine or ten months Symes and Co. had been using it regularly between their two pharmacies, and more recently between one of these and their warehouse in Wood Street, conversing with almost as much

ease as though in the same building. It was true that the diastase in malt liquors assists in digesting some kinds of food, but it should be borne in mind that the alcohol present retards digestion; this he had proved most conclusively some years ago in a series of experiments in the digestive power of pepsine. With regard to the Adulteration Act there was one point worthy of attention; it was this: a tradesman is summoned for selling a supposed adulterated article, defends the case, and not unfrequently proves at considerable expense and loss of time that the article is pure. In addition to the fact that his reputation has suffered, he rarely gets his expenses allowed. He held that this is not merely wrong but also a gross injustice, and discreditable to a Legislature which professes equity and justice in the administration of its laws. If a man has been unfairly prosecuted the legal authorities should make him every reparation that lies in their power, which at present they did not.

Mr. E. Davies, F.C.S., and others took part in the discussion, and the President having replied to the criticisms, the vote of thanks was carried by acclamation and the proceedings terminated.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual meeting was held at the Bristol Museum and Library, on Friday, October 4, when the following report was read and adopted.

Annual Report.

In presenting their annual report the Council of the Bristol Pharmaceutical Association have to regret a slight falling off of members and associates. They are, however, confident that the additional privileges and advantages now offered will induce their fellow pharmacists and students to assist in maintaining the high position which has been achieved by their Association.

Messrs. Stoddart and White report that all the specimens for the materia medica collection are now ready and will shortly be placed in the case at the Museum and Library. They have received many valuable specimens from the Pharmaceutical Society, from various wholesale firms, and from individuals, all of which have been suitably acknowledged.

The prize scheme of the Association for the past session was as follows:

Two prizes in Inorganic Chemistry.
Two prizes in Botany.

The candidates were required to have attended one of the systematic courses of instruction either at the University College, Bristol, or at the Trade and Mining School. The examinations were kindly undertaken by Messrs. Stoddart, Leipner and Schacht, and the result was as follows:

Inorganic Chemistry.

1st Prize of the value of £2 2*s.* 0*d.*....Mr. Hemmons.
2nd „ „ £1 1*s.* 0*d.*....Mr. W. Stroud.

Botany.

1st Prize of the value of £2 2*s.* 0*d.*....Mr. W. Stroud.
2nd „ „ £1 1*s.* 0*d.*....Mr. H. Stroud.

Three evening meetings were held during the session; at two of these the Association was favoured with lectures of much interest by Dr. S. P. Thompson and Mr. Stoddart, and the third was devoted to the reading and discussion of some papers on practical pharmacy.

The Council desire to impress upon all their fellow pharmacists,—principals, assistants, and apprentices,—the necessity of continued cordial co-operation, in order that what has been accomplished by past labour may be well preserved and amply enjoyed and that further efforts may be made in pharmaceutical progress.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting of the above Association, on Wednesday, October 9, Mr. W. Smart in the chair, Mr. J. T. Brown, F.C.S., read a paper on "Salicin and some of its Derivatives." The author treated the subject from a chemical point of view. He showed salicin to be obtained from willow bark, mentioned its various decompositions, one series giving hydride of salicyl, oil of meadow-sweet and coumarin, another giving salicylic acid. It was noticed that castoreum from the beaver contained salicin, and that a beetle, *Chrysomela populi*, contained hydride of salicyl, it being derived in both cases from the willow or poplar bark on which the animal and insect feed.

The artificial preparation of salicylic acid from carbolic acid was also explained. The author in the course of his remarks deprecated the practice of making light of researches in organic chemistry, of which the examples furnished by the subject of his paper were enough to show the practical importance. After a short discussion, a vote of thanks was awarded to Mr. Brown, and also to the chairman.

Donations of £1 1*s.* from Dr. H. Dobell, books from Dr. Muter and 10*s.* 6*d.* from Mr. Probyn (honorary member) were announced.

Parliamentary and Law Proceedings.

Alleged Poisoning by Mouldy Bread.

An adjourned inquest was held at Barnsley on Thursday, October 10, before Mr. T. Taylor, coroner, relating to the deaths of Henry Mason and Emma Thresh, two of eight persons believed to have been poisoned by partaking of bread pudding made at the Albert Dining Rooms, Sheffield Road, Barnsley.

Alfred Henry Allen, of Surrey Street, Sheffield, public analyst for the West Riding, North Derbyshire, and the borough of Sheffield, said he had further examined the liver and kidney of Mason, and the liver and lung of Emma Thresh, without finding any trace of poisonous metal. The remainder of the currants, sugar, and nutmeg used in making the pudding had been carefully examined with negative results. The glaze of the basin in which the pudding was cooked has been found to be free from lead or other poisonous metals. No. 1 pudding had been very carefully examined, and no deadly poison had been discovered. The negative results of the chemical examinations for various metallic poisons had been borne out by the failure of either pudding to produce purging or other poisonous effects on the puppy which was fed on the suspected puddings for two whole days. There were not a few cases recorded of irritant poisoning and death being produced by mouldy bread. Thus horses have been killed in a short space of time after eating such bread in their ordinary food. The symptoms were those of an irritant poison. In 1829 an investigation was made in France into the cause of the illness due to eating bread, and it was found by experiments on animals that bread in a particular state of mouldiness or decay may not only produce symptoms of poisoning, but actually cause death, and it was impossible to distinguish the harmless from the dangerous kinds of mould. As fungus or mould grows very rapidly, it is quite possible for mouldy bread to be quite poisonous at one date and to have lost its poisonous properties two days afterwards. One of the most poisonous of moulds or fungi is ergot. This produces symptoms very similar to those occasioned by the pudding, and the newspaper reports of the medical evidence have caused an eminent toxicologist to express a very strong opinion that the presence of ergot was the cause of poisoning by the pud-

ding. After some other evidence as to the tests he had made, the witness proceeded to say that he had carefully examined microscopically a sample of flour said to be the same as that used for making the bread supplied to Thresh's eating-house, but had found no trace of ergot. From the experiments and observations he thought it clearly shown that the pudding contained a substance which resembled ergot in its chemical reactions. That body was in all probability a fungus, and may be strongly suspected of poisonous properties—at least in a certain stage of its growth. The pudding was made of bread said to be mouldy, and which was several weeks old, and had been in contact with ham, butter, and miscellaneous scraps. The oven in which No. 1 pudding was cooked was notoriously a bad one. The pudding when made was "sloppy," and had the appearance of being imperfectly cooked. There was no trace of browning or crust; hence the heat must have been very slight. Mr. Allen then went on to add that he had consulted several of the leading toxicologists of the kingdom, and he then proceeded to read extracts from their letters:—

Dr. Hill, medical officer and public analyst for Birmingham, sent a letter, in the course of which he says:—

"Cases similar to the one on which you are engaged are by no means uncommon. I have had many such, and I can only arrive at the conclusion that you have done in this, viz., that putrefactive change was the cause of the illness and death. The symptoms are precisely those of a mineral irritant poison, but which if present must certainly be detected by a competent chemist. I believe, therefore, that the opinion you have given is a correct one."

Dr. Wallace, analyst for Glasgow, who had been consulted with respect to the case, wrote:—

"After reading over the case very carefully, my opinion is that the cause of the poisoning is fungous vegetation either in the bread or in the fragments of meat or fat mixed with it; and further, that the pudding was not sufficiently cooked. Had it been thoroughly cooked, I think the poisoning matter would have been rendered innocuous."

Dr. Charles A. Cameron, medical officer of health for Dublin and fourteen Irish counties, who had been consulted, wrote:—

"I have carefully read the report of the two inquests, which you have sent me. The symptoms exhibited by the deceased, especially by the adult, are exactly those which I know to have been produced from eating mouldy or rancid food. In 1873 a whole family were poisoned by eating rancid butter. There was, however, only one death. The matter was thoroughly inquired into, and that the rancid butter caused the poisonous symptoms was made absolutely certain. I have referred to this case in my 'Manual of Hygiene.'"

Other well-known analysts expressed similar opinions.

Dr. Stewart, who attended the Thresh family, said the pulses of all his patients were quick, which was not in accordance with ergot poisoning, and in the case of those who died he should have expected to have found the bladders full if poisoning had been caused by ergot. In a recent work on fungus poisoning by Von Boeck, three cases of poisoning from mouldy bread were recorded, and in these the symptoms were the same as in those cases, and the youngest child so affected, aged five years, died from the effects of it. In the absence of the detection of any mineral poison by the analyst, he was thrown back on the opinion that the poisonous effects were due to mouldy bread. In all the cases there was congestion of the eyes and face.

Dr. O'Connell, who attended Mason, agreed with the evidence given by Dr. Stewart.

William Robinson, the baker, and his man, William Hanger, who made the bread, said it was good and wholesome in every way. They supplied similar bread to other customers, but had heard no complaints.

The Coroner summed up the evidence, and in doing so pointed out that he had communicated with the Secretary of State on the subject.

The jury were left to themselves for ten minutes, and then returned the following verdict:—"The jury are of opinion that the deceased, Emma Thresh and Henry Mason, came to their deaths from eating a portion of unwholesome pudding, but how and by what means such pudding became unwholesome there is not sufficient evidence to show."—*Yorkshire Post.*

Poisoning by a Lotion.

An inquest was held by the Liverpool deputy borough coroner (Mr. C. S. Samuell), on Wednesday, October 9, on the body of Catherine M'Donough, aged four years. Deceased was an out-patient of the Eye Infirmary and also of the East Dispensary; and from the first-named institution a lotion was obtained, while from the other a bottle of medicine was procured. The mother accidentally gave the child the lotion about one o'clock on Sunday, and in about an hour or two she became so ill that her mother took her to the East Dispensary, where she was attended to by Dr. Osborne Limrick, who administered an emetic. The child, however, died early on Monday morning.

Dr. Limrick stated that the lotion was made from atropine, the active principle of belladonna, and that from an eighth to a quarter of a grain would cause death. The child had died from the effects of the poison. He should like to ask the court if he had done wrong in keeping the lotion, which he now produced. He thought it was dangerous to trust it among such people, and he had been told that he acted more like a detective than a doctor for doing so.

Mr. Samuell considered that the very first thing a doctor should do in these cases was to take charge of such bottles. He thought that Dr. Limrick had exercised great caution and discretion in the matter.—The jury returned a verdict of "Death by misadventure," and strongly recommended that bottles containing poison should be so shaped that they could not be mistaken for those containing physic.—*Liverpool Daily Post.*

Poisoning by Nitric Acid.

An inquest was held at Leeds on Friday the 11th inst, concerning the death of an infant, named Joseph M'Neil. The child had been ill, and while administering medicine, the father accidentally gave it a spoonful of nitric acid, from the effects of which the child died. A verdict of "Accidental death" was returned.

Obituary.

Notice has been received of the deaths of the following:—

On the 6th of September, 1878, at Lake Port, Lake County, California, Mr. William Charles Markham, Chemist and Druggist, fourth son of Mr. Markham, Chemist and Druggist, Reigate. Aged 24 years. Mr. Markham had been an Associate of the Pharmaceutical Society since 1870.

On the 16th of September, 1878, Mr. James Hartland, Pharmaceutical Chemist, St. Augustine's Parade, Bristol. Aged 66 years. Mr. Hartland was one of the Founders of the Pharmaceutical Society, having joined it in the year 1841.

On the 17th of September, 1878, Mr. Robert Bowles, Chemist and Druggist, East Street, Bedminster, Bristol. Aged 37 years.

On the 17th of September, 1878, Mr. William Bardsley, Chemist and Druggist, Failsworth, near Manchester. Aged 33 years.

On the 4th of October, 1878, Mr. Edward Hatton, Chemist and Druggist, Chesham, Bucks. Aged 42 years.

Dispensing Memoranda.

[167]. In answer to K., I should dispense the prescription as it stands; he will find that the ingredients Nos. 1 and 4 are in frequent use in most dispensing establishments. The following are the proportions for preparing them:—

Guaiacum Resin . . 4 ozs. to *O*j. S. V. R.

The process is the same as for B.P. tincture.

Colchicum Seeds, bruised . . . 2 ozs.
Sherry Wine . . . . . 1 pint.

Prepared by maceration for seven days.

DISPENSER.

---

[171]. In reply to "Sub Umbra Floresco" I have dispensed many different mixtures containing acid. hydrocy. dil. but never, to my recollection, put a "shake the bottle" label on them. Neither do I think it necessary providing the acid is compatible with the ingredients therein. The acid certainly decomposes rapidly on exposure to the light (in the case of the dilute), with the formation of ammonium formate and a deposit of a brown substance, but taking into consideration the small dose required, I do not think this applicable to the case in question.

MINOR.

---

[172]. How should the following prescriptions be dispensed?—

Magnes. Sulph. . . . . ℥ij.
Tr. Sennæ . . . . . ℥j.
Inf. Gentian. Co. . . . . ad ℥ss.

Mitte doses xij.

and

Magnes. Sulph. . . . . gr. 240.
Tr. Jalap. . . . . ♏ 20.
Spt. Chloroform. . . . . ♏ 20.
Inf. Sennæ Co. . . . . ad fl. oz.

Ft. haustus.

In the latter case I ventured to send ℥iss.

W. S.

---

[173]. I should like to know how the following prescription can be dispensed so as to form a presentable mixture:—

℞ Potassii Iodidi . . . . . ʒj.
Acidi Hydrocyan. Dil. . . . . ℥ss.
Liq. Bismuthi et Ammon. Cit. . . . ℥iij.
Quiniæ Sulph. . . . . gr. xii.
Acidi Hydrobromici . . . . . ℥iss.
Aquam . . . . . ad ℥vi.

M. ft. mist. Sig. A tablespoonful three times a day before meals.

BELFAST.

---

[174]. Will any one tell me if the following can be dispensed so that it it will not separate, and if so how it should be done?—

℞ Ol. Ricini . . . . . ℥ij.
Pulv. Gum. Acaciæ . . . . . ℥j.
Pot. Carb. . . . . gr. xii.
Am. Carb. . . . . gr. vj.
Vin. Ipecac. . . . . ♏ xxxvi.
Sp. Æth. Nit. . . . . ♏ xxiv.
Aq. Menth. Pip. . . . . ad ℥iss.

M. ft.

Highgate, N. W. F. CROWTHER.

---

[175]. I had the following to dispense a few days ago:—

℞ Camphoræ . . . . . ℥ij.

Ft. pil. xxiv.

Will any reader inform me what is the best excipient? I used suet.

Highgate, N. W. F. CROWTHER.

---

[176]. EXT. TARAX. LIQ.—What should be used when this is prescribed?

From the different answers received to this query it is evident an uncertainty exists about it. It is of the highest importance that the country chemist should be able to supply medicine of a similar colour to his town friend, and in a case like the above, when such a preparation, said to be prepared by the "dry air process," is used, a mixture resembling whitewash is the result, the large amount of starch present requiring a "shake the bottle label," whereas if the official succus be used we have at once an elegant and a reliable preparation of unvarying colour. It is scarcely necessary to add that physicians would confer a public good by abolishing such terms and using those only in the B.P. (as far as possible), and when any special make is required to mark the prescription to that effect.

1, *Bruce Grove, Tottenham.* WM. KENSIT GLOVER.

---

[177]. I sent out a blister the other day and put tissue paper on it. Can any of your readers inform me whether it is the correct thing to send it out as above, and whether the paper should be taken off before applying it on the patient or remain?

X. Z.

---

[178]. What is the correct method of dispensing this mixture, and what appearance should it present?—

Tr. Ferri Perchloridi . . . . . ℥j.
Glycerini . . . . . ℥ij.
Sodæ Hypophosphit. . . . . ʒj.

M. sumat gtt. x. ex aquâ ter die post cibos.

SUB UMBRA FLORESCO.

---

[179]. POTASS. BICARB. *versus* CARB.—Whether should potass. bicarb. ($KHCO_3$) or potass. carb. (K_2CO_3) be dispensed in the following mixture? Both these salts are antacid, antilithic, and diuretic in their effect, and their dose is almost similar, that of the former being ten to forty grains, while the latter is ten to thirty grains?—

℞ Potassæ Carbon. . . . . ℥ij.
Spt. Ætheris Nit. . . . . ℥ij.
Tinct. Aurantii . . . . . ℥iij.
Sp. Ammon. Aromat. . . . . ʒj.
Aquæ . . . . . ad ℥vj.

M. ft. mistura, cujus capiat partem sextam bis die.

SUB UMBRA FLORESCO.

---

[180]. What size of pills should be dispensed?—

℞ Atropiæ Sulphatis . . . . . ½ gr.
Excipien. . . . . q.s.

Ft. massa et divide in pilulas xl. quarum sumat unam mane nocteque.

SUB UMBRA FLORESCO.

---

[181]. How should the following prescription be dispensed and what is the nature of the precipitate formed?—

℞ Quinæ Sulph. . . . . gr. xij.
Acid. Sulph. Dil. . . . . ♏xx.
Mag. Sulph. . . . . ℥vj.
Ferri Sulph. . . . . gr. xij.
Tr. Zingib. . . . . ℥vj.
Aquæ . . . . . ad ℥xij.

℥i ter die.

P. C. F.

---

[182]. A prescription containing "liq. ferri chino. quinæ cit. ℥vj." was brought to me last week. Can any one inform me where it is to be obtained, having failed to procure it at the leading houses? The prescriber was a provincial surgeon, and the patient believed the article to be a "patent medicine."

J. WADE.

[183]. Can some one give a method for making the product of the following a "neat and elegant preparation?"—

℞ Ung. Hyd. Ammon. Chlor. . . . . ℥ss.
Glycerini Opt. . . . . ℥v.
Liq. Opii Sed. . . . . ℥j.
Acid. Hydrocyan. Dil. . . . . ♏ 40.

Ft. ung. mor. dict. utend.

I have tried, in different ways, to induce the liq. opii to combine with the other ingredients, but have hitherto signally failed and remain

BEATEN.

Notes and Queries.

[524]. PIL. ALOES ET MYRRHÆ.—About the commencement of the present year, two interesting papers on "Glycerinum Tragacanthæ as a Pill Excipient," by Mr. J. C. Thresh and Mr. G. Welborn, appeared in the Journal. Both writers detailed numerous experiments which they had made on the B. P. masses with various excipients, the pills being carefully examined in three and six months respectively, after date of manufacture.

With reference to pil. aloes et myrrhæ, Mr. Thresh remarks "that glycerine and tragacanth is totally useless for keeping those pills in a plastic condition," while Mr. Welborn mentions "that a mixture of one part of glycerine and three parts of treacle possesses the property of preserving this mass in perfect condition for the space of six years, with every probability of keeping good and fresh for another like period."

SUB UMBRA FLORESCO.

[526]. PILL COATINGS.—Can any reader inform me if pill coating with French chalk, or sugar and gum, either with or without a previous application of varnish, is quite unobjectionable so far as the effect of the medicine is concerned?

I have heard that some coated pills do not dissolve in the stomach, and shall be glad to hear the opinions of medical men or chemists who have had experience on this point. I find the coating is often one-fourth the weight of the pill, in some cases rather more.—W. M.

[527]. FIR. BALSAMI.—Can any of your readers inform me what "Fir. Balsami" is? If it can be made, how to make it?

G. H.

[528]. SOLUT. FERRI IODIDI.—One fluid drachm contains one drachm (by weight) of the solid iodide of iron. One part added to twelve parts of cold simple syrup will form syrup. ferri iodid., B.P. Could any reader kindly oblige with a recipe for preparing this liquor?

SUB UMBRA FLORESCO.

[529]. EAU DE COLOGNE,—I have nearly a gallon of eau de cologne made by myself, and containing oils of orange peel, neroli, bergamotte, rosemary, and rose, with orange-flower water, spirit of nitrous ether, spirit of wine (pure) and water. It was made two months ago, and is now the colour of tincture of ginger or myrrh, and quite unsaleable. I have long used this form. Once it has turned yellow before. I treated a portion with carbonate of soda as it reddened blue litmus, but the yellow colour remains. I treated another portion with burnt alum, and that considerably improved it; but it is too yellow still for sale. If any reader can tell me of any remedy, I shall feel particularly obliged.

TANTALUS.

[530]. ANILINE DYES.—Can any reader inform me of a good vehicle for mixing aniline dyes, to be used for painting woodwork or show cards? White lead has been tried but will not answer.

J. H. L.

[531]. OL. FLAV. CONC.—Could you kindly inform how the preparation me called "Ol. Flav. Conc." (1 part of which added to about 32 parts of oil or pomade will give the usual golden colour which is permanent) is made as sent out by some of the wholesale houses?

PHARMACIST.

[532]. QUININE AND IRON TONIC.—Would some one kindly give a good formula for "Quinine and Iron Tonic" which may be taken in dessert or tablespoonful doses, and one that would keep well?

DELTA.

[533]. TINCTURA CALENDULÆ.—Can some reader oblige me with a formula for above?

M. P. S.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

VIOLET POWDER.

Sir,—I am sorry that my remarks on this subject, notwithstanding the "grace" with which Mr. Brown has credited them, should have so greatly disturbed his equanimity as to drive him from fair argument into personal insinuations. This is the well-known advocate's dodge, and it may be taken to represent the position of the question at issue. As Mr. Brown is endeavouring to put me into a corner of his own selection, and to fix upon me an advocacy I have not undertaken, I must beg to be permitted to remind him and your readers that the only points I have contended for in this discussion are, firstly, that powdered selenite, which for a long series of years has been extensively employed as an ingredient of several of the different varieties of the powders sold as proprietary preparations, under the common but very indefinite name of "violet powder," is not unsuitable for the purposes for which these powders are generally used, which you, Mr. Brown, and the "shrewd old dame," he alludes to, have virtually admitted; and secondly, that as much difference of opinion exists as to whether powdered selenite or starch forms the better basis of the violet powders intended for nursery use, both being used and the use of each being strongly advocated, it is desirable that distinctive names should be applied to these and perhaps some others of the varieties of violet powder. I am glad to find that in regard to the latter point you only differ from me in proposing different distinctive names from those I have suggested.

T. REDWOOD.

MR. HENRY BROWN AND DR. REDWOOD.

Sir,—I look upon discussion in your Journal as an exchange or expression of opinion between friends at a distance, and that it should be conducted with the same good feeling as if it took place at a social gathering, the object being to promote mutual education. We may find our cherished opinions roughly handled, but so long as our opinions, and not our persons, are attacked, the discussion maintains its healthy and instructive character.

It is very pleasing to find members of the medical profession, like Mr. Henry Brown, taking part in our discussions, as we cannot be upon too good terms with each other, and they are in a position to impart valuable information to us which we should not otherwise be able to obtain; but when

discussion assumes a tone which Mr. Brown gives it in his letter upon Dr. Redwood to-day it ceases to be discussion, and becomes menace, declamation, and insult, calculated to promote no good object, but to provoke retort and personalities, especially in this case, from those who have a personal knowledge of Dr. Redwood, who has done more to educate (however imperfectly in Mr. Brown's opinion) the present generation of pharmacists than any other man living. When I read Mr. Brown's letter, I immediately referred to Dr. Redwood's to see what flagrant innovation he had been advocating, but to my surprise I found that his letter was simply a reply to the question, "What is Violet Powder?" which he asserts is of two varieties, both having their advocates, and that the public should not be deceived he recommends that the character of each should be defined upon the label. I may have read the letter in a different spirit to Mr. Brown, but really I can see nothing in Dr. Redwood's remarks to rouse Mr. Brown's ire, on the contrary, I think there is nothing in it but what is simple common sense, dictated by a consideration for public convenience. Had the question been, "What should Violet Powder be?" and Dr. Redwood had advocated selenite, there would have been scope for Mr. Brown to ventilate his own decided opinion, but certainly not in the dogmatic uncourteous language which he adopts, and that towards a veteran whose opinion is entitled to the very highest consideration. Evidently Mr. Brown considers himself an authority, and with the experience of the respected lady whom he quotes I look upon him as such, few of us being able to remember the experience of our mothers in such matters, whilst our recollections of early "dusting" are associated with other ideas than "allaying" irritation.

Mr. Brown says that the original violet powder was starch flavoured with orris root, whilst Mr. Siebold says it was powdered violet root pure and simple, but it was found unsuitable; hence I suppose the substitution of starch, which according to the fashion advocated by Mr. Brown of calling a spade a spade, should have been called starchen powder, certainly not violet powder.

If you once commence substitution, retaining the same name, there is no limit to the extent to which it may be carried, and in this case I am not prepared to condemn its being extended from vegetable to mineral powders, provided they are equally efficacious and innocuous, and even upon this authorities seem to differ. Mr. Brown is very strong upon the inferiority of selenite to starch, but it would be interesting to know how long the "shrewd old dame" had used the violet powder without finding that its only peculiarity was being heavy; even Mr. Brown admits that the two can scarcely be distinguished when bought put up in fancy boxes. I suspect that the sore place upon Mr. Brown, and there seems to be a tendency to soreness in his family, is caused by Dr. Redwood considering an old woman as good an authority upon the merits of violet powder as members of the medical profession. Individuals are not wanting who entertain the same opinion, although one would think no one weak enough to suppose that such a remark was intended to disparage professional ability.

I must apologize for troubling you at such length, but my object has been to show that letters like Mr. Brown's of to-day are wholly unjustifiable, and that your columns have no right to be used as a medium for vituperation.

Darlington. JAS. SWENDEN.

PHARMACY AS A CALLING.

Sir,—Your columns have recently teemed with letters on what may be called the general decadence of pharmacy, wherein the writers have usually contented themselves with simply enumerating their grievances, without apparently stopping to reflect on the causes thereof, and of the inevitable connection there always is between cause and effect.

The two chief complaints which have been most persistently urged, are first, the injurious effect produced on the trade pharmaceutical by the stores, and second, the deprivation caused to the dispensing department by the practice of dispensing adopted by the medical profession.

Now, it would be as well at the outset to admit that however much pharmacists would like to see these so-called interferences with their trade abolished, yet that in both respects they are powerless to help themselves; the stores and the profession alike have perfect legal right to adopt the courses now pursued by them, even at the risk of the ultimate occlusion of pharmacy as a distinct calling.

To take the stores first. They have taught three very important lessons, two of which are applicable to all trades alike, and the third to pharmacists in particular. The first and most important lesson is that credit in the retail trade is not a necessity; let the trader make cash payments the rule, and the public, as is abundantly seen, are quite willing to abide by the rule. But, as a consequence, the second lesson has to be learned, which is, that with cash payments on the part of the public, an equivalent on the part of the trader must be given, and this equivalent is a general reduction of prices. The Right Hon. R. Lowe, M.P., in a letter to the *Times* soon after the Civil Service Supply Association started, and in reply to a complaint on the part of the traders, told them distinctly that the remedy was in their own hands; go and do likewise, said he. And I am sure it is not too much to say that had his advice been followed, the stores would never have occupied the important commercial position they do now.

But this is not the only result that has accrued inimical to trade, for now the vast majority of retail traders have not only the stores proper to contend with, but also large grocers and drapers, who, uniting half a dozen businesses with their own, meet the stores on their own ground, and not unsuccessfully compete with them; the result of all this being, as is seen clearer and clearer year by year, that those who still cling to tho old style of doing business, find their customers fall off, and even among those who are left, they can reckon a larger proportion of persons who either do not pay at all, or only after long and uncertain intervals.

These are the plain facts of the case; the question is, have those who complain accurately gauged the cause, and traced it to its logical conclusion?

The third lesson, affecting pharmacists in particular, taught by the stores, is I fear no less real than disappointing to those who have the higher development of pharmacy at heart. Have not the stores degraded pharmacy to the same level as grocery and drapery? And have they not also shown that the higher education we have been striving for for years is not a necessary qualification for the safe and prosperous conduct of a chemist's business; for I suppose it will be conceded that the highest available talent is not employed at any of the stores. Pharmacy in fact loses all its attributes and becomes merged in the general business. Looked at by the light of old traditions and associations all this is no doubt very deplorable, but still it remains as an inexorable fact; we seem in this as in other things to be taking a leaf out of the book of our American cousins; what it is all to end in, or how far it may be combatted, each pharmacist must reason out for himself according to circumstances; beware only that he does not leave out of his calculations unalterable facts.

The second head of complaints is, if not more serious, certainly one of a more delicate character, I refer to that made against medical men, for dispensing, and I may say that I for one have read with pain some of the recent correspondence on both sides, because it betokens a state of feeling which one rather regrets to see between the two branches of medicine. Chemists have no more right to take the high tone lately adopted by some, and dictate to the medical man how he is to conduct his practice, than the latter has to dictate to the former what prices he has to charge for medicines; the whole question is one of great delicacy, and can only be approached in a friendly and conciliatory spirit on both sides.

Many writers in the Journal seem to have overlooked two very important points in connection with this subject, first, that medical men have a perfect right to dispense if they choose; second, many of them, as I have heard them say over and over again, cannot afford to carry on their practice in any other way. Then again, for chemists to publish the errors in prescriptions, as I have so often seen with horror and amazement, in the pages of our widely read Journal, and to talk of combining to compel medical men to relegate their dispensing to them! Surely, sir, this is not the way to secure our ends. Why, I can fancy the profession enraged at this sort of conduct, and saying, "Comfound these fellows; we will soon settle this question for them, and in spite of them, for we will all dispense." Then indeed, they might say with Othello, "Our occupation is gone." But even if dispensing were thrown open, it seems to me very problematical in the present state of things, how far pharmacists would be benefited; the stores certainly would, and not unlikely the grocer and draper before alluded to, would still more en-

large their sphere of operations, and instead of confining themselves to patents, would employ a qualified man and add the business of a chemist to their already long list of callings.

South Norwood, S.E. J. H. BALDOCK.

EMPIRICAL PRESCRIBING AND PROPRIETARY REMEDIES.

Sir,—I observe in your Journal for the past month that Dr. McSwiney is reported to have said at the Pharmaceutical Conference (*à propos* of the composition of violet powder) that "pharmaceutical chemists were slightly travelling out of their domain in determining what was or what was not a desirable application to the interior or the exterior of the body," followed by observations which amount to prohibition of the exercise of their faculties by pharmaceutical chemists in cases where, as Dr. Redwood sensibly remarks, "the old woman, whose opinion has been formed by direct observation and daily experience, is quite as capable of judging as the professional man whose knowledge is obtained second hand and whose judgment may be chiefly based on theoretic considerations."

The reproof appears to have been received with wonted humility, and if these remarkable opinions were confined to Dr. McSwiney, they might pass with a smile at the *gaucherie* which prompted the Doctor to select a conference of pharmacists for the purpose of propounding ideas so injurious to the self-respect of his hearers. But since a similar tone constantly pervades the utterances of the medical profession (note, for example, the serenely depreciatory style of Dr. Williams's letter, though he evidently means to be friendly), such observations demand firmer treatment.

The medical profession seem to regard certain, but unfortunately most indefinite, ground as consecrated to themselves, the avenues to which must be jealously guarded. Within this taboo none other, but especially no pharmacist, must venture to use his senses, although the subject may be easily within the range of his capacity and experience. The taboo is maintained on the strictly "protective" ground of the preservation of the licensed practitioner's fees. Such a state of repression cannot be borne, and the only way to establish good understandings is to give up the idea of artificial restrictions which have neither the sanction of reason, custom, nor law, and to endeavour to supply the public necessities in the most practical manner. The public depend too much upon the gratuitous good offices of the chemist ever to give up the habit of making use of them when it suits their purpose. It argues little wisdom on the part of the profession if they think the public ever gives up anything which it finds convenient.

Dr. McSwiney's remedy is as upside-down as his opinions. He proposes that the medical profession should be made acquainted with "the composition of proprietary remedies as they are called." How pharmacists must laugh at this from a member of a profession which claims an exclusive knowledge of what is good "for the interior or exterior of the body!" If he is right in his premises, the obvious remedy is for medical men to apply that knowledge and to find out for themselves what is good, and then to prescribe it by its *nomen officinale*. If they *will* prescribe empirical remedies, what is it but to acknowledge that the empirics, be they pharmacists or quacks, have found out something more beneficial for bodily ailments than their orthodox skill has been able to devise ?

NO PHARMACIST.

NOSTRUM LITERATURE.

Sir,—There is, I believe, a growing conviction that nothing has wrought so much demoralization within the drug trade and debased it in the eyes of the thoughtful and well-informed as the buffoonery almanacks and other gratis literature of the nostrum trade.

What are our more intelligent customers to think when on unfolding a purchase they find a handbill, similar to the one enclosed, announcing So-and-so, chemist, agent for Bluerapper's pills, which, to quote *verbatim*, "have restored thousands from the brink of the grave, after all hopes of recovery had been given up both by friends and attendants."

Or take the enclosed wrapper with an engraving of a star-spangled sprite mildly rampant over a gush of letterpress, exhibiting an inscription, pious, of course, on the fluttering drapery of what appears to be the tail of his shirt. I forbear quoting the incription, and content myself with observing that it might beggar the model mendicant, who with shaky pow and quavering voice foxes *his* geese with an appeal to the highest motives—"Dear Christian friends ! for the love of God, one penny !"

The purport of it all appears to be that readers may realize a most exalted idea of the proprietor, and interpret the star-girdled countenance to signify his present benignity, future apotheosis, and eternal beatitude.

A correspondent, over the signature, "Honesty the Best Policy," in your issue of August 31, page 179, in language not one whit too incisive, calls attention to a certain handbill, and the sinister use thereon of the pharmaceutical arms.

Certainly the armorial bearings of the Pharmaceutical Society are not intended to subserve such purposes, any more than it is the intent of the Bible to furnish texts for the purpose of rivetting attention to nineteenth century nostrums; surely, most of your readers will admit the prostitution of the latter to be by far a much greater abuse than the former.

That the extravagances of many nostrum makers are assuming an attitude increasingly inimical chiefly to the medical profession, next to the retail drug trade, and therefore to wholesale houses who supply both, may be inferred from the insatiate tendency, by means of inside wrappers for their wares, to engage the patronage of the public to various other articles thereon enumerated, to be had, when not procurable elsewhere, for stamps direct from themselves, and in this way they endeavour to plunge the trade, wholesale and retail, into the anxieties which invariably exhale from stock of precarious demand and inconvertible value.

York. ICTUS EQUI.

UNUSUAL DOSES.

Sir,—In reference to the correspondence about unusual doses, I should like to say I have been repeatedly thanked by medical men for not dispensing prescriptions that contained an evident Pharmacopœia overdose; in all cases, I think without exception, it was an error of the writer, and in some instances would have had fatal results.

I, therefore, ask Mr. Berdoe, Mr. Henry Brown, and medical men generally, if a chemist who has a reputation and a large stake at issue, is not abundantly justified, and even to be commended for acting with great caution in dispensing unusual doses ?

W. M.

THE NEW DOUBLE IODIDE.

Sir,—Allow me, through your Journal, to say that I regret very much that Mr. F. W. Fletcher should feel grieved at the simple remarks I made at the Dublin meeting of the Pharmaceutical Conference upon his new double iodide.

On the other hand, I am sorry he did not recall my attention to the subject at an earlier date, as he at once could have received the information which would have relieved him of six weeks' suspense. I have, however, written to the editor of the 'Year-Book of Pharmacy,' asking him to make the necessary correction to my remark, in the hope it may afford Mr. Fletcher some satisfaction.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Atkinson, Stubbs, Watson, Reynolds, Robinson, Glover, Morrison, Silverlock, Laing, Abraham, Ireland, Masson, An Aspiring Apprentice, Inquirer, Civitas, Taxus, Baccata, Alpha, A. P. S.

"THE MONTH."

The close of this month brings from various sources announcements that the scientific societies are about to resume their evening meetings. Thus the Quekett Microscopical Club held its first meeting last Friday, when papers were to be read on the Floral Development of *Helianthus annuus*, by Mr. W. H. Gilbert, and on the Fertilization of the Queen Bee, by Mr. John Hunter. The Chemical Society holds its first meeting on Thursday the 7th of November, when papers are to be read on the olefine produced by the reaction of ethylic iodide with zinc, by Professor Frankland; on the red colour of *Lithospermum Erythrorhizon*, by M. Kuhara; on the occurrence of nitrogen acids among the products of coal gas and hydrogen flames, by Mr. L. S. Wright; and a second report on chemical dynamics by Dr. Wright and Mr. Luff. The evening meetings of the Pharmaceutical Society will also commence on the 6th of next month.

This year the Faraday Lecture is to be delivered by Professor Wurtz, of Paris, who has accepted the invitation of the Council to undertake this duty. The subject of his lecture is to be "The Constitution of Matter in the Gaseous State." The lecture will be delivered in the theatre of the Royal Institution on Tuesday, the 12th of November, and on the following day the Fellows of the Society propose to entertain Professor Wurtz at dinner at Willis's Rooms.

Among the papers announced by the Society of Arts is one on the Land of Midian, by Captain Burton, and another on the Electric Light, by Mr. Shoolbred.

During the month public attention has been especially directed to two very important subjects, the condition of the water in the lower reaches of the river Thames, and the alleged discovery of a means of applying the electric light for domestic illumination and as a general substitute for gas. Though the pollution of the Thames by the daily discharge into it of the excreta of the metropolitan population, amounting to more than three million persons, has long ceased to be sensible within the more thickly inhabited area, it is very questionable whether the removal of the discharge to a lower point of the river has effected all that is requisite on the score of health or precluded the possibility of other evil results almost as important, such as the obstruction of the river channel by deposition of suspended material. The circumstance that the collision between the Princess Alice and the Bywell Castle took place close to one of the points where the sewage of London is discharged into the Thames, and just at that time of the day when the discharge is going on, has been the means of attracting notice to the state of the water in the river immediately above and below Barking, and a "Pharmaceutical Chemist," writing to the *Times* last month, suggested that the quality of the water would probably be found to constitute one of the reasons why on that occasion so many persons died immediately after their immersion. His description of the state of things is no less graphic than truthful. Close to the site of this dreadful catastrophe are the two great metropolitan outfalls, on the north bank of the river at Barking, on the south at Belvedere. At high water, twice in every twenty-four hours, the flood gates of these outfalls are opened, and there is projected into the river two continuous columns of decomposed fermenting sewage, hissing like soda-water with baneful gases, so black that the water is stained for miles, and discharging a corrupt charnel house odour that will be remembered by all who have passed through it on these summer excursions, as being peculiarly depressing and sickening. As sewage when extremely diluted—say one drop in 10,000—may when taken in milk or in water induce typhus or other fevers, it will probably be found that sewage when taken in a concentrated form, and especially when in a state of active decomposition, is a true poison, relatively as fatal as prussic acid.

The opinion thus expressed met with much concurrence, and a few days later the *Times* pointed out in a leading article that it appeared to be supported by some of the evidence given at the inquest, one of the survivors having stated that both for taste and smell the water was something he could hardly describe, while another gave evidence of having been under medical treatment on account of having swallowed some of the foul water. The rapidity with which decomposition of the bodies of those who were drowned set in, as well as the large number of deaths among those who were rescued, were also inferred to be due to the influence of sewage.

Whatever ground there may have been for these opinions, the association of the Princess Alice disaster with the condition produced in the Thames by the discharge of sewage soon brought to the front a number of advocates for various methods of dealing with sewage, and in the discussion of this subject in the daily papers a number of exploded projects and arguments have been brought forward, among which the most fallacious is the assumption that the constituents of sewage can be credited with a value equal to that which they would possess in the form of Peruvian guano or some other solid form. Calculations founded on such a basis require correction to such an extent, to compensate for the inaccessible condition of the constituents of sewage, that the possibly realizable value of this material as manure is reduced to an amount enormously less than the intrinsic value those constituents would have in a solid and concentrated state. The great obstacle to the realization of their value as manure is the enormous bulk of liquid through which they are diffused in solution and it is from failing to take due cognizance of this circumstance that most of the projects for the utilization of sewage have proved failures. The most delusive of these projects have for their object to submit sewage to some process of precipitation, by which it is supposed that the substances valuable as manure may be separated in a solid form, and these projects are not only the most delusive, as any one conversant with the solubility of any known compound of ammonia, phosphoric acid, or potash can at once perceive, but they are also the most mischievous, because they have in many, if not in most instances, a specious visible efficacy in so far as they clarify sewage and bring about a separation of the suspended material to the presence of which its most obviously noxious characters are due.

These methods of treatment may, indeed, be in some cases useful as means of lessening the pollution of rivers, but it is not too much to say that none of them can ever be expected to succeed as means of utilization. The trial and consideration of such methods have also done much to retard the adoption of more rational endeavours. Corporations have

been dazzled by the prospect held out to them of a large revenue to be derived from the use of sewage as manure, and without any capability of appreciating the facts of the case they have furnished opportunity for the formation of companies, the too confiding shareholders of which are even now mourning the day when they suffered themselves to be beguiled, to use the words of the *Times*, by chemical estimates of the value of sewage. This, however, is not quite a correct representation of the case, and it may be more fitly said that it is to the disregard of chemical as well as other scientific considerations that those unfortunate results are to be ascribed. The position of the projectors as well as the shareholders of these futile enterprises has been, at best, that of the blind leading the blind; they never had the warranty of chemical facts to encourage them, but were merely deluded by the misuse of such facts and by omitting to take into account all the other circumstances which so materially qualified the significance of those facts in regard to the object they had in view.

Though it cannot but be matter for regret that as stated by the *Times* about two millions sterling have been expended in this way, there is little to induce commiseration for those who have not only thus wasted their money without being able in any case to realize any satisfactory return, but have at the same time contributed to make the utilization of sewage a by-word of reproach rather than an object of the greatest national importance. It is in this latter aspect, however, that it should be regarded, as one of the collateral features of the larger question of sewage disposition, which it is the business of all town authorities to deal with, primarily, for the sake of maintaining a sanitary condition of the inhabitants.

The performance of this duty must always entail expense to the towns, and it is only after the sanitary object has been attained that it is admissible to consider how the constituents of sewage can be turned to account. In many instances the difficulty of disposing of vast quantities of sewage by discharging it on land, and making it filter through a considerable depth of soil before entering the river, is very great. In the case of large towns immense areas of land would be requisite for this purpose under existing conditions of town drainage, which allow the rainfall and storm water to flow into the sewers. But since this is not an essential condition of the water carriage system of removing the refuse of towns there is room to hope for improvement in this respect, which will much facilitate the utilization of sewage.

In the inaugural address delivered to the Social Science Congress, now sitting at Cheltenham, attention was directed to this point by the President, Lord Norton, who expressed the opinion that to arrive at a lucrative application of sewage to land the sole remaining problem was how to separate storm water from the sewers, and that when this was done even the sewage of London might be made to fertilize the neighbouring country without mischievously making mud banks in the Thames, or adding the poisoned to the black list of those drowned in its now polluted water.

Now that this question has become associated in some measure with the Princess Alice disaster it may be expected to excite renewed popular interest in such a way as to lead to some beneficial action throughout the country. As regards London a move has already been made by the Corporation, and at a late meeting of the Metropolitan Board of Works a letter was read from Mr. Monckton, the Town Clerk of the City of London, stating that the attention of the Port of London Sanitary Committee had been called to the foul state of the water in the river, near Beckton, by their medical officer of health, and intimating the desirability of taking some means to remedy the present evils consequent upon the state of the water near the sewage outfall. Here the matter rests for the present, but it will probably be heard of again very soon, and as the proper disposal of sewage so as to satisfy the requirements of health and, if possible, afford an opportunity of utilization is an object of interest in every town throughout the kingdom, this brief recommendation of it to the consideration of chemists and druggists may have the result of inducing them to give it the benefit of their special knowledge.

The use of the electric light has of late been considerably extended, especially in Paris, where it has been adopted for lighting railway stations, workshops and some of the larger streets. Mr. Blount, writing on this subject in the *Times* of the 4th inst., points out that the one important advantage of the electric light is its purity, freedom from smell, and the absence of products that contaminate the atmosphere. As regards cost, he considered that it was greater than that of gas, but that improvements might be looked for to diminish the expense.

The statements made at this time in regard to the possible application of the electric light as a substitute for gas had the effect of creating so great an alarm in the minds of shareholders of gas companies that the subject was taken up in the *Times* of the 4th inst. in a consolatory tone, to assure the public that the electric light cost so much more than gas that there was no occasion for panic, but at the same time with the saving reservation that only very sanguine people could contend that the ten per cent. dividend on gas shares was nearly so safe as the three per cent. on Consols. This certainly was comfort most judiciously qualified, and on the following day Mr. Hollingshead, who has been using the electric light outside the Gaiety Theatre for some three months, stated that while he believed people would be foolish to think that the electric light would at once supersede gas, they would be equally foolish to believe that it could only be produced at twelve times the cost of gas. In support of this he made the statement that he would be ready to give the opportunity of testing the two, and that he had no doubt of being able to prove that while his own wasteful experiments had come out about four-fifths the price of gas light, in a place like the Central Hall of the Alexandra Palace the electric light could be supplied at half the cost of gas.

The next issue of the *Times* contained a letter from M. Terrault, of Paris, in which he stated that he had just been informed that Mr. Edison, the inventor of the phonograph, had succeeded in subdividing the electric light so as to make it available for domestic use, and that he had done this in such a way that the existing gas fixtures would be available for its application at a very considerable reduction of cost. To this letter was appended an account of the capabilities of Mr. Edison's invention, taken from the *New York Sun*, the details of which are too vague and romantic for reproduction, but their tendency may be gathered from the concluding paragraph stating that it had been computed Edison's process would

give for about 6*d.* or 7½*d.*, the same amount of light given by one thousand feet of gas costing in New York ten or twelve shillings.

Mr. E. J. Reed also gave an account of the experience gained by the use of the electric light in the factory of Mr. Manchon, at Rouen, which showed that as compared with gas a saving of more than fifty pounds a year was effected by using the electric light. The applicability of this result to London was, however, quickly disputed on the ground that the price of gas had been taken as 7*s.* 2¼*d.* per thousand feet, while it was only 3*s.* 6*d.* per thousand in London, a difference which made the result of the comparison more favourable to gas light to the extent of some fifty pounds a year.

The next contribution to the subject was from the pen of Mr. W. Sugg, the well-known gas engineer. It contained a careful comparative examination of the cost of the two modes of lighting, using the data given by M. Fontaine in reference to the factory at Rouen. According to this the cost of the electric light was £377 16*s.* 6*d.*, or at the rate of 11*s.* 5*d.* per hour, while that of gas at 7*s.* 2½*d.* per one thousand, the price charged in France, was only 7*s.* 6¼*d.* per hour, and at the price of 3*s.* 6*d.* per one thousand cubic feet, charged in London, it amounted to only £143 18*s.* 7*d.*, or at the rate of 4*s.* 4½d. per hour. These comparisons were made between electric light used in a highly scientific manner, and gas used in a way so crude, that Mr. Sugg considers the result would be much more in favour of gas if it were burnt in the best form of burners, and in lights equal to one hundred and sixty candles each. In conclusion, Mr. Sugg expressed his opinion that though the electric light may be useful for many purposes, there are great practical difficulties to be overcome before it can take the place claimed for it by enthusiastic admirers.

In all these controversial communications no notice was taken of the remarkable statements made respecting Mr. Edison's invention, which indeed related to a use of the electric light quite outside that discussed. But, at the same time, this new and undisclosed invention had been described in such glowing terms that a very great depression in the nominal value of gas shares was the result, though probably the number which changed hands was not very large. Still there was a feeling of panic among the holders of gas shares, and to allay this Dr. Siemens addressed a letter to the *Times* in which he called in question the novelty of Mr. Edison's invention, and showed from his own experience in this subject that there was not adequate ground for the alarm that had been created. He also strongly deprecated the startling and sensational way in which the results of Mr. Edison's work had been communicated as being unworthy of science and mischievous to its true progress.

The conclusions to which Dr. Siemens came were that electricity might gradually replace gas in many of its most important applications, as being both cheaper and more brilliant under some conditions; but he still holds to the opinion that its application will be limited for the present, at least, to the lighting of coasts, harbours, quays, warehouses and public buildings, to naval and military signalling, and some purposes where the objections to gas are felt most strongly, as in picture galleries, drawing rooms, etc. Even to this extent, however, he regards the introduction of electric light as being a work of time and thinks that even when gas is so far superseded by its more brilliant rival, the consumption of gas will be maintained by the increasing area of application and its additional application to cooking and warming purposes.

An important step towards the adoption of the electric light has been taken by the Metropolitan Board of Works at a recent meeting, when it was resolved to test the applicability of the light along the whole length of the Victoria Embankment. The City Commission of Sewers has also decided to have some trials made upon Holborn Viaduct and in front of the Mansion House. The disposition to make a trial of the light is not confined to public bodies, for in the daily papers are advertisements in which the Aire and Calder Glass Bottle Company invites tenders for the lighting of its packing rooms at Castleford, the floor area of which is stated to be 30,000 feet.

As regards Mr. Edison's invention an announcement appears that his application for a patent was lodged at the English Patent Office on Wednesday last, so that there is reason to expect some further information respecting it becoming public very soon. Other inventors are, meanwhile, at work, and even at this early stage application has been made to the Court of Chancery in one case for an injunction to restrain an assumed infringement.

Although the trees in London have in a great measure became denuded of leaves, the country still boasts a large amount of foliage, and tints of red, brown and yellow still lend an autumnal charm to the landscape. The blossoms of the camomile may still be seen scattering their white stars on the green turf of suburban commons, and the bright scarlet berries of the dulcamara have not yet disappeared from hedge and thicket, while the golden blossoms of the ragwort still decorate the wayside hedge. This period of the year is abundant in fruits rather than flowers, and many which may now be found are worthy of examination, on account of their structure. It will not be necessary to examine very many before finding that fruits often scorn the definitions of the textbooks, and that they can only be approximately named. Thus the buckthorn fruit is not a berry according to botanical definition, since it is not inferior and the apparent seeds are endocarps. The dulcamara and belladonna fruits are also not true berries, since they are superior fruits and have axile placentation. The strawberry tree, so common in shrubberies, has also superior fruit and five cells, and therefore despite its name can scarcely be called a true berry, but must be called baccate or berry-like. The beautiful scarlet fruit and the delicate wax-like flowers of this plant may both be now found in perfection. The cause of this curious phenomenon is that the fruit takes a year to come to perfection. The flowers are worth examining, since the corolla presents an example of the shape called urceolate, and the anthers have not only porous dehiscence, but are furnished, like many of the Ericaceæ, with filiform appendages. The leaves look much like those of the bay tree, but differ in having serrate margins. The bark is astringent and has been used in tanning in Greece and Spain, while the charcoal obtained from the wood is highly valued. The fruit, although it has a taste by no means so pleasant as might be expected from its pretty appearance, yet contains sugar, which, as well as a spirit, are extracted from it in Spain. Although

occurring usually in a cultivated state in this country, it is considered to be a native at Killarney, where it is abundant. It appears to thrive well near the sea, being of very luxuriant growth on the cliff in Lord Lovelace's estate in North Devon, almost within reach of the sea spray.

To an ordinary observer the fruit of the horse chestnut and that of the Spanish chestnut are somewhat similar, and indeed it is only at this time of year that it is easy to say that the sweet chestnut is not a seed. But any one who will take the trouble to pick up one of the prickly burrs that look so much like a large stramonium fruit, may now see at the top of each of the two or three chestnuts it contains five or six thread-like styles, which at once show that they are fruits, and that the apparent ovary is a cupule, in fact that it consists of bracts. The horse chestnuts on the other hand will be seen to be perfectly smooth at the apex and to be perfectly enclosed in an ovary which splits when ripe, like the cupule of the sweet chestnut does. The leaves of the Spanish chestnut have been much used in America as a remedy for whooping cough, and the writer can certify that he has seen the decoction produce marvellous effects in that complaint. The venation of the leaves affords an excellent example of the kind known as feather-veined, while the bark contains a considerable amount of astringent matter. Large quantities of this bark are produced in Kent, where the chestnut is grown for hop-poles, and the bark is chipped off, and apparently allowed to rot.

The horse chestnut (*Æsculus Hippocastanum*), which belongs to the Sapindaceæ, is known at once from the Spanish chestnut by its compound, usually septenate, leaves. The seeds yield an oil which has been recommended for rheumatism, and a fluorescent principle, æsculin, allied to saponin; recently, gelseminic acid has been shown to be identical with this substance.

The name of "horse" chestnut was given, according to Evelyn, "from its curing horses broken-winded, and other cattle of coughs." Loudon, however, suggests that it was given ironically because its seeds resemble the sweet chestnut, but are unfit for food.

Bentley and Trimen's 'Medicinal Plants' for this month contains figures of *Hibiscus esculentus*, *Vitis vinifera*, *Dichopsis Gutta*, *Menyanthes trifoliata*, *Salvia officinalis*, *Metroxylon Sagu*, and *Aspidium Filix-mas*. The plates of buckbean and the sago palm are particularly good, and the latter is probably the best and most complete figure of the plant yet published. *Hibiscus esculentus* is an Indian plant, of which the fruit is official in the Indian Pharmacopœia, and is chiefly valued in medicine as a demulcent on account of the mucilage it contains. According to the authors the roots of the plant, which are one or two feet long, contain twice as much mucilage as marshmallow root. The well-known name *Isonandra Gutta* is here changed for *Dichopsis*, in accordance with the authors of 'Genera Plantarum.' The sago palm in like manner has changed its name from *Sagus lævis* and *S. Rumphii* to *Metroxylon Sagu*. The figures of spore cases, spores, antheridia, and archegonia on the plate devoted to the male fern will give the student a very good idea of the microscopical organs concerned in the reproduction of ferns.

How much there is yet to be learned about even our commonest plants is evident from a note communicated to *Nature*, by Mr. T. Whitelegge, of Ashton-under-Lyne. He states that he has found *Ranunculus repens*, *R. bulbosus*, *R. acris*, and *Stachys Germanica* each in a gyno-diœcious condition, the corolla being considerably reduced in size in all, while in the last two the stamens were either absent or reduced to scale-like bodies devoid of pollen. In the first two, although the stamens were not so much reduced, they appeared to produce little or no pollen. *R. acris* in this state is very common in Lancashire, but *R. repens* is rather rare. The same observer also found *G. rivale* with the stamens only well developed.

Mr. L. Lewis, of East Farleigh, in some experiments made upon hops, finds that the seeds of a monœcious plant produced one plant entirely male, and another entirely monœcious, but with a tendency to produce more hops than its predecessors.

During the month there has been a considerable amount of correspondence in the newspapers respecting the genus *Eucalyptus*, *à propos* of its proposed introduction into the island of Cyprus. Much that has appeared has been quite worthless, but one fact that seems to be demonstrated is that the *Eucalyptus globulus* is not, as a rule, able to brave the rigours of the English climate. Nevertheless it is stated that at Prince's Park, Liverpool, there is a eucalyptus tree which though planted when quite a small plant in the summer of 1876 is now 20 feet high, having made a growth of 12 feet in the summer of 1877. It has hitherto stood the winter well, only the tips being slightly injured last winter.

Professor Church, in some recent experiments upon chlorophyll, has discovered the curious fact that purified chlorophyll, which on keeping and exposure to the air assumes an olive brown hue, has its green colour restored so that it becomes far more intense and characteristic in hue than the best sample of leaf green he has ever seen, when heated in a water oven with four times its weight of zinc powder. That the chlorophyll is simply deoxidized and reduced to its original state appears evident from the fact that the red fluorescence and spectral bands of its alcoholic solution are those of the unchanged pigment. Another clue to the change of colour in leaves in autumn, as well as to the deepening of the green tint in summer, thus presents itself for further investigation.

A new proposed substitute for ipecacuanha is described under the name of batiator root by M. Stanislas Martin, in the *Bull. Gen. de Thérapeutique*. The plant is found in Senegal, and is now being grown in Paris from the seed. The roots are in tufts proceeding from a knotty rootstock which is covered with short, appressed, grey-brown, silky hairs. The roots are described as being thin, cylindrical, slightly flexuose, longitudinally wrinkled or striate, often with circular divisions, forming more or less elongated annulations, the fissures penetrating to the central thread-like wood fibre. Externally the drug is yellowish or greyish-brown, internally yellowish; it breaks with a smooth fracture, is inodorous, has a slightly acrid taste, and on mastication leaves a nauseous impression, like that of ipecacuanha. The properties are similar to ipecacuanha, and the root is given in similar doses.

The monks of Phanesomene Convent, in the Island of Salamine, Greece, prepare a remedy for hydrophobia from the root of *Marsdenia erecta*, by mixing it with equal parts of the powder of various species of Mylabris. This is given to the

person who has been bitten, the wound having previously been cauterized.

In the *Medical Times and Gazette*, it is stated that Dr. Jacquier, of Nantes has found oxide of zinc to produce rapid cure of diarrhœa. He gives it in the following manner:—Oxide of zinc 54 grains, bicarbonate of soda 7½ grains, to be divided into four packets, one to be taken every six hours. In several cases in which this remedy was found successful, diarrhœa had continued for several months, and other remedies had produced no improvement. In all the cases three or four doses were found sufficient.

The presence of a third alkaloid in *Hydrastis Canadensis*, which has already been noticed by Hale in 1873,* and Burt in 1875,† is now confirmed by Mr. Hermann Lerchen, who proposes the name of "xanthopuccina" for it. It crystallizes from alcohol in orange yellow needles, and differs from berberine in dissolving in strong nitric and hydrochloric acid without change of colour, and in sulphuric acid with a light yellow colour, and in giving light brown coloured spangles with solution of iodine in iodide of potassium. It is obtained by adding an excess of ammonia to the mother liquor after the separation of berberine and hydrastine, the berberine being thrown down by hydrochloric acid and the hydrastine by afterwards adding ammonia until the solution becomes neutral. The alkaloid, as described by Hale, would appear to have been contaminated with berberine, since it was reported by him to have turned red when warmed with nitric acid, and reddish-brown with sulphuric acid.

According to M. Jeremin, in a communication to the Russian Chemical Society, a solution of oxalic acid is capable of absorbing considerable quantities of ozone. Such a solution it is said may be preserved for a long time, an old solution being even a better disinfectant than a fresh one.

In a communication to the French Academy of Sciences, read on the 14th inst., M. Marc Delafontaine announced the discovery of the oxide of another new metal, to which he has given the name of philippium (Pp), in honour of M. Philippe Plantamour, of Geneva, a friend and pupil of Berzelius. M. Delafontaine describes the new element as forming a fourth member of the yttria group of earths; it is yellow, and assuming provisionally that the philippia obtained is in the state of protoxide its equivalent would lie between 90 and 95. Its concentrated solution examined spectroscopically showed a rather broad and very intense magnificent characteristic absorption band in the indigo (λ = about 450). The new element appears to have been obtained both from samarskite and gadolinite.

A new reagent for detecting the presence of alcohol in essential oils has been devised by A. Drechsler. It consists of 1 part of bichromate of potassium dissolved in 10 parts of nitric acid of sp. gr. 1·30. In using it five or six drops of the oil to be tested are poured into a porcelain capsule, two or three drops of the reagent are added, and the whole is allowed to stand. If the least trace of alcohol be present, the pungent odour of ethyl oxide is evolved along with the specific odour of the oil, whilst at the same time a very characteristic change of colour occurs, which is very different according to the quality of the different oils. In certain oils a beautiful play of colours appears in the mixture.

The difficulty of distinguishing between methylated and pure chloroform has recently attracted some attention, and the following test proposed by Mr. H. W. Langbeck is therefore worthy of notice. Ten volumes of the suspected sample are mixed with one volume of a solution of nitrate of silver containing 1·7 of the dry salt, and the mixture is allowed to stand for twenty-four hours. After the lapse of this time the line of contact of the two liquids has assumed a faintly reddish-violet colour and a reddish brown precipitate of silver oxide is found, more or less abundant, according to the proportion of methyl present.

The public analyst would appear to find a *raison d'être* in the United States, since it is reported that out of twenty-one samples of powdered ginger recently submitted to careful examination no less than fifteen were found to be adulterated with such substances as sago meal, tapioca, potato flour, wheat flour, ground rice, cayenne pepper, mustard and turmeric powder.

Some time ago a Hamburg house received from a drug miller in Hanover 100 lbs. of powdered cinnamon, which had been ordered of the best quality, but which when examined was found to consist of ground cedar wood and linseed each flavoured with a little oil of cinnamon.

According to *New Remedies* the extent to which cod liver oil has come into use in the United States has led to its sophistication there to a very great extent. Not only are the livers of other varieties of cod used as a source of supply, but oil is largely derived, it is said, from the entire menhaden, a small fish frequenting the bays and estuaries of the northern coasts. It has commonly been thought that by using Norwegian oil the risk of adulteration would be considerably lessened, but recent reports from North Germany state that in Norway it has become quite common to use the liver of a large fish caught on the coast which yields oil in large quantity. The oil from the latter source is of a light colour, remarkably bright in appearance, and quite free from unpleasant odour.

M. Maurel, in some experiments made upon the action of various substances on the teeth finds that citric acid attacks and renders soft and friable all the dental structure. Tannic acid does not act on the enamel, but renders the dentine softer and colours it light brown. Carbolic acid does not affect the enamel. Tincture of iodine causes the enamel to disintegrate, while chloride of zinc has no effect on the enamel, but renders the cement transparent, though it has but little effect upon the dentine. Arsenious acid is without effect on either the enamel, cement, or dentine.

An easy method of making a hole in plate glass is described in *New Remedies*, as follows:—Make a circle of clay or cement rather larger than the intended hole; pour some kerosin into the hole, ignite it, place the plate upon a moderately hard support, and with a stick rather smaller than the hole required and a hammer strike a rather smart blow; this will leave a rough edged hole which may be smoothed with a file. Cold water is said to answer even better than a blow.

According to the *Gardeners' Chronicle* it is reported from California that a company with a large capital is about to commence operations there in working up water melons for economic products. As the expectations of dividends are based upon getting 10 per cent. of sugar from the juice, alcohol (*sic*) from

* *Pharm. Journ.* [3], iv., p. 105. † *Ib.* [3], vi., p. 467.

the pulp and rind, and 25 per cent. of culinary oil from the seeds, it is hardly probable that the shares will compete seriously with those of the more profitable gold mines.

A correspondent of the same journal writes to say that a wineglassful of paraffin in four gallons of water forms a capital insecticide for the greenhouse, it being specially fatal to the mealy bug without injuring the flowers syringed with it.

Another case of fatal accident from the explosion of an oxygen gas retort was reported last week. According to one of the witnesses the explosion had been caused by the stoppage of the discharge tube of the retort, and a verdict of accidental death was returned.

An inquest has been held at Doncaster touching the death of a young child to whom two doses of a so-called "black currant elixir" had been administered. The medical attendant suspected opium poisoning, and analysis showed that the preparation did contain a small quantity of morphia, with sugar, vegetable red colouring matter, nitric acid, a little acetic acid, and a trace of alcohol. The label on the bottle described it as "a safe and efficient cure for asthma, consumption, whooping and other coughs, colds," etc., and the doses for children were stated in drops. The jury returned a verdict that the child had died through an overdose of the medicine, and expressed a strong disapproval of the use of opiates, such as morphia, except under medical supervision, whilst the coroner directed attention to the fact that the preparation should have had a stamp upon it, and remarked that it would probably thus have been brought within the provisions of the Poisons Act. The *Lancet* alluding to this case speaks of it *more suo* as a painful instance of the continued laxity of druggists in the sale of poisonous medicines, as if ignorant of the fact that enormous quantities of such preparations are sold every day by linen drapers and grocers under the cover of the stamp to which the coroner looks for protection, and that medical practitioners are by no means free from any blame that may attach to the issue of medicines containing poisons to the public under this form. Instead of this continued indiscriminate denunciation of a class it would be better to diffuse correct information on the subject, and thus prepare the public mind for the abolition of the present illogical distinction which the law makes between patent and other medicines containing scheduled poisons.

In a recent "Month" attention was directed to the fact that the report of a case stating that the death of a gentleman had resulted from the administration of "drops" instead of a "mixture" had furnished ground for the assumption by the *British Medical Journal* that the accident might have been prevented by the use of a fluted poison bottle, and this in its turn formed the basis of some strictures on the Pharmaceutical Society. A curious commentary on this occurs in the number of the same journal for the 5th instant, in the report of a case received in the Fulham Hospital, of a man who was poisoned by swallowing a teaspoonful of liquor atropiæ sulph., notwithstanding it had been dispensed in a regular fluted poison bottle.

The misreading of a carelessly written prescription which resulted in a fatal accident is reported from Rossla, in Germany. The prescription was written as follows:—"Chloral hydrate, 15·0; tinct. opii spl., 15; aq. dest., 60·0. D.S. A third part to be used as a clyster in the evening." The assistant into whose hands the prescription came, and who happened to be unqualified, without consulting his principal or the physician interpreted "tinct. opii spl., 15" as meaning 15 grams of tinct. opii, and dispensed it accordingly, the consequence being the death of the patient. The result of a legal inquiry was that the physician, apothecary and assistant were all held to be culpable, and sentenced to one, two, and three months' imprisonment respectively.

A correspondent suggests with reference to liq. secal. ammon., which has recently elicited some observations in the "Dispensing Memoranda," that there should be a recognized formula for its preparation. This course, however, might very properly be preceded by some reliable information as to the greater value of such a preparation as compared with the ext. ergot. liq. made in accordance with the official formula. The proximate principles of ergot to which it owes its medicinal value are very little understood at the present time, and it has not yet been satisfactorily demonstrated that an ammoniated menstruum possesses any more value than the solvents now in use, and if it can be extemporaneously prepared, as suggested by the same writer, the addition of ammonia may be left to the discretion of the medical attendant. If it can be shown that some active principle of the ergot can be better extracted, developed, or preserved by an ammoniacal menstruum, there would be a *primâ facie* case for a recognized formula; but up to the present time the literature of ergot is silent on the merits of ammonia as a menstruum, and testimonials as to particular preparations being valuable therapeutic agents are of value only as the result of a carefully conducted series of comparative experiments which some have not the time and others are wanting in the ability to institute.

The letter from Mr. Balthazar Foster, on etherized cod liver oil, communicated by Mr. Charles Swinn, may be taken as a guide for the make of this preparation, and agrees with the remarks on the subject in "The Month."

It matters little how the mixture No. 162 be prepared, or in what order the ingredients are mixed together, a separation of the potassæ chloras will, to a greater or less extent, take place. The solubility of this salt being, in cold water, 1 in 12, the six ounces of aq. camph. would be sufficient to hold in solution ℥ij of potass. chloras, but the solvent power is diminished by the presence of potass. acetas and the tincture of calumba. It has been remarked on previous occasions that if a salt be in greater quantity than the fluid will hold in solution, it should not be dissolved by heat, but rubbed in a mortar with the cold fluid and the undissolved portion diffused through the mixture; in the latter case theun dissolved salt is in a finely divided state, whereas, if heat be used, it is deposited in a crystalline condition, and is not so suitable for internal administration.

Mist. acaciæ is very often required in prescriptions where it does not form one of the ingredients, and is frequently ordered without the quantity being added, as in the mixture, No. 163. From ℥ss to ℥j may be used. Even then the suspension of the bismuth is only temporary, though probably sufficiently long to enable the patient to pour out and take the dose without leaving the bismuth as a sediment in the glass. There is no fixed rule with regard to the

quantity of mucilage; it is left to the discretion of the dispenser.

In mixing the strong acids, and allowing the mixture to stand for the preparation of acid. nitro-hydrochlor. (No. 164), decomposition takes place with development of chlorine, and probably this may continue to a limited extent for a time when in a state of dilution; but Dr. Wood's view that it proceeds "more rapidly" after dilution is unsupported. Dr. Tilden has investigated the character and progress of the changes which occur (*Pharm. Journ.*, 2nd series, vol. x., p. 580), and concludes that if the compound formed by at once adding the water to the mixed acids be allowed to stand a fortnight, its composition agrees with the diluted acid obtained by following the directions of the Pharmacopœia.

With reference to lapis divinus., No. 165, it is prescribed usually in the proportion of one and a half to two grains to the ounce. This substance was formerly more frequently met with in prescriptions than at the present time; even now it is a favourite remedy with some eminent oculists. Formulæ for its preparation have been communicated by several correspondents.

A mixture of ol. pini sylvest. with tr. benz. co. was referred to in last "Month." A correspondent, Mr. Green, alluding again to the composition suggests a mode of making it without the mucilage; but as he has written tr. benz. instead of tr. benz. co., it is possible that he has used the simple tincture instead of the compound ordered in the prescription.

Mr. J. W. Savage somewhat objects to the application of a general rule to "shake the bottle" when there is a precipitate, especially in the instance of his mixture commented on in last "Month," apparently because the precipitate is calcium carbonate in a crystalline condition, quoting Squire that these crystals produce "irritation of the bowels." The mixture contained about six ounces of lime water; if all were precipitated it would be represented by about six or seven grains of precipitated calcium carbonate. Mr. Savage's attention should be directed to the troch. bismuthi, B.P., each of which contains four grains of precipitated calcium carbonate, and the dose is one to six lozenges; the mixture as well as the bismuth lozenges are evidently given to allay an irritable condition of stomach.

No. 166. A comparison of the London Pharmacopœia with the British Pharmacopœia will show that the formulæ for infusions of roses differ in name, composition, and proportions. A prescription therefore written before the introduction of the British Pharmacopœia should be made up with inf. rosæ co., Ph. Lond., or a difference in taste may be detected by the patient. But if the prescription were written subsequently to the introduction of the British Pharmacopœia, although with inf. rosæ co., the inf. rosæ acid. should be used. Why physicians order an extra quantity of acid. sulph. dil. with inf. rosæ is a difficult question. Dispensers can satisfy themselves that the extra quantity is ordered, and may presume that the writer had good reasons of his own for so doing.

In prescription No. 167, tr. guaiaci is ordered. This preparation was official in P.L., and was sometimes written tr. guaiac. simp. to distinguish it from tr. guaiac. comp. The German Pharmacopœia still retains the two preparations. The simple tincture should be used in this instance. The vin. sem. colch. is frequently met with. It is not official in the B.P., but there is a formula for it in the U.S. Pharmacopœia, and in the German and Austrian Pharmacopœias the wine of the seed only is used. The tr. guaiaci and vin. sem. colch. are usually met with in dispensing establishments. "Dispenser" p. 317, gives the formula for each.

The mixture required in No. 168, cannot be combined so as to form a clear solution, provided the liq. ferri dialysati be in good condition and of the proper strength.

The preparation of the P.L. should certainly be dispensed when liq. arsen. chlor. is ordered in a prescription as in No. 169, and in the case of these two preparations it is important that the difference should be distinctly recognized. A note in the B.P., under the formula for liq. arsen. hydrochlor., states that "this solution corresponds with liq. arsenicalis, and is nearly three times the strength of the liq. arsen. chlor. P.L."

When pulv. aloes or ext. aloes is ordered in a prescription, the Socotrine aloes or extract of that aloes should be used. When Barbadoes aloes is intended it is specially designated as such.

In reply to No. 171, it is not usual or necessary when acid. hydrocyan. dil. is dispensed in a mixture to place a label "shake the bottle" on it. It would be a very proper precaution if the dose were excessive. On this point opinions may differ, but the acid hydrocyan dil., when once diffused through a mixture, would not be likely to separate, and if under ordinary circumstances a dispenser were asked why he put a label to indicate that the bottle were to be shaken he would have some difficulty in giving a satisfactory answer.

In the prescription No. 172, the quantity of fluid is insufficient for the solution of the magnes. sulph. If practicable the writer should be referred to; if not the dispenser must use his own judgment. Probably the best plan in the first prescription would be to increase the bulk to one tablespoonful and a half; the dispenser might plead as his excuse for so doing that it would be impossible for the patient to take the undissolved sulphate of magnesia in divided doses. In the second prescription the course pursued by W. S. was a very proper one.

In dispensing No. 173, the potass. iodid. should be dissolved in half the water ordered and to this should be added the acid. hydrocyan. dil., and the liq. bismuthi, then the acid. hydrobrom. and the remainder of the water, with about half an ounce of mucilage of tragacanth; the quinine should be put in last. The mixture has a very slight opacity but no appreciable deposit, and it remains in that condition for a moderate time. There is a tendency to the development of a reddish yellow colour which ultimately precipitates, but mixed as indicated this is to a great extent obviated.

The prescription, No. 174 may be made into a satisfactory emulsion by rubbing in a mortar the ol. ricini with the pulv. acaciæ, adding at once ℥iss. of the peppermint water and continuing the trituration until it emulsifies; finally the remainder of the peppermint water in which has been dissolved the potassæ carb., ammon. carb., with the vin. ipecac., and sp. æth. nit. The finished emulsion should be white, and thoroughly emulsified, and then no separation will take place.

The best excipient is required for camphor, and in this instance (No. 175) there being ℥ij of camphor to be made into 24 pills, the excipient should add little

to their bulk. A method that answers very well, and probably the best for this purpose, is 10 grs. of glycerine of tragacanth, well rubbed up with the camphor, and then equal parts of glycerine and sp. wine mixed together and added gradually with the usual manipulation until they combine sufficiently for a pill mass. The mass when made will weigh ʒij ϑj, and can easily be made into 24 pills which become firm and retain their shape. Sometimes conf. rosæ can. is suggested as an excipient for camphor, but when a substance like camphor is required to be made into pills, an excipient without colour furnishes a more elegant result. There is no necessity for the use of suet, and some medical men might reasonably object to the use of an animal substance such as suet, which has no place in a prescription.

It would obviate much inconvenience and confer a great boon on dispensers, if the medical profession, on the advent of a new pharmacopœia, would at once, in their prescriptions, make the transition from the old names to the new ones, but however desirable it is almost too much to hope for at once ; it requires that a generation pass away before the new preparations become known and the new names become as familiar as the old ones. Mr. Glover, in No. 176, refers to this inconvenience and deplores it; he gives ext. tarax. liq. as an instance, and some remarks on this preparation will be found in the "Month," of August, 1877, p. 145. The special preparation of taraxacum to which he alludes, as resembling whitewash in a mixture, is one with which the trade generally is not acquainted.

It is not correct to place tissue paper on a blister (No. 177) unless directed in the prescription or required by the patient. It is said that tissue paper obviates the liability to absorption of the active principle and production of strangury, but this is a contingency against which it is the duty of the writer, not of the dispenser, to provide. For the protection of a blister in transit a piece of tissue, or better, waxed paper may be placed over it, but it should be removed when the blister is applied to the skin. Any covering, however thin, left on the blister must more or less retard its action. Some remarks on blisters will be found in the "Month" of October, 1877, p. 323.

The mixture, No. 178, is not an elegant one, but it may be made by rubbing the sodæ hypophosph. in a mortar with the glycerine till dissolved, and gradually adding the tr. ferri perchlor. A thick yellowish-green compound is the result, which when freshly prepared may be readily dropped into water as required; on standing, however, a deposit forms at the bottom of the bottle which is difficult again to diffuse. The writer may know what he has ordered in this prescription, but it is doubtful if he knows what the patient is taking when the mixture is combined.

It is not always practicable to say what the prescriber means when he orders potass. carb. The dispenser must take the surrounding circumstances into consideration. Potass. bicarb. in a mixture such as No. 179 is quite usual, and the dose is an ordinary one, but it it is not usual to see potass. carb. prescribed in such a mixture and in doses of one scruple each.

The size of the pills when no special quantity of excipient is ordered must be left to the judgment of the dispenser. In the atropine pills, No. 180, the excipient may be glycerine of tragacanth with starch in powder to make one-grain pills. These will be very small, but not too minute for the patient to handle.

If the mixture, No. 181, be properly made there will be no precipitate. The quinine should be dissolved in a little water with the dilute sulphuric acid and added to the mag. sulph. and ferri sulph., dissolved in another portion of the water; lastly the tincture of ginger. The mixture is opalescent from the oleoresin of the ginger, but there is no deposit. If there has been a deposit from this combination put together in any order, that deposit must be due to impurity in the ingredients or in the water. Aqua is ordered, but in this mixture distilled water should be used.

The preparation referred to in No. 182 turns out to be one of the multitude of specialties now sent out which threaten to render the advertisement sheet a formidable rival, or perhaps rather a necessary companion, to the Pharmacopœia. It would frequently save much trouble if prescribers who feel compelled to order from this class of preparations would at the same time give some indication as to the source from which they are to be obtained.

It is apparently impossible to make a "neat and elegant" preparation of the prescription for ointment quoted in No. 183. The glycerine is in excess of what the ointment will combine with. If half the glycerine be omitted and its place supplied by lard a very satisfactory result may be arrived at.

THERAPEUTICAL PROPERTIES OF MONNINIA POLYSTACHIA.*

Amongst the medicinal plants recently suggested as possessing important therapeutic value is the *Monninia polystachia*, one of the Polygalaceæ, which has an extensive distribution, growing near the summits of steep mountains in South America, as well as in the woody plains and marshy districts of the same region. It is a pretty plant to which, however, hitherto but little attention has been paid by chemists. Therapeutic virtues have been attributed to two parts of the plant, the bark of the root and the recent leaves. The latter are regarded as expectorant, whilst the former is considered to be astringent. The root of the plant is fusiform, sixteen or eighteen inches in length, of yellowish colour, with scattered darker spots, slightly disagreeable odour, and taste at first sweetish, but subsequently becoming acrid and bitter and exciting salivation. Its infusion is turbid like soapy water. By the Americans it is named "yallhoy," and the bark of the root is pounded and made into a paste. No complete chemical analysis has as yet been made of this drug, but it is known that it contains a large proportion of resinous material. This appears to be divisible into three parts, one of which is soluble in ether, a second soluble in alcohol, and a third equally resinous, to which they give the name of monnininia. The drug can be administered both as a powder, and in infusion. The dose is from 10 to 12 grams per diem. The following are some of the preparations:—Tincture: bark of the root 100 grams, alcohol 300 grams, macerate for four days, frequently agitating and filter, then add sulphuric ether 150 grams, macerate for forty-eight hours more, and mix the two liquids. Ointment: Extract of monninia 4 grams, lard 20 grams, essence of lavender 4 drops. Ft. ung.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 26, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTRATION OF DENTISTS UNDER THE NEW ACT.

AT the recent meeting of the General Medical Council, summoned mainly for the consideration of measures to be taken in carrying out the Dentistry Act, a report was presented by the Registrar stating what had been done up to that time in regard to the registration of dentists. From this it appears that immediately after the issue of the circular and registration forms, recently referred to in this Journal, applications for registration were sent in in great numbers, and with urgent demand for immediate attention.

The results arrived at by this means were as follows: Up to the 17th inst. the number of dentists that had been thus provisionally registered was 930, all of whom duly satisfied the conditions for registration laid down by the Act, while a large number of other applications were standing over awaiting the mere formal steps connected with completing the registration, such as sending in diplomas, filling up papers, and the like, so that it may be said in round numbers about a thousand dentists have been registered up to the present time.

Of these 86 are licentiates in dentistry of the Royal College of Surgeons of England, who having produced or sent their diplomas to the Registrar were accordingly registered under the clause A of section 6 of the Act.

Of such dentists who claim to be registered under clause C of section 6, on the ground that they were "*bonâ fide* engaged in the practice of dentistry at the date of the passing of the Act;" 566 declared themselves to have been practising dentistry separately; 2 that they had been doing so in conjunction with the practice of medicine and surgery, and 274 as in conjunction with the practice of pharmacy alone; 1 in conjunction with the practice of medicine and pharmacy; and 1 in conjunction with pharmacy and surgery in Her Majesty's army.

Besides these registered dentists there are 44 other applicants whose claims the Registrar has reserved for the decision of the Council, and of this number 4 claim under clause B of section 6, as "foreign or colonial dentists," 35 under section 37, and 5 as licentiates in dentistry of the Royal College of Ireland. None of these Irish licentiates have as yet sent in the document conferring or evidencing the licensing or qualification, and in the course of a long discussion on this subject reference was made to a charge that the Irish College of Surgeons had been the first in a race to bid for lucrative custom, by granting diplomas on "easy terms" to those who prefer registration "with a title" to registration without a title, and in defiance of the principles of "home rule" had thrown their net so as to drag English waters. It was asserted that the Irish College of Surgeons had sent out a circular inviting persons to apply for the diploma—one of the stipulations being the deposit of a ten pound note, and within a short time 52 out of 54 applicants had been "passed."

In reference to these statements Dr. STORRAR said this was not the first time the Council had heard about "Dutch auctions" in diploma granting, and he added that questions would be raised as to the status of the examiners. Mr. SIMON said he was ready to believe in the honour of the Irish College of Surgeons, and could not readily accept the view that it had been a party to a "Dutch auction" of diplomas; but at the same time he thought the College had made a grave mistake in the action taken. He also questioned the power of the College to give a diploma to a person who had not passed through a course of study. Eventually it was resolved that the Executive Committee should require information as to the examinations exacted by the various medical authorities before granting dental qualifications.

Several letters have lately appeared in the *Times* which somewhat touch upon this subject, and as the medical journals have been by no means reticent in their deprecation of the practice of dentistry by chemists and druggists, it may not be useless to point out that these letters reveal a danger of discredit to the dental profession much more serious, and originating from medical authorities.

The first letter, from Mr. W. D. NAPIER, pointed out that though the Medical Act, 1858, prevented the use of the title "surgeon" except by such as were duly qualified, it failed to prevent a person who held no qualification from using that title, provided he did so in conjunction with some other title, such as accoucheur, oculist, aurist, dentist, etc. He also stated that more than one medical corporation had been induced by the bait of ten guineas to grant licences for various specialties of surgery, without requiring from the candidates a general knowledge of the whole body, thus facilitating the improper assumption of the title of surgeon. He therefore suggested the desirability of drawing a distinct line between dentists who are duly qualified "surgeons," and those who by merely paying the dental registration fee may consider themselves entitled thereby to style themselves "surgeon-dentist."

This view of the matter was warmly supported by Mr. J. H. CRAIGIE and by Mr. T. H. CARTWRIGHT,

who dwelt upon the injury done to qualified medical practitioners who devote themselves to the study of dental diseases as a specialty, and the opportunity offered for the practice of imposture and fraud by this misuse of titles, and urged that the assumption of the title "surgeon-dentist" should be restricted to those dentists who are surgeons.

THE WEIGHTS AND MEASURES ACT, 1878.

THE letter on this subject that appears in our correspondence columns will serve as the representative of several other communications we have received, the writers of which apprehend, like Mr. WOOD, that the new Act will be a source of inconvenience to chemists and druggists.

Other trades appear to have been influenced by similar doubts and several inquiries have been addressed to the Board of Trade (Standards Department) in consequence. In the *Times* of the 23rd inst. is a letter from Mr. FARRAR in reply to some such inquiries respecting the legal position of buyers and sellers of agricultural produce as it may be affected by the new Act.

In this letter it is first pointed out that in all the main features of the Act it is merely a measure for re-enacting and consolidating previously existing enactments, consequently it does not, generally speaking, make illegal anything that was not illegal under the previously existing law. This is the case in regard to the apothecaries' weights and measures, which have never yet received legal recognition. It is for this reason that the drachm and scruple of the apothecaries' weight are not included among the number of legal weights.

The admission of the fluid ounce as a legal measure represented by a Board of Trade standard would appear to be based upon its conformity with the gallon as the unit or standard measure of capacity, and with the imperial standard pound avoirdupois, which is the weight of one-tenth part of the gallon of distilled water, under certain specified conditions. The fluid ounce is one-sixteenth part of the pound of distilled water, and the fluid drachm as well as the minim are in like manner aliquot parts of the same quantity. These measures have moreover been indirectly legalized by the action of the General Medical Council in pursuance of powers conferred on that body in relation to the Pharmacopœia by the Medical Act.

In Mr. FARRER'S letter it is stated that all denominations of weight and measure now legally and commonly in use for trade purposes are represented in the second schedule of the Act by Board of Trade standards. The drachm and scruple are not included because they never have been legal weights, but the ounce troy, which is the same as the apothecaries' ounce, is represented by a Board of Trade standard.

Though clause 24 of the Act imposes a penalty on every person who uses or has in his possession for use in trade a weight or measure which is not of the denomination of a Board of Trade standard, it must be remembered that clause 8 gives the Standards Department the power to legalize from time to time the use for trade of new denominations of weight and measure, providing they are multiples or aliquot parts of the imperial weights and measures. Should the exigencies of trade at any time demand the legalization of any further standards it will be within the the power of the Board of Trade to legalize such standards. In this way it appears that it might be possible to obtain the legalization of a standard of sixty grain weight to supply the place of the drachm which retail druggists are continually using.

As regards the use of graduated glass measures of 10 and 20 ounce capacity we imagine they would be regarded respectively as pint and half-pint measures, though it is not quite so clear that they would be strictly legal measures for the smaller quantities indicated by the graduation.

The stamping of such glass measures appears under clause 29 to be essential, though there is not any indication in the Act of the mode in which these measures are to be stamped, such as is given in the case of the stamping of weights. In regard to these points we purpose endeavouring to obtain some information for the guidance of our readers, if possible, before the publication of our next issue.

AN EXPLOSIVE MIXTURE.

THE *Medical Press and Circular* quotes from a German source an account of the results following the formation of an "explosive mixture," which, if true, exceeds in singularity, both as to the ingredients and the containing vessel, any of those which have recently been the subject of comment in the Dispensing Memoranda. A man having swallowed four plates of potato soup, followed by numerous cups of tea and milk, took a large dose of bicarbonate of soda "to aid digestion." The consequence was that his stomach became enormously distended, and the diaphragm giving way caused immediate death.

THE CHEMISTS' BALL.

WE are requested to state that a meeting will be held at 17, Bloomsbury Square, on Monday evening, November 4, at 9 p.m., for the purpose of making preliminary arrangements for the ensuing Ball.

THE NEXT MEETING OF THE BRITISH ASSOCIATION AND THE PHARMACEUTICAL CONFERENCE.

WE are informed that the date for the commencement of the meeting of the British Association next year in Sheffield, which was originally fixed for the 6th of August, has been altered to Wednesday, August the 20th. According to the usual rule therefore the General Meeting of the British Pharmaceutical Conference will be held on Tuesday and Wednesday, the 19th and 20th of August.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A PAPER by Mr. GLOVER on "The Genus *Quercus* and its Pharmaceutical Interests" will be read at the meeting of the above Association, on Wednesday, Oct. 30, at 8.30 p.m., in its rooms, 32A, George Street, Hanover Square.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October 16, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Allen, Henry.....London.
Aston, Walter .....Tarporley.
Hobbs, Thomas Henry Hurle...Wells.

MINOR EXAMINATION.

Sixteen candidates were examined. *Nine* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bowen, Ebenezer .....Pendre Cilgerran.
Corfield, Edward .....Birmingham.
Davies, Philip Henry .....St. Asaph.
Garrett, John .....Guilsborough.
Goddard, Enoch William .....Nottingham.
Jarvis, Clarence Frank .....Handsworth.
Jones, William Henry.....Aberdare.

MODIFIED EXAMINATION.

Five candidates were examined. *One* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Miller, George Frederick .....Lewisham Road.
Pollard, Joseph.....Manchester.
Strode, Thomas.....Honiton.
Thomas, Thomas .....Portobello, Staff.

October 17, 1878.

Present— Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Nine* failed. The following *eighteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Aldridge, Josph Henry .....Brighton.
Bilton, John Walter.....Newcastle-un.-Lyne.
Binks, Burcham .....Lynn.
Brooks, Tom .....London.
Broughton, Owen .....Salford.
Cobb, George Myhill .....Nottingham.
Cowap, Samuel Evan .....London.
Dawson, William .....Kennington.
Hayes, James Roberts.....Lynn.
Hurley, Edward William .....Reading.
Jones, James.....Southport.
Lodge, George Henry .....Rotherham.
Marshall, Arthur Willis .....Rusholme.
Mason, William Brandwood ...Bolton.
Norman, John Turton .....Blackpool.
Patterson, James .....Landport.
Southern, Charles William .....Donington.
Swindle, Norman Vickers .....Carlisle.

October 23, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Taylor.

Dr. Greenhow was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Eleven* failed. The following *sixteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Borland, John .....Kilmarnock.
Bray, William John..... .....Saffron Walden.
Buck, Charles Burton .....Sandgate.
Bush, Arthur ..... Barnes.
Carrell, George..... ..East Southsea.
Cox, Joseph .....Nottingham.
Exley, John, jun. .....Leeds.
Jackson, Joseph John ....Bridgnorth.
Morris, John Lloyd .....Cardigan.
Owen, George Benjamin.....Sheffield.
Pocock, Wm. Fredk. Henry ...Cape Town.
Richards, Frederick Johnson ...Carlisle.
Ridley, Thomas .....Brampton.
Roberts, Henry.....Norwich.
Stuart, Charles Edward .....London.
Wyborn, Edward .....Reading.

October 24, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Taylor.

MINOR EXAMINATION.

Twenty-eight candidates were examined. *Eleven* failed. The following *seventeen* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Bates, Frederic William .....Crowle.
Booth, Thomas.....Bolton.
Burrell, John Benjamin .....Norwich.
Coles, William Edwin.....Newport Pagnell.
Graham, Henry .....London.
Hamer, Joseph Armitstead.....Southport.
Hinkley, Edward .....Newcastle-un.-Lyne.
Horton, Thomas .....Peterborough.
McBeath, John William.....Darlington.
Millen, Herbert Alfred .....Peckham.
Nowell, Barnes.....London.
Parkes, George James Robert...Tipton.
Rutter, John.....Cambridge.
Stott, Charles Thomas.....Sowerby Bridge.
Strachan, John.....London.
Ward, John .....Derby.
White, John Thomas .....Dudley.

PRELIMINARY EXAMINATION.

The undermentioned certificates have been received in lieu of this Examination:—

Certificate of the College of Preceptors.

Thomas, Ivor Edward.....Merthyr.

Certificate of the Faculty of Physicians and Surgeons of Glasgow.

Watkinson, James .....Farnworth.

Certificate of the Law Society of the United Kingdom.

Jones, John Owen .....Dolgelley.

Certificates of the Royal College of Surgeons of England.

Allison, William Billyard .....Retford.
Sawdy, George Samuel .....Blandford.

Certificates of the University of Cambridge.

Crowther, John W. .....West Bromwich.
Essery, William George .....Plymouth.
Jervis, John Edward .....Carmarthen.
Willson, Alfred.....Eastbourne.

Certificates of the University of Oxford.

Lord, William Henry .....Kennington.
Wootton, Henry .....Richmond.

Certificate of the University of Edinburgh.

Stewart, Charles .....Edinburgh.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The first meeting of the session was held in the Manager's Library, Anderson's College, 204, George Street, on Wednesday evening, the 16th inst., the President, Mr. A. Kinninmont, F.C.S., in the chair.

The minutes of the last meeting having been read and approved, the President delivered his inaugural address, which he devoted chiefly to considering the present, scanning the future, and viewing the past, with reference to the pharmacist. He dwelt on the advantages offered to youths for study and the legalized standing offered, and on certain disadvantages that existed now, which did not present themselves in the past, such as the dealing in proprietary articles and druggists' sundries by co-operative stores and others, who sold at ruinously low prices. This, however, he cautioned the trade against saying much about, even though it might be hard to see this department going away, as in this country the principles of free trade, at least, must be observed. He, however, advocated the appointment of a commission of duly qualified examiners to whom all proprietary articles should be submitted and by whom they should be approved before being launched forth to the public. The lecturer next dwelt on public analysts, who he thought had proved to be foes instead of friends as had been expected before the passing of the Act; they seemed to fight more for names than purity. A number of cases were instanced, one being the citrate of magnesia case. He held that when the customer asked for such and got the effervescing saline, commonly called citrate of magnesia and known to the public by such name, he got what he wanted and that to have supplied the true citrate of magnesium would have been to have given what was not wanted. The violet powder case was also fully dealt with, and the prosecutions described as a play upon words and not as to purity or to fitness for the purpose for which the article was required. Prescribing was next dwelt upon and the idea of fixing (by law or otherwise) a line and saying thus far you may prescribe but no further, was described as impracticable, the lecturer, however, held that there must always remain an unwritten law on this subject, which will be very much as at present. The question of medical men keeping open drug shops was also very fully discussed and the conclusions arrived at were, that chemists should be cautious how they approach this subject, else they may find that precipitate action may rebound on themselves.

A discussion on various points followed the lecture, after which, and various notices and arrangements intimated, the meeting was brought to a close.

Proceedings of Scientific Societies.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Animal Intelligence.*

BY GEORGE J. ROMANES, M.A., F.L.S.

Animal intelligence is a subject which has always been of considerable interest to philosophical minds; but, as most of you are probably aware, the interest attaching to this subject has of late years been greatly increased by the significance which it has acquired in relation to the theory of descent. The study of animal intelligence being thus, without question, fraught with high importance to the science of our time, in adducing before this illustrious assembly some of the results which that study has yielded, I shall endeavour to treat them in a manner purely scientific. I shall try, as much as possible, to avoid mere anecdote, except in so far as it is desirable that I should put you in possession of a few typical facts to illustrate the various principles which I shall have occasion to expound. I shall seek to render apparent the more important of the issues which the subject, as a whole, involves, as well as the considerations by which alone these issues can be legitimately settled. I shall attempt to state my own views with the utmost candour; and if I shall appear to ignore any arguments opposed to the conclusions at which I shall arrive, it will only be because I believe those arguments to admit of easy refutation. And, in order that my exposition may be sufficiently comprehensive, I shall endeavour to point out the relations that subsist between the intelligence of animals and the intelligence of man. The aim and scope of the present lecture will therefore be to discuss, as fully as time permits, the facts and the principles of comparative psychology.

As human intelligence is the only order of intelligence with which we are directly acquainted, and as it is, moreover, the highest order of intelligence known to science, we may most conveniently adopt it as our standard of comparison. I shall, therefore, begin by very briefly detailing those principles of human psychology which we shall afterwards find to be of the most essential importance in their bearings on the subject which I have undertaken to discuss.

When I allow my eyes to travel over this vast assembly, my mind receives, through their instrumentality, a countless number of impressions. So far as these impressions enter into the general stream of my consciousness, they constitute what are called perceptions. Suppose, now, that I were to close my eyes, and to fix my attention on the memory of some particular perception which I had just experienced, say the memory of some particular face. This mental image of a previous perception would be what is called an idea. Lastly, suppose that I were to analyse a number of the faces which I had perceived. I should find that, although no two of them are exactly alike, they all bear a certain general resemblance to one another. Thus from the multitude of faces which I now perceive it becomes possible for my mind to abstract from them all the essential qualities of a face as a face; and such a mental abstraction of qualities would then constitute what I might call my abstract idea of a face in general, as distinguished from my concrete idea, or memory, of any face in particular.

Thus, then, we have three stages:—first, that of immediate perception; second, that of ideal representation of particular objects; and third, that of a generalized conception, or abstract idea, of a number of qualities which a whole class of objects agree in possessing. It will be convenient to split the latter division into two subdivisions, viz., abstract ideas which are sufficiently simple to be developed without the aid of language, and abstract ideas which are so complex as not to admit of development without the aid of language. As an instance of the former class of abstract ideas we may take the idea of food. This is aroused in our minds by the feeling of hunger; and while the idea when thus aroused is clearly quite independent of language, it is no less clearly what is called an abstract idea. For it is by no means necessary that the idea of food which is present to the mind should be the idea of some special kind of food; on the contrary, the idea is usually that of food in general, and this idea it is which usually prompts us to seek for any kind of food in particular. Simple abstract ideas, therefore, may be formed without the assistance of language; and for this reason they are comprised within what Lewes has called the logic of feelings. But abstract ideas of a more elaborated type can only be formed by the help of words, and are therefore comprised within what Lewes has called the logic of signs. The manner in which language thus

* Lecture delivered before the British Association at Dublin, August 16, 1878.

operates in the formation of highly abstract ideas is easily explained. Because we see that a great many objects present a certain quality in common, such as redness, we find it convenient to give this quality a name; and having done this we speak of redness in the abstract, or as standing apart from any particular object. Our word "redness" then serves as a sign or symbol of a quality as apart from any particular object of which it may happen to be a quality; and having made this symbolical abstraction in the case of a simple quality, such as redness, we can afterwards compound it with other symbolical abstractions, and so on till we arrive at verbal symbols, of more and more complex qualities, as well as qualities further and further removed from immediate perception. By the help of these symbols, therefore, we climb into higher and higher regions of abstraction; by thinking in verbal signs, we think, as it were, with the semblance of thoughts, and by combining these signs in various ways, and giving the resulting compounds distinctive names, we are able to condense into single words, or signs, an enormous amount of meaning. So that, just as in mathematics the symbols which are employed contain, in an easily manipulated form, the whole meaning of a long calculation, so in all other kinds of reasoning the symbols which we call words contain, in an abbreviated form, vast bodies of signification. Indeed any one who investigates this subject cannot fail to become convinced that it is wholly impossible to over estimate the value of language as thus the handmaid of thought; for, as we have seen, in the absence of language it would be impossible for thought to rise above the very simplest of abstract ideas, while in the presence of language it becomes possible for us consciously to predicate qualities, and so at last to feel that we are conscious of our own consciousness.

So much, then, for our classification of ideas. We have, first, simple ideas, or ideas of particular perceptions; and, secondly, abstract ideas, or ideas of general qualities; and the latter class I have sub-divided into those which may be developed by simple feelings, and those which can only be developed by the aid of signs.

Now, with regard to ideas themselves, I need only add that they are the psychological units which compose the whole structure intellectual. They constitute, as it were, the raw material of thought, which may be elaborated by the reflective faculty into various products of thought. Once formed they present an essential property of occurring in concatenated series; so that the occurrence of one idea determines that of another with which it has been previously joined. This principle of the association of ideas, manifested as it is by the ultimate units of intellectual structure, is by far the most important principle in psychology: it is the principle which renders possible all the faculties of mind, memory, instinct, judgment, reason, emotion, conscience, and volition.

We are now in a position to investigate the facts of comparative psychology; and, in order to do so thoroughly, I shall begin by considering what I may term the physiological basis of mind. There is no reasonable doubt that all mental processes are accompanied by nervous processes; or, to adopt the convenient terms of Professor Huxley, that psychosis is invariably associated with neurosis. The nature of this association, according to the best lights of our present knowledge, is probably as follows. Nerve-tissue consists of two elementary parts, viz., nerve-cells and nerve-fibres. The nerve-cells are usually collected into aggregates, which are called nerve-centres, and to these nerve-centres bundles of nerve-fibres come and go. The incoming nerve-fibres serve to conduct stimuli or impressions to the cells in the nerve-centre; and when the cells thus receive a stimulus or impression, they liberate a discharge of nervous energy, which then courses down the outgoing nerve-fibres to be distributed either to other nerve-centres or else to muscles. It is in this way that nerve-centres are able to act in harmony with one another, and so to co-ordinate the action of the muscles over which they preside. This fundamental principle of neurosis is what physiologists call the principle of reflex action; and you will perceive that all it requires for its manifestation is an incoming nerve, a nerve-centre, and an outgoing nerve, which together constitute what has been called a nervous arc. Now there can be no reasonable doubt that in the complex structure of the brain one nervous arc is connected with another nervous arc, and this with another almost *ad infinitum*; and there can be equally little doubt that processes of thought are accompanied by nervous discharges taking place now in this arc and now in that one, according as the nerve-centre in each arc is excited to discharge its influence by receiving a discharge from some of the other nerve-arcs with which it is connected. Again, it is almost certain that the more frequently a nervous discharge takes place through a given group of nervous arcs, the more easy will it be for subsequent discharges to take place along the same routes, these routes having been thus rendered more permeable to the passage of subsequent discharges. So that in this physiological principle of reflex action we no doubt have the objective side of the psychological principle of the association of ideas. For it may be granted that a series of discharges taking place through the same group of nervous arcs will always be attended with the occurrence of the same series of ideas; and it may be further granted that the previous passage of a series of discharges through any group of nervous arcs, by making the route more permeable, will have the effect of making subsequent discharges pursue the same course when started from the same origin. And if these two propositions be granted, it follows that the tendency of ideas to *recur* in the same order as that in which they have previously *occurred*, is merely a psychological expression of the physiological fact that lines of reflex discharge become more and more permeable by use. We thus see that the most fundamental of psychological principles, the association of ideas, is merely an obverse expression of the most fundamental neurological principles, reflex action. But here we have an important qualification to take into account. All reflex action, or neurosis, is not attended with ideation, or psychosis. In our own organization, for instance, it is only cerebral reflexes which are so attended; and even among cerebral reflexes there is good reason to believe that the greater number of them are not accompanied by conscious ideation; for analysis shows that it is only those cerebral discharges which have taken place comparatively seldom, and the passage of which is therefore comparatively slow, that are accompanied by any ideas, or changes of consciousness. The more habitual any action becomes, the less conscious do we require to be of its performance; it is, as we say, performed automatically, or without thought. Now it is of great importance thus to observe that consciousness only emerges when cerebral reflexes are flowing along comparatively unaccustomed channels, and therefore that cerebral discharges which at first were accompanied by definite ideas may, by frequent repetition, cease to be accompanied by any ideas. It is of importance to observe this fact, because it serves to explain the origin of a number of animal instincts. These instincts must originally have been of an intelligent nature; but the actions which they prompted, having through successive generations been frequently repeated, became at last organized into a purely mechanical reflex, and therefore now appear as actions which we call purely automatic, or blindly instinctive. Thus, for instance, the scraping of gramnivorous birds in earth and stones was no doubt originally an intelligent action, performed with the conscious purpose of uncovering seeds; but by frequent repetition through successive generations the action has now become blindly instinctive. This is shown by the following experiment. Dr. Allen Thomson tells me that he hatched out some chickens on a carpet, where he kept them for several days. They showed no inclination to scrape, because the stimulus supplied by the carpet to the soles of their feet was of too novel a character to call into action the

hereditary instinct; but when Dr. Thomson sprinkled a little gravel on the carpet, and so supplied the appropriate or customary stimulus, the chickens immediately began their scraping movements. Yet, for aught that these chickens can have known to the contrary, there was as good a chance of finding seeds in the carpet as in the thin layer of gravel. And numberless other cases might be given to prove that animals acquire instincts by frequently repeating intelligent actions, just as we ourselves acquire, even in our individual lifetime, an instinct to wind our watches, an instinct which may become so pronounced as to assert itself even when a man is in the profound unconsciousness of apoplectic coma.

Thus we are able to explain all the more complicated among animal instincts as cases of "lapsed intelligence." But, on the other hand, a great many of the more simple instincts were probably evolved in a more simple way. That is to say, they have probably never been of an intelligent character, but have begun as merely accidental adjustments of the organism to its surroundings, and have then been laid hold upon by natural selection and developed into automatic reflexes. Take, for instance, the action of so-called "shamming dead," which is performed by certain insects and allied animals when in the presence of danger. That this is not a case of intelligent action we may feel quite sure, not only because it would be absurd to suppose that insects could have any such highly abstract ideas as those of death and its conscious simulation, but also because Mr. Darwin tells me that he once made a number of observations on this subject, and in no case did he find that the attitude in which the animal shammed dead resembled that in which the animal really died. All, therefore, that "shamming dead" amounts to is an instinct to remain motionless, and therefore inconspicuous, in the presence of enemies; and it is easy to see that this instinct may have been developed by natural selection without ever having been of an intelligent nature, those individuals which were least inclined to run away from enemies being preserved rather than those which rendered themselves conspicuous by movement.

So that we thus see how animal instincts may arise in either of two different ways; for, on the one hand, they may arise from the performance of actions which were originally intelligent, but which by frequent repetition have become automatic; and, on the other hand, they may arise from survival of the fittest preserving actions which, although never intelligent, yet happen to have been of benefit to the animals which first chanced to perform them. But now let it be observed that although there is a great difference between these two kinds of instincts if regarded psychologically, there is no difference between them if regarded physiologically; for, regarded physiologically, both kinds of instincts are merely expressions of the fact that particular nerve-cells and fibres have been set apart to perform their reflexes automatically, that is, without being accompanied by intelligence.

So much, then, for what I have called the physiological basis of mind; and now in taking leave of this part of my subject, I should like to point out that in recognizing the indisputable fact of mind having such a basis, we are not necessarily committing ourselves to the doctrine of materialism. That psychical phenomena are very intimately associated with physical phenomena, is a fact which does not admit of one moment's dispute; but concerning the nature of this association science must declare, not merely that it is at present unknown, but that, so far as she is at present able to discern, it must for ever remain unknowable. The restless tide of intellect for centuries has onwards rolled, submerging in its every arm those strong and rugged shores whose name is Why; but at the line where mind and matter meet there rises, like a frowning cliff, a mighty mystery, and in the darkness of the place we hear the voice of true philosophy proclaim, "Hitherto shalt thou come, but no further, and here shall thy proud waves be stayed."

Parliamentary and Law Proceedings.

Poisoning by Disinfecting Fluid in a Military Hospital.

Last week an inquiry extending over two days was held by Mr. W. H. Bale, Deputy Coroner for Rochester, at Fort Pitt Hospital, Chatham, respecting the death of a private soldier. It seems that two men belonging to the Royal Engineers, stationed at the School of Military Engineering, being unwell, went to the casualty hospital at Brompton Barracks, where trivial cases are treated, instead of being sent to the hospital at Fort Pitt, and were served with what was supposed to be medicine. Shortly afterwards the men were taken worse, and upon inquiries being instituted it was found that instead of medicine disinfecting fluid had been given to them. The usual remedies were applied in one case, almost immediately, and the man recovered; the fact of the other man having been supplied with the same liquid appears to have been overlooked for a short time, so that antidotes were not applied so promptly, and after lingering some time he died. Medical evidence, based upon a *post-mortem* examination was to the effect that death resulted from exhaustion due to the action of a corrosive fluid upon the intestines. The cause of the accident is sufficiently disclosed in the evidence of the three following witnesses.

James FitzPatrick, Sergeant A.H.C., in charge of the casualty hospital at Upper Chatham Barracks, deposed that he was a qualified compounder of medicine, having passed an examination in February, 1870. He had been employed as a compounder of medicines at the Garrison surgery. He also made up the returns for the whole of the officers, women, and children in Chatham Garrison, with the exception of those in Fort Pitt. On October 11th, he was engaged in making up the returns, and also acting as dispenser; he had to complete the returns by two o'clock on that day. Between twelve and one o'clock, Private Charles Davis, A.H.C., brought three bottles from Dr. Hunt's inspection room to be replenished with alum gargle, cough mixture, and a mixture of salts and senna. It has been usual for Davis to leave the requisitions and the empty bottles, and call for them after he had had his dinner, when they were replenished. Davis told him that he wanted the medicine quickly, as he was in a hurry. Bowle [the next witness] said to witness, "There's only the alum gargle to be made up, if you tell me how much alum to put in the bottle I will do it." Witness would not allow him to do it; and he went to the alum drawer. On turning round, witness saw Bowle and C. Davis standing at one end of the counter, near the place where the stock bottles are kept. The counter was five or six yards long. He saw Bowle pouring out the cough mixture from one bottle into the other. The salts and senna mixture was kept in a jar under the counter, and the jar containing the disinfecting liquid was near the other jar. There was no label on the first jar when he saw it on the following day, Saturday. The jars were similar in shape and size, except that the necks were slightly different. The jar containing the fluid was kept under the counter, because it was thought to be perfectly safe there. It has always been the custom for the compounder to allow the surgeryman to pour out mixtures, but not in the absence of the compounder. The fluid was not kept under lock and key because it was not considered as a medicine, but was used for domestic purposes. There was a regulation for the keeping of poisons under lock and key; no medicine labelled "poison" was kept on a shelf in the surgery; but under lock and key. He did not allow any one to dispense medicines. He could not account for how the bottle was filled from the wrong jar. On the 12th instant, C. Davis brought back a bottle, and witness heard him ask whether that contained the mixture of salts and senna. Davis was very agitated, and in a fainting condition. As soon as witness looked at it he could tell that it was not the proper

mixture, but disinfecting fluid. Bowle tasted it, and said Davis must have taken it out of the disinfecting jar. Davis said he had given F. Davis a dose, and by his (witness's) direction, F. Davis was brought to the surgery, and witness sent for Dr. Hunt, who treated the man, and he has recovered. While Dr. Hunt was attending to F. Davis, Private C. Davis reported that a man whom Dr. Hinkson had sent to Fort Pitt had taken a dose of the disinfecting fluid, meaning the deceased. Davis acknowledged that he filled the bottle. Davis was not authorized to pour the medicine or in any way to interfere. There were not a large number of stock bottles kept at the surgery.

Thomas Bowle, lance-corporal A.H.C., stationed at the casualty hospital at Chatham Barracks, said he was employed as an orderly under Surgeon-Major Hinkson and Sergeant FitzPatrick; he had been at the surgery two months. His work consisted of keeping the surgery clean and attending to any one in the absence of the serjeant; that is, to instruct any one who might bring a patient to go for a doctor. It was not his duty to mix up medicines. He had been forbidden to do anything of the sort, but he was allowed to pour from one bottle to another medicines already compounded or made up—medicines in common use. Cathartic medicine was kept in a large jar, kept under the counter since he had been there. He had poured medicine out of that jar into a bottle in the presence of the sergeant. He remembered being at the surgery when Dr. Hunt's requisition, produced, was brought. Charles Davis brought the bottles to be filled, and left them on the counter. One of the bottles was for cathartic medicine. Told the serjeant that there was only one bottle to be made up, as the expectorant and cathartic mixtures were already made up. The sergeant would not allow him to make up the alum gargle. Charles Davis was present. Whilst the serjeant was preparing the gargle, he exchanged the contents of a bottle of cough mixture into Dr. Hunt's bottle; the mixture had been made up by the serjeant. The bottle was properly labelled. He was not assisted by C. Davis. One bottle which came from Dr. Hunt was labelled "cathartic mixture"; he did not fill that. He gave no directions for Davis to fill it, but Davis asked him where the cathartic mixture was kept, and he said under the counter, where it was always kept; witness did not point out the jar. Davis did not say that he wanted to fill the bottle. He did not see the cathartic bottle with anything in it. Witness asked him if he had got all, and Davis replied, "All right." Witness had never seen Davis pour medicine from one bottle to another. He did not report the matter to the sergeant at the time. He knew that there was one jar under the counter, labelled "Poison," but he had never touched the contents of it. He identified the two jars and bottle produced. It would be more difficult for a man to get the jar containing the poison than the other jar, considering the positions of the jars. Davis must have passed him to get the disinfecting fluid. Without coming behind the counter no one could see the jars. On October 12th, Davis came into the surgery, and, holding up a bottle, said, "Is this cathartic mixture?" Witness tasted of the contents of the bottle, and told the sergeant that Davis must have taken the wrong medicine. Davis said that another man named F. Davis had taken a dose of the same stuff. He had nothing to do with giving the medicine to the deceased. The red label "poison" had been on the jar ever since he had been at the surgery. He passed an examination in 1876. Davis generally left the bag and the bottles and went to dinner; on the 11th of October Davis said he was in a hurry. He did not see the sergeant fill the bottle. There were other jars under the counter containing ointment and distilled water. He did not give Davis permission to fill the bottle.

Charles Davis, an orderly in the A.H.C., stationed at Chatham barracks at the time of the occurrence, said he was engaged at the medical inspection room as an orderly to Dr. Hunt. He had to keep the inspection room clean, to usher in the patients to the doctor, and give the doses of medicine ordered. He had passed the usual examination to qualify him, having been through a course of instruction at Aldershot. He had to go for the medicines required by Dr. Hunt, and make out the requisitions. The one produced was in his handwriting. Witness only gave out stock medicines, for which he took the requisitions. It was no part of his duty to fill the bottles. On the 11th of October he went to the surgery with three empty bottles, one being for cathartic mixture. He put the bottles on the counter, and told the sergeant that he would call for them after dinner. When he came back the bottles were not filled. Lance-Corporal Bowle had the bottles at the end of the counter; he saw him fill the expectorant bottle and put the water into the alum bottle, after the sergeant had put the alum in. Whilst that was being done and Bowle was filling the bottle with the expectorant mixture, he waited near the counter at the side of Bowle. The two bottles were placed on the edge of the counter, and Bowle told him to fill the cathartic bottle from the jar which, he said, was under the counter. Witness did not ask Bowle any question, because he had seen the cathartic mixture taken from a jar under the counter. Once or twice before he had poured mixture out of a jar, he was sure of that. He had been authorized by Bowle. Witness saw the two jars, and he thought that they contained the same kind of medicine; the jars were only two inches apart; the window was at the back of him; he was kneeling on one knee. He then poured some liquid out of one of the jars into Dr. Hunt's stock bottle—the one labelled "Cathartic mixture." He did not wipe the jar; he was quite sober; no one examined the jar. He took the bottles to the inspection room. He remembered Dr. Hunt prescribing for the deceased on Saturday, the 12th of October. His order was to give the deceased a draught of cathartic; and he gave what he thought two ounces out of the cathartic bottle, which he had filled. He could not tell that the fluid in the bottle produced was the same which he brought from the surgery; it looked like cathartic mixture. He gave the deceased the draught into his own hand, and saw him drink it. He gave another draught to a man named Davis, and it was from him that he found that there was something wrong; Davis said he had felt very bad since he had taken it. He tasted the contents of the bottle, and it burnt his mouth. He gave a mustard emetic, with plenty of warm water. He then took the bottle to the surgery, when he ascertained that it contained poison, and not cathartic mixture. Told the sergeant that he had given a dose of it to a man at the inspection room. He did not think of the deceased at the time.

After a long deliberation, the majority of the jury returned the following verdict—"That the deceased, James Bridge, came by his death by having received accidentally a dose of Burnett's disinfecting fluid in the place of cathartic mixture. We express our regret that the poisonous fluid should have been placed in close proximity to the other above-named mixture."

Suicide of a Chemist and Druggist by Prussic Acid.

An inquest was held in Southampton, on Thursday, the 17th inst., to inquire into the circumstances attending the death of Mr. George Dowman, chemist and druggist, of 160, High Street.

The first witness called was Sarah Moore, who said she was in the service of the deceased, as cook and housekeeper. She last saw deceased alive about half-past one o'clock on the previous afternoon, in the dining room, He had been very low and reserved of late. On Wednesday he got up from his dinner and went to business. About three o'clock in the afternoon she heard him go into the drawing room, and at ten minutes to five she

went to call him to tea, but found he was not there. She went to his bedroom, and found the door was fastened, on which she went down stairs and told Mrs. Dowman. Both returned, and knocked at the door, tried it, and called out, but could get no answer. They thought he was sleeping, and so said they would let him stay half an hour and call him again. After that they knocked repeatedly, but could get no answer, so Mrs. Dowman sent for Dr. Oliver, who came, and with the assistance of witness they broke the door open. They then found deceased kneeling down by the side of his bed with a bottle of prussic acid in his hand, and quite dead. The deceased was alone, and the door had been bolted on the inside. She had no apprehension at any time that he was likely to make away with himself, nor was she aware of any circumstance that might have been the cause of his doing so, except that he was in a low state, and she thought his mind was going fast. She had frequently seen him walking about the room, but on that day he was very quiet, and spent two hours upstairs reading his Bible.

William Henry Bodle, an assistant to deceased, said for a long time deceased had been in a very desponding state, and seemed to take very little interest in the business at times. He was not aware of any particular cause for his melancholy, except that it might have arisen from a pressure of work and want of change of air. Witness had no apprehension that deceased was likely to commit suicide. He had known him for twenty-three years, and knew that he was of a serious and religious turn of mind. He was in the shop when the door was forced, and Dr. Oliver called him and showed him a bottle of prussic acid, which he had not seen before. It must have been taken from the stores, because the bottles used in the shop for dispensing were still there. Four or five drachms must have been taken from the bottle, quite enough to cause almost instant death. It was quite an unusual thing for deceased not to take a great interest in his business until latterly. Previously he used to take entire charge. More especially was the change noticeable within the last few days.

Dr Oliver said he had known deceased about fifteen years. He had expressed a good deal of anxiety about business but did not say in what way. He seemed generally low, with loss of appetite, but it did not occur to witness that deceased's mind was affected in any way. He complained of sleeplessness, which was quite consistent with the mind being affected. Soon after 6 o'clock on Wednesday afternoon witness was sent for to see deceased, and he met Mrs. Dowman in the drawing-room. She expressed great anxiety about her husband, fearing he was ill, and witness went upstairs with the cook, knocked and hammered at the door, but could get no reply, and they then burst in the door, when they found deceased leaning over the edge of the bed, as if he had fallen forward. His knees were not actually touching the ground, and his face was buried in the bed. He was quite dead, and had a bottle of prussic acid (Scheele's strength) in his right hand, about half the contents of which were gone. Witness could detect from deceased's mouth that he had been taking prussic acid. A week ago witness saw deceased, and he seemed then very poorly.

The Foreman of the Jury.—Do you know that he was in the habit of taking narcotics for sleeplessness ?

Dr. Oliver replied that he was not aware.

The jury unanimously returned a verdict to the effect that the deceased died from the effects of taking prussic acid, and that he was of unsound mind at the time he took it.

Dispensing Memoranda.

[172]. I should dispense this as a six ounce mixture and label it "one tablespoonful for a dose." I should have sent an ℥iss. draught as W. S. did. C. E. P.

[172]. I should have no hesitation about either of these prescriptions; the former I should dispense in a six ounce bottle using twelve times the quantity of ingredients and directing one tablespoonful to be taken for a dose.

The latter is plainly directed to be made up with inf. sennæ co., to a one ounce draught, and I think W. S. should not have ventured to send 1½ ounce.

Πειθου εμου.

---

[172]. In answer to the first part of W. S.'s query, I should send a six ounce bottle with a "1-tablespoonful label." Some West-end chemists, however, send such prescriptions out in single doses. That would be twelve half-ounce vials.

H. K.

---

[172]. W. S. should have sent a six-ounce bottle of the preparation and labelled half an ounce for a dose.

In answer to the latter part of his question he was decidedly wrong in sending ℥iss draught as the prescription distinctly states inf. sennæ co. to a fluid ounce.

W. F. N.

---

[172]. Sulphate of magnesia is insoluble in alcohol. It is easily dissolved in its own weight of water at the temperature of 60° F., so that W. S. had plenty of scope for making the solution. In the cases adduced by him all that was necessary was to place the epsom salt in an evaporating basin, and apply heat until the salt was dissolved, and then add the tr. sennæ, or tr. jalap. and spt. chloroform.

Hy. Brown.

---

[173]. The mixture is altogether an incompatible one, and the only thing to do is to put the ingredients together and strain through tow.

Hy. Brown.

---

[174]. In answer to W. F. Crowther, I dispensed the draught he refers to very satisfactorily, and it still remains so after forty-eight hours' standing. The following was the method I adopted.

Rub the gum. pot. carb. and am. carb. with the oil in a mortar, afterwards add the aq. menth. pip. gradually, triturating briskly. The vin. ipec. and spt. æther. nit. being previously dropped into the bottle.

Minor.

---

[175]. In reply to W. F. Crowther, I have found that camphor can be made into pills easily by using castor oil as an excipient, about one minim in each pill.

Stamford. W. H. Newsam.

---

[175]. I consider ol. ricini. the best excipient to make 5 grains of camphor into a pill. Suet will do, but it augments the size of the pills more than castor oil.

C. E. P.

---

[175]. Pil. Camphoræ.—Castor oil is supposed to be the best excipient. The proportion being two drops to a grain pill. Minor.

---

[175]. W. F. C., after finely powdering his camphor with a little spt. v. r., will find a little ol. ricini make a good consistence. Honey is sometimes used, but the former answers the best and is generally used.

Frank O. Golding.

169, *Hemingford Road.*

---

[179]. In reply to "Sub Umbra Floresco," I have often dispensed mixtures containing pot. carb. (written as such) but have always been ordered to use the bicarbonate, the one being a synonym of the other. The doses are certainly very similar, also the medicinal properties, but the bicarbonate possesses less irritant properties.

Minor.

[179]. Were I a compounder I should use the potass. subcarb. in the instance given by "Sub Umbra Floresco." It is the same case, in a new dress, as the one on which I commented, and which was noticed in "The Month," about sodæ carb., subcarb. or bicarb. HY. BROWN.

---

[179]. I think the prescription should be dispensed as written, viz., potassæ carbon. C. E. P.

---

[180]. "Sub Umbra Floresco" asks in what sized pills the following should be dispensed:—

Atropiæ Sulph.	gr. ½.
Excipien.	q.s.

Ft. massa et divide in pilulas xl. quarum sumat unam mane nocteque.

I should say they are evidently meant to be small pills, I should therefore triturate the atropiæ sulph. well with 36 grains of sugar of milk, and make the pills up with honey and divide into 40 pills, which would make each pill weigh about 1 grain. C. E. P.

---

[180]. The size of such pills should be one grain, and it matters not what the excipient is. Add starch, or gum arabic, or any innocent substance in order to make up the mass. Such pills require great care in working the mass so as to have the atropia well divided.

HY. BROWN.

---

[181]. The following I should dispense thus:—

℞ Quinæ Sulph.	gr. xij.
Acid. Sulph. Dil.	♏xx.
Mag. Sulph.	℥vj.
Ferri Sulph.	gr. xij.
Tr. Zingib.	℥vj.
Aquæ	ad ℥xij.

M. Ft.

Dissolve the quinine in the acid. sulph. dil. mixed with a little water, and pour into the 12 oz. bottle. Dissolve the magnes. sulph. and ferri sulph. in some more water, and mix this with that in the bottle, nearly fill the bottle with water and add the tr. zingib. The cloudiness produced when the tr. zingib. is added is due to the separation of the resin contained in the tincture, which in this case cannot be avoided. C. E. P.

---

[182]. LIQUOR FERRI ET CHINO-QUINÆ CITRAS.—"Chinoquinine" is a "preparation representing the entire precipitated and bleached alkaloids, in the form of muriates of East Indian red bark and containing quinine, cinchonidine, and cinchonine."

Citrate of iron and chinoquinine is a "scale" preparation resembling in appearance and medicinal properties ferri et quinæ citras, B. P. It contains 25 per cent. of citrate of chinoquinine. Liquor ferri et chino-quinæ citras is a palatable solution of the above prepared for convenience in dispensing. It contains 10 grams of scales in each fluid drachm. These preparations were introduced and manufactured by Messrs. Wyleys and Company, of Coventry.

For further particulars I refer your correspondent to the advertisement pages of the present Journal.

FRED. J. BARRETT, F.C.S., *Coventry.*

Similar answers have been received from W. F. N., J. W. Axford, and H. E. Cullwick.

---

[184]. Will any dispenser who has experience of similar prescriptions say how the following should be prepared?

The first and third ingredients are unusual.

Should grains or grams be used? The caligraphy is evidently that of a foreigner, but he is unknown to the writer.

℞ Cerat. Saturnat.	30 gr.
Calomelas	5 gr.
Quinquina Pulv.	4.
Camphora	1.

F. s. a. Ointmn. Πειθου εμου.

---

[186]. ℞ Sodæ Biborat. . . . . ℥ss.
Aquæ . . . . . ad ℥viij.

Ft. lotio.

When dispensed as written this presents a deposit of undissolved borax. Would a dispenser be justified in adding a small quantity of glycerine to complete the solution? or should it be sent out with a "shake the bottle" label?

H. K.

---

[187]. In dispensing "ung. hydrarg. ℥j," is it customary to weigh an ounce or to fill a one ounce pot?

H. K.

Notes and Queries.

---

[521]. ARQUEBUSADE.

℞ Ol. Menth. Sativ.,		
Ol. Fœniculi Dulc.	āā	♏v.
Ess. Bergamot.		♏x.
Aquæ Rosæ		℥iv.
Sp. Vin. Rect.		℥xij.

M.

Of late years arquebusade seems to have gone out of fashion. The above is a very old form and I have always found it give satisfaction.

Sittingbourne. E. ROOK.

---

[524]. PIL. ALOES ET MYRRHÆ.—This mass keeps well when mixed with treacle and glycerine as recommended. Pil. coloc. co. can also be conveniently kept by the same means.

F. G.

---

[529]. EAU DE COLOGNE.—If "Tantalus" will get some freshly powdered animal charcoal, and shake up with his discoloured eau de cologne for a few days (shaking every day), and will then filter it through a double thickness of filtering paper, he will find the colour gone.

F. G.

---

[529]. EAU DE COLOGNE.—In answer to "Tantalus," I beg to suggest filtration through animal charcoal; to be repeated if necessary. The remedy for his next batch of eau de cologne is to omit oil of orange peel, oil of rose, orange flower water, and spirit of nitrous ether.

W. M.

---

[529]. I should recommend "Tantalus" to filter his eau de cologne through animal charcoal, by which means he will get rid of the objectionable yellow colour.

LAVANDULA.

---

[529]. EAU DE COLOGNE.—In reply to the query of "Tantalus," the only suggestion I could make in his case would be, as I presume he does a fashionable trade, to utilize it in making tincture of myrrh and borax with eau de cologne as prepared for the teeth and gums, as the colour that he complains of would not, in that case, be at all objectionable.

NIL DESPERANDUM.

---

[529]. EAU DE COLOGNE.—The coloration which takes place in the eau de cologne is due to the action of nitric acid eliminated from the nitrous ether on the oil of neroli and orange flower water.

In preparing it the nitrous ether ought not only to be made neutral to litmus paper by adding alkali, but excess must be added to neutralize any further acid that may be evolved.

DANIEL GORRIE.

[530]. ANILINE DYES.—I have found spirit varnish to be an excellent medium for painting showcards on glass and tinned iron. W. F. N.

[531]. OL. FLAV. CONC.—In answer to this query ol. flav. conc. is made by saturating olive oil with gamboge. C. E. P.

[531]. OL. FLAVÆ CONC.—I have been informed that this is made by dissolving gum gamboge in almond or olive oil, but have never made it.

F. G.

[533]. TINCTURA CALENDULÆ.

℥iv to the pint of proof spirit.

Dose, 1 to 2 drachms (Squire).

W. F. N.

[533]. TINCTURA CALENDULÆ.—Calendula was once officinal in the Edinburgh Pharmacopœia. It is the common marigold, and a tincture may be prepared by macerating four or five ounces of the flowers (dried) in one pint of proof spirit. More than a hundred years ago it was used in jaundice, small-pox, uterine affections, and cardiac diseases. The dose of the tincture is from one to two or three fluid drachms. In larger quantities it is emetic.

Northallerton. Hy. Brown.

[533]. TINCT. CALENDULÆ. — Flor. calendulæ, 4 oz.; proof spirit *O*j. Macerate seven days, strain, press, and filter.

C. E. P.

[534]. COD LIVER OIL EMULSION.—Would any reader inform of a good recipe for cod liver oil emulsion, flavouring included? I get a fair emulsion with a mixture of equal parts of cod liver oil and mucilage of tragacanth (℥iiss to ℥xvi of water) by simply shaking them together, but I am at a loss for a proper flavouring agent.

H. H. C. Puntan.

[535]. EMULSIO TAMARINDI.—Having recently met with an "Emulsio Tamarind.," should be glad of a form for the same.

X. Y. Z.

[536]. CRUSHED LINSEED.—Will some one kindly state through the Journal what should be the character and appearance of crushed linseed? To pass over No. 1, farini lini, B. P., I have met with, in one pharmaceutical West-end establishment, No. 2, crushed linseed of light colour and somewhat oily, whilst in another, No. 3, crushed linseed, very dark colour and very oily.

Am I right in believing No. 2 the correct, whilst No. 3 is a mixture of rape seed, etc., with the linseed?

Inquirer.

Correspondence.

Weights and Measures Act, 1878.

Sir,—It appears to me that the new Act, which legalizes some, and some only, of the weights and measures used by our trade, will be a source of some inconvenience to us. For although by section 20, clause 2, "drugs, when sold by retail, may be sold by apothecaries' weight," still the only weights (troy or apothecary) acknowledged by the Act are the ounce and the grain (section 14). And the troy ounce is not included in the Board of Trade standard in schedule 2. Thus the troy weights, one drachm and one scruple, which the retail druggist is continually required to sell by, do not appear to be rendered legal.

The only dram weight given in the Act is the avoirdupois of one-sixteenth of an ounce =27·3 grs.

As to the glass measures used by druggists, the stamping of which will be quite a new feature, and which I am told may be done by means of a metallic band placed round them, the largest size of measures used in the sale of drugs as provided by the Act is a 4-ounce. As no provision seems to have been made for the 10-ounce and 20-ounce graduated measures used by druggists, it appears to me that it will be illegal to keep them for use for purposes of trade. Doubtless you or some of your correspondents can suggest a happy issue out of these difficulties.

New Brentford, W., October 10, 1878. Alex. Wood.

Quinine Wine Again.

Sir,—By drawing attention to the above matter in your leader of the 19th inst, you certainly show your interest in trade as well as scientific matters.

The Inland Revenue regulations as to sale of quinine wine is a matter in which all your readers are interested and ought to sympathize with same, so far as the question of percentage of quinine is concerned, for it is well known that certain makers of the wine containing but a small quantity of quinine have hitherto enjoyed a large sale for the same, under the alleged protection of a patent medicine stamp; to sell such is, however, illegal unless the seller holds a sweet wine licence, and it is well it should be so, for the sake of the public, who are now more likely to be supplied with a genuine article at fair value.

But there is an important point raised by your concluding paragraph, with reference to the wine of standard strength. Suppose a party prepares a quinine wine strictly in accordance with the British Pharmacopœia, puts it up in bottles, and labels with directions, etc., adding "Prepared by So-and-so and at So-and-so," and retails this at so much per bottle, or wholesales same for the purpose of being retailed by others, and which can be sold without a licence. Does the law require this to have a patent medicine stamp affixed? This is rather an important matter affecting not quinine wine only, but various articles not being stamped at present; it scarcely seems fair that articles prepared strictly according to the B. P. and about which there is no secret should be so taxed. If such be the law or Inland Revenue regulation, I should like to know what should and what should not be stamped. We have a B.P. fluid magnesia, for instance, and fluid magnesia prepared and put up by various makers without the stamp. This and a host of other articles seem to me as much entitled to have the stamp as does quinine wine, and if we go on in this way we may, by-and-by, have to stamp our cod liver oil and castor oil, when specially bottled and labelled.

Glasgow, October 23, 1878. J. W.

[*** Such a preparation would not, in our opinion, require a patent medicine stamp, unless it were recommended for the relief of disease, or implied that there was something special or occult in its manufacture.—Ed. Ph. Journ.]

"Dr. Redwood and Violet Powder: Unusual Doses."

Sir,—When the spirit moved Mr. James Swenden of Darlington to pen his letter, a little more courtesy towards you and me might have been infused into it, to say the least. I think, sir, you are, or ought to be, as good a judge as Mr. Swenden is as to what you should permit to be printed in your columns; and I hope you will allow me to say that nothing was further from my intention than to offer an insult to Dr. Redwood personally, and so far as regards the genius of Dr. Redwood, I should not think of balancing my opinion in regard to it against Mr. Swenden's lest his should be found wanting even in a small degree. In charity I say so. I therefore tell Mr. Swenden he has no right to say such letters as mine are "wholly unjustifiable." You sir, are the judge, and I hope you will allow me to express my opinion, which is, that no journal with which I am acquainted is conducted so well, and is so thoroughly free from personal elements as the "Pharmaceutical." Surely then I may be permitted to denounce sophisticated violet

powder without offending Mr. Swenden; and I think I know, without being offensive, as much about the subject as any of your correspondents. Thus I leave the matter, and, as Dr. Redwood does not demand an apology, not having felt himself hurt, I am unwilling to tender one to Mr. Swenden who, I hope, is not over-offended at my denunciation of every trade dodge and sophistication. I again desire to say that starch, perhaps I may be permitted to add any kind of starch, should alone be considered as the basis of violet powder. The French violet powders sent out by Amand Fils, and in London by Cleaver, Piesse and Lubin, Gosnell, and other first class houses, are starch. I have examined them very carefully. And Dr. Redwood, in his 'Supplement' published in 1857, gives the following:—"Pulvis pro crine.—Hair powder.—Nursery powder.—Plain hair powder is merely starch, powdered and sifted through a fine sieve. Violet hair powder generally contains a little orris powder, and it may also be scented with essence of violets. Essential oils, musk, etc., are occasionally added to vary the character of the powder, according to fancy." I find no mention of selenite, and I am therefore driven to the conclusion that after the practice of powdering hair was abolished, violet hair powder was still made, and should only be made, from starch with a little orris root or perfume added to it, and this should alone be called "nursery powder." It was sold as such when asked for in days gone by, and used in the nursery for dusting children. I answer the question put by Mr. Swenden, or rather suggested by him, "What should violet powder be?" thus: Starch, usually wheat starch, with or without powdered orris root, or perfume; and all other substances, such as selenite, should be discarded and looked upon as adulterations. In regard to the statement of Mr. Siebold that violet powder was originally the powdered violet root, but that it was found unsuitable, and discarded, I do not wonder at that in the least. But where did Mr. Siebold gain his information? I may say Boullay many years ago found the roots of the various species of *Viola* to abound in a principle analogous to emetia of ipecacuan. I think after such a statement neither Mr. Swenden nor Mr. Siebold would like to use such powder for dusting children nor wonder at its rejection. It is not agreeable to contradict. I am glad so many medical men are readers of your Journal, and I trust in future that such expressions as this, written by Mr. Swenden, I hope inoffensively, will not be used. "I suspect that the sore place upon Mr. Brown, and there seems to be a tendency to soreness in his family, is caused by Dr. Redwood considering an old woman as good authority upon the merits of violet powder as members of the medical profession."

I am sure Dr. Redwood thinks no such thing: but, whatever Mr. Swenden may think is no reason for uttering such an absurd statement by way of a joke, and fathering it upon Dr. Redwood, who is universally admired by the medical profession. Before concluding allow me to say in reply to "W. M's" query under letter, headed "Unusual doses," that I consider chemists are to be commended for acting with caution when unusual doses are ordered by medical men. But, as I pointed out, the dose of cantharides was not excessive, and the prescription should have been dispensed.

Northallerton, October 19, 1878. HENRY BROWN.

UNUSUAL DOSES.

Sir,—I do not wish to enter upon the general question of "Dangerous Doses and Difficult Problems," which is in very good hands, and in a fair way, I hope, of being settled definitely, but should like to testify my approval of the practice of Dr. E. Berdoe and Dr. T. S. Dowse with reference to prescriptions containing unusual doses.

If the very sensible plan of marking in some generally recognized way an intentional departure from the doses of the British Pharmacopœia were universally adopted by prescribers it would be better for the patient, and the conscientious pharmacist would be relieved of much anxiety. How often I wonder does the patient get the "unusual dose" when ordered, and no further indication given of the intention of the prescriber? I fear that in not a few cases so occurring the safe thing is done, and the prescription passed on to the next dispenser for rectification, if necessary. I have had prescriptions ordering doses absolutely poisonous that have come to me bearing the usual *imprimatur* of the prescriber, and which had been dispensed before by a chemist, who nevertheless had not thought proper to note in what way, or to what degree he had departed from the *litera scripta*.

Obviously then it will be greatly to the interest of both patient and doctor when some plan shall have been arranged for giving extra indications to the dispenser in cases open to doubt.

Dr. Berdoe says that the posology of the Pharmacopœia is nothing to him. True enough it is not, but it was of use, how else could be obtained authoritative guidance when employing for the first time a new introduction to the Pharmacopœia? The posology of the Pharmacopœia has in view an average patient, and draws no hard and fast line for the prescriber; but for the dispenser it does. The former, acquainted with the constitution of his patients and its idiosyncrasies, orders what he knows to be fitting for the case; the latter has usually no such knowledge, therefore to him the dicta of the compilers of the Pharmacopœia must be law, and he dare not, without risk to the patient, and incurring responsibility for himself, lightly overstep the limits of dose there authoritatively laid down.

It is, of course, well-known that in certain continental countries the mode, as well as the practice, of indicating an unusual dose is prescribed by law, and to this must we come if the practice is to be both general and uniform, as it ought to be.

It will not do any longer to trust solely to good sense on the part of the prescriber. We know how often the cleverest men allow their judgment to be warped by mere hatred of innovation, whilst others would revolt at the idea of their freedom being limited by the introduction of a foreign practice unknown to the traditions of the British medical corporations.

Weymouth. THOS. B. GROVES.

POISONING BY MOULDY BREAD.

Sir,—The report of the case of poisoning by bread pudding at Barnsley, which appears in your columns of to-day, is necessarily incomplete, being apparently reprinted from a daily paper, and as the case presents several points of interest and is not unlikely to be referred to in the future, your readers may be interested in the following history of it.

At a cheap eating-house in Barnsley, kept by a Mr. Thresh, the cook made a bread pudding from the scraps of bread left from making toast and sandwiches. These scraps had been accumulating for some weeks, and when I visited the place similar scraps were shown me which were in a very mouldy condition and mixed with bits of ham, butter, etc.

The pudding was made of the above described scraps of bread, with the addition of milk, eggs, sugar, currants, and nutmeg; that was all. The pudding was divided and the two portions (called in the evidence Nos. 1 and 2) baked in separate ovens. No. 1 pudding was placed in a notoriously slow oven, and was subsequently eaten by the cook who made it, the proprietor of the eating-house, the waiter, and a customer. The remainder of No. 1 pudding was sent to Thresh's private house and was partaken of by four of his children. Every one of the eight persons who ate of that pudding was violently ill with symptoms of irritant poisoning. Only one person ate of No. 2 pudding, and she did not take much, and was not affected.

Thresh's youngest child (aged 3), and Mason, the waiter, ultimately died, the latter lingering a week. The child had very recently suffered from diarrhœa. Mason was given to drinking, and was frequently purged ten or twelve times in an afternoon! Hence his symptoms caused no astonishment at first. He did not commence vomiting till the second day. None of the eight persons suffered from bloody purgings.

The *post-mortem* examinations causing the medical men to suspect the presence of an irritant poison, the viscera were sent to me, together with the remains of both puddings and the materials used in making them, and sundry vomits and motions.

I made a most exhaustive examination for poison, looking, in accordance with a previous suggestion of the jury, for unlikely as well as likely things. Special search was made, in addition to the usual metallic poisons, for barium, chromium, oxalates, cantharides, hellebore, digitalis, and in fact all poisons which admitted of detection. As there was still left a considerable quantity of the pudding which had produced the poisonous effects, the search was made under

very advantageous conditions, and any of the recognized poisons would certainly have been detected if present. The result of the examination was wholly negative.

I also fed a puppy, six weeks old, on No. 1 pudding for two whole days without producing purging or any visible poisonous effect. A similar experiment, with like negative result, was made by feeding a mouse on oatmeal mixed with the alcoholic extract of the pudding.

From a suggestion made to me in a letter by Dr. Tidy, I was led to look for ergot in the pudding, and was startled to find that both the pudding and the alcoholic extract (but especially the former) gave an unmistakeable odour of herrings on treatment with soda, and that the alkaline mixture gradually became, even in the cold, of a brilliant lake-red colour (the colour is very permanent, being still very striking, though produced nearly three weeks ago). The tint was redder than that obtained when actual ergotized pudding was tested in the same way for comparison. A bread pudding made from pure materials failed to give either of the above reactions, nor did portions of the poisonous pudding which were visibly mouldy respond to either of the above tests.

I have since succeeded in growing the substance giving the reactions of ergot, by soaking a slice of bread in sugar and milk and spreading some of the poisonous pudding on one end of it. In forty-eight hours the lake-red reaction with soda was obtainable from an interior portion of bread several inches distant from the pudding, and in a longer time all parts of the slice became impregnated. A portion of the slice far removed from the pudding produced violent symptoms of poisoning (but not death) on a mouse which was fed with it for a day.

No. 2 pudding gave the ergotoid reactions with soda, but far less markedly than No. 1.

Under the microscope various structures were observed in No. 1 pudding which might be poisonous fungi, but I was unable to detect any ergot, nor had the pudding any violet tinge. Nor was I able to detect ergot in the flour said to be used for making the bread supplied to Thresh's eating-house, and the rye meal of the same baker contained only a doubtful trace of ergot.

From the fact that ergot itself was not recognizable in the flour or pudding, but that the latter contained a substance giving the chemical reactions of ergot, and capable of propagation, it seems to me clear that the reactions hitherto supposed to be peculiar to ergot, are common to other fungi. It seems possible that the dangerous moulds may contain a common poisonous principle, or one which is poisonous in a certain stage of its growth. This supposition, if correct, would account for the pudding still yielding reactions similar to those produced by ergot, and yet having lost its poisonous powers till reproduced on the slice of bread.

The medical evidence was to the effect that the symptoms were like those produced by ergot except that the bladder was found empty instead of full and that the pulse was greatly quickened instead of being reduced.

The substance (poisonous fungus?) giving the red coloration with soda appeared to exist throughout the mass of the pudding. The somewhat open verdict of the jury was due to the foreman not being able to conceive that a poisonous "mould" would not have been observed by the cook who made the pudding, and she stated that she had not observed anything the matter with the bread. Otherwise, every one connected with the case who was capable of forming an opinion of any value was fully convinced that the true explanation of the disaster lay in the condition of the bread.

I may add that the poisonous pudding had no sign of crust on it, but was "sloppy" and of the consistency of bread and milk. The lumps of bread in it were distinguishable and the starch granules were in many cases unaltered, a clear proof that it was very imperfectly cooked.

There was no suspicion of malice on the part of any one, and even Thresh himself suspects no trick, but attributes the effects simply to sour food.

I may say that I found recorded cases of exactly similar symptoms (and death) being produced by eating mouldy bread, and that various toxicologists whom I consulted expressed opinions fully bearing out this view.

I am not in the habit of commenting on reports of cases in which I am concerned, however incomplete or inaccurate they may be, but make an exception in this case, as the *Yorkshire Post*, whose report you reprint, contains a very imperfect account of the evidence, and that only of the adjourned inquest, without the previous history of the case.

Sheffield, October 19. ALFRED H. ALLEN,
Lecturer on Chemistry at the Sheffield School of Medicine.

POISONOUS DYES.

Sir,—I have had a case brought to my notice of irritation and eruption on the back of the hand and suspect it is similar to the one mentioned by Mr. Ekin in the *Times* last week. Is there a good work on the subject, or can Mr. Ekin indicate those dyes that are likely to be injurious and those which may be considered safe? It appears to be a matter of some importance, and no doubt the experience of analysts whose attention has been directed to it will be welcomed by others as well as myself.

London. W. M.

"*Civitas.*"—(1) There is no difficulty in preparing the excipient. See vol. vii., p. 348, and numerous other references in this Journal. (2) The candidate is expected to be able "to give the proportions of the active ingredients." (3) The book is published by Hardwick, Piccadilly. It is good as far as it goes, but cannot replace the practical botanizing that will best assist you to "recognize the more important indigenous plants used in medicine." Apply to the Secretary for the Regulations of the Board of Examiners.

"*An Aspiring Apprentice.*"—Any microscope maker would give you a copy of his price list on application.

J. W. Barnes.—The subject has been discussed in the "Dispensing Memoranda" columns. See vol. viii., pp. 359 and 407, No. 35.

J. T. Greenwood.—The use of the large label, recommending the wine as a remedy in disease, would in our opinion necessitate the use of a stamp; that of the smaller label would not. But it would be as well to submit the question to the Inland Revenue authorities at Somerset House.

S.—See some remarks on the strength of the tincture in the *Pharmaceutical Journal* for Jan. 15, 1876, p. 562.

L. S.—We are not acquainted with any authoritative rendering of the motto.

B. Newham.—The use of the name "Cough Lozenges" without a stamp is still, we believe, permitted by the Excise authorities, but your extension of the name is probably considered to overstep the limits laid down. You are recommended to send the inquiry to Somerset House.

G. B.—The exemption does not cover the recommendation of the wine as a tonic.

A. O.—Apply to the Secretary for a copy of the pamphlet entitled "Hints to Apprentices and Students."

W. Rogers.—The address of the Secretary of the Social Science Congress is Mr. F. G. P. Neison, 1, Adam Street, Adelphi, W.C., the office of the British Association is in Albemarle Street.

J. S.—The Sale of Food and Drugs Act contains no provision for the registration of the sale of poisons, neither does the Pharmacy Act, 1868, provide for such a case as that instanced by you.

W. A. Holmes.—We are afraid you do not read your Journal. You will find the information you ask for in the number for Sept. 21, p. 224.

"*Swag.*"—Probably the phenomenon was due to a fungus, some fungi being known to emit a kind of phosphorescent light.

A. P. S.—Blaine's 'Outlines of the Veterinary Art,' published by Longmans.

"*Novice.*"—See an article on the subject in vol. vii. of the present series of this Journal, p. 42.

W. J. Pinchin.—Thanks for your note, but see before, p. 73.

R. E. Williams.—*Polygonum aviculare.*

W. J. Williams.—(1) *Helianthemum vulgare;* (2) *Dactylis glomerata;* (3) *Thrincia hirta;* (4) *Heracleum Sphondylium;* (5) *Sonchus asper;* (6) *Chærophyllum temulum.*

R. Roberts.—Nos. 1 and 3 are correct. (2) *Spiræa ulmaria;* (4) and (5) Send better specimens, with stem, leaves and ripe fruit.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mee, Shields, Ellis, Ekin, Robinson, Rogers, Clarke, Symons, Smart, Pinchen, Parry, Sub Umbra Floresco, Minor, J. S., A. W. C.

THE PARIS EXHIBITION.

(*Continued from page* 307.)

Chemical Manufactures.—Manufactured Products.

Acids.

Sulphuric Acid. Notwithstanding the largely increased exportation of sulphur from Italy, as mentioned in a previous section, comparatively but very little of it is employed in the manufacture of sulphuric acid. Probably with the exception of specimens exhibited by Messrs. Cazalis and Leenhardt, of Montpellier, which are specially described as being manufactured from Sicilian sulphur, it would not be far wrong to assume that all the specimens of ordinary sulphuric acid exhibited have been prepared from pyrites. That firm, however, claims to prepare as much as 3000 tons of chamber acid (sp. gr. 1·635 to 1·650) yearly, at an average price of 7 francs per 100 kilograms. Under those circumstances it is not surprising that pyrites is being drawn from so many sources—chiefly, however, from Spain, Portugal and Norway—or that recent modifications in the roasting furnaces have taken the direction of utilizing the "smalls," or powder from the pyrites, formerly rejected. Nitrate of soda from South American *caliche* is also used as the source of the nitric acid required in the lead chambers. One of the most promising improvements that has been introduced into the sulphuric acid manufacture during recent years has been that of Dr. Sprengel, who substitutes for the steam formerly blown into the lead chambers a fine spray either of water or of the nitrous sulphuric acid obtained in the Gay-Lussac towers.

The progress of chemical industry in France, is roughly indicated by the official estimate that in 1866 the amount of sulphuric acid produced in that country was about 90,000 tons, and that in 1877 the amount had increased to about 150,000 tons. It is worthy of notice that the latter quantity is only a little in excess of the quantity (140,000 tons) estimated by Mr. R. Calvert Clapham to have been produced in 1867 in the Tyne district alone. A considerable development in the production of sulphuric acid is also reported from Belgium, where the province of Namur has become the centre of an active chemical industry. Fuming (Nordhausen) sulphuric acid was for a long time, as is well known, made principally in Bohemia and Saxony, but the demand for very concentrated sulphuric acid has during the last few years much increased, and attention has been directed towards methods of partially dehydrating the ordinary commercial acid. Winkler lets the acid trickle into retorts filled with porous materials and heated to redness, where the acid is decomposed into vapour of water, oxygen and sulphurous anhydride; the water is removed by passing the vapour through coke saturated with sulphuric acid and the sulphurous anhydride and oxygen are then made to form sulphuric anhydride. Messel and Squire use a white-hot platinum tube for the dissociation and fragments of platinized pumice to effect the recombination of the gases. Fuming sulphuric acid is also prepared now by distilling sodium bisulphate, but in all these operations a principal difficulty is that of obtaining apparatus that will resist the action of the acid.

Among the exhibitors of sulphuric acid are M. Blondel, of Marseilles (in whose case there is a photograph of M. Chaptal and of the works which were founded by Berthollet), a glass making company at Aniche, and several other French companies engaged in the manufacture of chemical products; M. Ketjen, of Amsterdam; the Livournaise Company (Italy); the Lysaker and Stavanger Companies (Norway), and Messrs. Tennant, of the St. Rollox Works, Glasgow.

In class 53 Messrs. Johnson, Mathey and Co., of London, exhibit a magnificent apparatus in platinum for the concentration of sulphuric acid. It is said to be capable of concentrating eight to ten tons of acid to sp. gr. 1·842 in twenty-four hours, and is valued at £1000. Faure and Kessler's concentration apparatus is exhibited by M. Chappuis, of Paris.

Liquefied sulphurous acid is exhibited by Messrs. Faure and Kessler, of Clermond-Ferrand, in whose case are also specimens of hydrofluoric acid together with fluor spar used in its preparation, and chloric acid and its salts.

Hydrochloric acid being now almost exclusively obtained as a by-product in the soda manufacture is generally exhibited with the specimens from alkali works. There is nothing, however, shown in connection with the subject that calls for remark, except, perhaps, a handsome model in terra cotta of an apparatus for condensing hydrochloric acid, consisting of a tower and a series of bonbonnes, shown by the Austrian Company for Chemical and Metallurgical Products, of Aussig, in Bohemia. In the same case, by the way, there is a two gallon jar full of thallium recovered from the dust deposited in the flues of the pyrites furnaces.

The manufacture of nitric acid has not undergone any very important modification during the past few years, and notwithstanding many attempts that have been made,—such as by the substitution of aluminum hydrate, calcium carbonate, or manganese chloride for sulphuric acid,—to obtain a more valuable by-product than sodium bisulphate, practically all the nitric acid is at present obtained by decomposing South American cubic nitre with sulphuric acid. Very little nitric acid is exhibited, but specimens may be found in the cases of Messrs. Readman, of Glasgow; Ketjen, of Amsterdam; Blondel, of Marseilles; and the Lysaker Chemical Manufacturing Company, of Christiania.

The organic acids exhibited call for little remark, beyond what has already been said. Tartaric acid and citric acid are exhibited by Messrs. Nascio and Co., of Messina; and Messrs. Mulaton and Co., of Lyons. The former acid is also exhibited by Messrs. Cazalis and Leenhardt, of Montpellier, who, according to a statement in their case, make 50,000 kilograms annually, at a price of three and a half francs per kilogram. The principal display of oxalic acid is that of Messrs. Jacobsen and Co., of Fredrikstad, Norway, in whose case are fifty or sixty bottles filled with it. Some good specimens of this acid are also displayed by Messrs. Chambers and Son, of London. Acetic acid as a product of the distillation of wood is exhibited by Messrs. Camus and Co., of Paris, and by the Société Anonyme de Produits Chimiques at Nogent-le-Rotrou. It is also shown in connection with the products of the distillation of sea-weed by Messrs. Glaizot of Abervrach, Finistère, and with those of the waste of the beet sugar manufacture, by M. Vincent, of Paris. The latter exhibitor also shows propionic, butyric, and valerianic acids and their salts. Pyrogallic acid is exhibited by M. Rousseau, of Paris, on behalf of the company for whom he is manager.

Alkalies and Salts.

The production of potassium salts has been so much circumscribed by the discovery of the potash beds at Stassfurt, Leopoldshalle and Kalusz, that the absence of German exhibitors has seriously affected the number of specimens shown. Nevertheless there is in the case of M. Vincent, of Paris, very interesting evidence of an improvement in the method of obtaining the potassium salts from the molasses left in the manufacture of cane sugar from beets, which contains the whole or the greater part of the potassium, sodium, and ammonium salts originally present in the beetroot. The molasses is first used as a raw material for the preparation of alcohol, after which the spent residue, or "*vinasse*," which has a specific gravity of about 1·027, is evaporated to sp. gr. 1·206, and then instead of being evaporated to dryness and calcined on the floor of a reverboratory furnace, as formerly, it is run into cast iron retorts and distilled, the operation lasting about four hours. In this way the other constituents of the waste are retained instead of escaping during the calcination, whilst there is left a porous carbonaceous residue containing all the salts, which is easily lixiviated. The tarry vapour passing over is conducted into condensers, where a portion is condensed, and the gaseous remainder is burnt to heat the apparatus. The condensed ammoniacal liquor is treated with sulphuric acid and concentrated to crystallization, when ammonium sulphate is obtained, sulphate of trimethylamine remaining in the mother liquor. During the concentration methylic alcohol, cyanide of methyl and other nitrile compounds are volatilized and collected, and these bodies when treated with lime yield methylic alcohol, ammonia and different acids that combine with the lime. As the salts of trimethylamine have at present no industrial application, M. Vincent, by further treatment converts them into ammonium salts. A small exhibit of pearlash occurs in the case of Messrs. Lyman, Clare and Co., of Montreal.

With respect to sodium salts perhaps the most important exhibit is that of Messrs. Solvay and Co., of Varangéville-Dombasle, in the department of Meurthe-et-Moselle, because it demonstrates that after upwards of a quarter of a century of more or less unsuccessful experiment the manufacture of soda by the ammonia process has become an established industry. Some particulars as to this process have already appeared in the present series of this Journal,* but the details of the working are not even now known with certainty. The process is based upon the fact that by the reaction that takes place between strong solutions of common salt and ammonium bicarbonate, sodium bicarbonate and ammonium chloride are formed. The ammonium chloride is decomposed by distilling it with lime, and by heating the sodium bicarbonate a moiety of the original quantity of carbonic acid is recovered for recombination with the ammonia set free. In this way the use of sulphuric acid is avoided and a very pure product is obtained without, as is claimed, the disadvantage of the noxious vapours inseparable from the Leblanc process. On the other hand instead of free hydrochloric acid a worthless residue of calcium chloride is produced, and since the reaction is not quite so complete as indicated by theory there has been a difficulty to overcome in the loss of ammonia, which for a long time was considerable. This loss it is said has now been reduced to a minimum, so as not to more than represent the sodium nitrate used in the manufacture of the sulphuric acid required by the older process. Mr. Weldon has proposed to substitute magnesia for lime in the decomposition of the ammonium chloride, and to decompose by heat the magnesium chloride so produced so as to recover the hydrochloric acid and obtain the magnesia ready for a fresh operation. This suggestion does not appear to have yet been practically applied with success, though until something is done in this direction the enormous demand for hydrochloric acid will probably render the Leblanc process a necessity. Nevertheless, the rivalry promises to be serious even under present conditions, as may be judged from the statement in the case above referred to that this one establishment already turns out annually 20,000 tons of sodium carbonate containing on an average not more than 1 per cent. of impurity, including water. The absence of sulphate from this product and especially its freedom from more than traces of iron render it extremely suitable for certain purposes. Messrs. Solvay and Co. further exhibit in the Belgian department the products from their establishment at Couillet, where 7500 tons of sodium carbonate are manufactured annually; they also show a model of the apparatus used in the distillation of ammoniacal liquor.

Some fine products of another modification of the ammonia process, patented by M. Boulevard, are exhibited by the Griffon Alkali Company, of Marseilles, who use the sodium chloride obtained from the Mediterranean salt marshes and the ammoniacal liquor from the Marseilles gas works. This establishment is said to manufacture about 3600 tons of soda salts annually by the ammonia process.

In the British Court Messrs. Golding, Davis and Co., of Widnes, exhibit salt cake made by Hargreaves' process, in which sulphurous oxide reacts in presence of atmospheric air and steam upon the sodium chloride—rendered porous by making into a paste and drying—with the formation of sodium sulphate and hydrochloric acid. This product is said to contain not more than 0·02 per cent. of chloride and no free acid. Coloured drawings of the apparatus used are also exhibited by Messrs. Hargreaves and Robinson, of Widnes, the patentees.

Another apparatus that promises to be of importance in the alkali manufacture is the horizontal rotary calcining furnace of Mr. Mactear, a model of which is exhibited in the machinery section of the British court. This furnace appears to have met with considerable acceptance, nearly thirty having been already erected, and others are in course of construction. It is said that its use in the making of black ash results in a saving 60 per cent. in labour and 30 per cent. in fuel as compared with the old fixed furnace, whilst the product gives more favourable results in the lixiviation. The mechanical furnaces originally used at the St. Rollox works turned out about 90 tons of black ash weekly; the last two that have been erected there produce 300 and 330 tons respectively in the same time. In fact the case of Messrs. Charles Tennant and Co., of Glasgow, in which firm Mr. Mactear is the technical partner, contains a series of specimens which very fully illustrate the manufacture of alkali (including caustic soda of especially high degree) and bleaching powder, as well as the regeneration of sulphur from the alkali waste before

* Vol. iv., p. 551.

referred to. The specimens are arranged so as to show the sequence of the manufacture, beginning with common salt and sulphur and ending with the finished products. On a platform underneath the case are specimens in bulk of the primary raw materials, such as coal, pyrites, limestone, manganese, etc.

The Messrs. Tennant's works were built in 1798 for the manufacture of bleaching powder, the quantity manufactured in the year 1799 being 52 tons, and being sold at £140 per ton. The amount now made in Great Britain is close upon 150,000 tons per annum and the price about £5 10s. per ton. The works of the Messrs. Tennant, situated at St. Rollox, Glasgow, Hebburn-on-Tyne and Carnoustie, cover in all about 190 acres, and produce from about 350,000 tons of raw material about 61,000 tons of finished products per annum. The length of railways in the works of the firm exceeds 20 miles, and a complete series of mechanics' workshops, including a large iron foundry, is in connection with the works, for the necessary repairs and constructions which in an establishment of this great extent are constantly going on. The tall chimney locally known as "Tennant's stack" is a familiar object to the people of Glasgow, rising to the total height of 455 feet. The privilege of visiting the St. Rollox works is readily granted and they are one of the most interesting technical sights in the city of Glasgow.

Although some few of the cases of the exhibitors of alkalies in the French court make but a poor show there are others in which the products are very fine, and, if the figures accompanying them may be trusted, of great purity. This remark applies to the specimens shown by Messrs Dècle, and Co., of Rocourt, and M. Nugues, of Saint Saulve-lès-Valenciennes, both of whose products are obtained from the beet residues. Another good exhibition of soda salts is from the alkali works in connection with the celebrated St. Gobain glass works. In the British court, besides those mentioned, some very fine caustic soda and soda crystals, black ash, etc., are exhibited by the Desoto Alkali Company, Widnes, the Tyne Alkali Company, the Runcorn Alkali Company, the Liver Alkali Works, and Messrs. Boyd, Son and Co. of Dublin. There are also one or two alkali exhibits in the Russian court.

In connection with the production of bleaching powder, in which the hydrochloric acid from the soda manufacture is utilized, the most notable fact is the progress that has been made on the continent by the Weldon process for the regeneration of binoxide of manganese in the manufacture of chlorine, an announcement that the Weldon process is used accompanying nearly every exhibit of bleaching powder. In France all but about 500 tons annually is manufactured by this process, whilst the Weldon apparatus has been erected at various places in Germany, Austria, Belgium, Russia and Norway. By the latest improvements the loss of manganese has been reduced to 2 per cent. In Great Britain the St. Rollox works is the only establishment where it has not been adopted, and there the Dunlop process is still followed. But even Messrs. Tennant have introduced the Weldon process into their other manufactory at Hebburn, near Newcastle. In fact it is estimated that out of 120,000 tons of bleaching powder produced in Great Britain in 1877, 105,000 tons were made by the Weldon process. It is also used in the manufacture of potassium chlorate, of which the principal exhibitors are the North British Chemical Company and the Tyne Alkali Company.

Among the exhibitions of chemical manufactures that most readily excite the admiration even of non-technical spectators must be classed the magnificent blocks of potash alum, shown by Mr. Peter Spence, of Pendleton, which lie piled one upon another until they tower above the surrounding cases, and are said to have drawn from the Prince of Wales the remark, "This is a trophy!" Alum now finds very extensive application in various manufactures. In dyeing and calico printing it is used as a source of alumina for fixing or mordanting colouring matters on the cloth; in the paper hanging manufacture it is the basis of the material called "satin white," which gives wall papers their beautiful glaze and prepares them for receiving the variegated patterns; in the paper manufacture it is employed in the sizing operation, imparting strength and stiffness to the paper as well as a surface which can be written and printed on without fear of the ink spreading and blurring. It is used also further for lining fire-proof safes, as the large amount of water it contains enables books and papers, phœnix-like, to defy a red heat for hours; also for preparing or "tawing" skins in the manufacture of white and coloured leather, and finally, for precipitating the mud or clay contaminations from drinking waters, a property taken advantage of in India, Australia, and other hot countries.

The following brief notice of the manufacture of alum is based on information that has been kindly supplied by Mr. Peter Spence:—

"Potash alum" is a crystallized sulphate of alumina and potash. In its preparation three materials are employed. (1) Alumina, as an impure silicate known as fire-clay, and found underlying the coal seams; (2) Sulphuric acid; (3) Potash, in the form of chloride or sulphate. For a long time, and until within the last few years, in consequence of the relatively high price of potash salts, ammonia almost universally displaced potash in alum making, the ammonia being generally obtained from the ammoniacal gas liquors produced in the distillation of coal and cannel for gas and oil. But owing to the increased demand on the part of agriculturists for sulphate of ammonia, and the comparative failure of the ammonia in the guano supplies, the price of ammonia salts has now risen to such a degree as to place them beyond the reach of the alum manufacturer, whilst the discovery of the Stassfurt deposits has opportunely very materially lowered the price of potash salts. Consequently most of the pure alum now used in manufactures contains potash, although the Pharmacopœia alum is, of course, still the sulphate of alumina and ammonia. The process devised by Mr. Spence in 1845, and since continuously improved by him, is now, almost without exception, the only method employed in the manufacture of potash alum. At present indeed alum cannot be made of sufficient purity by the old process to pay the manufacturer. The first operation is to calcine the fire-clay in large heaps, by which the alumina is rendered soluble and the clay becomes more easily acted on by the acid. The calcined material is put into large pans lined with lead, capable of holding 20 tons, where acid diluted with mother liquor from previous operations is added and the whole is boiled with steam until most of the alumina is converted into sulphate of alumina and dissolved. It is now

run into coolers, and sufficient potash salt is added to form alum. By agitating and cooling, the alum (being only slightly soluble in the cooled liquor) gradually falls to the bottom in the form of small crystals from which the mother liquor is drained in tanks with false bottoms. Repeated washings with pure liquor then follow and finally the crystals are removed from the tanks, dissolved by steam, and the hot strong solution run into large wooden tubs, where, by slow cooling, massive, hard and clear crystals, almost completely free from iron, are obtained in a fit state for the market.

The perfect standard of purity for alum is freedom from iron, and, judging from the statement of Mr. Spence, he must have almost reached the limits of practical results. His specialty is what is called "Turkey red alum," being the finest quality made for Turkey red dyers and others, to the brilliancy of whose colours the ordinary alum of commerce would be entirely fatal. It is of this special quality that the monument of alum referred to is composed, and some idea of the purity claimed for it may be formed when it is stated that one million parts of it are said to contain only two parts of peroxide of iron. Comment is obviously unnecessary, and it speaks volumes for the skill and enterprise of the proprietor of the Pendleton Alum Works that this high standard of excellence has been attained in spite of falling markets.

By the side of this alum exhibit are a number of slabs or cakes of another aluminous compound termed "alumino-ferric cake," the manufacture of which forms the subject of a recent patent by Messrs. Peter and Frank Spence. This compound, which contains a small proportion of ferric sulphate, is intended to realize the idea of a uniformly strong, acid free, form of sulphate of alumina at a very low price and is designed for the sizing of papers of all but the very whitest kinds, and also for precipitating muddy or clayey water (for drinking and manufacturing purposes), the waste waters of manufactories, and that strangely complex and variable fluid, the sewage of modern towns. It is claimed by Mr. Spence that for clarifying, decolorizing and, to some extent, preserving foul liquids from putrefaction, salts of alumina have no practical rival, since the lime process, which is a very cheap method, completely fails to decolorize the sewage, and the effluent is more apt to putrefy.

When the Native Guano Company commenced its "A B C process" some years ago its aluminous material was alum, then selling at £7 per ton. Mr. Spence now supplies it with an aluminoferric cake having 20 per cent. more precipitating power at less than one-third this price!

The valuable features of the aluminoferric cake for paper sizing are its high guaranteed proportion of alumina (14 per cent.) and its entire freedom from uncombined acid. The latter quality will be appreciated by those who have had anything to do with the analysis of cakes and know the large and varying percentages of this deleterious ingredient. It is singular if not somewhat unfortunate that the absence of free acid gives a darker colour to the cake, and the very appearance which should indicate the excellence of the aluminoferric proves in many cases a drawback to its introduction.

Mr. Spence, however, is not without rivals, and there are some very good exhibits of alum in the French court. Among these may be mentioned the collective exhibition of the alum and copperas manufacturers of the Aisne and Oise departments, where the material used is an "alumino-ferrous lignite," from which alum and ferrous sulphate are prepared. The Société Générale des Alums exhibits "Roman alum," made at the works at Civita Vecchia from alunite obtained from the Tolfa mines near by. This alum is also exhibited in the Italian court.

Sulphate of alumina is now used to a considerable extent for the same purposes as alum, certain disadvantages, such as irregularity of composition, excess of acid and consequent deliquescence, and the presence of a considerable quantity of iron, which formerly more than counterbalanced the advantage of a larger proportion of alumina, having been to some extent overcome. In this manufacture M. Augé, of Montpellier, uses "pale bauxite" from the mines of Baux (Bouches-du-Rhone) and Villeveyrac (Hérault). This mineral is essentially constituted of aluminum hydrate, together with 1·5 to 3 per cent. of iron and 6 to 20 per cent. of silica. This is treated directly with sulphuric acid and the solution yields on concentration a ferruginous aluminum sulphate. M. Augé's method of removing the iron from it is based on the fact that when plates of zinc are placed in a solution of aluminum sulphate containing ferrous sulphate, but no free acid, the zinc displaces the iron, which is precipitated under the form of peroxide as a black powder. Zinc sulphate, unlike ferrous sulphate, is of advantage in the sizing of paper. In this reaction also the proportion of alumina appears to be increased, as shown in the following table, which represents the percentage composition of the product before and after treatment with zinc.

	Crude Sulphate.	Sulphate treated with Zinc.
Alumina (Al_2O_3)	15·40	20·85.
Sulphuric Anhydride (SO_3) .	35·88	35·88.
Peroxide of Iron (Fe_2O_3) . .	0·95	0·04.
Oxide of Zinc (ZnO). . . .	,,	0·50.
Water, by difference . . .	47·77	42·73.

This bauxite is also calcined at a high temperature for the production of "emery."

Some handsome crystals of chrome alum are exhibited by M. Rousseau, of Paris.

A good collection of potassium cyanide and other salts used in photography is shown by M. de Plazanet, of Paris.

Fine-looking specimens of the yellow and red prussiates of potash are to be seen in the case of M. Moulin, of St. Denis, together with potassium cyanide, and stannous chloride in acicular crystals. But the display of yellow prussiate by the administration of the Bouxwiller Mines (Meurthe-et-Moselle) is simply magnificent, the case being filled with splendid masses of crystals. The specimens of the prussiates shown by Messrs. Chambers and Co., of London, and the Hurlet and Campsic Alum Company, of Glasgow, are also very good. Of prussian blue a crude specimen is shown by the Paris Gas Company, extracted from the spent oxides used in the gas purifiers.

Ultramarine is so associated in the popular mind with the beautiful blue colour of the pigment formerly prepared from lapis lazuli that many will be surprised at the variety of shades included under that name in the present exhibition, and not every chemist even will be prepared to see—as in the case of M. Guimet, the representative of the discoverer of

artificial ultramarine—a series of specimens passing from brown through green, blue, violet, and red to white. The development of this industry furnishes a remarkable instance of the service chemistry is capable of rendering to the arts. In 1820, just before the discovery of a method of producing ultramarine artificially, the pigment made from lapis lazuli sold for about £8 per oz. In fact the first artificial ultramarine was sold at 25*s.* per oz.; but at the present time the average cost of the same quantity is about 1*d.* Very great attention is paid to the manufacture in France and in Germany, and it is estimated that of the 10,000 tons said to be produced annually in Europe one-fourth is made in France. According to Plicque* the great advance made during recent years in delicacy of shade and in colouring power has not been marked by a corresponding increase in the capability of resisting the action of alum and aluminum sulphate, and this still remains a weak point in artificial ultramarine. Green ultramarine has long been known as an intermediate product, nevertheless, the industrial manufacture of green and violet ultramarines is quite recent, but the products are said to be coming into favour. M. Plicque considers the ultramarines to be double silicates of alumina and soda, in which oxygen is partially replaced by sulphur, and he represents the pure blue ultramarine as follows:—

$$\left.\begin{matrix} 3\,SiO_2\,.\,Al_2O_3\,.\,NaS \\ 3\,SiO_2\,.\,Al_2O_3\,.\,NaSO_2. \end{matrix}\right\}$$

Upon substituting oxygen for sulphur in the primitive molecule the colour passess from green to blue and from blue to violet, treatment by acids indicating that the violet ultramarine contains more oxygen than the blue, whilst the green contains more sulphur. Upon treating the ordinary blue ultramarine with silver nitrate sodium is displaced by silver, giving rise to a yellow product, and upon heating this yellow silver ultramarine with a metallic chloride, silver chloride is formed, together with a fresh ultramarine of potassium, barium, zinc, or magnesium, as the case may be. The subject, however, is not yet fully investigated, and it is believed that the delicacy of shade obtained by different makers is due to physical causes, and, as a rule, is at present dependent rather upon empirical skill in manipulation than to an exact knowledge of the principles to be followed in successful manufacture.

Ultramarine is exhibited in several cases in the French court as well as in those of Belgium, Russia, Hungary, and England. Some very good specimens are shown by the Comines and Asnières Chemical Company, and M. Armet de Lisle, and the blue, green, and violet varieties occur in the case of Messrs. Deschamps. M. Guimet, of Lyons, the original inventor of artificial ultramarine, also exhibits, as above mentioned, the blue, green, and other shades, though he seems to be *hors de concours*. Ultramarine appears besides in many specimens of washing blues, but the bronze lustre on many other specimens makes it evident that it has a strong rival in the colours obtained from aniline.

Ammonia salts obtained in the distillation of coal are exhibited by the Paris Gas Company and M. Biot. M. Tanneveau shows specimens obtained by evaporation of ammoniacal liquor in the open air, apparently by allowing it to run through frames containing porous materials and then evaporating to crystallization in shallow trays.

* *Moniteur Scientique* [3], vol. viii., p. 1048.

Ammonium fluosilicate, potassium fluosilicate, and other derivatives of fluor spar, are exhibited by Messrs. Faure and Kessler, of Clermont-Ferrand, the ammonium salt being described as for use in sugar refining. Potassium and sodium silicates and silicates for hardening stone and fresco paintings are exhibited by the Northern Chemical Manufacturing Company, of Lille. The Silicate Paint Company illustrates one of the advantages claimed for its product by a plank showing the difference in the action of sulphuretted hydrogen on white silicate paint and white lead paint, the part painted with the former remaining white and that with the latter being nearly black.

Carbonate of magnesia is exhibited by the Washington Chemical Company, of Newcastle-on-Tyne, in very fine blocks, one being about four feet in height. Mr. Jennings, of Cork, also shows some of good appearance in blocks and in powder, as well as calcined magnesia packed in tin cans. Barium binoxide, prepared from the sulphate, is exhibited with other bleaching materials by M. Tessié du Motay, of Paris, who uses it as a source of oxygen in the bleaching of tussah silk. Manganese borate, used as a siccative in preparing varnishes, together with boric acid in small crystals and scales, are shown by M. Desmazures, the sides of whose case are lined with beautiful cakes of borax crystals from the tanks.

Silver nitrate appears to be a specialty of M. Dubois-Caplain, of Paris, who exhibits it crystallized and fused, and in black and white cylinders. In this case are also shown the chlorides of gold, platinum, palladium, etc.

Cyanide of copper, arseniate of mercury and sulphate of mercury are exhibited together with Dubois' marine paint, but it is not quite clear whether they are constituents of it. Judging from the difference in appearance between the painted and unpainted portions of an iron plate shown the paint is capable of giving good results. Perhaps the finest specimen of acetate of copper is shown by Messrs. Camus, Neppel and Co., of Paris, consisting of a pyramid nearly three feet in height, standing in a handsome case among other products of the distillation of wood. The acetates of copper, lead and soda are also exhibited with similar products by the Nogent-le-Retrou Chemical Company, and by Messrs. Kestner and Co., of Bellevue, and Hardel and Duclos, of Croissot-lez-Rouen, who also show the pyrolignites of iron and of lime. White lead and the process of forming it are illustrated in several cases in the French court, and here also will be found litharge, massicot, minium, zinc-white and other similar products.

But when we come to the metallic pigments, as also colouring materials from other sources, the inconveniences attaching to the use of fancy names that reveal nothing of the composition becomes manifest. Of this a good illustration occurred a short time since, when the Privy Council wishing to diffuse popular information as to the best way to combat the expected Colorado beetle recommended the use of "Paris green," a name which, judging by the number of inquiries it evoked, was not associated in the minds of many of the readers of this journal, or *à fortiori* of the general public, with arsenite of copper. Under these circumstances the spectator is thankful for such slight indications as are given in the fine case of Messrs. Jacques-Sance and Co., of

Paris, where "jaune de zinc," probably a chromate, does duty for a beautiful canary-coloured powder. By the way a good chromate that could replace in colouring papers the lead chromate, which is liable to become blackened by contact with sulphuretted hydrogen, is a desideratum. "Bleu au cuivre" is the name given to a very delicate turquoise-coloured material, and "verts au plomb" covers four very good shades of olive green. This case also contains some very fine cochineal carmine. Here and there, too, are to be seen "antimony vermilions" and yellows. The show of colouring materials is very fine in the French court, but it hardly, if at all surpasses that in the British court, whilst in the beauty of the cases in which they are displayed our countrymen have decidedly the advantage. When all are so good it is almost invidious to single out any, but the cases of Messrs. Wilson and Co., of Mile End, London, and Berger and Sons, of Homerton, are certainly worthy of special commendation for their attractiveness. In the latter case a figure of Mercury stands upon a block of cinnabar, whilst a fine stream of mercury constantly trickles over the block into a pool beneath.

Notwithstanding the important position taken by the coal tar colours the old metallic and vegetable pigments are not beaten out of the field. Rather it may be said that, as in many analogous instances, severe competition has developed their capabilities. The position they may take is well illustrated in the case of Messrs. Storer, of Glasgow, which contains a fine series of the most important mineral or inorganic colours used for decorating, and in the various manufactures, paper staining, calico printing, etc. The series is arranged in pyramidal form, starting at the apex with sixteen small bottles, containing the chemicals, etc., used in producing the varied results shown on the lower shelves. These comprise chrome yellows, blues (Chinese and Prussian), orange chromes, copper and other greens, iron reds, blacks, browns, prepared earth colours, carmines, chrome reds, vegetable lakes, Indian reds, crocus, burnt earth colours, subchromates of lead, etc., all going to show the many changes which a few substances are capable of yielding under the hands of the chemist. The total number of specimens exhibited is over one hundred and fifty. Messrs. Storer claim that these pigments illustrate the permanent side of colour as against the fleeting effects of the coal tar colours when used for the purposes to which as yet, in their opinion, only mineral colours are adapted.

The colours exhibited by Messrs. Wilson and Co., of the East London Colour and Chemical Works, Jubilee Street, Mile End, are specially prepared for the printing of paper hangings and for making surface papers, and for conversion into paints; also for the manufacture of lithographic ink, and artificial flower making. The emerald greens are of various shades; the deepest is claimed to be of an intensity not produced by other manufacturers, while the paler shades are especially soft and possess great covering power. The pulp colours are particularly adapted for the paper hangings manufacture and fancy colour papers and are soft, with considerable body, and permanent. The carmines of cochineal are of various shades and, in consequence, of great utility in artificial flower making. Many of the lakes prepared from the derivatives of coal tar are used in the place of cochineal, the carmines and carmine lakes thus produced by special treatment being recommended as economical substitutes for those derived from the insect.

Of the exhibits of vegetable pigments several are worthy of notice. Among these may be mentioned some very good looking "carmine," for dyeing flowers and yarn, making rouge, etc., prepared from safflower, by Mr. Saint-Germain, of Paris; a collection of dyeing materials from Campeachy wood, "Cuba iaune wood" (in a fissure in a specimen of which wood there is a deposit of a substance resembling chrysophanic acid in appearance), Lima red, etc., shown by Messrs. Bandu and Sons, of Auple; and dye-wood extracts, by Messrs. Dubosc, Messrs. Kock, and others. A very fine collection of lakes is shown by Messrs. Coez and Co., of Saint-Denis. Messrs. Thomas Brothers, of Avignon, show garancine, together with the almost vanquished madder. In the case of M. de Vasselot, of Paris, together with cadmium reds and yellows, is a very fine specimen of orcine, the crystals being supported in a kind of nest made from *Roccela fusiformis* and *R. tinctoria*. Lastly there is an exhibit of "vegetable colours," specially intended for confectioners, by M. Landrin, of Paris, which recalls the fact that some similar materials when examined recently proved notwithstanding their name to contain a large percentage of oxide of tin! Colours for confectionery are also exhibited by Messrs. Bush and Co., of London.

The products of the destructive distillation of wood and coal and their derivatives form an important division in this class, but their multitude prohibits more than the briefest reference to them in this report. Many of the exhibitors show very complete series, illustrating well this now very intricate subject. Thus Messrs. Brigonnet and Son, of Saint-Denis, show a model of the apparatus used in the distillation, together with pure toluol and benzol, artificial oil of bitter almonds, toluidine, pseudotoluidine, artificial benzoic acid, aniline, chloroform prepared from chloride of methyl, together with methylamine, dimethylamine, methyl-diphenylamine, trimethylamine hydrochlorate, benzyl chloride, etc. M. Dehaynin, of Paris, shows, among other coal tar products, alliol, toluol, anthracene and alizarine, while in the case of M. Vedles, of Clichy, besides a fine show of aniline, is a specimen of xylol, the hydrocarbon that about five years since obtained a temporary reputation as a specific against small pox. M. Castelhaz shows different colouring matters having aniline or resorcine for their base, various picramates, phthalic acid and phthalamide, while in the case of M. Poirrier, of Paris, together with fine specimens of methylaniline blue and green, rosaniline blue, diphenylamine blue and safranine, are a splendid block of "violet de Paris," made from dimethylaniline, weighing about 1 cwt.; and a beautiful specimen of fuchsine. A fine show of aniline colours, said to be free from arsenic, occurs in the case of Messrs. Coupier and Co., of Creil, and M. Meissonier, of Paris, has two handsome specimens of sublimed purpurine and alizarine. Eosine, fluorescine, and safrosine, the new coal tar colours, are to be seen in several cases. Recent as has been its introduction eosine has already undergone several modifications, and the whole series is admirably illustrated in the case of Messrs. Bindschedler and Busch, of Basle, who give information respecting them which may be briefly epitomized as follows:—

Starting with resorcine, this when heated with three-fourths its weight of phthalic acid yields fluoresceine. This product treated with bromine and caustic soda yields yellow eosine, or tetrabromfluoresceine sodium, which is soluble in water, giving a solution that is beautifully fluorescent. The analogous tetraiodofluoresceine is blue, and is a new product of this firm, who have named it erythrosine; it is soluble in water, but the aqueous solution is not fluorescent. Safrosine, which is also soluble in water, is a nitrobrominated derivative of fluoresceine, obtained by treating tetrabromfluoresceine with potassium nitrate and sulphuric acid. It is also known in commerce as *écarlate lutécienne*, nophaline and coccine. It is said to dye wool a beautiful intense bluish red, and when mixed with naphthal orange to replace cochineal in some cases with advantage. The eosines soluble in alcohol, methyleosine, ethyleosine, and primrose, are obtained by heating tetrabromfluoresceine with a mixture of the respective alcohol and sulphuric acid, precipitating with water, and converting the precipitate into a potassium compound by boiling it with potassium carbonate. The product is a compound of the alcohol derivative of tetrabromfluoresceine with potash; it dissolves readily in equal parts of alcohol and water, giving a fluorescent solution. The varieties of eosine soluble in alcohol are said to give a more solid and pleasant colour than those soluble in water. This firm also exhibits a new dichroic blue from resorcine which is said to dye silk reddish blue with a very beautiful fluorescence. The difficulties in its preparation have not, however, yet been quite overcome.

In the English court, Messrs. Brooke, Simpson and Spiller, of London, have a very handsome case, containing a series of dyes and other products obtained from coal tar, and similar exhibits are shown by Messrs. Levenstein and Sons, of Manchester, and Messrs. Williams, Thomas and Dower, of Brentford.

"Rainbow dyes" and their applications are shown by Messrs. Carruthers and Allan, of Glasgow, together with a series of specimens of silks, wool, feathers, grasses, etc., dyed, and pieces of wood stained by them. These are said to be the work of unskilled hands, and if so, they certainly testify to the efficiency of the rainbow dyes.

In the French court also, there is a great variety of specially prepared colours for papers, grasses, artificial flowers, varnishes, etc.

(*To be continued.*)

FLUID EXTRACTS BY REPERCOLATION.*

BY EDWARD R. SQUIBB, OF BROOKLYN.

(*Continued from page* 288.)

A new menstruum was made consisting of 5 parts stronger alcohol, 4 parts water and 1 part glycerin. The s. g. of this mixture was ·9575 at 15·6° C.=60° F., or ·9496 at 25° C.=77° F. A cubic centimetre of this menstruum carefully weighed and evaporated on a watch-glass left 7·75 per cent. of glycerin not evaporable at the temperature to which the fractions of percolate were submitted. A new series of percolations was started with this menstruum, and was conducted precisely as with the former series. The first two percolations were made with the rich Java cinchona so as to compare the results of the two menstrua upon the same powder. The remainder were made with the Ceylon powder and new menstruum. In this series the percolate was divided into portions of 8 ounces=226·7 grams each, except the first portion of the first percolation, which was 6 ounces =170·1 grams, and the powder in each was moistened with 8 ounces=226·7 grams of menstruum or weak percolate. So moistened it could not have been passed through the sieve at once, but by standing for the prescribed eight hours in a closely covered vessel the liquid was absorbed by the powder, and then it was easily passed through the sieve. When moisted to this extent the powder must not be firmly packed, and it is quite important to use the largest practicable quantity of liquid to moisten the powder in repercolation. The results of these percolations are given in the following table which is printed on the next page.

This table fairly represents the application of the formula and process given before in all the details, and the actual practice of repercolation; only that the results are imperfectly examined and recorded here, for illustration by means of the table; and the table is presented as a model upon which every individual fluid extract should be studied. The weighings and measurings are not chemically nor critically accurate, nor is the basis of calculations mathematically correct. And when differences of specific gravity are given to the fourth decimal place, the reader must not accept them, or any of the figures as having anything like the extreme degree of precision which would be indicated by such figures. The weighings in all the tables were made to the nearest centigram, and the specific gravities were all taken in a rather rudely-made 25-gram flask, without corrections for temperatures, and the four decimal places come from multiplying the weights obtained with this flask in centigrams by 4. Hence these differences of s. g., although put down with the apparent accuracy of four decimal places are really the least accurate of all the determinations of the tables. In short the whole results should be taken as being only close and useful approximations, and such as most pharmacists could easily make. This table being the last of all, and not half completed when the paper had to be sent to the *American Journal of Pharmacy* for publication, embraces the experience and skill acquired in making the others, and its better results are therefore partly due, no doubt, to the dexterity obtained by a few months of personal practice on this small scale of working. It therefore may be accepted as representing good ordinary practice with repercolation as applied to one of the most difficult substances known, on the lowest scale of quantity likely to be needed by the pharmacist, and the fluid extract yielded seems to be of unexceptionable quality in every respect, both in sensible properties and when applied therapeutically in two cases. It is unfortunate that the presence of glycerin not only prevents the precipitation of alkaloids by ammonia, but also entirely invalidates the thalleioquin test as applied to the percolates; and that no test was found whereby to judge of the quantity of alkaloids in the different percolates better than by mere taste and colour. The final percolates were always very decidedly bitter, and never paler than a dark sherry colour, even when yielding not over one-tenth of one per cent. of total extract. Two very curious apparent results in the table are well worthy of further and more accurate observation. First, that the quantity of extract obtained from the different percolations as measured by that of the first simple percolation with new menstruum is in the aggregate over 100 per cent. while the exhaustions are apparently not so good as the first. The other result, which leads in the same direction, is that the difference between the s. g. of the menstruum, and the s. g. of the weaker percolates diminishes more rapidly than it should do, and finally gets to be a minus quantity, which *a priori* should be impossible. All this leads to an inference that the residue left behind in the percolator splits up the menstruum, and holds on to more of the water or more of the glycerin, or more of both, than it does of the alcohol.

JAVA CINCHONA.

This table again illustrates the disturbing effects of insensible variations in the packing of percolators, and how by repercolation such variations are so controlled as to give fairly uniform results in practice.

It remains now to give a summary of the results obtained from these two series, as bearing upon the relation between the weight and measure of the reserved portion of each percolation.

FIRST SERIES OF PERCOLATIONS.

Reserved Portions.	Weight. Grams.	Measure. Cubic Cent.	Difference Per cent.
1st Percolation	171·10	158	7·6
2nd ,,	226·80	214	6.0
3rd ,,	226·80	210	7·5
4th ,,	226·80	208	8·3
5th ,,	226·80	204	10·1
6th ,,	226·80	201	11·4
7th ,,	226·80	206	9·2

SECOND SERIES OF PERCOLATIONS.

Reserved Portions.	Weight. Grams.	Measure. Cubic Cent.	Difference Per cent.
1st Percolation	170·20	158	7·1
2nd ,,	226·90	210	7·5
3rd ,,	226·80	216	5·0
4th ,,	226·80	208	8·3
5th ,,	226·80	206	9·1
6th ,,	226·80	206	9·1
7th ,,	226·80	211	7·0

It will be seen by this table that the first series gives a relative varying between 89 and 94 minims to each 100 grains of the cinchona; and for the second series gives 90 to 95 minims to the 100 grains as the extreme limits of the series. Either of these is a great improvement upon the results of pharmacopœial practice.

The deductions which the writer draws from the work here given as applicable to the present pharmacopœial practice, and that which may be desired for the future are mainly as follows:—

First, that the present formulas and processes for percolation are so defective that the relation to the drug which they profess is not practically accurate, either as to quality or quantity, and therefore that a better process is greatly needed.

Second, that the process by repercolation, though it has some grave disadvantages, and is liable to defects in practice, yet gives far better results both in quality and quantity of product; while it is not difficult in practice except by comparison with the delusive simplicity of the former processes, and therefore that repercolation is better adapted to pharmacopœial use as a model or standard process than any which has yet been tried.

Third, that repercolation may be used on a scale as small as four or eight ounces, by great care and skill, but is not very successful with less than an avoirdupois pound of material for each percolation.

Fourth, that powders for percolation should not be finer than No. 60 for hard compact substances, nor coarser than No. 40 for more loose and spongy substances, with a few special exceptions.

Fifth, that the menstruum should be so adjusted as to dissolve out the medicinal prineiples with the least practicable disturbance of their natural relations to each other and to the extractive matters whereby they are rendered soluble and permanent. Next, that the menstruum should contain the smallest practieable proportion of alcohol, and glycerin only when absolutely neeessary, as in cinchonas. And finally, that the menstruum should be so adjusted that when the fluid extract represents the drug weight for weight it should also represent the drug by not less than 90 minims to the 100 grains, or more than 97 minims to the 100 grains, since by repercolation the exhaustion is never less than 90 per cent., and perhaps rarely more than 97 per cent. of the total soluble matter.

Sixth, that the powder be moistened with as much liquid as it ean be made to hold, and yet pass through a No. 8 sieve; that it be not tightly paeked; and that it be well maeerated before starting the pereolation.

Seventh, that the rate of pereolation be uniform and very slow. At first, for the reserved portion, the percolate in twenty-four hours should not exeeed the weight of the powder; nor need the rate be slower than to obtain the weight of the powder in forty-eight hours, although as a general rule the slower the rate the better the results. After the reserved portion the rate may be inereased gradually so that the last portion be received in about six hours. The separate portions of weak pereolate should not exeeed the weight of the powder.

Eighth, that a good practical exhaustion requires, as a general rule, for the first pereolation, with fresh menstruum, that the total percolates should weigh 3·5 times the weight of the powder. That for the second percolation or first repercolation, the weight should be 4·5 times that of the powder. And for all subsequent repercolations the weight should be 5, 6, or 7 times that of the powder, according to the nature of the substance percolated, and the skill and care with which the process is managed.

Ninth, that the relation of weight for weight, instead of minim for grain, should be established under proper controlling eonditions. But that unless properly guarded in the quality and moisture of the drug used, the new relation is liable to be even more inaceurate than the old, because, the poorer the quality of the drug the less dense will be the percolates, and the greater will be the volume for the prescribed weight; and this involves the serious difficulty that when the fluid extract is made by weight but administered by measure, the poorer the drug from which it was made the smaller, as well as the weaker, the dose will be.

Tenth, that some good practical method of comparing fluid extraets by a standard is very much needed; and that for such drugs as cinchona, a method of arithmetical dilution would be easy and practical if well worked out.

(*To be continued.*)

SOLUTION OF IODINE IN OIL OF BITTER ALMONDS.*

BY E. T. BLACKWELL, M.D.

The want of a solution of iodine which shall not precipitate in the stomach, and especially of one which shall be easily miscible with oil, has been long felt. The French chemists, by a tedious process, made a solution in oil of sweet almonds; but it was liable to raneidity, while the large amount of the solvent necessary to be taken with each dose rendered it unacceptable.

The writer of this article, very early in his medical career, had his thoughts turned towards a more complete iodizing of cod liver oil, thinking that the amount of iodine contained in this medicinal agent was too small to exert its full remedial power. Failing in his efforts to eause direct union, he gave up his attempt, but did not relinquish the idea.

Early in the year 1870, while engaged in pharmaceutical manipulations, he discovered the extreme solubility of iodine in the oil of bitter almonds. He was at that time ignorant of the reference in the United States Dispensatory* to Zeller, who speaks of this solubility as "slow and partial." His remark seems to have attraeted no attention; yet the faet is a most valuable one, opening the way to many combinations of great importance to therapeutists.

On placing together powdered iodine and the oil of bitter almonds, the violet eolour of the former is immediately, and with great intensity, imparted to the latter; and if they are allowed to remain in eontact for a rather long period,—two months or more,—they unite in the proportion of one of iodine to three of the oil. This solution mixes freely with oils, fats, glyeerin, alcohol, ethers, and fluid extraets of vegetable matter, and is alone a most eligible coneentrated preparation for applieation to parts wherc a thin fluid is liable to be swept away, as in the throat, the nares, vagina and uterus, and where, at best, only a small amount can be made to adhere. As the physiological rather than the chemical aetion is desirable in a topical application of iodine, this preparation merits acceptanee, because it leaves the tissue soft and in good condition for absorption.

Formula for Iodized Oil of Bitter Almonds.†

℞ Pulveris Iodinii . . . . . ℈j.
Olei Amygdalæ Amaræ . . . ℥j (by weight).

Mix, and shake occasionally for two months.

This may be eombined with many other remedies for external application, to meet many different indications. If the purpose be to induce resolution of swollen glands, soap liniment may be chosen; if to produce eounter-irritation or blistering, cantharidal collodion or eroton oil would be suitable. For general external use, in whieh an emollient, unstaining, and less eoncentrated artiele is desirable, the iodized oil of almonds with glyeerin fulfils all the indications, leaving the skin after its application supple and without stain. This is beyond eomparison superior to "iodine paint," whieh eorrugates the skin and hinders absorption; or to the greasy uncleanly ointment.

Formula for Iodized Glycerin.

℞ Iodized Oil of Bitter Almonds . . . ℥j.‡
Glyeerin . . . . . ℥vij (by weight)—M.

This is a most elegant form for external use, and may, properly diluted, be administered internally, in doses of two minims,=about $\frac{1}{16}$ gr. of iodine and $\frac{1}{5}$ oil of bitter almonds.

The system is said to be best affected by iodine in minute doses and in exceedingly dilute form, as in the natural mineral waters, all exeess of the remedy being carried off by the emunetories. To meet this view an iodized water may be made:

℞ Iodized Glycerin . . . . . ℥j.§
Water . . . . . *O*j—M.

This contains about the amount of iodine found in four pints of the water of Iodine Spring, Saratoga,‖ and has about the strength of Lugol's iodine lotion.¶

A tablespoonful, containing about $\frac{1}{16}$ gr. of iodine and $\frac{1}{5}$ gr. of oil of bitter almonds, may be taken, diluted at pleasure, for a dose.

It is, however, to the iodizing more eompletely than it exists in nature of cod liver oil, that the efforts of physicians and pharmaeists have been bent,—all feeling that the therapeutic value of this remedy would be greatly enhanced by combination with a larger amount of iodine. The discovery of the solubility of the latter substanee in oil of bitter almonds removes all the difficulty. We have only to add the iodized oil to the eod liver oil, and, on agitation, complete and permanent union takes place. I

* From the *Medical Times*.

* Art. Ol. Amygd. Amar., p. 614 (14th ed.).
† Containing twenty-five per cent. of iodine
‡ = 15 gr. iodine.
§ = 2 gr. iodine.
‖ Analysis of Emmons.
¶ Art. Iodinium, U. S. D., p. 507.

may add, what is well known, that a proprietary article, claiming to be composed of cod liver oil, iodine, bromine, and phosphorus, has been long before the public, and has received quasi-recognition in the United States Dispensatory, and the endorsement of many physicians. This compound is, however, vended at a very high price; its working formula is unknown to the writer and, he presumes, to the general pharmacist. The profession, therefore, may not be averse to a formula which may be filled by any physician or druggist. The following form I have used for several years in making

Iodized Cod Liver Oil.

℞ Iodized Oil of Bitter Almonds . gr. xvj.
Cod Liver Oil . . . . . Ȝ j.

Mix, and shake. A teaspoonful, containing $\frac{1}{32}$ gr. of iodine and $\frac{1}{10}$ gr. of oil of bitter almonds, may be taken for a dose.

If thirty grains of the iodized oil of bitter almonds, two drachms of phosphorated cod liver oil,* and one grain of bromine, be used to the pint of cod liver oil, the ingredients and proportions of Fougera† will be had, *plus* twenty-four grains of oil of bitter almonds.

Very efficient combinations may be made by uniting the iodized almond oil with alternative fluid extracts and potassic iodide:

℞ Pot. Iodidi . . . . . Ȝij.
Ol. Amygdalæ Iod. . . . . gr. iv.
Ext. Stillingiæ Fl. . . . . Ȝiij.
Syr. Helianthemi . . . . . Ȝviiss.

M. Dose, coch. mag. ter in die.

I may add that I have not discovered the influence of bitter almond oil as a factor in the various prescriptions used by me, except as a soothing remedy. I commend them with great confidence to the profession, believing they will meet with hearty acceptance and be greatly useful.

RESEARCHES ON ESSENCE OF VALERIAN.‡

BY G. BRUYLANTS.

The oil of valerian when fresh is slightly acid, the colour varies according to the kind of valerian used for its preparation: green when made from *Valeriana sylvestris*, and yellow when roots grown in a marshy ground are employed in its manufacture. The fresh oil is without smell, but if left in contact with the air, it becomes resinous and acquires a fetid odour, owing to the formation of valeric acid. The oil varies according to the age of the root from which it is extracted; when prepared from old roots it is much more acid and contains more resin than that from fresh roots.

The oil begins to boil at about 120°, but the temperature rapidly rises to 160°, when the distillation continues regularly to about 350°. A blackish resinous residue is left in the retort, having a strong smell of leather. When the oil is freshly prepared, it contains about 5 per cent. of this resinous substance. After a number of distillations (20), the following fractions were obtained:—

The first portion boiling between			155°	and	165°
„ second	„	„	205	„	210
„ third	„	„	220	„	225
„ fourth	„	„	230	„	235
„ fifth	„	„	240	„	245
„ sixth	„	„	285	„	290

Excepting the first and last fractions, the others were not obtained in a state of purity on account of the closeness of their boiling points, but nevertheless they were identified by their decomposition products.

The portion boiling at 155–165° contained a few drops of an acid body which was deposited on allowing the specimen to rest for some time, when it was collected, and a barium salt prepared from it. This salt on boiling with silver nitrate gave a black precipitate of metallic silver, and with lead acetate a white precipitate of formate of lead was produced. After boiling the barium salt with silver nitrate and filtering, the filtrate on cooling gave crystals yielding on analysis 58·02 per cent. of silver; this is fairly near the amount required (for formate), but might also indicate the presence of a mixture of acetic and valeric acids; the author is inclined to regard the latter as the correct view. There was not sufficient material to make further experiments.

The only liquid, boiling from 155–165°, was distilled several times over sodium to free it from traces of substances containing oxygen, valerianic acid, etc. The vapour-density for $C_{10}H_{16}$ was, 136 calculated, 138 found; the molecular weight 4·69 calculated, 4·76 found; the boiling point was 155–157°. After boiling for some hours with iodine, a large quantity of hydriodic acid was envolved, with formation of a hydrocarbon, $C_{10}H_{14}$, methylpropylbenzene, identified by its oxidation products, toluic and terephthalic acids. The terpene absorbs a large quantity of hydrochloric acid, giving a crystalline product.

The author promises another communication on the subject.

TANNIN AND BITTER PRINCIPLE OF HOPS.*

BY C. ETTI.

The substance named "lupulo-tannic acid" (*Dingl. polyt. J.*, ccxxvii, 491) by the author does *not* precipitate gelatine; if, however, it is dried at 120–130°, it changes from yellowish-white to red, loses water, and when dissolved in very dilute alcohol, precipitates gelatin completely just like ordinary tannin.

On heating the yellowish alcoholic solution of the original tannin on the water-bath, it becomes red, and on evaporation, a dark red residue remains which also precipitates gelatin when again dissolved in dilute alcohol. The author calls this "phlobaphen."

Analysis gives the same composition for this as for the red compound obtained by heating the lupulo-tannic acid at 120–130°, each having the formula $C_{50}H_{46}O_{25}$; and they may be supposed to result from the expulsion of a molecule of water from two molecules of tannic acid.

The coarsely powdered hop flowers are placed in an extraction apparatus, and after being freed from resin and bitter principle as much as possible, the mass is extracted with 20 per cent. alcohol. On evaporating to a small bulk and cooling, a red precipitate of phlobaphen is formed; this is dissolved in 90 per cent. alcohol, evaporated to dryness, and heated to 120–130°. If it tastes bitter, the bitter principle may be removed by ether. Phlobaphen is easily soluble in alkalies, and is precipitated unchanged by dilute mineral acids. On boiling the freshly precipitated and not previously heated phlobaphen with dilute mineral acids it is decomposed, glucose and one molecule of water being split off.

As the phlobaphen is easily prepared, is constant in composition, and precipitates gelatine solution completely, it may be estimated quantitatively like tannin, and may be used in standardizing the solution employed.

An ethereal extract of hop flowers contains, besides an essential oil, chlorophyll, a crystallized white and an amorphous brown resin, to which the bitter principle adheres. After driving off the ether, 90 per cent. alcohol dissolves brown resin and the bitter principle, which may be separated from each other by adding water as long as the resin continues to be precipitated. Repeated solution in alcohol and dilution with water frees the resin from the bitter principle. The aqueous solution is evaporated in a vacuum over sulphuric acid, the amorphous residue dissolved in 90 per cent. alcohol, again evaporated, and so on repeatedly, until well-formed extremely bitter colourless crystals are obtained. The crystals are completely soluble in water. These experiments oppose the idea that the "bitter resin" of hops can be dissolved in water only with the aid of sugar, tannic acid, gum, ethereal oil, etc. The brown amorphous resin and the bitter principle of hops are two fundamentally different substances.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 2, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE POSITION OF THE PHARMACIST IN REGARD TO THE REVISION OF THE PHARMACOPŒIA.

THE paper read before the late meeting of the Liverpool Chemists' Association, and published this week in our report of the proceedings of that Association, deals with a subject that ought to receive the earnest attention of every member of the trade, and the thanks of the whole body are due to Dr. SYMES for having brought it forward for discussion.

The opinion expressed by the author as to the desirability of having another edition of the British Pharmacopœia issued at an early date is one that is entertained by a large number of medical men, as well as pharmacists. Among the reasons that have led to this the chief one is the length of time that has elapsed since the publication of the present edition, which is now more than eleven years old. Moreover, the additions published as an appendix in 1874, as a means of supplying the deficiencies which had resulted from lapse of time and progress in the application of new remedies, did not so fully realize the anticipations that had been formed as to make them an adequate equivalent for a new British Pharmacopœia.

Consequently there is sufficient ground for desiring to see this work carried out as soon as may be consistent with necessary regard to revision and additions. Dr. SYMES suggests that if the new edition were brought out in 1880, it is not too soon to commence the work of revising and considering what additions should be made.

Then comes the question how this work is to be done, and it is this point which calls especially for the consideration of British pharmacists. Referring to the account given by the General Medical Council of the intended object of the Pharmacopœia, that it should afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide whereby the nature and composition of substances used in medicine may be ascertained and determined, and to the Pharmacy Act as defining the duties of the pharmacist in regard to the preparations of medicines, it will be seen that, while the Pharmacopœia is intended as a help and guide to both medical men and pharmacists, it is also something more for the pharmacist, and, as Dr. SYMES well points out, is a law which he cannot refuse to obey.

On this ground it is urged that the pharmacist has an inherent right to have a hand in the framing of the Pharmacopœia, which is to be the law by which the exercise of his art is to be controlled. There is unquestionably considerable cogency in this argument, and we think that it is one which should not by any means be lost sight of. But we also think there is another line of argument tending in the same direction, which is at least equally forcible. Taking the avowed object of the Pharmacopœia as above stated by the General Medical Council, and bearing in mind that in virtue of the Medical Act, 1858, it is one of the special duties of that body to cause to be published under its direction a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, etc., it is evident from this, and from what has already been said as to the object of the Pharmacopœia, that this book ought to be in the very highest degree precise and correct; its instructions should be in perfect accord with the nature of the materials to be operated upon and compounded for use as medicine. At least they should be in such accord with the existing state of our knowledge of those materials, and in all other respects the law laid down for governing the practice of the pharmacist should be consistent with general practical experience.

It is only by keeping in view these requirements that the main object of making the Pharmacopœia a guide for the medical profession can really be thoroughly attained. And to ensure such a result it is, we think, one of the most pressing duties of the Medical Council to call to its aid the co-operation of the pharmacist in deciding upon the manner of preparing medicines, since it is by means of his practical skill, guided by experience and sound scientific knowledge, that this part of its work can be efficiently performed, and that it is possible to avoid the dangers and difficulties resulting from the establishment of a law that is not only authoritative in all things, but in some respects erroneous.

It is upon this ground, therefore, that we would mainly urge the propriety, or we might even say the absolute necessity of making the Pharmacopœia Committee comprise practical pharmacists as well as medical men and suitable scientific advisers. The need of assistance of this kind has been demonstrated by the action of the Pharmacopœia Committee in the preparation of the present British Pharmacopœia, and the service rendered by Professor REDWOOD and the late Mr. WARINGTON deserves to be well appreciated, both by the medical profession and by pharmacists. However, those gentlemen acted not as the representatives of pharmacy on the committee, but merely as its agents to supply that pharmaceutical knowledge which the members of the Committee did not possess. The need of such assistance has also been acknowledged by the adoption of the results arrived at by pharmacists in studying particular subjects. It has also been more directly acknowledged by the circulation of proof copies of the Additions to the Pharmacopœia by members of the Medical Council among their pharmaceutical friends for perusal and suggestions. But this was at best but a back door

sort of procedure, which does not sufficiently meet the requirements of the case, and though it affords conclusive evidence that the need of pharmaceutical aid was felt by the Medical Council, that circumstance only augments its unsatisfactory character. Well, therefore, may Dr. SYMES ask the question whether there could not have been found in the United Kingdom a few pharmacists whose skill in their calling and social and scientific position rendered them worthy to sit with physicians in joint authority over so important a matter.

We trust that when the work of revising the Pharmacopœia is again commenced we may be able to speak of that method of obtaining pharmaceutical assistance as having been merely one of a series of progressive steps tending towards the establishment of an organization more fitly adapted to the production of a national pharmacopœia, one in which the pharmaceutical body will be represented as adequately as the medical profession, so that while the standard set up for the nature and composition of medicine may be above question or dispute, the guidance offered to the medical profession may not mislead, and the law to which the compounder of medicine is bound to render obedience may not occasion him inconvenience.

In conclusion, however, we must offer our apology to Dr. SYMES and to the Liverpool Chemists' Association for having to some extent disregarded the fact that the discussion of the paper was postponed to a later meeting, and we rely upon their sense of the importance of the subject to furnish an excuse for the liberty we have taken.

For our part we are rejoiced to see this subject fairly brought forward for discussion, which we hope will not be confined to the meeting room of the Liverpool Chemists' Association, but, on the contrary, be taken part in by all throughout the kingdom who are zealous for the interests of their craft.

THE BENEVOLENT FUND.

MENTION was made at the last meeting of the Council that about five hundred persons who last year subscribed to the Benevolent Fund have not yet subscribed during the present year. We understand that, partly with the object of refreshing the memories of some of these gentlemen, a circular has just been issued by the Secretary, and since he is able to intimate that it is intended to elect seven annuitants on the 18th of December next, thereby raising the number to thirty and the expenditure in annuities to about one thousand pounds annually, we hope that this appeal will meet with a hearty response.

THE NEXT EVENING MEETING.

AN Evening Meeting of the Pharmaceutical Society will be held at 17, Bloomsbury Square, on Wednesday next, November 6th. The papers to be read are entitled—"Some Bismuth Residues," by Dr. E. A. LETTS; "Tincture of Quinine," by Mr. W. MARTINDALE; and "Detection and Estimation of Small Quantities of Alcohol," by Mr. J. C. THRESH. The chair will be taken at half-past eight o'clock precisely.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

THE annual meeting and election of officers of the above Association will be held at 17, Bloomsbury Square, W.C., on Thursday, November 7, at 8 p.m., when Professor ATTFIELD will take the chair.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

October 21st., 22nd., and 23rd., 1878.

Present on each day—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

21*st.*—*Thirteen* candidates were examined. *Five* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cairnie, Robert.....Perth.
Careless, John .....Birmingham.
Duckett, George .....Preston.
Dunlop, Thomas .....Govan.
Ellsum, Wm. Augustine P. ...Hingham.
Hall, John.....Oldham.
Hill, John Rutherford.....Lasswade.
Irving, Thomas Stableforth ...Spalding.

22*nd.*—*Twelve* candidates were examined. *Four* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Kirk, John Johnston .....Kirkcaldy.
Lyon, John Mealmaker .....Dundee.
Lyon, Thomas .....Edinburgh.
Mackay, Alexander .....Aberdeen.
Mansbridge, Mathew Charles...St. Asaph.
Nicol, John Kinninmont.....Leslie.
Rigg, John.....Preston.
Smithson, Thomas Henry .....Bradford.

23*rd.*—*Four* candidates were examined. *Two* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

White, James .....Edinburgh.
Wood, Henry .....Oundle.

MODIFIED EXAMINATION.

23*rd.*—*Two* candidates were examined. *One* failed. The under-mentioned passed, and was declared qualified to be registered as a Chemist and Druggist:—

Walton, John .....Newcastle-on-Tyne.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting was held at the Royal Institution, Thursday evening, October 24, 1878. The President, Mr. T. Fell Abraham, in the chair.

The minutes of the previous meeting were read and confirmed.

Donations to the library were duly acknowledged.

Messrs. George A. Redford and Edgar Humphries were unanimously elected members.

Messrs. George Case, J. H. Ormond and Isaac Fisher were unanimously elected associates.

The following paper was read—

SUGGESTIONS FOR A NEW EDITION OF THE BRITISH PHARMACOPŒIA.

BY CHARLES SYMES, PH.D.

In treating this subject it is desirable to consider, first, the position of the work as it now exists; secondly, the reasons why a new edition is desired; and thirdly, how best this can be accomplished.

Up to the year 1864 (as you will be aware) three Pharmacopœias existed in the United Kingdom as guides and exponents of the manner in which medicines were to

be selected, prepared, prescribed, and dispensed, these being issued from the Colleges of Physicians in London, Edinburgh and Dublin respectively.

As facilities and necessities for travelling increased, and prescriptions written under one authority were not unfrequently dispensed under that of another, the evils attendant on such an unsatisfactory state of things became more and more apparent. The possibilities of a prescription written in England, containing a 2 per cent. solution of hydrocyanic acid, being dispensed in Scotland with one double that strength, and other anomalies of an almost equally serious nature, ultimately brought matters to a climax, resulting in the publication of the first British Pharmacopœia by the Council of Medical Education and Registration of the United Kingdom.

For the production of this volume some difficulties had to be overcome in reconciling the different usages in the three countries. These difficulties, however, appear to have been considerably magnified for want of efficient organization, and when the book, which was to be a guide to the physician and a law to the pharmacist, did appear we found that it largely failed to accomplish its object. A step, it is true, had been made in the right direction, but it had freed us from one set of difficulties only to plunge us into another even more serious, for its dictates were not only authoritative but erroneous. There were some exponents, many critics, and, if my memory serves me correctly, amongst the most severe of these was Redwood. Very telling, however, were the remarks of Attfield in the last lecture of a series on the Pharmacopœia.* "A review of the six lectures which have been delivered before you by request of your council, and of the criticisms which have been published by the various medical, chemical, and pharmaceutical journals, must be quite sufficient to show that while the materia medica portion of the book is, on the whole, a success, that which relates to the preparations and compounds is to an equal extent a failure. Nor is this result astonishing when we remember that the British Pharmacopœia for the most part has been constructed by physicians, gentlemen whose path of duty is the bedside of the sick, not the pharmaceutical laboratory. The physician best knows what natural and artificial medicinal agents are admissible into the materia medica, but the pharmaceutist best knows how these materials are to be prepared and compounded. It is as irrational to delegate the compilation of a pharmacopœia to one class only as to the other."

The dissatisfaction was not confined to pharmacists; medical men, and medical journals generally, participated therein, which soon brought its short reign to a close.

In 1867 a new edition appeared, also published by the Medical Council, but prepared by Dr. Redwood and Mr. Warington (chiefly the former), under the direction of a Medical Committee. What a change had the work undergone; it was received with general favour, and we felt that the severe criticisms to which its predecessor had been subjected had not been without some beneficial effect. Here medical talent and pharmaceutical skill had been blended, resulting in the most satisfactory book of the kind that had been produced in the United Kingdom; we found evidence of care and thought on almost every page, and there was a general desire amongst pharmacists to follow its dictates. Twenty thousand copies were published, and of these eighteen thousand were sold; a reprint was ordered in about two years, during which time discussions, explanations, and some criticisms had been made concerning its contents, some errors had been pointed out, but chiefly of a typographical nature, which could be corrected in a reprint. At this period both professors and practical pharmacists seem to have taken a special interest in the Pharmacopœia: amongst those who took a prominent part in papers, discussions, etc., might be mentioned Redwood, Bentley, Attfield, Wood, Haselden, Carteighe, Martindale and others; these referred not only to the work then of recent date, but suggestions were freely offered for a new edition when required.

In 1874 a further reprint of the Pharmacopœia being issued, it was thought desirable to add certain new and revived remedies, hence the 'Additions' were published both in a combined and separate volume, which latter, though only a small book of twenty-four pages, called forth an amount of criticism which one would scarcely have expected on a less pretentious work than the 'Encyclopædia Britannica.' The original volume though not faultless had won for itself an amount of esteem which might be best judged of from the following quotation from the *Lancet* of a slightly earlier date (March 21, 1874): "It will be seen that there is at least a promise of some valuable matter in these additions to our national Pharmacopœia, and if the practical knowledge and judgment displayed in preparing the previously published part of the work have been equally exercised in this, the profession will be indebted to the Medical Council and to the Pharmacopœia Committee for their labours in this direction." That these anticipations were not realized will be remembered by all who took part in or read the papers and discussions which followed its publication; Umney, Carteighe, Bland, Williams, Martindale and others in London, also many of us in the provinces, soon arrived at the conclusion that this recent production was an almost entire failure; whether such conclusions were too hastily arrived at, or whether the defects were less than they were at first assumed to be, sufficient time has now elapsed for proof.

This then, as a whole, the 1867 publication with 1874 additions, is the book which constitutes our national Pharmacopœia, possessing not only its self-constituted authority, but whose dictates are rendered imperative by Act of Parliament.

What has already been said will to some extent be suggestive of the second part of my subject, viz., the reason why a new edition is desired. Prior to the year 1864 no pharmacopœia had been published in the United Kingdom for thirteen years (and this was felt to be too long); for reasons already stated this was soon replaced by the Pharmacopœia of 1867, on the completion of which the Committee handed in their report, concluding thus: "The Committee feel that it will not be thought inconsistent with their duty to indicate the plan which seems desirable for watching over the progress of pharmacy and for making such additions and corrections as would facilitate hereafter the preparation of the next edition of the British Pharmacopœia. They would therefore suggest that a committee like the present should be appointed for the purpose just indicated, and that the sum of £50 be placed annually at their disposal to enable them to obtain such assistance as they might think necessary."

This was agreed to, and we must all regard it as a very wise course, except, perhaps, the constitution of the committee. In six years medicine and pharmacy, like other branches of science, had made such progress that it was thought desirable to publish certain additions, and in communicating this fact to a pharmaceutical meeting Professor Redwood said, "It was generally considered and recognized that ten years was about the time that a pharmacopœia should be allowed to remain in circulation before it was materially and generally altered, and therefore it was proposed merely to issue now a supplement or appendix with the reprint."

A month later the Editor of the *Pharmaceutical Journal* remarks,* "Therapeutical remedies are multiplying in such a ratio as to make the interval of ten years between successive editions of the Pharmacopœia far too long for the scientific pretensions or practical usefulness of that work."

* *Pharm. Journ.* [2], vol. vi., p. 14.

* Vol. iii., p. 705.

From these extracts it will be seen that ten years was then considered a full and ripe age for a pharmacopœia, and that such a period would be to it as the proverbial three score and ten to its authors and the rest of mankind.

The fifth decennial revision of the United States Pharmacopœia is now in circulation and in 1880 the National Convention will meet for a further revision and to appoint a committee for carrying this into effect. The British Pharmacopœia has already existed eleven and a half years, and if the work of revision and addition be thoroughly and efficiently carried out it is not too soon to commence at once for a new edition in 1880. Doubtless the work will be rendered more easy from the accumulation of facts under the grant "for watching over the progress of pharmacy," which must now amount to over £500. Much as this expenditure commends itself to us all, you will, I am sure, agree with me that it is a pity such an amount of information should be longer kept, as the talent of old, wrapped in a napkin. We are daily dispensing drugs and chemicals for which there is no recognized standard of quality or purity, preparations for which there are no legally recognized formulæ, and under such conditions, gentlemen, there can be no necessity for an apology in appearing before you this evening to advocate a new edition of the British Pharmacopœia.

In entering on the third division of the subject, let me say, it is always easier to criticize than to produce a work above criticism, to point out an error than to correct it; still the remarks and suggestions I am about to offer may prove useful in opening up the subject for discussion and thus assist in bringing about some satisfactory results.

The remarks already quoted from Attfield, those of Smith, Carteighe, Umney, Hampson, Greenish and others, as well as the opinions expressed during the friendly intercourse in which many of us in Liverpool and elsewhere have recently participated with Professor Markoe, of Boston, U.S., all point to the fact that the committee of publication might with advantage be somewhat differently constituted. The Pharmacopœia is, as I have said, a *guide* and *help* to the physician, but to the pharmacist a *law*; and it has been well said that we possess an inherent right to have a hand in passing this law which we are expected to obey. That the medical profession fully recognizes the *usefulness* of such a constitution is evident from the following:*—

"Many of the objections urged by Mr. Umney seem to indicate the necessity of giving greater prominence to the element of practical pharmacy in the Pharmacopœia Committee of the Medical Council. This has long been done in other countries, and the adoption of such a course would certainly be advantageous here; for though it is true that the decision as to the medicines to be comprised in the Pharmacopœia must always remain with those who have to prescribe their use, still questions as to the best means of preparing them for various purposes call greatly for the aid of the practical pharmacist, who being daily occupied in such work is enabled to bring to bear the results of his experience so as to advantageously promote the objects of the physician. If this were properly done we should then, perhaps, hear less of complaints that officinal formulæ were inferior to other methods of preparation. The material services which Professor Redwood has already rendered in this direction may, perhaps, not without advantage be supplemented by the aid of other pharmacists."

In nearly all continental countries, as well as in the United States, the Pharmacopœia is the production of the combined talent and skill of medicine and pharmacy; this has been arrived at as the result of experience and, I may say, necessity. It might be argued that in this country also the present Pharmacopœia is largely the work of a pharmacist; this I admit; a man whose talent no one will call in question and who is respected by us all, but he was not a member of the committee, and although constituting an important element in pharmaceutical representation, viz., the *science*, he cannot be regarded as embracing the *practice* of pharmacy, his experience in this respect dating back many years. It is the personal experience of to-day that must be brought to bear for the requirements of the present moment, and I venture to assert that if this other element (by no means the least important) had properly existed in the production of the present volume it would have been more perfect than it is.

We have been told that proof copies were distributed amongst members of the Medical Council for perusal by their pharmaceutical friends, but surely this was a most unsatisfactory way of conducting official business. Could there not have been found in the United Kingdom a few pharmacists whose skill in their calling and social and scientific position rendered them worthy to sit with physicians in joint authority over so important a matter?

The committee consisted of five physicians, well known as eminent and scientific men; but how many of these were engaged in active every day practice, so as to enable them to anticipate the wants of the profession generally, or to instruct the pharmacist how best those wants were to be supplied? This one thing is certain that before our Pharmacopœia will be able to lay claim to approaching perfection, its publishing committee must be constituted on a broader basis, so as thoroughly to represent the requirements of the practising physician and the practical pharmacist.

The arrangement of matter in the work has as far as I am aware given general satisfaction. The nomenclature, however, has largely ceased to be that used in modern chemical teaching, and therefore requires revision. This subject is well treated by Attfield,* who advocates that the compounds of the alkali metals and alkali earth metals, instead of being named as hitherto on two systems, should follow one only; that instead of salts of potassium and potash we should have salts of potassium only; instead of sodium and soda compounds, sodium only, and so with the preparations of lithium, calcium, magnesium, and aluminum. He points out also the desirability of abolishing the old chemical notation and the adoption only of the new atomic weights with unitary hypothesis, as being the most rational and least likely to change with any altered theory.

The system of weights, or manner of expressing quantities, also demands further consideration now that such facilities for international communication exist and are breaking down the narrow border lines of exclusiveness; and that a scheme has been set on foot for an universal pharmacopœia. Whether this latter be or be not realized, it is certain that our efforts should point in this direction; on the present occasion I would suggest that the quantities be expressed as at present and also in the decimal system in parallel columns; or what would be still better perhaps, that parts only be used, solids by weight, liquids by measure, as in Squire's 'Companion.' This subject has been ably treated by Redwood.†

The posology was attacked by the late Dr. Anstie in the *Practitioner*, and has been treated with some amount of contempt by certain other medical men, but I presume it was never intended that the Pharmacopœia should indicate the utmost limit of heroic doses, but rather to give the average adult dose used in general practice, and this it does fairly well.

We now come to what still more deeply concerns us as practical pharmacists, viz., the errors and omissions to be corrected, and the drugs, chemicals, and preparations it is desirable to introduce in a new edition. I have neither time nor disposition to be hypercritical, and will therefore confine my remarks on the present occasion to a few instances which occur readily to my mind, most of which have been noted from time to time at the London

* *Brit. Med. Journ.*, April, 1874.

* *Pharm. Journ.*, 3rd series, vol. i.

† *Pharm. Journ.*, vol. 2, p. 461, 3rd series.

and provincial meetings or in the journals devoted to pharmacy.

Powders, fine powders, and *coarse powders*, are all mentioned in the Pharmacopœia, the exact meaning of these terms being left to the judgment of the operator; it would be an advantage to adopt the description given in the U.S. Pharmacopœia, which is as follows :—

Powders passing through a sieve of 80 meshes to the inch, very fine.

Powders passing through a sieve of 60 meshes to the inch, fine.

Powders passing through a sieve of 50 meshes to the inch, moderately fine.

Powders passing through a sieve of 40 meshes to the inch, moderately coarse.

Powders passing through a sieve of 20 meshes to the inch, coarse.

Acidum Sulphurosum of the strength now indicated can be prepared, but is never found in commerce, as it will not keep for any length of time. A weaker acid, say 5 or 6 per cent., is more easily prepared, keeps well, and is therefore more reliable.

Acidum Nitrohydrochloricum Dilutum.—It has been shown that allowing the strong mixed acids to stand twenty-four hours before dilution is quite unnecessary; if the acid diluted on mixing is exposed to a good light for a few days or a week, the same chemical changes occur, the results are more constant and the product better answers the tests of the Pharmacopœia, which, however, as regards saturating power are incorrect.

Liquor Magnesiæ Carbonatis.—This solution, when freshly prepared, varies in strength according to the amount of pressure used. The test indicates about 12 instead of 13 grs. to the ounce as stated; but even this is too strong to keep well, and might be with advantage replaced by a weaker preparation, say 10 grs. to the ounce.

Liquor Epispasticus (blistering fluid).—This, prepared according to the B.P. directions, does not blister, a fact which has caused much disappointment to medical men, as well as inconvenience and annoyance to pharmacists. If prepared with glacial acetic acid or acetic ether, satisfactory results are obtained.

Extractum Ergotæ Liquidum.—It has been shown that treatment of the ergot with ether is superfluous, and the use of heat as directed is prejudicial; we trust, therefore, in a future edition these will be omitted.

Linimentum Terebinthinæ Aceticum.—This, liniment separates, and can be better prepared by the substitution of strong glacial acid in smaller quantity, or by the addition of a little castor oil.

Acetum Scillæ.—The addition of spirit is unnecessary for its preservation and causes it to deposit. In a future edition its omission will be an improvement.

Oxymel Scillæ.—The preparation of this according to the directions now given is exceedingly troublesome; it would be an improvement to go back to the P. L. formula, or to adopt some more satisfactory modification of it than that now officinal.

Linimentum Saponis.—This is still an unsatisfactory preparation, the amount of soap dissolved varying with the amount of moisture present in the sample used. Better results may be obtained by using a smaller quantity of soap in coarse powder, and altering slightly the proportions of spirit and water. I would suggest the following formula as giving satisfactory results :—

Hard Soap	8
Camphor	5
Oil of Rosemary	1·5
Rectified Spirit	68
Distilled Water	12

Suppositoria.—With such an excellent basis as oil of theobroma at our disposal it is difficult to understand why lard and wax are introduced into these; it has been demonstrated over and over again that for ordinary suppositories such as those of the Pharmacopœia, cacao butter alone is by far the best basis.

Extractum Cinchonæ Flavæ Liquidum.—The process for preparing this is an extremely wasteful one, fully one-half of the alkaloids present being left in the bark, rendering the preparation when finished less than half the strength it should be, *i.e.* if we were to assume that it represents the amount of bark used. The subject was well treated in an excellent paper on the Cinchona Preparations, by Mr. Ekin, read at the recent Conference meeting.

Unguentum Belladonnæ.—This should be prepared with alcoholic extract, which though not officinal might and should be made so; it is practically recognized in belladonna plaster (prepared in a somewhat extemporaneous manner). Why it should be suited to this and not to the ointment is not quite clear.

Injectio Morphiæ Hypodermica.—The process for this is a nice little operation but is tedious when the product is urgently required; it keeps very little better and is more liable to vary in strength and acidity than if prepared by the direct solution of the acetate. This might with advantage be altered to a ten per cent. solution.

Oleum Phosphoratum.—Heating the oil to 300° F. is, with the average samples, quite unnecessary, and it appears to have been directed to remedy an imaginary evil. It might with advantage be made a one per cent. solution.

Pulvis Glycyrrhizæ Compositus.—This was introduced in imitation of the Prussian compound liquorice powder, from which it differs materially; it is the mere ghost of the original preparation and medical men as a rule do not prescribe it. My experience is that we dispense at least fifty pounds of that according to the Prussian to one ounce of that according to the British Pharmacopœia.

Pilula Phosphori.—When this formula was introduced phosphorus pills were not so much used as in the present day. Experience has shown that prepared according to the B. P., they pass through the system undissolved, but that the addition of a little soap at the time of dispensing will to some extent correct this defect.

Tinctura Aurantii Recentis.—Tincture of orange peel is more largely prescribed than any other flavouring agent; that prepared from the fresh peel has frequently been advocated, and amongst others by myself.* I published my formula and reasons for adopting it after twelve years' experience. Why rectified spirit only was used in the Pharmacopœia formula I am at a loss to understand; but the fact proves to my mind most conclusively that the publishing committee did not give a single thought to this subject, for they as medical men would know that the process they adopt for hardening and rendering impenetrable organic tissues is maceration in rectified spirit or alcohol, and they would readily have seen the object of first treating the peel with water as in the process referred to.

This paper has already grown to a greater length than I had intended, in conclusion, therefore, it will suffice to enumerate, without comment on each, some of the additions which occur to my mind as desirable in the suggested new edition.

Gelsemium Sempervirens.
Tinct. Gelsemii.
Ext. Belladonnæ Alcoholic.
Butyl Chloral (Croton Chloral).
Iodoform.
Acid. Chrysophanic.
Hydrargyri Oleas.
Decoct. Cinchonæ Acidum.
Acid. Hydrobromic.
Vaseline, Unguent. Petrolei or Ozokerine.
Ferrum Dialysatum.
Syrup of Hypophosphites.
Salicin.
Rhamnus Frangula.
Decoct. Rhamni Frang.
Tinct. Colocynthidis.
Acid. Boracic.
Acid. Salicylic.
Sodæ Salicylas.
Eucalyptus Globulus.
Eucalyptus Rostrata.
Syr. Ferri Phosph. Comp.
Syrup Ferri et Quiniæ et Strychniæ Phosph.

This list could be lengthened, but abundant opportunity will doubtless be offered for suggestion before a new

* *Pharm. Journ.*, November 16, 1872, p. 381.

edition is issued, and I trust that the formulæ proposed to be altered or introduced will be brought prominently forward for discussion before being made officinal.

A short discussion followed the reading of the paper.

Mr. A. E. Tanner moved that the discussion be adjourned to November 21st. The motion was seconded by Mr. A. H. Mason, F.C.S., and carried unanimously.

A vote of thanks moved by Mr. Michael Conroy, F.C.S., seconded by Mr. Edward Davies, F.C.S., to the author for his able paper closed the meeting.

Dispensing Memoranda.

[153]. Lin. Æruginis.—I observe in "Notes" for last month, September, that attention is directed to a letter of Mr. Edwin J. Quekett, so far back as 1845, in which he states that the deposit thrown down after lin. æruginis has been kept for some time, is finely divided copper.

I have the letter now before me, and through the kindness of a friend I obtained a good specimen of deposit from a long kept liniment. I enclose you a dried sample and wish you to hand it over to be examined by some of the laboratory pupils. I find it to consist of sub-oxide in part, but it also, as Mr. Quekett states, is finely divided copper. The whole subject is one for careful study. Thanks to "Memoranda."

If any one specially desires to study the question, I will send him, post free, a sample of the deposit mixed with pollen, etc.

Northallerton. Hy. Brown.

P.S.—The deposit enclosed was washed for three days, so as to remove all the honey, etc., in a beaker, and the water used was pure rain water, close upon the boiling point. The deposit was washed upwards of twenty times. As a microscopist, I may state that neither Mr. Quekett, I, nor anybody could tell suboxide of copper from finely divided copper under the microscope.

H. B.

---

[165]. "Major" asks concerning "lapis divinus." It has been for a long time out of use.

So far as I can trace the formula it was thus prepared: ℞ Æruginis, Nitri puri, Aluminis, āā ℥iij. These are to be reduced to powder and then heated in an earthen crucible, and when the mass is liquefied, ℥j. of camphor is added and the whole stirred well, and then poured upon a slab. It should be kept in closely stoppered bottles.

From x. to xx. grs. are dissolved in half-an-ounce of distilled water, strained if necessary, and ℥j. to ℥ij. vin. opii added, and then ℥iv. aq. rosæ. This formed the once celebrated eye wash or collyrium.

I may state Pereira gives sulphate of copper instead of æruginis or acetate.

Northallerton. Hy. Brown.

---

[172]. The questions involved in the queries under the above number will well repay your readers for a little extra attention to them, inasmuch as the writer of "The Month" states that the Epsom salt is not soluble in the quantity of the fluid ordered (p. 327). I, however, state that it is (p. 336). I need not say I find I am right; but the solution gelatinizes at a temperature a few degrees below 60° F., and practically it is impossible to make a solution which will remain liquid without the addition of one fluid drachm of water or infusion extra. I am surprised that the latest work on chemistry, Dr. Tidy's, should give the following—"Magnesic sulphate,—it is soluble in water (1 in 3 aq.), at 60° F., and 1 in 1·5 at 212° F." Does Dr. Tidy mean the dried salt or the ordinary Epsom salt of the shops? I have been at some pains to elucidate the point. I can with the greatest ease and certainty dissolve ℥ij magnes. sulph. in ℥ij. infus. gent. co. without adding the ℥j. of tinct. sennæ. As I stated magnes. sulph. is insoluble in alcohol (absolute), but the addition of the tinct. sennæ would be no barrier but a slight advantage to the effective solution of the salt as it is made from proof spirit. The mode of dispensing such a draught should be to make up to five or six drachms with water, and send out in bottles singly, or a nine-ounce mixture might be made and the bottle marked so as to indicate twelve doses. It would never do to send out a draught which would not remain fluid. If necessary, an explanation should be given. I am not in favour of such concentrated doses.

The second query is to be answered in the same way, but there is only one draught. It should have been sent out as an ounce draught. I have gone to the trouble of making the draughts and testing the solubility of Epsom salt and have referred to Thomson, Neligan, Christison, Royle, Squire, Tidy (who is wrong), Fownes, and Muter, and I find these authorities state that ordinary Epsom salt is soluble in its own weight of water at 60° F. The solution is still more easily effected at 80° F., and, on cooling, no separation of crystals takes place. I am inclined to look upon such queries as those of W. S. with more than ordinary interest. Squire gives the solubility of Epsom salt as 10 to 13 of water, increasing the bulk to 18, which I have found correct, but the specimen which I have is soluble in its own weight of water at 60° F.

I hope the junior readers of the Journal will profit by the perusal of the "Memoranda," and carefully weigh the information conveyed, which is, I may say, information, to be nowhere else obtained.

Northallerton, October 26, 1878. Hy. Brown.

---

[172]. I should put the first in a ℥xij. bottle and label, "One tablespoonful for a dose." As to the second, W. S. had no right to deviate from the prescription.

Alpha.

---

[172]. The five friends who have kindly assayed to help me in my difficulty have surely forgotten Josh Billing's advice, "Nevver provisy till you kno," and Mr. Henry Brown has apparently had so much to write this week as to overlook the fact that his first two assertions contradict his third, that "W. S. had plenty of scope for making the solution." Mr. Brown also says, "Sulphate of magnesia is easily dissolved in its own weight of water at 60° F." May I ask has Mr. Brown ever done it? I do not ask if he has read that it can be done.

W. S.

---

[173]. This mixture, containing solution of bismuth, hydrobromic acid, quinine sulphate and potassium iodide, is an interesting one. By combining the bismuth with the iodide of potassium in the presence of a free acid, the prescriber has unconsciously ordered an excellent precipitant for the majority of the alkaloids. This precipitant, the double iodide of bismuth and potassium, originated by Dragendorff, who gives a somewhat tedious process for preparing it, may now be made in a minute by dissolving iodide of potassium in solution of bismuth. On adding it to a solution of quinine, as in the mixture above, an abundant bright orange-coloured flocculent precipitate is produced. This precipitate is no doubt identical with the new double iodide brought under the notice of the British Pharmaceutical Conference by Mr. Fletcher. I find that besides being soluble in an alcoholic solution of iodide of potassium it is also more or less soluble in excess of solution of bismuth and completely soluble in glycerine, forming a colourless transparent solution. The iodide of bismuth and atropia is of a dirty brick-red colour and is also completely soluble in glycerine, which substance I believe will be found to be a solvent for most of the alkaloidal salts precipitated by this reagent. Of course no amount of manipulation will

prevent the formation of the precipitate in the mixture in question, and as the mixture is a very unsightly one it would be desirable to show it to the prescriber, who would no doubt see the necessity of omitting one of the above-mentioned ingredients.

TH. GREEN.

---

[173]. Referring to Mr. H. Brown's remarks on this Dispensing Memorandum, perhaps that gentleman will be kind enough to state what dose of quinine etc., the patient would be taking after the mixture had been strained through tow; for if strained until a clear solution is obtained you get no bitter taste whatever. I maintain that whoever dispenses that mixture has no right to strain it, but should send it out as it is with a "shake the bottle" label. If a medical man orders such an incompatible mixture that is his look-out; surely we chemists are not to take upon ourselves the responsibility of entirely altering mixtures after they have been ordered by a qualified man who is supposed to know what are the incompatibles. I think the gentleman who prescribed this really did not know it was incompatible.

Mr. Henry Brown may be very well up in dispensing, but I for one should not take his advice and strain this said mixture.

A. P. S.

---

[175]. PIL. CAMPHORÆ.—*Erratum.*—In the answer of "Minor" to this question, before, p. 336, *for* "a grain pill" *read* "a 5 grain pill."

---

[179]. I should certainly use the carbonate.

ALPHA.

---

[180]. Option of the dispenser; about gr. j. pills, I should say.

ALPHA.

---

[184]. In reply to "Πειθου εμου," the prescription, which was in all probability written by a French physician, should be dispensed as follows:—

℞ Cerat. Saturn . . . . 30 grammes = ℥j.
(*i.e.*, Ung. Plumbi Subacet. Co.)
Calomelanas . . . . 5 grammes = 75 grains.
Quinquinæ Pulv. . . 4 grammes = ʒj.
(*i.e.*, Cort. Cinchon. Flav. Pulv.)
Camphoræ. . . . . 1 gramme = 15 grains.

M. Fiat Unguentum.

CHAS. STOCKS.

---

[184]. In answer to "Πειθου εμου," I have often dispensed similar prescriptions, and have no doubt in stating that grammes were intended. Cerat. saturnat. is a preparation of the French 'Codex,' and consists of cold cream with 10 per cent. of liq. plumb. subacet. It may be prepared in the same manner as ung. gallæ. Speaking of extraordinary ointments, I give you a copy of a prescription for an ointment which I had to dispense the other day:—

℞ Calomel	3	grammes.
Precip. per se	0·10	„
Acid Salicylic	1	„
Chloral Hydrate	4	„
Pulv. Camph.	2	„
Vaseline	30	„

M. Ft. ong.

Brussels. PHARMACIEN.

---

[184]. In answer to 184, I would dispense the ointment in grains instead of grams. Cerat. saturnat. is the same as the B.P. ung. plumbi subacet., only half the lead being used. Quinquina is simply pulv. cort. cinchon. flav.

ROBERT MCALLEY.

---

[184].

℞ Cerat. Saturnat. { Cérat Saturné, Codex. / Plumbi Subacet, 1 part. / Cérat de Galien, 9 parts. } 30 grams or ℥j nearly.

Calomelas . . . . . 5 grams or ℥j 15 grains
Quinquina Pulv. (Pulv. Cinchonæ) . . . . . 4 „ „ ℥j.
Camphora . . . . . 1 gram „ 15 grains.

M. s. a. Ft. ung.

The "Cérat de Galien" is prepared as follows:—

Ol. Amygd. Dulc.	4·00.
Ceræ Albæ	1·00.
Aq. Rosæ	3·00.

M. s. a.

S. B.

---

[186]. In reply to the query of H. K., I should have dissolved the borax in boiling water and filter when cool; on no account would I add glycerine.

ROBERT MCALLEY.

---

[186]. In reply to H. K., no dispenser would be justified in my opinion, in "adding" to a prescription, without previously consulting the prescriber. I see no occasion either to attach a "shake the bottle" label.

Has H. K. tried dissolving the sodæ bibor. in hot water and straining? By this means less of the salt will be deposited than if dissolved in the cold. I have tried this myself and find it answers well.

C. STOCKS.

---

[186]. The solubility of borax in cold water is 1 in 22, the borax (ʒss) should therefore be rubbed up with cold water (ad ℥ 8) and sent out with a "shake the bottle" label. H. K. would not be justified in adding glycerine, nor any solvents unless ordered in the prescription.

SUB UMBRA FLORESCO.

---

[187]. I usually fill a one ounce pot with "Ung. hydrargyri," when ordered, and I believe most dispensers do the same.

C. S.

---

[187]. In dispensing ung. hyd. ℥ it is customary to fill a 1-oz. bottle or pot.

ROBERT MCALLEY.

---

[188]. I wish to ask how the following prescription should be dispensed. It was written by a London surgeon, for an infant five months old:—

℞ Potassæ Bicarb.	ʒj.
Vini Ipecacuanhæ	gutt. xx.
Syrup. Simp.	ʒiij.
Magn. Carbon.	℈ j.
Aquæ	℥vj.

M. Ft. mist. Cap. coch. min. 4tis horis.

Communication with the writer of the prescription was not feasible, so I dispensed it with 1½ gr. doses of potassæ bicarbon. Double quantity of the mixture (ʒiss) was ordered and sent out.

T. H. N.

---

[189]. The following when made up at a London firm is quite clear and remains so for two days at least.

℞ Acid Phosph. Dil.		℥ss.
Acid. Hydrobrom., Fothergill's . .		ʒiv.
Sodæ Hypophos., Calcis Hypophos.	āā	ʒj.
Tinct. Nuc. Vom.		ʒj.
Syr. Aurant.		ʒj.
Aquæ		ʒiij.

M.

Would any of your correspondents inform me how it can be made up so as not to deposit? I have tried several plans but without success. G. CORMACK.

[190]. How can the following be dispensed without a deposit?—

℞ Tinct. Nucis Vom . . . . . ℥ss.
Acid. Nitro-Mur. Dil. . . . . ℥ij.
Tinct. Zingiberis. . . . . ℥j.
Aquam . . . . . ad ℥viij.

℥j. t. d. s. post cibos.

I found that after standing twenty-four hours a distinct deposit is formed. A remedy will oblige

MINOR.

[191]. Will any dispenser kindly inform me how the following prescription should be dispensed?—

℞ Acid. Hydrocyan. . . . . ♏viij. (Sch).
Chloroformi . . . . . ℥j.
Aceti Scillæ . . . . . ℥ij.
Tinct. Camph. Co.. . . . . ℥iv.
Syr. Tolut. . . . . ad ℥ij.

M.

Take a teaspoonful every three hours in a wineglassful of water if the cough is troublesome.

STUDENT.

Notes and Queries.

[521]. EAU DE ARQUEBUSADE.—An old Gray's 'Supplement' gives three forms for the above. A form for "arquebusade" as sold by my father for than fifty years is as follows:—

℞ Spt. Rorismarini,
Spt. Origani . . . . . āā ℥viij. M.

Rarely sold. Used as an application to the mammæ to dry up the milk.

Sheerness-on-Sea. JOHN SAFFERY.

[526]. COATING PILLS.—In coating pills with French chalk they should be varnished first, and they always give satisfactory results.

ALPHA.

[532]. QUININE AND IRON TONIC.—I think "Delta" will find the following a good formula for "quinine and iron tonic."

℞ Ferri et Quin. Cit. . . . . ℥ss.

ANIMAL CHEMISTRY; OR THE RELATIONS OF CHEMISTRY TO PHYSIOLOGY AND PATHOLOGY. By CHARLES THOMAS KINGZETT, F.C.S., etc. London: Longmans, Green and Co., 1878. From the Publishers.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

NOTE ON POTASSIUM PERMANGANATE IN WATER ANALYSIS.

Sir,—In a paper which appeared in the *Pharmaceutical Journal*, for Sept. 21, Mr. Stables claims to have discovered that an alkaline solution of potassium permanganate has a much greater oxidizing effect than a simple solution of the same salt. In the absence of any proof of this statement, either in the original paper or in a subsequent communication to the Journal, the following experiments were undertaken with a view to test it.

A sample of water, rich in organic matter, was taken from the river Avon at Bath, filtered, and divided into two parts. To one part was added a solution of $K_2Mn_2O_8$ until the pink colour became persistent, and to the other portion the same solution, in which some pure sodium hydrate was dissolved, was added. The alkaline solution was decolorized much more rapidly than the non-alkaline solution, and to a much greater extent, thus giving *primâ facie* evidence in favour of Mr. Stables's averments. Both waters were allowed to remain some hours until the lime precipitate in No. 2 had subsided. No. 1 retained its pink colour, but in No. 2 the pink had given place to a decided green tint, showing the reduction of $K_2Mn_2O_8$ to K_2MnO_4.

Sodium hydrate was added to the solution of $K_2Mn_2O_8$ used as above and after a short time the deep purple was changed to the characteristic green of the lower salt. It is evident then that it is the free alkali that reduces the $K_2Mu_2O_8$ and not the organic matter in the water.

Varying quantities of alkali were added to the test solution of $K_2Mn_2O_8$, and it was found, as might be expected, that with the smallest proportion the reduction takes place in a ratio exactly equal to the quantity of alkali added. With a slight excess of alkali, as, for instance, the proportion recommended by Mr. Stables, viz., of one grain of $K_2Mn_2O_8$

to 4 grains KHO, the reduction takes place, comparatively speaking, slowly, and when added to a water the green colour of the liquid is so faint as to be likely to escape the attention of a careless observer, and if not allowed to stand long enough is altogether masked by the pink colour of undecomposed $K_2Mn_2O_8$.

To see if any reduction by organic matter took place over and above the conversion of $K_2Mn_2O_8$ into K_2MnO_4, a sample of distilled water, containing a good deal of organic matter, was coloured with permanganate, and the water decanted from time to time from the sediment until MnO_2 ceased to be deposited. The coloured water was then rendered alkaline by sodium hydrate, and put into a 10,000 grain white glass stoppered flask, which flask was put into a window, and on a white ground, so that the least trace of sediment might be easily detected. The pink colour soon became green, but after standing some days it was manifest by the absence of any precipitate that no further reduction had taken place.

Of course, it it is essential that pure alkali be used. The ordinary cake caustic soda and potash, and some samples of the purer kinds made with alcohol, and even in the case of soda made from sodium itself, contain a perceptible quantity of organic matter, which would, of course, invalidate the results.

Mr. Stables speaks of the results obtained by the use of potassium permanganate in the estimation of organic matter as fallacious, but considers that the addition of an alkali obviates the defects of the process.

Instead of this being the case, however, it is evident that so far from remedying the evil it introduces sources of error which are fatal to its use, and in the place of being an improvement it takes away entirely the little reliability that was already left to the original "fallacious" method.

CHARLES EKIN.

In a recent number of the *Pharm. Journ.*,* an article was published bearing on the above subject, in which the writer observes "what is particularly wanted at the present day, and what has yet to be discovered, is a qualitative test which will at once determine whether or not a water is fit for dietetic purposes, and the introduction of such a reagent is the object of the present paper." No one acquainted with the subject will, I venture to think, care to dispute the truth of these observations; the introduction, however, of a universal test, which shall be at once easy of application, and practically safe and reliable in its indications, involves considerations and difficulties which are far from trivial.

Shortly after the publication of the paper alluded to a small quantity of three different waters was handed to me, with the request that I would give an opinion as to which was the most suitable for ordinary domestic use. Until after my report I had no knowledge of the history of either, and they were simply distinguished by the initial letters, A, B, and C. Unfortunately, the quantities placed at my disposal were too small to admit of "nesslerizing," and consequently the decisive information that would have been thus afforded was, I am sorry to say, lost. This is a matter I sincerely regret, for if it had been possible to estimate the free and albuminoid ammonia the anomalous behaviour of samples A and B would probably have been better understood. What was thus wanting, however, was in some measure compensated by the history of the waters as subsequently ascertained, and so far as negative evidence is admissible, I think, but little reasonable doubt could be entertained as to the decision to be arrived at. "Nesslerizing," as previously stated, being impracticable, it was decided to examine first by means of alkaline permanganate solution; secondly, microscopically; thirdly, to ascertain the amount of Cl, and lastly, if possible, the weight of solids per gallon with subsequent incineration of residue. Scarcity of material unfortunately rendered this latter out of the question, most of the following experiments being performed in duplicate. In his paper Mr. Stables gives the somewhat ambiguous direction to employ a test tube full of water; this was interpreted to mean a tube of moderate capacity, containing about half a fluid ounce. Into such a tube was put distilled water, and into three others the waters, A, B, and C; to each a minim of alkaline permanganate was added, and the whole set aside. Four hours afterwards the tubes were examined, when all were found to have more or less precipitated, each, however, retaining a distinct pinkish hue, with the exception of sample B, which was completely decolorized. Under the impression that less permanganate might be advantageously employed, a second series of tubes was set up. Into each, filled as before, was put one minim of a solution half the previous strength, with the unexpected result that sample A in a quarter of an hour became quite colourless, and B only after one and a half hours. The other two tubes some hours afterwards still retained their pink colour. Microscopically examined, B was found to contain living organisms; A and C were devoid of these. Further examination of A revealed the presence of a trace of Fe, samples B and C contained none. The waters were next titrated for Cl by Wanklyn's convenient method with the following results:—

A. 4·8 grains Cl per gallon.
B. 1·1 ,, ,,
C. 1·6 ,, ,,

A consideration of the foregoing readily shows how fallacious would have been an opinion founded alone upon the indications of the alkaline permanganate, for sample A, with its large excess of Cl, would have been readily approved, whilst B, probably a less objectionable water, would have been as unhesitatingly rejected.

As hinted, I am not unmindful of the fact that the non-estimation of the ammonia has left the subject open to the query that the large proportion of Cl found in A might probably be due, not to sewage contamination, but to the presence of NaCl, in which case the water would be of course wholesome, whilst B, which is the purest of the three waters as regards chlorides, and therefore cannot possibly contain sewage, might and probably does contain vegetable organic impurity. Such a supposition is certainly tenable, but the history of the supplies renders it improbable under any circumstances. I think it must be conceded that a test which would pass such a sample of water unchallenged is hardly of that reliable nature that would safely, as Mr. Stables remarks, "enable an ordinary inexperienced person to arrive at the conclusion whether or not a water is fit for human consumption."

The history of the waters proved to be as follows:—

A was from a well situated inside the house, where communication with the drainage had been previously suspected; B was from a well situated out of doors; and C from a similar source which for centuries had been celebrated for its purity over the entire district. It will thus be seen that in the case of A the suspicion of sewage approximates very closely to absolute certainty.

Thus far the test has been considered simply on its own merits, and as to how far capable of yielding in the hands of the inexperienced safe information as to the purity or impurity of a potable water, for this purpose I consider its indications unreliable. Used skilfully, however, and conjointly with other tests, it will doubtless be found to afford useful information. For instance, the ready decoloration as previously mentioned, of the dilute permanganate solution led the writer to suspect the presence of some reducing agent other than organic impurity, and it will be remembered the water referred to was found to contain a trace of iron. Similarly sample C, both with the strong and diluted permanganate responded admirably, and when considered with the other details of examination, leaves but little doubt that the long acquired reputation for purity of this water has a very substantial basis in fact. Whether it be possible by further experiment so to modify the test that it shall answer its ostensible purpose, must be a matter for detailed and careful experiment. Should such be accomplished, I think its value would be greatly enhanced if the introduction were accompanied by tabular statistics, showing how far its indications were in harmony within safe limits of the results obtained by the processes ordinarily employed in water analysis.

GEORGE MASSON, PH.C.

Sir,—Notwithstanding the decided opinion which has been expressed to the contrary in the Journal of the 12th inst., by the author of the paper "On Potassic Permanganate in Water Analysis," I do not find, on examining the method described, that the addition of alkali to the perman-

* *Pharm. Journ.*, Sept. 21, 1878.

ganate influences in any degree the value which is usually attached to the permanganate colour test.

On comparing the alkaline permanganate side by side with the ordinary permanganate test, on waters of known character, it was found that the difference in the degree to which the colour diminished in the two cases was very slight, and was in no way sufficient to warrant a nice distinction between them. The conclusion to be drawn from this result is obvious, when it is stated to "the ordinary inexperienced person" that it is generally accepted by chemists who are conversant with water analysis that the ordinary permanganate colour test is of no absolute value, but is rather an accessory after the fact has been almost proved by other data.

Further evidence to the same conclusion, but obtained under less favourable circumstances, although in the manner described by the author, that is, by employing a small quantity of the water for the test, is given in the following results:—

Unity is expressed in the two columns by ·002 and ·007 per 100,000 respectively.

	Free NH_3.	Organic NH_3.	Alkaline permanganate colour test.
1. Good potable water	1	1	No change in 24 hours.
2. Water unfit for potable purposes	12	1·1	Very slight change in 24 hours.
3. Water unfit for potable purposes	26	2·3	Very slight change in 24 hours.
4. Water unfit for potable purposes	6·5	5·7	No immediate change in colour. Turbidity and partial decrease in tint after half an hour, but sixteen hours elapsed before colour was entirely discharged.
5. Water unfit for potable purposes	1·0	6·0	

These facts speak for themselves. The positive tone adopted by the author in his last letter to the Journal on the subject scarcely requires an apology for advancing this adverse criticism.

106, *Fenchurch Street, E.C.* A. J. Cownley.

Unusual Doses.

Sir,—Now that the subject of large doses is on the *tapis*, I take the opportunity of bringing forward a query which I made some months ago in the "Dispensing Notes" of the *Pharmaceutical Journal* and which has remained hitherto unanswered.

I shall feel obliged if Mr. Henry Brown or any other reader will kindly give his opinion on the subject.

Towards the fall of 1877, at the Cape of Good Hope, a prescription was brought me to be dispensed. To the best of my recollection it ran as follows:—

℞ Ext. Ergotæ Liquid. . . . . ℥j.
Syrupi . . . . . ℥ss.
Aquæ . . . . . ad ℥ij.
M. Sumat ½ statim et reliquam post horas duos, si opus sit.

This was the result following the consultation of two well known physicians of the town. My chief being absent and the medicine being urgently required, I dispensed the prescription, putting one drachm in place of the one ounce of ext. ergotæ liquid. The next day I had a separate interview with each of the physicians, resulting in being commended by one and contemned by the other, who stated that he frequently prescribed doses of the above magnitude.

I may add that my chief on his return cordially agreed with me in my view of the case.

October 15, 1878. A. P. S.

Mr. Henry Brown and Professor Redwood.

Sir,—But for one remark in Mr. Brown's letter to-day comment from me would be unnecessary.

Mr. Brown in his try-to-be facetious reference to the Quaker spirit of our town invokes your sympathy in his behalf by making out that I have been uncourteous to yourself. If, sir, you feel that I have in the least lacked courtesy towards you, in the presence of your readers I humbly tender you my apology.

As for Mr. Brown's complaint of my want of courtesy towards himself, all I can say is "Those who live in glass houses should not throw stones."

I may add in reference to my statement that letters like Mr. Brown's are "wholly unjustifiable," judging from the congratulatory communications upon my letter of last week which I have received from entire strangers, others of your readers are of the same way of thinking as myself. However the propriety or impropriety of such letters cannot be left to a better authority than, as suggested by Mr. Brown, yourself.

Darlington. Jas. Swenden.

Tolerance of Morphia.

Sir,—Allow me to furnish another case of the tolerance of large doses of morphiæ hydrochloras. A gentleman whom I have known for some years to be in the habit of taking it for chronic dysentery has at last reached the extraordinary dose of eighteen grains daily. I have seen him take this quantity dissolved in a wineglassful of warm water on several occasions. He has also remained conversing with me in the shop for half an hour or so afterwards, and I have watched his gait in the street for an hour or two later on, and he has exhibited no trace of the usual symptoms of opium poisoning. He tells me that it tends to regulate his bowels and to produce healthy motions, but it certainly has no visible effect upon him whatever.

The Sale of Patent Medicines at Reduced Prices.—X. Y. Z. forwards a cutting from a provincial newspaper in which patent medicines are advertised as being sold at a particular establishment at a large reduction on the usual charges, for which he requests publication. He suggests that a petition should be got up and sent to Parliament as soon as possible, proposing the increase of the patent medicine licence from five shillings to twenty shillings a year, and that it should be restricted to chemists only. We fear that the facts disclosed in the advertisement are only too familiar to the readers of this Journal, and that the remedy would hardly prove equal to the removal of the evil.

T. Stokoe.—We see no reason to doubt that the business of extracting teeth would be held to be dentistry within the meaning of the new Act.

J. S. Whyte.—We believe copies of the pamphlet may be obtained from Mr. Kimpton, Bookseller, Holborn, London.

J. W. Hayton.—You are recommended to communicate with the Secretary and have his advice upon the subject.

R. J. Shields.—If such absurdities are at all worth contradicting it would be only in the columns of the journal in which they appear.

SATURDAY, NOVEMBER 9, 1878.

PROSECUTION UNDER THE APOTHECARIES ACT.

So far as regards the decision of the question as to the right of the chemist and druggist to prescribe across his counter, the case that has just been tried is almost as unsatisfactory as that of WIGGINS. The verdict given for the defendant relieves him from the penalty for infringing the 20th section of the Act, inasmuch as the jury considered that he had not, in the particular cases he was prosecuted for, acted as an apothecary; but it left altogether, as it seems, out of consideration the more important question, whether in virtue of usage prior to the Apothecaries Act, 1815, the chemist and druggist has a right to act as an apothecary in the treatment of minor ailments, and the administration of simple remedies for their relief.

This however, we apprehend, is the right which many chemists and druggists contend for, and it is only by the decision of this point that the matter can be finally disposed of. This was, in fact, the point to which the Lord Chief Baron's attention was drawn, when the appeal case was brought before the court, and it was with the view of affording opportunity for producing evidence as to what was the habitual practice of chemists and druggists before the passing of the Apothecaries Act, that an order was made for a new trial.

At that time it seemed probable that much would depend upon the evidence to be produced in regard to the usage before 1815, for the Lord Chief Baron stated that the defendant could not be held liable if it could be shown that in doing something more than compound, dispense and vend medicines across the counter, he was within the privilege of the chemist and druggist, though acting as an apothecary, in the one case as well as the other. This view, however, does not appear to have been entertained to anything like the same extent in the trial that has just been concluded, and the illustrations given by Sir HENRY JAMES of the "exercise of discretion" by chemists and druggists in dispensing and vending drugs and medicines, which he claimed as being within their privilege were not of such a nature as to comprise any action that would be complained of as an infringement of the Apothecaries Act.

For instance, in the case of an application to a chemist and druggist for a tonic, and still more so in the case of asking for a black draught, Sir HENRY JAMES contended for nothing more on behalf of chemists and druggists than the right to exercise for the benefit of their customers that knowledge of the qualities and efficacy of drugs which every chemist and druggist necessarily posseses. To ask whether the medicine be required for a child or for an adult, and to regulate the dose accordingly, requires no exercise of medical skill, and it cannot with any reason be termed practising medicine. Nor do we think such ordinary "exercise of discretion" would come up to the level of that "counter practice" which Mr. UPTON affirmed he would not authorize the prosecution of in the correspondence which took place between him and the Solicitor of the Pharmaceutical Society at the commencement of this year.

Notwithstanding the favourable verdict, therefore, we are disposed to think that little progress has been made towards a settlement of the real question at issue between medical practitioners and chemists and druggists in regard to counter practice, viz., how far the chemist and druggist can by right or by compromise act as an apothecary in prescribing medicine for the relief of bodily ailments. We are not surprised that in the particular instance with which the jury had to deal in this trial, and with the evidence before them, they should come to the conclusion that in looking at Mr. DEATH'S throat, telling him he had not much the matter, and giving him a saline mixture, the defendant did not act as an apothecary within the meaning of the Act, or in such a manner as that Act was designed to prevent.

There are so many occasions when persons require or desire to have recourse to the use of medicine under circumstances which do not justify their seeking medical advice, that the chemist and druggist is almost necessarily called upon frequently, as a person conversant with the nature and use of drugs, to recommend or to prescribe the medicine suitable. That he should in such cases supply an aperient pill, a black draught, a tonic, or some one of the many compounds whose medicinal action is familiar to most people, is we think but a natural exercise of the knowledge he possesses, and this counter practice is in many instances a vast convenience to the public. To endeavour to put a stop to this practice, even though it be strictly within the prohibition of the Apothecaries Act, would be, as Baron BRAMWELL well said, an unreasonable exercise of power, and the assurance given by Mr. UPTON seems to show that this view is adopted by the Apothecaries' Society. The Council of the Pharmaceutical Society has, however, declared itself prepared to consider the case of any chemist and druggist threatened with such vexatious proceedings, and if circumstances warranted to defend him On a subsequent occasion the Council passed a resolution authorizing its Solicitor at his discretion, and at the expense of the Society, to defend such a case of threatened prosecution by the Apothecaries' Society. But it would be wrong to disguise the fact that counter practice sometimes exceeds reasonable limits, and if we may judge from some of the accessory if not direct evidence given in the late trial, it would seem that the Apothecaries' Society in authorizing the prosecution had reason for thinking those limits had been exceeded. Mr. SHEPPERLEY'S evidence as to the recent alteration in the mode of conducting his business seems to point in this direction, and the pamphlet issued by him with the title, 'Every Man his own Doctor,' for the purpose of recommending specific remedies, lends further support to such a possible construction of his former practice.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, November 6, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Frazer, Gostling, Greenish, Hampson, Hills, Mackay, Robbins, Sandford, Schacht, Shaw and Woolley.

The minutes of the previous meeting were read and confirmed.

Diplomas to Pharmaceutical Chemists.

The following being duly registered as Pharmaceutical Chemists were respectively granted a Diploma stamped with the Seal of the Society:—

Allen, Henry.
Aston, Walter.
Hobbs, Thomas Henry Hurle.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Aston, Walter .....Tarporley.
Hobbs, Thomas Henry H. .....London.

Chemists and Druggists.

Adams, Thomas Edwin ..... Liverpool.
Johnson, Mark ....Liverpool.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Lumby, Fred.....Nottingham.
Passmore, Charles Frederick ...Cheltenham.

Modified.

Thomas, Thomas .....Potobello, near Wolverhampton.

ASSOCIATES.

The following having passed the Minor Examination and tendered their subscriptions for the current year were elected "Associates" of the Society:—

Adams, Thomas Edwin jun. ...Liverpool.
Bilton, John Walter .....Newcastle-under-Lyne.
Booth, Thomas .....Bolton.
Bush, Arthur .....Barnes.
Carrell, George .....East Southsea.
Cowap, Samuel Evan .....London.
Exley, John, jun. ....Leeds.
Garrett, John .....Guilsborough.
Hall, John... .....Oldham.
Hamer, Joseph Armitstead.....Southport.
Horton, Thomas .....Peterborough.
Jarvis, Clarence Frank ..... Handsworth.
McBeath, John William .....Darlington.
Morris, John Lloyd .....Cardigan.
Norman, John Turton .....Blackpool.
Nowell, Barnes .....London.
Owen, George Benjamin .....Sheffield.
Patterson, James .....Landport.
Pocock, Wm. Fredk. Henry ...Cape Town.
Ridley, Thomas.....Brampton.
Roberts, Henry .....Norwich.
Rutter, John .....Cambridge.
Strachan, John .....St. John's Wood.
Stuart, Charles Edward .....London.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination and tendered their subscriptions for the current year were elected "Apprentices or Students" of the Society:—

Crowther, John Woodward.....West Bromwich.
Drury, George John.....Aberdeen.
Hart, Frederick Charles .....Tongham.
Henderson, Alexander .....Cupar Fife.
James, Joseph .....Plymouth.
Linnell, George, jun. .....Bickley.
Lord, William Henry .....Kennington.
Low, David .....Hexham.
Pearson, Walter .....Manchester.
Smales, Alfred John .....Darlington.
Waller, Ernest George.....London.
Watson, William .....Aberdeen.
Willis, Henry James .....London.
Wootton, Henry .....Richmond.
Wright, Eli .....Tipton.

John Privett, of Sheffield, was restored to his former status as an Associate of the Society (1842).

Another person was also restored to his former status in the Society.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

At the meeting of this Committee a letter had been read announcing the death, on October 1st, 1878, of one of the annuitants. A discussion had therefore ensued as to the desirability of electing eight annuitants instead of seven. The Committee had decided not to recommend any alteration in the number to be elected. The following grants were recommended:—

£10 to a former member, who had had previous grants of £5 in December, 1876, and £10 in October, 1877.

£10 to the widow of a late member who has had three previous grants.

£10 to the widow of a registered chemist and druggist who had a grant of a like amount in October, 1877.

£10 to the widow of a member, formerly in business, who is in great distress.

Two other cases were referred for further information which was now produced by the President, and the Council having gone into Committee to consider them, a grant of £10 was made in each case.

The Council having resumed—

On the motion for the adoption of the Committee's report,

The President, referring to the question of the election of annuitants, said it had been considered by the Council at the last meeting that financially the Society and Subscribers might proceed to make up the number of annuitants to thirty, and as it was believed at that time that there were twenty-three annuitants on the Fund, it was decided that seven more might be elected in December. It turned out, however, that one annuitant was then dead, so that there were really only twenty-two annuitants. He had felt it his duty to bring this matter before the Committee, which, however, did not consider that under the rules it had any option. He did not agree with that view himself. The Committee had also heard that one of the candidates also was dead, so that there would be only twelve candidates instead of thirteen to go to the poll.

Mr. Shaw moved as an amendment—

"That eight candidates should be elected in December next."

He said the whole question turned on the 2nd rule, which was simply to the effect that in the month of October the Council should take into consideration the financial position of the Benevolent Fund, and determine at that meeting how many annuitants should be placed on the list. That was done on the last occasion and it was found that so far as the funds were concerned it would be justifiable to elect seven new annuitants on the

Fund as was stated to make up thirty. It being found that one of the annuitants had died, it was suggested that eight should be placed on the list, but some members of the Committee thought this could not legally be done. He failed to see that. It was entirely a financial matter which was taken into consideration. This would not dispose of a penny of the funds beyond what was determined at the last meeting. He thought it very desirable for many reasons to adopt this course. The only objection was that it was against the rules; but he thought this was one of the rules which might be properly taken advantage of, so far as the objects the Council had in view were consulted. The Council ought to administer the Fund in the spirit of the Fund. In illustration of his argument he referred to the fact that although it was determined at the last Pharmaceutical Conference that the next meeting should be held on the 6th August, the date had been since altered to the 20th. He did not believe a single subscriber to the Fund would object to an additional annuitant being elected.

Mr. BOTTLE seconded the amendment. If he had been present at the meeting of the Committee, which unfortunately he was not, he should have supported the view taken by Mr. Shaw. He would not himself have re-opened the question, because he held that decisions of Committees should, as far as practicable, be adhered to. It seemed to him clear that when the Council passed the resolution in October its knowledge of the circumstances was not perfect; it now learned that there were then only twenty-two annuitants, and he had no doubt that had it then known this fact, it would have decided to elect eight instead of seven. He did not see anything in the rule which debarred the Council from re-opening the question. The rule had been introduced for the convenience of the Council, in order that it might be known what the financial position of the Fund was, and how much was available to disburse. There was nothing in the rule which prevented the Council acting on the spirit of the charter, and it seemed to him that it could order the election of an annuitant at any period of the year if it were so minded. Holding that opinion he supported the amendment.

Mr. FRAZER sympathized entirely with the remarks of Mr. Shaw and Mr. Bottle, as he understood the Council voted to make the number of annuitants up to thirty, and there was nothing in the rule to prevent that. The rule said this should be decided in October, but it did not say it should not be done at any other time.

Mr. CRACKNELL said it was a common practice for charities to elect more candidates than the number of vacancies announced. Some instances of this kind had come under his own notice.

The PRESIDENT took it that Mr. Bottle was quite right in his reading of the rule; that whilst it was convenient that such arrangements should be made in October, since those arrangements depended on the financial position, and as this position had been found to be different from what was at the time supposed, there was no reason why the addition should not be made.

Mr. BETTY hoped the Council was as law-abiding a body as the Committee, and he hoped the rules would be respected. He should like to ask Mr. Shaw what he meant by "taking advantage" of the rules. Did he mean a fair or an unfair advantage? If it was an unfair advantage he would ask him how far he was prepared to go; and if he only meant a fair advantage, it was no advantage at all, but simply following out the rule. He first argued that his amendment was not in breach of the rule, and then he went on to argue that it was desirable. If it was according to the rule, the members of the Council all agreed that it was desirable to extend the operation of the Benevolent Fund as far as possible. The real point was whether they could do this consistently with the rules. It was very well to be benevolent, but certain regulations being drawn up, it behoved the Council to follow them as fairly as it possibly could. No one denied that if the knowledge of the Council had been fuller last month the result would have been different. Mr. Bottle said this amendment was in accordance with the spirit of the charter, but the spirit of the charter was that the Council should follow its rules. Any incorporated body having a charter was supposed to follow its rules to the very letter. Benevolence might in some cases tempt to go beyond the letter of the regulations, but he feared the letter would be too strong. If it could be shown by any subsequent rule that the Council had the power of rescinding or altering Rule 2 he should be willing for it to be done, but the general proposition that the Council might alter a resolution because it appeared that it had acted in ignorance of all the facts did not seem to him a sound one. It was true there was no rule to prevent it, because no one ever supposed there would be an attempt made to pass such a resolution as Mr. Shaw proposed. Rule 2 meant that the Council could only decide the number to be elected at one period of the year, because it was one of the best known rules of law that the enumeration of one case implied the exclusion of every other.

Mr. HAMPSON said he hoped he was as benevolent as any one there, but still he felt bound to object to the amendment. If the Council broke that rule it might break others, and raise the amount of the annuities in any spasmodic attack of benevolence. It would be a bad precedent, and therefore he must vote against it.

Mr. SANDFORD said it might be an ungracious thing to oppose the flow of benevolence, and it was with great regret that he opposed the amendment. Mr. Bottle had opened an entirely new question when he said that the Council could elect at any period of the year; that it could do so in March, April, or May, as well as in November. In that respect he submitted that Mr. Bottle was wrong. Those regulations were positively binding by the charter, and the regulations said that the Council should proceed in the month of October to consider how many annuitants it was expedient to elect, and should immediately publish the list of approved candidates. There was no power given to add to the list, and if the Council now added to the list he submitted it would again have to go through the candidates and make a new election. If it revised one part in November it must revise the whole. It was said that one candidate had died, but the consequence was if there were only twelve instead of thirteen candidates there would be only five disappointments instead of six; and he did not think the fact of having lost a candidate would at all justify the Council in choosing another one. He agreed that it should be according to the financial conditions of the Fund, but it had been a great question with many whether they should so far exceed the amount of interest on their invested capital in granting annuities.

The PRESIDENT said that was not the question before the Council.

Mr. SANDFORD said the last resolution was not to make the number up to thirty, but to elect seven annuitants.

The PRESIDENT said because the Council had believed that would make the number up to thirty.

Mr. SANDFORD said the Council might have had its own reason for making the number seven, but in his view it could not now alter that number.

The PRESIDENT said it had not been proved to his mind that the proposal to elect the extra one would really contravene the regulations.

Mr. SANDFORD said the Council had no power in November to add any one's name to the list of candidates. That was to be done at a specified time, according to the rule which he read, and though it was not said that the Council should not so act at any other time, yet power was given at that time and at no other.

The PRESIDENT remarked that the Council would not add any names to the list.

Mr. SANDFORD thought if the resolution were now altered, the whole of the business would again have to be

gone through and more names added. Suppose another annuitant should die?

The PRESIDENT said in that case he would elect another.

Mr. SANDFORD said Mr. Bottle had raised the very question which was involved, namely, the ability to do this at any other time than that prescribed by the regulations and on that ground it must be met. The resolution was that seven should be elected.

The PRESIDENT said owing to another vacancy it was now proposed it should be eight.

Mr. SANDFORD said there were no such things as vacancies. Suppose eight were elected this year, next year it might only be possible to elect four, which would be a great drop, and have a bad appearance; because people would naturally say the Fund was not doing so well.

The PRESIDENT said that would have the effect of bringing in more money.

Mr. SANDFORD did not concur with that view. It was prosperity which led to success. He felt that the Council would be infringing the rule if it now altered the number. The rule said that immediately on deciding how many should be elected, the candidates were to be informed whose names were on the list, which list the Council had no right to tamper with in any way. He hoped the Council would adhere to these rules and refuse to sanction the amendment.

Mr. WOOLLEY said Mr. Sandford laid great stress on the view put forward by Mr. Bottle, that the Council could proceed to order the election of an annuitant or annuitants at any time, but it seemed to him that this was somewhat enlarging the ground on which Mr. Shaw moved the amendment. The Council had agreed to elect seven annuitants upon imperfect information. It had been intended to go to the limit of the available balance, and it had appeared that seven annuitants would exhaust that fund. It now appeared that the Council had not before it the whole facts of the case, and therefore it would be only carrying out the spirit of the resolution in increasing the number to eight. If this were contrary to the law, let attention be addressed to that point. He did not want, if he knew it, to vote against the direct letter of the rule, but the amendment was certainly within the spirit of it, because the expediency was undoubted. He certainly was not prepared to say that the Council could proceed to order the election of annuitants in any month, because that was an annual election; but when the resolution was passed the Council was not in possession of all the facts on which its conclusions were based.

Mr. ROBBINS, as one of the Committee, desired to say that the opinion of the whole Committee was that if it could be done by the rules it would be desirable to do so, because the intention undoubtedly was that the number of annuitants should be raised to thirty. The question was whether the Council had power to do it. Mr. Sandford had made it out so clear that it had not such power that the Committee decided accordingly. Attention, therefore, ought to be confined to the question, whether the rule could be altered. If so, the number certainly should be raised to thirty, which was the original intention. If not, it would be better to leave the number at twenty-nine than to go against the regulations.

Mr. MACKAY was glad to find that the Members of the Council were all animated by one feeling, that if this annuitant could be put on the list, it would be a pleasant, right and proper thing to do; but still he could not vote for over-riding what to his mind was a settled rule. It would be in the recollection of the Council that there was nothing hardly that came before it which caused so much trouble and consideration as the framing of those very rules, one of the most important of which it was now proposed to completely set aside. Everyone was aware that sometimes it was necessary to do painful things because it was right to do them. The previous night, in Committee, he did not vote at all, though he was in favour of keeping to the rule; but on thinking it over since he was now prepared to vote with Mr. Betty and Mr. Sandford to abide by the resolution. In any case, the additional sum would not be lost, because the Benevolent Fund Committee would still have the power to vote it for the relief of distress in some other way. He would beg the Council to pause before deliberately over-riding a rule which had been established for its guidance as trustees administering this fund. Unfortunately it had come to a certain conclusion in ignorance of all the facts, but so long as the rule stood he did not see that the resolution then come to could be consistently rescinded.

Mr. SHAW said he regretted that Mr. Bottle should have raised a question with regard to the right of placing additional annuitants on the Fund at any time of the year. In the administration of any business there were certain regulations which should be adhered to as nearly as possible, but he was informed that at the very moment when the decision was come to last month, one of the supposed annuitants was then lying dead, and therefore as far as the spirit of the rule was concerned his amendment would be fully carrying it out. He had not heard a single objection to his proposition, except that there was a rule by which the Council must abide, under all circumstances, no matter what they were. Now there had just appeared in the *Times* a report of a speech of Sir Stafford Northcote on the subject of "Charities," showing what evils arose from the strict adherence to rules made in times gone by, one consequence being that in one place loaves of bread were thrown indiscriminately over the churchyard wall to be scrambled for. When the division had taken place in the Committee, seven gentlemen voted for the resolution, three against it, and two did not vote at all, and under those circumstances he had felt justified in bringing the question before the Council. Mr. Sandford, he thought, had added somewhat to the terms of the rule, because he said that after a decision had been come to in October the list had to be immediately published, but that was another rule.

Mr. SANDFORD said the two must be read together.

Mr. SHAW contended that the second rule had reference to the insertion of the names to be placed in the book already before the Committee, and that it did not refer to the point now being discussed. Mr. Sandford also used another argument that it would not look well to be electing eight on the present occasion, and, perhaps, only four next year; but he would call attention to the fact that last year an additional £1500 had been subscribed; and, therefore, the Council might be excused for putting on a little spurt.

Mr. MACKAY said there was no want of money; that was not the point before them.

Mr. SHAW said he was simply answering an argument of Mr. Sandford. This was a special year, immediately following a large accession to the funds.

Mr. SANDFORD said that the sum of £1500 referred to by Mr. Shaw, consisting of donations, was bound to be invested.

The PRESIDENT said this was quite beside the question before the Council.

Mr. BETTY said he should like to add a rider to the amendment, which perhaps Mr. Shaw would accept.

Mr. SHAW said he could not accept any compromise.

Mr. FRAZER wished to ask if the rule, on which so much stress had been laid by Mr. Sandford and Mr. Mackay, were a bye-law, with regard to which the Council was responsible to the Privy Council, or to any higher body than itself?

The PRESIDENT said, no. He would like to put one question to those who opposed the amendment, namely, supposing there had not been a quorum in October, and the Council had adjourned until November, would it then, because of the letter of the law, refuse to elect annuitants?

Mr. SANDFORD said he should consider the adjourned meeting would be the October meeting.

Mr. BETTY said it could not be an adjourned meeting if there had been no previous meeting.

The amendment was then put and negatived, the vote being as follows :—

For—Messrs. Atkins, Bottle, Cracknell, Frazer, Savage, Shaw, Williams and Woolley.

Against—Messrs. Betty, Churchill, Gostling, Greenish, Hampson, Hills, Mackay, Robbins, Sandford and Schacht.

The resolution for adopting the report of the Committee was then carried unanimously.

LIBRARY, MUSEUM AND LABORATORY.

The report of this Committee included the usual report from the Librarian to the following effect :—From July 10 to October 8, the average attendance in the Library had been, day, 9; evening, 7. Circulation of books, town, 269 ; country, 122; carriage paid, £2 17*s.* 3*d.*

The following Donations to the Library had been received :—

'Edinburgh University Calendar,' 1878-9 ; Glasgow University Calendar,' 1878-9. From the respective Universities.

'Calendar of University College, London,' 1878-9 ; 'Calendar of Royal College of Surgeons of England,' 1878 ; 'Register of Royal College of Veterinary Surgeons,' 1878. From the respective Colleges.

'Guy's Hospital Reports,' series 3, vol. 23, 1878 ; 'Statistical Table of Patients in St. Bartholomew's Hospital,' 1877. From the respective Hospitals.

'Papers read before the School of Pharmacy Students' Association,' 1876-7, vol. 3, M.S. From the Association.

Hooker's 'Flora of British India,' part 5. From the Secretary of State for India.

'Report on the Royal Gardens, Kew,' 1877. From the Royal Gardens.

'Arrangements of the Radcliffe Library,' 4th edit., 1877 ; 'Report to the Radcliffe Trustees,' 1873–4, 1876; 'Catalogue of Transactions of Societies, etc.,' 3rd edit. 1876 ; 'Catalogue of Students' Library,' 3rd edit., 1877 ; 'Catalogue of Books added during 1877.' From the Radcliffe Library.

Cooley's 'Cyclopædia of Practical Receipts.' 6th edit., parts 5 and 6. From Messrs. Churchill.

Gibert's 'Enumeratio plantarum sponte nascentium agro Montevidensi,' 1873. From Mr. W. B. Cranwell.

'Register of the Institute of Chemistry,' 1878. From the Institute.

'On the Bael fruit,' 1878. From Sir Joseph Fayrer.

'On Mosses,' 1878. From Mr. William West.

'Report on the Manchester and Salford Provident Dispensaries Association.' 1878.

Dragendorff :—

'Ueber einige abyssinische Heilmittel.'

'Notizen zur gerichtlichen Chemie.'

'Materialien zur Werthbestimmung der flores Cinæ.'

'Notizen über Theobromin.'

'Analyse der Zwiebeln von Erythonium dens-canis, L.'

Johanson: Einzelne chemische Bestandtheile der Weiden.' From Professor Dragendorff.

'Nuova antologia di scienze, lettere ed arte,' Indice 1866-78. From the Editor.

Flückiger's 'Pharmaceutische Chemie,' I. Theil. From Professor Flückiger.

The Committee recommended the purchase of the following books :—

General Fund:—

Miller's 'Elements of Chemistry,' 6th edit., part 2.
Napier's 'Manual of Dyeing,' 3rd edition.
Beasley's 'Druggist's Receipt Book,' 8th edition.
'Italian Grammar.'
'Spanish Grammar.'
Kingzett's 'Alkali Trade.'
Lettsom's 'Origin of Medicine, etc.' 1778.
'Pharmacopœa Borussica,' 2nd edition, 1801.
'Chirurgical Pharmacy,' 1761.
'Pharmacopœia reformata,' 1744.
Fuller's 'Pharmacopœia extemporanea,' 5th and 6th editions.
Fuller's 'Pharmacopœia domestica,' 1739.
Lemery's 'Pharmacopée universelle,' 2nd edition.
Jahr's 'Homœopathic Pharmacopœia,' 1842.
Reids 'Medical Botany,' 2nd edition.
Quincy's 'Lexicon physico-medicum,' 7th edition.
Quincy's 'English Dispensatory,' 8th edition.
Quincy's 'Medicina statica,' 4th edition.
Magendie's 'Formulary,' by Haden and Dunglison, 4th edition.
'Trousseau et Pidoux's 'Thérapeutique et Matière Medicale,' 1837–9.
Maugham's 'London Manual of Medical Chemistry,' 1831.
Griffin's 'Treatise on the Blowpipe,' 1827.
Bartholinus, 'De nivis usu medico observationes variæ,' 1661.
'Pharmacopœia Londinensis,' 1787 (with M.S. additions by Cowland?).
'Pharmacopœia of St. Bartholomew's Hospital,' 1799. Two copies interleaved with M.S. additions.
Caventou's 'Du Carapa Touloucouna,' 1859.
Fayk Bey's 'Monographie des Opiums de l'Empire Ottoman,' 1867.
Karsten's 'Die medicinischen Chinarinden Neu Granada's,' 1858.
Lefranc's 'Etude sur l'Atractylis gummifera,' 1866.
Colebrooke on 'Indian Menispermum,' 1819.
Colebrooke on 'Boswellia, etc." 1826.
Bentham's 'Revision of the genus Cassia.' 1871.
Rosenthal's 'Synopsis plantarum diaphoricarum,' 1862. (Also a copy for the use of the Curator.)
Barham's 'Hortus Americanus,' 1794.
St. Hilaire's 'Plantes usuelles des Brasiliens, 1824.

Hanbury Fund:—

Hooker's 'Niger Flora,' 1849.
De Candolle's 'Suites au Prodromus.'
Roques' 'Phytographie médicale,' 1835.
Berg's 'Atlas zur pharmaceutischen Botanik.'
Risso and Poiteau's 'Histoire naturelle des Orangers, 1818-22.'
Miquel's 'Illustrationes piperacearum,' 1844.
Horaninow's 'Prodromus monographiæ scitamnearum,' 1862.

The Librarian had also reported that he would soon require additional shelf accommodation. He also presented a report of the meeting of the Library Association at Oxford, on October 1, 2, and 3, which he had been directed to attend.

The Professors had attended the Committee and reported that the condition of their respective classes was satisfactory. Professor Attfield had also reported that he had had an application from a lady student, who had already attended the other classes, for permission to study in the laboratory. In face of the discussion and resolution of the Council on July 1, 1874, he had been obliged to refuse the application, but on the lady stating that the present regulations of the laboratory were all that ladies would require, he had promised to bring the matter before the Committee. He and his colleagues saw no objection to the application being granted.

The Curator had reported that in July the average attendance in the Museum had been, day 11 ; evening 2. In August and September the attendance had been but small owing to the holidays. The following donations had been received:—

Specimens of Native Borate of Calcium, from San Francisco, from Mr. J. W. Bennett. Specimens of Sugar and Cassava Starch, brought from Jamaica, by Mr. Sherring. Oil from the Liver of the Walrus; Resin Oil distilled from resin, used for adulterating linseed and other oils ; and Calamine, from Santander, Spain, from Mr. W. W. Stoddart. Specimen of Exudation from the Skin of Frogs, used in Chinese Medicine, from Mr. A. C. Abraham. Fruit of *Garcinia indica*; Herbarium speci

mens of the plant; Wakina Root (*Aconitum* species); Tragacanth, from Persia; *Illicium species* (fruit); Seeds of *Hydrocarpus Wightiana*; Resinous Exudation of *Calophyllum inophyllum*; Fruit of *Aristolochia indica*; Bark of *Nerium odorum*; Atees Root (*Aconitum heterophyllum*); *Justicia ecbolium*, from Dr. Dymock, Bombay. Very fine specimen of Lactucarium, from Messrs. Burgoyne, Burbidges and Co. Bark of *Pterocarpus flavus*; *Pæonia moutan* Root; *Coptis tecta*; Soap Berries; Malwa Flowers; Seeds of a Species of Lucuma, with three other specimens of Seeds unknown, from Messrs. Curling and Co. Specimen of Chewstiek, used on the West Coast of Africa, from Mr. J. R. Gardner, Yarmouth. A Series of Uncoloured Plates of Medieinal Plants, from the Artist, Mr. D. Blair. Specimens of Bark of Balsamo Negro Tree; Specimens of Cedron Seeds; Specimens of Chichniora Seeds, from Venezuela, from Mr. E. Fielding. Speeimens of Cinehona Bark, collected by Mr. R. Cross, and described in the Journal, from Mr. J. E. Howard, F.R.S. Speeimens of False Senega Root, from Professor Flückiger. Speeimens of False Senega Root, from Messrs. Curling and Co. Specimens of Chaulmugra Seed, of the oil pressed in this country, and the oil pressed in India, from Mr. Thomas Christy. Specimen of Root of *Gentiana punctata*, gathered in Switzerland, from Mr. O. Corder. Fine speeimen of Crystals of Sulphoearbolate of Zinc, from the President.

The Curator had laid before the Committee his report on the cultivation of cochineal, which was directed to be sent to the Colonial Office, with a request that it might be allowed to be published in the Journal. He also reported that Mr. Stanford, Glasgow, had offered some fine specimens of crystals if they could be safely conveyed to the museum. Letters were read from Mr. T. Christy, Fenchurch Street, and from Mr. Gerrard, offering speeimens of Japanese drugs and of hydrochlorate of pilocarpine and gelseminic acid, which were accepted. The Curator had been requested to proceed to Paris with a view to securing specimens from the Paris Exposition for the Museum, pursuant to a resolution of Council in August last.

Several letters had been laid before the Committee relative to the distribution of duplicate materia mediea specimens, and the Curator had been instructed aeeordingly.

The Committee had held a second n eeting on Oetober 23, when the Librarian reported the following additional donations:—

Catalogue of Books in the Radcliffe Library. From the Trustees, through Dr. Acland.

'St. Thomas's Hospital Reports,' new Series, vol. 8. From the Hospital.

McTurk's 'Woods of British Guiana,' 1878.

'British Guiana at the Paris Exhibition.' Edited by W. Walker. From Mr. W. Fresson.

The Committee reeommended the purchase of the following books:—

Wood and Bache's 'United States Dispensatory,' 7th edition.

Wood's 'Therapeutics and Pharmacology,' 1856.

Frazer's 'Materia Medica,' 2nd edition.

Darby's 'Botany of Southern [United] States,' 1857.

Huxley's 'Physiography,' 1878.

The question of publishing a new edition of the Library Catalogue, adjourned from the previous meeting, had been eonsidered, with an estimate whieh had been obtained, and it was reeommended that a new edition of five thousand copies be printed, and a copy sent to all Members and Associates in Business.

Mr. MACKAY suggested that the catalogue of the books in Edinburgh should be added to the catalogue. There were now some very valuable books there; and it was only proper the fact should be made known.

The PRESIDENT asked, whether he suggested that the list should be published separately, or as a supplement.

Mr. MACKAY thought it would best appear as a supplement.

The PRESIDENT thought that the members of the Council would all see the propriety of the suggestion at once. No doubt a complete catalogue ought to be published, not only of the Soeiety's books in London, but also those in Edinburgh.

Mr. MACKAY said, additional frames were now being put up in one of the rooms in Edinburgh, and other arrangements were being carried out with regard to examinationspecimens and cases. When these were eompleted the Branch would take advantage of the offer with regard to duplicate specimens.

The VICE-PRESIDENT asked how many copies of the catalogue would be required to send one to eaeh member and associate, as proposed by the Committee.

The SECRETARY said about 4000.

The VICE-PRESIDENT thought it would be preferable to do with a less number and only give them to those who applied for them.

Mr. ATKINS hoped a smaller number only would be printed, for he really thought it would be waste of money to print so many. He would move as an amendment that 2000 copies only be printed, and that that part of the report recommending the distribution to every member and associate be not earried out. He thought it would be a mistake to send an expensive work like that to many who would not value it as eould be desired. He also wanted to ask if the Museum eatalogue ineluded the specimens in the Museum of the North British Branch.

The PRESIDENT said, no.

Mr. ATKINS said it would be only a eorollary of what had just been agreed to, that when the Museum eatalogue was next issued it should be made complete by inserting the contents of the Edinburgh Museum.

The VICE-PRESIDENT seeonded the amendment.

The PRESIDENT said the catalogue of the Hanbury eollection was now in hand, and it would be very easy to publish the eatalogue of the Edinburgh Museum in conjunction with it.

Mr. GREENISH said he differed entirely with the Vice-President as to the distribution of the eatalogue. The Council was now largely inereasing the Library, and taking great eare with regard to the books ordered; so that if it was not at present, he hoped it soon would be one of the finest in the kingdom for books on pharmaey and the allied sciences. The number of books being sent out was gradually inereasing, as was also the number of students attending the Library, and he thought it would be the best possible means of making the Library better known if the catalogue were distributed as the Committee eonsidered it should be.

The PRESIDENT said it was estimated the first 2000 copies would cost £95, and an additional £30 for every 1000 afterwards. There had been a strong feeling expressed that there had not been enough copies of the Museum catalogue printed to distribute to members, and that had great weight with the Committee in the recommendation they now made.

Mr. SCHACHT hoped the Vice-President would not lead the way in a movement which would appear to many living in the country to be limiting the usefulness of the Library. He quite agreed with the argument of Mr. Greenish that the efforts of the Couneil had for a long time been systematieally directed to perfecting the Library. He had sometimes thought that rather more money was spent than was absolutely needed, but he had been over-ruled by the argument that it was the duty of the Couneil to provide as nearly as possible a perfect Library. But, granting that, the next effort should be to make it as widely useful as possible; he hoped therefore that the Viee-President and Mr. Atkins would not do anything to alter the reeommendation of the Committee on that point. The catalogue would be highly appreciated in the eountry, and though it might not here and there be so mueh appreeiated as eould be wished, the very introduction of it into the house

of a pharmacist would direct his attention and that of his pupils to the fact that they had this Library at their disposal.

Mr. HAMPSON also hoped the decision of the Committee would be adhered to. He could see there was something to be said on the other side, but still he believed it would do good to the Society, and that it would be a false economy to limit the distribution in the way suggested.

Mr. FRAZER supported the same view. He believed this would bring in funds to the Society, and be the means indirectly of increasing its influence. He himself was continually receiving catalogues, of a very extensive nature, both of books and other articles, and these would certainly not be circulated unless there were something to be gained by their circulation.

Mr. CRACKNELL supported the views of the Committee. It had been said that if the catalogue was worth having those who wanted it would send for it. That was very well as far as it went, but it did not, to his mind, fulfil the duties of the Society. The Council did not want those who desired the catalogue to come and fetch it, but it wanted to force upon the attention of those who did not come and fetch it that there was a good library, and that there were books of great value to be had from it. Every sower when he scattered his seed knew that some of it would fall on barren ground, but nevertheless he sowed it broadcast, and he hoped the Council would send every member a copy of the catalogue.

Mr. SHAW said he should support the larger number being printed; but he would not distribute it to every member and associate, which he thought was unnecessary. Mr. Greenish had alluded to an increase in the circulation of the books, but he believed it was less last year than the previous one, taking into account the money paid for carriage. He would only send the catalogue to those who applied for it.

Mr. GREENISH said that both the students in the Library and the circulation of books had very much increased within the last few years.

Mr. GOSTLING supported the suggestion of the Committee.

Mr. ATKINS said seeing the general opinion of the Council he would withdraw the amendment. He hoped it would not be supposed that those who took his view did not approciate as highly as others the importance of the Library being generally known. Though he withdrew the amendment he must say he had not heard a single argument to upset the view that if the members sufficiently valued the catalogue they would apply for it. He believed in the good old rule, that what was worth having was worth asking for.

The report was then carried unanimously.

On the motion of Mr. MACKAY, seconded by Mr. HILLS, it was resolved—

"That a catalogue of the library of the North British Branch be published as a supplement and bound up with the one about to be printed for the Bloomsbury Square collection."

Mr. SAVAGE then moved, and Mr BOTTLE seconded—

"That females be admitted, in accordance with the approval of the professors, to the laboratory."

The PRESIDENT suggested that the discussion on this motion should be taken in Committee.

Mr. HAMPSON, Mr. CHURCHILL, and others objected. After some little discussion it was resolved by ten to seven to do so.

The matter having been discussed in Committee, the Council resumed, and the resolution was carried unanimously.

Mr. MACKAY moved and Mr. FRASER seconded—

"That the *Pharmaceutical Journal* be forwarded to the Mitchell Free Library, in Glasgow, as published."

Mr. SHAW objected that as the Journal contained many matters simply affecting the trade it would not be wise to send it to a public library; but, on the motion being put it was carried by a large majority.

HOUSE.

The report of this Committee stated that the Committee had inspected the premises and found that all the works ordered to be done had been performed satisfactorily. Some matters respecting the drainage were postponed for further information.

The report was received and adopted.

GENERAL PURPOSES.

The report of this Committee included the usual report from the solicitors with regard to business in their hands. It stated that the appeal case of the Society *v.* Mackness would very shortly be argued. The Secretary had reported that he had communicated with Local Secretaries and informants in cases of infringement of the Pharmacy Act reported in July, and in two cases had received satisfactory replies. In a case of alleged improper registration, a communication having been received from the magistrate who signed the declaration, saying, that he did so under a misapprehension, and that he withdrew his name, the Committee recommended that the name of the person be erased from the Register. In another case, in which it had been shown that the title "Pharmaceutical Chemist" had been improperly used, the solicitor had been instructed to take proceedings. The question of the legality of sales of a proprietary article containing chloral hydrate by unregistered persons having been raised, it was recommended that the opinion of the solicitor be taken upon the point. The attention of the Committee had been called to an advertisement in which the "Homœopathic Pharmaceutical Society" was mentioned, and the Secretary was instructed to obtain the fullest information possible as to the constitution, etc., of the Society.

The report and recommendations of the Committee were received and adopted, and the name of

William Peake Webster, of Colchester,

was ordered to be erased from the Register.

REPORT OF THE BOARD OF EXAMINERS.

October, 1878.

ENGLAND AND WALES.

Preliminary Examination.

Candidates. Examined.	Passed.	Failed
195	92	103

Twelve certificates were received in lieu of this examination:—

1 College of Preceptors.
1 Faculty of Physicians and Surgeons of Glasgow.
1 Law Society of the United Kingdom.
2 Royal College of Surgeons of England.

4 University of Cambridge.
1 University of Edinburgh.
2 University of Oxford.

The SECRETARY said he had recently expressed his opinion that the larger number of failures on the last days of the examinations arose from the weak men coming into the examination on those last days, they being examined in the order in which they sent in their names. On the last occasion the men who gave in their names last were examined first, and the result fully confirmed his views. Out of the whole ninety-eight who came up for examination, forty had been up before, some as many as four times, and some as many as six times.

The PRESIDENT said he had conferred with the Board of Examiners on this subject and in accordance with their views had instructed the office to arrange the names of candidates alphabetically in future.

Mr. MACKAY said in Edinburgh it had always been the practice to place the names of the candidates alphabetically. In connection with the examinations he might be allowed to say that they were sometimes annoyed by candidates who had entered their names not coming up. At the time the deputation visited Edinburgh in the spring, this matter was talked over. The two Boards came to a resolution that in future any candidate failing to appear on the day appointed, having paid his fee and been summoned accordingly, should forfeit one guinea as a penalty, unless he produced a reason for his non-attendance, which should be satisfactory to the Board. On the third day of the last examination there were three candidates for the Minor who did not make their appearance. Two of them sent medical certificates, but while the Board was sitting waiting for the other, he not only failed to appear, but at twelve o'clock on that day he sent a telegram saying he was indisposed and would not be able to attend, and requested that his fee and name should be carried over to the next meeting. The Board felt that without some good excuse he ought to pay a penalty of one guinea, and he wrote in the name of the Board asking for a medical certificate as to the nature of his illness. He received a reply saying he was not so ill as to require the attendance of a medical man. The Board felt this was not satisfactory, and if it met the approval of the Council, it was proposed to inflict the penalty of one guinea. If this course were sanctioned he should also propose that in the next edition of the Calendar the Regulations should read thus:—If a candidate fail to present himself for the examination for which he has given notice, he shall forfeit one guinea, unless a satisfactory reason for his absence be given.

The PRESIDENT said the Boards of Examiners had not power to authorize such a proceeding without the consent of the Council. This matter had been brought forward on more than one occasion, and he had urged that the Council should authorize the imposition of a fine in such cases, but he must say that hitherto the Council had not agreed to do so, and therefore it had never been acted upon. Such behaviour often caused great inconvenience, and it was evident at the last examination in Edinburgh two days would have been sufficient for the examination, instead of three, but for these men sending in their names who did not attend.

The VICE-PRESIDENT said there was another point he desired to advert to. It might be very desirable as a general rule to arrange the candidates' names alphabetically, but some times cases would occur in which this would prevent a man being examined on account of his age, if he were placed early on the list; whereas, if he were put at the end he might be able to come up.

The SECRETARY said he hoped the matter would be left as hitherto in his hands to arrange.

The VICE-PRESIDENT said as long as there was an understanding of that kind he was satisfied, but if the rule were to be carried out strictly without exception, it might be a hardship in some cases.

In accordance with the suggestion of the President, Mr. MACKAY said he would give notice of a motion for next month to carry out the plan he had mentioned.

Mr. BOTTLE said he thought the return drawn up by the Secretary, showed very clearly that his view was a right one with regard to the cause of the greater percentage of failures on the latter days of the examination, and he was very glad that it had been brought forward, because he had heard expressions of dissatisfaction as to these returns. The only matter of regret was that the Board of Examiners did not seem able to afford the Council any further information.

ELECTION OF BOARDS OF EXAMINERS.

It was moved by Mr. MACKAY, seconded by Mr. HILLS, and carried unanimously—

"That as the Boards of Examiners for the ensuing year must be appointed at the next meeting of the Council, it is desirable that any member of Council intending to nominate any Pharmaceutical Chemist as an examiner, should send the name of any such person to the Secretary, before Thursday, the 21st inst. That the Secretary be instructed to communicate with any persons whose names may be suggested as suitable persons for examiners, asking if they will accept the office if elected."

The motion was carried unanimously.

PHARMACEUTICAL SOCIETY OF IRELAND.

The SECRETARY read a letter from the Registrar of the Pharmaceutical Society of Ireland, enclosing a resolution of the Council of the body, and thanking the Council of the Pharmaceutical Society of Great Britain for its donation of copies of the Journal and other works, also asking whether the reports of the proceedings of that body might be published in the Journal if forwarded to the editor.

The SECRETARY said, that after conferring with the editor, he had replied to the effect that such reports would be inserted if sent officially.

Parliamentary and Law Proceedings.

THE SOCIETY OF APOTHECARIES *v.* SHEPPERLEY.

This case was tried on Thursday last, November 7, before Mr. Baron Pollock and a special jury.

Mr. Day, Q.C., Mr. Morgan Howard, Q.C., and Mr. Stanger appeared for the plaintiffs; Sir Henry James, Q.C., and Mr. Higgins for the defendant.

Mr. Stanger having opened the pleadings, a discussion took place as to whether the plaintiffs did not admit that if the custom as pleaded by the defendant were proved it would be a good defence in law, they not having demurred to it. It was ultimately arranged that the whole matter should be put before the jury.

Mr. Day, Q.C., then opened the case as follows:—

May it please your Lordship, gentlemen of the jury.—This is an action brought in point of form by the Apothecaries' Company to recover a penalty against the defendant, Mr. Shepperley, who is a chemist and druggist, carrying on his business at Nottingham; although really the action is brought not to recover a penalty, but to test the question of right whether persons carrying on the business of a chemist and druggist are entitled to practise medicine or to act as apothecaries in the manner and under the circumstances under which Mr. Shepperley undoubtedly did act, and with respect to which he claims the right to act.

Mr. Shepperley claims the right to practise in the treatment of what he terms simple complaints, and the question which will have to be determined, either here to-day or hereafter by the Court, is whether a chemist and druggist is entitled to treat that which Mr. Shepperley here terms simple complaints, or is not entitled so to

do. Now, gentlemen, this is a question which really will not raise, I think, many very serious questions for your determination, because it does occur to me that it is a question of law, a question of law arising upon the construction of the statute of 55 George III., chap. 194, and a question which has already been determined in two or three cases which have been before the Court.

Now, gentlemen, I should tell you, and very shortly, for the purpose of making the argument on this subject understood, what the state of medical practice was prior to the passing of the Act, 55 George III., a statute passed if I remember rightly, in the year 1815. Prior to the year 1815 there were three sets of persons, if I may say so, who were connected, to use a general term, with the administration or dealing in drugs. First of all there was the College of Physicians. The College of Physicians tested the qualification of persons who sought the position of physicians by examination. Some were admitted as members of the college, and others were licensed to practise, and those persons devoted themselves to the treatment of disease, but they were prohibited, as you may remember, from administering their own medicines. A physician used to prescribe either by writing or word of mouth—in modern time certainly always by writing—and say what drugs should be given to the patient, but he did not himself provide the drugs ; he did not deal in drugs, he made no profit by drugs. He simply ordered drugs to be administered, said what drugs should be administered and in what quantities, and those drugs had to be provided either by the apothecary or by the chemists and druggists to whom I will next refer.

But first of all I must explain what the apothecary was. The apothecary also was a person licensed by a corporate body. The Apothecaries' Society had long been in existence; it existed by charter, I think more than one charter; these charters were renewed, and the powers of apothecaries, and also their liabilities and duties, were enforced by the statute of 55th George III. That statute contained numerous provisions, to some few of which I shall have to call your attention. The apothecaries had long existed. The apothecary was originally no doubt a person very inferior, I am now using the word in no offensive sense, in point of training. In point of rank and social position he was inferior to the physician, and probably, if I may draw any inference from the name which he assumed of apothecary, he was originally a person who kept a drug shop, which was I daresay also as we find in many places also a grocer's shop, and he sold spices and things of that sort. He was the person to whom the prescription, if I may so say, of the physician would be sent. But after a while he assumed to do that which Mr. Shepperley now assumes to do, namely, to treat disease, and we find apothecaries from a very early period advising as to diseases, and also supplying drugs, that is to say, acting very much in the same way in which Mr. Shepperley claims to act. An apothecary, as we know, is what is ordinarily termed a general practitioner. He sees the patient, examines him, ascertains what is the matter with him, and then himself provides the drug; making, if he sees fit, a profit on the drug supplied. He, therefore, if I may use the expression in no offensive sense, combines the profession of physician with the trade of drug seller. That was the apothecary before the statute and that is the apothecary now.

But after a while it was found by the State that it was absolutely necessary that persons claiming to practise medicine should pass some well ascertained qualification. Apothecaries were required to pass an examination ; an Apothecaries' Society was constituted which was chartered by the Crown and subsequently regulated by Act of Parliament, and persons seeking to practise as apothecaries were subjected to a strict examination.

Now, gentlemen, when the apothecaries had, if I may so say, gathered themselves together and become liable to these restrictions which were imposed upon them, another class of men sprang up who claimed to do that which apothecaries had previously done, only without examination, and the chemists and druggists who supplied the drugs which the physician ordered after a while assumed to occupy the position which the old apothecaries had formerly occupied, limiting themselves, as Mr. Shepperley now does, to the treatment of simple complaints, a word about which I shall have something to say by and by. But this being the state of things when the statute was passed in 1815 and when the mischief of allowing—I will not say unqualified in the sense of not possessing sufficient ability, because it may be that a person who has not passed any examination, who carries on the business of a chemist and druggist, may be better qualified to treat disease than another person—that is not the question ; if I use the term qualified I am using it in the sense of a legal qualification. It was deemed desirable then that all persons who claimed to treat disease, who laid themselves out to treat disease for money, should be persons whose qualification had been ascertained by a recognized examination. Therefore it was that the Legislature thought fit in the year 1815 to impose penalties on all persons practising as apothecaries who had not subjected themselves to the examination of the Apothecaries' Society and received due licence to practise after such an examination.

Now we are not here to consider whether it is desirable to have free trade in physic as in anything else. That is not the question we have to determine. Some people may think it reasonable that the State should require that persons claiming to treat the poor and ignorant should have passed some sort of qualifying examination, that their merits should be ascertained not by the poor and ignorant who are unable to test them, but that they should be tested and ascertained by some recognized body. The Legislature took that view in 1815, and we are not here to consider whether the Legislature was right in doing so or not. It may be that there are persons who think it would be better that anybody should be at liberty to treat anybody else for any remuneration he may get. Those gentlemen are fully entitled to retain their own opinions, but we must adopt for the purposes of to-day the views of the Legislature as expressed in the statute, whether the Legislature was right or not in requiring those who treat others for reward to have a licence of some qualified body or not. We have now only to consider whether the spirit and the letter of the statute has been infringed, and if so my clients will be entitled to your verdict.

Now, gentlemen, what is an apothecary ? Because this Act provides by section 20 that no person shall practise as an apothecary, and it is important that you should ascertain what an apothecary is. I have given you very briefly the substantial history of the origin and rise of the apothecary, and the subsequent development of chemists and druggists, but I find in a case, to which I will refer presently, a definition given of apothecary by a very learned judge in a case similar to the present. It is a definition which, I am sure, will commend itself to you ; it is exceedingly clear, and puts in a few words the idea which we all have of an apothecary. This is what that learned judge. Mr, Justice Cresswell, says, in the case of the Apothecaries' Company *v.* Lotinga, 2nd Moody and Robinson : "The sole question," says Justice Cresswell, "that I should put to the jury is this, whether the defendant had practised as an apothecary, for it is not pretended that he had obtained any certificate to authorize him to do so. Now, I apprehend that an apothecary is a person that professes to judge of internal disease by its symptoms, and applies himself to cure that disease by medicines; and if you think the defendant has in either of the cases brought before you acted in that way, I recommend you to find your verdict for the plaintiffs." You see the learned judge uses the expression "judge of internal disease by its symptoms." He distinguishes it therefore from surgery, and I have carefully avoided referring to the College of Surgeons, because a surgeon is supposed to apply himself to the treatment of outward

disease, whilst a physician or an apothecary deals with internal disease by its symptoms and apply themselves to cure that disease by medicine.

Now, gentlemen, this view has been adopted by Mr. Justice Field in a very recent case of the Society of Apothecaries v. Wiggins, which was decided, I think, in the month of May, 1878. That learned judge says:—"I have before me the definition of an apothecary as I find it laid down by those who have gone before me. I should tell you that the duty of an apothecary is that he is a person who professes to judge of internal disease, but internal here merely means as distinguished from surgical, it is not intended to mean one particular part of the body, to distinguish ailments such as fevers; it would be difficult to find one word which expresses it all, but you know the meaning of that, 'to judge of internal disease by its symptoms, and applies himself to cure the disease by medicines.'" He then refers to that being the definition laid down by a very learned judge, Mr. Justice Cresswell, in a case he left to the jury, as far back as 1845, and says, "I adopt that and tell you that is the law. I take his language, adopt that language, and tell you that a person practises as an apothecary, if he does what Mr. Justice Cresswell here says: 'If he professes to judge of internal disease by its symptoms, and applies himself to cure that disease by medicines.' I should ask you to keep that definition in your minds when I come to read you the evidence, and to see whether or not what the defendant did here falls within that. Then I find another definition some years before, in which the learned Lord Chief Justice of the Queen's Bench of that day was of opinion that a man who kept no shop, but advised patients, and made up and sold to them medicines which he himself ordered, did act as an apothecary in the ordinary sense of the term, and that it made no difference if he prescribed as well as prepared the medicines; he was still acting as an apothecary."

Mr. Baron Pollock: Can you let me see that case?

Mr. Day: Yes, my Lord. My friend, Sir Henry James, has the first case I refer to.

Mr. Baron Pollock: It is the second case I mean.

Mr. Day: I am reading from the verbatim report of the case in the *Pharmaceutical Journal;* it is not the *Apothecaries'*, so it comes from the other side; it is my friend's report. Now, having thus explained to you after reading the words of that learned judge, what an apothecary is, it may be as well just to consider two or three other sections of the Act with a view to ascertain the meaning of a section which will be relied on on behalf of the defendant. I find by section 5 of this statute it is recited, "Whereas it is the duty of every person using or exercising the art and mystery of an apothecary to prepare with exactness, and to dispense such medicines as may be directed for the sick, by any physician lawfully licensed to practise physic by the president and commonalty of the Faculty of Physic, in London, or by either of the two universities of Oxford and Cambridge." That supports the view I was suggesting to you before, that the apothecary historically was nothing more than a man who kept his shop, as you would gather from his name; a person who kept a warehouse or shop where drugs were kept and stored for his use, and dispenses in accordance with the prescription of the physician. But he developed himself at last into practising on his own account, just as the chemist and druggist now seeks to develop himself. These apothecaries were chartered, and the statute of 1815 merely confirms the ancient charters which gave them certain privileges, required a certain examination, and prevented other persons practising in the same way. There the Act recites that all apothecaries were bound to supply physicians' prescriptions. No doubt when the apothecary developed himself into a full-fledged practitioner, when he kept his carriage, or perhaps a carriage and pair, and drove about and saw people of position in the world, and associated on a footing of equality with what I may call the best people of the town, he would feel it rather a grievance to have brought to him, by a boy, a dirty piece of paper, with instructions to put together some rhubarb and magnesia, and supply it to somebody whom a physician desired him to supply it to. No doubt the apothecaries got to feel themselves quite independent of the physician, and became persons who only supplied medicines to their own patients. Many apothecaries did not keep open shops but had their surgeries where they dispensed their goods; but every person who was a member of the Apothecaries' Society, practising as an apothecary, was bound, as the Act provides, to compound medicines, and dispense medicines in the sense of providing medicines required at the bidding of any physician. Now you will see what the true meaning of the 28th section is hereafter.

The defendant, Mr. Shepperley, says, I am entitled to deal with simple cases, because prior to the year 1815, other chemists and druggists used to deal with simple cases; and the statute says, I may do whatever was done before 1815. Let us see what foundation there is for that contention. The 28th section on which they rely is in these terms, "Provided always, and be it further enacted, and nothing in this Act contained shall extend, or be construed to extend to prejudice, or in any way to affect the trade or business of a chemist and druggist, in the buying, preparing, compounding, dispensing and vending drugs, medicines and medicinable compounds, wholesale and retail; but all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner, and as fully and amply to all intents and purposes, as the same trade or business was used, exercised or carried on by chemists and druggists before the passing of this Act. Therefore it is said a chemist and druggist is now entitled since the Act to carry on his business as a chemist and druggist, as fully as he did before the passing of the Act; but it is the business of a chemist and druggist in particular ways, not generally. It is not that a chemist and druggist may do since the Act whatever he did before; that a chemist and druggist may carry on his business pure and simple since the Act as he did before; but it is limited strictly to the buying, preparing, compounding, dispensing, and vending drugs, things, gentlemen, which are prohibited by the 20th section, because the 20th section provided that a penalty should be incurred by practising as an apothecary or acting as an assistant to any apothecary, in compounding and dispensing medicines. Therefore the Act provided that if any person, except such as were then practising, should after the passing of the Act practise as an apothecary, he should for such an offence pay the sum of £20; and if any person, except his apprentice, should assist in compounding and dispensing medicines without having obtained such certificate, he shall for such offence forfeit and pay the sum of £5; but section 28 says he may still buy, sell, compound, and dispense, I think, drugs as fully as he did before. So he may. We do not question the right of the druggist to buy drugs, to sell drugs, to dispense drugs, to compound drugs. That is not the question. But what we do question is his right to prescribe drugs, to ascertain a particular disease by the examining of symptoms, and to advise medicines to be taken to cure such particular disease, because that is practising as an apothecary.

Now the 5th section of the Act provided, as I told you, that any person using and exercising the mystery of an apothecary who shall refuse to mix, compound, prepare, give, apply, or administer to any person any prescription of a physician would also incur a penalty. That, it was deemed might interfere with the business of a druggist, but section 28 says he may still compound drugs just as he did before. The only restriction is on his acting as a practitioner; that is advising in diseases, ascertaining internal disease by the examination of symptoms and advising drugs to be taken in consequence. Therefore reading

these sections together, sections 5, 20, and 28, it is quite clear what was intended. A chemist and druggist may carry on the business of a chemist and druggist as distinguished from an apothecary's business, that is to say as distinguished from advising and prescribing drugs, as fully as he did before, but he must not himself act as an apothecary; that is to say, ascertain the presence of internal disease, by symptoms, or prescribe medicines for the treatment of such internal disease.

Now I want to say one word on another portion of this case; that is, where this gentleman claims the right to prescribe for what he terms simple diseases. In one case to which I shall call attention, as it will be matter of form more than anything else to put before you two or three cases, because Mr. Shepperley claims the right to treat disease, and we are here not so much to recover a penalty as to try the general question of a right to practise for what they term simple complaints. I shall be prepared to show you with reference to these simple complaints, if I may so say, that they are as much within the meaning of the statute as any other complaints. A simple complaint is a term probably not well understood in the higher walks of the medical profession. One of those persons who will be called before you as a witness will say that he had a sore throat; he went to Mr. Shepperley; Mr. Shepperley immediately told him to open his mouth—that I suppose is a reasonable precaution to take—and then he looked down it. Then having looked as far down his throat as he possibly could, he set to work to beat the man about the chest; percussed him or osculated him, and performed various operations of that kind; and then eventually told him that he had some stuff he thought would do him good. He prepared a bottle of it and told him to be sure and come again. Now it is all very well to say it is only a sore throat, that is very true; but you will remember that many of the most fatal diseases are only sore throats to begin with. Perhaps the highest art of a physician is to diagnose the symptoms in the early stages of disease. It is a matter requiring great experience and great knowledge, and, I was going to say special qualification, readily to diagnose one disease from another. Many diseases begin by a sore throat; it is a common form at the commencement of some of our worst diseases. I need not state them to you; they are innummerable, as you will be told, if need be, by doctors There is no such thing as a simple internal complaint. A man may have a very small pain in his stomach, and it may be the beginning of inflammation of the intestines; he may have a very small pain anywhere. Some of the most serious diseases begin with very small pains, and require to be dealt with instantly. Therefore it is that there are no such things understood in medicine as simple complaints as Mr. Shepperley says. We are not dealing with surgical cases, cut fingers, and the like, the extent of which we can see and ascertain, but of internal disease, the existence and character of which is to be ascertained by its symptoms. It is idle to talk of simple complaints. Much mischief is done by neglecting persons who have simple complaints, or what they term simple complaints, which are very often truly serious, though they began with small symptoms, and if they had been dealt with in the first instance serious complaints would not have arisen; but the neglect of a disease in the early stage, or defective diagnosis, may lead to a fatal result. It is true that in this case Mr. Death was not suffering much. He was employed by the Apothecaries' Society to ascertain the extent to which Mr. Shepperley was practising, because he had not then acknowledged that he prescribed, prescribes still, and intends to prescribe, as he has now, defending the action with a view to defend that right. Therefore we have nothing really to do with the circumstances under which Mr. Death was treated. I only give you the sore throat which Mr. Death was suffering from at the time and with respect to which Mr. Shepperley treated him, as an illustration of the folly of talking about slight or trifling complaints. It will be for you to say, when you have heard the little evidence that will be given on one side and the other, and the direction of my Lord, whether the defendant has or has not brought himself within the terms of this statute, within the letter of the statute and the spirit of the statute. My Lord will direct you on the subject on all questions of law that arise. I have no doubt we shall have, because I am told they are going to produce, an ancient apothecary, or an old chemist and druggist, or somebody who practised before 1815, and he will say that all and every chemist and druggist used to practise on anybody they could get who paid them. I readily believe it. I do not question for a moment that chemists and druggists then, as now, did what everybody else would do, make the best of their business, and extend it as far and as widely as possible, and as long as they were not interfering with the practice of apothecaries they may do so; but the Legislature says if they wish to practise let them pass the examination of the Apothecaries' Society. They are quite at liberty to go in and pass the examination, and then they can practise. But, no, they prefer to practise without examination; perhaps they deemed it would be inconvenient to go in for an examination, and that is just what the Legislature wished to prevent—to prevent persons practising on the poor and ignorant who were not physicians, or had not passed the needful examination—it might be a needful examination of the Apothecaries' Society. The case I think will occupy really but a very little while, because the questions of fact are really very simple, and the questions of law have been substantially determined. My learned friend will now call the witnesses.

Thomas Jolly Death sworn. Examined by Mr. Stanger.

Do you live at Brighton Street, Pease Hill Road, in London?—That was my address at the time in Nottingham. My present address is 28, Basinghall Street, City.

On the 22nd of August, 1878, did you go to the defendant's shop, Mr. Shepperley's?—In 1877 I did.

Mr. Baron Pollock: Where was that?—At Nottingham, my Lord.

Mr. Stanger: Did the defendant keep a chemist and druggist's shop at Nottingham?—He does.

Did you see the defendant when you got into the shop?—I did.

Will you tell us what you said to him?—I complained of my throat, of a difficulty in breathing and tightness of the chest, more particularly the left side, the left lung, and sleeplessness. Mr. Shepperley told me to face the light; it was evening and the gas was alight. I faced the light and he came from behind his counter.

Mr. Baron Pollock: Do you say it was gas-light?—Yes; it was gas-light; it was evening, at about seven, or perhaps later. He told me to open my mouth. I did so, and he looked at my throat, he said, "I do not see much amiss with you."

Mr. Stanger: Did he examine your chest at all, the left side of the chest?—He did not examine it at all, but he said, "Is the tightness there," indicating the spot.

He did not sound you himself?—No.

Did he give you any medicine?—Yes, a bottle of medicine.

What did he say when he gave you this medicine?—He said, "You will find that will do you good. Come again in a few days when you have used it."

Did you pay anything for that?—He told me to keep off smoking a few days. The medicine was one shilling, and that was all that passed.

Were there any other customers in the shop when you went in, or did any come in during the time that you were there?—There were.

There was some one else in the shop?—There was a poor man, apparently a poor tramp, or some labourer.

Sir Henry James: Do you propose to prove this case? I object. Particulars have been delivered.

Mr. Stanger: A summons was taken out and that was refused.

Sir Henry James: We have two cases given, the one is the case of Death, and the other was Hubbard.

Mr. Stanger: There are two cases named, and there are various cases mentioned. A summons was taken out either to dismiss or to furnish further particulars under it. The summons was dismissed with costs. I think it came before Mr. Justice Field.

Mr. Baron Pollock: Then you are confined to the two cases of Death and Hubbard.

Sir Henry James: I am told the summons was heard before your Lordship. I understand that the ground of it was in order that the defendant might be cross-examined as to several points, but I understand that no evidence could be given in order to support that case, in order that penalties might be recovered. My friend was there, and he may be able to bring back to your Lordship's recollection what it was.

Mr. Baron Pollock: It is certainly confined to the two cases of Death and Hubbard.

Mr. Stanger: The 5th paragraph gives other cases.

Sir Henry James: How many penalties do you go for?

Mr. Stanger: We have given several cases.

Mr. Baron Pollock: According to the Act it is every person so offending shall pay for every such offence a penalty.

Sir Henry James: Certainly.

Mr. Stanger: May I refer you to the case of the Apothecaries' Society *v.* Bendal, in Carrington and Paine, as to whether fresh penalties attach to each case.

Mr. Baron Pollock: Of that there is no doubt.

Mr. Stanger: Several cases were put in to prove the material facts.

Mr. Baron Pollock: I should like to see the summons; have you got the endorsement on it?

Mr. Stanger: I have not the summons here.

Mr. Baron Pollock: Something must have taken place on that summons. Is there any doubt as to how it came before me as to particulars. Were you present?

Mr. Stanger: No I was not present myself, but some arrangement was made.

Mr. Baron Pollock: What do you understand the ground for refusing the particulars to have been?

Sir Henry James: What do you want to have proved?

Mr. Stanger: I was going to put a general question as to the admissions made by Mr. Shepperley himself.

Mr. Baron Pollock: Any admissions made by the defendant, of course, is another matter.

Sir Henry James: You did not mention it in the County Court.

Mr. Stanger: As I understand the ground was this. It was to prove the practising on the part of the defendant. That practising might be constituted by one or two, or by a great number of acts, and if at the last moment we obtain knowledge, we might give it.

Mr. Baron Pollock: Surely it is only just to the defendant that you should state it. How is the defendant to meet it if you merely say that he practised at any time during a period going over, perhaps, a month? I have no recollection of having heard the case myself, and I do not think I did hear it.

Mr. Stanger: Here is the summons, my Lord.

Mr. Baron Pollock: What is the endorsement upon it?

Mr. Stanger: "I do order that the summons be dismissed, the costs to be plaintiff's costs in any event." That is the whole of the order. As to the question, I was going to put, I do not press it at all. The summons came on before Mr. Justice Field. I think, my Lord, that the point arises in the case of The Apothecaries' Society *v.* Wiggins, and your Lordship has the report in the *Pharmaceutical Journal*. I think, if I remember right, the point was raised in that case and Mr. Justice Field did allow further cases to be proved at the last moment.

Mr. Higgins: That is not so really. I was in that case.

Mr. Baron Pollock: In the case you have just cited there were particulars. The order was, "I do order that you deliver particulars of the other persons and the cases complained of in the statement of claim, or that you file an affidavit stating that the plaintiffs can give no further particulars than those delivered." They did give the names, and the only question at the trial was whether they ought not to have given the addresses of the persons, and the learned judge said it was immaterial inasmuch as they were not asked for. Something must have passed at Judges' Chambers to prevent the order being made for particulars. The learned judge says there on the trial of this case, "The information is given by particulars embodying the statement of claim. I think the parties had better deal with it as it stands. The difficulty I feel is that you have no notice of this case. You had notice in the other case."

Mr. McIntyre: Not except by name.

Mr. Baron Pollock: Mr. Justice Field says, "Now if there were witnesses who might have assisted at the trial, that is a matter which ought to be considered." I am afraid I must receive the evidence now as it stands. I have some difficulty about it. It seems very hard on the defendant.

Mr. Stanger: I will not press it as regards this particular man that came into the shop, as Mr. Death said. But the question I am going to put is as to the conversation which he had with Mr. Shepperley.

Mr. Baron Pollock: Anything that Mr. Shepperley said is another matter, for it may throw a light on the matter.

Sir Henry James: I cannot object to that.

Mr. Stanger: Now, did you on the 28th, or at some time in November, see the defendant personally?—I did.

Mr. Baron Pollock: First of all, did you go again. He said you were to go back again in a few days?—No, my Lord, I did not go again to the shop.

You did see him again shortly afterwards, although not at his shop?—On the 28th of November—that is, sometime afterwards I saw him. Of course I saw him almost daily.

Mr. Stanger: Had you a conversation with him on the 28th of January?—I had.

Mr. Baron Pollock: Where was that, at his shop, or where?—My Lord, I was keeping observation on the shop, just seeing who were going in and who were going out, and the defendant did not see me, I have reason to believe, but his next door neighbour, Mr. Pulficer, a watchmaker, did see me and he brought Mr. Shepperley out, and they followed me into a refreshment room a few doors from his shop. He said, I am told your name is Death and that you are watching my shop, and you are endeavouring to obtain evidence against me for selling medicine and for prescribing. He said that being a nervous man he was at first frightened, and did in one instance send a woman over to a doctor and she came back, and she brought with her a prescription which she said had cost her five shillings, and he made up the prescription and charged her two shillings, when she complained that he might have done all that for a shilling.

She complained that he might have done all that. That is both of those operations?—Yes, I understand so. He said yes, this is what the doctors are doing for poor people, and they are about prosecuting me for prescribing. He went on to say he had taken the advice of his friends in the trade, and Mr. Atherton and others. The matter had also been discussed in the journals of the trade, and they had decided to fight the matter. If we would only fight fair he would.

Mr. Stanger: Did he say anything more about prescribing?—I am coming to that.

Please to confine yourself to that. He said, if you will fight fair we will. He said I am prescribing, and I shall go on prescribing. Those were the last words he used. He mentioned from the county court to the highest.

Mr. Baron Pollock: He said he should go on prescrib-

ing?—He said I have prescribed and I shall go on prescribing, and we will fight the matter from the county court to the highest.

Cross-examined by Sir Henry James.

When you went to the defendant's shop the date was the 22nd of August, 1877?—Yes, it was.

I have got a little confused as to where you were living at that time?—At that time I was living at Nottingham and had been there for four years.

What was your business?—I had two businesses. I was the manager and trustee of an estate in the lace trade, and I was also an inquiry agent, as I had been in London for twelve or thirteen years previous to that time.

You were an inquiry agent?—Yes.

Were you in partnership with any one?—Thomas Foster.

Carrying on business as Foster and Death?—Yes.

As inquiry agents?—Yes.

Your firm sometimes act as detective policemen, do you not?—No, sir.

I thought you had been employed in bringing criminals to justice?—I have in extradition cases.

And also in internal complaints with home offenders. You look after murderers sometimes, do you not, here in Great Britain? Have you not been engaged in tracing criminals in America who have committed murders here?—Never.

Have you never been employed in arresting criminals?—I have had a great deal to do with criminals, but not in arresting them.

You say you have had a great deal to do with them, but you do not arrest them?—No.

Mr. Baron Pollock: Have you been employed to take steps against them?—I have been employed to collect evidence, and to ascertain the whereabouts of persons, but I have never arrested them, simply because I do not hold the warrant.

Sir Henry James: You are not a police officer, but you have traced them?—Yes.

Who employed you to trace Mr. Shepperley?—I was first waited on at my house when I resided at Carrington by a doctor or surgeon of the name of Huthwaite.

What instructions did he give you?—Not any, for I was not in. I did not see him.

Did you ever see him?—I did.

When you saw him, what instructions did he give you?—He told me generally what was required.

Well, what was required?—Evidence against him or any chemists in Nottingham who were prescribing over the counter, making up, and selling medicines without prescriptions.

Prescribing over the counter or making up and selling medicines?—Making up and selling medicines over the counter without the patient handing in a prescription.

Did he tell you for what purpose he wanted that information?—He referred me to the solicitor to the Medical Defence Association, Mr. Brown, of Nottingham, from whom I received more minute instructions.

Then in consequence of what this Nottingham gentleman said to you, you went to Mr. Brown?—I did.

From him you received more minute instructions as to what you were to do. What were those instructions?—I was to endeavour to ascertain the names and addresses of persons who were being treated by chemists, and that I was also to go myself and apply for medical advice and relief, and I was to take particular notice of what took place and to take care of the bottle of medicine, and report every such case. I did so at a number of chemists.

Did he refer you to the Act of Parliament?—No.

Did he tell you what it would be necessary to prove before the chemist could be convicted; what it was that you should procure him to do?—He told me that it would be advisable that I should get sufficient evidence; that is to say, to get him to feel my pulse, to sound me, to examine me and so on.

This attorney told you it was advisable that you should get sufficient evidence of his feeling your pulse, sounding you, examining you, and anything else?—And the sale of the medicine and the identity of the person who supplied it.

Of course you would take care of that, to get sufficient evidence of the sale of the medicine and the identity of the person who supplied it; but I want to know what you were to do. Did he tell you you were to endeavour to get advice from the chemist?—I do not know that he did, but as a matter of course with medicine the doctor would give advice. He did not tell me that, but that followed as a matter of course.

That was your view that if a person sells you medicine he naturally gives you advice, you say that follows as a matter of course.

Mr. Stanger: Without a prescription.

Sir Henry James: Of course; otherwise that would be making up a prescription.

Have you been a witness in any other case?—No.

This is your only case?—I have reported in several; this is the only case which has resulted in a prosecution.

Did he tell you you were to have a serious complaint or a minor complaint?—He did not say.

That was left to your discretion?—Yes.

Or to your good fortune or your ill fortune?—I do not see any fortune in it.

I want to know what was the matter with you on the 22nd of August?—Well, I thought I was all right, but every chemist I consulted told me I was not, so that I began to think I must be ill.

But you see, you, Mr. Death, told this chemist, and I daresay you told the other chemists, that you had got a sore throat. Now, was that true?—I had a different complaint for every chemist and they all found it to be true.

You had a different complaint for every chemist. Was that a true complaint or a false complaint?—I said before I did not think I was ill.

Just answer my question. Was it a true statement you made to the different chemists, of your complaints, or a false statement. Answer the question, was it true or false?—I thought I was in as good health as I am now.

I presume you do not like the word, but it was a false statement, was it not, that you made to each and every one of those chemists?—My answer is, I believed at the time I was in good health, and I was told I was not.

Mr. Baron Pollock: No, no; that is not an answer.

Sir Henry James: No; do not put your falsehood on the chemist. When you went there you said you had a sore throat. My question is whether you had or had not a sore throat?—I believed at the time I did have a slight sore throat, but not of such a nature as that I should go and get advice for it.

I thought you told me you thought you were all right?—So I thought.

Had you a sore throat or had not you? Never mind what you thought.—I had got a sore throat, if I recollect rightly.

I thought you said you had a sore throat?—And so I had.

Tell the jury now what you mean. Do you mean that when you went to Mr. Shepperley's shop for this pretended advice that you had a sore throat or not?—I had a little sore throat just as I have now. I caught a cold last week, and I have a little one now.

Have you taken any advice for that?—I have not, nor should I have done so then.

When you went and said you had a sore throat you had one?—Yes; that is so.

Mr. Baron Pollock: But in fact you had no sore throat for which you wished advice?—That is so.

Sir Henry James: So far as your having a sore throat and wishing to get advice was concerned that statement was without foundation?—So far as really requiring advice it was.

Had you any tightness of the chest?—No.

Nothing like it?—I should not like to have.

You did not like the sore throat, did you?—No, I did not; but I should think a tightness of the chest would be very much worse.

What were you paid for this?—Not a penny; I am some pounds out of pocket.

Have you had nothing?—No.

Have you made any agreement with the attorney?—No.

Is it customary to make arrangements for the payment?—I shall not get paid until the final result.

Have you got paid anything?—No, not until the final result.

Do you call this trial the result?—The jury will find that.

You are quite right?—I am only giving evidence.

Do you say you are to be paid according to the final result?—I did not say so. I do not expect to be paid by the result at all, but I am sure to be paid.

This was August, 1877. This is a long time to wait. The trial has something to do with the payment?—No, it has not, nothing whatever.

Have you any arrangement with the attorney?—No, I have had a shilling with the subpœna.

He will give you what he deems reasonable?—I shall tell him what it has cost and the time and the money.

Will you put the sore throat in?—No.

You say there was nothing the matter with you. He looked down your throat, did he?—He did.

He did not sound you?—He simply said a tightness there, touching me.

That was put to you by way of interrogatory?—I understood it as indicating the spot I complained of. I have never said I was sounded.

You did not follow your instructions. You did not get your pulse felt?—I did not hold out my hand, and I was not asked to. I was not likely to say feel my pulse unless I was asked to.

I do not know that. The attorney told you to do it. You did not do it?—No.

There is only one other point I want to ask you about. Do you mean to swear Mr. Shepperley told you to call again?—I swear that most positively.

You say you did not think of putting out your hand to have your pulse felt. Did you not ask him to look at your throat?—I did not.

That you will swear?—I will.

I think you told the jury the charge which he made for the medicine was a shilling?—Yes, a shilling.

Did Mr. Shepperley tell you he did not see anything amiss with you?—He said I do not think there is much amiss with you.

That was after he looked down your throat?—After.

There was nothing the matter with you that he could see. You had not irritated your throat?—Oh, dear no, I should not be so foolish as to do that.

Mr. Baron Pollock: There were no objective symptoms.

Sir Henry James: No, they were subjective.

Are you certain that on the second occasion you saw him he used the word prescribed?—Yes, three times.

That is what you have said.

Re-examined by Mr. Stanger.

I understand you to say in some cases you have been paid by the results, but not in this.

Sir Henry James: He says he has not been paid at all.

Mr. Stanger: He said he is not to be paid by the result?—I say I am not to be paid until the matter is finished.

Dr. Henry Reginald Hatherly sworn. Examined by Mr. Stanger.

Are you a medical practitioner at Nottingham?—I am.

Mr. Baron Pollock: Is he anything besides being a medical practitioner?

Mr. Stanger: Are you a member of the College of Surgeons?—I am.

Were you present at the County Court of Nottingham when this case was tried?—I was.

Did you hear Mr. Shepperley examined?—I did.

Mr. Stanger: My Lord, as to the case of Hubbard, which has been mentioned in the statement of claim, I should tell your Lordship that the man Hubbard is in America, and I have consequently to obtain the evidence in rather a round-about manner. Did you hear questions put to Mr. Shepperley with regard to his attendance on Hubbard?—Yes.

Sir Henry James: I am going to call Mr. Shepperley, and whatever he said at the County Court he will probably say here. My friend can recall this gentleman afterwards, if it is necessary.

Mr. Stanger: I have the shorthand writer's notes of what took place, but I will put this general question—Did you hear Mr. Shepperley make a statement there as to his general habit of prescribing?—I heard Mr. Shepperley make the statement that he sometimes prescribed and sometimes he refused to do so; but he only prescribed simple remedies for simple complaints.

In your opinion as a medical man, from your experience, is it possible to draw a sharp line between simple complaints and serious ones?

Sir Henry James: Stop, if you please. My friend surely does not think this gentleman is prescribing for us now.

Mr. Baron Pollock: I do not think you can put that question. I do not see that it is a question for a medical man exactly.

Mr. Stanger: It is a question which a medical man is qualified to answer. Part of our case is that these so-called simple complaints may be some of the most serious complaints.

Mr. Baron Pollock: Then we have first to find out what a simple complaint is and what a simple remedy is. One man might suppose it a very simple remedy in some cases were he to cut off a man's leg. I suppose it must be a very grave question as to what is meant by a simple remedy.

Mr. Stanger: It is an expression used by my friend and his witnesses. We say there is no such thing known.

Mr. Baron Pollock: I do not think that is a question you can put to the witness; it is a question for the jury.

Mr. Stanger: Then I will put it in this form: Whether it is not the case that serious complaints often begin with what appear to be simple symptoms.

Sir Henry James: I will admit that.

Mr. Baron Pollock: I should think everybody will admit that.

Mr. Stanger: Will you give instances?

Sir Henry James: I object to that.

Mr. Baron Pollock: We cannot have that.

Mr. Stanger: Then in the case of a sore throat—

Sir Henry James: I object to this.

Mr. Morgan Howard: I have not had the advantage of being in court and therefore I have not followed up the questions; but I submit as a general abstract question we might ask the question and go into it to a certain extent, and that is all my friend was going to do.

Mr. Baron Pollock: If it becomes material you can ask him whether in particular cases the symptoms are so-and-so.

Mr. Stanger: Besides the question of sore throat there is the defendant's own admission that he prescribed in several cases.

Mr. Baron Pollock: I cannot deal with rebutting evidence now, because he admitted that. There may be nothing in it on the other side. There is always this very important question in these cases for the jury whether the man really prescribed or not. I should think one has heard that in country towns the chemist generally has a long conversation of perhaps ten minutes before he gives

a box of pills; but it does not follow that because there was that conversation the chemist prescribed; that is another question which is open to both sides, and whether the condition of a man is simple or serious or whatever adjective you like to use is another question. I shall direct the jury in the words of the Act of Parliament, whether it be simple or otherwise.

Mr. Morgan Howard: My friend and I have agreed that if it is necessary we shall recall this witness.

Sir Henry James: All I have agreed is that if it should become material, with your Lordship's permission, we will recall him to ask him a question or two.

Mr. Morgan Howard: I understand my friend is going to call Mr. Shepperley.

Sir Henry James: Yes, certainly.

Mr. Stanger proposed to put in the shorthand writer's notes of what took place at the trial at the County Court.

Sir Henry James objected to their being put in and admitted. Mr. Morgan Howard could cross-examine Mr. Shepperley upon them.

This was the case for the plaintiffs.

Sir Henry James: May it please your Lordship, gentleman of the jury. I might submit to your Lordship that there is no case to go to the jury, but I do not purpose taking this course. There is this question for your determination, if I may be allowed to say so, and then to give my reasons, a very serious matter in relation not only to the interests of the two professions but also in relation to the interests of the public and a portion of the public whose interests ought to be considered by you. When I say that the facts will affect not only this particular case that is now before you, but it also must affect the dealings of persons in every day of their lives, throughout the whole of this country, you will see how important this case is to those persons to whom I have referred. And, gentlemen, my learned friend has put this case before you as if this were a patriotic action brought on behalf of the public for the purpose of protecting the public against the action of ignorant persons who may endeavour to impose upon it a pretence of knowledge which they do not possess, and by so imposing the pretence of that knowledge the public would be injured, and seriously injured, in relation to its health. But, gentlemen, when you consider the matter, and when you consider under what circumstances this action is brought, the only imposition that has taken place in the matter is by those who instructed my learned friend to make that statement. This is an attempt, and only an attempt, by gentlemen belonging to the honoured profession of apothecaries, or as they are generally wrongly termed doctors, to prevent the sale of drugs by a chemist in his shop beyond the sale of specific drugs asked for by name, and to prevent chemists from bringing the slightest discretion to bear in relation to the sale of those drugs. If you, by your verdict, accept the view that is attempted to be placed before you on the part of the plaintiffs you will be shutting every chemist's door against any one going into the shop and receiving the benefit of the discretion of the chemist in the sale of his drugs. And, gentlemen, when you for one moment, as I am sure you will, bring common sense and reflection to bear on the effect of such a determination, unless you do find yourselves compelled to arrive at it, when of course you must, at the same time I am sure you will see it will be attended with very serious consequences. Let me give you an example of what I mean. There are many persons—I do not wish to use the cant phrase "poor persons"—but many persons who feel something the matter with them. As I think my Lord referred to this morning, a person may at some period of the day feel a headache, and may go into a chemist's shop and say, "Give me a tonic"—any person in the ordinary position of life. What is a chemist to do? He must say to him, "Is your headache a severe headache, or is it slight?" He must say to him, "Have you been accustomed to take tonics?" and he must see from what does that headache proceeds. What does he do then? He exercises some discretion as to the tonic that he gives. He does not receive the instructions of his customers as to what tonic shall be given; probably the customer would not know what he was to give him; he would not know of what that tonic should be composed. You must leave to the chemist who is selling his drugs some discretion as to the drugs he should sell. Take the case now in which even a specific article is asked for. Take the case of a customer, going into a chemist's shop for, let me say for example a black draught. What is the chemist to do? He must look, even if he does not make inquiry of the customer and see first whether it is a strong built man who could take and ought to take, to be of any use, a strong dose of medicine he is asking for, or, if it be a little child two or three years old, and must apportion the dose according to the capability of the person who makes the application for such medicine. There is the discretion of the chemist. The person who asks for the black draught would not say, "Give me so many drachms and make it up of salts and senna," or whatever it may be composed of. He leaves that to the discretion of the chemist in making up that medicine. The chemist exercises a certain judgment, and leaving that to him the chemist acts and is bound to exercise his judgment before he makes it up. And mind you, if he did not exercise that discretion—I say it in the presence of the learned judge—he would be guilty of manslaughter if he gave a wrong dose of medicine, say, for instance, to a young child, instead of a proper one. Gentlemen, it is this discretion in the sale of wares and drugs (and I will establish this proposition to you I believe in one moment), that these medical gentlemen in their desire to obtain this business—for it ceases to be a profession when we deal with it in this sense—to obtain this business for themselves, thought it right to employ a detective policeman to simulate disease, to pretend he was suffering in some way, and then to obtain the benefit of that falsehood by preventing chemists from exercising such discretion.

Now let us see if that is not so. Gentlemen, I have a difficulty, I must confess, in placing the complete answer to this case before you, because it is partly, it seems to me, a matter of law and partly a matter of fact very much mingled together, and much that I should have to address to my Lord, I am unwilling of course to address to you. I have on the other hand matters of fact to state to you which I submit to the learned judge must be determined by you alone. But I will endeavour to separate these two matters, the questions of law and the questions of fact, as much as I can, and as far as these are questions of fact, I will now invite you to arrive at certain conclusions which certainly according to my view will give the defendant the verdict in this case.

Now, gentleman, in the first instance, this is a proceeding upon a penal statute. I am not as my learned friend suggested supporting any case on the part of my client by way of an evasion of that statute. As far as I can judge of this statute it was a wise and proper statute to be passed, not so much for the protection of apothecaries, but for the protection of the public principally, and even if it were not a wise and beneficial statute it would be unbecoming in me as the advocate for the defendant, for one moment to suggest that that statute should not be carried out. It is on the statute book, and, of course, the law is to be obeyed; but I thought it right to say this, which I am sure the learned judge will justify me in saying, that being a penal statute the evidence from which the penalty springs must be clearly and distinctly proved. Before, therefore, the defendant can be convicted (which is the proper term to apply) of the charge which is made against him of having broken this statute you must be satisfied that he has clearly infringed the provisions which the Legislature has imposed. Now, let us see if that is so. You have to find under the section which is relied on, first, that the defendant comes within the provisions of the penal section of this Act, viz.,

the 20th, and you have also to find that he does not come within the protection of the 28th section, which comes by way of proviso upon the 20th.

Gentlemen, I will now submit to you two answers to this attempted conviction of the defendant, first, that he has not infringed the penal clause at all, and secondly, that if he has infringed the 20th clause, if it stood alone he is protected by the proviso of the 28th; and I think I shall establish both those propositions to your entire satisfaction.

Now, gentlemen, let me remind you, for the words will pass from your memory, that under the 20th section the offence that he, the defendant, must be found to have committed before he is convicted is that he has practised as an apothecary without having obtained such a certificate, and that if he does practise as an apothecary he shall be liable to a penalty of £20.

Now, gentlemen, I come upon that doubtful ground which I spoke of just now, where the questions of law and fact become mixed up together, and perhaps I may, if my Lord will permit me to do so, to some extent address both him and you at the same time in what I am about to say as to the definition of the words, "practise as an apothecary." I am asking you to find that there has been no proof in this case that the defendant practised as an apothecary, and I agree with my learned friend that before you can come to a conclusion under the direction of the learned judge as to what constitutes the practising as an apothecary you should look to find what apothecaries were at the time of the passing of this Act, in the year 1815. Now, gentlemen, I have been bothered very much from my learned friend's view of the proposition, not so much as to the practice of an apothecary, for I think that you and I will, probably, and I hope he also, be agreed on this, that his definition was not quite complete, at least in matter of detail. Apothecaries, I fancy he is right in saying were at one time mere sellers of wares; that they culled their remedies from the fields; that they then sold them in shops, and they would be found to be classed with druggists or grocers, and we know they oftentimes were mentioned together, both being sellers of commodities of somewhat the same character; not the same, but somewhat the same. Time passed on, and there came to them a recognized status and position; and about the time of the Charter of James I. they had certain privileges given to them and they, probably, from time to time began to be merged into the practice of a profession, rather than remaining as the mere sellers of drugs. They were distinct, no doubt, from the surgeon, who in early times was more approximate to the barber, as we hear from time to time of barber-surgeons who dealt with wounds and ailments that were apparent to the eye. We cannot fix the exact time, but I think they did from a period either within the reign of James I. or shortly afterwards commence a profession distinct and entirely distinct from the mere selling of drugs in a shop; and we know this, that as time went on they did what they do now, they became the attendants on persons who were suffering from what one judge called not quite accurately "internal diseases." They became attendants on persons suffering from all diseases that did not require actual surgical treatment. They attended at the houses of patients, of course, and attended them at the severest moments of illness. They attended persons suffering from such diseases as fever, infectious and contagious diseases, and they attended persons in consumption, and persons suffering from any fatal disease; but they had to attend them not as mere sellers of wares, not as mere persons saying, "I have come to give you so much medicine to take," but they attended them so as to give them general advice as to the course which was to be taken in relation to their illness. For instance, the advice of an apothecary may be, "Do not take any medicine at all." Perhaps, gentlemen, if they gave that advice oftener than they do it would be very good advice indeed. It may be their advice would be, "Seek fresh air, alter your diet, take another course of living, leave off this habit of smoking," or what not. "I give you this general advice; I am selling you no ware or drug, but telling you what you ought to do." Or it may be that he would find it was some mental ailment which nothing in the shape of medicine could cure, something which only the advice of a man of the world, apart from much medical skill, would be able to assist in removing. Those were the duties of the apothecary as distinguished from the duty of a physician in this respect, that the physician did not up to a certain time certainly do more than prescribe the medicine; he did not furnish it; whilst the apothecary with his advice to the patient, given at the patient's own home, keeping himself, it may be, no shop for the purpose of carrying on his profession, did make up the medicine which he himself ordered the patient to take. Gentlemen, there was another incident too attaching to his duty, and here I think I may quote a case to my Lord, if it will be necessary so to do. I say that he did not charge for the medicine he supplied unless he liked. I can give my Lord the authority if he wishes it, to show that the apothecary was entitled to charge for his attendance; he could do just as he thought proper. He could say, I will charge for my attendance, that is, I have come twenty miles, it may be on a journey into some rural district to see you—I charge you nothing for that—I have only supplied you with medicine, which would not be worth half-a-crown, I charge you the attendance, but I charge you nothing for medicine. That is all he does. That, it has been decided, an apothecary would be entitled to do. Now, gentlemen, there was another duty the apothecary had to perform. Very often, of course, he had to make up the prescription of a physician. The physician first prescribed in writing that which he deemed the proper medical remedy for a patient to take. The patient would go with the written prescription to the apothecary, and the apothecary would make it up. There at once you come to that which is a part of the druggist's business to this day. And now I will call my Lord's attention, if he will allow me, to the question whether practising as an apothecary under the 20th section means that any person who does any part of that which was an apothecary's—I can hardly say duty—but that which was an apothecary's practice before the Act of 1815 means that the person so doing is to be convicted.

Mr. Baron Pollock: No; I think that is quite clear.

Sir Henry James: If that were so, every chemist and druggist must be convicted, because he clearly to this day makes up the prescriptions of physicians, and nobody complains of that. Mr. Death would not complain of that, and I daresay Mr. Hatherley would not complain of that, but that was what an apothecary did, therefore it cannot mean that it is an isolated portion of that which was the practice of an apothecary which will justify a conviction in this action. It must be that it is the substantially, the generally practising as an apothecary, that is, the holding himself out as an apothecary, and as being such to any person who chooses to apply to him for medical advice. Gentlemen, I of course have no right to press my definition upon you too confidently, but it is this. Of course, as I have said, it is entirely for the learned judge to direct you upon, but I am asking you, consistently with every one of the cases which have been decided on this matter as I think the learned judge will tell you, to say that under this 20th section you must do more than find that the druggist has done any act which an apothecary would do. You must find that he has generally, in the ordinary sense of the word, held himself out as an apothecary to those who chose to seek advice. I have given you as an example a reason, and I hope you will allow me to repeat it, that inasmuch as the making up of drugs from the physician's prescription was always the act of an apothecary before 1815, and inasmuch as chemists and druggists are without doubt allowed to do that now, whilst they are doing therefore an act which was the practice of an apothecary before 1815, they

cannot be convicted for it. And why? Because that is a thing which, whilst it was the duty of an apothecary, does not amount to a practising as such, which are the words of the statute.

Now, gentlemen, dealing first with the 20th section, I ask you for one moment (before we come to the very facts of this case) what a chemist and druggist may clearly do. A chemist and druggist is entitled by law to open his shop for the sale of his drugs, and when my friend Mr. Day spoke of the protection of the public requiring that this detective policeman should be employed and that he should simulate this sore throat, he surely must have forgotten that the Legislature has thought of the public interest and has passed an Act of Parliament which requires chemists and druggists to be properly qualified persons; and that by the statute of 1868, which I am sure my Lord will recollect, any person who becomes a chemist and druggist and dispenses his drugs is bound to go through an examination in a great many things, some of which I know and one or two subjects I do not recognize as they are so very profound. Here is the Act of Parliament of 1868, which makes it necessary for every chemist and druggist who is to open a shop to pass through an examination and become a skilled person, for the very purpose and reason that his skill should be tested and that he should thereby become a person who might protect the public when he is dealing with things within the scope of his business. And, gentlemen, what is the scope of his business? I quite admit that the chemist and druggist has no right to fulfil the duties of the apothecary; to attend to persons at their homes, to hold himself out as one who brings medical skill to bear in relation to the patient. That is a proposition which I cannot say I abandon, because I never took it up, and no one on the part of the chemists and druggists who are fighting these actions has ever taken up that position. It comes, I submit, within the clause of the Act of 1815, but unless you are going by your verdict to prevent chemists and druggists carrying on their business at all, protected as they are by the Legislature, skilled as chemists are by the direction of the Legislature, unless you are going to prevent them carrying on their business at all, you must allow them some discretion in the sale of their wares at the time they sell them. And, gentlemen, if you were to present to your minds another course of things, what is it you are going to reduce chemists and druggists to? You would allow them, I presume—I do not know whether the prosecutors in this case would—but I presume they would still be allowed to make up prescriptions for physicians; they would be allowed to sell patent medicines, which I think are always sold at 1*s.* 1½*d.* a box, or some particular sum like that, and they will be able to sell specific chattels when asked for by name over the counter. But if you forbid them to exercise a discretion in the sale of their wares you would make them say to a person who came into their shop, and said to them, "Give me a draught composed of so-and-so, or a pill composed of so-and so," one of two things; you would compel them to take one of these two courses, either to say, "Leave my shop, and I will not serve you," or serve the specific amount of ingredient although they knew it was a false and improper proportion to use. Gentlemen, do not let this be misunderstood, I am not asking that they should be allowed to give advice apart from that which is necessary for the sale of their wares. I do not say that they ought to be allowed to attend a patient who comes to them, and says, "I have a general complaint, tell me what to do, whether to take medicine or not; whether to go to the seaside, or whether I ought to have an operation performed; give me general advice." I do not say that, but when a person comes in and asks for that which the chemist and druggists obtains his living by selling, the chemist and druggist not only ought to be allowed, but from such reasons has the very duty cast upon him of telling that man the best thing he ought to take in relation to the purchase of the ware he is about to buy.

Gentlemen, in the very commonest trade that is allowed. One's very tailor says, "You had better not have that at this time of year, it is too warm, or it is too thin." The tradesman who sells you anything over the counter says, "I cannot recommend you that particular article; I find from experience that it is likely to wear out; it does not serve its purpose." In every trade you allow that to be done; but these gentlemen are seeking for their own gain and their own profit—these medical men who insist that the chemist and druggist, who knows, it may be, that what the customer asks for is an improper drug to give him, should give him the improper drug, and shall not be allowed to say to him, "I advise you not to take that. I advise you to take something else." That is what they say should not be done.

Now, gentlemen, we come nearer the facts of this case. Supposing a customer goes into a shop and says, "I have a sore throat, I want to take something,"—let me say by way of example—"I want to take a decoction of arsenic for it." Is the chemist and druggist to say, "Go out of the shop, I'll not sell it," or to say, "Here it is, because you ask for it?"

Putting aside the question of arsenic because that would not be a remedy, take something which would come under the title of a remedy, say nitrate of silver, or anything else. He says, "I have a sore throat,"—perhaps nitrate of silver would not be a remedy, but something which would be no remedy at all. Is the chemist to say, "No, I really cannot serve you—Leave my shop;" or else say, "Here it is because you ask for it." Is it a chemist and druggist's duty to say, "You had better not buy that proposed remedy for I think it will do you more harm than good, but I recommend you this specific. I will sell you something else." Now let us approach a little nearer. A person comes into a shop and says, "I want a certain medicine. I have a slight sore throat. I want some nitrate of silver to cure me, and I want it in such and such proportions—so many drachms to two ounces of water, or whatever the correct term may be." Ought the chemist and druggist to go instantly to his counter and make this up or has he not the right to say, "Let me look at your throat and see whether the proportion you are asking for is the right proportion;" is he not entitled to see that a person gets the right proportion when he comes and says, "Give me something to cure my throat?" Is he not, before he sells the medicine to see what is the proper medicine to sell? Gentlemen, that is all the chemists and druggists are asking for. It is against these proceedings that these gentlemen instruct my learned friend to speak of the benefit to the public. It is against that proceeding they are warring for the purpose that they as medical men may obtain their fees of five shillings or ten shillings, or whatever they may be, to make every poor person come to them for advice, and prevent them from going into a chemist and druggist's shop and saying, "I have a sore throat. Give me the proper remedy for it."

Now, gentlemen, you have to determine if this is to be done. If it be, mind you that which has occurred for years and years can occur no more. Unless chemists and druggists are willing to run the risk of these penalties you can have no poor person even go into a chemist's shop and say, "Give me something for a cold in the head." You can have, if the law is observed according to this decision, no gentleman who may have been a little excessive in his conduct the night before go in and ask for a tonic—my learned junior tells me the proper term is "pick-me-up." He will not be entitled to leave that to the discretion of the chemist, but he must go into a chemist's and say, "I want it according to a physician's prescription." My learned junior, I dare say, could tell me what it would be which would be a tonic which could restore him in relation to the excesses of the night previously. This

comes within that which my friend makes his attack upon, and that which you are asked now to justify and say ought to exist within the provisions of this statute. Gentlemen, there is one phrase—it is not wise probably for counsel to be answering one another, because juries do not attach, perhaps, so much weight to what we say as we sometimes think—but there was one phrase repeated over and over again by my learned friend, that Mr. Shepperley claimed as a right to treat patients for their ailments. I hope I have drawn a clear distinction between that which is done as treating a patient generally, and that which is done as incidental to the selling of drugs in a chemist's shop. Of course, if this were treating a patient where the attendance may be at the patient's own house, where it may be treating of a particular disease according to the view of a medical man, where, as I pointed out before, no medicine may be given or operation performed, that would justify the use of the word treating. But when a person goes into a chemist's shop open for the sale of drugs and asks for the purchase of a composition, and then simply leaves full discretion to the chemist in relation to the sale of that drug, that is not treating a patient. It is simply what every person ought to do, namely, exercise his discretion in relation to the sale of his drugs. I do not wish to limit myself in the matter, but I think I shall have my Lord's judgment for this, that if you are to say this discretion is not to be exercised by a chemist, there will be on the other hand, a most unfair corresponding obligation cast on him in relation to this question under the state of our law at the present time. If, through want of skill, he were to give an overdose of any medicine, say laudanum, he may be tried for manslaughter, because he had given too large a dose of that particular medicine; and at the same time you are imposing a penalty upon him if he has told a person who came in to buy the medicine, "I do not think you ought to take laudanum, you ought to take a weaker decoction of the same herb, or take some other medicine." Gentlemen, chemists and druggists must obey the law, but it will be a hardship which they will be placed under which one can hardly understand if in such a case as this they were to find a penalty has been incurred.

Now, I have to call your attention to the facts of the case in relation to this 20th section, and to submit to you that the facts of this case do not bring Mr. Shepperley within its terms, and also with regard to the exemption in the 28th section, which will protect Mr. Shepperley and every chemist and druggist in this country from any penalty, if the course which has been pursued comes within the terms of the 20th section. My friend did read it, but let me remind you that that section was inserted for the purpose of allowing chemists and druggists to do as they had done before, and the section is very clear. My friend divided it into halves, and seemed to think that the first half was all that affected the question. With submission to him, I think both halves must equally apply. It says:—"All persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner, and as fully and amply to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act." It, therefore, becomes a question of fact, if chemists or druggists carried on the business, whether it was in the dispensing of medicine, as it says in the first part of the clause, or whether it was generally as chemists and druggists, I say is immaterial. But however chemists and druggists carried on their business before 1815 they are entitled to carry it on after the passing of this Act, and therefore at the present time. Now, gentlemen, that is a question of fact. If my Lord will allow me to call his attention, partly in consequence of what fell from my friend Mr. Day, and partly affirmatively, I wish to do so, to the course taken by Mr. Justice Field in a previous case, and probably the view that learned judge took then will meet with his acquiescence, and I should not dissent from it. This case is the one probably which my friend Mr. Day had in his mind when he said this case had been previously determined. To that view I dissent as much as I could dissent to aynthing he could possibly say. In that case the chemist had attended three young children with most serious complaints; they all three died, and substantially died under his treatment; and, therefore, the cases are quite different. There Mr. Justice Field put this question. He said, "The second question is whether the complaints under which the children were suffering, were complaints of a character which it had been the common practice to treat in the trade or business of a chemist and druggist before 1815." Then, my Lord, the jury it seems found in terms, "My Lord, we find that the defendant acted as an apothecary in taking cases that were dangerous." That was the question that the learned judge put. Now, my Lord, you will see how that happened. Witnesses were called then to establish what was the practice of chemists and druggists before 1815, and their evidence was as matter of fact clearly and distinctly that chemists and druggists, of course, without running the risk of attending persons or giving medicines to persons who had serious illnesses, gave them medicine in cases of minor illness like sore throat, cold, or aught else. Then that being the evidence on the part of the defendant, the learned judge, if I may say with submission, most properly said, "Do you think these three cases of young children suffering from convulsions, pneumonia, and scarlet fever were minor diseases? Were they not serious cases?" In fact they all three died. Therefore of course it was established that the diseases were serious, and leaving that to the jury you see that the jury found that it was acting as an apothecary, because the diseases were serious. I think that view is the view that I should wish to present to you. Now you have to find in this case before you convict, that Mr. Shepperley has attended persons with serious diseases. Of course in order to show to you what chemists and druggists did before the year 1815 I must call witnesses before you. In some of the cases which probably are in the mind of the learned judge, no evidence was called at all, but you see we have now these prosecutions following one another very quickly, established by means of these detective gentlemen. 1815 is a long time ago; sixty-three years have passed, and of course it is difficult to bring oral evidence before you of what was the practice before 1815 And these gentlemen know that year by year it wil. ecome more difficult, and the time will come in the course of nature when no living witness can be called to speak of what chemists and druggists did before 1815, and then no doubt we shall have more actions such as this, because they know this proviso cannot be utilized to protect chemists and druggists. But fortunately, gentlemen, time has spared some of these chemists and druggists who did practise before 1815. I will call several such elderly gentlemen before you—they must be old—and they will tell you that which the evidence given in Wiggins's case and in other cases showed, that in regard to minor diseases the universal habit of chemists and druggists was to do that which necessity demanded—I will not say charity required, but which necessity demanded—and that was to exercise discretion. There can be no evidence given to the contrary; there never has been, and there never will be. I fancy these gentlemen's evidence will be deemed by you to be true. They are persons whose testimony cannot be doubted, that in minor cases of disease, chemists and druggists did prescribe over the counter—it was called counter prescribing or counter dispensing, or counter practice—that they did before 1815 pursue that course, not in dangerous diseases where great skill was required, but that in common ordinary affairs of every day and every hour of a man's life; they did exercise that discretion, and to permit that to be continued to be done, the Legislature in its discretion in 1815 inserted this proviso and allowed that course to be pursued. I will under-

take now to call before you several witnesses, gentlemen, of undoubted respectability, and veracity, who will tell you what was the practice of that comparatively remote time before 1815. I will then show to you that now and then these things were done which these gentlemen with the aid of their detective policeman, knowing that this testimony is rapidly passing away, are anxious to shut out by preventing effect being given to this proviso, in order that they may put this money into their pockets at the expense, not only of chemists and druggists, but of the persons whom they wish to bring into their own surgery. Gentlemen, the fact is they desire to convert an ordinary customer who purchases in a simple case a box of medicine which will cure him into a patient upon whom they may practice with far greater expense to the patient, without one atom of corresponding benefit to him. That is all I have to say to you with relation to the issues to be placed before you.

Mr. Baron Pollock: Sir Henry James, before you leave that point I should like to ask you your construction of the 28th section? I was not aware that this had been discussed before, and I want to know whether this exception, "Nothing in this Act shall extend or be construed to extend to prejudice or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, and vending drugs, medicines, and medicinal compounds, wholesale and retail," whether the whole section is governed by that when it afterwards says that "persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise and carry on the same trade or business in such manner and as fully and amply, to all intents and purposes as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act." Does not that mean that the trade or business in that part of the Act means the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, and vending drugs?

Sir Henry James: With submission my Lord, I should say not.

Mr. Baron Pollock: That is a very important point.

Sir Henry James: I quite appreciate the importance of it, but even if that view were to prevail I should say what the defendant has done is nothing more than the dispensing of drugs.

Mr. Baron Pollock: That is another point. I thought it right to mention that now.

Mr. Howard: In Wiggins's case, my Lord, that point was made at the trial. I am reading, if your Lordship will permit me, from page 974. When my friend Mr. McIntyre was addressing the jury, Mr. Justice Field said this:—"Did the defendant dispense, compound, and vend drugs in the same way as before the Act? Mr. Morgan Howard: That is almost a question for your Lordship. Mr. Field: That is my impression. Mr. Morgan Howard: I submit that it is. Mr. Justice Field: I think it is." His Lordship afterwards said, if it became necessary to go into the construction of that section, he should have a good deal to say to the jury about it, but it did not become necessary because the jury there found that the complaints treated were not simple.

Mr. Baron Pollock: I want to avoid the use of a word which is not in the Act of Parliament. I do not find the word simple or compound, but I do know it will become my duty to tell the jury what is the construction of this 28th section, and I wanted Sir Henry James, when he was upon it, to know what my view was. To my mind, as at present advised, I think this section is intended in the latter portion of it to apply to the trade or business of a chemist and druggist, not as it was used and exercised and carried on generally, but to the trade or business of a chemist and druggist limited by the words, "in the buying, preparing, compounding, dispensing and vending drugs," and so forth. That is my impression.

Mr. Howard: That was the view Mr. Justice Field took.

Mr. Baron Pollock: I think so. I only mention the point.

Sir Henry James: I think my case is so strong that I do not want to take any point I may be in doubt or danger about. Assuming the words "in such manner" in the second part referred to the manner mentioned before, it will include the buying, preparing, compounding, dispensing, and vending of drugs. I should say this, my Lord, there must be some meaning given to the words "dispensing" and "vending" drugs. I think these two words will assist me more than the others—preparing, compounding, dispensing, and vending. My Lord, if I show that before this statute passed chemists and druggists were in the habit of dispensing and vending drugs to persons to whom they gave advice to the extent of saying what drugs they ought to dispense and vend, that is a thing incidental to the dispensing and vending, which certainly must be added to these words, not added to the word vending by itself, but which will be quite sufficient to protect the defendant in this case from any of the consequences. It is impossible to say that its means dispensing in the sense only of making up a physician's prescription. No person desires that a druggist should not do that. Taking that with the word selling, it means this. We find an illustration in the common use of the word "dispensary." Persons go there and get the advice of a surgeon or medical man, have their drugs given to them, not by way of purchase only of a well known chattel, but as a medicine which is mixed up for them with a skill brought to bear on the object for which that medicine is given. I would submit, therefore, my Lord that, in these words "dispensing and vending" there must be incidental to them the exercise of the discretion in relation to the object to which the medicine is applied. Of course that is quite apart from the question whether the defendant is within the 20th section at all; whether he has practised as an apothecary. I am now coming back to the 20th section to ask you whether on the facts of this case, to which I wish shortly to call your attention, the defendant has practised as an apothecary. I am anxious not to repeat myself, but practising as an apothecary no doubt includes a great many things. The apothecary, as I pointed out before, attends patients at their dwelling houses, brings skill to bear generally on their complaints, then says if any medicine is necessary, and then gives them an order either for the medicine which he things right, or he charges specifically for his attendance and advice if he thinks right to do it. That is, I think, one description of an apothecary's duty.

Mr. Baron Pollock: I think the older practice. This is not matter of law, but I happen to know as a matter of fact that in some cases the older practice of apothecaries was to charge simply for the medicine.

Sir Henry James: In the older practice my Lord.

Mr. Baron Pollock: I do not say that it affects the argument. It was in this way, a man who kept his carriage and drove about, if you looked at his bill you would find "a bolus" so much, so many pills, so much, "administering a clyster" so much. I have seen such bills in which what has been supplied only is charged for, although the greatest skill was added. But I do not think that is material.

Sir Henry James: If your lordship will forgive me it has been decided in several cases—I might refer to the case of Towne *v.* the late Lady Gresley, 3 Carrington —that an apothecary may recover for his attendance.

Mr. Baron Pollock: He certainly may recover. I only mentioned that as a matter of history. I thought it would rather assist you than otherwise.

Sir Henry James: Then what is the primary duty of an apothecary? It is to advise. That is his primary duty. He is to make what my learned friend calls a diagnosis. He is to advise, to look after the patient's

general condition, and has to say, "Remain in a horizontal position," or "stand up" for asthma, and do whatever he thinks right, and then incidental to that "You want a little medicine, you may get it from a chemist and druggist, or I may send it to you, and I may charge for it or not, as I think right." But when the chemist and druggist who has his name over his door as a chemist and druggist, with his red bottle—artifical blood, I believe—in the window as an inducement to persons to enter his shop as one in which they will receive great ocular delight—for I suppose that is the reason those things are always exhibited—who has to sell his goods across the counter, who primarily is dealing with those goods, and only incidentally dealing with a particular case, does say, 'Do this or do that;" that I ask you to come to the conclusion is not practising as an apothecary at all, but dealing as a chemist and druggist.

Now, gentlemen, I come to the easier part of my case. I do not want to make any amusement out of it. First, was the complaint Mr. Death suffered from a minor complaint? and, secondly, was there here any attending on Mr. Death, and giving him general advice as an apothecary? Gentlemen, I know from experience it is bad policy for an advocate to place his case too high, as against those to whom he is opposed; and therefore I do not wish to criticize the conduct of the prosecutors in this case very severely. But I should like them to reflect whether they have done quite rightly as professional men in trapping this defendant in the way they have done. Mr. Shepperley shall give you an account of himself. He has carried on business in Nottingham. He was dispenser at the dispensary for a considerable time; and, mind you, as against him, in the practice of his trade as a chemist and druggist, not one word of irregularity could be alleged. Has he been to the house of anyone? Has he been holding himself out as an apothecary by false pretences at all? He has been simply a pharmaceutical chemist and druggist, selling his wares fairly across his counter; and against him the very plaintiffs in this case cannot give you—although Mr. Death was told to try and obtain the information—the name or address of one single person he has ever seen visit his shop, or even charged for acting towards him as an apothecary. They have nothing of that sort against him after all the exertions of the detective gentleman, Mr. Death, not one person who has received advice from him as an apothecary. They cannot, I say, bring one case against him in which he has so acted. But they have to tell you that in order to convict him they had to instruct a man to go into his shop to make a false statement and to obtain or endeavour to obtain advice upon false pretences. It has been thought right by a solicitor of this court, to advise a detective policeman to go into that shop, and say, "Get your pulse felt," when his pulse was perfectly sound; "get him to examine your chest," when his chest had nothing the matter with it; "tell him you had a sore throat," when his throat was not suffering from any disease at all. That was done for the purpose of endeavouring by questions and by inducement to get this druggist to exercise that simple discretion which it is his very duty, I say, to his fellow men to exercise. An attorney and surgeon after consultation and consideration come to the conclusion that it was by such means advice would be given, and the penalty should go into the pocket of the informer to whom the advice was to be given. As professional men they may think that is right. It is not for me to judge them; I appear for the defendant, but do you consider that the advice of an apothecary was given? I suppose Mr. Death thinks the penalty of £20 a good thing. He says, "I have a sore throat," which was a perfect untruth in the proper sense of the term. He opens his mouth and Mr. Shepperley looks down it. That is the whole acting as an apothecary that exists in this case because if he said I have a sore throat, I want some medicine, I suppose that neither Mr. Day or Death the detective would say that is acting as an apothecary. It is looking down his throat that constituted acting as an apothecary as far as I can see. He did not feel his pulse, because, if so, he would have put that down in his note book; it would have been exactly what he wanted. Tapping him on the chest would have been acting as an apothecary, according to the combined views of this Nottingham solicitor and surgeon; striking him on the chest, tapping him, that would have been what my friend called coming within the diagnosis. He would have said, "I shall get this £20 because that was acting as an apothecary." But it was interrogatory. "Was it a tightness of the chest," he said, and he answered he had or had not, I forget what, to do him justice; but if he said he had he had not. I am told he said he had when he had not. Under these circumstances there was no inquiry or observation made by Mr. Shepperley to find out whether the statement of Death was true. He acted of course most foolishly and erroneously in thinking that Death was telling him the truth. If he had known him better he would not have thought so, because he would have known the object for which he came there. That was a falsehood. Where was the acting as an apothecary here? Looking at that man's throat to see whether the disease, which he falsely said existed, was a severe one or not, in order that he might give that medicine which was, I presume, good for sore throats in proportion to the severity of the sore throat—being made up in a certain proportion—and say how that remedy was to be applied. I do not know whether Mr. Shepperley would like to tell you what he gave for that sore throat. It was something, you may depend upon it, perfectly harmless. It was, you may depend upon it, a saline mixture, or something which means nothing serious; something intended to be as negative as possible, and which has done Mr. Death I hope as much good as he deserved to have done to him; that is, I presume, produced no effect at all upon him. There is a good deal more to be said about it, but I will abstain from saying anything further in the case. I want to deal with it seriously, with regard to the manner in which the chemist's business will have to be carried on in future, and I venture to point out the very serious effect your verdict will have if you say that this was acting as an apothecary; without attendance, as exists in almost all the cases previously referred to, at the house of the patient; without giving any advice except that which was necessary—in fact giving no advice; exercising no discretion except that necessary to see what was the proper ware or drug to be sold; the shilling only charged for the drug, which was a fair price without a farthing being added on for any investigation, and in fact, if it had been a prescription that had been brought to be made up by a patient, it would have been no less—perhaps even more, but I have a perfect right to say that not one coin was charged for anything except actually the drug sold.

Gentlemen, there is one very small matter and that is the question whether Mr. Shepperley did or did not state that the man was to call again. I may tell you that according to his view he did not state that, and if it comes to a question of veracity, I shall ask you to say that Mr. Shepperley's statement is true. He has not told any falsehood; he has not said he had a sore throat when he had not one. He was not instructed by his employers to state falsehoods; and therefore I shall ask you to accept his statement and not that of the detective policeman but I do not think that is very material.

In order that we may save the attendances of gentlemen who are here, I will call some of these elderly gentlemen first who have a knowledge of the practice of chemists and druggists before 1815. Mr. Shepperley will then tell us what he has done, and I shall ask you then to do that which is exactly, if his Lordship will allow me to say so, your duty in this case; not to be affected either by the speech of my learned friend or by what I have said with relation to the conduct of the prosecutors,

but simply to confine yourselves to the question as my Lord leaves it to you according to the justice of the case. I do trust that in your minds the justice of the case will be to find that what has been done is perfectly necessary to the proper carrying on of this useful trade of a chemist and druggist.

Mr. Francis Cupiss sworn. Examined by Mr. Higgins.

Do you reside at Diss, in Norfolk?—Yes.

I think you are 80 years of age?—Yes.

In 1814 did you go to Mr. Woolrych, a chemist and druggist?—Yes.

Where was that?—At Uttoxeter.

Were you bound to him for four years?—Yes, for four years.

Where did you go after that?—To Lichfield.

In what capacity?—As an assistant to the son of the gentleman that I was apprenticed to.

How long did you stay there as assistant?—I think about a year, or thereabouts.

Have you your indentures with you?—Yes.

Sir Henry James: I want the date—from what time were you apprenticed?—I went to Uttoxeter to Mr. Woolrych in the year 1814, and I was bound in the July following.

You have your indentures here?—Yes; shall I show them to the jury?—The date of them is the 6th July 1814.

The jury: We can take his statement as to his indentures.

Mr. Higgins: After you left Litchfield did you go to Messrs. Ingatston and Osborne in Gracechurch Street, London?—Yes.

How long were you there?—Not quite twelve months.

Next you went as a dispenser to a Mr. Addington in Bishopsgate Street?—Yes, he resided in Spital Square and he had a dispensary in Bishopsgate Street.

After ceasing to act as dispenser also, I think you left the business for a short time and went to live at Uxbridge?—Yes.

Did you go down to Diss in the year 1823?—In 1823 on the 1st of November I took possession of a drug business there.

Did you continue in business there until the end of the year 1876?—Yes until the year 1874, which was fifty-one years, and two months. I left on the 31st of December.

You were carrying on the business of a chemist and druggist during the whole of that time?—During the whole of that time without intermission.

Now, during the time that you were with Mr. Woolrych, that is, during the year 1814, will you tell me what his practice was as regards supplying medicines?

Mr. Morgan Howard: I am anxious at this point to say once for all that I object to anything done by witnesses after the year 1815.

Mr. Baron Pollock: Yes, of course.

Mr. Morgan Howard: If my friend will confine himself to that I shall not object.

Mr. Baron Pollock: The question now asked is as to 1814.

Sir Henry James: Before that is determined I want to ask your Lordship to consider if that is so. I apprehend that what has taken place since 1815, if it goes to show that a certain practice was continuous or not with what took place before, I think it would be evidence.

Mr. Baron Pollock: The words of the Act are that they are to practise and act as chemists and druggists as fully and as amply to all intents and purposes as they did before the passing of the Act. Then you must take the Act to speak from the time of the passing of the Act.

Sir Henry James: The point is that that which occurs continuously afterwards is strong evidence of there being a custom before. The objection that my friend Mr. Morgan Howard takes now was taken by my friend before Mr. Justice Field, and Mr. Justice Field admitted the evidence.

Mr. Baron Pollock: Is that so?

Sir Henry James:—Yes, my Lord. Your Lordship will find it is so if you refer to the evidence. [His lordship referred to the report of the Apothecaries Company *v.* Wiggins.] So the thing must exist from time immemorial, and you have the limit of 1815, if you prove that it existed in 1815 you prove that it existed before 1817. Supposing instead of our trying this case in 1878, we were trying it 50 years hence, and you got old witnesses to say it existed ever since they can remember. That might be some evidence that it existed before 1815.

Mr. Baron Pollock: At present I am against you, Sir Henry, and I think that evidence ought not to have been admitted by Mr. Justice Field as Mr. Howard objected.

Sir Henry James: I am going to put the question in another way.

Mr. Baron Pollock: Now you go on to prove that it was before 1815.

Sir Henry James: Perhaps you will allow me to ask one or two questions first, as this is very technical. [To the witness]. Will you bring your memory back to the time when you were at Uttoxeter. You told my friend that the date of your indentures was the 6th of July, 1814?—Yes.

I believe you had been with the gentleman to whom you were apprenticed some month or two before. You went in May?—Yes. I went in May.

Bring your mind, if you please, to the first year that you were there. The date of the passing of the Act is the 12th of July, 1815, and it was before the passing of this Act. You recollect the first year that you were with Mr. Woolrych?—Yes.

What was his practice as to selling or dispensing medicines across the counter?—Dispensing medicine, recommending the use of it, and protecting the public against any improper——

Mr. Higgins: Before the question is answered I desire to submit it is very much following the observations made by the Bench already.

Mr. Baron Pollock: This gentleman is saying what Mr. Woolrych did before 1815.

Mr. Higgins: My friend put it, what was his practice as to dispensing.

Sir Henry James: And selling.

Mr. Baron Pollock: You should keep to the words of the section.

Sir Henry James: Those are the words that I rely on, with the exception of selling instead of vending. If you wish me to alter it I will. I am following the statute.

Mr. Baron Pollock: The words in the section are the "buying, preparing, compounding, dispensing, and vending."

Sir Henry James: I have chosen to limit my question to the dispensing and vending. I can take it a word at a time if I like.

What was the practice of this gentleman as regards dispensing and vending?

Mr. Baron Pollock: I think you should take the two words together, Sir Henry.

That is what I am trying to do. Because dispensing and vending and selling it, or giving it to the patient, involve opinion as well. I did put the two things together and the learned counsel on the other side objected to it. Now explain what he did?—That is what he did.

What? Tell us what he did?—Making up the medicine; gave it to the individual with certain instructions taking care that he had nothing that was injurious.

Mr. Baron Pollock: The practice was to make up the medicine, and give it to the patient or customers?—Yes.

Sir Henry James: Now, would he or would he not make inquiries of the customer as to what was the nature of his complaint?—If it were necessary to do so.

What do you mean by saying if it were necessary to do so? As to the complaint do you mean?—Necessary to know what to prepare.

He would make inquiries you say?

Mr. Baron Pollock: That is a further question. In what respect or how did he make inquiries of the patients as to what was required?

Sir Henry James: When you say as to what was required did he ask the patient what do you require, or would he ask the patient what was the matter and then determine what he required?—The individual might come in and say "I have got a cold."

Say a sore throat for example?—Yes, he would prescribe then.

Supposing he said he had a sore throat would he look at his throat?—I do not know that he would.

Supposing he said he had a cold?—He would ask him where it was, because there are colds in their different stages. A common cold which is the general expression generally comes in the nose.

Mr. Baron Pollock: That is a good illustration. That is what you call a simple cold?—Then it may extend to the bronchial tubes.

Sir Henry James: If it extends to the bronchial tubes would he ask about that?—Yes, I daresay he would.

And some discretion would be brought to bear on the matter as to the medicines to be given?—Yes, the person prescribing would bring discretion to bear.

That is the chemist?—Yes, my master.

He brings his discretion to bear on the nature of the complaint. Do you know the difference between subjective and objective symptoms in a patient?—Yes.

Mr. Baron Pollock: They did not use those terms in those days.

Sir Henry James: I think they have come into existence since railway accidents.

Some diseases you can see, and some you cannot?—Yes.

Now take this case. Supposing a patient has got pimples on his face?—Well, you can see pimples.

And I suppose a chemist would look at them?—Yes.

And looking at them he would then exercise his discretion as to what kind of ointment or remedy he would give?—Yes.

Did your master do that?—Yes.

Mr. Baron Pollock: I think the fair result of this is that he would ask questions and bring his discretion to bear on what remedies were needed.

Sir Henry James: Yes, my lord.

Mr. Baron Pollock: Without knowing what you call the diagnosis.

Sir Henry James: Now I am coming to the objective symptoms. Supposing a patient said he had got a cold, would he feel his pulse?—Yes; I should think he might.

Would he look at his tongue?—Yes, he might; and if the gentleman wished him, he would feel his pulse.

I see. Mr. Brown, the attorney, did wish. If he wished it, he would feel his pulse, and whether he wished it or not he would look at his tongue?—Yes.

You do not get as far as his throat, but you say he would look at his tongue?—Yes.

Supposing a patient asked him to look at his throat?—He would look at it if the patient asked him to look at his throat.

And he would exercise his discretion as to the medicine he would give him?—Exactly so.

I suppose the chemist would be paid for his medicines?

Mr. Morgan Howard: I wish Sir Henry James would put a question.

Sir Henry James: Will you tell me what you wish me to do?

Mr. Morgan Howard: No, I should not presume to do that.

Sir Henry James: Was the chemist paid for his medicines?—For his medicines only; never paid for advice.

This was done at the shop?—I have anticipated the learned gentleman's objection.

If you will not mind letting me act as your junior, I think we shall be a match for him.

Mr. Baron Pollock: The question is whether you are the senior of Mr. Cupiss or not?

Sir Henry James: I wish to act as his junior.

Now, Mr. Cupiss, of course this was all done in his shop, and I suppose there was a shop kept as a chemist and druggist's with the ordinary sign over the door?—Yes.

I propose to ask this question. We have it on the notes that this gentleman acted as chemist and druggist down to the year 1874. Now, Mr. Cupiss, do not answer this question at present. What I propose asking him is a question which was admitted before Mr. Justice Field, whether that practice has existed from that time down to the time that he ceased to be in business. Of course, I must take your ruling, my Lord.

Mr. Baron Pollock: My note is that Mr. Morgan Howard objects to your proving the practice which existed subsequent to 1815. I shall not exclude any evidence before 1815.

Sir Henry James: That involves that we commenced this practice in 1815, but I should like to have it whether that practice, which this witness speaks of as having existed before 1815, did or did not exist down to the time that he left business in 1874.

Mr. Baron Pollock: Do not answer that question yet.

Mr. Morgan Howard: I renew my objection.

Mr. Baron Pollock: I reject that evidence. I see the force of what my learned brother said and what Mr. Morgan Howard said.

Sir Henry James: I think I may as well ask you this. If a person had come to a chemist with a dangerous disease such as scarlet fever or small pox or any other serious or dangerous disease, I suppose the chemist would not have treated him?—No; he would have sent him to a medical man.

He would send him to a surgeon of course?—Yes; or to a physician.

He would send him to some medical man. My friend put the case of acute inflammation of the lungs. Of course a chemist would send that to a medical man?—I think you will see that I have said that since I have been in business I have treated people for inflammation of the lungs and most successfully too.

You have?—Yes, I have.

I will only advise you to keep out of Mr. Death's way.

Adjourned for a short time.

Cross-examined by Mr. Morgan Howard.

We have met before to-day?—Yes.

Sir Henry James: And who had the best of it.

Mr. Morgan Howard: You will see presently. My friend asks you, and you may as well tell him. Who was the verdict for, for the plaintiff or the defendant? Do you remember it?—We had a different case then.

Quite so. It was only to oblige my friend, Sir Henry James. I do not know I have very much to ask you. In the year 1814, I will take the liberty of asking you how old you were?—Sixteen the 20th of April.

It was only during the year 1814 that you continued at Uttoxeter?—Yes.

Were you four years at Uttoxeter?—Yes.

Did your master keep open shop?—Yes.

And you were acting as the apprentice?—As an apprentice.

As an apprentice. You are simply, Mr. Cupiss, a chemist and druggist?—And veterinary surgeon.

Be it so. You do not profess to be an apothecary?—No.

Still less to be a physician or surgeon?—Exactly.

You had no medical education, I believe?—Yes.

You know the sense in which I use that term?—Yes.

What?—I attended Dr. Harrison's materia medica lectures.

You had no course of education?—No.

You told me you had a course of education by attending a course of materia medica lectures?—Yes, and also

Sir John Brodie on anatomy, and Dr. Bell on anatomy, and Dr. Abernethy on anatomy.

So that when you went into business you felt yourself a thoroughly qualified practitioner?—I felt myself capable of doing what I did.

I suppose that was the reason why you treated persons, as I understand you to say, to take the case of acute inflammation of the lungs, for instance?—Yes.

May I ask you to tell me what you were referring to. Can you refer me to a particular case of acute inflamation; can you remember it?—Yes, I can.

When was it and where was it?—I cannot tell you the day; it was thirty years ago.

Mr. Baron Pollock: Are we not going out of the diagnosis. What this gentleman did thirty years ago cannot affect the question.

Mr. Morgan Howard: My friend attached no date to it.

Mr. Baron Pollock: We have it that he attended some one who was suffering from acute inflammation.

Mr. Morgan Howard: In 1815 you did not presume to be capable of treating acute inflammation of the lungs?—I was then under my master.

May I take it your master treated cases of acute inflammation of the lungs?—No.

In the year 1814, from your recollection, were persons in the habit then of coming into your shop and being prescribed for over the counter?—Yes.

You are speaking now with reference to your own personal recollection of individual cases?—Not of sixty years ago.

I am bound to ask you, it struck me it was improbable. Just tell me are you able to give more than a general notion, as you have stated to-day, or are you able to state particular cases?—I am able to tell you what the trade did at that time.

I think I must trouble you to answer this question in this form. Are you able to say it now to-day, on your oath, that you remember any individual cases in the year 1814 of chemists prescribing?—I would not say that I could,—not individual cases,—but as a general practice and prescribing when asked to.

In many of the cases that you did observe at that time, were they cases which had been dealt with by physicians and surgeons who had been consulted in the matter?—Well, I suppose every physician has had a cold come under his notice, and every physician has had children to attend to.

Every physician has had a cold?—I do not say so. My learned friend misunderstood me. I wish you to understand, my Lord, that every physician has a cold to treat, and also other diseases during his lifetime—almost every disease that the human subject is liable to. That was the answer I wished to convey to that question.

You wished to convey that to your learned friend. I am very glad you should call me so, and I quite reciprocate the compliment.—I have not the pleasure of knowing your name.

Just tell me what your notion of the Act of Parliament was. When did you first make the acquaintance of the Act; when did you know its provisions?—When it was passed.

In the year 1815?—Yes.

I asked you this question before and I will ask it again. Your idea is that you may examine patients, pronounce on the case, and give them medicines, so long as you do it within the four corners of your shop.—Yes.

Mr. Baron Pollock: That is not his idea as to what was done.

Mr. Morgan Howard: All I can say is that this question was put before and he answered that question, "Yes, that is my idea, and I did it under the authority of the Act."

Mr. Baron Pollock: You have excluded yourself evidence as to what was done under the Act. I have only on my note what chemists did before 1815.

Mr. Morgan Howard: I will put the question in this way: was it your idea in 1814 that you might examine patients and pronounce on the cases and supply the medicines to cure them so long as you did it within the four corners of your shop.

Sir Henry James: I object to that question.

Mr. Baron Pollock: Is it not a pity?

Sir Henry James: I cannot help it, my Lord.

Mr. Baron Pollock: I am rather suggesting it to Mr. Morgan Howard. It reminds me of a case some years ago where a number of plumbers were called to give their opinion on the construction of the Water Works Act.

Mr. Morgan Howard: Your Lordship sees how I put it. The chemists and druggists, I assume for the purposes of my argument, formed their opinion in the year 1815 as to what they were entitled to do. This gentleman says he considered he was entitled to do certain things.

Mr. Baron Pollock: But that does not affect this question. I shall tell the jury, and I think they will follow me in that, and will be bound by what I tell them; they will act on what I have already laid down as the guiding point as to what was done before 1815, therefore the opinion of this gentleman as to the construction of the Act is perfectly immaterial. He might have attended a case of pneumonia or anything else as a doctor. I do not know the one question takes it further than the other.

Mr. Morgan Howard: I am quite willing to take it so, but I will frame the question thus. In the year 1814 are you able to say one way or the other whether your masters did examine patients, pronounce on their cases, and supply them with medicines to cure them, in their own shops?—Yes, I have answered that.

That is in the year 1814?—Yes, that is in the year 1814.

Mr. Baron Pollock: That is higher than we have had it at present?

Sir Henry James: Yes, my Lord; he pronounces on their cases.

Mr. Morgan Howard: I will ask you this. In your judgment, is that dispensing medicines?—It belonged to the drug trade, I considered.

Your opinion is that the doing of that belonged to the drug trade?—Yes.

In your opinion was that dispensing medicines?—Yes; and so long as I did not go out visiting I considered I was within the bounds of the Act, but——

Sir Henry James: It was before the Act?—But the Act now protects us.

Mr. Baron Pollock: At the time of the Act you were only sixteen years old. You are speaking now of what was done in the year 1814; surely what you considered as a boy of sixteen is hardly material?—The gentleman asked me——

Mr. Morgan Howard: I will limit my question to the year 1814.

Sir Henry James: Oblige me by not saying anything after the Act, but before the Act.

Mr. Baron Pollock (to the jury): Now see, gentlemen, these gentlemen will prescribe for each other.

Mr. Morgan Howard: Now as far as you can bring your recollection back do you recollect your master giving any particular thing to any particular person?—I cannot recollect any particular thing.

You cannot recollect any particular class of disease?—No, it is sixty years ago. I cannot charge my memory.

Mr. Baron Pollock: Even the very names have changed. We have not the same diseases by name now.

Re-examined by Sir Henry James.

You say you do not recollect exactly the cases?—No.

I suppose you do not recollect the names of any of the persons that came into the shop at Uttoxeter in 1814?—No, I do not.

But, taking the fact and speaking generally, are you certain that the course was pursued by your master that you have mentioned to us to-day?—Yes.

And was that pursued in reference to what you call simple complaints?—Yes.

Now only answer this question, yes or no. Is your memory, or is it not confirmed as to what took place before 1815 by your practice since?—Yes, decidedly so.

Mr. Parsons sworn. Examined by Sir Henry James.

Do you live near Loughborough in Leicestershire?—Yes.

I think you are upwards of eighty-five years of age?—Yes, last August.

In the year 1809 were you apprenticed to Messrs. Blews, Chemists and Druggists, in Worcester?—Yes, that was for seven years.

I believe, like Mr. Cupiss, you have preserved your indentures?—Yes, I have.

You are now, I believe, a Freeman of the City of Worcester?—Yes.

How long did you remain with them?—At Worcester? Yes.—For seven years.

Where did you go then following?—I went to London, to Alcheston, Stead and Brodon.

Did you afterwards go to Leicester?—I settled at Leicester.

And I believe you remained in Leicester as a chemist and druggist until 1872?—Yes.

Will you bring your mind back please to what was the practice of the Messrs. Blews, of Worcester, whilst you were apprenticed there? You stopped there for seven years. That would take you from 1809 to 1816?—Yes.

What was the habit in relation to the dispensing and the vending of drugs in their shop? How did they carry on their business in relation to dispensing and vending their drugs?—In a general way, as a druggist dispensing and prescribing.

Dispensing and prescribing?—Yes.

What do you mean by prescribing?—Any cases that were brought into the shop were treated and prescribed for.

Persons, I think you said, who were brought into the shop, were treated and prescribed for?—Yes, if required.

Would the chemist ask what was the nature of the complaint?—The patient coming into the shop, as far as I can recollect, would explain the nature of the case so far as he was able.

The patient coming into the shop would explain the nature of the case as far as he was able, and then what would the chemist do? What would happen then?—He would prescribe and order medicine for the cure of the patient as far as he was able. If it was a serious case it would be put into the hands of the head partner of the firm.

Was this called counter prescribing, or was there any name given to it at all? Was it called counter dispensing?—I do not know that there was any term of the kind given to it. It was not so much prescribing in that establishment, for that was a wholesale business as well.

Now when the chemist in this way gave the patient, as you term the customer, the medicine, did he charge for the medicine that he gave him?—Yes, certainly.

Did he charge anything for what a surgeon would call "advice," or did he only charge for the medicine?—He charged only for the medicine, for nothing more.

Which I suppose he would make up according to his discretion and sell it to the customer in such quantities as he thought right?—Quite so.

Would he, or would he not give directions as to the doses in which the medicine should be taken, and the times at which the medicine was to be taken?—Proper directions would be given.

Now just answer this question, yes or no—Did you eave business in 1872; I think you told me it was 1872, or was it 1862, which was it?—It was earlier than that; I have been away from business twenty years or more.

I think the date was 1862, my Lord. Now just tell me this, only say yes, or no—is your memory as to what took place before 1815 assisted by the course that you have pursued since. Only answer that yes or no as to whether it is or is not?—I have a perfect recollection of what took place at that time.

Is your recollection clear as to what took place up to the year 1815, whilst you were at Worcester?—The conducting of the business I perfectly recollect.

I will only ask you this. As far as you know, however far that may be, was the course that your masters pursued the same as the course pursued by other chemists and druggists? Was there anything peculiar about your masters, or did other chemists and druggists as far as you saw practise the same course?—It was not different from any other.

Cross-examined by Mr. Morgan Howard.

As I understand you every serious case was sent to the head partner or to the senior partner of the house?—Any serious case would be referred to him.

May I ask you was he a medical man or a chemist?—A chemist, and the fact is he had been in the profession.

Was he a medical man in point of fact?—He was not practising then.

Had he ever received a medical diploma?—I suspect so, and I believe so, because he was practising as a regular medical practitioner.

Sir Henry James: Before the year 1815 there was no diploma required, so that that would be so.

Mr. Morgan Howard: And this was before 1815?—Yes.

Did you confine your practice to your shop, Mr. Parsons?—Yes, certainly.

I do not want to go into too much details. Can you give me an idea what class of cases came under your own personal observation before the year 1815?—What was the practice and the custom at that period?

Yes.—It was not different from anybody else's.

I do not want to press you too much upon this. I want to know if you can remember any particular class of cases which came under your own personal opservation before 1815?—They were of the lower classes.

Do you mean the cases of the lower class of people?—Yes; that came for advice chiefly, and for medicine.

Sir Henry James: I have nothing to ask you.

The Witness: Will you allow me, my Lord, to make a trifling remark?

Mr. Baron Pollock: I should be very glad to listen to your remarks, but I am afraid it is against the usual rule.

The Witness: It is merely to call attention to the fact that the chemists and druggists of the present age are a much superior and a better educated class of men to what they were forty or fifty years ago.

Mr. Baron Pollock: He has made an observation, Sir Henry, which I hope he has not taken out of your mouth. It was a very kind one.

Sir Henry James: A similar observation was made with reference to the Pharmaceutical Acts. It was stated that they have to pass much severer examinations.

Mr. George Godden sworn. Examined by Mr. Higgins.

Do you live at Arthur Street, Plumstead?—I do.

Are you eighty-two years of age?—Eighty-three.

Were you apprenticed in July, 1812, to Mr. Phillipson, of Chichester, a chemist?—I was.

Did you remain with him for five years?—Yes.

A Juror: My Lord, the jury think it is thoroughly established as to what took place in 1814. It is no use going further into the case.

Mr. Baron Pollock: Very well.

A Juror: It is an unnecessary waste of time.

Sir Henry James: We were very fortunate in finding so many of these gentlemen alive.

A Juror: Have you many more?

Sir Henry James: I think we have four on this point, but I shall not call any more, but I will now call Mr. Shepperley, the defendant.

Mr. Shepperley sworn. Examined by Sir Henry James.

You are the defendant in this action?—I am.

I believe you are by business a pharmaceutical chemist?—I am.

Your establishment we have heard is at Nottingham—at Long Row?—Yes.

How long have you been in business there?—On my own account about ten years and a half.

It was your uncle's before that time, and you were his assistant?—Yes.

And you succeeded to it?—Yes.

Were you also appointed Dispenser to the Nottingham General Hospital?—I was.

I believe you held that office for many years?—Nine years and a half, about.

Your shop, I presume, is an open shop as a chemist and druggist?—It is.

I suppose you, for instance, make up prescriptions of physicians?—To a great extent.

Will you give the jury some idea of the prescriptions you make up in the year?—Last week it was 251.

What is the number in the course of a year, some thousands?—Some 12,000 perhaps; it is a rough guess.

Those come from prescribing physicians?—Yes, all of them.

Those you have to enter in a book?—Yes, old prescriptions repeated, and new ones as well.

Those persons who bring the physicians' prescriptions from the neighbourhood include a vast number of patients?—Yes.

Some of them are new and some are repeated.?—The bulk of them are old ones.

In addition to that in your shop, do you sell specific articles?—Yes.

I suppose, we will say, a box of lozenges?—Yes.

And even some things not strictly medicine?—Yes, we do.

Will you give an instance of what you sell. Do you sell acidulated drops?—Yes, jujubes, and acidulated drops.

Mr. Baron Pollock: And possibly a tooth brush?

Sir Henry James: Yes, and soap perhaps? I want to show the way, my Lord, that he carries on a trade. And perfumery, for instance?—Yes.

And such things as are generally seen exposed for sale in a chemist's shop—those sort of articles you sell there?—Yes.

Now I will come to the general practice afterwards, but I presume you must have a great number of persons coming into your shop asking you to give them things?—Yes.

Will you be kind enough to recollect what occurred, and to give the jury what occurred at the time when this inquiry officer, Death, came into your shop?—I was standing at the principal counter of the shop, and he came straight up to me telling me he had a cold and pointing to his throat which he said was sore. He said, "Will you look at it?" He thereupon opened his mouth. I did look at it, and I told him I saw nothing the matter with him.

You seem to have been right there.—He replied, "Will you give me something for it?" I said, "Perhaps a saline mixture might answer your purpose." He said, "Will you give me one, then." I replied, "Yes." I gave him one and I charged him a shilling for it.

I will ask you about this saline mixture. It was perfectly harmless, I suppose?—It was perfectly simple.

You told him there was nothing the matter with him?—Yes, I told him so.

And you gave him something that would suit him?—Yes.

Then was something said about the tightness of the chest?—Nothing was said about tightness of the chest.

Did you examine him in any way?—Not in the least.

Did you say "Tightness here," as he put it?—I did not.

Before we leave the question of the shilling, did you charge him a single farthing for any advice that you gave him?—Not a halfpenny, not a farthing.

If a person had come in and said, give me a saline mixture you would have charged him the same price?—Yes, the same price.

And you would have given him the same mixture?—Yes.

And if he had come in and brought you a prescription, would you have charged him the same?—A trifle more, to repay us for the trouble of entering it in the book.

That must be gratifying to the patient. I suppose if it had once got into the book he could come again without having to pay more?—It is a shade more for copying it in.

You do not charge anything more the second time?—No.

Then the ordinary charge without the copying in the book is a shilling?—Yes.

That is what you charged this man?—Yes.

This man says you told him if he was not better he was to come again. Did you tell him so or not?—I did not tell him so. I should hardly be likely to do so when I had already told him I saw nothing the matter with him.

Mr. Baron Pollock: That does not always follow.

Sir Henry James: It is very seldom they say there is nothing the matter. You never did see him again?—Not in my shop? not for the purpose of buying any medicine.

Now I will ask you about the case of this man Hubbard. He was an assistant to Death, was he not?—An *employé*.

I will go further into this. It is the case of the man who went to America. Do you know where that man is?

Mr. Baron Pollock: We have no evidence at present of Hubbard.

Sir Henry James: This is the matter that my friend was going to prove by Dr. Hatherly as to what took place at the County Court, and I said I would call Mr. Shepperley and they could ask him. I will ask him if you will allow me in anticipation of the cross examination.

Mr. Baron Pollock: I do not know that they intend to go into it.

Sir Henry James: It is one of the particulars of the statement of claim.

Do you know who this man Hubbard was?—I heard that he was an *employé* of Death's, that he was in his service.

He was not a Nottingham man to your knowledge. You did not know him?—I did not.

What occurred with regard to Hubbard?—I believe he came into my shop some time after the detective did, and he had some pimples on his face.

He stood before you?—Yes.

Did you see the pimples?—Yes.

There was a simple remedy you were going to give for those pimples?—Yes.

Did you look at him?—Yes, I must have looked at his face.

Had he got any pimples?—He had.

What did you do?—He told me a long history in the first place, of his having been under a club doctor, as he termed him, in whose drugs he had little faith. I told him I did not give advice.

You told Hubbard?—Yes, I told Hubbard so. And I said if you can tell me what you have been taking, or give me an idea of what you have been taking, I will endeavour to give you something like it.

Mr. Baron Pollock:—A kind of *cy près*.

He said I have been taking something that leaves a disagreeable taste in my mouth.

Sir Henry James: I suppose you knew by that what he had been taking?—Not from that exactly. I said to him, what do you think it is?

Had he the bottle with him?—He had a bottle.

In which a previous mixture had been?—No, there was nothing in it at all. He had a bottle and laid it on the counter. I said, "What would you imagine you have been taking?" and he said "I think there was potash in it." I then questioned him as to the taste which he had in his mouth and he said it left a disagreeable taste in his mouth.

What did you do?—I said possibly it is potash. I said, "Was it white or was it brown?" He said it was brown—the mixture was brown. I then said "Was there sarsaparilla in it, do you think?" he said, "Perhaps so." I said, "Well, I can give you these two things if you wish it," and I repeated to him I did not give advice.

Did you give him those?—I gave him those two things compounded in a bottle together.

What did you charge him for that?—Either 10*d.* or 1*s.*

Did you charge him anything for the advice or only for the drugs?—Only for the drugs and the trouble.

Would that be the same price that you would charge for the articles?—Yes, the same charge.

And your answer applies I suppose with reference to the prescription of the physicians?—Yes.

Now as to your course of counter practice, I must ask you, do you ever go and attend patients at their houses?—Never.

Do you ever charge any one for giving advice to any one?—Never.

Should you in any way deal or attempt to deal with the case of a serious complaint?—No, I should not.

Not having directions or prescription from a medical man?—Just so.

Do you or do you not do more, if you are selling your drugs, than endeavour to know for what purpose the drug is intended to be applied?—That is all.

There is only one thing more that I have to ask you. This man Death said that at the interview at the Talbot, on the 28th of November, in a conversation which you had with him you said you had prescribed, you were prescribing, and you would prescribe, and I do not know how many tenses he used?—I did not say those words,

What did you say?—I asked him if he had been watching my premises, he said, "No, I have not." I said, "I cannot believe you because I am told you are doing so." I then asked him what he had against me, as I conducted my business on the usual terms of other chemists. He said, "You have already prescribed for me." I said, "possibly so. I am sure I gave you what was simple." He then attempted to define the law on the subject which I told him I thought was all rubbish.

Then you got into legal matters. Did you use the terms that you had prescribed, and that you should continue to prescribe?—I did not use the terms.

You got into a legal discussion you say as to what your rights were?—Yes.

Cross-examined by Mr. Morgan Howard.

How long have you been in business as a chemist?—On my own account ten years and a-half—about.

You have no medical qualifications?—Not any.

You were dispenser to the General Hospital?—Yes.

And upon your bills, I believe, you do advertise that you were dispenser to the General Hospital?—Yes, I state that.

And you also have that over your door?—Yes.

Now, the instance which you have given to my friend of treating people in the way you have described, is that what you call counter practice or counter prescribing?—Yes.

I may ask you if you are carrying on that is called counter prescribing? You carry that on and do a large business at Nottingham?—I do.

Do you still carry it on?—Not on the same footing.

I do not quite follow that?—I have taken more to general advertising.

You have taken to more general advertising?—Yes.

Do you mean recently?—Within the last twelve or fourteen months.

That relates, I suppose to the sale of specific articles?—Yes.

By that you mean the sale of patent medicines?—Yes.

And the sale of patent medicines only?—Yes.

Have you not for a very long period carried on a very extensive counter prescribing business?—No larger than is usually done in a business of a large character.

As a chemist and druggist?—Yes.

Is your memory to-day fresher on the circumstances of Death's case and Hubbard's case, than it was when you were examined in the County Court?—Yes, it is.

How have you refreshed it?—By hearing his evidence to a certain extent.

In the County Court?—Yes.

You mean Death's evidence?—The general evidence.

Did you hear Death examined?—I did.

Do you adopt his evidence?—No, I do not.

I ask you how your memory is refreshed to-day with reference to Death's case. It is clearer to-day than it was in the County Court. How is that?—I could not recall everything at the moment.

What was it that refreshed your memory; tell us shortly?—I heard his statements.

And you believed them?—No, I did not.

Then why did they refresh your memory if you did not believe them?—They refreshed my memory as they occurred.

Do you recollect this question being put to you, "Do you recollect Death calling on you and asking you to look at his throat," and did you answer then very indistinctly?—I did.

Was the question put by the judge, do you recollect that or not?—I believe he did put it.

Because I am told he did. Is that accurately reported?—It is.

Sir Henry James: Was it not before Death's evidence was given?

Mr. Stanger: Yes, it was.

Mr. Morgan Howard: "Are you able to say he did call on you and ask you to look at his throat?—I believe he did.—Yes.

You do say positively he did; were you in doubt about it at the trial?—No I had not much doubt about it.

Had you any doubt about it?—I had not.

Then why did you say "I believe he did?"—I was not liking to convey on myself a penalty, if I could avoid it.

"Did you examine his throat." Can you tell me what the answer was to that question in the County Court?—I said I should do so, I believe, if he asked me.

Is this it "If he asked me I should, but I do not remember"?—I think I did.

Have you any doubt about it?—I think I did.

Did you say so?—Yes.

You are now able to say positively that you did examine his throat?—Yes.

When you were examined before the County Court Judge did you not say you could not positively say that you had?—I thought I had.

Had you any doubt?—Very little.

Had you any?—Scarcely any.

Any at all?—None.

He brought no prescription with him?—Not any.

Do you remember being asked what you gave him?—I think the question was asked, but I do not remember.

Do you remember what you said?—A simple saline draught, I think.

Is this right: "What did you give him?—I do not remember?"—I could not recollect exactly; I thought it was a saline draught.

Did you know at the time you were examined at the

County Court that it was a saline mixture?—I thought it was of that character.

You did look down his throat, did you?—Yes.

You examined his throat?—I looked down it.

You examined it?—That is looking down it.

Medically?

Sir Henry James: I object to that question, my Lord. The witness has said what he did. My friend said having looked down his throat, did you look down his throat medically; I ask my friend to define to the witness what he means by looking down a throat medically?

Mr. Baron Pollock: You may ask him for what purpose he looked down his throat, but how he looked down his throat, whether legally or medically, I do not know.

Sir Henry James: Or whether he looked down it chemically.

Mr. Morgan Howard: Did you look down his throat with a view to determine by your inspection what disease he was suffering from?—No, to verify his statement that he had a sore throat.

You might have accepted his statement, you know, if you had chosen and have acted on it. But did you look down his throat for the purpose of forming your own conclusion as to whether he had or had not a sore throat?—Yes.

Did you come to the conclusion that he had any sore throat?—No. I have already said so.

Say it again, if you please, that he had not. You affirm that he had not?—Yes.

Did you tell him he had not?—I told him distinctly I saw nothing the matter with him. Those were my words.

And you prescribed for him accordingly?—I suggested the medicine I have already stated.

That you thought was necessary to cure nothing, and you charged him a shilling for it?—I left him to say, on suggesting it, whether he would take it or not.

When he told you, if he did tell you, that he had a sore throat he did not ask you for a saline mixture?—No, he did not.

That was your selection of the medicines, was it?—Yes, it was.

Did you make up the draught, whatever it was, in his presence?—Scarcely that.

Well, "scarcely" is somewhat ambiguous. Did he see you do it?—I do not think so, because it would be behind a little counter, where he would not see.

While he was in the shop?—Yes.

Did he drink it off in your presence?—No.

Then it had a label on it?—Yes.

Directions how to take it?—Yes.

Telling him what?—Two tablespoonfuls, I think, three times a day.

Mr. Baron Pollock: That was the old label. You did not put a fresh label on?—Yes; I put a fresh one on.

Mr. Morgan Howard: Did you tap him on the chest?—I did not.

And did he tell you he thought he was suffering from any affection of the lungs?—No.

Did you ask him any questions about his lungs?—No.

Then all you did was to look down his throat and judge for yourself whether he had a sore throat?—Yes.

You judged that he had, and you gave him some medecine to cure it.

Sir Henry James: He said what he did

Mr. Morgan Howard: Mr. Hubbard, I daresay you know, has gone away to America. You are aware of that.—I heard so only yesterday.

Did you hear that in the County Court?—No.

Did you hear he was elsewhere than in Nottingham?—No.

He was not there?—Not to my knowledge.

Mr. Hubbard was the man we have heard of with the pimples?—Yes.

Did you examine his face?—No.

You looked at it?—I must have looked him in the face.

As you are looking at me?—Yes.

Sir Henry James: But with a different result.

Mr. Morgan Howard: Did you see pimples (I do not mean to-day), but did you see the pimples?—Yes.

You formed your conclusion about them, did you not, that they wanted some treatment?—I do not know what I did.

Do you know you did not. Pray, answer me frankly. Did you or did you not come to the conclusion that the primples needed some sort of treatment?—I did not come to any conclusion.

Did you come to the conclusion that they did not want treatment?—I did not.

Did you treat them also?—I gave him——

Answer my question. Did you in fact treat them?—I gave him some medicine.

Did you give him medicine with a view to treating them?—No, not to my knowledge.

Did you give him the medicine which you gave him, with a view to treat the pimples?—I have already explained on what account I gave the medicine. I have told you I gave him the medicine from certain questions and suggestions made by him.

When you put certain questions and had certain suggestions made to you you gave him the medicine?—Yes.

Made up, I suppose, from some selection of medicines in your shop?—Yes.

You made up some compound mixture and gave it to him?—Yes.

Then having made a compound mixture, you made it with a view to treating him for the pimples of which he was suffering?—That would be the natural view to take of it, I suppose.

Is it not the truth?—I had told him that I did not give advice; and having told him that, I could not be said to do so.

I want to have it on the notes for what it is worth. Tell me aye or no, on your oath, whether you gave him this compound, having made it up for the purpose of treating the pimples?—For the purpose of his taking it for his pimples.

Did you form any opinion as to what had produced the pimples that he had?—I did not.

Why did you not?—I had already had a visit from the detective.

Never mind the detective.

Sir Henry James: Yes, but we do mind the detective. You ask him why not, and he gives you his reason.

Mr. Morgan Howard: Tell me, if you please, why did you not form any conclusion as to what caused the pimples! That would not depend on the detective. I am asking you, as a chemist and druggist, as to the cause in the man. Why did you not form any conclusion as to what caused the pimples?—I cannot say why I did not, but I did not do so.

Were you, in your opinion, competent or incompetent?—I consider myself as competent as any chemist could be.

You considered yourself as competent as any chemist could be to do it?—Yes, to form an opinion on the matter.

Now, considering yourself competent (do not let us linger on this, but let us deal frankly with each other), did you not prescribe in your own mind?—I did not.

Did you not select the mixture for the disease?—I did not I asked him what it was.

What did you suggest it was?—That it was iodide of potassium.

Did you suggest it was?—I did not.

Mr. Baron Pollock: What did he say to iodide of potassium?—He said he thought it was potash. I said it would probably be iodide of potassium, and I asked him if it left a disagreeable taste in his mouth, which it does.

Sir Henry James: He went through this in his examination in chief.

Mr. Baron Pollock: Only he did not introduce iodide.

Mr. Morgan Howard: Now, in the County Court do you recollect being asked this question, "What medicine did you give him?"—Yes; I remember that.

Do you equally well remember your answer?—Possibly sarsaparilla. I think I said so.

Do you remember saying, "I cannot recollect?"—Possibly sarsaparilla.

Do you recollect saying "I cannot recollect?"—Yes.

Was it true at the time that you did not recollect?—I had an indistinct recollection. It was not a perfect recollection. I could hardly remember then.

What was it in fact. Give me the name of what you did give him?—Iodide of potassium and sarsaparilla with water.

Did you, in fact, come to the conclusion at the time that the man was suffering from an impure condition of the blood?—I came to no particular conclusion.

Did you come to that conclusion, never mind whether it was particular or general. Did you come to any conclusion, and, if so, was it that he was suffering from some disordered state of the blood?—I came to the conclusion that it was a disordered state of the blood that caused the pimples.

Then before you administered the drug you did come to the conclusion that he was suffering from a disordered state of the blood, more or less?—Yes.

Now one word more I ought to have asked you about the saline mixture. You have told me about the mixture you gave Hubbard. Now a saline mixture is not a simple mixture, it does not consist of one drug?—No.

Then it is a compound mixture?—Yes.

A saline mixture is frequently an element, or at all events it is an element in a prescription which is frequently prescribed by medical practitioners?—Yes.

And bears oftentimes upon the speciality or the nature of the disease?—No doubt.

Then you made up this compound mixture for your patient, as I call him, at the time you formed you own conclusion that the elements of which a saline mixture is compounded were necessary for his recovery?—I made it up according to the things that saline mixtures are made of.

How is it that you remember Hubbard's case better to-day than you did in the County Court?—You have told me about Death's case.—I have a more distinct recollection of it now than I had then.

Would it be too curious to ask you how it is that you have arrived at a better conclusion? Let me remind you in fairness to you that Mr. Hubbard was not examined?—No, he was not.

Now tell me how it was?—My nephew who was with me in the business reminded me to a great extent of the occurrence.

Is he with you always in the shop?—Nearly always.

Does he assist you in this large counter practice that you have?—I have not said that I do a large counter practice.

I will not press you on that. Does he assist you in doing what you do?—He does.

Is he apprenticed to you?—Yes, he is.

Now let me ask you this. I need not pass it over to you, you know what this is (holding up a book)?—Yes.

This is a prescription list of Mr. Shepperley's family medicines for 1878, entitled 'Every one his own doctor.'

Sir Henry James: You had better put it in.

Mr. Baron Pollock?—They say the man who is his own lawyer is the best friend to the profession, I do not know if that observation holds good in this case.

Mr. Morgan Howard: Only one question I want to ask you, in what respect is it that you have altered your mode of doing business or practice, if you will have the word, during the last twelve months?—I beg your pardon?

In what respect have you altered your practice during the last twelve months. You told me you have done so?—Yes, I have resorted to the desire of trying to increase my business by advertising certain things.

Have you abstained at all from seeing patients and making your own judgment of their disease and prescribing for them?—To a very great extent.

You have to a very great extent?—Yes.

Then let me ask you do you think it was wrong to have done it to the extent that you formerly did it?—I do not.

It was very profitable?—It is equally profitable in the present form.

You advertise extensively you say?—Yes, I do.

That brings you a large number of such persons, I suppose, to consult?—No, that is the reason of my advertising.

Do they come in your shop in large numbers?—They come in large numbers to purchase these articles.

Do they come with various complaints?—They do not mention their complaints.

Mr. Baron Pollock: You advertise specific articles?—Yes.

Sir Henry James: My friend had the list of them, and did not refer to it.

Mr. Baron Pollock: That brings the persons to the shop to buy the articles.

Mr. Morgan Howard: Are not those persons who come and tell you they have something the matter with them, and who consult you, and you look at them and look at their tongues?—No, I do not.

Do you mean to say you do not look at their tongues and feel their pulse?—If one asked me to look at his tongue I should do so.

You would not ask him to let you do so?—No, not now.

I think I can infer what you mean.

Re-examined by Sir Henry James.

I think at the County Court Mr. Brown, who instructed Death appeared against you?—Yes.

And the first witness he called to support his case was yourself. He did not call Death to let you hear what he was going to say?—No.

Then not hearing what Death was going to say, Mr. Brown put you into the box and asked you questions without your knowing what Death was going to say?—Yes, to convict myself.

You did not know who Death was when you saw him; he was no customer of yours?—No.

You have a great deal to do in your business, and in the first instance I suppose you do not recollect the circumstances of each particular case?—No.

But you have thought over these circumstances since Death has given his evidence?—Yes.

Your nephew was in the shop at the time?—Yes, at the time of the occurrence.

And after hearing what Death had to say and after talking the matter over with your nephew you have given the evidence you have given here to-day?—Yes.

Now is that evidence true which you have given us to-day?—It is.

Now as to Hubbard's case; I believe my friend seems to make it a point that there was a direction on the label to take two tablespoonfuls?—Yes.

If a customer came in and asked for a specific lotion, or draught, would you in such a case put on the directions as to the time at which it should be taken and the quantities in which it should be taken?—Yes, it is usual to do so.

I believe that is the general practice of a chemist?—It is the general course.

My friend has also asked you some questions rather abstract in their result as to how you formed your opinion about Hubbard's pimples. Are you sure that took place which you told us in your examination in chief, as to the conversation as to the medicine that he had taken, and as to what he thought it was?—Yes.

You were asked as to whether you were competent to

form an opinion as to what he was suffering from. Could you see them?—Yes, I could see them distinctly.

And after he spoke about the iodide of potassium and the sarsaparilla, you gave him the things he had had before?—Yes.

Which would be a proper medicine?—Yes, a proper medicine, I believe.

And for which you charged him only the price of the draught?—Yes.

My friend, Mr. Morgan Howard, asked you whether you thought it right to advertise, and he put this in your hands, and as he alluded to it, I should like to refer to it. I should like the jury to see it. I believe you do advertise these specific medicines?—I do.

Mr. Baron Pollock: Have you another copy of that?—I have a copy of it, my Lord.

Sir Henry James: Yes, he has brought some with him. (Some copies were handed in). I do not know if it is the same?—No, it contains the same items, only it is in a cheaper form.

You got down to 7½d. before that?—Yes.

I forget what number you got to, ninety-eight is it not?—Ninety-nine.

No, I am told it is ninety-seven. I suppose the jury will see the numbers. There is number fifty-three "white powder and purifying pills," and so forth. I suppose that is a sort of medicine that is advertised like Holloway's pills and so on?—Yes.

And this is the specific medicine appropriated to specific causes?—Yes, for simple cases.

And I suppose you have a patent medicine stamp on them?—Yes, on each of them.

Mr. Baron Pollock: Have you a patent medicine stamp on them?—Yes, on every one of them.

Sir Henry James: There is the patent stamp on the 1*s.* 1½*d.* package. There is one question I forgot to ask you. I am told, but it escaped me, that this man Death said you told him to leave off smoking, did you give him any such advice?—I never mentioned a word about it, nor he to me.

You are quite sure you never mentioned the advice about smoking?—Not a word.

Did he say anything to you about smoking?—Not a word.

When you came to the conclusion that he had nothing the matter with his throat, did you say he had better leave off smoking?—I did not say a word about it.

Frederick Shepperley sworn. Examined by Sir Henry James.

Are you apprenticed now to your uncle, the last witness?—I am.

Of course your attention has been called to the first trial and to the matters connected with this case. Do you recollect this man Death coming into your uncle's shop?—Perfectly well.

Where were you at the time that this detective officer came into the shop?—Close to Mr. Shepperley, at the same counter.

Now, will you tell the jury, if you please, what took place between Death and your uncle, Mr. Shepperley?—The detective came into the shop and he came close up to the counter and he said to Mr. Shepperley, I have a cold and a sore throat, and he leant a little way over the counter, opened his mouth and said, Will you look at it.

Was there any turning to the light or going to any particular place, or did he put his head over the counter?—He put his head over the counter, and he said it catches me here, touching his throat.

The man putting his head over the counter, and opening his mouth, your uncle did look down his throat?—He did.

What did he tell him?—He told him he did not see anything the matter with him.

Was anything said about touching the chest?—Not at all.

Or anything about the tightness of the chest?—No, not at all.

Was there anything said at all about smoking?—No.

That you are sure of?—I am sure.

Then, having done this, did your uncle give him the draught?—He gave him the medicine.

Did he say, "Possibly a saline draught will answer the purpose"?—As near as I can recollect, those were the words.

Then did he pay him the shilling for the draught?—Yes. He gave him the shilling for the bottle.

Was he or was he not told to call again?—He was not.

Cross-examined by Mr. Morgan Howard.

You were not at the County Court, were you?—Yes.

You were there?—Yes.

You were not examined, were you?—No.

Mr. Baron Pollock: How came it that this case was brought in the County Court and then afterwards removed?

Mr. Morgan Howard: The offence being at Nottingham, action was brought at Nottingham, as it may be under the statute, and the judge found his verdict for the plaintiff.

Sir Henry James: Subject to a special case.

Mr. Morgan Howard: There was no case at all.

Sir Henry James: The Judge says "I have no question about it, but you will have the full benefit of the case." On that we came to the Court of Exchequer, and then I will tell your Lordship what the Court of Exchequer did.

Mr. Morgan Howard: All we know is that my learned friend appeared, and a new trial was ordered. My friend ought not to make *ex parte* statements.

Sir Henry James: My friend was going to say that the Judge found a verdict for the plaintiff, and that must be withdrawn or the jury must know the whole of it.

Mr. Morgan Howard: I wish that they should know the whole of it.

Sir Henry James: Then, when this matter came before the Lord Chief Baron and Baron Cleasby, as soon as they heard the matter,—it was very fully discussed, for it occupied two days' argument—they said it must come before a Supreme Court, and we undertook to remove it by a *certioriari*, and here it is.

Mr. Morgan Howard: I have another question to ask. You were in the County Court, but you were not examined?—Yes.

You were there when your uncle was examined?—Yes.

Did you hear him pressed by counsel, when he was unable to give his account of what took place with Death or Hubbard?—Yes, at the County Court.

Did you hear the counsel press him, and did you hear him unable to give anything like a definite answer?—I did.

Mr. Baron Pollock: Was he unable to give anything like a definite answer?—Some questions that were put to him he could not answer very distinctly.

Mr. Morgan Howard: You appear to know all about it; why were you not called. Were you asked if you could say anything?—I was not.

Your uncle knew you were in Court?—He did.

Does your Uncle keep any books; I mean containing the names of customers or patients or anything of that sort?—He keeps the books which are full of the physicians' prescriptions.

Do you write in them?—No, I do not. His assistant keeps the physicians' prescriptions, if that is what you refer to.

How old are you now?—Nineteen.

Sir Henry James: That is the defendants' case, my Lords.

Mr. Howard then submitted that even on the evidence as it stood it was a question of law, whether what had

been done was not a violation of the statute. He did not propose to argue that at any length now, but he wished to call attention to Mr. Justice Field's view in Wiggins's case.

Mr. Baron Pollock said ultimately there might be a question for the Court on the construction of the statute, but he should not feel it right to withdraw the case from the jury.

Mr. Howard was proceeding to make some further remarks, but Sir Henry James protested that it was irregular.

Sir Henry James then summed up the case for the defendant, as follows :—This course which my friend is pursuing is to me novel, and I was almost about to say, unconstitutional, because I cannot conceive it possible that a man is to be convicted in a penalty or penalties, and that he is to pay a sum of money for doing a certain act without its being left to the jury to determine whether he has done the act or not. But my friend wishes now and has gravely submitted to the learned judge, that it is to be assumed that he has done the act which makes him liable for the penalty, and that the learned judge is to tell you, the jury, that you have no function to exercise, that you have no question whether the man has done the act or not ; that he tells you he has done it and therefore you are to find its. Gentlemen, my Lord, I am sure will not misunderstand me when I say there is no such power as that existing in a judge, and that before a man can be convicted of being liable for a penalty for doing an act which is a question of fact, whether he has done it or not, the jury, those at least who have to decide the question of fact, must find that act has been done. Of course you will understand that which probably was in my friend's mind to say, and that which I am sure I mean to say, that that which my friend talks of law you will fully accept from his Lordship, and when you have had that direction you will then have to determine whether, in accordance with it, the act has been done, and I only, and my friend, when he addresses you, can anticipate that which my Lord will deem it right to tell you will, as a matter of law bring the defendant within the 20th section. But as a matter of anticipation I now purpose addressing you on what I believe will be the questions left to you.

Gentlemen, before the plaintiff, the informer in this action, can recover at all it must be found by you that the defendant has done that act or acts which are mentioned in the 20th section of this old Act of 1815. You must find as a fact from the evidence that has been given before you upon this trial on the part of the plaintiff, aided if necessary by that which is given on the part of the defendant, that the defendant did act or practise as an apothecary. My friend may use what arguments he likes on the question of law, but subject to that which my Lord shall tell you amounts to an acting or practising as an apothecary, a direction by which, of course, I wish you to be bound, you will now have, whatever that direction may be, to bring your common sense to bear on that question, and determine whether the defendant, Mr. Shepperley, has acted or practised as an apothecary. And, gentlemen, I now submit to you, although I hope I shall not be censured by you for repeating myself, but yet in the sense of the grave importance of this case, not only to surgeons, not only to druggists, but to all the humbler members of this community, I am now going again to press as strongly as I can, in a very limited time, the position that the defendant and others who are acting with him seek to occupy, and to submit to you that this defendant has not acted or practised as an apothecary.

Gentlemen, do let me remind you, as I said before, that apart from definitions that we have in our books of what amounts to an acting or practising as an apothecary, and without evidence being given before you, as men of general knowledge you must be aware of what that amounts to. An apothecary is that person who is in fact the general practitioner we meet with almost always in country towns. The general practitioner has a diploma very usually from the College of Surgeons to enable him to deal with surgical or clinical cases and to attend persons with wounds and what are wrongly termed sometimes external diseases, cases of lesion and hurt to the body ; but he has also a diploma from the Apothecaries' Hall, which entitles him to attend persons who are suffering from diseases requiring medical treatment, not surgical treatment in the sense in which those cases are known to the profession. By having that diploma from Apothecaries' Hall it of course imposes upon him many duties. He has of course to attend persons where skill may possibly retrieve them from illness ; he has to attend persons where everything depends upon the apothecary's skill whether the patient lives or dies ; he has to stand by the patient's bedside, and he has to form first his opinion as to the source of the disease, the nature of the disease, the probable tendency of the disease, and the best remedy that can be applied to it. All that must come from much study, theoretical study perhaps, and from experience not only obtained in course the of his pupillage, but also study and experience extended into the time of his practice. He is entitled, therefore, under the circumstances, according to his skill, according to the length of his visit, according to the distance he has to travel, to charge for that skill, for that trouble and for that time which he expends in attendance on the disease. Take a case by way of example. I forget whether a gentleman like Sir William Gull is a physician or a surgeon; but there are many of course who are known to us in the medical profession, who are not physicians, but still gentlemen of the highest eminence, who attend on patients suffering from disease other than surgical. I think Sir James Paget is a surgeon, not a physician, and a gentleman going probably from one end of the country to another, and he is entitled—I need not deal on that matter—of course to receive a very large remuneration for nothing but the advice that he gives. I presume he would not even prescribe ; he would have nothing to do with the consideration of the mere condition of the patient, but only the general nature of the disease, and would give general advice, perhaps that which may effect the cure of the disease. These gentlemen possess the highest knowledge, and the highest skill, and these gentlemen are apothecaries. If it is not a surgical case, if it is one of high fever, and he is there, the patient is attended by an apothecary, by virtue of his diploma from the Apothecaries' Hall, and he is acting and practising as an apothecary within the meaning of this Act. So whilst that is an example of a distinguished man practising his profession in the highest branch, so too is the general practitioner in the country town, who goes from house to house, sits by the bedside of the patient, and recommends what course should be pursued under the circumstances. He takes the general charge of the patient's health, gives in that patient's own house, or in his own surgery, instructions what to eat, to avoid that, to drink this, or to avoid that liquor which may be drunk. He says this course you ought to pursue ; alter your mode of life ; leave your present residence, or whatever he thinks necessary, and with the advice he may order some particular medicine—that is acting and practising as an apothecary. Now we come to the case of a chemist and druggist who is doing none of these things; who, as in the case of Mr. Shepperley, has an open shop and wares exposed to view in the shop, and not only these medicines are to be made the subject of his dispensing, but these ordinary articles of trade. He gave one instance to my Lord, and mentioned an article of the toilet, and other such things like acidulated drops and things of that kind that are goods exposed for sale in the same way that a grocer exposes for sale goods of a similiar quality. That is his primary business. Another business, which it is admitted he is entitled by law to carry on, is the making up of prescriptions which

the physician has drawn up and given to the patient. There he has to bring knowledge to bear to some extent in the compounding of these prescriptions. But now comes a more indirect ground, where it gets into a different condition of things. A person goes to him and he does not go to the person, but a person comes into that shop for one object only, and that is to buy goods, which in that shop are exposed for sale. He does not come there for general advice, he does not go there to ask that druggist whether he had better take medicine or not, not even for advice so general as that. He does not come there to ask that druggist, Had I better leave off what I am eating or what I am drinking? had I better change my residence? had I better seek a different air, or better pursue a different mode of life? What he comes to ask for, and what he invariably asks for is this, Will you give me something? That means will you sell me something, that is, one of your wares. It is a general formula, an ordinary expression, for that is involved in the articles he has made, and it involves the result of selling of the article by the chemist and druggist who has been asked for the article. Now the only suggestion that can be made that the chemist is acting or practising as an apothecary I submit to you appears to have been this. Admitted that he does not go out of his own shop, admitted that he gives no advice except that which is in relation to the sale of his drugs, admitted he charges nothing for that advice, admitted that he only charges for the drug, admitted that all that he does is incidental to the selling of the drug, yet he is acting as an apothecary. I submit to you that is a complete and entire fallacy. It is not for me—it will be for my Lord to guide you—not for me to tell you confidently that this is the view you ought to take, but I submit to my Lord and leave it to your common sense and ask you to say that if this which is done is a thing incidental to the proper and discreet sale of the article which is sold, that that is acting as a chemist and druggist and not acting or practising as an apothecary. Gentlemen, I gave you some instances before, but if you were to come to a different result do let me ask you to consider what if it is to be the result what the result must be, and also the effect of the result. If you are to say that a chemist and druggist is to exercise no sort of discretion as to what he sells, what he ought to sell, as to the article he should sell, in what position do you land him, and in what position do you land his customer. He is first to obey the mandate of the customer who comes and says I will have so-and-so for a sore throat, if he knew that it was the most inapt remedy for a sore throat. He would not, if the verdict goes against Mr. Shepperley, be allowed to say, you had better not take that; you are going to assert that a chemist and druggist shall say nothing, he has no right to inquire whether your sore throat is a severe one or a slight one. A man says, Give me a suitable article for a sore throat. Are you going to forbid the chemist from doing that, from selling a drug that is suitable for a sore throat? There can be no reason why, if the chemist is asked for that which the patient or customer thinks suitable, he should be bound to give him that, and at the same time be disentitled to say, I think I can give you a better article. Surely if it be a mere sale he must be entitled under the provisions of this Act to do it. And, gentlemen, if he be not, can you conceive anything more absurd than to suppose that the Legislature ever intended, or that these words can be so defined as to mean that the man is to be prevented doing it. And in the instance I gave you, are you to carry your judgment to the extent of saying that the chemist is to exercise no discretion as to the quality of the article, or the quantity? I gave you the example before of a person who goes into a shop and says I want a certain article and a certain draught which I am to take internally formed of certain ingredients that must depend on the amount of each ingredient in the mixture. Is he to look at the person who asks for it, and yet form no estimate of what is the proper proportion to be given to the person who has to take it. Whether he is a man of middle life, six feet high, who might take a prescription of a certain strength, while a child of three or four might be killed, simply by taking that same strength and the same mixture. If a chemist were to give a child a mixture of that strength, and the jury were to find that a reasonable man ought to know it would kill the child, and the child should happen to die, with submission to my Lord, that chemist would be guilty of manslaughter. And yet, if its guardian came and asked for the mixture of that strength, the chemist, according to my learned friend, must have given it or not sold it at all. If he went on, I give you this advice; I look at the child, I think the child is not strong enough to take it; or if he says you are asking for too much laudanum in the mixture, according to my friend's contention to-day, that chemist comes within the penalty of this Act. Can you say for a moment that in and about the sale of that mixture the chemist is not to take wise precautions, and in order to do that, to learn for what purpose and under what circumstances the mixture was about to be taken? Can you say that in doing this he acted as an apothecary? What he did was to act or practise as a chemist and druggist, and in acting or practising as a chemist and druggist he did that which is his duty clearly—that is to find out the destination and purpose for which the article sold was to be employed. Gentlemen, you are restricting the chemists and druggists more than any other trades ever have been or are restricted at this moment if you do not allow this advice to a customer to be given. I say you are carrying this giving advice to a customer to the extent of acting or practising as an apothecary. Where the line is to be drawn it is not for me to say, but until that line is passed, I submit to you, you ought not to find that the fact does exist. Has that line been passed in this case? That must depend to some extent on what you believe took place. I should say if this gentleman, Death's, statement was believed, you would come to the conclusion that there was nothing like acting or practising as an apothecary; but if there be a question which account is to be believed let me ask you to determine first, which has told the truth here to-day? Are you going to believe this detective officer employed for the purpose of convicting Mr. Shepperley or are you to believe Mr. Shepperley and his nephew who confirms him as to what did take place? I know it is inexpedient, and I do not wish to go over the ground again as to the propriety of the course taken to get up and create a case. I should have thought these medical gentlemen in Nottingham who are to get the benefit of stopping chemists and druggists from giving advice would have been satisfied to stop the evil, when the evil existed, and not to create it by means of a fictitious statement by sending a detective officer saying he was ill when he was not. However they must satisfy themselves of their own good feeling. I may be wrong and be judging them too harshly in the matter, but you must recollect that this detective person is a person who had one object in view, a conviction, and who is not yet paid for his trouble. When Mr. Shepperley tells you who he is, confirmed as it is by the evidence, I ask you to accept his statement as truth. As regards what took place with Hubbard there is no contradiction. He was a detective employed by Death.

Mr. Howard: That is not so.

Sir Henry James: I can only say that for some good reason he is not here.

Mr. Howard: He is in America.

Sir Henry James: I am very glad to hear it. I do not know whether he has gone on an extradition journey or whether he is wishing to be spared an extradition case; but at any rate he is not here to give you his account of the transaction, and he never has given any account, and therefore you are bound to be guided by the evidence of Mr. Shepperley, who was present himself. The only observation which can be made is that Mr. Shepperley did not speak so specifically before the County Court as he has spoken to day. I

should have been very much surprised if he had. The attorney who instructed Mr. Death to go and say he had a sore throat when he had not, and told him to have his pulse felt and to have his chest felt when there was nothing the matter with it, thought it right in the practice of his profession to launch this man as a witness to answer a charge which he had never heard made; he thought it right to put Mr. Shepperley into the box and make an answer and give his own defence, before Mr. Death had been called as a witness. I should think it probable that Mr. Shepperley might well hesitate and might well say, "Let me hear what the man has to say and I will bring my mind to it and consider the case. But when you ask me about one case out of thousands of people that come into my shop I cannot tell you with accuracy until I have had time to think of it and inquire into the matter in exact detail." And, besides, if a man knows by the answers he is giving he may subject himself to a penalty, I can perfectly well understand that a person does speak with caution or reticence, and will not be disposed to make the full and ample admission which, after full and ample reflection, he is able to place before a jury. I say that course was not only taken, but that it was not a proper course for a professional man to endeavour to obtain penalties for his employers, apart from the course he had taken in instructing this Mr. Death. Not to give the defendant an opportunity of hearing the charge before he asked him for his defence, and before Death had spoken, and before even there was an opportunity, it may be, for him to identify the man, Mr. Shepperley is put into the box and asked to give particulars of a case upon which no evidence had ever been given. I ask you therefore to believe his statement, to take his statement to be true. Has he practised as an apothecary? Not in this case. All that he has done was apparently to look down the man's throat and tell him he had nothing the matter with him; then to give him a saline draught, because that was a negative medicine, because it could not do the man any harm, and there was no necessity for it doing him any good. That is not practising as an apothecary. In Hubbard's case, on the evidence as it stands, uncontradicted, it is most singular the caution he took. He says I told him I gave no advice and I repeated that, I told him I wished to know what he had had before, so that as a chemist and druggist, I might have the advantage of the previous apothecary's skill, and acting on that I came to the conclusion that he had had given to him this sarsaparilla and potash; and I gave the same mixture as the medical man had given, because I believed that to be the medicine he had previously taken." Gentlemen, my friend cross-examined, which was very amusing. Were you competent to know whether the man had pimples? Of course he was. Were you competent to know from what the pimples came? Of course he was competent. Did you form a judgment what the pimples came from? If he did form a judgment that does not make him act and practise as an apothecary. The giving medicine to a man, who has pimples is not acting or practising as an apothecary; if it is the proper ware to sell him, because he has pimples on his face. It is almost laughable to deal with this case as it stands. After all this inquiry I forgot to ask him how long he watched this shop. This man is at the doorway and saw people go in and out. This medical gentleman, and this attorney, and this detective have been unable by their joint exertions, to find any one patient whom they could call as a witness, or about whom my friend could cross-examine, to whom one syllable of medical advice has been given, except these two detective people, one of whom has been here and has told you to what extent that went. I really beg pardon for occupying so long a time, and if it were not for the importance of this case to every poor person who may not have the means to pay for a medical man, who must have and must continue to have the quick and prompt, and simple advice in these simple cases from these chemists and druggists; I say if it were not for the importance to these I should not have troubled you with one word in the way I am now troubling you a second time; but I am anxious that there should be no injustice done in this case, and I do pray you to consider whether for one moment it has been established to your satisfaction, that Mr. Shepperley has acted or practised as an apothecary in the sense in which you understand a person to be acting and practising as an apothecary, who gives advice to his patients.

There is only one other matter to refer to, because you happily relieved me on one point, and I was obliged to one of your body who intimated your views on that point, that was that you thought the practice of chemists and druggists before July, 1815, had been established. My friend was proceeding to cross-examine those witnesses, and, I presume, would have done so if you had not intervened, and I endeavoured to convince you that those gentlemen were stating to you what was quite correct. I do not apologize for not having more than five witnesses here, because, of course, 1815 is a long time ago, and we cannot produce men here in the prime of life who were practising as chemists and druggists before 1815. But certainly those whom I did call who were practising before that time were very fair specimens to establish the fact, that even if physicians cannot heal themselves chemists can take very good care of their own health, for they certainly appeared in as strong health, bodily and mentally, as even my friend could wish for, and they have established to you now that chemists and druggists did exactly what Mr. Shepperley has done. And with submission I must now just ask my Lord to consider whether taking his ruling,—which for the moment and for the purpose of this inquiry, being anxious to obtain a full defence for my client, I adopt,—taking my Lord's ruling as to the 28th section, I must submit to him and to you that the evidence you deem sufficient does establish Mr. Shepperley's immunity under the protection of that 28th section. If my Lord will forgive me, I will take the section in the sense in which he thought for the moment it ought to be read. I do not make any admission, if the argument be open to me hereafter, but assuming that my Lord's direction shall prevail to the end, I am saying that before 1815, it has been established that chemists and druggists, in and about the buying, preparing, compounding, dispensing and vending of drugs and medicines, and medicinal compounds, pursued exactly the same course that Mr. Shepperley has pursued; and you yourselves seem to be satisfied that it had been established, that before that date the chemists and druggists so carrying on their business used, exercised and carried on the trade and business, in a certain manner and in the same way that Mr. Shepperley has carried it on. I am rather calling my Lord's attention to the words used in the first portion of the section, to show that those words were intended to cover the whole of a chemist and druggist's business. There is first, the act that they had to do first, namely, to buy their drugs; secondly, the preparing of those drugs to be compounded; thirdly, the compounding of drugs when bought and prepared; and there is next the dispensing drugs as distinguished from the selling drugs; and it is in the dispensing drugs and in the selling combined that come in the two operations which it was said chemists and druggists should be allowed to pursue.

They had dispensed, which is quite certain. You heard the words of the old witnesses; they spoke of what the profession or trade has called since counter practice, and they called that the dispensing or prescribing of the drug, and it was that dispensing and that selling that the chemists and druggists were by the Legislature enabled and entitled to carry on in the same way as previously. Now, gentlemen, you heard from Mr. Cupiss and Mr. Parsons what was the dispensing and what was the selling to persons with minor complaints. A customer came into the shop and said, "I am suffering from a cold." In Mr.

Cupiss's case, if it was a severe cold he was told, go to the gentleman who was entitled to look upon you as a medical practitioner would; he required no diploma, because that was before 1815 and he was an apothecary. If it were a minor case, what did the chemist do? He investigated the cold, as far as it required investigation, and without being bidden by the patient he gave him the very article, gave him that article which he thought was suitable for that cold. I am not labouring this; you yourself said you thought that had been established to your satisfaction, that it was the practice before 1815. Has Mr. Shepperley done more than that? If he had not done more than Mr. Cupiss said was done before, that which was done before was done in and about the dispensing and vending of drugs. Mr. Shepperley has compounded, dispensed and vended those drugs. It is exactly the same operation now as then, and although my Lord deemed it right to say we could prove nothing which had taken place since, Mr. Cupiss's answer to what has occurred since confirms him in his memory, and I think entitles me to say that you are asked now, when the time has long passed since 1815, the witnesses growing fewer and fewer, to establish what occurred before. You are asked in the pecuniary interest of medical gentlemen who wish to draw away all these customers of chemists and druggists, and convert them into the patients of these medical men, to prohibit the chemists and druggists from using the simplest amount of discretion in and about the sale of their wares.

I beg to apologise for having occupied your time so long, but as I have said looking to my client and those with whom he is acting and to the public generally, your verdict will be of the utmost importance; and I do trust you will not impose this prohibition on freedom of action in a trade which is most useful and beneficial, merely to increase the pecuniary gain of some gentlemen who wish by means of this technicality to obtain profits for themselves.

Mr. Baron Pollock asked if Mr. Howard would be able to conclude his speech that afternoon?

One of the jury expressed a wish that the case might be concluded, but

His Lordship said it was a very important case and might probably go further, and it would not be wise to hurry it.

It was then adjourned until the following morning.

Friday, Nov. 8.

The case being resumed on the Friday morning, Mr Morgan Howard addressed the jury as follows:—

May it please your Lordship, gentlemen of the jury. When I rose to address you last night I was not aware that the clock was so near to four, or probably I should have been spared even getting up. But I think when you come to look through this case, and reflect not only on the views of it presented to you by Sir Henry James, but on the views of it, which, as it strikes me and those associated with me in this case, are views of the utmost possible importance, both from a public and a private point of view, you will not regret the interval of adjournment, since it has afforded us all an opportunity for reflection and dispassionate consideration. The case has been, I may say, dealt with by my friend Sir Henry James—I ought not to presume to say so, perhaps—with all his accustomed ability, but I must also be permitted to say, that it has been done with all the art of a practised advocate, given to make strong assertions where strong assertions are necessary, and not sparing to introduce topics of prejudice where they might be useful to his client. I shall endeavour to justify what I say directly by a reference or two, briefly, and I hope succinctly, with a view to persuade your judgment on the point. He endeavoured to surround the case by some amount of prejudice with reference to the employment of the detective policeman, and he talked of this case as if it were a prosecution for misdemeanour, involving liability to personal imprisonment; and he has called this, contrary to the common usage in such cases, a case of conviction before a court of justice. But you will by-and-by receive a proper definition of what the law in this case is, and what the practice in reference to this case is, from my Lord who is trying this case. It is not a case of conviction in the sense in which my friend chose to use the phrase.

It is a proceeding invented, justified and persisted in by the Legislature for the last sixty or seventy years, not for the purpose of gratifying the particular objects of a particular section of the community, but for the purpose of surrounding the whole of the community with a salutary protection in the performance of some of the most important duties which any body of men can discharge. It is no secret to anybody, it would be an infamous piece of ignorance if it were, that before the year 1815 the Legislature of this country, as is notorious in modern history, had become bound to recognize the fact that was staring it in the face that the malpractice of unqualified practitioners of one sort or another in the medical world was doing an incalculable amount of mischief to the people who came in contact with it, and that it was necessary that the Legislature should interfere, and I shall have to remind you by-and-by that so far from there having been in that respect any relaxation of the care and judgment of the Legislature, there has been a progressive attempt on the part of the Legislature to repress it, because, and that is one good reason for it, there has been not only no diminution of malpractice, but a constant increase of it ever since the Act of 1815 was passed.

Now, gentlemen, let me say, and have done with it at once, the detective policeman, as he was called, and erroneously called, is not the person who governs this case. He is not the genius in the case, he is not the spirit of the case, but if the evidence which he has given to you is the truth in substance, then your verdict will proceed on that evidence, and I shall ask you by-and-by to say that not only is it true, but that it has been demonstrated to be true out of the mouth of the defendant himself when he was called into the box before you yesterday, and, if it be, then, I think, that although some observations in some cases may be made about the employment of detective officers, in this case they were altogether out of place.

Now, gentlemen, it was a little hard, and I think my friend, Sir Henry James, would really regret on consideration that, led away by the impulse that is natural to all advocates, he strongly reflected on the assistance rendered to the Medical Defence Association in Nottingham by the gentleman who instructed me, Mr. Brown, the solicitor, who was simply discharging his duty according to his instructions, in employing persons legitimately and properly to discover, if they could, the malpractices of which Mr. Shepperley had been suspected notoriously in Nottingham for a great many years past. It is scarcely necessary to vindicate a member of a profession who has held his head high in the profession for many years in Nottingham. I will not do that, because it would be a bad compliment to him, but I resent the attempt to depreciate him at the expense of the case, or the case itself at the expense of him—it is not generous, it is not expedient. The question is, what is the truth in this case; and a further question is, when you have ascertained the truth, whether it comes within the mischief which was aimed at by the Legislature in 1815 in passing this statute.

Now, gentlemen, in 1815 there were physicians and there were apothecaries, and there were chemists and druggists. The law was not well defined, but it was notorious that the chemists and druggists were in the habit of invading the domain of the physicians and the apothecary, and assuming to themselves functions for the discharge of which they were entirely unfitted; for the discharge of which I shall venture to submit to you, not on any statement of mine, but on reference to absolute material before me, that they are unfitted to this day.

And now, I pray you, as a matter of fairness,—it is scarcely necessary to do that with a special jury in London,—but I invite your dispassionate attention to this case from this point of view, that it is not only a case which affects the medical profession itself, and therefore affects us all, but affects us in a large sense as a great community, whose health and lives are constantly dependent—not on practitioners of this class or that class—but on a well qualified class who can bring learning and experience to bear in the judgment of the various ills to which we are subject. It is, therefore, in the interest of yourselves, for you form a portion of us, that I ask you to give to this case some further reflection and to hold in suspense the judgment which you, I thought, rather prematurely, passed yesterday, to which I paid as I always pay to the opinion of a jury, the most respectful consideration, but as to which I to-day invite you to give a little further consideration. The Act was passed in 1815, and it prohibited the practice of medicine and surgery by chemists and druggists, and all that it did for them, as my Lord will tell you, and as you already know, was to give to them thereafter the right to do that which theretofore they had been in the habit of doing, not as apothecaries, for there comes the pinch of this case, but as chemists and druggists. What they did as chemists and druggists is not mere matter of conjecture, speculation, or prejudice, as was attempted to be shown on the other side, but a definition is given in the statute itself, a matter which I rather think during the course of the proceedings yesterday occurred to my Lord's own mind; a definition of what the chemist did in the day before the statute, beyond which they cannot therefore to-day go, is contained in the four corners of the statute itself, and by that we are all bound. Furthermore, gentlemen, that statute was passed at a time when this practice was rife, against which legislation was necessary to be directed. It was passed with all the moderation that became a Parliament who took a question of that sort into its consideration. Although the state of things at that time was sufficiently serious to justify the Parliament of England—if it had thought proper—in marking its sense of the importance of the wrong of usurping medical functions and surgical functions by enacting that it should be a misdemeanour, it did so in a much more temperate and moderate way, because it said it should be only the subject of an action for a certain small penalty to be recovered, in order to work out in a merciful moderate fashion the repression of practices against which Parliament felt bound to set its face. That was done. Parliament did not enact it as a misdemeanour; it has subjected no man to imprisonment, but it has said when you have broken this statute, unfairly lost sight of the provisions which it enacts, you must pay for it, and in the paying for it, it is not so much a question of the money as to convey to chemists and druggists in general, and so to the world at large, this distinct warning, there is a limit set to your trade, as there is to the medical profession itself, beyond which they cannot and ought not to go.

Now, very likely I cannot see so far as my friend, Sir Henry James. I do not suppose I can, but I thought at the time it was a fallacy which he fell into when he compared the practice of a chemist and druggist's business with the practice of a tailor. You go into a shop—I suppose we all do, if we want a pair of trousers—and you order them and select your cloth, and there is an end of it. You pay your bill and you have done with it. There is no question of a statute. But you go into a chemist's shop and if you do as he is willing to advise you, as if he were a well qualified practitioner skilled in the symptoms of disease, and you are willing to trust yourself in his hands, it is not a question of selecting a particular medicine, and saying I am willing to take it, there is 6*d*. for it; but it is this question, that the man immediately forms a relation between him and you, puts himself on the footing of an adviser, and puts you in the perilous position of a confidant in him, and sometimes, I am afraid more frequently than we know, turns out to be an unqualified and dangerous friend, who often brings the poor, and sometimes the destitute who go to him for assistance, into plights from which they would have been free, if they had the advantage of well skilled medical advice. Now, gentlemen, do not let us linger on the illustration about the tailor, but let us pass on to a somewhat more important suggestion which was made. We do not, says Sir Henry James,—trying to enlist your sympathies at all events, as if he thought he had been doing wrong, or his client, in advising people in his shop, as I should show you by-and-by, thinks he has himself,—we do not go into people's houses and therefore we do not do any harm. Surely that is a monstrous fallacy. In the case of Wiggins, which has been made evidence in this case by frequent reference to it, this happened to the people there: the young people who were suffering from scarlet fever and acute inflammation of the lungs went to the shop.—

Mr. Baron Pollock: I do not know really whether the facts of Wiggins's case should be referred to.

Mr. Howard: They were referred to yesterday, my Lord; but I will not go into them if your Lordship is in doubt about it—

Mr. Baron Pollock: I do not think the facts were referred to, only the observations of my brother Field and the legal argument.

Mr. Howard: Wiggins' case was constantly referred to, but if your Lordship is in doubt about it—

Mr. Baron Pollock: I think it would be a dangerous precedent.

Mr. Howard: I say with reference to the suggestion that they do not go to peoples' houses and visit patients, what in the world is the difference whether a person goes to your shop, or you go to his house? The question after all is this, do you undertake to judge by examination of the symptoms of the disease, and do you prescribe or select, which is the same thing in your own mind, and make up medicines with a view to treat and cure? It cannot turn on any such question as to whether you go to a house, or whether they go to your shop. The question is whether they do prescribe or select medicines, after having judged of the complaints, with a view to their relief and cure.

Now, gentlemen, let us reflect for a moment as to the relative position of medical men as such, and of chemists as such. Medical men are prohibited by law from invading the trade or profession of chemists as such, and chemists are prohibited from invading the profession of medicine, and you may depend upon it for very good purposes, and for very good reasons. If you want an elucidation of that, let me give you an authority that was not altogether revealed to you, and call your attention in two words to the difference that exists, down to this very hour, between the examinations to which medical men, on the one hand, are subjected, and chemists on the other, from which gentlemen, believe me, you will derive a most instructive lesson as to what the Legislature intended when it said a chemist shall only be concerned in the preparation and vending of drugs, not in the judgment of diseases. The Pharmaceutical Society of Great Britain which has received the sanction of the Legislature in reference to modern Acts of Parliament affecting chemists and druggists, provides that the examination to which chemists are liable, and to which they must instruct themselves are these.

The learned counsel read the regulations for the examination of pharmaceutical chemists, and continued.—Where is the suggestion that they are to be skilled in the diagnosis of disease? Where is the suggestion that they are to undergo any examination, or any training whatever in anatomy, or morbid or any form of anatomy, in attendance in the hospitals, or in walking the hospitals? Where are they to get any idea of the nature of disease, still less of therapeutics, without which it it impossible for a medical man to understand the treatment of disease!

There is no such provision. They do not want it. They are protected in all respects. They have simply to perpare and vend drugs, and get their money for that; and they do it under the protection of the law, with the assistance of competent advisers, physicians pure and simple or surgeons pure and simple, as the case may be; or physicians and surgeons both holding as they do, commonly hold, the licence of the Apothecaries' Society. Now I shall call attention, but only for a moment, by way of contrast, to the examination which medical men, as such, including apothecaries, undergo, indeed I refer specifically to the examination of Apothecaries' Hall, to see what the legislature had in view and what it insisted upon. We are administering the law, not making it. We never endeavour to do so, but to administer the law as we find it; and if any alteration is necessary, parliament must be consulted on the question, when public opinion has been to some extent aroused, when they think that there is any cause for alteration. Now, the Apothecaries' Hall examination is this. In order to pass the licence of the the society it is necessary to pass a preliminary examination in arts. Then to show a pupilage or apprenticeship, to be of full age, to have a certificate of proper conduct, to attend the following lectures, and I pray your kind attention to this. In the first year chemistry—you find chemistry goes through it—they get chemical knowledge as well as the chemist. But they get much more which the chemist does not; anatomy, physiology, dissections; summer session, botany, materia medica, therapeutics, and practical chemistry; second year—anatomy and physiology, including dissections, demonstration, the principle and practice of medicine, clinical and medical practice, midwifery, diseases of women and children, vaccination, forensic medicine, toxicology, and clinical and medical practice. In the third year, the principles and practice of medicine, clinical and medical lectures, and morbid anatomy. Now, therefore, see the difference! See the wise purpose for which the restrictive legislation has been enacted! The chemist himself is educated, and educated only in the learning which belongs to drugs, and drugs without reference to their application; whereas the medical man proper is educated both in chemistry and drugs, and in the principles and practice of medicine, derived from walking the hospitals, attending lectures, performing dissections and acquiring that medical knowledge without which it is impossible to treat diseases at all. Therefore, there is no justification for the assertion, rather hastily made yesterday, that there is, after all, a slight resemblance between the two branches of the medical profession, and that a chemist has a knowledge somewhat equal to a medical man himself.

Now my friend, Sir Henry James, said persons going into a chemist's shop, persons like Mr. Death, or Mr. Hubbard, or anybody else, to buy his drugs. Now is that really a fair way of putting it to you under the circumstances? Let me ask you this: Do you think that the poor people who go and get this advice in crowds during the year at Mr. Shepperley's shop—do you think that if he told them when they came and asked him for advice, "I really cannot go into that with you; I can only sell you an article if you ask for it"—do you think they would go at all? Of course not, which clearly shows that they do not go to buy a drug, because they do not know what to get; but, they know that Mr. Shepperley will tell them how to take it and what it is suited for; and so they get in a cheap way, under a charge nominally for medicine, both medicine and advice. It is that spirit of delusion which has crept into this case, which ought not for a moment to be warranted.

Now take this case itself: It is said you cannot trust Mr. Death's evidence. But, can you trust Mr. Shepperley's? I will ask you this. You stand fairly between these two men: Do you think Mr. Shepperley has been as candid as he might have been? Do you think in the County Court he was candid? You heard my cross-examination of him which I endeavoured to make as brief as I could under the circumstances. He told you he was not perhaps as frank in the County Court as he ought to have been, and whereas in the County Court it stands here on record, which indeed he admitted the truth of to me, that he had said he could not remember whether he looked down his throat; he could not remember this, that, or the other. Yesterday he came into the box, having for reasons of his own got into a different frame of mind on the question, and avowed he had not said anything in the County Court which he ought to have said, and substantially confirmed the account of Mr. Death himself. Did he look down his throat? He does not deny it. Did he form a judgment of what was the matter with the man, if anything? He does not deny it; he came here and said there was nothing the matter with him; but that is forming a judgment. If you are a physician, and I come to you and say, "I do not feel altogether comfortable; I cannot help feeling I have something the matter with me," and you feel my pulse or look down my throat or look at my tongue, and come to the conclusion that I have nothing the matter with me and tell me so, that is forming a judgment just as much as if you came to the conclusion that I was suffering under some very serious illness. If Mr. Shepperley did look down the man's throat or otherwise deal with him with a view to coming to a conclusion whether he were ill or not; that is not acting as a chemist, but it is acting as an apothecary. Now he says I did, I gave him a saline mixture. I asked him, Is not a saline mixture a compound mixture. He said it was. I asked him whether in making it up he had not exercised judgment, with a view to producing a given result. He had, of course, he had. Is not that practising as an apothecary, and if it becomes necessary in the result of this case to put to you the question as to whether or not this is a simple complaint; still, gentlemen, it is practising as an apothecary, as distinguished from practising as a chemist in the treatment of a simple complaint. Then I cannot help thinking that my Lord will direct you, as has been done on a previous occasion in a similar case, that that is practising as an apothecary in a simple complaint, and that although it is pleaded as a simple complaint in this action, it would be no defence, because the object of the Legislature is to prevent chemists from practising as an apothecary at all, and make them confine their attention to the business of a chemist and druggist. Now, just a word or two, and in doing this I must be understood, with my lord's permission, to be partly addressing you and partly addressing him, in referring to this subject for the same reason that Sir Henry James mentioned yesterday, that the question is more or less a mixed one of law and fact, and therefore we cannot help in this case dealing more or less with the law as well as the facts. But it is exceedingly important when you come to look at the 28th section, on which this defence is founded, to see what the terms of it are. My Lord will have to deal with this to you in a way I shall not presume to do, except to invite your attention and his to it, but it appears to me the section is so clear as to what is intended that no doubt ought to prevail about it what-ever. It is this: "Provided always, and be it further enacted that nothing in this Act contained shall extend to or be construed to prejudice or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing and vending drugs, medicines and medicinal compounds wholesale and retail, but all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise and carry on the same trade or business in such manner and as fully and amply to all intents and purposes as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act. So that the whole question is on that Act. What was

the business or trade of a chemist and druggist as practised before the passing of the Act? It is by and by defined, because it is declared to be the trade or business of a chemist or druggist in the buying, preparing, compounding, dispensing and vending drugs and medicine. Now, then, do you think that this is a case falling within either of those words? It is not suggested that it falls within anything except one, and that one is dispensing. Now, gentlemen, do you think it is dispensing drugs when a man goes into a shop and submits himself to your examination and to your judgment and then you decide that he ought to have a certain mixture? Do you think that is dispensing? Gentlemen, dispensing in that day was, as it is now, the setting aside of medicines in obedience to some other authority, such as a physician or surgeon; selecting it in that sense, and dispensing it. I might very well have said, dispending it because that word, as is known not only to grammarians but to medical men and all other persons, signifies that you are to weigh up. It comes from a Latin verb, if I remember rightly, "pendo" to weigh, and signifies the weighing up of drugs, not the selection of them according to medical education; the weighing them up, putting them aside in obedience to the prescription of a physician on the directions of a competent practitioner and then vending them to the public for money. I shall not weary you with a further discussion of what the statute means, but I only invite your attention to the fact that, in my view, that is the proper construction it has received, a definition already in another case, and I trust my Lord will think, that is the direction which he feels at liberty to give you in this case.

Now, gentlemen, on the law of the case I will just, if my Lord will allow me, refer you to what was said as to the law in Wiggins's case, and only to one sentence on this very point. Mr. Justice Field in addressing the jury, after having cited the section I have read to you, says, "The word there which counsel for the defendant of course very naturally puts his case strongly upon is the word dispense, but now you will see whether this Act of of Parliament throws any light on the meaning of the word dispense."

Mr. Baron Pollock: I really do not like to interrupt a gentleman of your experience, who always does what is right, but I have always considered myself that counsel ought not to tell the jury what a learned judge has said in another case.

Mr. Howard: I was rather suggesting it to your Lordship than addressing the jury.

Mr. Baron Pollock: I say so only for this reason, that if that were done then the whole case must be argued before the jury. It disturbs their mind and gives them no assistance.

Mr. Howard: I shall be content if your Lordship will take it from me, with submission, as not addressing the jury. It was rather done in the same way as was done yesterday, because of the difficulty of separating law and fact. If I err, I err in following an example of a far abler advocate, Sir Henry James. At all events, as far as a judicial exposition of that very statute is concerned you have it, and my Lord will direct you from his point of view what the proper definition is. If the proper definition of the word in that statute which they fix their contention upon is what has been said in another place, namely, that it does not mean the selection of medicines by the exercise of judgment, the making up of medicines, and the vending them in accordance with some superior authority, then surely this case is an undefended action.

Again, they say, well, but we have given the jury evidence here that before 1815 chemists and druggists were in the habit of making up medicines of their own selection for the cure of simple complaints. Now, gentlemen, I desire—perhaps I ought, strictly speaking, to address his Lordship almost directly, and I do so, and I submit it to my Lord in this way—that this statement of defence as prepared is manifestly prepared without a proper reference to the statute itself; that it omits important words of the statute; that it is no defence upon the face of it. Of course we shall see by-and-by what my Lord will direct you with reference to that when he comes to explain that statute to you, but I am only just now asking my Lord's attention to the fact that whereas the statute itself speaks of buying, preparing, compounding, dispensing, and vending, the plea upon which the defendant relies here does no more than use the words prepare, compound, and supply medicines of his own selection for the cure of simple complaints. Gentlemen, that is not the statute; the plea is no reflection of the exception contained in the statute, and therefore, without talking to you upon what is so much matter of law, but rather with a view to submitting, with deference, my view to the court, I should suggest that it is impossible for the defendant to succeed on this plea, even if you are satisfied that the custom is proved up to the very hilt.

I do not propose to go at any length into the evidence which has been laid before you, but I must remind you of one thing, and now I may reciprocate the compliment to my learned friend, Mr. Cupiss, who is near me. My learned friend, Mr. Cupiss, did admit that serious cases were treated in his time in his establishment, and that when they were treated the senior partner was consulted. The truth is that serious cases are very often treated, and it is against dangers of this kind that the Legislature has desired to guard. Now legislation on this subject has been going on for a considerable period, but the Legislature has not relaxed on this question, but has rather tightened its hand, and I pray you to remember this, that they prevent a medical man or anybody from trenching on the province of the chemist, and the chemist is left with the notoriously large profits which are to be got in his trade, and he has a very wide sphere of action in the preparation of drugs and in the selling of patent medicines with the enormous profits to which medical men can never pretend. Now let me say a word or two about patent medicines, and use the illustration of the difference between going into a shop for advice and going into it for medicine. You know there are many popular medicines, such as Gregory's powder, Cockle's antibilious pills, and things of that sort. In small matters you can tell yourself that a pill will set you right. You go in and ask for a box of Cockle's pills and the man gives it to you without discussion, and takes the money for it, 1*s.* 1½d There is no advising with him about it, or asking whether it will suit you. And so if you take Gregory's powder you will have a bottle for 1*s.* 6*d.*, and there is no discussion over it. But if you go to him aud say, "I do not feel up to the mark this morning, I am out of sorts," and he goes into the whole matter with you, feels your pulse, looks at your tongue, and then says you are not as well as you might be, I will try what I can do for you, and forms his own judgment and makes up a bottle of mixture, that is a simple complaint in a sense. It may become anything but simple in result, but at the moment it is only a simple complaint. Still, I submit this to you, and to my Lord, as the true view of legislation on this subject as it stands, that in that transaction which I have described, that may be as simple a one as you can conceive of, that is applying yourself within the meaning of the case of Lotinga, which has been accepted as a judicial explanation of the statute, applying yourself to judge of internal ailments by symptoms and putting yourself to the selection of medicines with a view to cure the complaint. Take it, therefore, if you please, for the purpose of the argument in this case, that this was a simple complaint in Mr. Death's case and Mr. Hubbard's. Nevertheless, if he set himself to cure it by the application of his mind to the selection of medicines, I submit to you and to my Lord that that is acting as an apothecary in that case, however simple it was, and that he is prohibited

from doing that under the terms of the statute itself. Now, gentlemen, what did Mr. Shepperley say in answer to a question of mine, whether he had not been in the habit of prescribing very largely? He practically said he had, but he had not done it recently to so large an extent. He admitted that recently he had refrained from forming judgments on cases brought to his shop. He tells you now, knowing quite well from his experience that he must have been infringing the provisions of this statute, that he has refrained for some time past—a year or something like that—recently, at all events, from forming judgments on medical cases brought to him. Do you think he would have done that if it had not been for the proceedings which had been instituted in this action? I beg you will remember that when you come to pass judgment. Pray remember that always, that but for this action and these proceedings, you would not probably have had any such alteration in Mr. Shepperley's business, and you would not have had him here confessing in the presence of the Court, and to you, that he had been refraining of late considerably from forming medical judgments. Therefore this proceeding which is so strongly denounced by the advocate for the defence is the very proceeding which has led to the beneficial change in the practice of this kind of things, and has saved probably a great many people from a great deal of trouble, which otherwise they would have been subjected to: because, mark you, the practice of chemists is mainly with the poor. The case was very much put on the poor in this matter, and I put it on the case of the poor too. I claim the protection of your verdict on behalf of our poorer fellow-countrymen and women. It is on their behalf; I profess I feel anxious about them in this respect. I have scarcely the right to say this perhaps as an advocate, but so far as I do feel anything I do feel that the protection of the Legislature and of juries administering the law is necessary in the interest of this class of people, and I will give you my reasons. Their diseases are the same as ours, but they have not the same means very often of forming a judgment, for want of intelligence and education, as even we ourselves, and therefore they are more at the mercy of persons who choose to assume to themselves the function of medical advisers. But in these days there is no necessity why they should be remitted to the unskillful care of unskillful persons, because they have never had a medical training. You have an abundance of hospitals, you have an abundance of dispensaries, you have, I am happy to say, an abundance of gratuitous care on the part of medical men themselves—be it said to their honour—you have institutions constantly established in all parts of the world—dispensaries—private dispensaries, private hospitals, convalescent homes, everything, thank God, to take care of the poorer classes of the country: and in addition to all that, in cases of extreme destitution and indigence, which I hope are not as common as they were, you have the care of the well-trained, and well-educated surgeon of the parish, who attends to them, so that there is not even the necessity there was in old days to remit poor people, on whose behalf this case this is put, to the tender care of persons who have had no medical training at all. I pray you, therefore, on behalf of the plaintiff in this case not to run away with any feeling about Mr. Death because he happened to be employed. The question is whether he found out what he did, and that is practically admitted. Let me look at this case, as my Lord rather suggested when we parted yesterday, as a case of very great importance, and as a case which, if your verdict were for the defendant here, would amount really, as I submit, to a premium on the practice, and constant practice of untrained—medically untrained—chemists and druggists in the treatment of disease, and if I may say a word on behalf of the medical profession itself, though I think it would be really on behalf of the community, because we depend upon them for our care and treatment, it is not a fair thing for a large body of medical practitioners to have their rights and privileges invaded by men who have never been trained, and had never gone through the lengthened and expensive curriculum to which they had been subjected, who have never had to endure the constant practice in hospitals and wards, and in performing various operations and in acquiring the various knowledge they have to acquire at an enormous expenditure of money and of time. It is only fair to them as professional men that there should be liberal protection afforded to them by juries, that they should not have their property taken away by those who are not competent to discharge those duties. By your verdict, however, you will not only protect the medical profession, but will protect the public itself. It is to them we go in moments of peril and trouble, it is on them we rely because they have received what the chemist has not received—a liberal professional training for the treatment of disease.

Now I think I have submitted to you the observation I thought necessary to be made from a general point of view, and I have but little to add. You have had before you Mr. Shepperley himself, and I submit to you that his evidence proves the plaintiff's case. Not to repeat, but only to remind you of the former submission, I say that if this is is a simple complaint, he has treated it by his judgment, selected the medicines and prepared them, and although he has not charged for his advice, he has acted as an apothecary in the matter, and that, therefore, he is within the statute. I have nothing to say about the witnesses called for the defence, except to say that if they had established any custom at all — I respectfully ask my Lord's consideration of this as a submission to him—they have established too large a custom. They have gone beyond the licence of the Act of Parliament and in this respect that they have not proved that they did these particular things in 1814 which a chemist and druggist then lawfully might do but that they did those things which apothecaries had to do in 1814 and if they did them they invaded the statute, and that was the real mischief that statute was intended to remedy, if they have gone beyond the trade or practice of chemists which is declared by this statute and have done these things, then I say that the custom to which they speak is bad, and that up to 1814 they had invaded the domain of the apothecary proper, therefore even supposing you are satisfied that their evidence shows that this custom has been proved, it is a custom outside of the statute, and therefore not being a compliance with the statute they have as much infringed the law as if they had not given this evidence at all.

Gentlemen, notwithstanding the powerful speeches which my learned friend addressed to you yesterday, which we all admired, I venture to submit to you with confidence, that when this is carefully and broadly looked at, it is really an undefended action, because how can it be said here consistently with truth that Mr. Shepperley did not act as an apothecary by applying, which, mark you, is the very text and definition drawn by the court in the case of Lotinga, which has been accepted as an authority, applying his mind with a view to judge of illness by internal symptoms, and to the cure of it by the selection of his own medicine. I may be permitted to remind my Lord what I have no doubt he remembers at once, that it is not necessary that there should be any charge for advice. It has been distinctly held otherwise, in the case of Greenhough, where an attempt was made to distinguish between the apothecary and a chemist on the ground; and, it was said the point is not whether he charged as an apothecary, but whether he acted as an apothecary That case of Greenhough's is a direct authority to show that he need not charge for advice; it is sufficient if he acts as an apothecary, and then takes his money as for the medicine. But in another case to which I ask my Lord's attention, Mr. Justice Wightman says, "However unwilling I may be to grant a new trial,"

and so on—"it may be the plaintiff charged as a chemist, although he acted as an apothecary." But he said that question was quite beside the point. That was a case where the same point was taken as in Greenhough's case. It is not necessary that there should be a charge for advice. That is not the law. The question is not whether he has charged for the medicine, but whether he has acted as an apothecary. Let me say one word in conclusion about the penalties attached to this case. If you are of opinion when my Lord comes to deal with you on the construction of this statute, for of course we have the statute to administer, if you should be of opinion that these cases of Hubbard's and Death's are true, and you know practically they are not denied, there would be a right on the part of the plaintiffs here to recover a penalty for each offence, as I submit to my Lord; but we do not desire that. That is not the object of this proceeding at all. We cannot help suing for the penalty, because we must comply with the forms of the statute; it is the only way of enforcing this legislation. But the object is not to recover the money, but the repression of an unlawful practice dangerous to the community at large; and I wish you to understand, on the part of the plaintiffs that we repudiate any such mere desire as that of the penalty. We are bound to sue for it, because we cannot help ourselves; still it is not with the object of recovering the money, but to put a stop to this modern form of proceeding, which is a dangerous innovation on the rights of medical men.

Now, gentlemen, I do not think I ought longer to detain you. My Lord has probably some remarks to make to you on this very important question, but I cannot help thinking that you must now see that the practically admitted evidence of Death and Hubbard, after you had Mr. Shepperley in the box, shews you conclusively that he had this man in his shop, that he looked down his throat, that he formed his conclusion, and that he administered the compound mixture, which he had in his own mind selected as the proper remedy; and in the case of Hubbard he actually came to the conclusion—he was a reluctant witness, but he was bound to admit it—that he had formed a conclusion, and that he considered himself competent to form a conclusion, and he came to the conclusion at last that this eruption on the face, which he called pimples for the purpose of this case, was traceable to impurity of the blood, and then he said he gave a medicine accordingly. I say he there formed a conclusion, that is a judgment in his mind, and diagnosed that case. It may have been comparatively a simple case, possibly. But he formed his judgment upon it, and in doing that and in prescribing for it—that is, not writing down, because that is not necessary for the cure of the disease—but in selecting medicines, and in appropriating them, he exercised his judgment as an apothecary within the definition of the law, namely, that he judged of the ailment, whatever it was, by the symptoms which he discovered, and then applied himself to cure it, by selecting and preparing medicines.

Gentlemen, I would only add to that the concluding remark, that Shepperley himself admitted the practice is a general country practice. In that respect, I think you may take it that Mr. Shepperley, the defendant, who publishes 'Every Man his own Doctor,' and announces that he is from the General Hospital, and attracts a very large and continuous stream of poor patients who cannot very well judge whether they are well treated or not, when he admits that he has been in the habit of largely and generally practising in this sense, you may depend upon it, he does, what it is notorious he does, a large business of this class, and in the doing of that I ask you whether it is not a violation of the law, and an unfair infringement of other persons' rights, and a dangerous avoidance of that rule which the Legislature, in its wisdom, even to as recent a period as the Medical Act of 1858 has thought proper to enact for the benefit of the people of this kingdom.

SUMMING UP.

Mr. Baron Pollock: Gentlemen, we have now come to the conclusion of the case so far as the evidence and the observations of counsel are concerned, and it is a case certainly of a most important character; not of so much importance in consequence of the penalty which it is sought to recover from the defendant, because that penalty is small in amount, but it is an important case in consequence of the fact which is obvious on the face of it, that this case has been made a test action, and therefore on the part of the Society it is a test action to obtain the opinion, as far as they can, of the court and the jury upon a question which is of considerable importance to the medical profession and the public at large, and inasmuch as the decisions and verdicts of juries from time to time, have, and always ought to have a considerable effect, when they are disseminated throughout the country on these different matters, which are apparently tinged with questions of law, it does become a very important question. And therefore it was that yesterday, although I was quite sure you appreciated all the evidence which was given yesterday, and the remarks made by the learned counsel, I thought it was very desirable you should not, at the close of the day, proceed to give a verdict which possibly might be open to observations hereafter, and certainly would be canvassed—I do not mean merely canvassed in public—but which would become very likely a matter of discussion in the court above.

Now, gentlemen, this action is brought by the Apothecaries' Company to recover from Mr. Shepperley, the defendant, two several penalties, and those penalties are sought to be recovered from him in respect of two cases, one the case of Thomas Jolly Death, and the other case is the case of the man Daniel Hubbard, as to both of which it is said and alleged that he has infringed the law as laid down by the Act of Parliament of 1815. Of course it will be open to you and to me to consider both those cases, inasmuch as in each case the penalty is severable. If he has infringed the law in both of those cases, he would be liable to both penalties; but if he did not infringe the law in either case, he would be liable to neither; but if you think he infringed the law in one case and not in the other, then in respect of that particular case you will say he is liable.

Now this is no new law; it is law which was passed so far back as the year 1815, therefore it is a law which not only was then considered and passed, but which has likewise governed and controlled the conduct and actions of mankind, so far as they relate to this subject matter, ever since. As it is a law which governs a matter of considerable importance to the profession and the public at large, it is well that you should carefully see what is the real intention of the Act of Parliament. I am sure I need hardly say more to you, but in looking at the Act of Parliament, and in acting on it, we must be guided by what are the terms of the Act of Parliament, and not by what seems to us to be or by what ought to be the terms, or by what might seem to us to be the better course to regulate the matter, There is a very old maxim, which is founded on sound good sense, as well as on sound law, which is that no man shall be wiser than the law. I suppose there are a very few of us who have not had occasion to see the great kindliness, and the great attention and unselfish care which is bestowed, not only by members of the medical profession, but by chemists and druggists, on the poor when they are in need of their assistance. I suppose there are very few of us who have not needed, ourselves, to resort in cases of emergency to the very same sources of assistance, and I am sure we have never found them unwilling to give us the assistance we have needed. But that is not the question, or the foundation upon which we can decide this case.

Then, again, nothing is more dangerous in cases of this kind than being governed by extreme cases. Ex-

treme cases may be put on the one side and on the other. It may be said, what is a man to do in the case of some immediate danger? a man is taken with a fit in the street, or the man meets with a street accident. Where life is in peril, is no man to put forward the knowledge he possesses to save life or prevent serious illness? That of course is an observation which might be made, not only with regard to the Act of Parliament, but with regard to any one of us who might be present on such an occasion, and who possesses any knowledge on the subject. Again the case might be put, which has been put, how unreasonable it seems to put in the hands of uneducated, or partly educated men that which it was intended should only be done by persons of the highest education, who have received proper diplomas for the purpose. There are extreme cases on the one hand and on the other, and it is extremely unwise, if I may be permitted to say so, to let those cases weigh in our minds either the one way or the other when you have the plain words of the Act of Parliament to meet. Now the section under which this penalty is sought to be recovered is this, "If any person shall after the 1st day of August, 1815, act or practise as an apothecary without having obtained a certain certificate which is mentioned, then every person so offending shall fer every such offence forfeit and pay the sum of £20." Therefore the question is, Did the defendant upon one or either of those occasions act or practise as an apothecary? The difficulty which arises is rather in seeing what is the acting or the practising as an apothecary.

Now some observations have been made by the learned counsel in this case in referring to what was said by learned judges before as to what is the proper definition of the word apothecary. It is no part of my duty, nor is it the duty of any learned judge to define what is the meaning of the word apothecary. The word apothecary is no word of legal art, but a word in common use in the English language which is to be properly understood and appreciated, having a particular meaning attributed to it by the world at large, and in this particular case by you, the jury, whose duty it is to apply the law in this particular case. But I am far from quarrelling with what has been said by the learned judges who preceded me, especially with what was said by so distinguished a judge, as Mr. Justice Cresswell, when he said that an apothecary is a person who would judge of internal disease by its symptoms, and apply certain medicines to the cure of it. I do not suppose he meant by internal disease as opposed to external—in the sense of a man having a sore or an eruption on his outward skin which was produced by some disordered condition of the body—that would not in the least be less a disease, and it would apply to that if he could have judged of it by its symptoms and applied medicine to the cure of that body. It would equally apply to the case of a man who attempted to cure a diseased condition of the body brought about by indigestion or the diseased condition of the lungs, or anything which had to do with the throat, or anything which might affect a man's condition internally. But we are not, and you are not, without assistance as to what an apothecary is, because there can be no rule of construction so plain and so useful as regards Acts of Parliament and documents as to see, when you are looking at a word which is used in a statute or in a document, that you have reference to the other words, which are of a complex nature, in the other part of the statute. Now, we find this statute, which was passed in the year 1815, assumes the existence of apothecaries, and from the mode in which it speaks of them, and deals with them, it tells you very plainly what the duty of the apothecary was, as distinguished from the duty of a chemist and druggist. We find the Act is passed in consequence of what is said to be a deficiency in the clauses of the charter granted so far back as the reign of James I., to the Company of Apothecaries, and it then deals from time to time and creates a system by which the apothecaries are to be examined, and by which certificates are to be given to them, and it then deals with the different duties which the Legislature put upon them with regard to their conduct under this Act. For instance in the 5th section it says, "It is the the duty of every person using or exercising the art and mystery of an apothecary to prepare with exactness and to dispense such medicines as may be directed for the sick by any physician lawfully licensed to practise physic by the president and commonalty of the faculty of physic." That shows that it clearly was their duty before the passing of this Act to dispense and prepare medicines in the cases where the physician had written a prescription, so that in that case the apothecary would merely mean a man following up and carrying out what was ordered by the physician, and he would be merely doing what is done by a chemist and druggist. Now you will find from different parts of the Act it is perfectly clear that he had not only prepared the medicines prescribed by others, but that he did see persons, and act on his judgment, and give the medicines without any written prescriptions. Preparing those medicines, and selling them, and prescribing them are part of his business. Now the Act goes on, and we find in several of the sections that the same sort of assistance may be gained by reference to them. For instance, in section 14 we find this, where it is said that no apothecary is to practise without an examination. It says that there is to be a Court of Examiners appointed, and so forth, and they are hereby authorized and required to examine all persons applying to them for the purpose of ascertaining the skill and abilities of such person or persons. In what? Not in the mere compounding and dispensing of the medicine, but "in the science and practice of medicine." Therefore it shows that the apothecary was a person who is to be skilled in the science and practice of medicine and the examination was to test his fitness or qualification to practise as an apothecary. Therefore the fitness to practise as an apothecary involves that examination and involves that certificate which shows the persons to have skill and ability sufficient according to those examiners to enable him to practise in the science and practice of medicine. That clearly shows that the apothecary is a different person from a chemist and druggist.

Then you have that section which I read to you, the 20th section, upon which the penalty is now sought to be recovered for practising as an apothecary; and then, last of all, for fear there should be any doubt upon the subject, or whether they were putting a penalty upon chemists and druggists for doing what they had properly done before, you have the 28th section. "Nothing in this Act contained shall extend or be construed to extend to prejudice or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing and vending drugs, medicines and medicinable compounds, wholesale and retail; but all persons using or exercising the said trade or business or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner, and as fully and amply to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act." I mean to say the trade and business of a chemist or druggist is the buying, preparing, compounding, dispensing, and vending of drugs, medicines, etc., and if witnesses could be called in court to say that before the year 1815 there were chemists and druggists who acted as surgeons, or who acted as physicians, of course the obvious answer would be this, that they were doing that which was illegal, they were doing that which was not contemplated by this section, and the fact that they did it then can in no way assist those who seek to do it now if it be contrary to law, and contrary to the spirit of this exception in this Act. Therefore we get rid of all the questions of what they did in fact, excepting in so

far as what they did in fact was in conformity with this section. As I said before, it is quite distinct that the buying, preparing, compounding, vending and dispensing of drugs and medicines is not that duty of the apothecary which is contemplated by this Act to require the person to be skilled in the science and practice of medicine. Now, gentlemen, that being so, let us now see what were the facts of this particular case, and to what extent the defendant has acted as an apothecary in either of the cases in which it is sought to make him chargeable with the penalties—what has been done, and what has been done with reference to the statute. With reference to some of the observations made by the learned counsel which are often made in cases of this kind, that it is a penal statute, I can only say for myself, although I can understand with the jury when it is said that it is sought to take money out of the man's pocket, that they would see that the facts are clearly and properly proved; but I for myself can make no distinction between a statute which is passed for one purpose and a statute which is passed for another, so far as the the construction of the statute is concerned, whether it is a remedial Act of a very slight nature, or whether it is an Act which sentences, or enables the Court to sentence, a man to a very severe punishment—the same rule of obstruction must be observed in either case.

Again, I should make this one observation with regard to the language that was used in making the plea. I cannot myself at all assist you, nor can I see the proper value of that language which is used in the plea as far as it refers to the matters, which it states are of a simple nature. It has been said that these were simple cases. But when is a case of a serious nature, and when is it of a simple nature? We can say what is simple and what is serious. There are symptoms, as we know, which to a skilled mind will show without examination that death is stamped upon the man's face, and there are symptoms again which the merest examination will lead to the conclusion on the part of the medical attendant that the symptoms are of the most alarming and serious character. But on the other hand, there are some things which may seem to be very alarming and very serious, and often are to the patient distressed with them, and which may excite in his mind the gravest foreboding, yet really those symptoms are sometimes symptoms pressing on a nervous imagination, and are of very little consequence at all in testing what is the matter with the man. I cannot deal with that. I cannot tell you anything about serious or simple cases. The question is, Did the defendant act as an apothecary? With regard to that, I have already given you as much assistance as I can.

Now then comes the question, What is the evidence upon which it is said he acted as an apothecary? Of course in dealing with that part of the case it is really for you; you must, inasmuch as there is some conflict, not a very great conflict, but still there is some conflict in this case, between the account given by Death, the principal witness in the plaintiff's case, and the defendant Mr. Shepperley, apply your mind fairly to the facts as you would do in any case where there was a conflict of facts either great or small, and it is for you to say what you believe to be the real state of the facts. There may be a little want of memory, or there may be a little feeling on the one side or on the other, or there may be, of course, a little aberration from the actual truth on the one side or the other; but I do not think it would be fair to make the remark which the learned counsel has suggested, that there was an absolute attempt on the one side or the other to mislead you; still the facts of the case and what is passing through their mind at the time the thing is taking place influences them when they come to give their evidence hereafter.

Now before you form an opinion on that I would only make one other observation with regard to the evidence, and that is what has been said on both sides with regard to the sort of impossibility of a man selling medicines without in some way or other expressing an opinion with regard to those medicines, or with regard to the mode in which those medicines should be taken. This is a matter not for me, but for you; it is only a matter which passed through my mind, and what I suggest to you is this. It may very well be that a conversation may have taken place and an opinion may have been expressed as to the articles sold, without in any way intrenching on the duties of the apothecary, that is, forming an opinion of the case, and then advising and giving medicines in consequence of that opinion. There may be such a case as this. Take the case of a poor man or an aged man who goes into a shop and says, "I want some pills for constipation or because I do not sleep well." The chemist may say, "This is a well known remedy, I will sell you this box of pills." That really could not be said to be an infringement of the Act; but it may also be that he might go further, and the man might say, "Very well, I will take six of these when I go to bed to-night." The chemist might, in common charity, say, "No, sir, you cannot take six pills; if you look at the box you will find you should only take one or two; and if there was nothing on the box, he might say, "This is a strong medicine, and you must only take so much." It might be said that that would be giving advice with regard to the medicine, and of course, with regard to the body with reference to which the medicine is taken; but that would be very far from bringing a man within the scope and intention of the Act of Parliament, which was intended to prevent people from prescribing in the case of what they themselves consider to be the cause of the condition of the patient. It is only fair to make that observation, because anything which takes place in that way cannot be said to be acting and practising as an apothecary. You may dismiss, therefore, from your consideration all cases of that kind, as not giving you any real assistance.

Now, let us see what are the real facts of the case, and apply your mind to those facts fairly and reasonably, and then say to yourselves, first, what the real facts were, and then having ascertained what the real facts were, you will say from the facts, Did the defendant act as an apothecary in either of those two cases within the true intention and meaning of this statute? Now, the first witness, Mr. Thomas Jolly Death, says this—it is admitted he went there for the express purpose of seeing how far the defendant would go. As far as I can judge the remarks which the learned counsel made for the defendant, he was perfectly entitled to make, and you will say how far you think they were worthy of your attention. The witness says, "I went to the defendant's shop on the 26th of August, 1877. I complained to him of a sore throat and a difficulty of breaking and of a tightness of the chest and of sleeping badly. He asked me to open my mouth and I did so. He looked at my throat, and he said, "I do not see much amiss with you." When you heard Mr. Death's cross-examination you heard what it was. He said he really could not say there was anything the matter with him. That is beside the question, because if it had been an absolute fiction on the part of Mr. Death, it would not prevent that which the defendent did from being a breach of the statute. He said "He gave me a bottle of mixture, and said you will find that will do you good; come again in a few days when you have used it. He told me to keep off smoking for a few days." That seems to me to be in the nature of advice. "I gave him a shilling for the medicine, and did not go to him again." I should tell you the learned counsel for the plaintiff is quite right in telling you that the fact that the defendant did not charge for the advice has nothing whatever to do with the question. Whether it was gratuitous or not, or whether it was included in the price of the medicine or not, is perfectly immaterial. The question is did the defendant practise

as an apothecary within the meaning of the Act? He was cross-examined on that, and he gave us an account of what he had the matter with him. He had no tightness of the chest, but he had a slight sore throat, but really none for which he wished for any advice or for which he would have gone to a doctor at all.

Now the account which was given by Mr. Shepperley, the defendant, is this, "I remember Mr. Death coming to my shop. He said, 'I have a cold and a sore throat, and he leant over the counter and he said, 'Will you look at it.' The difference here seems to be this, that Death says he was asked to show his throat, and the defendant says that he, Mr. Death, volunteered himself, over the counter to show his throat. What Mr. Shepperley, the defendant, said was this: "When Death came in he said he had a cold, and he pointed to his throat, which he said was sore. He said, 'Will you look at it,' opening his mouth. I looked at it, and I said I saw nothing the matter. He said, 'Would you give me something for it?' I said perhaps a saline mixture might answer. He said, 'Would you give me one?' I did; and I charged him a shilling. Nothing was said about the tightness of the chest, and nothing was charged for except the medicine. I did not tell him to call again." Mr. Frederick Shepperley's evidence is in confirmation of that. Then, on cross-examination, the defendant says this: "I called what I did counter-prescribing. I examined Death's throat to verify his statement, and to form a conclusion as to whether he had or had not a sore throat." That certainly looks very like the examination of a man to see what is the matter with him. A person very often says, I have got this and that the matter with me, and it often turns out although the person thinks himself ill and affected in a particular manner, it is not so. He says I did not select the medicine. But it really is not like a man saying give me a bottle of medicine, or a box of pills, but here the defendant selected the medicine, put it in a bottle, and put a label on the bottle. The quantity that was to be taken was two tablespoonful three times a day. "I did not tap him, or ask him whether he had anything the matter with his chest." That is the case as far as Death's case is concerned on both sides. It is for you to say whether that is a compounding, dispensing, or vending of the medicines, or whether it was acting as an apothecary within the definition that you have heard is fairly applicable to that word.

Now Hubbard's case varies slightly, and the evidence we have was got principally from the defendant himself. Hubbard he says was an *employé* of Death. "He came some months after Death came, and he asked for something for some pimples on his face. He had some pimples on his face. He said he had been under a club doctor. I told him I did not give advice, but if he could tell me what he had taken before I said I would give him something like it. He said he thought it was potash, and it was something that left a disagreeable taste in his mouth. He said it was brown. I said was there sarsaparilla in it? He said probably. I gave him potash and sarsaparilla and I charged him one shilling for it, I charged only for this. Then he was cross-examined on that, and he said, I did not come to the conclusion that Hubbard's pimples wanted treatment. I gave him the mixture on questions and suggestions, I formed no opinion of what had been the cause of the pimples. I considered myself as competent as any chemist to form my opinion. I gave him iodide of potassium and sarsaparilla, and supposed he was suffering from a disordered state of the stomach. A saline mixture is frequently prescribed by physicians in such cases." I suppose he would put more of the sarsaparilla and less of the iodide of potassium, or *vice versâ*, according to what he considered was the condition of the blood, and therefore in that sense he does exercise a discretion. He does not give to one man a mixture which he would give to another under different circumstances, but he exercises his discretion as to what was the cause, or what produced those pimples.

Now one other piece of evidence which is important is this, which Death gave in his evidence with reference to a later conversation. That was given in order to show the spirit in which the thing was done, to show that there really was an exercising of the art of an apothecary by the defendant on those occasions. What he says is this, "On the 28th of November, on being near the defendant's shop, the defendant came out and asked me about it." He said that being a nervous man, at first he had sent a woman to a doctor who gave her a prescription, and charged her five shillings for it, and that she came back with it, and that he made up it and charged two shillings, and she complained and said all this might have been done for one shilling by you." That is a remark to show the convenience of the system, but of course it cannot have any real effect. He said, "Yes, this is what the doctors are doing for poor people, and they are about prosecuting me for prescribing." He said he had taken the advice of his friends in the trade, and the matter had been discussed in the journals of the trade, and he had resolved to fight the matter. He said, "I have been prescribing, I shall go on prescribing and fight the matter from the County Court to the highest court."

Sir Henry James: The defendant denies that on his oath.

Mr. Baron Pollock: Quite so; I am coming to that. Then when Mr. Shepperley is called, he says this. "I did not say anything of what Mr. Death states I said on the 28th of November."

Now the first question for you to say is, which you believe. What one man says in the affirmative, although it may be contradicted, you may sometimes think more favourably; of that is, what a man says was said, than what another man says he did not say. But the first thing for you to decide is, was that said or not, and then even if it was said, has it any material bearing? You would always remember what is said afterwards in the course of a discussion, and it is hardly probable to alter the view which you may have taken with regard to the facts which have occurred before; there it is for what it is worth; the object of it is to show that he intended to fight this question, and to fight it on the point whether he might prescribe or not. I think, however, that is a point which you must rather discard, and not give any very great effect to it, and you must rather act on what you think took place on the other occasions when Death and Hubbard went into the shop and received a mixture from the defendant.

Now, gentlemen, those are the facts of this case. You have had called before you men whom it is pleasant to see after a long life in a very interesting business who have come here to speak with zeal, as was done by Mr. Cupiss and the other gentlemen who came, as to what was the practice which you yourselves were perfectly satisfied of before the year 1815. What they tell you is beyond all doubt that before 1815, to take the case that Mr. Cupiss gives of Mr. Woolrych, in the dispensing and vending of medicine the practice was to make up the medicine, and give it to customers, taking care that there was nothing injurious, and making inquiries of the patient as to what was required. He would not look at the throat of a man if he said he had a sore throat, but he would ask him questions and bring his discretion to bear on what remedies should be used. He said he would feel the pulse if the customer wished it, or he would look at the tongue, and at the throat if was asked to do so, and the money was paid for the medicine. You were perfectly satisfied, and there could be no doubt on what was done, and the only observation to be made is one that was made in the course of the case namely that because it was done then will be immaterial, because if it was done in fact, but was not done within the meaning of the 28th section, then you must lay it aside altogether, just as if a man had said that before the year 1815 apothecaries were in the habit of cuttin

people's legs off. That must be laid aside. If you think what was done then and what is done now, fairly comes within the spirit of this statute as to "dispensing and vending drugs, medicines, and medicinable compounds, wholesale and retail," then of course the defendant is entitled to your verdict.

Gentlemen, I think those are all the remarks which are pertinent to this case which I have the power to make to you. I shall leave the whole of the evidence which I called your attention to, but if you think there is any part of it which has any bearing on it in the course of your consideration, or if you wish to refer to any particular part, I shall be most happy to refer to it. It is for you to say whether you think in one or either or both of these cases the defendant has brought himself within the meaning of this statute under which they are seeking for this penalty. Of course the law must be obeyed, and these people must be stopped if it is unlawful. If he has not brought himself within the meaning of this statute, then in that case your verdict will be for the defendant.

The Jury consulted.

Mr. Baron Pollock: It struck me, Sir Henry, that you might wish me to put the words of your plea to the jury. I will do so if you wish it, but I cannot think it will have much effect; I mean about the serious complaints, and so on.

Sir Henry James: I had that in my mind, but I would like to hear what is said first and then ask your Lordship to put it if it is necessary.

Mr. Baron Pollock: I should think it is better that the jury should have a fair exposition.

Sir Henry James: I think so.

The jury retired to consider their verdict at fourteen minutes past twelve and returned into court at fifty-five minutes past twelve.

The Associate: Gentlemen, have you agreed?

The Foreman: We have.

The Associate: How do you find?

The Foreman: For the defendant in both cases.

Mr. Baron Pollock: Then, Sir Henry the question will arise as to the plea.

Sir Henry James: No. I understand the jury to say they find for the defendant in both cases. That refers to the two cases. They also find the protection of the 28th clause exists.

Mr. Baron Pollock: I cannot ask them to tell me the grounds.

Sir Henry James: When they say they have found in both cases, as I understand, they have found on all the questions your Lordship left to them.

Mr. Baron Pollock: I only gave them my view of the law.

The Jury: We found on Hubbard's case and Death's case.

Sir Henry James: Yes, but there are questions raised in the statement of defence by the 5th and 6th paragraphs, which are unanswered. Supposing the Court should find as regards those questions in the affirmative as to the 20th section.

Mr. Baron Pollock: How can they find it?

Sir Henry James: The Court may say they wish this matter further inquired into. I should like to rely on the 5th clause also.

Mr. Baron Pollock: The defendant cannot be in a better position than by having a general verdict for him.

Sir Henry James: I should be perfectly satisfied if the jury said in both cases.

Mr. Baron Pollock: They said in Hubbard's and Death's.

Sir Henry James: I want to know what becomes of the fifth paragraph of the statement of defence.

Mr. Baron Pollock: I cannot try that further. The new mode of procedure and the new mode of pleading does not alter it.

Sir Henry James: This is the old mode of pleading. Supposing this were a case to recover money, and the plea is "never indebted," you are entitled to the finding on both issues.

Mr. Baron Pollock: I understand that there is only one issue.

Sir Henry James: Do I understand that the verdict is for the defendant on all the issues raised?

Mr. Baron Pollock: Yes, certainly. I should say there would be judgment for the defendant, and costs.

Sir Henry James: If your Lordship pleases. [After a pause.] I understand your Lordship to say there would be judgment for the defendant, with costs.

Mr. Baron Pollock: Yes.

Provincial Transactions.

COVENTRY AND WARWICKSHIRE PHARMACEUTICAL ASSOCIATION.

The first general meeting of members and associates of the above Society, for the present session, was held on Thursday evening, 10th ult., in the committee room of the Provident Dispensary, Coventry. There was a large attendance of students, and the President (Mr. Councillor Wyley) occupied the chair.

The Chairman, in opening the proceedings expressed the pleasure it gave him to meet so many students at the commencement of their second session. He hoped with the advantages they now possessed the classes would be of such a character as to give every satisfaction to the gentlemen who had kindly volunteered to conduct them. After some remarks upon the importance of zealous application to the study of the various sciences connected with their business, the Chairman called upon the Honorary Secretary to read the usual monthly report. The report contained a statement of the financial status of the Society which was said to be satisfactory. The classes would recommence on the 23rd inst, under the charge of Mr. F. J. Barrett, F.C.S. They would be rendered as interesting as possible by the exhibition of specimens, diagrams, experiments, etc., and it was hoped there would be a very large attendance. Mr. Holdcroft (the students' secretary), then gave a humorous sketch of the origin of the students' section, and concluded by expressing the gratification of the associates at the complete and liberal manner in which the members had caused their room to be fitted up, and thanked the teachers (Messrs. Barrett, Axford, and Wells) for their attention and efficiency in conducting the classes.

Mr. A. H. Newton, pharmaceutical chemist, was elected a member, and Messrs. Turner and Barton, associates.

Messrs. Jenkins and Mr. Loveitt were then elected auditors of accounts for the present year.

The Hon. Sec. then announced the following donations:—A valuable collection of Materia Medica specimens, from Messrs. Evans and Lescher, London (per Mr. Sumner); a series of specimens illustrating the products of Iodine and Bromine, from Messrs. G. Atkinson and Son (per Mr. F. T. Best, F.C.S.); Chemical apparatus from Messrs. Aug. Bel and Co.; *The Pharmaceutical Journal*; *The New York Druggist and Chemical Gazette*; *The Canadian Pharmaceutical Journal*; Two books of Chemical Labels from Messrs. Mawson and Swan, Newcastle, etc.

After hearty votes of thanks had been passed to the donors, the President announced that at the end of the session the following prizes would be awarded to the most successful students. To Minor students—First prize: A two guinea materia medica cabinet (by the President); Second prize: Books or chemical apparatus,

value one guinea; One prize, value one guinea, to the most efficient "Preliminary" student, and a prize, value one guinea, for the best original essay on any subject connected with Pharmacy, Chemistry, or Materia Medica.

After some further remarks, he called upon Mr. George Walker (of the firm of Wyleys and Co.) to deliver his lecture on "The Model Pharmacist."

After a humorous introduction the lecturer enlarged upon the importance of every candidate for pharmaceutical distinction taking the highest possible ideal as his model. The more unattainable it might be the more he would benefit by his endeavours to imitate it. Quaint George Herbert said—

> "Pitch thy behaviour low; thy projects high;
> So shalt thou humble and magnanimous be,
> Sink not in spirit; who aimeth at the sky,
> Shoots higher much than he who mounts a tree."

Following the example of the eminent divine who preached the celebrated impromptu sermon on the word "malt," Mr. Walker proceeded to divide his text "Pharmacist" into the following headings:—P. perseverance, H. honour, A. ability, R. receptiveness, M. manliness, A. accuracy, C. calmness, I. industry, S. sympathy, T. tact. These qualifications were necessary to form a "Model Pharmacist," and although not quoted in all the wholesale drug lists, undoubtedly had a market value and were "kept by all respectable chemists." To succeed in life it was absolutely necessary to be gifted with the bump of *perseverance*. This term was derived from the Latin. How seldom as we were whirled along through a railway cutting did we pay due honour to the pickaxe and shovel, which had "persevered" through the obstructive hill, and thus enabled us to reach our destination more quickly. To reach the terminus which most young chemists aimed at—a corner shop, and the right to use the mystic letters "M.P.S.," it was equally necessary to ply manfully the pickaxe of perpetual, persevering, painstaking, pharmacological study. The model pharmacist must be a man of *honour*, for his customers were frequently entirely ignorant of the drugs they required, and had to trust implicitly in his fair dealing. This confidence should never be betrayed. The model pharmacist must possess *ability*, for without this it would be impossible for him, even if he managed to pass the various examinations satisfactorily, to carry on a profession embracing a knowledge of so many branches of science. Ability without *receptiveness* was a gift of little worth, and this power should be cultivated methodically to render it of real practical value. A man gifted with the power of memory was like a room filled with disarranged books, but he who also possessed method had the same amount of knowledge stored on shelves and ready for immediate reference and use. The quality of *manliness* was appreciated by all true men and women, and must be possessed by the model pharmacist. He would not stoop to take advantage of those who depend on his honour, because he thus lost his rank as a lord of creation, and sank from a tradesman into a trickster. To all business men *accuracy* was of the utmost importance, to the pharmacist it was especially so, for the dispensing scales sometimes held in their pans the very existence of some of his fellow creatures. The model pharmacist possesses the gift of *calmness* or self-possession. Cowper gives a picture of a lady possessed of this gift, whom he describes as "mistress of herself tho' China fall," arguing by analogy that the female mind which can bear with equanimity the crash which tells that her best set of crockery has performed a sum in compound division must have a model mind. It was certainly of great importance to cultivate a habit of calmness even when surrounded by petty annoyances and difficulties. The possession of the qualification of *industry* was of so much importance that too much could not be said in urging young men to gain it. The Chinese proverb said that "By patience and perseverance the mulberry leaf becomes satin." And we may depend upon it that in this as in many other instances we may learn a profitable lesson from the "heathen Chinee." The model pharmacist is a man full of *sympathy*—which like pity is akin to love. The lecturer did not refer to that dreadful form of heart disease, which has for its symptoms a craving for moonlight walks with a beloved object, and culminated in taking part in that ceremony in the prayer book which begins with "dearly beloved" and ends with "amazement"—but rather to that intense sympathy with his profession which is a great incentive to acquiring a thorough knowledge of all its branches. He should also be plentifully endowed with *tact*,—the art of "putting things"—an art which had achieved more victories than the sword or the bayonet. The lecturer concluded his most interesting lecture as follows: "We have thus rapidly and imperfectly placed before you some of the qualifications which should be possessed by the 'model pharmacist.' We have not referred to the scientific side of the question, because we are sure it will be more forcibly inculcated upon you by the course of study pursued here than by any words of ours. Let us by all means cultivate the *head* but do not therefore slight the education of the *heart*. Unlike the alchemist of old, our path of duty leads us not away from the world, but into the thickest of its struggle. We have heard of a misanthropic man who caused to be inserted upon his gravestone some such words as these—"Born to be a man, but died a druggist." Let us make no such mistake. The world is bad enough, let us strive to make it better. A Yorkshire legend runs—

> 'The world is full of fools, and he
> That would not see an ass
> Must stay at home, lock himself in,
> And break his looking glass.'

—If there be any truth in this dark picture of life, how needful it is that we, who by education should be scholars and gentlemen, should prove our right to the title we bear. To sum up the whole matter in one sentence—wherever we find a model pharmacist, we should also find a model gentleman."

The lecturer was listened to with the greatest attention, and was frequently very heartily applauded. Mr. Hawthorne (Wallsgrave) proposed, and Mr. Hodgkinson seconded a vote of thanks, which was carried by acclamation.

The remainder of the evening was spent in examining the various specimens of materia medica, chemicals, etc., with which the table was covered, and a vote of thanks to the Chairman brought the meeting to a close.

It was announced that the Students' opening meeting would be held on the 22nd inst, when Mr. Fred. Barrett would deliver an address "On Michael Faraday," and there would be an exhibition of various interesting specimens, microscopes, etc. The next monthly members' meeting would be held on the 14th prox., when Mr. J. C. Gibbes, would deliver a lecture "On Nothing."

Correspondence.

"Unusual Doses."

Sir,—I quite agree with A. P. S. and others, that the subject of unusual doses is one which should be settled as quickly as possible. I have dispensed the following prescription several times, and consider it to be another instance of an excessive dose:

℞	Liq. Ext. Ergotæ	℥iss.
	Acid. Gallic.	ʒij.
	Tinct. Cinnam. Co.	ʒiss.
	Aquam. ad	℥vj.

M. ft. mist. One tablespoonful two or three times a day in a little water.

The directions being strictly observed, the patient would be taking at least two or three drachms of liq. ext. ergotæ in a day, a quantity which I thought fully justified an interview with the prescriber, who at once stated he intended that amount to be given. The mixture being repeated several times, and for a comparatively young and weakly person, certainly caused a little anxiety at the time.

79, Abbey Road, N.W. J. W. BARNES.

Sir,—A.P.S's query is one which can only be answered in this way, Was the dose of ext. ergotæ liq. too large under the circumstances in which it was ordered? Now in the case given, one physician says it was, and the other says it was not. What is a dispenser to do in a case like this? He knows the usual dose; but there are occasions in which the ordinary dose of a drug, or its preparations, must be augmented.

I therefore say that when such a large dose of ext. ergotæ liq. is ordered as half an ounce immediately, and another similar dose in two hours, caution should be observed I have often given, in the space of an hour, half an ounce of ext. ergotæ liq., all the while watching its effect, and not long since my whole stock of six drachms was expended upon a patient in the country, and whose life was despaired of, and I also in the short space of the same half hour emptied my bottle of sal volatile and chloric ether, equivalent to six drachms, before I got uterine action restored. We had no brandy, no gin, no whisky; but it was a lesson to a staunch teetotaler, which neither he nor I and the friends can ever forget. I may say the patient is now perfectly well, and did not, so far as I could observe suffer from the unusual dose. When, however, an "unusual dose" is prescribed it should initialed over and above the prescriber's name, usually written at the bottom of the prescription. If this was done, what a vast amount of trouble it would save the compounder and at once free him from all responsibility.

Northallerton Nov. 2, 1878. HENRY BROWN.

P.S. Will you permit me to say to Mr. JAMES Swenden, of Darlington, that I wish to instruct, and cannot find time to squabble with him in your columns.

H. B.

,—M. Raspail in his system of organic chemistry, § Sir says that 29·5 and even 59 grains of the acetate of morphia do not produce death; whether taken internally or injected into a vein. The same quantity of narcotine (29·5 grains) he says will kill a dog, but does not produce any effect on man, though taken in doses of several drachms daily. An acquaintance of my own who had just recovered from a severe attack of rheumatic fever, used 20 grains hypodermically within the space of one hour, and this more or less, daily, for some months. One day he used the same quantity twice within six hours, the only ill effect being a slight headache.

With respect to ext. ergotæ liq. In obstetric practice four drachms is not an unusual dose. Larger quantities have been given without producing any marked effect.

Victoria Hospital. J. LAKER MACMILLAN.

THE POSITION OF THE PHARMACIST IN REGARD TO THE REVISION OF THE PHARMACOPŒIA.

Sir,—The perusal of your article on the above subject cannot, I think, fail to interest very many, if not all, the readers of the Journal, and your comments on Dr. Symes's very excellent paper, entitled "Suggestions for a New Edition of the British Pharmacopœia," and read at an evening meeting of the Liverpool Chemists' Association, are well worthy of note; the more so, perhaps, in consequence of their contrasting in a singularly interesting and instructive manner the position which, through the perseverance and indefatigable labours of the founders of our great Society, pharmacists of the present day occupy, in contradistinction to that of twenty years ago. And if you will turn with me to page 504 (*Pharm. Journ.*, May 1, 1863), you will there find one of the best and most practical letters ever written by a living pharmacist, bearing upon this subject. I refer to a letter written by Mr. R. Reynolds, entitled, "Systematic Scientific Inquiry." Mr. Reynolds commences as follows:—"In an address delivered to the British Association for the Advancement of Science, at its meeting at Aberdeen in 1859, the late lamented Prince Consort forcibly expressed the truth in the following words: 'Economy of labour is the essence of good husbandry, and no less so in the field of science.'"

In the same number, page 476, a leading article appeared under the heading, "Work to be Done, and How to Do It." In this article especial attention is drawn to the honourable and responsible position taken by continental chemists in suggesting and revising the processes to be introduced into the new Pharmacopœia.

The physician may possess all knowledge and wisdom and skill, but he will never allay the fever or check its onward progress unless you supply him with the remedies properly prepared. The surgeon may be clever too, but he will not succeed in his operation and will never carry off the laurels of fame unless you supply him with a knife which has been tried in the fire and manufactured by good workmen under skilful supervision. The Pharmacopœia may bear the name and the arms of the nation, together with the resemblance of reality, but it will never be the Pharmacopœia of practice until pharmacy has assigned to it its proper place in the ranks of the committee formed for its compilation. The physician must lead, and the pharmacist must follow in the train, if a really practical result is to emanate therefrom.

Dr. Symes refers to lectures which have been given, papers which have been read, and discussions that have followed. Surely, sir, the cart was placed before the horse by first issuing the Pharmacopœia and then turning round and showing its defects. And if, as suggested in this Journal fifteen years ago, the services of the most able and experienced pharmacists had been enlisted in the work of investigation, and the results of their investigations published and fully discussed by those interested in them before the final selection of the processes to be adopted, a much better work would have been moulded into shape, whilst at the same time there would have been good occupation for committees in different parts of the country, through whose instrumentality much valuable information could doubtless have been collected.

It is greatly to be hoped that some such step as this will be taken when a future edition is contemplated.

There is one other point which I hope to draw attention to, and it is the desire which I know is very commonly felt, that we should have a larger number of official formulæ, so as in some respect to supersede "secret remedies," a class of medicines which are a great trouble to the dispenser at home and abroad.

Why could we not have a Pharmacopœia containing all the more important preparations, and in addition a comprehensive sort of supplement, embracing new remedies and well brought up to the present time?

35, *Baker Street, W.* A. W. POSTANS.

"*Apprentice*" (Hull).—It is practically the same thing.

J. G.—In our opinion, so far as that is of importance, an answer to the question was not compulsory. But we recommend you to consult the Secretary.

"*Student.*"—We do not know that it has been decided to have a new Pharmacopœia.

F. P. W.—See the question of chloric ether discussed in "Dispensing Memoranda," vol. viii., pp. 19, 38, 67, etc.

S. L. C.—It would not be difficult to purchase a packet of the article and examine it.

"*Student.*"—The first form of expression, perhaps, follows the original most closely, but the latter is most frequently used. It seems to be a matter of very little importance.

"*A Pharmacist.*"—We do not see that any useful purpose will be served by the insertion of your question.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Brown, Tudor, Wright, Moore, Fletcher, Kemble, Green, Barrett, Brown, Macmillan, Symons, Garrett, Barnes, Cardwell, Abraham, Fox, Cock, Stocks, Stevens, Stevenson, Postans, Mumford and Son, Rimmington, Stewart, A. L. Ness, An Apprentice, Pharmacist, Student, Sub Umbra Floresco, Pulvinus, Coventry, Llet, Apprentice, Beta, Artium, Socius, P. B., J. G., W. S., H. K., T. S., C. R., J. N. W , H., J. H. G.

SOME BISMUTH RESIDUES.*

BY E. A. LETTS, PH.D., F.R.S.E.

Professor of Chemistry at University College, Bristol.

The following short communication was to have been made to the Pharmaceutical Conference at its last meeting in Dublin. Owing, however, to my inability to be present on that occasion the paper was not read, though I intended that it should appear in the report of the Conference and that a notice of its contents should be announced at the Conference itself. On subsequently communicating with Professor Attfield, he suggested that it should be read at the November meeting of the Pharmaceutical Society, and with this suggestion I readily concurred, trusting that on the one hand the members of the Conference will not think that I have defrauded them of their dues, and on the other that the members of the Pharmaceutical Society will not charge me with bringing old wares to market.

In the spring of the present year Mr. Schacht brought me some residues which had been left on dissolving commercial bismuth in dilute nitric acid (2 parts strong acid and 3 parts water), and asked me to examine them. The occurrence of such residues Mr. Schacht told me is very unusual, and as he has had a very large experience of the behaviour of commercial bismuth in the manufacture of his well known soluble preparations, and yet had not previously noticed the occurrence of any considerable residue on dissolving the metal in nitric acid, he suggested that the examination of the residue might perhaps lead to interesting results.

I need scarcely recall to the minds of those present the fact that many of the rarer elements were first discovered in residues from various chemical operations; that Crookes discovered thallium in the dust accumulating in a vitriol chamber in the Hartz; that Bunsen and Kirchhoff discovered rubidium and cæsium in the mother liquors from the salt springs of Dürkheim; and, most interesting of all to the pharmacist, that Stromeyer discovered cadmium in a specimen of oxide of zinc, which as Government Inspector of Pharmacy he examined in consequence of its dark colour and the suspicion that it was adulterated. Stromeyer indeed was led at first to believe that the oxide contained arsenic, as its solution in acids gave a yellow precipitate with sulphuretted hydrogen, but on examining this precipitate more closely he soon satisfied himself that it contained no arsenic, and eventually showed it to be the sulphide of a new metal.

These considerations, interesting alike from a purely scientific as well as practical point of view, induced me to undertake the investigation of Mr. Schacht's residues, and although it has resulted in the detection of no new substances, I think that the facts regarding certain well known and comparatively well investigated bodies, which have been brought to light during its course, are of sufficient interest to be made known. The experiments were made by my pupil, Mr. J. E. Baker, and by myself.

The residue, as it reached me, was in the form of a grey almost impalpable powder. But Mr. Schacht informed me that when freshly prepared it was brick red.

One ounce of the residue was left on dissolving fifteen pounds of bismuth, *i.e.*, the former amounted to nearly one-half per cent. of the metal.

Among the preliminary experiments which we tried was heating a little of the residue on platinum wire in the flame of a Bunsen's burner. It imparted a fine azure blue colour to the flame, and at the same time white vapours were disengaged, possessing an odour that led us to suspect the presence of selenium, and on applying Bunsen's film test, *i.e.*, on heating a little of the substance on a charred match saturated with carbonate of soda beneath a cold porcelain surface, the characteristic red film made its appearance.

We soon found that selenium was present in considerable quantity, which is interesting, as that element seldom occurs associated with bismuth. It is a well known fact, however, that bismuth is found in nature alloyed with tellurium to the extent of 0·042 per cent., and telluride of bismuth, Bi_2Te_3, the *Tetradymite* of mineralogists, is a natural compound of bismuth not unfrequently found.

The occurrence of selenium and tellurium together is, however, seldom observed, so that we scarcely expected to find the latter. Nevertheless we searched for it and adopted the method for separating the two elements proposed by Oppenheim, viz., by fusing the suspected mixture with cyanide of potassium in a stream of hydrogen.

The cyanide under these conditions combines directly with selenium to form seleniocyanate of potassium, analogous to the sulphocyanate, whereas tellurium is reduced to the elementary condition, and combines with potassium to form telluride of potassium. On treating the fused mass with water, both the products are dissolved; but on blowing air through the solution, tellurium is precipitated as such, leaving the seleniocyanate unaffected.

Twice we made the experiment and on each occasion failed to detect a trace of tellurium, and we therefore concluded that that element was absent.

Our next experiments were to detect the metals combined with the selenium. A portion of the residue was boiled with strong hydrochloric acid. A certain quantity dissolved, leaving a black substance, which disappeared on the addition of a drop or two of nitric acid, but was replaced by a white precipitate.

The latter was soluble in a considerable quantity of strong hydrochloric acid, but was re-precipitated on the addition of water—far too little, however, to cause the precipitation of basic bismuth compounds.

This behaviour puzzled us somewhat at first, but its explanation soon became apparent.

A quantity of the white insoluble matter was fused with cyanide of potassium and yielded with ease a globule of brilliant white metal, malleable and somewhat hard, which was not affected by hydrochloric acid, but dissolved with ease in nitric acid.

The solution gave a curdy white precipitate with hydrochloric acid, soluble in ammonia; when neutralized a red precipitate with chromate of potash, and a yellow precipitate with iodide of potassium, thus proving clearly enough that the bead consisted of metallic silver, and the white insoluble matter from which it was reduced of the chloride of silver.

One is so apt to ignore the solubility of chloride of silver in strong acids, and to regard it as practically insoluble, that it was somewhat startling to find such considerable quantities dissolved. Chloride of silver, however, is soluble in fuming hydrochloric acid to

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Nov. 6, 1878.

the extent of one-half per cent., and in a mixture of the fuming acid and an equal volume of water to one-sixth per cent., whereas strong nitric acid only dissolves one five-hundredth per cent.

The solution filtered off from the chloride of silver was saturated with sulphuretted hydrogen, the precipitate that resulted digested with sulphide of ammonium, and the insoluble portion treated as is recommended in the seventh (English) edition of Fresenius's 'Manual of Qualitative Analysis' for the detection of the rarer metals, *i.e.*, fused with carbonate of soda and nitrate of potash, the fused mass treated with water, and the solution tested for ruthenium and osmium with nitric acid,—neither of which we could detect. The portion insoluble in water, after digestion with nitric acid to dissolve bismuth, etc., was tested for palladium by dissolving it in aqua regia, cautiously evaporating to dryness, dissolving in water and adding iodide of potassium, which gave a black precipitate disappearing on boiling. This reaction is characteristic of palladium, but the occurrence of that element in association with selenium and bismuth appeared so startling that we hesitated to admit its presence without further proof.

Up to this point we had failed to detect other elements in the residue than selenium, bismuth, and silver, but quite accidentally we discovered gold.

In attempting to determine the three elements just named, we fused a portion of the residue with cyanide of potassium and treated the metallic bead which resulted with nitric acid; a brown residue was left which dissolved with deep yellow colour in aqua regia, and yielded the characteristic purple of Cassius with chloride of tin solution.

It occurred to me that what we had taken to be palladium iodide was really nothing more than iodine itself, formed by the action of auric chloride on hydriodic acid,—these two substances reacting to give aurous iodide, water and iodine. We therefore repeated the experiment for the separation of palladium, and found that the sulphide of gold did not dissolve completely in sulphide of ammonium, though the precipitate was digested with two separate quantities of that reagent, and it is usually stated that sulphide of gold is readily soluble in sulphide of ammonium. The sulphides, after treatment with the sulphide of ammonium, were fused with carbonate and nitrate of potash, the gold was reduced to the metallic state, was of course insoluble in nitric acid, but dissolved in aqua regia, and the solution behaved, with iodide of potassium, like a palladium compound.

In order to verify this result we treated a little chloride of gold, known to be pure, with iodide of potassium, and found that it reacted as a salt of palladium.

I have, therefore, very little doubt that the residues contain no palladium, though there does not appear to be a satisfactory process for separating that element from gold in minute quantities, nor for discriminating it in the presence of the latter.

Having ascertained the above facts with respect to the qualitative composition of the residues, it appeared to us to be of interest to determine the quantities of bismuth, selenium, gold and silver to ascertain whether those elements were present in atomic proportions—whether, in fact, the residue consisted of a compound or was simply a mixture.

The plan which we proposed to adopt for the quantitative analysis was to separate the selenium by fusion with cyanide of potassium and to determine the metals in the resulting bead.

Accordingly weighed quantities of the residue were mixed with about ten times their weight of cyanide of potassium and fused for some time in a curved tube of hard glass through which a stream of hydrogen was passed. The mass was then treated with hot water which dissolved out the greater portion of the product, but left a metallic bead and a grey metallic-looking powder, both of which were filtered off from the clear solution of the seleniocyanate of potassium. From the latter the selenium was precipitated by hydrochloric acid and collected on a weighed filter.

In one experiment we found 16·8 per cent. of selenium. In another, no selenium at all separated on adding hydrochloric acid to the filtered solution of the fused mass, and in a third the latter instead of being colourless as in the two preceding experiments was claret coloured, and after filtration began to deposit a grey crystalline metallic looking powder. This led us to suspect tellurium, in spite of our former negative results, and on examining the precipitate our suspicion turned out to be well founded. Tellurium was indeed present in the residues, and that too in considerable quantity, and I can only account for our having failed to detect it previously by the imperfection of the method employed. Perhaps it is not fair to condemn a method without having seen the original memoir, but certainly both in Watt's and Würz's Dictionaries of Chemistry, no special precautions are given, the neglect of which might account for our results. It is simply directed to fuse the mixed telluride and selenide in a stream of hydrogen with cyanide of potassium, to dissolve the fused mass in water, and to pass a current of air through the filtered solution until the whole of the tellurium is separated.

We have tried again and again to separate the tellurium in this manner. By conducting the fusion at as low a temperature as possible some of the tellurium certainly does dissolve in the cyanide, but the moment the fused mass is dissolved in water the tellurium begins to separate, and with such rapidity that the solution cannot be filtered without a considerable quantity of the element remaining on the filter.

If the fusion be conducted at a high temperature and for a long time, the tellurium remains entirely undissolved by the cyanide, partly in the globule of reduced metal and partly as a grey powder. And as I have already stated, in one case, not only could no tellurium be detected by this method, but the selenium also failed to separate on adding hydrochloric acid to the filtered solution which ought to have contained seleniocyanate.

I am therefore inclined to regard the cyanide method for separating the two elements as inaccurate, unless performed with special precautions as regards temperature of fusion and filtration of the solution of the fused mass in an inactive atmosphere, which I have nowhere seen given, although it is possible that they occur in the original memoir.

As regards the determination of the other constituents of the residue, we have ascertained that the silver amounts to about 5 per cent., the bismuth to about 44 per cent., and the gold to about 2 per cent.

The percentage of the latter is, however, probably too high, as we experienced great difficulty in sepa-

rating it from the tellurium. In one experiment we fused the sulphides of gold, selenium and tellurium with an oxidizing mixture of nitrate of potash and carbonate of soda, which treatment we thought must be effectual in oxidizing the selenium and tellurium, and thus separating them from the gold which would remain unaffected. We noticed that the metallic bead which was produced was *white* and that it floated about and refused to be altered visibly, even though it remained in contact with the oxidizing mixture for a considerable time. When cold we found that it was quite brittle, and on heating some on platinum wire in the Bunsen's burner flame the azure blue colour of selenium vapour was first apparent, followed later by the pale green of tellurium. It is remarkable that these elements, even if combined with gold, should offer such resistance to oxidation.

As regards the percentage of tellurium present in the residues, we have not succeeded in making any exact determinations, owing to the difficulty of separating it from selenium, but it certainly amounts to 12 per cent. of the weight of the residues, and we are inclined to think that 20 per cent. is nearer the mark.

The residues consist in all probability of a mixture of tellurides and selenides of the metals gold, silver and bismuth. We have failed to detect any sulphur or other electro-negative constituent, and, with the exception of traces of copper, any other metals.

The firm who supplied the bismuth from which the residues were obtained, when communicated with on the subject, stated that the metal was part of a parcel of impure bismuth imported from Australia and subsequently refined by them, and they could not understand how it came to contain selenium and tellurium.

Crude bismuth is usually refined by fusing it with saltpetre, and if that was the process adopted the occurrence of selenium and tellurium is perfectly intelligible after what I have stated respecting their behaviour with fused nitrate of potash and carbonate of soda when they are combined or alloyed with gold.

TINCTURE OF QUININE.*

BY W. MARTINDALE.

The process for making this preparation according to the different pharmacopœias in which it has appeared has never been satisfactory. According to the London Pharmacopœia, 1851, in which it was first official, and there called tinctura quinæ composita, the quinine was directed to be "digested in the tincture of orange peel for seven days, or until dissolved, and filtered." In the British Pharmacopœia, 1864, the formula for tinctura quiniæ composita was practically the same: "digest for seven days and strain." In the present Pharmacopœia of 1867 tinctura quiniæ of the same strength is directed to be prepared by dissolving "the sulphate of quinia in the tincture with the aid of a gentle heat; then allow the solution to remain for three days in a closed vessel, shaking it occasionally, and afterwards filter."

There is here an acknowledged difficulty in making the preparation, recommending the employment of a "gentle heat" (according to the British Pharmacopœia 1867, a "gentle heat" is not defined, it was in the London Pharmacopœia, 1851); but a heat more than that of digestion is required to dissolve the quinine, showing that it is a nearly saturated solution, or digestion, or maceration even, would dissolve it ir less than the time ordered. In strictly following the present Pharmacopœia process the sulphate of quinine dissolves readily enough in the tincture of orange peel on the application of heat, but after three days' setting aside, and occasional agitation, a quantity of white sediment forms, which by some has been supposed to be tannate of quinine, tannic acid from the orange peel; by others, sulphate of lime, as the orange peel contains some lime also, and the precipitate is formed by double decomposition from the sulphate of quinine. That it is not tannate of quinine, I shall have occasion to show in what follows. After filtering, the tincture thus formed keeps fairly bright at the ordinary temperature, but if below 40° F. is reached, the sulphate crystallizes out in large crystals at the bottom of the bottle. To judge how far the tincture of quinine generally sold corresponds with the preparation of the Pharmacopœia, I obtained four different supplies, and examined them; the results are tabulated below:—

		S. G.	Quinia obtained from one fluid ounce.
No. 0 .	Definitely acid	·955 . . .	5·2 grains.
No. 1 .	Very faintly acid	·938 . . .	7·2 „
No. 2 .	Definitely acid	·955 . . .	5·0 „
No. 3 .	Slightly acid .	·964 . . .	5·0 „

A fluid ounce of each was concentrated by evaporation to drive off the spirit. Then to each ten minims of diluted sulphuric acid was added, followed by thirty minims of solution of ammonia to precipitate the quinia, and afterwards this was separated by three successive half ounces of pure ether. The ethereal solution, on evaporation, gave the amounts of quinia, not quite pure, as above. It was evident that only No. 2 approached the Pharmacopœia standard, from which I got 7·2 grains of quinia, equal to about eight grains of the sulphate. The specific gravities of the others, I think, indicate that the tincture of orange peel could not have been made with full strength of proof spirit. This, to some extent, might account for their not containing the full quantity of quinine, and their being definitely acid would show that to aid its solution a little acid had been added.

I find if an additional quantity of rectified spirit be added to the tincture of orange peel in making the tincture of quinine the sulphate of quinine is less liable to crystallize out. I have therefore lately used one part of rectified spirit and seven of tincture of orange peel in place of all tincture in making this preparation, dissolving the quinine in the spirit first, by the aid of heat, and adding the solution to the tincture. Still a quantity of sediment forms, which has to be filtered out. I have tried dissolving an equivalent quantity of pure quinia in the tincture of orange peel, but thus made it does not bear dilution with water so well, the alkaloid not being so soluble in water as its salts. I therefore thought I would try other salts than the sulphate, and taking the hydrochlorate, as being a very soluble salt, I added sixteen grains of it to two fluid ounces of tincture of orange peel in a test tube and was lighting the spirit lamp to heat it, but found it had dissolved almost instantly. This was on the 17th September, last. I made a bright solution and has kept nearly

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Nov. 6, 1878.

so, although it has been exposed in the open air where it has been subjected to great variations of temperature, as low as 32° F. and frequently below 40° F. This tincture is not distinguishable in taste from that prepared according to the Pharmacopœia. There is no white sediment formed in it soon after it is made, showing that the precipitate formed in making the British Pharmacopœia tincture is not a tannate of quinine, else it would separate from the hydrochlorate as well as from the sulphate. Altogether I think that this mode of making the preparation is free from objections.

The hydrochlorate of quinine is recommended by Messrs. Howards, on account of its being more soluble in water than the sulphate and being richer in the pure alkaloid quinia. It contains according to them 82 per cent., against 74½ per cent. in the sulphate. I find it dissolves readily in water without the aid of heat, simply by agitation, to the extent of one part in 36, or 12 grains in the fluid ounce, forming a neutral solution which is not fluorescent. It is considered therapeutically often an advantage to give quinine without an excess of acid. We have in this salt a ready mode of administering it. We can at least make a tincture with it without excess of acid and of the definite strength of one grain of it in the fluid drachm, which is not the case with the present tincture. As an antiseptic solution for injecting into the bladder, or as a collyrium, being free from excess of acidity it offers special advantages. One drop of the solution, 12 grains to the ounce, dropped into the eye caused at first a little irritation, which, after some lachrymation, in five minutes entirely passed off. I hope, therefore, that in our next Pharmacopœia the hydrochlorate of quinine may find a place.

[*The discussion on this paper is printed at p.* 418.]

DETECTION AND APPROXIMATE DETERMINATION OF MINUTE QUANTITIES OF ALCOHOL.*

BY J. C. THRESH,

Pharmaceutical Chemist.

That the detection of small proportions of alcohol is a matter of some importance is evident to any one who looks through the Year-Books issued by our Conference, no less than sixteen papers bearing on the problem being abstracted in the volumes already published. The analyst desires a test which will enable him to detect with absolute certainty the presence of alcohol in essential oils and other medicaments when mixed therewith, and the physiologist requires such a test to solve a number of problems relating to the action of alcohol upon the system and its presence or absence in the tissues and animal fluids. Hitherto no process has been published which is capable of giving certain results in such cases, either qualitative or quantitative.

Probably the best test as yet proposed is that of Lieben as modified by Hager (abs. Y.B.P. 1871, 237), which depends upon the formation and deposition of crystals of iodoform, when solutions of iodine and potassium hydrate are added successively to the warmed fluid containing alcohol. This test is said to be capable of detecting 1 part in 2000 of water, but I have failed to obtain by it any decided reaction with so dilute a solution. Moreover a number of other volatile and non-volatile compounds yield the same reaction under similar circumstances (*e.g.* aldehyde, actone, methyl alcohol, propyl alcohol, volatile oils, gum, sugar, lactic acid, etc). Another general test is Hardy's (abs. Y.B.P. 1872, 161) depending upon the production of a blue colour when guaiacum resin, hydrocyanic acid and sulphate of copper are added to an aqueous solution of alcohol, but it is incapable of detecting less than 1 part in 150. In the same Year-Book (page 160) is an abstract of a method proposed by M. Berthelot. Benzoic chloride is mixed with the suspected solution, the mixture warmed, and a little caustic potash added, when a characteristic odour of benzoic ether is evolved if alcohol be present. This test is very sensitive with a 4 or 5 per cent. aqueous solution, but when smaller proportions are present, or the fluid contains other odorous substances, it is quite useless.

The old chromic acid test as hitherto applied is perhaps the most fallible of all, since innumerable substances give the same reaction, in virtue of their greed for oxygen. A more modern test is that proposed by Davy (abs. Y.B.P. 1877, 109), and depends upon the production of a blue coloration when molybdic acid dissolved in sulphuric acid is added to the fluid containing alcohol, but Hager (abs. Y.B.P. 1877, 285) failed entirely to obtain the reaction. Besides these general tests a great many others have been proposed for use in special cases, thus Boettger (abs. Y.B.P. 1873, 164) recommends solid caustic potash for detecting alcohol in ether, and anhydrous glycerine for its detection in essential oils. Fuschin, tannin, aniline red, jalap resin and many other substances have also been similarly employed, but scarcely one of the tests emmerated, it is worthy of mark, is capable of being employed to make even an approximate quantitative determination of the ethyl hydrate.

Some time ago, when examining a solution containing aldehyde, I was struck by the remarkable delicacy of the caustic potash reaction, I found that an aqueous solution containing one one-thousandth part of pure aldehyde, when boiled with a fragment of solid caustic soda or potash and allowed to stand for a little while, exhibited a distinct yellow colour. If a solution containing ·5 per cent of aldehyde be thus treated, the liquid becomes deep yellow, and a flocculent yellow precipitate gradually subsides, and this solution when diluted first with a little alcohol, and then with 50 volumes of water still exhibits a yellow tint when examined in a long test tube over a sheet of white paper or a porcelain slab.

I then commenced a series of experiments, having for their object the detection of minute quantities of alcohol by converting it into aldehyde, and treating the resulting solution with caustic alkali. After making a great number of attempts I succeeded in devising a method which is not only reliable as indicating with certainty the presence of alcohol, but which within certain limits gives fairly approximate quantitative results.

Distillation with sulphuric acid and permanganate of potash was first tried and it was found that with a given proportion of permanganate, a ·1 per cent solution of alcohol could readily be detected, but with even a slight excess of permanganate the results were entirely negative. Other oxidizing

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Nov. 6, 1878.

agents were then tried, and bichromate of potash found to be the most reliable, since an excess, unless large, did not materially decrease the yield of aldehyde. Still the quantitative results obtained from the same solution varied very considerably, and for some time the cause was apparently inexplicable. At length, noticing that when the determinations were very low considerable bumping took place during the distillation, several substances were added to obviate this, and it was found that when a few small pieces of pumice were placed in the flask the distillation proceeded evenly and the results were remarkably uniform. Fresh pumice must be used for each distillation. For an aqueous solution containing from ·04 to ·4 per cent of alcohol the following method may be relied upon for quantitative determinations, whilst it will detect with certainty ·01 per cent. or 1 in 10,000. When the quantity of alcohol present differs much from the proportion here given the determination is too low, becoming more and more unreliable as the percentage rises above or falls below these limits.

The requisites are a saturated solution of bichromate of potash, a dilute sulphuric acid (B.P. acid and water, equal quantities), a syrupy solution of caustic soda, methylated spirit free from aldehyde, a 200 c.c. flask with good condensing arrangement attached, and a long narrow test tube graduated to 3 and 23 c.c.

One hundred c.c. of the dilute alcohol are placed in the flask, 2 c.c. of bichromate solution, 8 c.c. of the dilute acid, and a few pieces of pumice are added and 20 c.c. distilled (not too rapidly), and the distillate conveyed by a long tube to the bottom of the test tube in which has been previously placed 3 c.c. of the soda solution. The liquid in the tube is then heated, kept at the boiling point for a few seconds and placed aside for a couple of hours. If ·1 per cent. of alcohol was contained in the original solution the contents of the test tube will be of a deep yellow colour and will have deposited flocks of aldehyde resin; with ·05 per cent., no resin is formed, but the fluid is deep yellow and perceptible opalescent; with ·01 per cent. the colour is just perceptible, but the characteristic odour is still very distinct. To make a more accurate determination, dilute 1 part of pure aldehyde with 200 of water, to this add 30 parts of the caustic soda solution and treat in the same way as the above distillate. After the lapse of two hours (the reaction not being complete for nearly this length of time) dilute with 200 parts of warm methylated spirit and add water to 500 parts. This solution is quite clear and of a reddish yellow colour and will keep for some time, especially if not exposed to the light. Mix 5 c.c. of this solution with 45 c.c. of water in a glass such as is employed for nesslerizing, and take this as a standard solution. It does not keep more than two or three hours, hence fresh standards must be from time to time prepared, or a solution of bichromate of potash made of equal depth of colour (the tint being almost identical) and kept as a standard of reference. To make the quantitative determination dilute the distillate with sufficient warm spirit to make a clear solution and add water to 50 c.c. Upon ascertaining the quantity of this solution, which must be diluted with water to 50 c.c. to bring the depth of colour to that of the standard solution, the percentage of alcohol in the original solution is immediately known. The following are fair specimens of the results obtained.

Strength of Alcoholic Solution.	Strength calculated from result of experiments.
·02 per cent.	·012
·1 „	·089
·1 „	·1
·1 „	·088
·1 „	·092
·2 „	·166
·2 „	·208
·05 „	·039
·2 „	·170
·4 „ (3 c.c. $K_2Cr_2O_7$ Sol.)	·308

Having ascertained the reliability of the method, where the alcohol was diluted with water only, the effect of the presence of other substances was tried. Städeler has shown that albumin, fibrin, gelatin, and lactic acid, yield a trace of aldehyde when treated with sulphuric acid and bichromate of potash, or peroxide of manganese, hence these compounds must be removed from solution before the test is applied. No substances, with these exceptions, besides the ethyl compounds are known to yield aldehyde when thus treated. Various essential oils, chloroform, amyl alcohol, etc., were shaken with water and the solution distilled with these oxidizing agents, but no yellow colour was produced. The distillate from clove water was pink, but when ·1 per cent. of alcohol was added the pink tint was quite overpowered by the yellow colour of the aldehyde resin produced. Ether of course yields aldehyde when oxidized, hence this test will not serve to detect alcohol in ether. To detect alcohol in essential oils and chloroform, agitate the sample with an equal quantity of water, and when the aqueous solution has become clear, remove with a pipette and distil with the bichromate and acid. ·5 per cent. is thus easily detected. The subjoined table gives the results of several quantitative experiments. Four c.c. of the substance examined were shaken vigorously with 8 c.c. of the dilute acid, and 92 c.c. of water, and when clear 50 c.c. of the acid liquid placed in a flask and distilled with a sufficient quantity of bichromate. Ten c.c. of distillate are collected in a tube containing 2 c.c. of soda solution and boiled, diluted, and nesslerized.

Name, etc.	Quantity of Bichromate Solution added.	Result.
Oil of Lemons	2 c.c.	none
„ „ with 5 p.c. alcohol	2 „	3·6 p. c.
„ Rosemary with 5 p. c. alcohol	2 „	3·9 „
„ Bergamotte	2 „	none.
„ „ with 10 p. c. alcohol	2 „	9·7 „
„ Lavender, English . . .	3½ „	none.
„ „ Foreign . . .	3½ „	3·6 „
„ „ „ with 2½ p. c. alcohol	3½ „	6·3 „
„ Lavender, Foreign, washed	3½ „	none.
A Pure Chloroform	2 „	a trace.
„ „ with 5 p. c. alcohol	2 „	4·2 p. c.
with 1 p. c. alcohol . . .	2 „	·92 p. c.

The oil of lavender (exot.) was undoubtedly adulterated, since after being washed with water, and examined, no reaction was obtained. Deducting 3·6 from 6·3, we have 2·7 as the percentage of alcohol added.

Alcohol is said not to suffer decomposition in presence of pure water. To confirm this a sample of well boiled water had ·1 per cent. of alcohol added, and determinations made daily. After ten days the quantity of alcohol was found undiminished. An impure tank water to which ·1 per cent. of alcohol had been added did not contain a trace twenty-four hours afterwards. The presence of decaying organic matter of all kinds has this effect, and no doubt this reaction is in some degree a measure of the quality of a water.

Rajewsky (Pflüger's 'Archiv.,' xi., 122, abs. Y. B. P., 1876, 125) when investigating the action of alcohol upon the system, its passage into the brain and muscle, and the length of time which it remains there, came to the conclusion that the iodoform test is either not applicable to the detection of alcohol in the tissues or that alcohol is a normal constituent of brain and muscle. I have applied the aldehyde test to a number of infusions of fresh muscle, or rather to the distillate from this infusion, but have failed to detect the slightest trace of alcohol.

The chromic acid reaction is still often quoted as a test for alcohol in the urine, but as shown by Chaumont (abs. Y. B. P., 1855, 147) the test is not to be relied upon even when applied to the distillate. A number of experiments were tried with various samples of urine, with and without the addition of alcohol. By adding a sufficient quantity of bichromate to oxidize all the oxidizable matter present in the urine good quantitative results were obtained. By distilling the urine and estimating the alcohol in the distillate, the results were all much too low, but when about a gram of ferrous sulphate was added to the urine previous to distillation, the results were much more approximate. Should the urine contain albumen it must be distilled and the distillate examined, but otherwise equally good results are obtained without distillation. After partaking of an alcoholic fluid, distinct traces of alcohol are found in the urine two hours afterwards. The quantity (after taking 12 c.c. of absolute alcohol) in the urine two hours after was about ·02 per cent., and about the same proportion was found ten hours afterwards, and traces were present for upwards of twenty-four hours. Forty hours after no alcohol could be detected. From the quantity of urine excreted, the results of two determinations went to show that not more than ·7 per cent of the alcohol taken passes in the urine unchanged.

By concentrating fluids supposed to contain alcohol by one or more distillations exceedingly minute traces can be detected by this process, especially if only one-tenth instead of one-fifth be distilled.

[*The discussion on this paper is printed at p.* 419.]

AN ADULTERATION OF SENEGA.*

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

One of the most decided cases of adulteration of drugs that it has ever been my lot to investigate has recently come under my notice.

A sample of senega root, forwarded to me by a London firm for examination, was found to contain a considerable quantity of vincetoxicum root (*Asclepias Vincetoxicum*, L.).

That the admixture was evidently not an accidental one, as is the case with ginseng root, and that it must have taken place in some European country other than England is evident from the following considerations:—

1. *Asclepias Vincetoxicum* is not a native of the United States, and is not quoted in American drug lists.
2. It is not used in medicine in this country, and cannot, so far as I have been able to ascertain, be obtained in herbalists' shops in this country.
3. The quantity in which the root is mixed with senega, about 33 per cent. of the bulk, is too large to be accidental.

On making further inquiries, I obtained the following particulars from Mr. Squire, of the firm of Hearon, Squire and Francis, who had also detected the adulteration some time since.

"The adulterated senega first came over to this country some five or six months ago, and then only a small quantity appeared, which was apparently sent over to this country to see if its sale could be effected. My suspicions were aroused by seeing that it came from Brussels, where senega is certainly not grown, and I noticed it was mixed with a root unknown to me. The first parcel finding a sale, a large quantity, I believe about a ton, has since followed, and has recently been offered in the London market."

Following up the clue thus offered, I have found that the vincetoxicum root, under the French name of "dompte venin," figures in a Brussels price list of "Herboristerie," at 2·20 to 2·40 francs per kilogramme, while senega varies from 10·50 to 11·0 francs per kilogramme, a difference in price which was evidently sufficient to repay the trouble of adulteration, especially when made to the extent of 33 per cent.

As the effects of vincetoxicum differ from those of senega, it has appeared to me to be desirable to point out to pharmacists the characters by which the two roots may be distinguished. This is more especially necessary, since senega is not the only root with which the vincetoxicum has been mixed.

In the *Journal de Pharmacie* last year, p. 346, a note by M. Charbonnier, pharmacien at Caen, was published, in which he stated that he found valerian root to be adulterated with vincetoxicum root (here called asclepiade) to the extent of 30 per cent.

The root so closely resembles valerian in appearance that only a practised eye could distinguish them when mixed.

A few months since, Professor Redwood showed me a sample of root, of which he informed me two tons had been purchased, in July, 1877, by a broker, as white hellebore root. This root consisted entirely of *Asclepias Vincetoxicum*.

It is evident therefore that the root is in this country in considerable quantity, and a look out should be kept for its appearance among other roots than those mentioned. That the root mixed with senega is that of *Asclepias Vincetoxicum* there can be no reasonable doubt, for through the kindness of Mr. Thomas Greenish, to whom I supplied a portion of the root found with senega and a specimen of the root of *A. Vincetoxicum* obtained from the Royal Botanical Garden, I have been able to compare microscopical sections of the two, and find that they are absolutely identical in structure.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Nov. 6, 1878.

The following description will serve to identify the root:—

Asclepias Vincetoxicum, L.—The so-called root is in reality a rhizome, having a well-marked pith, remarkable for its pale colour and smooth unbranched rootlets. The main portion is smooth, cylindrical, and pale, and from about one-fourth or one-third of an inch in thickness; at intervals of a half or one inch tufts of rootlets arise. The rootlets are smooth, scarcely furrowed, and by their number often nearly conceal the stouter portion of the rhizome. The taste presents nothing remarkable and the odour is faint and earthy.

When broken across, the rhizome is seen to have a yellow centre and white cortical portion. On examination with a pocket lens the yellow portion is seen to consist of wood, and to have in its centre a well-defined pith. The rootlets are similar in structure, but have no pith.

From the above description it will be seen that it has no resemblance to senega, except in colour, but senega being sometimes composed largely of small roots, the asclepias might easily be overlooked when mixed with it.

From valerian, which it much more resembles, it may be known by the smoothness of the rootlets (those of valerian being furrowed), and by the more slender cylindrical stem between two tufts of rootlets, the rootstock of valerian being so closely covered with rootlets that its larger size is only visible at the upper end, where it may be seen to be one-half or three-quarters of an inch in thickness, and of a dark colour internally. For convenience of reference these distinctions may be tabulated thus:

Polygala Senega.	Vincetoxicum.	Valerian.
Root one-third inch tapering	Rhizome one-third inch thick, cylindrical.	Root one-half to one-quarter inch, concealed by rootlets.
In section, centre pale, no pith.	In section, centre yellow, evident pith.	In section, darker, rootlets brown with darker centre.
Root spirally twisted, sparingly branched below with keel on concave side.	Rootlets numerous, in tufts an inch apart, pale, smooth.	Rootlets greyish, furrowed, covering the root.
Taste acrid, causing salivation.	Taste and odour slight.	Tastebitterish, odour strong.

If this root has been used in making a decoction its presence may easily be detected by tincture of iodine, for the cortical portion of vincetoxicum contains an abundance of small starch granules, while senega contains none. This may be easily ascertained by applying a drop of solution of iodine to the rootlets, when the cortical portion of vincetoxicum becomes of a blackish colour, the central portion remaining unaffected, while senega does not darken at all.

A curious property of the decoction of vincetoxicum is mentioned by Feneulle.* He found that the decoction was opalescent when heated, but became transparent on cooling. This might also serve to reveal the presence of this drug.

Asclepias Vincetoxicum and Polygala Senega.

The plant received its name of *dompte-venin* from its supposed properties as an antidote to poisons, a reputation probably founded on its powers as an emetic. It was formerly also used in dropsy, cutaneous diseases, and scrofula, but is now little used, at least by the medical profession, but enters into the composition of the Vin diurétique amer de la Charité. According to Wood and Bache's 'Medical Dispensatory,' it is capable in large quantity of producing dangerous, if not fatal, inflammation of the stomach. Whether this be the case equally in the dried state is doubtful, but its presence in senega must, to say the least, depreciate the effect of that drug by dilution.

[*The discussion on this paper is printed at p.* 419].

NOTE ON AN ADULTERATION OF SANTONIN.

BY WILLIAM STEVENSON.

Having received a sample of santonin at a remarkably low quotation we carefully analysed it with the following results:—

An aqueous solution had a strong acid reaction. A large residue being left on ignition proved, on examination, to consist of boracic acid.

The percentage was as follows:—

	Per cent.		Per cent.
Santonin	38·7.		
Crystallized Boracic Acid	61·3	Anhydrous Boracic Acid . .	34·84.
		Water	26·46

The sample had the appearance of pure santonin, the boracic acid having been apparently obtained in small crystals for this purpose. It bore the name of a foreign manufacturer.

Laboratory, 16, *Coleman St., E.C.*

* *Journal de Pharmacie*, 1825, p. 305.

CIMICIFUGA RACEMOSA, ELL.*

BY FRANK H. TRIMBLE, PH.G.

The concentrated tincture of black snake root was precipitated by water and the resin collected and put aside. The aqueous filtrate was precipitated by basic acetate of lead, the precipitate suspended in alcohol, decomposed by sulphuretted hydrogen, and the alcoholic filtrate evaporated. The residue was amorphous, could not be obtained in crystals, and gave with ferric chloride a dark green colour, similar to that produced by quercitrin, but appears not to be a glucoside, since after boiling with muriatic acid Trommer's test failed to indicate the presence of sugar. The aqueous filtrate from the resin yielded with gelatin a white precipitate, which, however, after having been washed with water, was not coloured black or dark green by ferric chloride, proving the absence of tannin.

The resin of cimicifuga was freed from fatty matter by petroleum benzin and afterwards exhausted with chloroform, which dissolved an uncrystallizable resin, soluble in alcohol and ether, but insoluble in oil of turpentine and bisulphide of carbon. Its alcoholic solution, which has an acid reaction, was precipitated by subacetate of lead, the filtrate freed from lead by sulphuretted hydrogen, and evaporated spontaneously. It was expected to yield the crystalline principle described by T. E. Conard (*Am. Journ. Phar.*, 1871, p. 152); but crystals could not be obtained, though the yellow resinous mass had the behaviour described by him.

The lead precipitate with the chloroformic resin was decomposed by sulphuretted hydrogen; the filtrate had a decided acid reaction, was freed from some matter yielding with ammonia a brown precipitate by precipitating with water and redissolving in alcohol. After concentrating and evaporating spontaneously over sulphuric acid, greenish prisms were obtained, which were deliquescent on exposure, had an acid taste, were soluble in ether, alcohol and water, yielded with ferric chloride a white precipitate, and when heated on platinum foil fused, burned, and finally left some red-brown residue.

The fatty matter left on evaporating the benzin solution yielded to alcohol a yellow acid matter, which was partially soluble in water, soluble in ether and chloroform, gave with ferric chloride a yellow solution, had an agreeable odour, resembling that of pineapple, and was completely dissipated by heat. The fat was a soft solid at 60° F., but liquid at 100° F., was entirely free from inorganic matter, and on saponification yielded glycerin.

On treating the resin left by benzin and chloroform with alcohol, subacetate of lead, alumina, etc., as described by Mr. Conard, a little resinous mass was obtained having a behaviour very similar to that of his crystalline principle.

No indications of a volatile oil or of an alkaloid were obtained. The principle which is coloured green by ferric chloride entered to some extent into the various solutions made with simple solvents, but was wholly precipitated by basic acetate of lead.

BALATA, A SUBSTITUTE FOR GUTTA-PERCHA.†

Balata, which has only been known for a short time, is inferior in the extent of its uses to caoutchouc, but surpasses gutta-percha, and is said to have already become an important article of commerce. It is the milky sap of the bully tree, that flourishes on the banks of the Orinoco and the Amazon in South America. The operation of collecting the gum is similar in every respect to that employed with caoutchouc and gutta-percha, and need not therefore be described.

It resembles gutta-percha so closely in its general properties that much of it is shipped from Guiana and sold yearly for gutta-percha—although it has many points of superiority. It is tasteless, gives an agreeable odour on being warmed, may be cut like gutta-percha, is tough and leathery, is remarkably flexible, and far more elastic than gutta-percha. It becomes soft, and may be joined piece to piece, like gutta-percha, at about 120° F., but requires 270° F. before melting (higher than gutta-percha).

It is completely soluble in benzole and carbon disulphide in the cold. Turpentine dissolves it with the application of heat, while it is only partially soluble in anhydrous alcohol and ether.

It becomes strongly electrified by friction, and is a better insulator of heat and electricity than gutta-percha, on which account it may find considerable application for electrical and telegraphic uses.

Caustic alkalies and concentrated hydrochloric acid do not attack it; but concentrated sulphuric and nitric acids attack it as they do gutta-percha, which it closely resembles in all other properties.

---

† *Boston Journal of Commerce.* From *New Remedies*, September, 1878.

PHARMACY ACT, 1868.

RECTIFICATION OF THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS.

We are requested by the Registrar to publish the following List of persons whose names will be erased from the Registers unless they communicate with him on or before 30th December next.

Those marked (*) *are Pharmaceutical Chemists.*

Adams, Edmund Tapley	St. Mary Church, Torquay.
Adams, Rowland	1, Merrivale Street, Balham, Surrey.
Aitken, John Borland	Dalbeattie, Kircudbrightshire,
Aldcroft, John	6, Greengate, Barrow-in-Furness.
Anderson, Thomas Sherman	30, Duke Street, Manchester Square, London, W.
Arnold, William Isaac	75, Brooke Street, Ratcliff, London, E.
Atkins, Edwin	218, Oxford Street, Stepney, London, E.
Ball, William	Warrington, Lancs.
Bastick, Samuel	332, Kennington Road, Surrey.
Beaumont, John Henry Holmes	Wilmslow, Cheshire.
Bell, Henry Wheatley	45, Mulberry Street, Radnor Street, Hulme, Manchester.
Bell, William Dickinson	85, Kirkgate, Leeds.
Bell, William Henry	6, Cleveland Terrace, Bath.
*Bennett, Charles	Bristol.
Benson, George William	George Street, Welshpool, Montgomeryshire.
Biddle, Charles John	36. Oakfield Street, Altrincham, Cheshire.
Bird, Walter Strickland	87, Regent Street, London, W.
Bishop, John	Gosberton, Lincolnshire.
Bishop, Walter	11, Hopefield Terrace, Battersea Rise, Surrey.
Blades, Frederick	Northwich, Cheshire.
Blankley, Charles Steele	Gainsborough, Lincolnshire.
Blankley, William Henry	Silver Street, Gainsborough, Lincolnshire.
Bolt, Richard Tanton	368, Clapham Road, Surrey.
Bond, James Benjamin	1, Wellesley Road, Croydon, Surrey.
Boyd, Robert	12, Kelvingrove Street, Glasgow, N. B.
Bradley, Thomas Dunstall	33, Bond Street, Brighton.
Braidley, John Clive	218, High Street, Dudley, Worcestershire.
Brocklehurst, Thomas	Hull.
*Brookes, Frederick James	300, Holborn, London, W.C.
Brooks, Charles Theodosius	4, Palmerston Road, Upton, Essex.
Brothers, Francis	Tontine Street, Folkestone.
Browne, William	381, Walworth Road, Surrey.
Buck, Alphéus Ferdinando	35, Swanmore Road, Ryde, Isle of Wight.
Bullock, John Alfred	16, Johnston Terrace, Edinburgh, N.B.
Burgess, James	21, High Street, Northwich, Cheshire.

Bush, William	38, Hungerford Road, Camden Road, London, N.W.
Butler, Alfred Bulteel	1, Walton Terrace, Cotham, Bristol.
Campbell, James	Barrhead, Renfrewshire.
Carroll, Denis	13, Mornington Boad, Bow Road, London, E.
Cartwright, James	Staveley, near Chesterfield, Derbyshire.
Challener, Theophilus	Aldridge Road, Perry Barr, near Birmingham.
Charles. Michael	2, Barford Terrace, Liverpool Road, London, N.
Cheffers, Charles Venus	Seaman's Hospital, Greenwich, Kent.
Chick, William	39, St. Paul's Road, London, N.
Child, William	Carlton Cottage, Pontefract,
Clark, George	1, Chalk Street, Stockton-on-Tees, Durham.
Clarke, George Herbert	130, Shoreditch, London, E.
Clarke, Thomas Watson	108, Queen's Road, Bayswater, London, W.
Clode, Charles	16, Green's End, Woolwich, Kent.
Cocks, William Petty	9, Chesnut Street, Mount Pleasant, Liverpool.
Codd, Charles	52, Freeman Street, Great Grimsby, Lincs.
Coke, Richard	Keynsham, Somerset.
Comley, Herbert	71, Whitechapel High Street, London, E.
Cooper, Harriet Elizabeth	23, Haddon Street, Beswick, Manchester.
Coulson, Robert	31, High Street, Gosport, Hants.
Cutts, Thomas	New Basford, Notts.
Dale. Samuel	3, Bermondsey New Road, Surrey.
Daniel, Edward	4, Strand, London, W.C.
Daves, William	Blue Bell Hotel, Falkirk, N.B.
Deans, John Kerr	Galashiels, N.B.
Dixon, Frederick	189, Southgate Road, London, N.
Dodridge, Samuel Henry Stephens	3, Portland Place, Balham Hill, Surrey.
Dodridge, Thomas Mitchell	8, Branksome Terrace, Acre Lane, Brixton, Surrey
Dunbar, William A.	14, Saville Place, Lambeth Walk, Surrey.
Dunstan, William	5, Northgate Street, Bath.
Dunston, John	Retford, Notts.
Durnford, John	1, Marsham Street, Maidstone.
Dutton, John	Blenheim House, Medina Road, West Cowes, Isle of Wight.
Dyer, William George	3, Swan Place, Blackman Street, Southwark, Surrey.
Eason, John	8, Fairfield Crescent, Prospect Vale, Liverpool.
Elder, William Nind	Pulteney Town, near Wick, Caithness-shire.
Emerson, Robert	2, Dorcas Terrace, Hammersmith Road, London, W.
Emsley, Joseph	Scarborough.
Farrar, William	75, Stamford Crescent, Ashton-under-Lyne.
Field, Cornelius	146, Regent's Park Road, London, N.W.
Fleming, James	305, New City Road, Glasgow, N.B.
Flintoff, James Henry	Chippenham, Wilts.
Fremlin, William Henry	Banwell, Somerset.
Fuller, John William	343, Edgware Road, London, W.
Garratt, James	Kingston Cross, Landport, Hants
Garsed, Joseph	Hill House, near Huddersfield, Yorks.
Garstang, James	Grimshaw Park Road, Blackburn Lancs.
Gater, James	251, Ball's Pond Road, London, N.
Gibb, David	7, Lothian Road, Edinburgh, N.B.
Ginner, James Edward	166, Lambeth Walk, Surrey.
Goodman, Godfrey	13, Ogwen Terrace, Bethesda, Carnarvonshire.
Goodridge, William	Shepton Mallet, Somerset.
Goodworth, Thomas Moore	Swinefleet, Goole, Yorks.
Gordon, James	Juniper Green, Edinburgh, N.B.
*Gordon, John	5, Minerva Street, Glasgow, N.B.
Gould, Edward Gardiner	Bowmont Lodge, Queen's Road, Richmond, Surrey.
Gould, James Emery	Bowmont Lodge, Queen's Road, Richmond, Surrey.
Graves, Jesse	64, Park Street, Hull.
Gray, William James Sunderland	104, Islington, Birmingham.
Greenacre, James	22, Seething Lane, London, E.C.
Greening, William	Victoria Street, Bristol.
Greenshields, Henry David	153, Sandringham Road, Dalston, London, E.
Greenshields, William	24, Portland Street, Commercial Road, London, E.
Griffiths, Joseph	1, Abbey Street, Carlisle.
Haire, William Harland	Audlem, Cheshire.
Halket, William	51, High Street, Camden Town, London, N.W.
Hamilton, Mary Urie	Dunoon, Argyleshire.
Hammond, Henry	101, Western Road, Brighton.
Harmer, Mary Sophia	8, Ebenezer Terrace, Millwall, London, E.
Hart, George Francis	7, Lillah Street, Liverpool Street, Cross Lane, Salford, Manchester.
Hateley, John Henry	11, Bridge Street, Wallbrook, near Coseley, Staffs.
Hedley, Robert	31, Coney Street, York.
Henderson, John Brown Stevenson	Hill Street, Brierley Hill, Staffs.
Heppell, Henry Huggins	Albany Lodge, Great Church Lane, Hammersmith, London, W.
Herbert, Joseph	82, Myrtle Street, Liverpool.
Herring, John	Audlem, Cheshire.
Hilton, Frederic Henry	11, Hopefield Terrace, New Wandsworth, Surrey.
Hindson, James Alfred	4A, Clayland's Road, Clapham Road, Surrey.
Hobson, Frederick Eland	2, Western Place, Hove, Brighton.
Holland, Henry	141, Sand Pits, Birmingham.
Holyoake, Francis	11, Green's End, Woolwich, Kent.
*Hornsey, William	1, James Street, Portobello, N.B.
Horsfield, Robert Francis Wm.	96, Walworth Road, Surrey.
Horton, Samuel	20, Gloucester Street, Haulgh, Bolton.
Hosie, John	104, Strand, London, W.C.
Howard, Henry	Weston-super-Mare.
Howell, John	Swansea.
Howorth, Walter Septimus	North Road, Highgate, London, N.
Howse, Frederick	1, Alexander Road, Kilburn, London, N.W.
Howse, Henry William	23, Pentonville Road, Islington, London, N.
*Hudson, John William	76, Linthorpe Road, Middlesborough-on-Tees.
Hulbert, Robert Skeat	West End Villa, Basingstoke.
Humphreys, John, jun.	11, Sussex Street, Nottingham.
Huxley, John Holden	127, New Kent Road, Surrey.
Huxtable, James	80A, St. Paul's Churchyard, London, E.C.
Irving, John	English Street, Carlisle.
Jackson, Daniel Randall	Skipton, Yorks.
Jackson, Leonard	8, Ward Street, Langston Street. Strangeways, Manchester.
Jackson, William	15, Alfred Place, Leeds.
*James, Alfred	Carmarthen.
James, David Owen	19, Queen Street, Carmarthen.
Jamson, William Samuel	70, Newland, Lincoln.
Jennings, Henry William	174, High Street, Lincoln.
Jones, David	Llanelly, Carmarthenshire.
Jones, Edwin	Hollinwood, Lancashire.
Jones, John	The Barracks, Wrexham.
Jones, John	Hollywell Flints.
Jones, Robert	Buttermarket Street, Warrington.
Jones, William Henry	22, Parkfield, Birkenhead, Cheshire.
Keast, Samuel John	Market Square, Camborne. Cornwall.
Kent, William	123, Upper Thomas Street, Acton, Birmingham.
Kiddle, Richard Neller	61, Wiltshire Road, Brixton, Surrey.
*Kiddle, William Lambert	4, Portland Place North, Lower Clapton, London. E.
Kinsey, Esther Amelia	Ellesmere, Salop.
Kitchen, George Seaton	3, Carlton Street, Nottingham.
Knowles, Wm. Henry Haley	Upper Bridge, Holmfirth, Yorks.
*Laing, Richard Willlam	38, Bloomsbury Street, London W.C.
Laugher, John	Beoley Road, Redditch, Worcestershire.
Lawrance, John Wilcox	7, Burney Terrace, Greenwich, Kent.
Laxton, Thomas	199, Southwark Bridge Road, Surrey.
Legg, Matthew Henry	343, Edgware Road. London, W.
Le Page, William	Shincliffe, near Durham.

Levie, Alexander Mair	73, Wales Street, Aberdeen, N.B.
Lewis, Edward William	4, Sherwood Crescent, Upper Westbourne Park, London, W.
Lilwall, Thomas Edward	15, Stratheden Villas, New Road, Shepherd'Bsush, London, W.
Linay, Thomas William	3, Lodge Road, Birmingham.
Linder, Charles	104, Strand, London, W.C.
Lloyd, James	22, Boundary Road, St. John's Wood, London, N.W.
Longmore, Henry Edward	4, Edward's Terrace, Kensington, London, W.
McGruer, John	Buckie, N.B.
Machon, Robert	Chapel Street, Ripley, Derbyshire.
Mackaness, Charles	42, Fentimam Road, Clapham Road, Surrey.
*Mackmurdo, Walter George	Lower Edmonton, Middlesex.
Maclagan, James	34, West Blackhall Street, Greenock, N.B.
McNay, Thomas	3, Hindpool Road, Barrow-in-Furness.
Macpherson, Richard	10, Hope Street, Greenock, N.B.
Margetts, George William	2, Market Terrace, Upper Holloway, London, N.
Marlow, John James	1, Emmetts Cottages, Hornsey Road, London, N.
Mason, James Thomas	10, Norwich Street, Cambridge.
Mathieson, Alexander	7, Balls Pond Road, London, N.
Maude, William Robert	75, Belle Vue Street, York.
Mayhew, Austin	111, Cirencester Street, Harrow Road, London, W.
Mayor, Robert	12, Poplar Street, Marsh Lane, Preston, Lancs.
Medland, James	Camberwell, Surrey.
Meller, Edward	2, Springfield Street, Liverpool.
Mercer, Francis Montier	1, Camden Villas, Holmesdale Road, Selhurst, South Norwood, Surrey.
Michael, Thomas	Creetown, Kircudbrightshire.
Middleton, John	6, Bird Street, West Square, Lambeth, Surrey.
Millar, Charles	14, Arthur Street, Edinburgh. N.B.
Miller, Mary	Rochester.
Milne, John Peter	Buckie, Banffshire.
Milton, Timothy Booth	66, Walshaw Street, Oldham, Lancs.
Mitchell, Thomas	179, Marsh Lane, Leeds.
Morgan, Alfred	41, Queen's Road, Dalston, London, E.
Morgan, Henry Alfred	53, Parkstone Road, Peckham, Surrey.
Morris, Samuel Henry	87, Islington, Birmingham.
Morris, William, jun	15, Gas Street, Coventry.
Muir, John Fleming	Argyle Street, Dunoon, N.B.
Nance, William	4, Dante Road, Newington, Surrey.
Nickson, Thomas	Burton-upon-Stather, Lincolnshire.
Nightingale, Henry Lewis	Albion Street, Southwick, Sussex.
North, Mary Anne	Earlswood, near Birmingham.
Norton, Chas. Benjamin Spragge	High Street, Moreton-in-Marsh, Gloucestershire.
Ogden, Hiram	11, Edge Lane, Stretford, Manchester.
Papps, Francis	630, Mile End Road, London, E.
Parker, Matthew	3, Ord Street, Gateshead-on-Tyne.
Parry, Thomas Jones	Union Row, Criccieth, Carnarvonshire.
Paterson, Alexander	4, Shamrock Street, Hutcheson Town, Glasgow, N.B.
Peacock, William Spencer	1, High Street, Lower Norwood, Surrey.
Perrin, James, jun.	Stockport Road, Gee Cross, Manchester.
Philp, Nicholas Cornelius	5, Market Street, Devonport.
Pittis, Alexander Clarke	172, Friar Street, Reading.
Price, David	Handsworth Woodhouse, Sheffield.
Pringle, George	Marsh Street, Walthamstow, Essex.
Radford, William Rangeley	Baker Street, Enfield, Middlesex.
Ragsdell, Walter	3, Luxor Street, Cold Harbour Laue, Brixton, Surrey.
Ramsden, Thomas	29, North Audley Street, London, W.
Rawlings, Francis Charles	48, Fulham Road. London, S.W.
Reichardt, Emil	336, Oxford Street, London, W.
Reynolds, Walter John	99, Davenport Street, Bolton, Lancs.
Richards, James	47, Lower Calthorpe Street, London, W.C.
Richards, William Bevan	4, Princes Street, London, E.C.
Roberts, Anthony Tucker	11, Lamb's Conduit Street, London, W.C.
Robinson, Christopher William	127, Gosford Street, Coventry.
Robinson, John	7, Symons Street, Swann's Estate, Hull.
Robinson, John Edward	Nuttoft, Lincolnshire.
Rome, George William	43, Caledonian Road, London, N.
Saunders, John	60, Leather Lane, London, E.C.
Savidge, John Mason	1, Beck Street, Nottingham.
Scholes, Frederick Darfield	Upper Hebble Terrace, Bradford Road, Huddersfield.
Sealy, William	Kingston Cross, Portsea, Hants.
Shearer, John	Wick, N.B.
Simpson, Frank Hardinge	69, Pentonville Hill, London, N.
Simpson, Robert Scouller	96, Taylor Street, Glasgow, N.B.
Smith, Samuel Hallen	8, Branksome Terrace, Acre Lane, Brixton, Surrey.
Soppett, Robert	74, White Abbey Road, Bradford, Yorks.
Southworth, Robert B.	14, Bath Street, London, E.C.
Sowter, George	6, Royal Parade, Blackheath, Kent.
Sparrow, Wm. Cunningham Fairlie	5, Pimlico Road, London, S.W.
Springall, John Barcham	8, Junction Street, Carlisle.
Stables, Walter B.	11, Chester Street, Kennington Lane, Surrey.
Stainburn, Joseph	Highgate, Hawkhurst.
Steel, George Payne	123, Buchanan Street, Glasgow, N.B.
Steward, Theophilus	Trimpley, near Bewdley.
Stokes, John	Riccall, Yorks.
Stovell, Edwin	Guildford Street, Chertsey, Surrey.
Sturdy, Thomas Metcalfe	372, Oxford Street, London, W.
Sutton, John	216, Hoxton Street, London, N.
Sutton, Theophilus Edward	66, Great Howard Street, Liverpool.
Swaine, Charles Henry	Somers Road, Southsea, Hants.
*Swann, William Henry	Farnsfield, Southwell, Notts.
Swift, Joseph	Milnrow, near Rochdale, Lancs.
Swift, William	Chesterfield Road, Staveley, Derbyshire.
Taylor, Thomas	Bloxwich, Staffordshire.
Thompson, Henry	43, Halton Road, Canonbury, London, N.
Thompson, Robert	91, Tontine Street, St. Helens, Lancs.
Thomson, Matthew	66, Cadzow Street, Hamilton, N.B.
Thorn, James William	Kilham, near Driffield, Yorks.
Tipper, John Swindon	Black Horse Hotel, Cheadle, Staffs.
Tryon, Samuel	North Finchley, Middlesex.
Twemlow, Thomas	105, Devonport Street, Little Bolton, Lancs.
Valentine, William Middleton	65, Haddon Street, Woodside, Aberdeen.
Wade, John	Fishguard, Pembrokeshire.
Wakefield, Henry Edward	37, Fishergate, Nottingham.
Walton, John	Church Lane, Tipton, Staffs.
Ward, Joseph	Leek, Staffordshire.
Wardle, James	Bootle, Liverpool.
Warland, Francis William	Forest Hill, Kent.
Waterson, Cornelius	86, Macdonald Street, Birmingham.
Waterworth, William	Sheffield.
Weaver, Alfred	Eastwood, Notts.
Welch, Geo. Edwin Andrew	Ripley, near Derby.
Westlake, William Charles	70, East Street, Walworth, Surrey.
Wetherhead, Emil	Fairford, Gloucestershire.
Whinfield, Chas. Edgar	14, Cantlowes Road, Camden Town, London, N.W.
Whitby, John Hunter	47, Mortimer Road, Kingsland, London, N.
Wilday, George Evans	Bicester, Oxon.
Wilkinson, Mence	Pilsea Island, Emsworth, Hants.
Wilkinson, Robert	38, Northumberland Street, Newcastle-on-Tyne.
Williams, John Alderslea	Hale Road, Ditton, near Warrington.
*Williams, Thomas	Carlton, Selby, Yorks.
*Wingate, Stephen	25, Southgate Street, Gloucester.
Wood, John	9, Market Street, Faversham, Kent.
Woodall, John	8, Conference Place, Great Thornton Street, Hull.
Woolley, Hardy	Moulton, near Spalding, Lincolnshire.
Woolley, William Edward	Gatis Street, Whitmore Reins, Wolverhampton.
Wrigglesworth, George	55, Myton Gate, Hull.
Wright, Thomas Newton	Lymm Cheshire.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 16, 1878.

THE OPINIONS OF THE PRESS ON "COUNTER PRACTICE."

VARIOUS articles that have appeared during the last few days in the newspapers have furnished abundant evidence that the question raised in the Court of Exchequer last week is not merely a question between medical practitioners and chemists and druggists, but one in the decision of which it will be requisite to have regard to another and a more important factor than the privilege of the one or the right of the other. It is, we believe, not so much by the consideration of these points as by the inquiry how the convenience and general interest of the public are affected, that the maintenance of the medical man's privilege or the recognition of the chemist and druggist's right will be brought about more or less completely.

Since the public is so largely interested in this question, we have always anticipated that its ultimate decision must be arrived at in this way rather than by the aid of subtle legal definitions or by the argumentative ingenuity of the advocates for either of the actually contending parties. That this is felt to be the case even by the advocates on both sides is evident from the pains bestowed by them in both instances to show that the result they are contending for is the one most conducive to the public interest. On the one hand it is urged that the person seeking the benefit to be derived from medicine is to be protected against the risk of injury by the injudicious or improper administration of drugs; on the other hand it is urged that a person so situated is not to be debarred from obtaining aid in a manner involving but little trouble or expense. Neither of these propositions, in the abstract, admits of being objected to; but though they are opposed to each other the admission of the one by no means involves the rejection of the other, and the practical difficulty is to devise a course by which the observance of both may be sufficiently ensured.

In this sense the question between the Apothecaries' Society and chemists and druggists is now being tried at the bar of public opinion, and the general tendency of the articles that have been written on the subject in the *Standard*, *Morning Advertiser*, and *Daily Telegraph* shows that the issue raised is not so much the strict legal rights of the several parties as the extent to which the recognition of those rights is to be made subordinate to the general convenience and welfare of the public. Let us see what are the conclusions thus arrived at by consideration of the evidence and arguments brought forward in the case of the SOCIETY OF APOTHECARIES *v.* SHEPPERLEY, and in the first place we will confine ourselves to what bears upon the interpretation of the 20th section of the Apothecaries Act.

The *Standard*, having regard to the existing position of things, and to the provisions of the 20th section of the Act says there can be little question that the spirit as well as the letter of the Act is violated every day, and in London more perhaps than in other places. It is pointed out that while medical advice obtained in the regular way is expensive, and if accepted gratuitously carries with it a consciousness of something like degradation, it is difficult to avoid the belief that the chemist and druggist, always accessible in his shop, understands the properties of the drugs with the handling of which he is so familiar, the writer admitting the fact that many people, especially among the poorer classes, readily resort to the chemist and druggist for medicine, and perhaps a little advice, considers it absurd to suppose that he is not competent to deal with trifling ailments, and it expresses the opinion that the Society of Apothecaries will act prudently in not seeking to press the privileges of its licentiates too far, since the public is not disposed to look with favour upon prosecutions the chief object of which appears to be the putting of fees in the pockets of the doctors or into the coffers of privileged bodies. The opinion here expressed is almost a reiteration of the remark with which Baron BRAMWELL qualified his interpretation of the scope and effect of the Apothecaries Act in regard to counter practice by chemists and druggists.

At the same time the writer of the article recognizes the stringency of the Act under which the prosecution was instituted, and he recommends that the weakness of the evidence adduced for the plaintiff should be carefully considered by those who stand in the same position as Mr. SHEPPERLEY. He adds that chemists and druggists would be rash in the extreme if they concluded from the verdict given in this case that they might prescribe either for sore throats or any other complaint with impunity; or that a jury would refuse to recognize an infringement of the Act, if satisfactory evidence to that effect were adduced,

The soundness of this opinion is shown by the result of the previous case of prosecution under this Act, and although the verdict given on that occasion may perhaps have had a somewhat sentimental foundation it is desirable not to lose sight of the fact that since a jury is liable to be materially influenced by accessory circumstances really of little importance as regards the merits of the question to be decided, there is always a risk of such provisions as those of the 28th section of the Apothecaries Act, being literally construed on such grounds. Thus while in the SHEPPERLEY case the weakness of the evidence may have had much to do with the finding of the jury in favour of the defendant, the death of some of the children referred to in the other case may have operated in the contrary direction.

The article in the *Morning Advertiser* suggests that the public will be disposed to agree with the verdict, and it expresses the opinion that as chemists

and druggists have now to pass an examination of some stringency they are probably in the main qualified to give the over-counter advice for which they are usually asked. It credits them also with frequently showing the possession of the rare faculty of knowing the limit of one's own powers by advising their patient to consult a doctor. It is further contended that it would be absurd to adopt a strict interpretation of "acting as an apothecary," and to suppose that a man is bound to consult a doctor for a cut finger or a cold in the head, since that would be a tax even upon the rich and plain cruelty for the poor, who look upon the nearest chemist and druggist as possessing all the knowledge requisite to provide for their wants. Looking at the subject in this light we are not surprised to find the writer of this article declaring that the world's business is not to be conducted on such refinements as would limit a chemist and druggist to the mere making up of prescriptions, and that the Apothecaries' Society has no alternative but to give up the attempt to enforce its supposed rights or to submit to fresh legislation.

In the same spirit the *Daily Telegraph*, in dealing with this aspect of the case, points out that if such a strict interpretation of the law be adopted perhaps every chemist and druggist in the kingdom might be held to violate it, for while hardly an hour of the day passes without a customer entering to complain of some common ailment or accident and asking for some known and approved remedy, the appeals of the poor for relief to their children suffering from a customary infantile illness are still more frequent, and to put all this down with the strong arm of the law would inflict on the masses of the people considerable hardship. It then goes on to add that the head of even a middle class family often hesitates to call in a medical man, because his—

"Bill at Christmas may be swollen by *visits sometimes repeated beyond the necessity of the case;* and how much more do the needy shrink from incurring such expense! They know as a matter of fact that both as regards themselves and their children there are ailments that simply require a little medicine promptly given; and, instead of summoning the doctor, or calling at his house on the chance of seeing him, they enter the next chemist's shop and for a few pence obtain at once the means of cure. Recourse to a doctor in such cases, means not only loss of money but loss of time—in a double sense. The professional man may not be at home or cannot come immediately when called; while the chemist is always behind his counter. In addition, a working man cannot give up half a day waiting at his own house or in the doctor's ante-room, while he can easily call at a shop on his way to or from work. A still more important consideration is involved. If we prohibit the chemist from seeing customers and selecting medicine for them, we shut off from the poor cheap and ready medical assistance, and thus force upon them one of two alternatives—expensive treatment or neglect. The latter will probably be preferred, and thus many a slight indisposition will grow uncared for into a grave illness, causing heavy loss and requiring in the long run first-rate medical advice. We often see this result amongst the poorer middle class. No people so severely suffer from want of medical aid as those whom we may call the "genteel poor." They do not belong, like artizans, to sick clubs; they shrink from contact with the crowds who besiege the doors of the great hospitals; they are ashamed to visit a physician at the hours he devotes to gratuitous advice. If they have "seen better days" they remember bitterly when they need not have had recourse to these devices of the necessitous. They cannot command the guinea fee for the regular physician, and they anticipate with dread the bill of the general practitioner, who, if once called in to a chronic case, may come day after day, adding each time to their obligations. Consequently there is amongst these classes almost as great a need for the cheap and ready help of the chemist as amongst artizans. Nor is it any wonder that they prefer his aid and advice. He is their neighbour, and he probably knows, or soon learns, all about them. He can—remembering the rheumatism last year, or the child's cough in winter—drop a word of warning that strikes home. Besides, he is easily visited and easily seen. There is another advantage in the chemist's shop. A working man, with his limited income, may not be able to afford a regular fee for advice, and yet may be ashamed to class himself with the gratuitous patients of the hospital, or the out-door paupers who call in the parish doctor. The chemist supplies a middle way, for, though he does not charge much, his patients are not humiliated or pauperized by consulting him, as they pay full price for what they have. Are we, by prohibiting his useful services, to divide all sick people into two clases— those who, at the hospitals or "on the parish," pay nothing, and those who must call in and fee a medical man? Such a course seems to us injudicious, since it would impose on the needy heavy burdens, tempt them to neglect the first symptoms of illness, or force them down into the ranks of those who rely on charity for medical advice."

The opinion conveyed in this extract, even more pointedly than in the other articles referred to above, may be regarded as a popular verdict against the claim to enforce a strict interpretation of the 20th section of the Apothecaries Act, and we think that in this, chemists and druggists have greater reason for satisfaction than they can have in the decision of the SHEPPFRLEY case, which is at best but an imperfect decision accompanied by many reasons for doubt, and as will be seen from our law report this week not yet conclusively established even as regards this particular case.

RECTIFICATION OF THE REGISTER.

WE wish to direct attention to the List of Names of persons liable to be struck off the Register of Chemists and Druggists, which is published in another part of this Journal. To all of these persons the Registrar has, in compliance with the terms of the Pharmacy Act, sent two registered letters addressed according to the Register, without obtaining any response, and he now gives notice that unless they communicate with him on or before the 30th of December next, he will, in virtue of the power conferred upon him, erase their names from the Register.

IN explanation of the late delivery of many copies of the last number of the Journal, which has been the subject of numerous complaints addressed to the Secretary, we have to state that the publication was intentionally postponed for a few hours to allow the report of the case of the APOTHECARIES' SOCIETY *v.* SHEPPERLEY to be included in it, and that after that had been provided for in time for Saturday's post this delay was unexpectedly increased by the operation of the Factory Act, which prevented the copies being folded on Saturday afternoon.

Transactions of the Pharmaceutical Society.

PHARMACEUTICAL MEETING.

Wednesday, November 6, 1878.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

An Evening Meeting of the Pharmaceutical Society was held on Wednesday evening last, when the chair was taken at half-past eight. The minutes of the previous meeting were read and confirmed. The first paper read was on—

Some Bismuth Residues,

BY DR. LETTS, F.R.S.E.

The paper is printed at p. 405, and gave rise to the following discussion :—

The President said this was a most interesting communication. It seemed that the author had not found in the bismuth the ordinary impurities which were generally expected to occur in commercial bismuth, although he stated that the bismuth was a very impure sample from Australia. The ordinary bismuth of commerce generally contained arsenic, copper, and sometimes tin, and yet none of these elements were alluded to. The bismuth referred to seemed to have been an exceptional sample, and if it contained selenium, tellurium, and also gold, it must certainly be regarded as a very curious specimen of a native metal. He should like to ask whether the bismuth had been treated by the ordinary processes for its purification, namely, fusion with nitrate of potash, and also fusion with sulphocyanide of potassium in order to remove the copper which was the process generally adopted, or whether it was simply treated as a crude material ; also whether the silver was thrown down as a chloride, or how the residue occurred. They knew that when ordinary bismuth containing arsenic or tin was treated with nitric acid, the residue consisted of arseniate of bismuth, or peroxide of tin, but if the bismuth in this case were simply treated with nitric acid, the residue appears not to have contained what they should have expected it to contain, namely, the tin or the arseniate of bismuth, but the other rarer elements.

Mr. Schacht said the bismuth in question was part of a parcel received in the ordinary course of business, and had no doubt been purified in the usual way. He had no doubt that precaution had been taken to separate the arsenic by the process generally adopted. Copper was a more frequent impurity, but on treating the solution in nitric acid with ammonia, there were no indications of the presence of copper. What had struck him as very unusual and led him to hand the matter over to a professional chemist, was the fact that instead of dissolving almost entirely in moderately dilute nitric acid (two parts nitric acid and three parts water), it left a very considerable amount of undissolved matter, and it was that residue which was handed over to Dr. Letts for further elucidation. Of course, a man of business could not follow up such an investigation in the sagacious and elaborate manner that a professor of chemistry could, and hence he had availed himself of the opportunity of giving the residue to a man of Dr. Letts's ability. It might be safely taken that this residue did not contain either arsenic or copper. All gentlemen who had made preparations of bismuth knew that there was often the very great inconvenience, he might say the horrible inconvenience, to some patient who had taken it, or some medical man who had prescribed it, namely, that the patient would be tormented by a strong smell like that of garlic. This was generally attributed to the presence of tellurium, and Bunsen stated that this was the explanation. He (Mr. Schacht) would freely confess that he was ignorant of any proper process for the elimination of tellurium from a sample of bismuth, although he had met with complaints of this kind more than once, and it had been to him a matter of grievous import. He had therefore thought this was a fair opportunity of putting the matter in the hands of an able man who, notwithstanding his great ability, at first altogether failed to detect its presence. He first stated that he thought he had detected selenium, but that there was no tellurium present ; afterwards when he discovered its presence he stated that he had been misled by the inaccuracy and imperfection of the usual method of testing by fusing it with cyanide of potassium and separating it by passing atmospheric air through its aqueous solution. It appeared that unless a very exact temperature were hit upon the test and process failed altogether. He was glad that Dr. Letts had made this point so clear, so that future experimenters would know what to direct their attention to. There was no doubt whatever that this impurity did frequently occur in commercial bismuth and he would just give one practical hint to those who were interested in the subject. Let them take a sample, and after dissolving it in aqua regia, treat it with sulphurous acid, either by passing the gas through the solution or by using sulphite of soda in sufficient quantity to make the solution smell strongly of sulphurous acid, and that would reduce the selenium if it were present ; of course it would also reduce gold if that were there, but if it were first dissolved in nitric acid, then the acid evaporated and the residue redissolved in hydrochloric acid it would be certain not to have gold present. If after being dissolved in nitric acid and treated with sulphurous acid neither a black nor a red precipitate was formed it might be safely concluded that both selenium and tellurium were absent. On the other hand, if there were a black precipitate the best plan was to reject the sample.

Professor Attfield said the last speaker had re-opened a question of considerable interest which had troubled pharmacy some years ago, and which he was inclined to think might receive its solution if this question were followed out. He referred to the cause of that fœtor of breath which undoubtedly followed the administration of some samples of bismuth preparations. It was now about two years since Mr. Ekin drew attention to this subject in the pages of the *Pharmaceutical Journal*. There could be no question whatever that a very disagreeable odour was communicated to the breath and probably to the skin of some patients who took preparations of bismuth. Mr. Brownen had stated that a sample of carbonate of bismuth which had caused these unpleasant effects contained tellurium, so the public, or at any rate, certain newspaper writers had jumped to the conclusion that the fœtor was due to the tellurium, but this was not yet proved. In this sample, however, there was not only tellurium present but also selenium, and Dr. Letts had advanced greatly their knowledge of the chemistry of this matter. Although it was known that the tellurium occurred frequently in bismuth, it was seldom that any selenium was found in bismuth ores. He should like to ask Mr. Schacht whether the preparations of bismuth obtained in this case did, to his knowledge, produce this unpleasant effect which had been referred to; if they did, the fact would no doubt be communicated to him in some way or other. He should also like to know if Mr. Schacht had any reason to believe that the preparations of these particular samples of bismuth contained tellurium and selenium as the residues did. If the preparations contained these two elements it would be important to know whether there was any evidence that they did or did not produce this fœtor of breath. It would be a great advantage if Mr. Schacht could give the full history of the preparations of the sample from which these residues were obtained.

Mr. Schacht was sorry to say that the question could not be answered as he would have wished. He had not the slightest doubt that the preparations did contain something that caused these unpleasant symptoms. Some of the accounts he had received were scarcely credible, and he could not think that the whole of the effects said to be caused by an exceedingly small dose of tellurium were due to that cause. A fellow pharmacist had

told him that he had given to his daughter, a little girl of about six years of age, a dose of this bismuth, and that it had made her breath smell of garlic for more than a week. On inquiring how large a dose was administered, he found that it corresponded to less than one grain of the oxide of bismuth. As the residues only amounted to about one-half per cent. of the metal, and had been eliminated, it would be seen what a wonderfully minute dose of tellurium would be present in this very small quantity of the oxide, and it was difficult to believe that this could have resulted in such a remarkable physiological phenomenon as tainting the breath and all the excretions of a child for a whole week. He had no doubt the child exhibited this unpleasant phenomenon, but could not help thinking there was some other cause in operation. Professor Attfield had very properly asked if this sample of bismuth exhibited in its preparations the supposed evidence of tellurium and selenium. He was not aware that it contained selenium, but they had discovered chemical signs of the presence of tellurium.

The PRESIDENT said that during his late visit to Dublin he had been informed by Dr. Aquilla Smith that he had on some occasions been called in to prescribe for cases of shamming illness under certain circumstances of a criminal nature, and he had administered very small doses of nitrate of tellurium and found it perfectly successful in curing patients of shamming illness. It was so exceedingly powerful a substance that no one wanted a second dose of it.

Mr. UMNEY said it appeared to him that for the manufacture of soluble bismuth preparations nothing could surpass the basic nitrate or the oxide as a starting point. As tellurium and selenium were not (at any rate under certain circumstances) freely soluble in moderately dilute nitric acid they could hardly exist in the official nitrate or oxide made from it. This was doubtless in the minds of the framers of the addendum, who introduced the oxide for the express object of making pure liquor bismuthi.

Professor ATTFIELD hoped the physiological chemists would keep an eye on selenium as well as on tellurium, as seleniuretted hydrogen was said to be very much more pungent and powerful than tellurietted hydrogen, and a very minute quantity of selenium might thus cause all the mischief.

Mr. SCHACHT said Mr. Umney suggested the use of basic nitrate of bismuth, to obviate the difficulty with reference to this substance tellurium. He would no doubt remember that a solution of tellurium in nitric acid, which would be probably tellurious acid, was—like bismuth—capable of precipitation by the addition of water, and he was afraid that any tellurium present would largely go down with the basic nitrate. This constituted one of the chief difficulties in working with this metal.

Mr. J. S. TAYLOR said one impurity in bismuth which had not been alluded to was lead.

The PRESIDENT said it was probable that the telluride of bismuth was as insoluble in weak nitric acid as arseniate of bismuth, and it would therefore probably go into the residue.

A vote of thanks was then passed to Dr. Letts.

The next paper was on—

TINCTURE OF QUINIA.

BY MR. MARTINDALE.

The paper is printed on p. 407, and gave rise to the following discussion:—

The PRESIDENT said it was often found very difficult to make a tincture of quinia which would keep bright, and no doubt the suggestion to use hydrochlorate instead of sulphate was very valuable. It must be remembered that in using the exact quantity of hydrochlorate they would be using rather more than the equivalent of sulphate. There was of course the objection that the hydrochlorate of quinia was more difficult to prepare on a commercial scale than the sulphate, and would be always more expensive to separate from the other constituents of the bark. He did not think that should be any objection if the preparation were really superior for medicinal purposes, and therefore he welcomed the suggestion.

Mr. GREENISH did not think that Mr. Martindale had shown sufficient reason for any alteration in the process for making the tincture given in the Pharmacopœia. Mr. Martindale had mentioned that the quinine sometimes crystallized out, but he (Mr. Greenish) had never yet met with crystals of quinine out of any sample he had made, using tincture of orange peel of the proper strength. It was a curious fact, mentioned by Mr. Hustwick, who had given great attention to the subject, that if a little more water, say one-eighth, were added, crystals came down readily. The crystals might, therefore, arise from a deficiency in strength of spirit. With regard to the powder deposited, that was unquestionably sulphate of lime; he had separated it several times, and washing it with spirit had determined the presence of the sulphate of lime by the usual tests for acid and base. With regard to the orange peel, he might add that in examining a section under the microscope he found in some of the interior cells oxalate of lime, and thought it probable that when this came in contact with sulphate of quinine mutual decomposition occurred and sulphate of lime was formed. He had made tincture of orange peel with rectified spirit and fresh orange peel. He had dissolved quinine in this, and from it there was no precipitation of sulphate of lime, but there were at the bottom crystals of oxalate of lime which had not undergone decomposition in the presence of rectified spirit. There seemed no reason why this preparation of hydrochlorate should be used in preference to the sulphate. If tincture of quinia were simply sent out by the ounce or two ounce, as a retail article, there would be less objection, but they could not tell what difficulties might arise from its being mixed with other ingredients, and possibly setting up unforeseen decompositions.

Mr. UMNEY thought Mr. Greenish had touched the key of the whole thing—the presence of lime in the tincture of orange, and on that very ground he should strongly support Mr. Martindale's suggestion. The addition of sulphuric acid to lime in solution must inevitable produce sulphate of lime, which would fall as an insoluble powder, or in a crystalline form, whereas, if they had a soluble hydrochlorate of quinia, they would get the full value of quinine, and also have a soluble chloride of calcium.

Mr. SCHACHT said he spoke with some deference in the presence of chemists of superior knowledge, but he did not understand how a large amount of the supposed insoluble oxalate of lime would dissolve in weak spirit and become precipitated as sulphate of lime in the presence of sulphate of quinine.

The PRESIDENT pointed out that a sample of tincture of quinine of the sp. gr. ·938, contained, 67·2 per cent. of quinine, whereas, one with a sp. gr. of ·960, only contained on the average 5 per cent. A stronger spirit had therefore evidently great influence on the solution.

Mr. SCHACHT asked if citric acid happened to be present would it decompose the oxalate? He might be at fault, but he did not understand it. If those cells contained raphides he did not see why the citric acid should take them up and convert them into citrate, or if they were soluble why sulphate of quinine should throw them down as sulphate of lime. On the contrary he was strongly of opinion that this was a condition which pharmacists had no right to experience. If the tincture were made of the Pharmacopœia strength they would get no quinine thrown down at all, and any insoluble matter which might be there might be left alone. He should like to know what Professor Attfield had to say on the matter.

Professor ATTFIELD said he knew nothing of the matter experimentally; but he was bound to accept the evidence brought forward that tincture of quinine did often contain crystals of sulphate of quinine, and also crystals of sulphate of calcium, and he could not refuse to believe what Mr. Greenish had said, that orange peel did contain oxalate of calcium. Thirdly, he knew that most of these

vegetable substances contained organic salts of calcium, such as citrate, tartrate, and malate. His inference was that such solutions as this tincture would contain possibly oxalate of calcium, but also probably soluble organic salts of calcium, and that these when attacked by a sulphate would yield sulphate of calcium.

Mr. POSTANS said that some years ago he had experimented a good deal on this tincture, and his experience certainly corroborated Mr. Martindale with regard to sulphate of quinine crystallizing out under certain conditions. What he made was prepared according to the Pharmacopœia, and a gentle heat used for digestion by putting the bottle on the top shelf in the laboratory. After frequently shaking, and leaving it for some time, he got a good tincture, but in cold weather there was a liability to change, and on one occasion he remembered a number of bottles in which some very fine crystals formed, aggregated together not at all unlike a sea anemone in appearance and in miniature. He should like to know if Mr. Martindale had tried citrate of quinine, which he had found on several occasions to yield very good results. If the tincture of orange were made from fresh peel, he found that the sulphate of quinine dissolved much more readily, and the aroma was very beautiful.

The PRESIDENT thought it was a recognized fact that oxalate of lime was soluble in all organic acids except acetic. Therefore if citric acid existed in the tincture the oxalate of lime would be held in solution, and thus the precipitation of sulphate of lime would be accounted for. The suggestion to use citrate of quinine was no doubt valuable, but that salt was even more expensive than the hydrochlorate.

Mr. GREENISH asked if he had correctly understood Mr Schacht to say that he had not met with the powder which fell from tincture of quinine.

Mr. SCHACHT said no, he did not say that. A few weeks ago he examined the result of manufacturing a Winchester quart of the tincture, and he found there was a little, which was not perfectly dissolved. The tincture was made with proof spirit prepared with distilled water; moreover the orange peel did not, he believed, contain any citric acid. Seeing there was a slight turbidity he filtered it off, dried the filtrate, and found the result from the whole Winchester quart yielded five or six grains of precipitate. He put that on a platinum foil into a Bunsen flame, and found that it was apparently a lime salt. It seemed to him to be an organic salt of lime and not a sulphate, though he could not say positively, because he did not examine it for sulphuric acid. He did not think it was clearly made out that the sulphate of lime was due to the decomposition of oxalate previously dissolved by weak spirit, and then precipitated by the quinine.

Mr. LONG was surprised to hear the remark that perhaps the tincture was not made with proof spirit, but he feared there was some foundation for it. He had heard of such a thing as "half-and-half," which, though it might be very well in some places, was not the right thing in pharmacy. He should think that every pharmacist used distilled water, however. There was sometimes a difficulty in making tincture of orange, and the character of the orange peel might make a difference; he used the thin rind without the pithy albuminous matter inside. If they could get a better preparation they ought not to haggle about the cost. He said, let them get the best of everything, and the best remuneration.

Mr. MARTINDALE had only this to say in reply to Mr. Greenish, that it had been noticed by several writers in the Journal that crystallization of quinine did take place out of the tincture of the sulphate. He was always careful in making tincture of orange to have the peel carefully dried, ground, and percolated. A great deal depended on its being so dry that it would powder. If it were not well dried you might get a variable quantity of moisture in it, which would indicate a weakness in the tincture as shown by its greater gravity, and this must, to some extent, interfere with the solubility of the quinine. He always used distilled water, therefore that was not the source of the lime. Most pharmacists must have found that there was a sediment formed in making the tincture, which he had always looked upon at sulphate of lime, but no trace of it was found in thas made from the hydrochlorate. The solution was made much more easily, and it was richer in quinine. There was a difficulty in the ordinary mode in the application of the heat. He had had a Winchester containing the tincture, crack when placed in a water-bath at as low a temperature as he could use to effect the solution, and thus there was a great risk of waste. The plan of dissolving the quinine in spirit he had described was communicated to him by a candidate whom he was examining. As to the hydrochlorate he should not use it certainly until it was authorized by the Pharmacopœia, but he had thought it right to bring it forward. In a cool shop where the tincture was exposed to a temperature at all below 40°, quinine sulphate was sure to crystallize out. With regard to the citrate there was the objection that the customer would not get the full proportion of quinine, citric acid being of high molecular value; he would therefore be defrauded, whereas by using the hydrochlorate the proportion was slightly in excess.

A vote of thanks was passed to Mr. Martindale.

The next paper was on—

THE DETECTION AND APPROXIMATE DETERMINATION OF MINUTE QUANTITIES OF ALCOHOL.

BY J. C. THRESH.

The paper is printed at page 408, and gave rise to the following discussion:—

The PRESIDENT said the meeting was much indebted to Mr. Thresh for his paper, though it was not quite perfect, as the results did not appear to be quite accurate.

Professor ATTFIELD said the results obtained by Mr. Thresh were so important that he hoped he would carry his researches a little further, and see whether he got any similar results from other aldehydes than the vinic. He believed the aromatic aldehydes did not yield a colour when acted on by soda or potash, but that the other vinic aldehydes did, although not so much as the common ethylic aldehyde. The lower members of the vinic series especially, he believed, yielded much colour, and the higher members some colour also, and that therefore ethylic alcohol was not the only one which would be discovered by this test, though the ethylic aldehyde yielding so much more intense a colour than any other the test probably had all the merit claimed for it.

The thanks of the meeting were voted to Mr. Thresh.

The last paper was on—

AN ADULTERATION OF SENEGA,

BY E. M. HOLMES, F.L.S.

The paper is printed at p. 410, and gave rise to the following discussion:—

Professor BENTLEY said it was very desirable that public attention should be called to this matter, as this drug was largely in the market, and they were much indebted to Mr. Holmes for his paper in reference to it. The facts having been brought forward he thought that no one who had passed his examination would be likely to confound this drug with senega root.

Mr. GREENISH said that Mr. Holmes some time ago asked him to examine a root microscopically, which he had found mixed to the extent of 30 per cent. with senega; he believed it to be the *Asclepias Vincetoxicum*, but there was no specimen of the root in the Museum to compare it with. One was obtained from the Botanic Gardens, and on making sections of the two and comparing them microscopically, there was no doubt of their identity. Mr. Greenish then drew attention to a drawing he had made on the black board, showing the different structural character of senega root and this adulteration. The latter had starch cells outside the woody tissue, and pith in the centre, while the senega had neither.

The PRESIDENT then moved a vote of thanks to Mr. Holmes, and also to Mr. William Squire, of the firm of Messrs. Hearon, Squire and Francis, who had forwarded the sample to him. This was carried unanimously.

Mr. MARTINDALE referred to two other samples of senega in the market to which attention had recently been called as differing from the true root of the Pharmacopœia. Mr. Greenish had drawn attention to one at Dublin. Neither of them had the keel present, but Mr. Greenish and Mr. Squire thought this might be, because it was a young specimen, not developed. He could hardly agree in that opinion, because it did not look young, and was more developed than specimens he had seen of true senega showing the keel well developed. It was not so strong in taste as true senega. The other specimen which was noticed in "The Month," in September last, was stronger in taste, and he had no doubt belonged to some allied species.

Professor BENTLEY said this was another illustration of the unsatisfactory nature of imported drugs in the market. He hoped the time would soon come when a properly qualified drug inspector would be appointed to examine all importations of drugs.

The meeting was then adjourned until Wednesday December 4.

NORTH BRITISH BRANCH

The first meeting of the twenty-fifth session was held in the Society's rooms, 119A, George Street, on Friday, November 1, 1878 ; Mr. J. B. Stephenson, President of the Branch, in the chair.

The Honorary Secretary announced the following donations :—

1st.—*To the Museum.* - Cobra Heads, in spirit ; Dyak Arrow Poison ; Various Specimens of Tin Ore, from Mr. Jamie, Singapore, per Mr. H. C. Baildon ; Fine Specimen of Cajeput Oil, from Mr. J. B. Stephenson.

2nd.—*To the Library.*—Proctor's 'Pharmacy ;' 'Fern World ;' Miller's 'Chemistry ;' Cooley's 'Receipts ;' Martin's 'Microscopic Mounting ;' Fownes' 'Chemistry ;' Squire's 'Companion to the Pharmacopœia ;' Royle's 'Materia Medica ;' Bentley and Trimen's 'Medicinal Plants,' from the Society in London ; Nineteen parts 'Journal of the Chemical Society ;' Gamgee's 'Researches on the Blood,' from Mr. Mackay.

The President then opened the Session with the following introductory remarks :—

Gentlemen,—I have to thank you for the renewed expression of your confidence in again placing me in this chair. The duties connected with it are certainly neither very onerous nor responsible, but such as they are, I have striven to discharge them with the simple desire to promote the interests of our Society and to maintain the credit and dignity of the office, and I hope I am not presumptuous in interpreting my re-election as an indication of your opinion that I have not been altogether unsuccessful. And I can only promise my best services, and cherish the hope of your kind indulgence, as in the past, so in the future.

It is usual and fitting on an occasion like the present, to look round the world of pharmacy, and to exchange views and opinions on some of the multitudinous questions of interest related to it. But on this occasion my remarks shall be very brief, and this for two reasons ; first, all the questions to which I have referred are so ably and fully treated nowadays in the correspondence in the Journal, and elsewhere, that one can hardly hope to say anything original or striking, and second, I have on two previous occasions had to complain of the backwardness of our members to contribute to our scientific meetings, and on the last occasion I resolved that instead of scolding any more, I would take the other plan of setting an example, and being very far from prolific in composition, I meant that the paper which I proposed to read should constitute the whole of my performance this evening. However, I was advised that an introductory address, however short and formal, would be expected, and I am therefore led to offer you a very few remarks, confining them to two subjects. One of them is our examinations, assuredly the most vital interest of the Society. The discrepancy in the results as obtained by the two boards, has, as you all know, been a subject of great discussion for at least a year past, and it is mainly because, having had in my official capacity to take a prominent part in the proceedings in connection with it, I can speak with somewhat of confidence, that I venture to address you on the subject. You are aware that the subject has been under the consideration of the Council, who appointed a deputation of the London Board to come to Edinburgh at our examination in February, and also a deputation of our Board to visit their examination at London in June last. Both these deputations have reported, and there in the meantime the matter rests. Of course I cannot go into the details of these reports, but I have no hesitation in assuring you, that the results have been eminently satisfactory, that various points have been brought out explanatory of the discrepancy mentioned, and generally, that it is the opinion of every one of us who has watched the examinations at both Boards, that apart from such variation as the personal element will produce in an examination as conducted by two different bodies of men, or even by one body of men under different circumstances, these are as at London and Edinburgh practically and to all intents and purposes identical.

The other subject to which I would invite your attention for a few minutes is the proposed revision of the Pharmacy Act, for which purpose a committee was appointed at the last meeting of Council. I do not know what particular points the proposers of this revision had in view, but I think the Act admits of amendment in several clauses, more especially that one which requires the winding-up of a deceased chemist's business and so forbids the carrying it on for behoof of his widow or family. No doubt there are difficulties in the way of altering this, but it involves such a manifest and cruel hardship in many cases, that I cannot but think the wisdom of the Council will devise a means of modifying it. There is also the clause which provides exemption of all patent medicines from the provisions of the Act. This appears to me to be a direct violation of its spirit. The law, as I take it, provides in the interests of the public that no one shall be allowed to sell what it defines as poisons unless he possess a certain qualification, yet here we have the right to do so made dependent not on qualification but upon attaching a stamp of a certain value. If this be not a compounding on the part of the Legislature with the parties who send out these articles to evade or violate the law, I am at a loss how to describe it. In France the author of every patent medicine is required to declare the composition of it. This requirement is strictly on the lines of our own Pharmacy Act, the principle of which is the protection of the public. And by the way, here is the answer to the indignant complaints which have been lately made that the French do not allow the importation of our patent medicines. The whole matter is simply this, that they will not allow an exemption in favour of British quackery which they refuse to their own. I would rejoice to see such a requirement introduced by ourselves, and I think it would constitute an admirable amendment in our Act. It would at once efface the stigma of our Legislature bolstering up a gigantic system of humbugging the public, and remove, or at least greatly diminish, the greatest obstacle in the way of the progress of legitimate pharmacy. There is another exemption which rests on altogether different grounds, that in favour of the medical man. The Act properly assumes that his qualification to practise medicine generally, being the greater, naturally comprehends the lesser one to dispense it. And I am sure every one of us would hesitate to disturb medical

men in the exercise of their undoubted rights. Yet when we find that this exemption is utilized by doctors in the way of keeping open shops, not only for dispensing their own medicines, but for all the purposes of an ordinary druggist's business, and that these are managed by parties who may or may not be qualified in the sense of our Act (in some cases by females), as is done, according to my information, extensively and increasingly in the West, although we here experience nothing of it, then I say most emphatically that it is high time that this clause were subjected to reconsideration. The plan would be to provide that any one conducting the practical management of such an open shop, for it is apparent that the proprietor cannot, must be a qualified person according to the meaning of our Act. And probably such a provision might be found to cover the case of the deceased chemist as well. I confess difficulties begin to crop up as we continue to consider these matters, and I can only trust that our Council, if it sees fit to enter upon their consideration, will have wisdom and courage to cope with and overcome the difficulties. One word in closing. Don't expect too much from any Act of Parliament. Assuredly we need not expect the Legislature to confer on us a monopoly in selling quack medicines, or to interfere with co-operative stores selling medicines and dispensing as long as they have a qualified party to do so. Even if they could they would not be justified in so doing. The advancement of pharmacy is not dependent so much on Acts of Parliament as on the actings of every one of us in our individual capacity. Let our endeavours be directed not only to our own personal interest but to the interests of our common profession. Cherishing a lofty ideal of this, as well we may, let us strive to realize and adorn it by acting and living in every way worthy of it.

The President then proceeded to read the following:—

Notes on the Pharmacopœia.

The plan of the following paper is a very simple one. It is merely a noting of ideas or hints, which have either occurred to myself or been suggested by others, on the various preparations of the Pharmacopœia. These notes are exclusively of a simple and practical character and of course are suggested as improvements. I hope it is not presumption in me to say so. I have a very great admiration of our present Pharmacopœia, believing it to be very nearly perfect. Still I think it may admit of improvement. I look on it as peculiarly the chemists' book, so that, as we may put it, all that is necessary to constitute a perfect pharmacist may be summed up in what is implied in an intelligent apprehension of its meaning and a loyal obedience to its requirements—and this view of it brings it, I think, specially within the scope of our criticism. Our body has already had assigned to it a prominent and honourable place in constructing it, and a free criticism and discussion of it by our members would seem to be eminently calculated to bring out suggestions towards its improvement. I shall therefore speak out freely and plainly, hoping thereby to provoke others to come forward with suggestions of their own or with objections to mine, in either of which cases my object will be abundantly accomplished.

Our present Pharmacopœia dates 1867. The former edition of '64 was the first B.P. and occupies a distinguished position as harmonizing the three previous Pharmacopœias of London, Edinburgh and Dublin, a task which has been accomplished with great skill and judgment. The '67 edition is in many respects an improvement on that of '64. Notably it for the first time arranges all the materia medica and preparations in one alphabetical series, and it not only expresses the formulæ in English, which had been done in the '64 edition and in the Edinburgh Pharmacopœia even prior to that, but it has also adopted the Arabic numerals in expressing the quantities. The advantage, even the necessity, of simplicity of expression and arrangement in a Pharmacopœia is self-evident, and it will be observed how all these changes are meant to attain this. By the way, although it may not be desirable nor practicable to write medical prescriptions in English, I have often thought it would be an advantage to express the quantities in the Arabic characters. Compare these with the Roman for such numbers as 8, 12, 18, 24 and so on, and it will be seen at once how much more easily expressed and less liable to be mistaken the former are. The doses of the different articles were also for the first time introduced in this edition, and the authoritative standard of doses which we have thus acquired has been a great boon to us. There is another standard which it is very desirable to have in the Pharmacopœia (I offer this suggestion on far higher authority than my own), viz., that of the quantity or accent of names of medicinal substances. A moment's reflection will bring to mind many words which are pronounced differently—and often very doubtfully as to the right way (I speak for myself). Let me instance Piperita, Conium, Ergota, Camphora, Cubeba and many more. Of course there is already a standard or rule for some of them, but for many, I believe the Pharmacopœia would have to determine the quantity, and it would be very satisfactory to find an authoritative standard for all of them.

Acetum Scillæ contains an ounce and a half of proof spirit to the pint to prevent it spoiling. I have noticed it mentioned by several parties that this not only did not preserve it, but had the tendency to make it go wrong. Be this as it may, I can testify that it keeps perfectly without it.

My next remark has reference to what I have always looked on as a disregard of that simplicity which I have just alluded to as a characteristic of the Pharmacopœia. I refer to the formulæ for the three diluted acids, hydrochloric, nitric and sulphuric. For the first, we are told to dilute eight ounces acid with sixteen ounces water, and to add more water so that at a temperature of 60° it shall measure twenty-six and a half ounces, and similar directions are given for the nitric and sulphuric. Now, if great exactness were necessary in the strength of the diluted acids why not ascertain how much water was required to make up the measure, and specify it in the formula? But is such exactness necessary? The acids are used solely for medicinal purposes, where a little variation of strength, such as might arise from expansion or condensation, is of no moment. It can hardly be expected that all chemists will follow out these directions. Most of them will dilute the acid with the full quantity of water at once, in which case there is presented to them a rare facility for blundering.

Let me say a word about Aqua Aurantii with reference to the discussion lately about its strength. I have always understood that distilled waters were saturated solutions of the principles which distil over with the water. The question of dilution is one merely of expense, and must not be entertained with reference to the B. P. water. Let me also insist on the using the Aqua Anethi as distilled from the seeds. It is quite a different article from that prepared by rubbing up the oil, which although good enough at first, becomes quite vapid in a very short time so as to be quite unfit for the purpose it is mostly put to, viz., a carminative for infants. I am induced to mention this from having accidentally come across the vapid article several times lately. The same remark applies to Aq. Cinnamomi as prepared by distillation and by rubbing with the oil.

Emp. Belladonnæ is directed to be made by a very roundabout process. The simpler way would be to introduce into the Pharmacopœia an alcoholic extract of the leaves, or perhaps, better, of the root, an article which is sent out by the London houses, and to dilute this with the resin plaster.

We have two Essences, Anise and Peppermint, about which I have only to say that I think them too strong. Half the strength would be much more convenient.

Ext. Cinch. Flav. Liquid.—I have to repeat an old objection to the strength of this preparation. I find that it throws down in a short time a large mass of crystalline deposit, showing that it cannot retain all the active principles in solution. Would it not be well to reduce the strength, and that of Sarsa as well, to the standard of the other liquid extracts, viz., one ounce of the substance to one fluid ounce of the extract? Ext. Ergotæ Liquid.—It is generally admitted that the washing with ether may be dispensed with, more especially if cold instead of hot water be used. I find cold answers quite well; indeed, the extract made with it is, I think, richer than that made with hot, and I have medical testimony that it is quite as powerful. It is advisable to digest the ergot in it twice or even three times. The liquid aqueous extracts one would expect to prove a most important and useful class of preparations, but in my experience they are somewhat unsatisfactory from their all throwing down in a comparatively short time a large quantity of muddy deposit. Probably in some cases this is inert, yet we cannot always be sure of this, and, at least, it involves considerable loss. The same remark applies to the concentrated infusions, which are a similar class of preparations, and which of late years have almost forced themselves by irresistible considerations of expediency on chemists. I may mention while on these preparations, that I have been very successful in making most of those in common use by cold water percolation. The substance should be in moderately fine powder, and digested for twenty-four hours in enough water to wet it thoroughly, then set to percolate slowly with more water. The first percolate (say about the same measure fluid as the weight of the solid ingredients dry) is set aside, and the percolation continued until the ingredients are exhausted. This second percolate is evaporated till it is so far reduced that along with the first product, and the spirit necessary to preserve it, it yields the desired quantity. By proceeding in this manner we avoid the application of heat to the first portion, which will generally contain by far the greater part of the strength of the ingredients. This is, of course, a great matter where pungency or flavour is concerned. I may mention, notably, senega as admitting of this treatment, and yielding a beautiful result. But, as I before remarked, however perfect all these preparations are at first, they soon begin to deposit largely, and if re-filtered, soon begin again to deposit as at first. How different from this the comparatively unchangeable character of tinctures!

Glycerinum Acid. Tannici and Glyc. Boracis are inconveniently thick preparations. I was applied to, some time ago, by a doctor about the former, which he found very inconvenient and wasteful as applied with a pencil to the throat. I prepared some with glycerine diluted with one-third part of water, and the result was so satisfactory that I have thought it worth while bringing before you. The Glyc. Boracis is a still more satisfactory article when prepared with diluted glycerine. When prepared with pure glycerine it forms a thick tenacious fluid, which retains the air bells for a long time, and in such abundance that the compound is quite white, as if the borax were suspended in it. With one-third water added to the glycerine it forms a clear thickish preparation at once.

Lini Farina is described as "the cake of linseed from which the oil has been pressed, reduced to powder." I cannot doubt but that this definition will be altered to "linseed crushed with the oil," an article which is sent out in great perfection now.

Liniment. Aconiti et Belladonnæ.—I cannot help repeating the old grumble that these are far too strong. I have no doubt that by continuing the percolation until we got one half more product, we should obtain a product perhaps as strong, certainly strong enough. Liniment. Potass. Iod. c. Sapone.—Is it not a mistake to have a formula like this in the Pharmacopœia? Liniment. Saponis.—I am aware that by carefully following the directions as to temperature and proportion of water the risk of subsequent gelatinization is avoided, but why should not proof spirit be ordered as the menstruum? It has always appeared to me the simplest way of avoiding the difficulty, and I know of no objection whatever to it.

In a paper by Mr. Barton read before the Pharmaceutical Conference, consisting of practical remarks very much like these of my own, I find him recommending Liq. Ammoniæ Citratis to be kept in a concentrated form and diluted as required. I do not think the preparation is in such demand here as to be generally kept in stock, so that this measure may not be called for in regard to it, but I have found it very applicable with the Liq. Ammon. Acet. The 1864 Pharmacopœia ordered it in the concentrated form and to be made from the caustic ammonia, and I found this so much more manageable than the old, which was always going wrong, that I have kept it so ever since. Of course the carb. ammonia as ordered in the 1867 edition may be used, although I confess I have never been able to see the advantage of it. What I wish to point out is simply the advantage of keeping it in the strong form to be diluted as required.

I pause in passing Mucilag. Tragacanthæ to note a wrinkle which I got long ago from a London expert. Put the pulv. tragacanth. into the bottle dry, add a little rectified spirit (about twice as many minims as you have grains of powder), shake together and add the water gradually and with shaking.

Pil. Quinæ has 60 grs. quinine and 20 grs. confection of hips. There is here small provision for pills containing 1, 1½, or 2 grains of quinine, and one is puzzled in thinking how the formula ever gained admittance to the Pharmacopœia. In passing let me advert to the circumstance that tartaric acid forms an excellent excipient for forming quinine into a pill mass, a fact which I saw mentioned very recently, but which I have utilized for many years. One drachm of quinine with 6 or 8 grs. tartaric acid and a very little water and a good deal of hearty working forms a perfect pill mass. This plan is very suitable when we want 3 or 4 or 5 grains in each pill. I think we should have a Pil. Opii in the Pharmacopœia. One grain of powdered opium forms with syrup a nice small pill, and seems to meet medical requirements, which the Pil. Saponis Co. does very imperfectly.

Spiritus Chloroformi.—I was surprised to find in the paper by Mr. Barton which I have already referred to, a suggestion that the strength of chloric ether should be recognized as 1 in 10, as in Tr. Chlorof. Comp., and I have heard lately in several quarters a doubt expressed as to what should be sent out as chloric ether. I shall be glad to be put right if I am wrong, but I have always understood that the Pharmacopœia of 1864 afforded us a much needed settlement of the question, by declaring that chloric ether was a solution of chloroform in rectified spirit, and by fixing the strength at what is a very convenient point, 1 in 20.

Most of the syrups are ordered as saturated solutions of the sugar, but if made of this strength they crystallize freely in our stock bottles. Would it not be better to adjust the proportion of sugar so that the syrup would keep fluid under any circumstances? In Syrup. Sennæ the quantity of sugar, twenty-four ounces, makes it very thick, sixteen ounces I think would be an improvement.

Tinct. Aurantii can be made by percolation the same as the generality of the tinctures. The orange peel is readily reduced to powder if previously very slightly heated. Tr. Ferri Perchloridi would be better prepared with proof or even a weaker spirit. Indeed as has been often pointed out water is the best diluent for the strong liquor. We want very much a Tinct. Iodi of convenient strength for external use. The present is useless in that respect, being apparently intended for inhaling and internal use, and the Liquor Iodi, which might do as far as strength is concerned, is a solution in water which is not so suitable as spirit. Tincture of Iodine is largely wanted

by the public, who understand its use, and I observe that many doctors order either the old Edinburgh tincture, or a mixture of the present liniment and tincture, so as to bring it to about its strength. I would say, keep the watery liquor, or adjust its strength if necessary, for internal use, and let us have a tincture about the strength of the Edinburgh Pharmacopœia one (℥ss. ad ℥i.). The maceration in making Tinct. Myrrh. is worse than needless. It is obtained in perfection by putting the myrrh at once into the percolator and passing through it the spirit which will quite exhaust it before the process is half over. For Tinct. Valerianæ Am. maceration without percolation is ordered. I do not know why this should be, for one of the greatest advantages of percolation is thereby lost, viz., the more thorough exhaustion of the ingredients, because in pressing the marc after maceration, all the liquid left behind is tincture of full strength, whereas after percolation it is nearly clean spirit. The Tinct. Zingiberis Fort. might have the ordinary directions, which apply to it the same as the other tinctures.

Unguent. Iodi.—A few minims of plain water will dissolve the iodine and iodide more readily than the proof spirit ordered.

Vinum Colchici is still ordered from the corm. I find most medical men order vin. *sem.* colch., which necessitates the keeping it, and suggests the question whether in view of the preference for it the seeds might not be substituted for the corm. Vinum Ferri is prepared by digesting iron wine in sherry for thirty days. The 1864 Pharmacopœia formula which prescribed Ferri tart. was much more convenient, but the objection to it is the very large deposit which takes place with it in even such a weak alcoholic spirit as sherry. I believe the citrate of iron to be the most suitable form of iron to use for steel wine. It dissolves at once in sherry, and keeps perfectly with scarcely a vestige of deposit. We have it already in the Vin. Ferri Citratis, where it is dissolved in orange wine.

We had a supplement to the Pharmacopœia issued in 1874, which I do not think sustains the reputation of the parent work. With the exception of Chloral and Pepsine, there is really nothing to justify the publication. Pulv. Glycyrrh. Co. is introduced to represent (and under the same name, which is quite misleading) a preparation which has been popular for some years, but in attempting to improve the German formula by omitting sulphur and fennel, the authors have given us a different article altogether, which, as far as my experience goes is already obsolete.

And I conclude these desultory remarks with the reflection which has often forced itself on me that conservative principles should be kept steadily in view in framing a Pharmacopœia. There are so many new remedies constantly being introduced, and highly vaunted, that if even a small proportion of them is to find a place in the Pharmacopœia, not only will the pages be overloaded, but, in a little time they will be the only place in which the articles will be found. The Roman poet's rule to keep his work so many years before publishing it is very applicable to the introduction of new remedies into the Pharmacopœia. Just let any one look back for a few years and recall the many new medicines that have been introduced, each highly spoken of at the time, and then observe how very few have held their ground.

At the close of the address, Messrs. Napier and Gilmour made a few remarks on some of the preparations mentioned, and while generally concurring with the President they differed from him in one or two of his views. Both gentlemen felt that the meeting was under great obligations to the President for his excellent address and paper.

Mr. H. C. Baildon moved a hearty vote of thanks to the President, which was cordially seconded by Mr. J. R. Young, and received with acclamation.

The Honorary Secretary announced that the next meeting would be held on November 27, when Messrs. H. C. Baildon, Gilmour and Mackay would give communications.

Provincial Transactions.

PHARMACEUTICAL SOCIETY OF IRELAND.

Meeting of the Council.

Wednesday, November 6, 1878.

Present—Charles R. C. Tichborne, LL.D., Ph.D., President; Aquilla Smith, M.D., Vice-President; Sir George Owens, Dr. Collins, Dr. Ryan, Messrs. Allen, Bennett, Boileau, Brunker, Goodwin, Hayes, Holmes, Oldham, Pring (Belfast), and Simpson.

The minutes of the previous meeting of the Council, and of the third annual meeting of the Society, held on Monday, October 7, were read and signed.

The Registrar read a letter from the Secretary of the Pharmaceutical Society of Great Britain, acknowledging the receipt of his two letters of the 12th ult., and stating on the part of the Editor of the Journal, "That if the reports of the meetings of the Pharmaceutical Society of Ireland are communicated to him officially, he will have great pleasure in inserting them in the *Pharmaceutical Journal*."

Proposed by Mr. Brunker, seconded by Dr. Collins, and resolved, "That the thanks of the Council be conveyed to the Editor of the *Pharmaceutical Journal* for his kind compliance with its request to publish reports of its proceedings in that Journal."

Proposed by Dr. Ryan, seconded by Dr. Collins, and resolved:—"That the Council of the Pharmaceutical Society of Ireland authorize Mr. Fennell, the Registrar, to forward an abstract of report of its proceedings to the Editor of the *Pharmaceutical Journal*, subject to the revision of the President."

Letters were read from two members of the Society, Mr. William C. Dobbin, of Belfast, and Mr. John Watters, of Kilkenny, in connection with a proposal from the Editor of the *Chemist and Druggist* to publish the transactions of this Society, which proposal had been read at the meeting of Council on September 4.

Proposed by Mr. Oldham, seconded by Mr. Pring, and resolved:—"That the Registrar be directed to forward an abstract of the proceedings of the Pharmaceutical Society of Ireland (subject to the revision of the President) to the Editor of the *Chemist and Druggist*."

Proposed by Mr. Oldham, seconded by Mr. Simpson, and resolved:—

"That a Committee be appointed to consider the Journal question. The Committee to consist of Messrs. Hayes, Holmes, Collins, Boileau, Oldham and Simpson."

Letters were read from Mr. John Acheson, of Portadown, Mr. Peter Baikie, Armagh, and Mr. George R. Eakins, of Dublin, asking questions on particular passages of the examination rules.

The Registrar was instructed as to the replies to make to their inquiries, and to state in each case that the regulations of the Society could not be broken through.

Letters were read from four members of the Society, and one pharmaceutical chemist, drawing the attention of the Council to various alleged infringements of the Pharmacy Act, Ireland, 1875.

After considerable discussion, the Council was of opinion that no case likely to lead to a conviction had been laid before them. Some of the letters were of a general nature, and contained no specific charges. Finally, the Registrar was directed to inform the writers that the whole question is under the consideration of the Council.

The Examiners' report of the Preliminary examination held on Monday, October 7, was laid on the table. The following passed the examination—

John Acheson, Portadown.
Peter Baikie, Armagh.
Alex. Carson, Lisburn.
Patrick F. Christal, Benbulben Grange, Co. Sligo.
James Guiler, Holywood.
Henry P. Lawson, Merrion.
W. H. MacEwen, Portadown.
James J. Scott, Dublin.
Edward Smyth, Dublin.
John MacGeagh, Ballymena.
William J. Madden, Portadown.

A printed summary of the income and expenditnre of the Society for the year ended October 2, 1878, was submitted, showing an available balance to the credit of the Society amounting to £301 19*s.* 1*d.*

Parliamentary and Law Proceedings.

THE SOCIETY OF APOTHECARIES *v.* SHEPPERLEY.

In the High Court of Justice, Exchequer Division, Westminster Hall, on Wednesday, November 13, 1878, before the Lord Chief Baron and Mr. Baron Cleasby, Mr. Gore asked that the time for moving for a new trial in this case, which was concluded last Friday, might be extended from that day, which was the last day for moving, until Thursday or Friday, which was acceded to by their Lordships.

In the High Court of Justice, Exchequer Division. Westminster Hall, on Thursday, November 14, 1878, before the Lord Chief Baron and Mr. Baron Cleasby, Mr. Day, Q.C., on behalf of the plaintiffs, asked the Court that the time for moving for a new trial in this case might be extended for three weeks, on the ground that notice of motion had been given to move the Court of Appeal, *non obstante veredicto*, on the ground that the judgment of Mr. Baron Pollock was wrong, because it was clear the plaintiffs were entitled to the judgment of the Court upon the admitted facts in the pleadings. He would have to move their Lordships for a new trial on the ground that the judge misdirected the jury, and also on the ground that the verdict of the jury was against the weight of evidence, and therefore he thought it would be more convenient that Mr. Baron Pollock (the learned judge before whom the case was tried) should be present when the motion was made. He pointed out to their Lordships that under the Judicature Act it was necessary to give fourteen days' notice of their intention to move the Court of Appeal, which notice had been given yesterday and the motion would come on for hearing, before the Court of Appeal, on the first Wednesday after the expiration of the notice. He also pointed out that their Lordships had no jurisdiction to reverse the judgment of one of their learned brothers sitting at *nisi prius*. The learned counsel added that as his clients were the Society of Apothecaries, and had, as he was informed, a good stock of drugs, the defendant would be sure of his costs, and as he was a chemist and druggist of very great respectability in Nottingham, he would not be distressed by the delay.

The Court allowed the time to be extended, adding that the plaintiffs must give notice of it to the defendant.

Obituary.

JOHN BROAD.

The Society has lost by the death of Mr. John Broad, of Hornsey Rise, another of its founders and one who in every way did his utmost to promote its interests. He was born in 1815 and served his time to Mr. Woodruffe, of Islington, afterwards of Stamford. Thence he passed into the employ of Messrs. Godfrey and Cooke, working with Mr. Griffiths, Mr. Bradley, Mr. Bourdas, and others whose names are well known to pharmacy. On the experience there gained he was never tired of dilating.

Mr. Broad's first start in business was at Bedford Row; he then removed to Barnsbury, where after some years of industry he was obliged by ill health to leave business for a time. When restored to health he went to Hastings, but after three years was again compelled by failing health to retire.

In 1862 he opened a business at Hornsey Rise where he resided till his death, which took place last Friday, November 8, 1878, after an illness of twenty months.

Of the kindness and courtesy of his character it is needless to speak, those only who knew him and now cherish his memory can know what a true friend they have lost.

It was always his endeavour to improve the position of pharmacy, and he insisted that the practice of medicine and pharmacy should be separated, which was shown by his last idea to offer a prize for the best essay on the subject, a project which has been mentioned recently in this Journal.

Notice has also been received of the deaths of the following :—

On the 17th of June, 1878, Mr. Thomas Walker, Chemist and Druggist, Peckham. Aged 42 years.

On the 30th of September, 1878, Mr. Enoch Durband, Mill Street, Liverpool. Aged 50 years.

On the 6th of October, 1878, Mr. William Henry Owen, Chemist and Druggist, Charing Cross, London. Aged 28 years. Mr. Owen had been an Associate of the Pharmaceutical Society since 1869.

On the 16th of October, 1878, Mr. Edward Foulkes, Chemist and Druggist, Town Hill, Wrexham. Aged 37 years.

On the 16th of October, 1878, Mr. George Dowman, Pharmaceutical Chemist, Southampton. Aged 61 years. Mr. Dowman had been a Member of the Pharmaceutical Society since 1844.

On the 18th of October, Mr. John Timothy Charles O'Dowd, Chemist, Pontypridd. Aged 36 years.

On the 28th of October, 1878, Mr. William Croley, Pharmaceutical Chemist, Causewayside, Edinburgh. Aged 55 years.

On the 31st of October, 1878, Mr. Charles King, Chemist and Druggist, Marske-by-the-Sea, Yorkshire. Aged 61 years,

On the 7th of November, 1878, Mr. George Pile, Chemist and Druggist, North Street, Chichester. Aged 43 years.

On the 10th of November, 1878, Mr. James Fulleylove, Chemist and Druggist, Netherton, Worcestershire. Aged 47 years.

On the 10th of November, 1878, Mr. Frederick Joseph Rouse, Pharmaceutical Chemist, High Street, Clapham. Aged 67 years. Mr. Rouse was one of the Founders of the Pharmaceutical Society, having joined it in 1842.

Correspondence.

T. S.—See vol. vii., p. 1055.

J. W. Moore.—Wanklyn's "Water Analysis" (Trubner), Sutton's "Volumetric Analysis" (Churchill), or the article on "Water Analysis" in Watt's Dictionary.

C. R.—For an answer to your question as to Liq. Cinchonæ, see before in the present volume, pp. 167 and 178.

F. R. Bessant.—We do not think there would be any advantage in publishing the communication.

"*Africa*" is referred to the rule relating to anonymous communications.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Clarke, Page, Knight, Wright, Price, Swire, Mumford, Swendon, Raynor, Stuart, Pharmaceutical Chemist, Pulv. Opii Rect., Sub Umbra Floresco, Tyro, Grumpy, Dispenser, H., W. F. N., C. P., J. K. N. We are compelled by want of space to defer noticing several communications.

THE PARIS EXHIBITION.

Chemical Manufactures.—Manufactured Products.

(*Continued from page* 347.)

Varnish, Glue, Gelatine, Albumen, etc.

A considerable number of exhibitors of varnishes are to be found in the French courts. With respect to carriage varnishes the French makers appear to be at least attempting a serious competition with the English, although some of them pay their rivals the sincerest form of flattery by declaring that their wares are equal to the English. There are also in the French court a very great variety of fancy varnishes, such as artificial flower varnishes, spirit varnishes for metallic capsules, lacquers and varnishes for metal work, gold and silver varnishes, *varnish épargné*, for preventing a deposit on the coated part in electro-plating, etc.

Of the British exhibitors of varnishes it may be fairly said that they present some of the most beautiful cases in the building. Mention has already been made of the fine case of Messrs. Gidney, Clarke and Co., when referring to the resins shown by them. The cases of Messrs. Wilkinson, Heywood and Co., and Messrs. Turner and Son, of London, form a very handsome block, the dividing partition being of plate glass and greatly adding to the effect. Near by is the fine case by which Messrs. Mander Brothers, of Wolverhampton, have replaced their original exhibit, destroyed by an unfortunate accident only a day or two before the opening of the exhibition. Here, again it is difficult to pronounce upon the quality of these exhibits after a simple inspection of them. Messrs. Wilkinson, Heywood and Clark, however, assist in this respect by showing the practical application of their varnishes upon a number of natural woods, suitable for various purposes where the display of the natural grain of the wood is desirable; also on boards that have been "grained," others that have been painted in white and delicate tints, and representations of coach panels. Above the doorway leading to the machinery department close by is a board belonging to this firm, which is said to have been painted for the London exhibition in 1862, exposed also in the Paris exhibition of 1867, and now again exhibited without having been retouched or revarnished, and it certainly bears testimony to the excellence of the material used. A similarly practical case is that of Messrs. Jenson and Nicholson, of London, which includes a very good looking japan varnish used for the black parts of carriages, and other varnishes which, although applied to unpolished wood, present an admirable face and gloss. Among the exhibitors of varnishes and the resins from which they are prepared is also to be noticed a name familiar to pharmacists in Messrs. John Mackay and Co., of Edinburgh.

Another allied class of preparations are the harness compositions, boot varnishes, leather revivers, etc., which are to be seen in many cases in the French court; in the British court they are well represented by Propert's preparations, exhibited hy Messrs. Beddow and Son, of London.

In the French court there are a number of cases devoted to preparations of gelatine and other products from bones, hides, etc., including carriage grease, some fine samples of bone black, and various boot varnishes and blackings. Some of the gelatine in sheets is brilliantly coloured and is prepared for wrapping up bonbons. Messrs. Totin Brothers, of Montreuil, show gelatine from fish skins, for clarifying beer, and a light brown opaque kind, from rabbit skins, for dyers' use.

There are some very good exhibits of glue, but perhaps the finest is that of M. Froger-Bourdon, of Chateau-Renault. The factory of this firm is situated in the Indre-et-Loire department, in the heart of the tanning district, and is thus near an ample supply of raw material. Some of the samples of glue shown are beautifully clear and transparent, and they are said to be prepared entirely from the parings of skins and the sinews, the use of bones being eschewed as yielding a light glue deficient in strength. A glue prepared entirely from tendons is described as being particularly strong, which almost smacks of the doctrine of signatures. Another specialty is a "*colle gélatine*," in the preparation of which materials obtained from the calf only are used. Two bottles contain specimens of glue in the gelatinous form which it assumes just after it comes from the boilers; this jelly solidifies when exposed to the air, and being dried, yields the sheets of glue as met with in commerce. The regular drying of such large sheets as those shown must, however, demand much care. In other bottles are specimens of the residue obtained in glue making, which is used as manure, and of the fat skimmed from the surface during the boiling. Glue is also shown in the Italian court by M. Fino, of Turin, and Messrs. D'Aste and Fortini, of Florence, and in the Uruguay court by Messrs. Quetglas and Palmer.

The most interesting cases of products obtained from animal and other refuse are those of Messrs. Arlot and Co., and Messrs. Souffrice and Co. The latter deals with animal refuse from all sources, the garbage from the slaughter-houses, curriers' fat, kitchen stuff from the restaurants and barracks, suint, chiffonniers' pickings, spoilt American lard, etc. Even the "Seine scum" is contracted for by this firm, and is collected by means of gratings placed at the mouth of the drains running into the river at Asnières. Amongst the booty obtained there the principal consists of the dead bodies of animals, straw which has collected fat from the surface of the water, and corks which are cleaned with hydrochloric acid and thus fitted for fresh service. The animal refuse is thrown into large vats and subjected to the action of a jet of steam, when the fat collects at the top and is run off into other vessels. The residues are used chiefly as manure. Messrs. Arlot and Co. confine their operations to the refuse of the slaughter-houses.

Another firm that contracts with the city of Paris is Messrs. Artus and Co., who pay 125,000 francs yearly for the right of treating all the sheep's feet from the public abattoirs for the extraction of the oil, after which the feet have to be sent into the market as an article of food. About 4,500,000 sheep's feet pass annually through the establishments of this firm at Villette, Grenelle, and Villejuif, and it is claimed that the "trotter oil" obtained from them is superior to neat's-foot oil, of which there are also some very good displays.

Lubricants appear in several cases, and M. Houzeau, of Reims, exhibits animal, vegetable, and mineral carriage grease, some of which is as white as snow; while in the English department there is a very good show of carriage grease, etc., by Sir W. Rose and Co.

The cases of M. Bourgeois, of Ivry, and M. Gerbout, of Nancy, illustrate the products obtained from blood. They include a decolorized blood albumen, recommended as a substitute for egg albumen and nearly as white, a pale brown kind in flakes, a grey white coagulum, blood albumen in powder, and "crystallized blood," in black shining flakes, for dye works and sugar refineries. Except the statement that the dark albumen is from the blood of oxen and the lighter coloured from that of sheep, no clue is given as to the method adopted in obtaining the excellent products here exhibited, but the process followed in this country has been recently described by Dr. Ballard, in his report on effluvium nuisances. The operation consists in separating the serum from the blood-clot, and the drying of the former into transparent flakes of a reddish yellow colour varying in depth according to the quality of the serum. Blood-clot is absolutely useless for the purpose if it be not fresh, and the more recently it has coagulated the more valuable it is for albumen making. The clot is carefully sliced and the slices are arranged upon iron strainers, each with a pan beneath to receive the serum which flows out as the clot contracts. In the summer this draining is continued for about twelve hours, but in the winter it is prolonged during eighteen or twenty-four hours. From the pans the serum is transferred to a settling tank, where it remains about two days, until all the suspended colouring and other matters are deposited. The serum is then run into shallow iron trays and evaporated to dryness by means of steam pipes at a temperature of about 120° F. Lastly, the dry brittle albumen is scraped from the trays and sorted. The waste clot is usually used for manure making.

Blood albumen and "crystallized blood," from the public albattoirs of Florence, are also exhibited by Messrs. D'Aste and Fortini, and there is also an exhibition of blood albumen in the Belgian court by M. Defay.

Soap, Candles, Paraffin, Mineral Oils, Glycerine, etc.

The exhibitors of soap and candles make an important appearance in the class for Chemical and Pharmaceutical Products, the former numbering in the French court alone about sixty, and the latter about half that number. Two-thirds of the French exhibits of soap come from the neighbourhood of Marseilles. The manufacture of soap in France appears to be nearly stationary, and is estimated at about 220,000 tons annually; in fact a recent writer in the *Journal de Pharmacie et de Chimie* laments the signs of decadence in the Marseilles soap industry, and these he attributes among other causes, to practices not very creditable to the soap makers.

The best white soap and the marbled or "mottled" soap of Marseilles formerly contained 31 per cent. of water, and in the case of the latter the marbling was looked upon as a guarantee of the quality, as the addition of the least excess of water caused the separation of the insoluble salts which constitute the marbling. But since it has been found that in the presence of talc and other earthy materials this separation is retarded, the addition of such materials and excess of water has been practised to such an extent as to impair the public confidence in the article. This result has been hastened by the substitution of cotton seed, nut, and sesame oils, for olive oil in years when the crops of olives have been short.

Soaps made with olive, sesame, and other liquid oils dissolve without producing much lather, but if these oils be replaced by a concrete fat the soap yields an abundant lather, and rightly or wrongly that appeals by appearance to the favour of the laundress. This led to the introduction of soaps made especially to produce this effect (*savons mousseux*), and so long as these were properly prepared the fact that they contained only 29 per cent. of water so far justified the preference; but *savons mousseux* are said now to be found in the market containing as much as 40 per cent. in excess of that quantity. It must not be supposed, however, that these remarks are meant to imply that such practices are universal, for the samples of white, yellow, marbled, soft and resin soaps in the French court are of admirable appearance, and, as mentioned before, some of the cases are made additionally interesting by specimens of the seeds, etc., from which the fats used are expressed. In the case of Messrs. Serpette and Co., of Nantes, there is an apparatus for estimating fat in oil-cake, etc. It consists of an ether reservoir, from which when heat is applied the ether vapour rises through a tube to a condenser placed transversely with a slight slope, which causes the condensed ether to flow downwards into another bulb containing the oil cake; percolating through this it runs with the removed fat through another tube back into the ether reservoir, from which the heat again drives off the ether, the action therefore being continuous.

There are also a number of special soaps shown, such as glycerine, extract of bran, salicylic acid, carbolic acid, alcoholic and petroleum soaps. The last is said to be prepared by using carnauba wax as a means of solidifying the mixture, and by this means as much as one-fourth its weight of petroleum may be incorporated with and retained in a soap. Whether this petroleum soap has the special detergent properties claimed for it is open to question.

There are also some good exhibitions of soap in the English court. Messrs. Cook and Co., of Bow, among other products, show nice specimens of white soft soap, neutral soap for use in manufactures where excess of alkali would be injurious, and a reddish palm oil soap for perfumers. Messrs. Hodgson and Simpson, of the Calder Works, Wakefield, also have some very good looking soaps nicely displayed. One feature in connection with soaps in the British court is the number of "soap powders" shown, and the last named firm exhibits a specimen under the name the "Queen's Condensed Soap." The soap powder of Messrs. Glover and Co., of Bradford, who state that they have made it since 1847, is beautifully white. Other exhibitors are Messrs. Hemingway and Co., of Bradford, who also claim to have first introduced this article in 1867; Messrs. Jerratt, also of Bradford; Mr. Hudson, of London; Mr. Shaw, of Dukinfield; and Mr. Colman, of Norwich.

The industry of candle making has been more fruitful of improvements during recent years than that of soap making, and very few even of the greatest admirers of olden times would now cling to tallow dips in preference to the "stearine" candles that have resulted from the practical application by De Milly, Wilson, and others, of the principles underlying the facts discovered by the chemical researches of Chevreul and Fremy. Although the number of stearine candle factories in France has not increased much, the production has augmented 40 per cent. during the last ten years.

Up to the year 1867 the process adopted for the separation of the fatty acids in France and elsewhere was that of saponification by lime, the proportion of lime, however, used during the previous dozen years having been much reduced by operating under a pressure of eight or nine atmospheres. In 1867 saponification by sulphuric acid came more into play.

According to M. Riche* it is now the practice in many French factories to use both materials successively, first separating the glycerine by forming a lime soap, then decomposing that soap and submitting the acids to the action of sulphuric acid, and finally purifying by distillation. The yield of solid acids is said to be augmented in this way to the extent of 15 or 16 per cent., though the melting point is somewhat lowered, and these results are conjectured to be due to the conversion of some oleic acid by the action of the sulphuric acid into its isomer elaidic acid, the melting point of which is 45° C. This is in accord with what M. Fremy published so long ago as 1836, when he stated that in laboratory experiments he had obtained 60 per cent. of solid fatty acids from olive oil by the process of sulphuric acid saponification.

Until recently one great disadvantage in this process has been the blackening of the mass by the reaction of the sulphuric acid and the nitrogenous matters present in the fat, and the consequent necessity of purifying by distillation the fatty acids obtained. This distillation M. Fremy has always looked upon as avoidable, either by the previous removal of nitrogenous matters from the fat or by allowing the action of the sulphuric acid to go on more slowly and moderately, pressure then being sufficient for the purification of the product. This he has long urged upon manufacturers in his professional courses and elsewhere, substantiating his statements by the exhibition of perfectly white acids obtained in his laboratory without distillation, and recently he had the satisfaction of announcing to the French Academy of Sciences† that this process has at last become an industrial operation. It seems probable, however, that its applicability will be limited to the higher class of uncoloured fats. The firm of De Milly, of Paris, exhibits some very fine specimens of candles made from solid fatty acids obtained thus by sulphuric saponification without distillation together with the brown residue separated by the expression, and also candles from materials obtained by other processes of saponification, as well as intermediate products.

There are several very fine displays of candles from factories in or near Paris, and the joint exhibit of the stearine makers of Lyons is worthy of notice. Messrs. Carrière, Bros., of Paris, show some large ornamental candles, presumably intended for ecclesiastical purposes. Some rather exaggerated forms of such candles, made from beeswax, occur in the French forestry department; and in the Italian court there are some that are even painted. M. Venèque, of Ivry, exhibits a variety of candles, having three circular holes distributed round the wick and running from end to end, the device being intended to prevent guttering.

The case of M. Fournier, of Marseilles, contains material worthy of special notice, for besides candles and specimens of the volatile fat acids, caprylic, caproic, sebacic, ipomic, etc., there is some palmitic acid that is labelled as the result of the "transformation de l'acide oléique." This is said to be obtained by the reaction of caustic potash upon oleic acid as originally observed by Varrentrapp, and it is stated that in the factory of M. Fournier sixty tons of oleic acid are now in this way converted into palmitic acid yearly. Again quoting from M. Riche, it appears that when this method is applied on the manufacturing scale there is produced in this reaction, besides palmitic acid, also acetic acid, hydrogen, and a number of other products that have not yet been all defined, but amongst them are a number of saturated hydrocarbons of the series $C_{2n}H_{2n+2}$, of which marsh gas is the lowest term, and the highest term is a paraffin having a high melting point. They are accompanied by a series of fat acids, consisting of sebacic acid and homologues of it, which remain in the lye as salts of potash. Caprylic acid is also formed. M. Fournier's manufactory has been for some time lighted by burning the gaseous portion of the hydrocarbons.

In the Austrian court the erste österreichische Seifensieder-Gewerksgesellschaft, of Vienna, exhibits its celebrated "Apollo" soaps and candles, together with specimens of stearic and elaidic acids. It is reported that in this establishment the preliminary lime saponification is dispensed with, the treatment consisting of sulphuric saponification and separation of the solid acids by direct pressure, and subsequent saponification of the liquid acids alone with lime. This would appear to be confirmed by the statement in the special official catalogue that among the bye-products in the candle making in this factory is a large quantity (1700 tons annually) of elaidic acid, most of which is worked up in making "Apollo soap." It is suggestive also that this company sends into the market "oleo-margarine" and artificial butter. Stearine, wax, and paraffin candles, and various soaps, are also exhibited by the house of F. A. Sarg, Son and Company, of Vienna, whose business was first established by A. de Milly. There are also some other good exhibits of soaps and candles in the Austrian court.

The high reputation of the "Apollo" brand is evident, for the name is adopted by several makers in various ways, and from the British colony of Victoria an Apollo Stearine Company sends some very good looking candles. Although only founded in 1872, this company claims to be making 4000 boxes of 25 lbs. each annually, the raw material being principally beef and mutton tallow. Another British colony is represented in this department by Messrs. Waterman Brothers, of London, Ontario, and there are also some very good exhibits of soap from Canada.

At Schiedam there is another "Apollo" company that has a display of stearic candles, stearine, oleic acid, etc., in the Netherlands court. In this establishment the process adopted is sulphuric acidification and distillation, ice being used to assist the separation of the solid acid in summer, and it is said that although only established in 1869, products valued at nearly £350,000 are turned out from it yearly. In the Dutch court there is also a "trophy," which has come from the Royal Candle Manufactory at Amsterdam. Like many other trophies, it does not lend itself readily to description; but it is sufficient for the present purpose to say that it reaches to a height of about 40 feet and is composed of stearine. In this factory, which is said to use about 4000 tons of palm oil and 5000 tons of tallow annually, a cold air machine

* *Journal de Pharmacie et de Chimie* [4], vol. xxviii., p. 334.

† *Comptes Rendus*, vol. lxxxvii., p. 5.

connected with a Carré's ammonia refrigerator is used during hot weather to facilitate the separation of the stearine from the oleic acid, and in this way the yield of stearine is stated to be increased 5 or 6 per cent. In the Belgian court there are several exhibits of candles, soaps, etc., that from the "Royal Candle Manufactory" including some fine crystalline stearine obtained from shea butter from Central Africa. In this court, however, evidence was met with of the fallaciousness of testing by the eye alone, for a surreptitious opening of a bottle containing an extra nice looking specimen of soft soap was promptly punished by the inhalation of a most sickening odour.

There are not many exhibits of candles in the British court. Messrs. Simpsons, Payne and Co., of Millwall, show paraffin, stearine and composite candles, and their case also contains some interesting illustrations of the products obtained by the treatment of palm oil and other materials with 5 per cent. of sulphuric acid at 240° F. Messrs. Simpsons, Payne and Co., are also large manufacturers of sulphate of ammonia from the waste liquor of gas works.

But undoubtedly amongst the exhibitors who have most profoundly influenced the art of candle making in all countries, a prominent, if not the first, place must be given to Price's Patent Candle Company, whose "kiosk," adorned at the upper angles with drooping palm leaves, occupies a conspicuous position in this court. In fact the history of the numerous patents held by this Company since its establishment in 1829 as a private firm, which in 1847 was converted into a limited liability company, is to a considerable extent the history of candle-making, in this country at least. Several of these patents have now expired, and the processes have become available to competitors, whilst some of them were very speedily adopted by foreign makers. The first important stride made by the firm appears to have been in connection with the "self-snuffing composite candles," made, with the Cambacères' plaited wick, from a mixture of equal parts of stearic acid and cocoa nut stearine, and introduced to meet the demand created by the illumination in honour of the marriage of Her Majesty Queen Victoria. Then in 1840, 1842 and 1843, came patents in connection with the discovery that the fatty acids could in an atmosphere of steam undergo distillation without being decomposed, and thus be purified from the impurities that formerly gave a dark colour to the candles made from them. These were followed by the discovery that the quantity of sulphuric acid indicated by Fremy for the acidification of fat,—half its weight,—could be reduced to one-third its weight by the application of heat, and that quantity has been further diminished by successive stages to 3½ per cent. through other modifications. Fremy found that fat treated with half its weight of sulphuric acid, the materials being kept cool by a freezing mixture, became much harder. Wilson showed that by substituting a heating for a cooling application to the material all the good effects noted by Fremy were obtainable with a much smaller proportion of acid. The first could not have become a practical process, the second came into actual use at once. This modification greatly extended the number of fats available, and instead of being confined to the better kinds of tallow, as while only alkaline saponification was practised, the candle-maker was enabled to obtain a white and inodorous material from bone fat, fish oils, grease recovered from various sources, and above all from palm oil. The distillation of the acids rendered it more practicable also to utilize the oleic acid, produced in large quantities, as "cloth oil." Then, in 1854, came Tilghman's patent for a method of separating fats into fatty acids and glycerine by heating them in contact with water to a high temperature, under great pressure, followed in the next year by the discovery, made the subject of a patent by the Company in the names of Messrs. G. F. Wilson and G. Payne, that the same result could be obtained with neutral fats by distillation with superheated steam alone.

The following details, which have been courteously supplied, will give some idea of the extent of the operations of Price's Patent Candle Company. The Belmont Works at Battersea, occupy an area of about ten acres, and the Bromborough Pool Works, near Birkenhead, about seven acres. Of these seventeen acres nine acres are actually roofed in with iron. The operatives number about 1300, and for their comfort various arrangements have been made that can only be now alluded to. The Company has no less than sixty-one named and specified sizes of candles, and makes thirty-two qualities, dependent on variations in material, size and colour. Practically the factories may be called on to supply any of at least one thousand varieties, and the storeroom of the Belmont factory usually contains about two hundred and forty different kinds in stock. During the four years from 1872 to 1875 inclusive the saleible produce amounted to 47,832 tons, and in 1875 thirty-two and a half millions of night-lights were sold by the Company.

The case of this Company contains some fine specimens of transparent candles, made of pure paraffin, colourless and tinted; "palmitine," and other semitransparent candles, made of paraffin and different proportions of "hard stearine;" "composites," wax, sperm, carriage, and other candles, night-lights, tapers, etc. But probably what will first catch the eye of the scientific man is a series of fourteen photographs placed around the case, and illustrating an attempt that has been made to use polarized light as a means for distinguishing between the different solid fat acids and mixtures of them. The slides, which have to be very thin, uniform, and free from air bubbles, are prepared by placing a drop of the melted acid or mixture between two object glasses and subjecting them to pressure while the acid is cooling. The crystallization that takes place in cooling is very characteristic, and is easily discernible in the enlarged photograph, but is said to be much more so in the slide examined by polarized light. In this way the imperfect indications of the thermometer can be usefully supplemented, for it is found that frequently mixtures of fat acids have melting points considerably below that of either of the constituents, and that the same minimum is reached by two mixtures in which the position of each acid as to preponderance is reversed, the thermometer failing to show which is present in the largest proportion. Thus a mixture of 93 parts of palmitic acid with 7 parts of stearic acid and one of 36 parts of palmitic acid with 64 of stearic acid solidify at the same temperature, about 58·4° C., and therefore cannot be distinguished by the thermometer, but the photographs clearly demonstrate the difference. Similarly the addition of other substances, such as wax or spermaceti, is revealed. A series of these photographs has been kindly supplied for the Society's Museum.

The case of Messrs. Young's Paraffin Light and Mineral Oil Company (Limited) contains two classes of exhibits, the one consisting of specimens of oils, paraffin, paraffin candles and lamps, and the other of a collection of products from shale and shale oil prepared in the laboratory. In the former class solid paraffin occupies the most prominent place, the centre of the case being filled up with a large and beautifully pure, white, transparent block of this material, weighing seven hundredweights. All the varieties of paraffin and composite candles, some beautifully white and others coloured, made by the Company are shown. Samples of bituminous shale and of the crude oil obtained from it are exhibited, as well as samples of the shale spirit, burning oils, and mineral lubricating oils manufactured at the Company's works.

The laboratory series included in the case is of considerable interest to the chemist, and although it is not a complete collection of the bodies obtainable from shale and shale oil, it is still a valuble representation and is evidently the result of a good deal of labour. The collection includes a series (ten in number) of paraffins, separated from shale spirit and light burning oil, ranging from heptane (boiling point 105° C.) to hexadecane, the boiling point of which is 278° C. A second series, also consisting of ten members, is shown of the paraffins obtained by fractional crystallization from burning and heavy oils. These paraffins extend from one having the melting point of 9° C. (48° F.) to 65° C. (151° F.) so that the lower numbers will be liquid during the greater part, if not the whole, of the time they are in the Exhibition.

In addition to paraffin another solid substance, chrysene, is obtained during the distillation of paraffin oil, towards the end of the distillation, and after most of the paraffin has passed over. A good specimen of this yellow crystalline body is exhibited.

A specimen of shale residue, *i.e.*, of shale after the oil has been distilled off, is shown. This consists chiefly of silicate of alumina and iron with some carbon, and it accumulates to a great extent in the neighbourhood of oil works. No use on any scale of consequence has yet been found for this material, but specimens of ammonia alum and of sulphate of iron prepared from it and the waste sulphuric acid are exhibited.

The impurities removed from crude paraffin oil by the action of the chemical agents employed, viz., sulphuric acid and caustic soda, are known as "acid tar" and "soda tar." Specimens of these are exhibited with the bases leucoline, iridoline and cryptidine, prepared from the former. Specimens of metacresyl ($C_9H_{12}O$) and xylenol ($C_{10}H_{14}O$), among other constituents of soda and tar, are likewise included in the collection.

It is expected that before another International Exhibition is opened, further additions will be made to the above interesting collection. The case is somewhat relieved by two beautiful groups of artificial fruit, prepared from the Company's paraffin by Mrs. Mackay, of Edinburgh. The fruit is quite equal in appearance to any made of wax.

A card placed in the case gives the following statistics of the annual produce of the Company's operations, which extend to twelve pits, and employ 2100 hands and steam to the extent of 3495 horse power.

Shale distilled	233,000	tons.
Crude Oil made	8,040,000	gallons.
Crude Oil purified	9,680,000	,,
Naphtha made	500,000	,,
Burning Oil made	4,000,000	,,
Heavy Mineral Oil made	1,035,000	,,
Intermediate Oils made	200,000	,,
Crude Paraffin made	6,190,000	pounds.
Refined Paraffin made	3,940,000	,,
Candles made	3,800,000	,,
Sulphate of Ammonia made	1,150	tons.

Total annual value of products at existing market prices £500,000.

Similar products to a certain extent, obtained by the distillation of shale, are exhibited by the Oakbank Oil Company, of Glasgow. Besides "kerosene," having a flashing point at 52° C., and "mineral colza," flashing at 120° C., this Company makes a specialty of lubricating oils, which are claimed to possess, as compared with other mineral oils, great viscosity and lubricating power, a high flashing point, and sweet smell. The viscosity of the lubricating oils is determined at a fixed temperature by noting the time taken by a measured quantity to run through a given orifice, the comparison being made with water and with colza oil. The Company's "cylinder" oil is said to have a viscosity equal to that of ordinary animal oils, whilst it is not decomposed by high pressure steam at a temperature of 400° F. The Company also exhibits sulphate of ammonia as a product of distillation of shale.

Ozokerite or earth wax products find their principal illustration in cases in the Austrian court, for although this remarkable mineral occurs sporadically in other parts of the world it is at present only worked remuneratively at Boryzlaw, in Galicia. A most interesting display is that of Herr Paul Dobel, of Boryzlaw, who has kindly supplied some information upon the subject. Ozokerite occurs in the same district as petroleum, of which it is perhaps a residue, and it is accompanied by bituminous sandstone, clay schist, gypsum, and especially salt, either as brine or crystallized. The mining operations, which have been in operation about fifteen years, extend at the present time to about nine hundred pits, which yield yearly about 8500 tons. The seams are unfortunately not regular, but run in veins both horizontally and vertically, sometimes thick and sometimes thin, with frequent faults, so that the mining returns are very precarious. The gas developed underground also exerts an enormous pressure upon the workings, and occasionally breaks through and necessitates costly repairs. The earth wax occurs at a depth of from 20 to 180 metres, sometimes in numerous layers together, but also frequently at considerable intervals. No properly conducted deep borings have yet been made, 200 metres being the greatest depth yet attained. The whole district is in the hands of Polish Jews, and naturally there is much that is unsatisfactory. Of the discovered ozokerite land only about one-third is at present being worked, consequently there is still opportunity for the employment of larger capital to bring it into use.

Until the last few years the chief employment of ozokerite was for the production of paraffin, of which it contains about 42 per cent. of about 62° B. At present it is directly manufactured by bleaching and deodorizing into an imitation of beeswax, which is sent into the market from various manufactories as ceresin or mineral wax. According to the quality of the ozokerite it yields from 50 to 70 per cent. of

ceresin, having a melting point of from 60° to over 70° C. In the locality of the mines, at Boryzlaw and Drohobycz, about 2200 tons of ozokerite are thus worked up yearly; in other parts of Austria about 5500 tons are used; whilst only about 800 tons are exported to Italy, France, Germany, Russia, etc. Since 1867 the price of the raw material has risen from 13 florins per 100 kilograms to 30½ florins, and if the production does not keep pace with the consumption a still higher price may be expected.

In the case of Herr Paul Dobel is to be seen the crude ozokerite, as dug from the earth, of the most diverse colours, melting points, and formation, fibrous, conchoidal, yellow to black, as soft as butter and as hard as stone. The occurrence together with bituminous sandstone, clay schist, and especially with salt, is illustrated by handsome specimens of the mineral. In another part of the case are shown specimens of mineral wax and oil obtained from the crude ozokerite by melting to separate it from earthy substances, and these specimens also incidentally evidence the great difference in price of the different qualities. Herr Dobel makes a specialty of the qualities best suited for export.

A good display of candles and other products, such as a paste for waxing floors, "cobbler's wax," thread wax, etc., in which "ozocerotine" is used as a substitute for beeswax, occurs in the cases of Herr Ziffer, of Vienna, where also is some well-bleached Carnauba wax, which appears to find considerable employment in the hardening of beeswax, paraffin, mineral wax, etc. It is rather startling candour, however, on the part of this exhibitor to announce that he is prepared to supply a product from a Galician mineral with the mark "anglaise" or "abeille."

Herr Wagenmann, of Vienna, also shows some fine blocks of crude ozokerite and some grey coloured cakes of the product obtained by melting it to separate earthy substances, and subsequently treating it with fuming sulphuric acid.

The only exhibit of mineral wax, noticed in the French department was that of Messrs. Crémieu, who claim by special treatment to prepare for pharmacy, candle-making, perfumery, modelling, and other purposes a chemically pure mineral wax, corresponding in all its physical qualities with beeswax, although rather inconsistently a higher fusing point is claimed for it. Mineral wax is said to mix in all proportions with animal, vegetable or mineral fats, and with all essential oils and resinous bodies.

Closely connected with soap and candle manufactures, in fact dependent upon them, stands glycerine. Few things in the history of chemical industry are more wonderful than the enormous development in the use of this substance, which a few years ago was thrown away as a waste product, but which now finds so many useful applications in the arts and sciences. According to an estimate of M. Riche,* the consumption of glycerine now amounts to about 10,000 tons annually, and the proportions produced in different countries are as follows:—

France	4000 tons.
Germany and Austria	1500 „
Holland	900 „
Russia	900 „
Belgium	800 „
Italy	400 „
England	300 „
Spain	100 „

* *Journ. de Pharm. et de Chimie* [4], vol. xxviii., p. 407.

According to these figures the production of glycerine in France more than quadruples that in any other country and this would be in accord with what is known of the soap and candle industries.

But although the principal seat of the glycerine manufacture would appear to be at present in France, yet this manufacture is based upon a discovery made by an Englishman, Mr. G. F. Wilson, in 1855, that glycerine could be purified by distillation. Before that time chemically pure glycerine was unknown, but the discovery having been made the subject of a patent by Price's Patent Candle Company, such an article was introduced into the market, where it has attained a considerable reputation, and "Price's glycerine" holds a place in the case of the Company in the present exhibition. At first this article was imported into France for perfumery, but a Frenchman has recently stated that it now is only represented there by the labels on the bottles, the greater part of the glycerine sold under that name being supplied by makers in Paris and its environs.

Among the exhibits of glycerine worthy of special notice in the French court is that of M. Clolus, of Billancourt, who exhibits "glycerine for beer and wine," perfumery, pharmacy, salicylated glycerine, and one beautiful chemically pure specimen. Other good displays belong to Messrs. Carrière, of Paris, who show some free from lime for making nitroglycerine; M. Bouquet, of Ile St. Denis; M. de Milly, of St. Denis; Messrs. Sarg, of Berlin; and in fact in connection with most of the displays of candles.

(*To be continued.*)

EUCALYPTUS OILS.*

Eucalyptus amyydalina.—Essential oil, pale yellow thin liquid. Odour penetrating, resembling somewhat oil of lemon. Taste mild and cooling, afterward bitter. Sp. gr. 0·881 at 15° C. Boils at 165—188° C., deposits a stearopten at 18°. Resinifies when exposed to air.

E. oleosa.—Oil thin, mobile, pale yellow; of mild, camphor like taste, somewhat resembling oil of turpentine. Odour mint-like. Sp. gr. 0·911. Boils at 161—177° C.

E. Sideroxylon.—Oil very pale yellow, thin. Odour and taste like preceding. Sp. gr. 0·922. Boils at 155—178° C.

E. Goniocalyx.—Oil pale yellow, of penetrating pungent, disagreeable odour. Taste very disagreeable. Sp. gr. 0·918. Boils at 152—175° C.

E. Globulus.—Oil thin, very pale yellow. Odour like oil of cajuput, but less agreeable. Taste cooling, mint-like. Sp. gr. 0·917. Boils at 149—177° C.

E. corymbosa.—Oil colourless, odour faintly lemon and rose-like, taste feebly bitter, slightly camphoraceous. Sp. gr. 0·881.

E. obliqua.—Oil yellowish red. Odour mild, taste bitter. Sp. gr. 9·899. Boils at 171—195° C. Becomes cloudy at 18° C.

E. fissilis.—Oil pale yellowish red. Odour like preceding. Sp. gr. 0·903. Boils at 177—196° C.

E. odorata.—Oil pale yellowish, with a greenish hue. Odour aromatic. Sp. gr. 0·899—0·922. Boils at 157—199° C.

E. longifolia.—Oil thicker than others. Taste cooling and aromatic; odour strongly camphoreous. Sp. gr. 0·940. Boils at 194—215° C.

E. rostrata.—Oil pale-yellow to amber. Odour and taste as preceding. Sp. gr. 0·918. Boils at 131—181° C.

E. viminalis.—Oil pale greenish yellow. Odour disagreeable but feeble. Sp. gr. 0·921. Boils at 159—182° C.

THE HISTORY OF THE TWENTY-EIGHTH SECTION OF THE APOTHECARIES ACT.

IT is most likely that the question as to the right of the chemist and druggist to carry on counter practice will for some time continue to command attention, not only from those whose exercise of that practice is objected to, but also from the public, who find the practice a convenience. The present moment, when there is an interval in the active proceedings of litigation is therefore a suitable one for carrying out the suggestion made some weeks ago by Mr. HUMPAGE to reproduce an account of the occurrences connected with the two previous occasions when chemists and druggists took concerted action in regard to proposed legislative enactments affecting their interests.

The two periods we refer to are respectively comprised within the first fifteen years of the present century and within the year 1841, the passing of the Apothecaries Act being the result of the steps taken in the former period, while the formation of the Pharmaceutical Society of Great Britain was the ultimate result of the action taken in the latter period.

In the first instance we purpose confining our attention to the circumstances under which the Apothecaries Act became law, and more especially to mention those points which may serve to elucidate the history of the 28th section of that Act, wherein chemists and druggists are specially referred to. In a subsequent article we shall deal with the events immediately following the introduction of a Bill of medical reform by Mr. HAWES, Mr. EWART and Mr. HATTON early in the year 1841.

At the commencement of the present century the Apothecaries' Company was nominally in possession of a monopoly of the right to sell pharmaceutical preparations and to compound medicine according to the prescriptions of physicians. The charter granted to that body in 1748, besides conferring other privileges, was no doubt intended to restrain druggists from practising pharmacy as well as to prevent physicians or surgeons from preparing or selling the medicines they prescribed, inasmuch as this was held to be the exclusive business of the apothecary, and the druggist of that period was considered to be unqualified for its proper performance.

But long before the end of the eighteenth century the monopoly of the apothecaries in the dispensing of physicians' prescriptions had practically ceased to exist: they found it impossible to secure to themselves those exclusive privileges provided for in the charter, the law was constantly evaded, and in the year 1793 they instituted an inquiry into the defects and privations which existed among them. The circumstances which led to this step on the apothecaries' part will be apparent from the statement made by them that the existing state of things was due partly to "the encroachment which chemists and "druggists have of late years made on the profession "of the apothecary by vending pharmaceutic prepa-"rations and compounding the prescriptions of "physicians;" partly, also, to "the want of a com-"petent jurisdiction in the profession itself to "regulate its practice and to restrain ignorant and "unqualified persons from practising at all."

The controversial works published during the years between the grant of the charter and the year 1793, in reference to the functions of the Apothecaries' Society in examining drugs and preventing adulteration, etc., furnish abundant evidence of the struggle that was being carried on between the licentiates of the Apothecaries' Company on the one hand and the druggists on the other, while at the same time a further contest between apothecaries and physicians was being developed by the former undertaking to practise medicine. In one of these works entitled 'The Apothecaries' Mirror, or "the Present State of Pharmacy Exploded,' it is argued that "the compounding of medicines pre-"scribed, and knowing *why* they are prescribed, are "two different things; one is an ordinary habitual "thing, the other depends upon the circumstances of "the case and cannot possibly be judged of unless by "one who understands the natural history of the "human body and is acquainted with the mechanism "and operations of nature. These are heights of "knowledge at which few apothecaries arrive."

It would be waste of time to do more than illustrate in this cursory way the gradual growth of those difficulties between apothecaries and physicians, and between apothecaries and chemists and druggists, which in the one case led to the passing of the Act of 1815, and in the other to the position of conflict which still prevails; but it will be to the purpose to refer to the report presented at a general meeting, attended by about two hundred apothecaries, held at the Crown and Anchor, on the 17th of June, 1794. This report had been drawn up as the result of the inquiry into the abuses by which it was held the apothecaries were interfered with, and it described the exercise of pharmacy by druggists as an "unjust and innovating usurpation," and "a national evil of no small magnitude," which together with "the intrusion of uneducated and un-"skilful persons into *professional practice*," was represented as calling loudly for some speedy and effective Act which should at once destroy the obstructions

complained of, and restore credit and respectability to the profession.

The words we have italicized seem to show that the interference of druggists with the apothecaries extended even at that time to something more than the compounding of physicians' prescriptions, and this view is supported in a subsequent part of the report, where it is stated that the alleged evil of dispensing by druggists was not confined to the metropolis, but was so general that there was scarcely a town, village, or hamlet, without a druggist, and that "if the sale of medicines and the *giving of* "*advice*" was not there sufficient to support the vendor, he added to this occupation the sale of other articles. In both these expressions, "counter-"practice" seems to be referred to, though in a vague way, which was probably expedient at a time when the apothecary himself practised medicine illegally. Further on, however, this complaint is stated more plainly, and the report goes on to urge that if the dispensing of prescriptions, and the vending of pharmaceutical preparations, be a source of national abuse and deceit—

"What infinite injury must result from the still bolder "practice such men often allow themselves, of adding "pretended medical advice to erroneous medical com-"positions! Men who have never enjoyed any other "medical education than what their own counters have "afforded; and who can know nothing of the powers of "diseases, or of the powers of medicines to remove those "diseases when present! To attempt to demonstrate "this to be a public evil, and one that calls loudly for "redress, is altogether to lose time; it is to light up the "sun at noonday with a candle."

In order to put an end to these abuses it was proposed to form a general association of the Apothecaries of Great Britain, and endeavour to obtain the necessary reform by application to Parliament. That Association, under the title of "The General Phar-"maceutical Association of Great Britain," undertook by means of correspondence to collect evidence in support of its propositions, and meetings were held periodically at the Buffalo Tavern, Bloomsbury Square, to report progress. The communications sent in represented that the druggists throughout the kingdom were grossly ignorant and guilty of gross enormities in selling adulterated drugs and disregarding the directions of the College Dispensatory, the druggists at Manchester appearing "to "excel all others in such nefarious ingenuity." At the same time it was reported that, notwithstanding all this, the increase in the number of druggists was so great as to claim particular attention, and one correspondent, who reported the opening of three new shops in one town, within twelve months added—

"Pharmacy alone comprises too small a field for these "men of letters and ambition—they prescribe whenever "applied to, though totally ignorant of medical science, "and even pretend to reduce fractures."

Without going into further details as to the energetic efforts of this Association to bring about reform, it may be mentioned that a petition was presented to Parliament on its behalf by Sir W. Dolben on the 6th February, 1795, and that one of the main objects of it was that the liberty to vend pharmaceutical preparations, compound physicians' prescriptions, etc., etc., should appertain to the apothecary alone. The result of these exertions was not, however, so successful as was anticipated, and the Pharmaceutical Association of 1794 was soon broken up without having effected the subjugation or extinction of the class against which its efforts were directed.

With the exception of the action taken in 1802 in regard to the Medicine Stamp Act, when the apothecaries and chemists and druggists made common cause together, nothing further was done towards effecting reform in the practice of medicine and pharmacy until the year 1812, when a heavy duty was imposed upon glass, and a meeting of apothecaries was convened by Mr. Burrows, Mr. Cates and Mr. Wills, at the Crown and Anchor Tavern, to devise some means of obtaining relief from the effect of this tax. Several meetings were held for the same purpose but with little result so far as it was concerned, and at one of them attention was directed by Mr. A. T. Thomson to the more important matter of improving the condition of the apothecaries' branch of the profession.

Another association was then formed under the title of the Associated Apothecaries, comprising as active members Mr. Kerrison, Mr. Thomson, Mr. Good and Mr. Upton, with Mr. Burrows at its head and Mr. Ward as secretary. Its efforts were directed to the framing of a bill with the object of regulating the practice of apothecaries, surgeon-apothecaries, practitioners in midwifery, and compounders and dispensers of medicine throughout England and Wales, and preventing the practice of medicine, surgery, midwifery or pharmacy by uneducated persons by establishing an examining body empowered to grant licences to such persons as they found competent. Failing to obtain the co-operation of the College of Physicians, or the College of Surgeons, or even of the Society of Apothecaries, such a bill was introduced into Parliament independently at the beginning of March, 1813, by Messrs. Wilberforce, Calcraft, Whitbread and Rose.

This was the origin of the Apothecaries Act, 1815. Some of the most important provisions of the Bill, as originally drawn, were directed against chemists and druggists, and in consequence the Standing Committee formed in 1812 for the protection of Chemists and Druggists' interests at once convened a meeting at the Freemasons' Tavern, on the 12th of March, for the purpose of organizing opposition to the Bill. The chair was taken by Mr. Hudson, of the Haymarket, and in the course of the proceedings it was resolved that the Bill contained—

"Many clauses deeply injurious to the chemists and "druggists who compound and dispense medicines, and to "the public at large, inasmuch as the operation of these "clauses will be to put all compounders and dispensers of

medicines under the control of a Committee of Apothecaries (distinct from the corporate body of Apothecaries), "and to give that Committee a power, by the making of 'bye-laws, and the issuing of annual licences, to use means 'of the greatest oppression and injustice, and eventually "to place a monopoly of compounding and dispensing "medicines in the hands of the apothecaries, which will "increase the price of medicines, and consequently "diminish the means of a large body of the community "to procure necessary medical assistance.

"*Second*—That the chemists and druggists having, for "a great number of years, exercised the trade of com-"pounding and dispensing medicines (by which they "mean making up the prescriptions of physicians and "surgeons) to the satisfaction and advantage of the "public, consider it highly important to oppose this bill "in all its stages, so far as it interferes with their estab-"li-hed and universally acknowledged business.

"*Third*—That a Committee be chosen, five of whom "shall be a quorum, to take the necessary steps for "opposing the bill; and that the Committee do consist "of the following persons, with power to increase their "number:—

Mr. Allen, Plough Court.	Mr. Hastings, Haymarket.
,, Bell, Oxford Street.	,, Hume, Long Acre.
,, Cooke, Southampton Street.	,, Hudson, Haymarket.
	,, Phillips, Poultry.
,, Cole, Newgate Street.	,, Savory, Bond Street.
,, Complin, BishopsgateSt.	,, Smith, Haymarket.
,, Curtis, Old Fish Street.	,, Tebbs, Bond Street."

This Committee published an address to chemists and druggists throughout the kingdom, counsel was engaged, and a circular was sent to members of Parliament setting forth, among the objections to the provisions of the Bill, that its obvious tendency was to depress and ruin, and eventually to extirpate, the compounding chemists and druggists; also that any medical advice or interference on the most urgent or most trivial occasion, whether real or pretended, might subject chemists and druggists to frivolous and vexatious proceedings and penalties. It further urged that while in large towns, it was usual for physicians to prescribe *gratis* for the poor, and to send them to a chemist and druggist for the medicines, and while in populous places, ineligible for the residence of a physician and unfavourable for the formation of local charitable institutions, simple remedies were often procured from the chemist and druggist at a cheap rate, that if those classes were obliged in every slight ailment to employ a professional man, who could legally charge for attendance and medicine, they must encounter the greatest pecuniary inconvenience or the distressing consequence of protracted sickness.

A petition was also drawn up for presentation to Parliament by the hands of the members most favourable to the cause, and in consequence of these steps the Committee of the Associated Apothecaries considerably modified the Bill, sending notice to the members of the House of Commons previously to the second reading, that in the event of the Bill passing into Committee it was intended, among other changes, to expunge from it everything affecting the compounding chemist and druggist, and that the views of the Bill would be altogether confined to rendering the apothecary and apothecary-surgeon competent practitioners, by examination and obtaining for them a different mode of recompense for their visits and professional skill.

Eventually this Bill was withdrawn, and in reporting that result to a meeting of chemists and druggists held at the Freemasons' Tavern on the 8th of April, 1813, Mr. Hudson remarked that the avowed intention of the apothecaries to introduce another Bill, and the recollection of the previous harrassings the trade had experienced, could not fail to convince them of the necessity of continued watchfulness to protect and preserve the interests of all concerned in it. In accordance with this recommendation, the Committee was made permanent and steps were taken to add to the funds which had already been raised.

The efforts of the Associated Apothecaries were then directed to conciliating the Colleges of Physicians and Surgeons and the Society of Apothecaries and, after much discussion as to the retention or repeal of the powers vested in the Society of Apothecaries, they so far succeeded that a Bill was introduced by the Society of Apothecaries, in conjunction with the College of Physicians, in February, 1815, for enlarging its charter and better regulating the practice of apothecaries throughout England and Wales. This Bill also was opposed by the chemists and druggists on the ground that it contained much matter highly injurious to them and to the public at large.

At the request of the Chairman of the Chemists and Druggists' Sub-Committee the Master of the Society of Apothecaries received a deputation consisting of Mr. Hudson, Mr. Savory, and Mr. Smith, and he then declared it to be the intention of the Society of Apothecaries not to interfere at all with the chemists and druggists by the Bill then in Parliament, at the same time offering to prepare a clause to that effect to be added to the Bill, for the satisfaction of chemists and druggists.

At a meeting of chemists and druggists, held at the Globe Tavern, on the 21st of April, 1815, the chairman reported that he had received from the Solicitors of the Society of Apothecaries a letter inclosing the draft of the clause proposed to be added to the Bill then in Parliament for exempting chemists and druggists from the provisions and effect of the said Bill. In this letter it was stated that the Committee of the Society of Apothecaries saw with concern that misrepresentations had been made of the Society's object, which was the improvement of its branch of the profession in medical knowledge. The views of the Society were represented as being so entirely directed to this end that it had no disposition to insist on any clause not essentially connected with it. The clause here referred to was, with the exception of the words defining the scope of the business of a chemist and druggist, nearly the same as the 28th section of the Apothecaries Act as it now stands. It was submitted to counsel on behalf of the chemists and druggists, together with the Society's charter and the Bill then in Parliament, and in the settling of this clause certain verbal amplications were recommended which were adopted by the chemists and druggists and agreed to by the Society of Apothecaries without alteration

Provincial Transactions.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual general meeting of the members and associates of the Midland Counties Chemists' Association was held at the Great Western Hotel, Birmingham, on Tuesday the 12th inst., at 8 p.m. Mr. Wm. Jones, President, in the chair. There was a good attendance.

The notice convening the meeting having been read, upon the motion of the President the report was taken as read.

In this report the Committee commenced by calling attention to the prosperous condition of the Association. Notwithstanding the somewhat increased expenditure of the past year, the balance in the Treasurer's hands amounts to £57 13*s.* 3*d.*

The election of representatives on the Committee of the Chemists and Druggists' Trade Association of Great Britain being considered a matter of great importance to the trade, the Committee had held a meeting with the object of nominating and recommending gentlemen to represent Birmingham on that Committee, and reported the election of the President, Mr. W. Jones, as one of the three whom the town is entitled to send.

The Committee had heard with regret of the decease of the late Mr. C. F. Palmer, and had arranged that a deputation of chemists should follow the remains of their townsman and brother chemist to their last resting place.

The librarian had reported the increasing use that is made of the library; and the attention of chemists and their assistants was called to the additions which have been made during the past year, rendering the library a valuable aid to the student, and very useful to the chemist in business. The Committee recommended that a further grant of £5 be voted, to purchase additions to the library, so as to render it more complete and useful.

The educational work had proceeded satisfactorily, and a number of students have passed their respective examinations from the Birmingham school; two only of whom have claimed the Society's grant of money in part payment of their fees.

On the 23rd January last, an exhibition and soirée, in connection with the Association, was held in the Town Hall. The soirée was highly successful, and notwithstanding the necessarily heavy expenditure, the Committee were pleased to announce that the profits on this occasion were £28 13*s.* 8*d.*; an amount much greater than has been realized at any former soirée.

The funds of the Association being in so flourishing a condition, the Committee recommended that a sum of £10 be handed over to the Chemists and Druggists' Trade Association, as a donation, to assist in continuing to protect and further the interests of the trade; and the Committee took the opportunity of publicly acknowledging the sound and useful work that body has accomplished.

The Committee reported that arrangements were being made for a series of lectures to be delivered during the winter session, and that several gentlemen have kindly volunteered their services.

In June last, the Duke of Richmond's Bill for amending the Medical Acts, having passed the House of Lords, was before the House of Commons for its second reading, and the Secretary received a communication from the Secretary of the Trade Association, asking the co-operation of the Association. A meeting was then at once called, and a petition against the bill in its objectionable form was forwarded to the Parliamentary representative. A successful canvass, also, of the town was made, and a large number of signatures of chemists obtained to a petition against this bill, which the Committee believe contributed materially towards it postponement. As it is highly probable that similar measures will from time to time be brought before Parliament, the Committee would impress upon chemists the great value of local associations, which enable each district promptly to petition against legislation injurious to the trade.

The examinations for prizes awarded to students who have passed their respective pharmaceutical examinations from the Birmingham school have been held, and the report is as follows:—*Preliminary Candidates*: Mr. Bloomfield, first; Miss Powell, second. *Minor Candidates*: Mr. A. J. Bambridge, first; Mr. J. Austin, second.

The election of officers was the next business, and Mr. W. Southall, F.L.S., was unanimously elected President, in place of Mr. W. Jones, the retiring President. Messrs. Holdsworth and J. Green were appointed Vice-Presidents; Mr. J. Lucas being re-elected Treasurer; Mr. Stokes Dewson was re-appointed Hon. Secretary, and the work of the Association having greatly increased, Mr. J. Austin was elected joint Secretary; Messrs. F. Gibson and J. Green consenting to act as Auditors for the ensuing year.

The Committee, chosen by ballot, consists of the following gentlemen:—Messrs. T. Barclay, Haydon, Arblaster, Pare, R. Brown, Jones, Thonger, J. Bellamy, F. Gibson, A. Southall, J. Crookes, H. Sanderson, Snape, Grieves, Wilcox, Gould.

Cordial votes of thanks were given to the retiring President, Mr. W. Jones; Mr. F. S. Morris, Vice-President; Mr. Lucas, Treasurer; Mr. Stokes Dewson, Hon. Secretary, and Messrs. Grieves and Brown, Auditors, for their valuable services during the past year.

The best thanks of the meeting were also accorded to Mr. W. Southall, F.L.S, and Mr. F. J. Barrett, F.C.S., for their kindness in examining the papers of candidates for the Association prizes.

A lengthened discussion took place upon the Shepperley case, much satisfaction being expressed at the result of the trial; and a vote of thanks to the Chairman brought a very pleasant and successful meeting to a conclusion.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The tenth annual meeting took place at the Memorial Hall, Albert Square, on Wednesday evening, Nov. 13. Mr. J. T. Slugg, F.R.A.S., Vice-President, occupied the chair.

The minutes of the previous meeting having been read and confirmed, the Chairman called on Mr. Hermann Woolley, one of the Honorary Secretaries, to read the Annual Report, as follows:—

"Your Council regret that the record which they have to lay before you of the transactions of the Association during the past year does not offer much matter for congratulation,

"The first ordinary meeting of the session was held on Tuesday, December 11, 1877, when, in the unavoidable absence of Mr. Benger, a lecture by whom had been announced, Mr. Siebold kindly read papers on 'Tests for the Indication of Acidity and Alkalinity' and 'Poisonous Wall Papers.'

"A meeting was also held on Friday, February 1, 1878, when Mr. Benger exhibited and explained the principle of the telephone, after which a paper by Mr. J. B. Payne, on 'Patent Medicines, by Whom should they be Sold and under what Restrictions?' was read. Messrs. Kay Bros. also contributed a paper on the same subject; and, after considerable discussion, a resolution was passed to the effect that it was undesirable for the time to agitate for any alteration in the law as to the sale of patent medicines.

"At the last meeting of the session, on April 8, 1878, Mr. J. T. Slugg, F.R.A.S., Vice-President, delivered a short lecture on "Glass," and Mr. F. B. Benger, F.C.S., showed and explained some new and interesting forms of Geissler's tubes, after which the President, Mr. W. S. Brown, announced that he did not intend to accept nomination for re-election as a member of the Council of the Pharmaceutical Society, and proposed a resolution pledging the meeting to support Mr. G. S. Woolley as the representative of Manchester and the surrounding district, which resolution was carried unanimously.

"It is noteworthy that whereas there was only a meagre attendance at the first and last of the evening meetings, the second one, on the contrary, was largely attended, a fact which seems to indicate that trade questions are more attractive than scientific subjects to the majority of our members.

"During the early part of the session, the Honorary Librarian attended every Thursday evening at the Society's Rooms, Blackfriars Street, for the purpose of exchanging books, but reported that there were very few applications,—on the average two or three per week—and as this number subsequently fell still lower, it was decided in April last that such a small result did not justify the expense incurred in renting and maintaining the rooms.

"Accordingly the secretaries were instructed to make arrangements for the removal of the books, specimens and furniture belonging to the Association from the premises at 37, Blackfriars Street, and it remains with the present meeting to decide as to their future location.

"From inquiries that have been made, it is considered probable that arrangements might be made with one or two other scientific societies in Manchester to occupy jointly rooms with sufficient accommodation to contain the books, specimens, etc., of the several societies and to admit of their respective meetings being held therein on different evenings by mutual arrangement.

"The session of the school of pharmacy commenced September 28, 1877, and terminated May 3, 1878. The following lectures were delivered by Mr. Louis Siebold, F.C.S.: 35 on Pharmaceutical Chemistry; 30 on Materia Medica and Pharmacy; and 20 on Qualitative Analysis. Total, 85.

"In consequence of an insufficient number of entries the course of lectures on Botany was not given. Twelve students entered for the Chemistry, 13 for the Materia medica, and 8 for the Qualitative Analysis lectures; total number, 33.

"The fees were as follows:—Chemistry Course, £1 15*s.*; Materia Medica, etc., £1 10*s.*; Qualitative Analysis, £1; composition fee for the three courses, £3 10*s.* The total fees received amounted to £43 10*s.*

"The attendance of the students at the lectures was good and regular; but the extraordinary falling off in the number of entries from 84 last year to 33 is a subject for the deep concern of all who are interested in the objects for which this Association was formed."

The Treasurer, Mr. G. S. Woolley, presented the following statement of accounts:—

General Fund.

The balance sheet of the Library Fund showed a balance of £10 16*s.* 1*d.*, including the above item due from the General Fund.

Mr. Benger said it had struck him that at the conclusion of the tenth session of their Association a brief *résumé* of what had been accomplished might not be uninteresting, and possibly not altogether useless, especially as at the present moment they were somewhat depressed and disappointed, more ready to lament over their failures than to rejoice in their successes, and a little disposed to turn back in disgust from the plough to which in 1868 they set their hand. He was disposed to hope this retrospect might afford some encouragement. Mr. Benger then sketched the establishment of the Association in 1868, of Pharmacy Act renown, alluding to the enthusiasm which appeared to have suddenly kindled amongst the chemists of the district; the monthly meetings were crowded, so were the classes, one hundred and seventy-seven students having entered the first session, and two hundred and seventy-six persons connected themselves with the Association. The papers read at the evening meetings during the ten years' sittings of the Association were then enumerated, and the beneficial influence which many of these had exerted commented on. Members were reminded of the fact that upwards of six hundred lectures had been delivered in their school, and that some of the most distinguished students, medallists, and others, at Bloomsbury Square had acquired their first taste for science in the Manchester School of Pharmacy. More than fifty papers, many of very considerable importance, had been read at their evening meetings, and more or less fully reported. A small but valuable library of pharmaceutical literature had been formed. A price list, of much service to members, had been issued. Earlier closing had been promoted with some success, and many pleasant friendships had been formed. He hoped the Association had not entirely failed in the objects with which it charged itself ten years ago, and it remained with the members to decide whether the next decade should show a better or a worse result.

In moving the adoption of the report and Treasurer's statement, the Chairman said he regretted their respected President, Mr. Brown, was not able to be present through indisposition. He always discharged his duties in such a felicitous manner, that he, Mr. Slugg, felt that he should make a very inefficient substitute. Notwithstanding the desponding tone of the report which had been read, the history of their ten years, proceedings which had been presented to them by Mr. Benger proved that their Association had been anything but a failure. Looking at it as a whole it had been a great success. Considering the results, first as to the large number of young men who had, by the means which it had put within their reach, received a sound pharmaceutical education; also as to the good which had been effected throughout the whole trade of the district, by their price

list whereby much fairer prices for dispensing were now obtained; and also as to the much earlier closing of many establishments. He thought these results alone, even if there were no other, were sufficient to prevent them being ashamed of their past history. They must not give way to discouragement. Instances were to be seen all around of the alternation of success and failure. It was so with the trade of the country; first seasons of prosperity, then of commercial depression, then of returning prosperity; the tide ebbed and flowed. And if they looked above they found many of the stars, known as variables, shining for a season with considerable effulgence; then their brightness gradually faded until they seemed as if about to expire, when again their brilliance returned, and they shone with their former splendour. Let them hope it will be so with their Society, that although their former glory was just now dimmed, it would return again, and they would meet with even more success than in days gone by.

Referring to the recent prosecutions for counter prescribing, the Chairman said he agreed with the Editor of the *Pharmaceutical Journal* in considering that the question was not yet satisfactorily settled. Neither indeed would they be able to settle the question, he thought, but upon the principle—at which they must arrive some day, though it would not be in his day—of the shoemaker sticking to his last. Let the medical man find the advice and the druggist the medicine. Then all temptation would be removed from the druggist to prescribe. If this arrangement were enforced it would be better for the doctor, he would have more patients and would be able to save the expense of drugs and a dispenser; it would also be better for the druggist, as he would have more custom; and better for the patient, for undoubtedly in the end it would be cheaper for him.

Mr. Boden seconded the adoption of the report which was unanimously agreed to.

Mr. G. S. Woolley said that the books and specimens belonging to the Association were at present placed in a room on his premises, 69, Market Street, where they might be referred to by members and associates.

The Chairman then announced that it had been suggested to defer the election of officers until the next monthly meeting, which would be held in that hall on Wednesday evening, December 11. It might possibly be thought desirable to make some alteration in the executive, to infuse a little new blood in fact, and this adjournment of the annual meeting would afford members an opportunity to nominate any persons they might consider suitable to hold office. Nominations must be in writing and addressed to the Secretaries, in whose hands they must be not later than December 1, ten days before the meeting. This course was unanimously agreed upon, and it was further announced that at the adjourned meeting Mr. J. B. Payne would read a paper on "The New Weights and Measures Act as affecting Chemists and Druggists," a subject, the importance of which it was hoped would attract a large meeting.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, November 5, a lecture was delivered in the rooms of the above Association, Halford Street, by Mr. W. B. Clark, on "Bones and their Derivatives." The President, Mr. Brampton, occupied the chair. The lecturer gave a very minute description of the processes for the manufacture of the various products, also their uses and medical properties. All the terms used were also explained so that the lecture was instructive and interesting to all present.

A vote of thanks was proposed to the lecturer by Mr. Brampton, and seconded by Mr. Thirlby, and carried unanimously by the members.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The first meeting of the session of this Association was held at the rooms, Britannia Chambers, Pelham Street, on Friday, November 8, 1878. The chair was occupied by the President, Mr. R. FitzHugh, F.C.S., and there was a fair attendance of members and associates.

After the minutes of the last meeting had been read and confirmed, the Honorary Secretary, Mr. R. Jackson, announced that the *Pharmaceutical Journal* had been received regularly since the last meeting, and a vote of thanks was awarded to the donors.

Two new members and thirteen associates were elected.

The President then presented the prizes to the successful associates in last session's classes, accompanying each with a few suitable remarks. Mr. J. Brown took first prize in Inorganic Chemistry, and also in the afternoon Botany class; Mr. Young also took two prizes, and the others were awarded to Messrs. H. Clower, F. Savage and F. C. Shaw.

The President then delivered his inaugural address, which was devoted to a sketch of the position of the Association and the work that had been done in the past, and what was proposed for the immediate future. The address, which was eminently practical, was listened to with great attention, and applauded at the close.

Mr. Lewis in a few well chosen remarks proposed a vote of thanks to Mr. FitzHugh for his interesting address, which was seconded by Mr. Bolton in a lengthy speech and supported by Mr. Warriner and Mr. Rayner, and carried unanimously.

Mr. FitzHugh suitably responded, and announced that the next meeting would be held on December 11, when the council had made arrangements with Mr. H. Major, B.A., F.R.G.S., to deliver a lecture on "The Deep Sea," and he hoped to see a good attendance.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

A meeting of the Executive Committee of this Association was held at the office, 23, Burlington Chambers, New Street, Birmingham, on November 13, 1878, at 1 p.m.; Mr. Thomas Barclay (Birmingham) Vice-President in the chair.

Present—Messrs. Andrews (London), Arblaster (Birmingham), Cross (Shrewsbury), Cubley (Sheffield), Delves (Exeter), Fairlie (Glasgow), Greaves (Chesterfield), Hampson (London), Holdsworth (Birmingham), Jervis (Sheffield), Kerr (Dundee), Shaw (Liverpool), Walker (Coventry), Southall (Birmingham), and the Solicitor of the Association.

The minutes of the Executive Committee meeting held on May 27 last, and of the meetings of the Sub-Committee held since that date, were read and confirmed.

The report of the Law Committee was then read. It dealt with prosecutions instituted against chemists and druggists by the Apothecaries' Company, with the action taken by the Committee in regard to the Medical Bills, which came before the Legislature during the last session, and with the various cases in which members had been defended by the Association in actions brought against them under the Adulteration Act.

Mr. Shaw said he thought the decision arrived at by the Law Committee in reference to cases in which members had been defended for alleged infringements of the Adulteration Act must commend itself to them all, but with regard to Wiggins's case; in his opinion the Executive should have been called together prior to a defence of that being ordered. By the tenth rule of the Association the Executive was empowered to determine when action should be taken in cases suggested to it for prose-

cution or defence, and before a case was defended the whole particulars respecting it should be ascertained and considered.

The Secretary said that the Law Committee were by a resolution passed by the Executive, especially empowered to deal with such cases.

The Vice-President said that the action of the Association in regard to Wiggins's case had been in certain quarters misrepresented and very generally misunderstood. At the time Mr. Wiggins was sued by the Apothecaries' Company for the sum of £40, he had an interview with the members of the Law Committee, and was fully and carefully questioned by the members of that Committee as to the nature of his business. His replies to the questions put to him being satisfactory a resolution was passed instructing the Solicitor to put in an appearance to the writ with a view to obtain particulars of the cases in which it was alleged that the defendant had acted and practised as an apothecary, as no particulars were stated on the writ. On an appearance being entered to the writ particulars were asked for, and refused by plaintiffs. An application was then made to a judge in chambers for an order to compel plaintiffs to furnish particulars, when Mr. Baron Cleasby ordered particulars to be given. The particulars that were then furnished consisted of certain names of persons, no addresses or information as to the nature of the complaint. Counsel then applied to a judge for an order for additional particulars, which was refused, and in the opinion of counsel it was considered unwise to appeal against this decision, so that until the witnesses for plaintiffs gave their evidence the Solicitor of the Association had no idea of the specific charges that were to be brought against the defendant. He continued to say that as the new trial in Shepperley's case was at that time pending, the Association would have failed in protecting the interests of the trade had it permitted an action, the particulars of which were unknown, and which might at the trial have proved to be a case of the most simple and trivial description of counter practice, to pass undefended.

Mr. Hampson said that every care had been taken to ascertain the facts in the case, and he thought the Law Committee were in no way responsible for the adverse result of the trial. He did not regard the decision as entirely unfavourable to the trade, because the finding of the jury was not simply that the defendant had acted as an apothecary, but that he had acted and practised as an apothecary in taking cases that were dangerous.

Mr. Andrews said that he and others had been appointed by the Executive to watch the hearing of this case, and it was considered advisable to let the case go to the jury.

Mr. Fairlie said the case came before the Executive at its meeting in London prior to the last annual meeting, and he did not think the Association could have done otherwise than defend Mr. Wiggins.

Mr. Cubley thought it would be well if the powers granted by the Executive to the Law Committee in the resolution referred to by the Secretary were renewed from year to year, as it would be inconvenient to call the Executive together to discuss every case that might arise.

Mr. Holdsworth thought the Law Committee should have more definite instructions than were contained in the resolution.

Mr. Shaw said he had no motion to make on the subject; what he had said had been in a friendly spirit. He simply called the attention of the Executive to the matter, and if the gentlemen present were satisfied with the facts and circumstances as they existed with regard to this rule he had nothing more to say.

It was moved by the Vice-President, seconded by Mr. Andrews, and unanimously resolved :—"That the report of the Law Committee be received, adopted and entered on the minutes."

The report of the Finance Committee was then read.

Mr. Fairlie said he found great difficulty in obtaining donations in Scotland at that time, particularly in Glasgow, but he hoped things would improve towards the close of the year, and he would move—"That the report of the Finance Committee be received, adopted and entered on the minutes."

Mr. Hampson, in seconding the resolution, said he thought at the present time a good opportunity existed of increasing their funds, as the decision in Shepperley's case had given great satisfaction to the trade and there was a spirit of rejoicing abroad. It must be quite evident to all that the Association could not continue to carry on the defences of trade rights and privileges unless substantial financial support was forthcoming, and he trusted a report of the proceedings of the trial would be issued from the office, making known their want of funds.

Mr. Arblaster said that at the annual meeting of the Midland Counties Chemists' Association, held the preceding day, £10 had been voted to the funds of the Trade Association.

The resolution was then put to the meeting and carried unanimously.

The Vice-President said that it might be advisable to consider the question raised by Mr. Hampson. They were embarked in a heavy law suit, which might ultimately be carried to the House of Lords, and it would be well to consider the means by which funds were to be raised for carrying on the work of the Association.

After some discussion on the advisability of making a spirited appeal to the entire trade for support, it was moved by Mr. Greaves, seconded by Mr. Cubley, and unanimously resolved :—"That the Law Committee be hereby empowered to take such action as they deem desirable in regard to the case of the Apothecaries' Company *v.* Shepperley."

It was moved by Mr. Fairlie, seconded by Mr. Hampson, supported by Mr. Jervis, and unanimously resolved :—"That an abstract of the report of the hearing of the new trial of the case of the Apothecaries' Company *v.* Shepperley be prepared under the direction of the Finance Committee, printed and issued to the trade."

In reply to questions, the Solicitor said that with regard to the case of the Apothecaries' Company *v.* Shepperley, plaintiffs' solicitor had intimated to him that it was their intention to apply for a new trial; this might be done on the grounds of misdirection of the jury, wrongful admission or exclusion of evidence, or that the verdict was against weight of evidence.

Mr. Shaw asked if the Solicitor thought any of these circumstances existed.

The Solicitor said in his opinion they did not.

Mr. Delves inquired if the plaintiffs had any further appeal if their motion for a new trial was refused.

The Solicitor said in that case they might appeal on a point of law to the Court of Exchequer, from there to the Lords Justices of Appeal, and then to the House of Lords.

Mr. Cubley said there appeared to be no end to it.

The Solicitor said the House of Lords was the termination.

The Vice-President then called upon Mr. Fairlie to move a resolution of which notice had been given.

Mr. Fairlie then moved the following resolution :—"That a sub-committee be appointed to consider the desirability of this Association taking official action in the next election of the Pharmaceutical Council by promoting the candidature of at least seven gentlemen who will pledge themselves to support trade interests." He said he was formerly somewhat opposed to the Association taking any decided action in the matter before the meeting, but he must say that within the last few months his eyes had been slightly opened with regard to the position of affairs in relation to the Pharmaceutical Council as then constituted. He thought that Council

should have some control over the editorial articles in the *Pharmaceutical Journal* so long as that Journal was the property of the Pharmaceutical Society; but it was evident to all of them that the Executive of the Association had not been treated well by the Editor of the Journal, yet the Council did not interfere. It had been shown time after time that by the present mode of electing members of Council the majority of the trade did not know for whom to vote, and a large portion of the voting power was not employed at all. The power to sue illegal traders for penalties under the 15th section of the Pharmacy Act was vested in the Council, and unless the majority of the Council were prepared to vigorously enforce that section it became worthless. Amendments of the Pharmacy Act were urgently needed, and a committee appointed by the Council to ascertain what amendments were required, but he did not apprehend anything very vigorous would come of the matter. It had been suggested that the Legislature should be requested next session to repeal the 20th, or penal clause of the Apothecaries' Act under which many vexatious prosecutions had been brought against chemists. But would the present Pharmaceutical Council assist the trade in such an endeavour? He thought not. If they were to have the true interests of the trade carried out there must be a majority representing those interests on the Pharmaceutical Council. The minds of the gentlemen present had been fully drawn to the question, and what they had to consider was whether the time had arrived when some action should be taken. In his opinion it had.

Mr. Cross said it appeared to him that chemists were at present assailed by numerous enemies, and the Association, being in existence for the defence of chemists, would not be doing its duty unless it did all that lay in its power to present a solid front to the enemy, and if they were moving in one direction and the Council of the Pharmaceutical Society in another, little good would result. It was an acknowledged fact that the Association had done much good work already, and he thought the Pharmaceutical Council should consist of gentlemen willing to assist it in that work. He therefore had much pleasure in seconding Mr. Fairlie's resolution.

Mr. Walker, in supporting the resolution, said the election of any man who would infuse into the Bloomsbury Square Council a little go-a-head spirit would be an advantage to the trade.

Mr. Jervis said he thought the time had arrived when action must be taken in the matter. There were some good men on thc Council, but more must be added.

Mr. Kerr supported the motion. He said that in carrying it out the Association would be taking the best possible steps to advance the general interests of chemists.

Mr. Hampson said that he thought the step suggested by Mr. Fairlie's resolution required great consideration. The Association, although young, had shown signs of possessing great vigour and strength, and he thought it would soon be found to have considerable weight with the trade, and it would so be able to reflect its opinions and thereby influence indirectly yet very potentially the election of the Pharmaceutical Council. He would ask the gentlemen present to hesitate before they agreed to the resolution proposed. If there were very grave dangers and issues before them, that required as it were immediate decision, he would, under certain conditions, support the resolution before the meeting; but such a state of things did not then exist. It should be borne in mind that the Pharmaceutical Council was compelled by Act of Parliament to perform other functions than those relating to matters of trade interest; he might mention that it was an educational and examining body;—and he thought it would be unwise to import into that Council too large an admixture of advocates for the advancement of trade matters. It was, however, extremely desirable that questions affecting the interests of the trade should receive more attention and better consideration than the present Council thought fit to bestow on them. He hoped that the motion would not be pressed.

Mr. Greaves said he thought the time had come when they should take action in the matter. Nothing had convinced him more than the leader in the *Pharmaceutical Journal* of November 9, that the trade had nothing to hope for trade interests in that quarter.

Mr. Shaw said it was undesirable to make trade questions so prominent as to exclude others at the Council Board, and it would be a mistake to develop party feeling between the Societies.

Mr. Andrews said he should like to ask if gentlemen elected on the Council of the Pharmaceutical Society to represent trade interests would necessarily neglect educational and scientific matters? Was it not possible to find candidates who would take an interest in all these questions?

Mr. Cubley said he and many others were tired of constantly seeing some few members of the Council endeavouring to assist the trade from time to time and having their efforts repelled by the majority.

Mr. Churchill said there could be no doubt that the Association was not fairly represented on the Council, but there had latterly been an improvement in that respect, and it was quite probable they might have an acquisition of two or three members at the next election. To his mind it was questionable whether they would not be doing more harm than good by officially placing members of the Association on the Council of the Pharmaceutical Society.

Mr. Arblaster said that as there was no need to hurry the decision of this question he thought it would be advisable to defer the final consideration of the proposal until the next meeting.

The Vice-President pointed out that the motion before the meeting was simply a resolution suggesting the appointment of a sub-committee to consider the question.

Mr. Hampson said he should move an amendment unless Mr. Fairlie curtailed his motion, letting it terminate at the words "Pharmaceutical Council."

Mr. Holdsworth said he thought Mr. Fairlie might very well adopt Mr. Hampson's suggestion, as the curtailment did not interfere with the spirit of the motion, seeing that no decided action could be taken until the Executive was in possession of the report of the sub-committee.

Mr. Fairlie said he had obtained the permission of his seconder to amend the motion to meet Mr. Hampson's, views, and he should ask the Vice-President to put the resolution to the meeting in the following form:—"That a Sub-Committee be appointed to consider the desirability of this Association taking official action in the next election of the Pharmaceutical Council." The resolution was carried *nem. con.*

It was moved by Mr. Fairlie, seconded by Mr. Delves and unanimously resolved:—"That the Sub-Committee consist of the officers of the Association, together with Messrs. Arblaster, Cross, Cubley, Earle, Greaves, Jervis, Reynolds and Walker."

Some discussion took place on the advisability of adding to the Law Committee a member of the Executive residing in Scotland, when it was moved by the Vice-President, seconded by Mr. Hampson and unanimously resolved:—"That Mr. J. M. Fairlie be appointed a member of the Law Committee."

It was moved by the Vice-President, seconded by Mr. Walker and unanimously resolved:—"That Messrs. Andrews, Churchill, Fairlie, Greenish, Hampson and Shaw be appointed a Sub-Committee to consider the advisability of publishing a quarterly or monthly report of the proceedings of the Association for circulation among the members, and to report on same to the Executive."

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting held in the Association's room, 32a, George Street, Hanover Square, W., on Wednesday, October 23, Mr. F. W. Branson read a paper on "The Chemistry of Aloes." After describing the more important varieties of aloes, a detailed account of the modes of preparation was given as helping to explain the varying quantities of mucilaginous matter which ordinary commercial samples contain. The isolated position of the vessels containing the bitter juice of the plants was pointed out. The preparation of the different aloins was fully described, and the decompositions they undergo when treated with oxidizing and other agents explained. The residual portion of aloes obtained in the preparation of the extract was shown, and the relative percentage of the so-called resin, which is rendered permanently soluble when treated for a lengthened period with boiling water, given. The paper concluded with some remarks upon the loss of bitterness which takes place in the compound decoction and wine of aloes when kept for some time. Specimens of nataloin, barbaloin, socaloin, chrysammic acid and the bromo-derivatives of barbaloin, prepared by the author, were shown, and a number of slides illustrative of the paper exhibited under the micropolariscope.

The paper was followed by a good discussion. After a vote of thanks to Mr. Branson the meeting terminated.

At a meeting held on October 30, Mr. W. K. Glover read a paper entitled "The Genus Quercus and its Pharmaceutical Interest." Special attention was directed to the two official species, *Q. pedunculata* and *Q. infectoria*, and the non-official *Q. suber*, which supplies the invaluable substance, cork. That oak bark has never beeen greatly esteemed as a medicine, but chiefly used for tanning purposes, and the fact that quercitannic acid does not yield gallic acid by oxidation was mentioned. The production of galls on the leaves and young shoots of *Q. infectoria* by the female of the fly *Diplolepis Gallæ tinctoriæ* was explained. Allusion was made to the excrescences produced on other plants by insects of class cynipida. The composition of galls was stated, the percentage of tannin being given as 60 to 70 per cent. in good samples. Mention was made of the earliest notice of chemical reaction being connected with galls. A good description of the *Q. suber* was given and the stripping of the stem explained. The manufacture of corks for stopping vessels was also described, and the various purposes to which cork has been applied enumerated.

The paper was followed by a short discussion. After a vote of thanks to Mr. Glover the meeting terminated.

CHEMICAL SOCIETY.

A meeting of this Society was held on November 7, Dr. Gladstone, President, in the chair. After the confirmation of the minutes of the last meeting, etc., the following certificates were read for the first time, W. J. Noble, L. Green, H. Green, H. J. H. Fenton, H. T. Cheshire, G. H. Hatter, Kingo Takemura, D. McAlpine, Shigetake Sugira, E. Waller, H. Eccles, and A. E. Arnold.

The following papers were read—

Contributions from the Laboratory of the University of Tokio, Japan, on the Red Colouring Matter of the Lithospermum Erythrorhizon. By M. Kuhara. The root of the above plant occurs in commerce in thick lumps, purple externally, but yellowish-white inside. It was largely used for the manufacture of "Tôkio purple," but from the fugitive character of the colour and the introduction of aniline dyes, its use has becn almost abandoned. The root contains about 10 per cent. of glucose and 4 per cent. inverted sugar. The purple colouring matter is extracted almost completely by alcohol, and resembles, in some respects, anchusin, the colouring matter of alkanet; it is prepared from the root by extraction with alcohol, acidulating the extract with hydrochloric acid and distilling off the alcohol. The impure colouring matter thus obtained was purified by precipitation with plumbic acetate, etc., in the usual way. It was finally obtained as a dark resinous uncrystallizable mass with a metallic green reflection; it is soluble in alcohol, ether, benzol, oil of turpentine, methylic alcohol and carbon disulphide, but almost insoluble in water; it has a feebly acid reaction and a peculiar odour; it softens at 95° C., and then partially volatilizes in red fumes, which condense on the colder part of the tube. The alcoholic solution has an absorption spectrum resembling that of alkanet; stannous chloride decolorizes the solution. It has the formula $C_{20}H_{30}O_{10}$. A barium salt was prepared and decomposed. The paper also contains an account of a bromine and a chlorine compound. Further experiments are in progress.

Dr. Gladstone drew attention to the activity prevailing in the laboratories in Japan, and Dr. Frankland said that the Society was much indebted to its Fellows in Japan for examining substances which could not be obtained here, and such researches as the above were always very welcome. The best thanks of the Society were then given to the author for his communication.

Dr. Wright then read—

A Second Report on some points in Chemical Dynamics.—By C. R. A. Wright and A. P. Luff. In the former report it was shown that no practical difference exists between the temperatures of initial action of carbon oxide, hydrogen and carbon, respectively, on cuprous oxide and on cupric oxide, provided the physical state of the two metallic oxides is approximately the same. The authors find that the same rule applies to the oxides of iron. By leading a mixture of equal volumes of carbonic oxide and carbonic acid over pure Fe_2O_3 at a bright red heat, an iron oxide closely approximating to FeO is formed, the composition $Fe_{16}O_{17}$ being attained in eight hours, and remaining unchanged during a second eight hours' exposure. Samples of pure ferric oxide prepared by ignition processes, when compared with this oxide and with Fe_3O_4 from purified scales of boiler-plate rolling, gave the following temperatures of initial action (tested by baryta water, loss of weight during fifteen minutes' exposure, as previously described, and corrected in the case of $Fe_{16}O_{17}$ for gases occluded by the substance, such gases not being contained in the other specimens).

Reducing agents.	Fe_2O_3.		Fe_3O_4.	$Fe_{16}O_{17}$.
	From ignition of $FeSO_4$.	From ignition of ppted. Fe_2O_3.		
CO . . .	202	220	200	275
H . . .	260	245	290	305
Carbon .	430	430	450	450

Hence, probably, the "heat of formation" of all the oxides of iron is much about the same, just as with Cu_2O and CuO, calculated per constant quantity of oxygen. Julius Thomsen finds the heats of formation of ferrous hydrate FeO,H_2O and ferric hydrate $Fe_2O_3,3H_2O$ are respectively 68280 and 191130, or 68280 and 63710 per 16 grams of oxygen.

Magnetic oxide of iron that has been fused and contains titanic oxide, etc. (New Zealand iron sand), is much less readily reduced than the porous boiler plate scales; the temperature found for CO, H and C being respectively 360—420, a few degrees higher and about 480. That CO will reduce at a lower temperature than H was shown by sealing up iron sand in tubes filled with the

two gases and heating to 360 for several hours; CO_2 was formed in the first tube, but no conversion of H into H_2O took place. In the case of the oxides of manganese the instability of manganese dioxide on heating would naturally lead to the idea that the heat of formation of MnO_2 is considerably less than that of a lower oxide (reckoned per constant quantity of oxygen). J. Thomsen finds that the heats of formation of $MnOH_2O$ and MnO_2H_2O are respectively 94770 and 116280, or 94770 and 58140 per sixteen parts of O; in accordance with the thermic rules previously deduced, reduction of MnO_2 should commence at a much lower temperature than that required for lower oxides. On comparing various oxides of manganese the following numbers were obtained:—

	Essentially MnO_2.		
Composition by analysis.	Mn_7O_{13}.	$Mn_{15}O_{28}$	Mn_5O_7
Physical texture.	Amorphous fine powder.	Crystalline compact.	Fine powder amorphous
CO begins to act . .	below 15	87	97
H „ „ . .	145	190	240
C „ „ . .	260	390	410
First evolution of oxygen	„ 260	390	Nearly white heat.

Composition by analysis.	Mn_3O_4	Manganous oxide MnO.
Physical texture.	Fine powder amorphous.	Amorphous.
Temperature of CO action	240	No action at 600.
„ H . . .	255	„
„ Carbon .	430	„
First evolution of oxygen.	No action at white heat.	„

The oxide Mn_7O_{13} was prepared by warming potassium permanganate with nitric acid; when dried at 100 it had the composition $Mn_{21}O_{39},5H_2O$, becoming anhydrous at 200 without loss of oxygen. Another oxide prepared by precipitating pure $MnCl_2$ by KHO, and digesting in the cold with excess of bromine, contained when dried at 100° $Mn_{11}O_{20},4H_2O$. The oxide $Mn_{15}O_{28}$ was a finely crystallized natural pyrolusite. The oxide Mn_5O_7 was prepared by roasting at a red heat manganous carbonate, whilst the Mn_3O_4 was obtained by long continued ignition over a powerful gas blowpipe of the Mn_5O_7, and the MnO by igniting the same in H. The authors find that the oxide formed by igniting in a platinum capsule over an ordinary large Bunsen burner either $MnCO_3$ or precipitated MnO_2 invariably contains much more oxygen than Mn_3O_4, which can only be obtained by long continued heating almost to whiteness over a glass blowpipe. Accordingly serious errors are apt to be introduced in manganese determinations by following the directions of the text books and igniting $MnCO_3$, etc., until they cease to gain in weight. Precisely similar results were obtained with various oxides of lead, thus:—

Composition by analysis.	Litharge PbO.	Red lead Pb_5O_6.	Dioxide $Pb_{11}O_{21}$.
Initial temperature of CO action . . .	160–185	200	80
Initial temperature of H	190–195	230	140
Initial temperature of Carbon	415	330	260
Initial temperature of evolution of O . .	—	above 360	260

Nickel and cobalt oxides yielded precisely similar results. The monoxides of these metals were prepared by Russell's process (strong ignition in CO_2), the superoxides by precipitating with alkalies and digesting with excess of bromine; in all cases the same results follow as with manganese and lead, *i.e.*, that the superoxide is first reduced at much lower temperatures than the monoxide.

Composition by analysis.	Cobalt. CoO.	$Co_{12}O_{19}$	Nickel. NiO.	Ni_9O_{11}.
Temperature of initial action of CO . . .	155	below—11	120	30
Temperature of initial action of H . . .	165	110	220	65
Temperature of initial action of C . . .	450	260	450	145
Temperature of evolution of oxygen . .	—	260	—	145

In no case, out of very many examined, has any exception been found to the general rule that the temperature of the action of CO lies below that of H, which again is below that of carbon. This rule, as well as each of the other observations made, appears to be a special case governed by the general law that, *cæteris paribus*, the greater, algebraically speaking, is the heat evolution taking place during a reducing action on a metallic oxide the lower is the temperature at which the action is first noticeable during a few minutes' action. Incidentally the authors have made some experiments on the absorption of CO and CO_2 by metallic oxides, from which they conclude that whilst a carbonate sometimes results by the action of CO on a superoxide, the action is not one of direct combination (as, for instance, with lead), $PbO_2+CO=PbCO_3$, but takes place in two stages: $PbO_2+CO=PbO+CO_2$ and $PbO+CO_2=PbCO_3$. In the case of manganese the combination of monoxide and CO_2 only takes place when both are nascent, which condition is not requisite with lead.

After some remarks by Messrs. Neison, Kingzett, and Perkiss,

Dr. Frankland read a *Note on the Constitution of the Olefine produced by the Action of Zinc upon Ethylic Iodide.* By Dr. Frankland and Mr. Dobbin.—This short paper contains an account of experiments made to determine the question whether the gas given off in the above reaction was ethylene $\left\{\begin{matrix}CH_2\\CH_2\end{matrix}\right\}$ or ethylidene $\left\{\begin{matrix}CH\\CH_3\end{matrix}\right\}$. Many litres after passing through alcohol and sulphuric acid were led into a long bulb tube, containing antimonic chloride. The contents of the bulb tube were finally mixed with water and distilled. The boiling point, as determined by Chapman Jones's method, was 83° C., and was therefore that of ethylenic and not of ethylidenic chloride, the latter substance boiling at 60°.

In answer to a question of Dr. Armstrong, Dr. Frankland said that although his expectations of obtaining ethylidene were certainly less than before, he should be very sorry to say that it did not exist, and would be still inclined to try further experiments if a reaction could be discovered to eliminate C_2H_4 at a low temperature.

On the Occurrence of Certain Nitrogen Acids amongst the Products of Combustion of Coal Gas and Hydrogen Flames. By L. T. Wright.—The apparatus of the London Gas Referees for determining the sulphur in coal gas was used by the author throughout his experiments. The combustion of 1000 litres of ammonia-free coal gas in a Bunsen burner gave 0·00051 gram nitrogen as HNO_3, and 0·00058 gram nitrogen as HNO_2. 1000 litres of coal gas charged with ammonia gave 0·01071 gram N as HNO_3 and 0·00168 gram N as HNO_2.

The combustion of 1000 litres of coal gas charged with ammonia in a normal atmosphere, in a Bunsen burner with air holes closed, gave 0·01595 gram N as HNO_3 and 0·00238 gram as HNO_2.

The combustion of 1000 litres of ammonia-free coal gas in an atmosphere charged with ammonia, in a Bunsen burner, gave 0·03938 gram N as HNO_3 and 0·1115 gram as HNO_2.

When hydrogen passed over strong sulphuric acid was burned in an ordinary atmosphere, about 0·013 gram N as HNO_3 and 0·0002 gram N as HNO_2 were produced per 1000 litres; when the air was thoroughly purified by passing over strong sulphuric acid, etc., no nitric acid, and less than 0·00001 gram N as HNO_2 were obtained.

By a still more efficient purification of both hydrogen and air the condensed water was obtained free from nitrates and nitrites.

The author in conclusion expresses his belief that the origin of the nitrogen acids found in the condensed water, procured by burning coal gas or hydrogen in the air, is ammonia, either free or combined.

Dr. Frankland said that the experiments just detailed raised some interesting points as regards the combustion of coal gas. In the combustion of ammonia-free coal gas. the temperature never rose high enough to cause the oxidation of any large amount of nitrogen. An interesting experiment on the subject was the following:—If a jet of hydrogen be lighted in a glass bell jar, no red fumes are formed, but on adding oxygen to the atmosphere an increase of temperature soon produces preceptible red fumes in the bell jar. In connection with the arc of the electric light, the temperature of which must be enormously high, it would be most important and interesting to determine whether any oxides of nitrogen were formed and in what quantity.

On the Action of Bromine upon Sulphur. By J. B Hannay.—In former papers the author showed that when sulphur and bromine were distilled together, distillates of any desired composition might be obtained, but that the residue was never free from bromine. The author in the present note attributes this retention of bromine to the sulphur passing into the viscous state and finds that at 15° complete dissociation can be effected.

Researches in Dyeing. Part I., Silk and Rosanilin. By Dr. Mills and G. Thomson.—The authors have investigated the nature of the transaction which occurs when a vat is exhausted of its tinctorial ingredients. The experiments consisted in immersing a constant area of white silk in a solution of rosanilin acetate, etc., at a constant temperature, for varying times, and determining the loss of strength of the rosanilin solution. They have arrived at the following conslusions:—1. That when silk is dyed with rosanilin salt, that salt is deposited as a whole. 2. That a boiling weak solution of rosanilin salt may undergo dissociation so as to become quite colourless, in which state, however, the dissociating force is wholly overcome by silk (*i.e.* silk is dyed red by immersing it in a solution containing 0·0000003 gram in 1 c.c., previously rendered colourless by boiling for half-an-hour). 3. That for periods of four days, at the ordinary temperature, a magenta vat is exhausted at compound interest. 4. That the rate of exhaustion of a magenta vat is retarded by sodic or potassic chloride, and not improbably to an equal extent by equal weights of those chlorides.

Comparison of the Actions of Hypochlorites and Hypobromites on some Nitrogen compounds. By H. J. H. Fenton.—Both the above reagents act rapidly on ammonium carbamate, but as with urea, only half the nitrogen is evolved with hypochlorite, whilst hypobromite causes the evolution of the whole of that gas. The residue from the hypochlorite does not contain nitrogen as a cyanate, but probably in the form of sodium carbamate. Guanidine yields to both reagents two thirds of its nitrogen. The residue behaves like that from the action of hypochlorite on urea. Biuret gives one third of its nitrogen with hypochlorite and two thirds with hypobromite, the residues resemble those from urea.

The author's results are given in the following table:—

	Urea.	Ammonium carbamate.	Guanidine.	Biuret.	Ammonia salts.	Cyanates.
NaClO evolves	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{2}{3}$	$\frac{1}{3}$	all	none
NaBrO . . .	all	all	$\frac{2}{3}$	$\frac{2}{3}$	all	none

In conclusion the author discusses the formulæ of the above bodies.

Notes on Two New Vegeto-Alkaloids. By F. Von Muller and L. Rummel.—Alstonin is obtained from the alcoholic extract of the bark of *Alstonia constricta;* it forms an orange yellow brittle mass, of a bitter taste, melts below 100° C., is soluble in alcohol, ether and dilute acids, sparingly soluble in water; dilute solutions have a strong blue fluorescence, which is unaffected by acids and alkalies; it is precipitated by the usual alkaloid reagents. Duboisine is a volatile alkaloid obtained from the leaves and twigs of *Duboisia myoporoides* by a process similar to that employed for the extraction of nicotine. Duboisine is probably identical with Staiger's piturine. Duboisinc is a yellowish oily liquid, lighter than water, with a strong narcotic odour and alkaline reaction. It is very soluble in ether, alcohol and water, and is not precipitated by phosphomolybdate of soda, picric acid or platinic chloride.

On the Determination of Lithia by Phosphate of Soda. By C. Rammelsberg.—Berzelius detected lithia in Carlsbad water by evaporating the solution of the alkalies with phosphoric acid and sodium carbonate. On treating the whole with water an insoluble phosphate of sodium and lithium remained. This double salt the author has shown to be a variable mixture of the two phosphates. Mayer, however, contradicted these results, and denied the existence of a double phosphate, and contended that the above residue was pure lithium phosphate. The author has repeated his former experiments and completely confirmed them, preparing synthetically double salts, having sodium to lithium as 1 to 3 or 9 to 2, and therefore the author concludes that lithium cannot be determined by Mayer's method, which is also recommended by Fresenius. The employment of this process for the estimation of lithium in micas has led to too high a percentage of lithium. The author in conclusion gives analyses of micas, especially as regards lithium; the lithium and sodium chlorides being separated by treatment with ether alcohol, as suggested some time ago by the author.

The Society then adjourned to November 21, when the following papers will be read:—The Processes and their Comparative Value for Determining the Quality of Organic Matter in Potable Water, by Dr. Tidy; A Chemical Study of Vegetable Albinism, by Professor Church; Researches on the Action of the Copper-Zinc Couple on Organic Compounds, by Dr. Gladstone and Mr. Tribe; On a New Gravimetric Method for the Estimation of Minute Quantities of Carbon, by Drs. Dupré and Hake.

A special meeting of the Society was held on Tuesday, November 12, to hear the Faraday Lecture, which was delivered at the Royal Institution by Professor A. Wurtz, and was entitled "La Constitution de la Matière à l'Etat Gazeux." The President, Dr. Gladstone, introduced the lecturer as an investigator whose beautiful researches were known to all chemists, and expressed his conviction that he would be welcomed not as a stranger, but as one with whom, although he lived on the other side of the water, the fellows through his work were well acquainted.

The lecturer commenced by expressing his sense of the great honour which had been conferred on him by inviting him to speak in a theatre sacred to the name of Faraday. The subject of the evening's lecture, the constitution of matter in the gaseous condition, was one of great interest, both to physicists and chemists. He would consider the subject first from a physical and finally from a chemical point of view. For a long time gases and vapours were separated from each other by the distinction that vapours could be condensed to fluids, whilst gases were not so condensible. This distinction has gradually been broken down, the line of demarcation has disappeared, and the existence of a body in the state of gas or liquid has been reduced to a simple question of temperature and pressure. Young Faraday while assistant at the Royal Institution read a paper before the Royal Society on fluid chlorine. In it he described the liquefaction of that gas (the classical glass tube in which this was first effected was exhibited). The method of experimenting was simple: chlorine hydrate was placed in the one leg of a bent tube which was heated, the gas was disengaged and liquefied by its own pressure in the other leg. Very soon liquid hydrochloric acid was prepared in a

similar manner by heating in a sealed tube ammonium chloride and sulphuric acid, and in the course of the year Faraday succeeded in liquefying many other gases, sulphurous acid, ammonia, cyanogen. Liquid ammonia was produced by heating argentic chloride saturated with ammonia at a low temperature in one leg of a bent tube, the other leg being immersed in a freezing mixture ; this experiment was repeated and the liquid ammonia shown. In all these instances the gases were disengaged in closed spaces and liquefied by their own pressure. Pressure was the principal agent employed. The lecturer then threw on the screen the image of a capillary tube connected with a small glass tube containing mercury cyanide; the cyanide was heated and gradually from the disengagement of cyanogen and the increase of pressure, first drops and then liquid appeared in the capillary. On cooling the tube the liquid gradually disappeared, and the capillary tube became again empty of liquid. Some gases resisted, however, all attempts to reduce them to the liquid state, even when enormous pressures were employed. From Andrews's researches on the continuity of the liquid and gaseous states it was proved that for every liquid there is a temperature, the "critical point," above which it is impossible for the liquid to exist as such, however, enormous the pressure may be. It must assume the gaseous condition. The lecturer then proceeded to give an eloquent explanation of the liquid and gaseous states according to the dynamical theory so completely developed by Clausius, Clerk Maxwell, etc., and showed how beautifully this theory explains the phenomena referred to above. An experiment performed in an exceedingly elegant manner was here introduced showing the continuity of the liquid and gaseous states. The image of a tube three parts filled with liquid carbonic acid was thrown on the screen, the dark meniscus of the liquid was well defined ; on heating the tube, this dark line became gradually fainter and fainter and the boundary line between the liquid and gaseous states of matter flickered for an instant and then the whole tube was filled with gaseous carbonic acid under enormous pressure, but above its critical point. On cooling, the beautiful dark cloud effect was magnificently shown, for an instant the upper part of the tube was quite black and opaque, the mixture of condensed vapour and gas completely stopping the light. From the researches of Andrews it was clear that the employment of intense cold as well as enormous pressure was necessary to bring some gases below their critical points and thus liquefy them. The apparatus employed by Messieurs Cailletet and Raoul Pictet were then described in a most eloquent and lucid manner, the descriptions being illustrated by diagrams. M. Cailletet's apparatus was first described, the principle of his method being to force a gas under enormous hydraulic pressure into a small space and then suddenly relieving it from all this extra pressure allow it to expand, the sudden expansion producing such a sudden and intense lowering of temperature that some of the gas liquefied, giving up its heat to retain the rest of the gas in the gaseous condition. The lecturer threw the image of the capillary tube on the screen, liquefied some carbonic acid under the eyes of the audience and then showed the effect of suddenly relieving the gas of all pressure. M. Raoul Pictet, on the other hand, used enormous force coupled with intense cold in a most ingenious manner; his method offers advantages over that of M. Cailletet, in that the liquefied gases when obtained can be kept for examination. In the first place M. Pictet imitated Faraday in generating gases in small but exceedingly strong retorts of iron.

M. Raoul Pictet's apparatus is so well known in all scientific circles that it will be unnecessary here to detail the lecturer's account. Diagrams of the apparatus were shown and described. The agents employed were a pressure of 600 atmospheres, and a temperature of -140° C. produced by the rapid evaporation of liquid carbonic acid, which in its turn was first cooled by the rapid evaporation of liquid sulphurous acid. In this way M. Raoul Pictet succeeded in liquefying even hydrogen, which accumulated in the copper tube connected with the generating flask until, on turning the tap which closed the tube, liquid hydrogen rushed out, the sudden cooling of one portion solidified the remainder, and there fell on the ground a shower of metallic hail, thus verifying the prediction of the illustrious Faraday, "hydrogen is a metal."

Thus the experiments of MM. Cailletet and Raoul Pictet have abolished the distinction between the permanent and non-permanent gases, because there are no longer any permanent gases. The lecturer then proceeded to the chemical part of his subject—the discussion of the molecular theory of gases, stating, however, that he would confine himself to one general proposition which we owe to Avogadro, "Equal volumes of gases and vapours enclose the same number of molecules," the integral molecules of Avogadro being the molecules, and the elementary molecules the atoms, of modern chemistry. This beautiful idea of Avogadro suffered after his time a long eclipse, until it was revived by Gerhardt and Canizzaro. If one atom of hydrogen occupies one volume, the molecules of all compound bodies in the gaseous state occupy two volumes. This proposition was illustrated and developed by the lecturer with the aid of some glyptic models in a manner which will long be remembered by those who were fortunate enough to be present. The lecturer showed how from the above properties of molecules the specific gravity of any compound gas or vapour was connected with its molecular weight and deduced the law that the specific gravity of every compound gas and vapour was equal to half its molecular weight, the specific gravity of hydrogen being equal to 1. The professor then proceeded. This law applies to nearly all compounds, but there are some bodies whose molecule in the gaseous condition does not occupy two volumes. Are we to say that these are exceptions? No; in all these so-called exceptions the substance cannot be converted into the gaseous condition without decomposition, so that we have a mixture of gases, each molecule of each gas occupying two volumes. The experiment which proves this decomposition in the case of chloral hydrate was then explained and performed by the lecturer. Chloral hydrate when heated decomposes into chloral vapour and water vapour, each of whose molecules occupies two volumes, and the two together four volumes. Dry oxalate of potash when heated in dry air is decomposed, but if the atmosphere be saturated with moisture its decomposition is completely prevented. The experiment was performed as follows: Two ordinary graduated gas measuring tubes were filled with mercury, and inverted in a mercury trough; into one was introduced some dry air, into the other enough chloral hydrate to bring the mercury level with the meniscus of the mercury in the dry air tube, when the two were heated by surrounding them with steam. Into each tube was introduced a little platinum vessel containing some dry oxalate of potash. The oxalate of potash should, if the chloral hydrate were not disassociated into chloral and water, decompose in both tubes, and the level of the mercury fall in both. If, however, the chloral hydrate when converted into vapour is disassociated into chloral and water, the latter saturating the atmosphere of the tube will prevent the decomposition of the oxalate of potash, and the level of the mercury of that tube will remain constant, whilst that of the air-containing tube will descend. This was found to be the case: the mercury levels of the tubes were marked at the beginning of the experiment, and at the end of a quarter of an hour the mercury of the air tube had descended, whilst that in the chloral hydrate tube remained at its original height. In conclusion, the lecturer made some remarks as to the value of hypotheses, and pointed out how by means of the kinetic theory we obtain a glimpse of the rapidity of movement, the size, numbers, etc., of the invisible atoms, and thus we approach the problem which has excited the interest of humanity from the first ages up to the

present time, a problem which no man has yet solved, viz., that of the constitution of matter. In this nineteenth century a step has been made of the utmost importance. This step is the discovery that permanent gases can be liquefied. With this discovery posterity will ever couple the glorious name of Faraday.

Dr. Frankland rose to propose that the best thanks of the Society be given to Professor Wurtz for the admirable discourse to which they had just listened. As a specimen of a graphic, clear and eloquent lecture, he did not believe it had ever been surpassed, even in the renowned theatre of the Royal Institution. The Society had listened with equal pleasure in the first part of the discourse to the admirable skill with which the problem of the liquefaction of gases had been treated and the connection of the liquid and gaseous states of matter traced, and in the latter to the exposition of the law of Avogadro, so important in studying the constitution of gases and especially in the control which it gives to the chemist in assigning formulæ to organic and inorganic bodies. He would not trespass on the time of the meeting, but would propose that the best thanks of the Society be given to the lecturer for his admirable discourse.

Professor Odling, in seconding the vote of thanks, said that on no previous occasion had the memory of Faraday been so honoured. It was a lecture worthy of the occasion and illustrated in a manner which would have gladdened the heart of Faraday.

The President said it was his duty to put the proposition to the meeting that the best thanks of the Society be given to Professor Wurtz for his magnificent lecture. It seemed to him a very happy circumstance that these lectures, now given for the fourth time, should be delivered in the room in which Faraday lectured and in the building in which he made his most important experiments. The theatre, too, was lighted by means of Siemens's magneto-electrical machine, the first spark of which new force Faraday saw. It was, too, a happy thought to choose a subject starting from Faraday's discoveries. Faraday loved to break down barriers, and he thought Faraday would have been glad to have been with the Society that night and heard Professor Wurtz declare "there were now no permanent gases." He hoped that the Society would show its appreciation of the admirable discourse and experiments by a hearty vote of thanks.

The Faraday Medal, struck in palladium, was then handed to Professor Wurtz.

The vote of thanks was carried by acclamation.

Professor Wurtz, in reply, said,—Mr. President, gentlemen, and dear colleagues. You have rewarded me too well. I thank you from the bottom of my heart. I am very sensible of the honour you have conferred on me by entrusting me with the Faraday Lecture. How is it possible for me to speak in terms worthy of my audience or of my subject? I will preserve this *souvenir* for the rest of my life.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The opening meeting of the above Association for the present session took place on Thursday, the 7th inst., at 8 p.m., when Professor Attfield, President, occupied the chair.

The minutes of the last meeting were read and confirmed; these included the report of the committee for the past session, in which it was stated that during that period fifteen meetings had been held, with an average attendance of twenty-four at each meeting, the total number of members being ninety-two. In addition to the President's opening address, the number of papers read before the Association had been twenty-two, as follows:—"The Microscope and its Application in Pharmacy," by Mr. H. G. Greenish; "Coal-Gas," by Mr. Parker; "Blood," by Mr. Shapley; "Chemical Science some 200 Years Ago," by Mr. Allen; "Salt," by Mr. Sangster; "The Telephone," by Mr. H. Senier; "Cyanogen," by Mr. Mason; "Test for Bismuth," by Messrs. J. Savory and H. G. Greenish; "Some of the Substances used in Perfumery," by Mr. Mead; "Blatta Orientalis," by Mr. Hart; "The Chlorides of Iodine," by Mr. Dunstan; "Valerian," by Mr. Atkins; "Note on *Eucalyptus globulus*," by Mr. Parker; "The Action of Glycerine on Borax," by Dr. Senier and Mr. Lowe; "The Flame Test for Boracic Acid," by Mr. Mason; "Explosives," by Mr. C. Graham; "Water; its Impurities and Contaminations," by Mr. Gutheridge; "The Non-Official Remedies," by Mr. Bullen; "Soap," by Mr. Naylor; "The Microphone," by Dr. Senier; "The Form of Leaves," by Mr. Walton; "Molybdic Acid as a Test Agent," by Mr. Allen.

The President then addressed the meeting. After welcoming new members and referring to the relation of the Association to the School and to the Pharmaceutical Society, he noticed the object for which it had been established, the promotion of certain branches of knowledge "by the reading and discussion of papers." He dwelt especially on the advantage gained by the writer of a paper himself; the arranging and grouping of matter necessarily involved in the preparation of a paper training the powers of the mind to a far greater extent than any mere accumulation of facts, however thoroughly acquired. There was a certain kind of knowledge, and that the very best kind, not to be gauged by any known method of examination, which could be by no other means better gained than by the investigation of some particular subject, the compilation of its scattered details in an intelligible and connected manner, and the communication of the same in the form of a paper to such an Association as their own.

Professor Attfield then introduced the question "What kind and amount of knowledge should an English pharmacist possess to properly practise his calling?" Referring to the list given in the Regulations of the Board of Examiners, he said that most diverse opinions were held as to the amount of knowledge necessary or desirable for the successful carrying on of the practice of pharmacy. Some were of opinion that the examinations as at present conducted comprehended too much; others thought that a wider range of subjects should be adopted; others, again, doubted whether the knowledge required were of the right kind. It had been thought by many that more extended knowledge of the principles upon which pharmaceutical operations were based should be required of candidates, and that on this account the science of mechanics should be recognized as a distinct branch of pharmaceutical education, and should find a place in the list of subjects for examination. The whole subject was one on which the youngest apprentice or student could offer an opinion, and he therefore recommended it with confidence for the discussion of members of the Students' Association.

After some remarks by Mr. Postans, it was unanimously resolved that a discussion on the subject brought forward by the President should be held at the next meeting, together with a discussion on the revision of the rules of the Association.

Messrs. Branson and Graham having been appointed a Committee to examine the voting papers, the following members were declared duly elected as officers of the Association:—Vice-Presidents, Messrs. C. H. Hutchinson and R. H. Parker; Committee, Messrs. J. H. Allan, W. R. Dunstan, R. Stobbs and F. W. Warrick; Secretary and Treasurer, Mr. H. Allen, 17, Bloomsbury Square, W.C.

A motion having for its special object the accommodation of older members now engaged in business was then carried, by which the time of meeting was altered from 8.0 to 8.30 p.m.

Votes of thanks having been passed to the retiring officers of the Association and to the President, the meeting adjourned.

Correspondence.

The Board of Examiners.

Sir,—*Inter arma, leges silent.* But though the Court at Westminster has scarcely lost the echoes of a trial having deep issues for pharmacy, we may still give a fitting consideration to other interests that concern us.

On the importance of the work performed by the Board of Examiners it is needless to enlarge. It is "the one plank between us and the deep blue sea." Happily, our Board has usually enjoyed the immunity from comment parallel to the case of the judges of our land. The exception has been when the Council, at its meeting in September, discussed the results of the examinations. That discussion was quite inconclusive, and the general fog was reserved for the November meeting to clear up. Outsiders, like myself, have had to suspend any opinion until those who had asserted that there was a mystery, reported that they had discovered the secret. At the September meeting of the Council a member made a detailed statement upon the results of the July examinations. He showed that an enormous excess of failures occurred upon the last day of the examinations. The Secretary gave a clue to the probable reason for this in the practice of sending candidates to the Board of Examiners in the order in which they entered themselves. But the matter was directed to be brought under the notice of the Board of Examiners.

Now, in November we are informed that the hypothesis of the Secretary has been proved to be correct. The list of candidates has had its usual order reversed, and the heavy day for failures came first instead of last. As a consequence the very sensible plan of taking candidates alphabetically, long adopted by the Board at Edinburgh, is ordered to be used in the case of examinations in London. The member who raised the discussion is reported to have said that "the only regret was that the Board of Examiners did not seem able to afford the Council any further information." But need this excite surprise? Should not that feeling be reserved for the action which placed the Board of Examiners for two months in the public position of having something to explain and perhaps to justify? The Board could not fairly be looked to for an explanation upon any such question, and facts, not words, have now justified it. As taking its authority from the Crown, the Board of Examiners has an independence and dignity that forbid such explanations.

I will take this opportunity of expressing the opinion that the sum devoted to the remuneration of its members is not adequate to their services. It is now proved that the Council itself, by its method of making up the list of examinees, had caused the supposed difficulty.

As an advocate of free speech and free reporting, I cannot but regret that either process should be used unfairly, and if the plea be put in that "good has come out of evil," I reply that the evil was not in this case a necessary instrument to effect the desired good end.

Leeds. Richard Reynolds.

Tincture of Quinine.

Sir,—I am pleased to find Mr. Martindale state that tincture of quinine made with the hydrochlorate is "free from objections."

If your readers will turn to page 440 of the Journal for December 1, 1877 they will find a letter in which I anticipate Mr. Martindale's proposal and suggested also that the hydrochlorate of quinine ought, by merit, to have a place in the next pharmacopœia. I have used it regularly in the preparation of the tincture for several years and should be sorry to discontinue it. I am not in other cases an advocate for "half-and-half," but I consider tincture of orange peel better made with this weaker spirit and a tincture of quinine produced from it is without fault.

A statement was recently made that milk is a solvent and a good excipient for quinine, which so administered is said to be tasteless. I think the fallacy of this is proved by dissolving a little hydrochlorate of quinine in water and adding to milk; it will be found that when really in solution all the bitterness remains.

Scarbro', John Whitfield.

Sir,—Mr. Martindale's suggestion to use hydrochlorate instead of sulphate in making the above tincture is not a new one, as will be seen on reference to the present series of the Journal, vol. viii., page 440, where it is recommended by Mr. Whitfield of Scarborough. My experience rather coincides with that of Mr. Greenish, for although I have made large quantities, it is only within the last few weeks that I have met with any crystallization of the quinine. I made some tincture just before the present cold weather set in, and about a week ago on taking the bottle from the shelf, was surprised to find the bottom studded with small crystals, and these have gradually grown, until they are now aggregated together, and, as Mr. Postans said, are not at all unlike a sea anemone in miniature. The tincture was made from tincture of orange some of which had been previously used for the same purpose, but no crystallization had taken place, and as the tincture of orange had been carefully kept in a stoppered bottle, I am inclined to ascribe the deposition of crystals rather to the lowered temperature than deficiency in strength of spirit. As the use of the hydrochlorate would be free from the objection (which has been frequently noticed) I should strongly support it; for it is our duty as pharmacists to study appearance and stability of preparations as well as therapeutical value, that is of course where, as in the present instance, the latter would not be sacrificed to the former. As the revision of the B.P. is now on the *tapis*, it may not be out of place to mention here another preparation, which in the present cold weather has anything but an elegant appearance, viz., Lin. saponis. I would repeat the suggestion for the introduction of oleic acid soda soap as being well suited for the preparation of this liniment and other uses in pharmacy.

Mevagissey, J. Kemble.

Sir,—In connection with Mr. Martindale's paper on tinct. quiniæ, read at the last evening meeting, it may not be amiss to recall to mind a letter from Mr. Whitfield in the *Pharmaceutical Journal* for December 1, 1877, in which quiniæ hydrochlor. is suggested to be used instead of quin. sulph. in making tinct. quiniæ.

To have the tinct. the same strength in quinia only 145 grs. of hydrochlorate would be required for one pint. The price of hydrochlorate is not so very much greater than that of the sulphate, and when the reduction in quantity required is taken into consideration the difference, at present prices, would be about nine pence an ounce, a trifle to those who are troubled with precipitates, and if the demand were greater for the hydrochlorate the price would probably be less.

While admitting that the present tinct. quiniæ is a good preparation if made according to the Pharmacopœia, I think it would be an advantage to have a tinct. quiniæ hydrochlor. If such a preparation should be introduced in the next pharmacopœia, it would of course, be a matter convenience to have it like the present tinct., gr. j. in ℥j.

Belfast, P. B.

"*Pulv. Opii Rect.*"—For information respecting thymol and its preparations, see several papers in the last volume (vol. viii.) of this Journal, as for instance those on pp. 645, 666, 706, 776, etc. Your third question has been inserted recently for the second or third time.

H.—Indexes of the first fifteen and following twelve volumes of the Journal have been published and may be obtained from the Secretary. An index of the next ten volumes is being prepared.

"*Associate.*"—A person whose name is neither on the Medical Register nor the Register of Chemists and Druggists cannot legally dispense and supply medicine containing a poison included in the schedule to the Pharmacy Act.

W. H.—The price charged was undoubtedly too low, but the insertion of similar inquiries on previous occasions has failed to evoke unanimity of opinion.

G. Stuart.—A good French 'Grammar' and a Latin 'Dictionary' may be obtained through any bookseller. We cannot recommend any as being specially suitable for preparing for the Bell Scholarship.

"*Sub Umbra Floresco.*"—(1) The plaster is, we believe, a specialty of an American house. (2) The question as to the cinchona preparation has been practically answered before on p. 167.

C. H. B.—Recipes for "nervine balsam" may be found in the number for March 30 last, pp. 773 and 782.

Communications, Letters, etc., have been received from Messrs. Shillcock, Parker, Freeman, Stevenson, Woodland, Wilford, Salmon, Dispenser, Delta, Inquirer.

"THE MONTH."

November is perhaps the dullest month of the year for pursuing the study of flowering plants. Dead leaves and withered stems are redundant everywhere, while the sole redeeming feature in the gardens at this time of year,—the bright chrysanthemums,—soon become soiled and bespattered, and then increase rather than relieve the dreary and desolate aspect of the garden. In the south, however, they are more favoured; a correspondent writes from Mevagissey, in Cornwall, that about the 20th inst. he gathered some hedge strawberries, nearly ripe. Those also who live in cities where there are botanical gardens may find here and there a flower to represent some of the natural orders. Thus, at Kew the Iridaceæ are represented by the bright red *Schizostylis coccinea*, the Solanaceæ by the pretty white panicles of *Solanum jasminoides*, and Convolvulaceæ by the shrubby *Convolvulus Cneorum*, while here and there a flower belonging to the Liliaceæ and Amaryllidaceæ, and a late colchicum, or the glaring spike of the "red-hot poker plant," *Uvularia tritoma*, may still be seen. In florists' windows, too, the student may still find a few flowers procurable for purposes of study.

Nature, however, ever fertile in resources, provides an ample field for those who study botany from the love of it, in the abundance of cryptogamic vegetation which is to be found at this time of year. Fungi are especially autumn plants and are therefore becoming less numerous than a month ago, but mosses are perhaps in greater perfection from November to March than during any other part of the year, while lichens and algæ provide interesting material for microscopic study all the year round. The fronds of some of our ferns, such as the *Polypodium vulgare*, present a very pretty appearance from the bright tints of the sori, which in this species are now in capital condition for examination.

A propos of ferns, it is well known that the prothallia of ferns usually produce the reproductive organs and roots on their under surface. The reason of this has not hitherto been explained; recently, however, M. Leitgeb has shown that it is connected with the influence of light. By causing the prothallia to grow vertically and by allowing the light to fall on the underside, he has established the fact that the reproductive organs and roots are always formed on the side least illuminated.

The discovery in Sumatra, by Dr. Beccari, of a gigantic plant of the Arum family, which he has named *Conophallus Titanum*, and an account of which was read by Dr. Masters at a recent meeting of the Linnean Society, is worthy of note. A plant that can produce a tuber five feet in circumference, and so heavy as to require two men to carry it, would probably contain a large amount of starch, and if capable of cultivation might become a valuable addition to our known economic plants. To this it adds the advantage of having only a single leaf, which is furnished with a long stout petiole and a blade covering an area of 45 feet, so that it might evidently be grown amongst smaller plants. It would be interesting to know if, like so many of the Arum family, it contains a volatile acrid principle. It is to be hoped that ere long more will be learnt about this marvellous plant.

At the same meeting, Mr. A. W. Bennett explained his views on cleistogamous flowers, which he considers owe their origin to degradation. In these flowers, according to Mr. Bennett's statement, some curious phenomena take place in the emission of the pollen tubes, which in the cleistogamous flowers of *Oxalis* travel through the air vertically upwards from the anther, and in some other plants horizontally, while in *Viola canina* they creep along the surface and even the back of the ovary. An unseen agency appears to direct them, since none of the pollen tubes wander with uncertainty; a very singular fact, since when not in proximity to the stigma, the pollen tubes are protruded from the pollen grains in all directions. The cause of this is not explained, but it seems to suggest the existence of an electric current between the anther and stigma.

Some interesting notes are to be found in Gehe's report for September, which give some idea of the drug commerce of Germany. This firm states that the Dalmatian insect powder (*Pyrethrum cinerariifolium*) is preferred to that made from the Caucasian plant, *P. roseum*, which is somewhat neglected. Considerable quantities of benzoic acid are said to be now obtained from gum acroides, the resin of one of the Australian grass trees (*Xanthorrhœa arborea*). Now that almonds are scarce and of high price, the same resin might probably also be turned to account in making essential oil of almonds by oxidation of the cinnamic acid it contains. Cabardine, Siberian or Russian musk, which formerly came through Russia, now comes also from Shanghai, and bids fair to almost supersede, at least for a time, Tonquin or China musk, which has been scarce and much adulterated of late. Of chemical products benzoate of lithium appears to be much used, it being considered the best salt for use in gout. Benzoate of sodium as a remedy for intermittent fever also continues in favour, while sclerotic acid does not appear to meet with the success which was expected. Naphthaline, particularly the darker kind, is said to be coming into considerable use in India and South America for destroying moths and other insects. Toluol and xylol are recommended as menstrua for use in the laboratory, in preference to benzol, as they possess equal solvent powers but are less volatile.

With regard to products obtained from gas tar, the price will probably be considerably modified if the electric light takes the place of gas, since many substances now obtained as bye-products will have to be specially manufactured.

One of the results of the annexation of Cyprus will probably be an abundance of good colocynth apples, since the best are produced on that island.

Thymol, jaborandi, Goa powder, iodine, camphor, Calabar beans, cardamoms and especially quinine, are said to be likely to increase in value, while otto of rose will probably become cheaper, since there is a large quantity of it still unused at Kejanlik, the quality not being first class.

In the London market two or three tons of costus root have recently appeared. A full account of this root may be found in the last volume of this Journal, pp. 41 and 200.

Nepaul cardamoms have also been offered. These are described in the 'Pharmacographia,' and recently formed the subject of a paper which appeared in the *Journal of the Linnean Society*, in which they were said to be produced by *Amomum subulatum*.

Under the name of Calabar beans, the seeds of *Entada scandens* and a species of *Mucuna* have been put up for sale during the past month, the genuine

beans being very scarce at the present time. Both of these differ from Calabar beans in shape. The *Entada* bean is circular, from one to two inches broad, and about one-third of an inch thick, with an extremely small hilum. The *Mucuna* is also circular, about three-quarters of an inch broad and one-third of an inch thick, with a large hilum extending round a considerable part of the seed.

At this time of year it may be worth mentioning that for whooping cough hydrobromate of quinine has been used with some success in Germany.

Dr. Z. T. Dellenbaugh, writing to the *Philadelphia Medical Times*, recommends the use of picrate of ammonium in whooping cough. He gives the following formula:—

Picrate of Ammonia.	1 grain.
Muriate	26 grains.
Powdered Extract of Liquorice .	1 drachm.
Water	3 ounces.

Of this mixture a teaspoonful every three hours is given to a child under six months, doubling the dose for children one to two years old, and three teaspoonfuls for three to five years.

In an account of plants used by the North American Indians as food, etc., by Dr. E. Palmer, the writer mentions that the use of the gum of *Prosopis juliflora* by the Indians as a hair dye. The mode of application, however, is one that will scarcely recommend itself to Europeans: it is mixed with mud and their heads covered with it for two or three days, and when washed away it is said to leave the hair of the oldest as black as jet.

With regard to the "koromiko," which was so highly spoken of a short time ago as a remedy for diarrhœa, Mr. T. H. Hustwick, of Blenheim, New Zealand, writes that he has been informed by the Government botanist there that the plant is the *Veronica salicifolia*, well known in cultivation in this country.

In the *Practitioner* for this month will be found a paper on an East Indian drug which is at present attracting some little attention in England. The writer, Dr. D. Young, of Florence, finds that "in the macular and in the early stages of the anæsthetic forms of leprosy chaulmugra oil appears to be of decided value," and thinks that some of the facts which he has noticed "may point to the probable usefulness of the oil in affections of the chest." He further remarks that "the oil has a deserved reputation in cases of itch and parasitic pediculi, and forms a valuable addition to the ordinary sulphur ointment."

The Japanese seem to be as forward in medical as in other science. Professor Baily, of Tokio, reports remarkable and favourable results from the use of paracotoin, which he tried on five patients in the outbreak of cholera which occurred last year at Yokohama. It was administered in the form of a 0·2 gram subcutaneous injection suspended in glycerine and water, equal parts of each. He promises to publish any further results which he may obtain. It may be here remarked that the coto bark now in the market is that which yields paracotoin, the original bark which contained cotoin not having been seen in trade since its first importation.

The *Boston Medical and Surgical Journal* reports the successful use of an American drug in chorea. The drug in question is the root of *Dracontium fœtidum*, or as it is more commonly called, "skunk cabbage." Like most of the plants of this family its active principle appears to be volatile, and the tincture should therefore be made directly from the fresh root, not dried, collected in the autumn when it is most active. The dose of the "saturated" tincture that has been prescribed is 90 drops, three times daily.

Another plant *Anemone Pulsatilla*, which, like the last, possesses a volatile active principle has recently been written upon by Dr. H. G. Piffard, in the *New York Medical Record*. He has used the remedy in dysmenorrhœa, etc., and has arrived at the conclusion that the tincture of the fresh plant or its active principle should alone be used. Of the latter (anemonin) the dose is $\frac{1}{6\frac{1}{5}}$ of a grain. The tincture may be prepared by adding one-fourth of its weight of alcohol to the expressed juice of the plant.

A. Pulsatilla has long been used by homœopathic practitioners as a remedy in various female disorders, and probably deserves more attention than it has hitherto received in this country, although it is better known in Germany. Probably the difficulty of procuring the fresh plant, which is very local in Britain, is the reason why pulsatilla has been thus neglected.

Another species, *A. Ludoviciana*, has been stated by W. H. Miller,* to be a valuable remedy in cataract, amaurosis and opacity of the cornea. The juice of this plant when heated gives off a vapour which irritates the eyes.

Mr. M. G. Bruylants, who has recently examined oil of valerian, finds that it pre-exists in the plant, together with valerianic, formic, and acetic acids, which are found in it in small proportions in the recently distilled oil, but in larger proportions in that which has become resinified. He recommends as the best method of obtaining the valerianic acid from the roots, to coarsely powder old roots, keep them three or four months and then to heat them with potash or soda lye. The alkali is then neutralized and the resulting magma distilled with water acidulated with sulphuric acid.

M. M. R. Bellini reports that lupin seeds, which have been used as a vermifuge from the time of Dioscorides, contain a poisonous active principle, soluble in water. He thinks, therefore, that they ought only to be used externally as a parasiticide or resolvent.

A curious story comes from California concerning a specimen of meteoric iron found in the Mohave desert. It is said to have some uncombined gold on its surface, to be not magnetic, and to have successfully resisted the action of various acids. One of its surfaces presents a crystalline appearance, and a steel grey colour, tinged with yellow. Heavy blows neither break nor chip it, and it defies the action of the best cold chisels. It might, therefore, if its composition could be ascertained afford valuable information to iron-founders, and render it possible to prepare an alloy harder and tougher than any yet known.

Two caustics which promise to be most valuable, have recently been introduced to the notice of the medical profession by Dr. B. W. Richardson; they are sodium and potassium alcohols. When applied to the skin these alcohols are said to cause a "gradual destruction of tissue, which may be so moderated as hardly to be perceptible and may be so intensified as to act almost like a cutting instrument." These caustics have the advantage that they will dissolve

* *American Journal of Pharmacy*, xxxiv., 1862, p. 300.

opium like ordinary alcohol, and also that their action can be stopped immediately by dropping on the eschar a little chloroform, which decomposes the caustic into chloride of the metal and triethylic ether, which is inert locally. A fuller account of these alcohols and their mode of preparation will be given on another occasion.

Myriogynic acid is the name given by Baron Müller to a substance separated by him from *Myriogyne minuta*, Less., and *M. Cunninghami*, D.C. (*Zeits. öst. Apot.-Verein*, Nov. 1). It was obtained by treating a watery extract with alcohol, evaporating the solution, redissolving the residue in water containing a little ammonia, acidulating with hydrochloric acid, shaking with ether and evaporating the ethereal solution. After washing with cold water the new acid, which is compared to santonin by the discoverer, forms a brittle yellowish or brownish mass having a bitter taste. It is very slightly soluble in cold water, more soluble in boiling water, very soluble in alcohol, less so in ether, and readily soluble in alkaline solutions. Sulphuric acid forms with it a red brown solution that is precipitated by water; strong nitric acid gives a yellow solution, and hydrochloric acid does not affect it. The plants also contain an essential oil. As both species exercise a stimulant action almost equal to arnica, Baron Müller suggests that they might possibly find a use in medicine as stimulants of the muscular and nervous systems. *M. minuta* is distributed almost throughout Australia and Southern Asia and *M. Cunninghami* over the greater part of the Australian continent.

In some experiments made with the object of throwing light upon the constitution of strychnine Messrs. Gall and Etard have found (*Comptes Rendus*, vol. lxxxvii., p. 363) that when this alkaloid is heated to 135° or 140° C. in sealed tubes two new bases are formed. One is obtained by removing the baryta by carbonic anhydride, filtering in an atmosphere of the same gas, and evaporating in a vacuum, when it is deposited in white interlacing acicular microscopic crystals, only slightly soluble in water and most solvents, but very soluble in hydrochloric acid, with which the base forms a deliquescent salt; it also forms with tartaric acid an acid salt that crystallizes in brilliant prisms. The authors have named this base "dihydrostrychnine," it being represented by the formula

$$C_{21}H_{26}N_2O_4 = \underbrace{C_{21}H_{22}N_2O_2}_{\text{Strychnine.}} + 2H_2O.$$

Upon further evaporation the mother liquor yielded a brown deposit which when purified by crystallization from boiling water forms brilliant yellow crystals, differing in composition from the preceding by one equivalent of H_2O, and therefore named "trihydrostrychnine." Both bases, though stable in the dry state, are very instable in solution, and it is necessary whilst preparing them to avoid contact with air. In certain circumstances these bodies behave like aldehydes, particularly in their action upon ver salts and bisulphite of soda. A mixture of sulphuric acid and bichromate of potash does not produce with them the characteristic reaction of strychnine.

The Council of the Royal Society has made its annual award of medals and these will be presented at the anniversary meeting of the Society on the 30th inst. The Copley Medal goes to M. Boussingault, for his researches and discoveries in agricultural chemistry. A Royal Medal will be given to Mr. J. A. Brown, for investigations in magnetism and meteorology, and one to Dr. A. Gunther for his contributions to the zoology and anatomy of fishes and reptiles. M. Alfred Cornu will receive the Rumford Medal for his optical researches, and Messrs. Cailletet and Pictet, for their researches on the condensation of gases, will receive the Davy Medal.

The periodicity of commercial crises has long been recognized, and it has not been unreasonable to associate them to some extent with deficient crops, and these again have in recent years been connected with what is known as the sun-spot period. In an ingenious paper published in *Nature*, Nov. 14, Professor W. Stanley Jevons has now endeavoured to establish a direct relation between this period and times of depression of trade, and certainly some of the data he gives show at least curious coincidences. Thus going back a century, commercial crises occurred in 1772-73, 1783, 1793, 1804-5? 1815, 1825, 1836-39, (1837 in the United States), 1847, 1857, 1866, 1878. The periodicity in these dates is marked and Professor Jevons has no doubt that the principal commercial crises of the past, so far as they can be traced, "do fall into a series having the average period of about 10·466 years," which is almost coincident with Brown's estimate of the sun-spot period, 10·45 years. The moral drawn is that an empire upon which the sun never sets cannot wisely neglect to keep a watch on that great fountain of energy, since "from it we derive our strength and our weakness, our success and our failure, our elation in commercial mania and our despondency and ruin in commercial collapse."

One of the most recent phases in the progress of scientific research is the introduction of the sensational method first illustrated by the surprising announcements of undescribed discoveries that were to extinguish the gas companies and make the electric light familiar in every household. For the initiation of this mode of enlightening the public credit is due to America, but its success in attracting attention has not been without effect in quarters where it might have been expected a more philosophic spirit would have prevailed.

An announcement made on behalf of Mr. Norman Lockyer, in the French Academy of Sciences, on the 4th inst., has aroused considerable curiosity in the chemical world. It was to the effect that, reasoning from the analogies furnished by the behaviour of known bodies, Mr. Lockyer had demonstrated that, independently of calcium, many bodies considered to be elements are really compound bodies. Photographs of spectra and details necessary for the "conviction of the Academy" were promised and it was understood that the subject will also be brought before the Royal Society on an early occasion. Meanwhile a correspondent of the *Daily News* states that on Monday last, in the presence of a small party of scientific men, Mr. Lockyer, by the aid of a powerful voltaic current, volatilized copper within a glass tube, dissolved the deposit formed within the tube in hydrochloric acid, and then showed, by means of the spectroscope, that the solution contained no longer copper, but calcium. In a similar way, it is alleged, nickel was converted into cobalt and calcium into strontium. It is evident that here not only the science of chemistry is on its trial, but that of spectroscopy, as well as Mr. Lockyer's experiments, and it is not difficult to adopt the opinion of the *Daily*

News correspondent that large as have been the drafts of late upon scientific (?) credulity, there has hardly been one which makes so heavy a demand on the powers of faith as that involved by the statement that Mr. Lockyer has realized the alchemist's dream, by the transmutation of the elements.

Not long ago, the Paris *Figaro* contained an article describing an apparatus which was shortly to be made known under the name of the "microdor" by which the sense of smell was to be intensified to such a degree of exquisite sensibility as to enable any one to identify individuals by their peculiar smell or to detect the presence of a person suffering from any morbid affection, and thus to place in the hands of the physician a means of attacking, in its incipient stages, disease which might otherwise have had a fatal result, or of enabling the officers of justice to recognize the perpetrators of crime, or a husband to tell who has been flirting with his wife. Truly it is difficult here to draw the line between science and burlesque, and though it may not be surprising to find such a difficulty arising from the lively columns of our French contemporary, it is not so easy to understand how the more sober *Daily News* should provoke a similar mystification, as would appear to have been the case from the letter of Mr. Lockyer on the day following the publication of the communication above referred to, in which he says "there was no meeting of chemists in my laboratory yesterday, and no dissociation of calcium into strontium."

In former years opportunity has been taken to put on record the names of pharmacists who have been chosen by their fellow-townsmen to fill municipal posts in the elections that take place in November. This year it is pleasant to be able to add the names of Mr. Alexander Bottle, Pharmaceutical Chemist, and many years past a member of the Council, who has been elected Mayor of Dover; Mr. William Ballard, Pharmaceutical Chemist and one of the Founders of the Society, who has been elected Mayor of Abingdon for the fourth time; Mr. F. Fisher, Pharmaceutical Chemist, of the firm of Ekin and Fisher, who has been elected Mayor of Grantham; Mr. Francis J. Clarke, Chemist and Druggist, elected Mayor of Lincoln; Mr. J. D. Williams, Pharmaceutical Chemist, elected Mayor of Bodmin; and Mr. H. M. Troake, Pharmaceutical Chemist, elected member of the Town Council of Helston.

The value of such a medium as is afforded by the "Dispensing Memoranda" to aid in arriving at something like uniformity in dispensing prescriptions cannot be better exemplified than in the great variety of opinions called forth from time to time, as difficulties present themselves for solution. The first of those prescriptions, under No. 172, in which the solubility of sulphate of magnesia is called in question, may be taken as an instance, with the contradictory statements on this subject in books, each one claiming to be considered as an authority on this and kindred subjects. With reference to this particular prescription, that which most concerns the dispenser is the fact, very simply determined by experiment, that the fluid is incapable of holding the sulphate of magnesia in solution. It may be dissolved in the infusion by heat, but after the addition of the tincture, and being allowed to cool, crystallization takes place, and the mixture becomes solid.

In another case it is suggested that a certain mixture should be strained through tow. This method of procedure in case of decomposition of any one of the ingredients of a mixture requires judgment in its application, and when adopted care should be taken that no important element of the combination ordered by the prescriber be strained out.

Castor oil as an excipient for camphor pills seems to be very generally adopted, but it is not so satisfactory in the result as the method recommended in the last "Month," and from pills of camphor, made with castor oil, there is generally more or less exudation of the oil after the pills are finished.

With regard to potass. carb., when thus written, there has been a considerable diversity of opinion as to whether in these instances potass. carb. or bicarb. should be used. The dispenser must exercise his judgment, and nothing further need be added to the remarks on this subject in a preceding "Month."

The size of a pill and the best excipient for atrop. sulph. has also called forth several correspondents. All agree that the pills should be one grain, but as regards the excipient there is great divergence of opinion. In one instance sugar of milk with honey is recommended. This surely must have been stated not as the result of experiment or due reflection. Sugar of milk and honey will not make a good pill where there is nothing else in the mass to bind the ingredients together.

The decomposition which takes place in the mixture (No. 173) commented on in last "Month" is well treated by Mr. Green, p. 356, and a careful perusal of his remarks will repay the dispenser to whom the difficulty first presented itself.

Explosive mixtures have attracted considerable attention where bismuth. subnit. and sodæ bicarb. have formed two of the ingredients. From some experiments on the action of sodæ bicarb. on bismuth. subnit., it would appear that part of the bismuth is converted into subcarbonate; the amount of bismuth thus converted averaged one-third of that of the bismuth employed. The result does not appear to be materially influenced by temperature or dilution. The change commences almost immediately and is complete in about half an hour. The cause of the disengagement of carbonic acid gas is due to the use of the bi- or acid carbonate of soda; if neutral carbonate be used the same change takes place, but without disengagement of gas. This confirms a suggestion in "The Month," July, 1877, page 66, that the explosion was probably due to "decomposition of the bismuth salt in presence of bicarbonate of soda." That the whole of the bismuth is not converted into carbonate is evident from the fact that, under the microscope, the crystals of subnitrate may be seen mingled with the amorphous particles of subcarbonate.

The first prescription requiring notice is that of No. 184. There is a foreign character about this prescription which suggests that "grams" are intended, and with regard to some of the ingredients reference should be made to the French Codex. Mr. Charles Stocks has very fully replied to it, and to his remarks nothing need be added. It may be almost assumed by the dispenser that the "gr." referred to grams. If dispensed in grains the whole of the ointment would have been only two scruples, whereas in grams it amounts to about one ounce and a half.

The lotion, No. 186, should be dispensed as written, but the borax should not be dissolved by the aid of heat, or in cooling it will crystallize out

beyond the point of saturation. The borax must be rubbed to a very fine powder, dissolved to as great an extent as possible in a mortar, and the remainder diffused through the solution; glycerine should on no account be used, except with the sanction of the writer, and a "shake the bottle" label should be attached to the bottle when dispensed.

In dispensing ung. hydrarg., as in No. 187, when ℥j is ordered the quantity should be weighed into a pot. It is a heavy ointment, and the usual ℥j covered dispensing pot, which is filled by ℥j of ointment, such as is represented by the average of prescriptions, will contain ℥ij of this ointment. This may or may not be of importance to the patient, but it would be a loss to the proprietor of the establishment.

The mixture, No. 188, should be dispensed exactly as written. The dose (six grs.) of potass. bicarb. every four hours although somewhat unusual does not appear to be excessive, but the dispenser seems to have misread the prescription. It is a ℥x mixture, and double the quantity would be ℥iiss. If ℥iss was, as he states, sent out as double the quantity it was an error on his part, and may in some measure account for his regarding the dose as unsafe.

The mixture from prescription No. 189 is opaque, but shows no sign of deposit, the opacity being due to the separation of resin from the tr. nuc. vom., when added to water, and this will necessarily fall in course of time as a fine flocculent matter. It is difficult to see whence a deposit other than that just mentioned could occur, unless the acid. hydrobrom. be impure. This preparation was introduced by Dr. Fothergill, but made according to his published formula the resultant acid is impure, containing acid tartrate of potash, and probably the deposit in the mixture, if this acid were used, would be tartrate of lime. The hydrobromic acid for the purpose of dispensing should be pure, and then this mixture will be opaque without showing any signs of immediate precipitation and a remote one can hardly be anticipated. See remarks on this acid with reference to a prescription of a somewhat similar character on page 772 of *Pharm. Journal*, 1877-78.

There must necessarily be a flocculent precipitate, if time be allowed, of resin from the tinct. nuc. vom. and tr. zingib. in prescription No. 190. There is no necessity for any addition to the mixture with reference to preventing this deposit, although very likely a little mucilage would retard if not prevent it.

Great care is necessary in dispensing chloroform in a mixture such as No. 191, or it will entirely separate, and the whole of the chloroform may be taken at one dose. A little mucilage will effect the diffusion of the chloroform, and perhaps the best method of procedure would be to rub the chloroform with ℥ss pulv. acaciæ, adding to it gradually with constant trituration the acet. scillæ to emulsify the chloroform, and finally the other ingredients; the chloroform will thus be thoroughly diffused, and each dose will contain its proper proportion. The writer could scarcely have been aware how dangerous a prescription he was giving into the hands of his patient, and if dispensed just as written it may have resulted in most serious consequences. It affords another instance of the dependence of the physician upon the practical aid of the intelligent dispenser.

THE FERMENTATIVE ACTION OF THE JUICE OF THE FRUIT OF CARICA PAPAYA.

BY HERR WITTMACK.

At a recent meeting of the Berlin Natural History Society the author gave an account of some researches and experiments he had undertaken upon this subject.

A perfectly ripe undamaged papaw fruit measures from seven to eight inches in length and three to four inches in width and has the appearance of a rather long melon; it has a beautiful yellow rind which in its taste also resembles the lemon, though with a slight flavour of turpentine. The most interesting and important property attributed to it, however, is the power of its juice to rapidly render hard flesh tender.

As far back as the year 1750 Griffith Hughes says, in his 'History of Barbadoes,' "This juice is of so penetrating a nature that if the unripe peeled fruit be boiled with the toughest old salted meat it quickly makes it soft and tender, and if pigs be fed with the fruit, especially unripe, the thin mucous matter which coats the inside of the intestines is attacked, and if the food be not changed is completely destroyed." According to Browne, meat becomes tender after being washed with water to which the juice of *C. Papaya* has been added, and if left in such water ten minutes it will fall from the spit while roasting, or separate into shreds while boiling. According to Holden the flesh of an animal hung to a branch of the tree is rendered tender. Karsten says that in Quito the use of carica juice when boiling meat is very general, but in Venezuela and Costa Rica the practice is unknown. Some further experiments were made by Roy, who obtained by making incisions in a single fruit 28·39 c.c. of the milky juice, which after evaporating to dryness and again diluting with water had a powerful action upon flesh, albumen and gluten, while starch remained unaltered by it.*

Herr Wittmack, the author of the present paper, obtained after repeated incisions of a half ripe fruit only 1·195 grains of white milky juice of the consistence of cream. This dried in a watch glass to a hard vitreous white mass, having what appeared to be greasy spots on the surface, but what really were flocks of gelatinous substance that always adheres to the more hardened material. The odour and flavour of the fresh juice recalled that of petroleum or of vulcanized indiarubber. The microscope showed it to be a fine grumous mass containing some larger particles and isolated starch grains. Iodine coloured the juice yellowish brown.

A portion of the juice was dissolved in three times its weight of water and this was placed with 10 grams of quite fresh lean beef in one piece in distilled water, and boiled for five minutes. Below the boiling point the meat fell into several pieces and at the close of the experiment it had separated into coarse shreds. In the control experiments made without the juice the boiled meat was visibly harder. Hard boiled albumen, digested with a little juice at a temperature of 20° C., could after twenty-four hours be easily broken up with a glass rod. 50 grams of beef in one piece, enveloped in a leaf of *C. Papaya* during twenty-four hours at 15° C., after a short boiling became perfectly tender; a similar piece wrapped in paper and heated in the same manner remained quite hard. Some comparative experiments

* Herr Wittmack notices the failure he and others have met with in attempts to refer to the original paper of Roy. We believe they have been due to the curious fact that in the first abstract of it that appeared in European literature the author's name "Chunder Roy" was transformed into "Dr. C. Roy," the Scotch appearance of which led probably to the paper being referred to the transactions of a non-existing society in Edinburgh. It may be mentioned that some interesting information on the papaw tree and its juice will be found in Colonel Drury's 'Useful Plants of India,' 2nd edit., p. 113. See also *Pharm. Journ.* [2], vol. v., p. 1029.—Ed. Ph. J.

were also made with pepsin, and the following are the conclusions arrived at by the author.

(1). The milky juice of the *Carica Papaya* is (or contains) a ferment which has an extraordinarily energetic action upon nitrogenous substances, and like pepsine curdles milk.

(2). This juice differs from pepsine in being active without the addition of free acid,—probably it contains a small quantity,—and further it operates at a higher temperature (about 60° to 65° C.) and in a shorter time (five minutes at most).

(3). The filtered juice differs chemically from pepsine in that it gives no precipitate on boiling, and further that it is precipitated by mercuric chloride, iodine, and all the mineral acids.

(4). It resembles pepsine in being precipitated by neutral acetate of lead, and not giving a precipitate with sulphate of copper and perchloride of iron.

PELLETIERINE, THE ALKALOID OF POMEGRANATE BARK.*

BY C. TANRET.

The author, who recently announced the discovery of this liquid alkaloid,† has communicated the following additional information respecting it to the French Academy of Sciences.

The alkaloid is obtained in a pure state by distilling its ethereal solution in a current of hydrogen, and maintaining the residue at a temperature of 130° to 140° C. until it no longer gives off the vapour of water. The temperature is then raised and the liquid collected that distils between 180° and 185° C.

Pelletierine so obtained is colourless, but in the open air or in flasks incompletely filled it becomes colcured very rapidly. At zero its sp. gr. is 0·999 and at 21° C. 0·985. It is very soluble in water with which it undergoes a contraction of volume, a mixture of 1 part of pelletierine with 2·5 parts of water having at 21° C. a sp. gr. of 1·021.

Pelletierine is dextrogyre, having in aqueous solution a rotatory power of $[\alpha]j = +8°$., that of the sulphate prepared with the distilled alkaloid is + 5·9°. With sulphuric acid and potassium bichromate pelletierine gives a green colour as intense as alcohol in the same conditions.

Analysis of the alkaloid as well as of the crystalline salts that it forms with sulphuric and hydrochloric acids indicate the formula $C_8H_{13}NO$. It therefore furnishes another example of a volatile oxygenated base, near to conhydrine, $C_8H_{17}NO$, and tropine, $C_8H_{15}NO$.

Some experiments have been made in order to ascertain the amount of the alkaloid contained in bark from different parts of the plant and the influence of vegetation upon its formation. The bark used was all taken from ten-year old plants grown in Troyes, in the open air during the summer and in a greenhouse in winter. The results obtained therefore are considered to be comparable between themselves, although plants grown entirely in the open air under a warmer sky might yield different quantities of the alkaloid. The following figures show the yield in sulphate from 100 parts of bark:—

	Gathered June 10.	Gathered August 3.
Fibrillæ, entire, dry	—	1·30
Bark of fibrillæ, obtained by ccntusion, dry	0·66	2·25
Meditullium of fibrillæ, dry	—	0·63
Bark of roots larger than a pigeon's feather, fresh	0·60	0·92
Ditto, dry	1·20	1·54
Bark of large and medium-sized branches, fresh	0·34	0·37
Ditto, dry	0·68	0·66
Bark of small branches, dry	0·32	—

* *Comptes Rendus*, vol. lxxxvii., p. 358.

† *Pharmaceutical Journal* [3], vol. viii., p. 1023.

The author states that the result of physiological experiments made at his request by several medical men in Paris and Troyes has been to demonstrate that pelletierine is the tænicide principle of the pomegranate.

FLUID EXTRACTS BY REPERCOLATION.*

BY EDWARD R. SQUIBB, OF BROOKLYN.

(*Continued from page* 349.)

Whilst the before-mentioned work on cinchona was in progress a paper by Mr. J. U. Lloyd of Cincinnati appeared in the *American Journal of Pharmacy* for 1878, p. 1, upon "Fluid Extract of Cimicifuga." This paper contains so many valuable observations made without bias, and with such care and labour as at once to command attention. The results, however, were in many important respects so at variance with those of the previous experience of this writer as to force upon him the conclusion that Mr. Lloyd might have misinterpreted some of his observations: and if so it was important that his work should be gone over in the light of the many useful suggestions it contains for those who might follow him. It is regretted that he did not refer to later papers on the subject of percolation and repercolation, or at least did not adopt some important modifications that are published in later papers.

His work upon cimicifuga has been repeated by precisely the same method as given above for cinchona, that is in accordance with the later experience on percolation and repercolation, and the results are given. Those who will compare these results with those of Mr. Lloyd will find important discrepancies which must belong to one set of observations or the other. On one important point Mr. Lloyd must reach a wrong conclusion, for it certainly can be demonstrated upon well known physical laws, that maceration to a proper extent is useful and necessary to other conditions of the problem. This point is so well established by general experience that this part of his work was not gone over. The formula and process adopted here were as follows:—

Take of Cimicifuga, in powder No. 62 32 parts.
Stronger Alcohol, s. g. ·819 at 15·6°C = 60°F.,
or s. g. ·811 at 25°C = 77°F., q. s.

Moisten 8 parts of the cimicifuga with 2 parts of the alcohol, and pack it firmly in a percolator. Then pour alcohol on top until the moist powder is thoroughly filled with liquid and the air is forced out, cover the percolator, and macerate for 48 hours. Then arrange the percolator for an automatic supply of menstruum, and start the percolation at such a rate as to give about one part of percolate every three hours, Reserve the first 6 parts of percolate, and continue the percolation to practical exhaustion, receiving the weaker percolate in separate portions of about 4 parts each.

Then moisten a second portion of 8 parts of the cimicifuga with 2 parts of the second percolate from the first portion of powder, pack it firmly in a percolator, and supply it on top, first with the remaining 2 parts of the second percolate from the first portion, and then with the successive weak percolates in the order in which they were obtained, until the moist powder is entirely filled with liquid. Then macerate for 48 hours, and percolate to practical exhaustion at the same rate as in the first portion of the cimicifuga, using, first the weak percolates in their proper order, and then fresh menstruum. Reserve the first 8 parts of percolate, and receive the weak percolate in separate portions of about 4 parts each.

Then moisten a third portion of 8 parts of the cimicifuga with 2 parts of the second percolate from the second portion of the cimicifuga, and conduct the percolation in exactly the same manner as in the second portion, reserving the first 8 parts of percolate.

Then moisten the remaining 8 parts of the cimicifuga

* From the *American Journal of Pharmacy*.

for a fourth percolation, and conduct it in exactly the same manner as the second and third portions.

Mix the four reserved percolates, weighing 30 parts, and set it by as finished fluid extract of cimicifuga; and having properly labelled and numbered the separate portions of weak percolate, set these by until the process for making this preparation is to be resumed, and then use them exactly as in the second, third, and fourth percolations, reserving 8 parts of the first percolate from each 8 parts of powder as the finished fluid extract, ever after, and setting aside the weak percolates from each operation to be used in the next succeeding one.

In applying this formula and process each part was represented by a troy ounce, and therefore the percolations were made with 8 troy ounces of powder each. For the purposes of this trial the percolate was separated in portions of about 2 troy ounces or 62 grams each instead of 4 troy ounces as indicated in the process, and each separate portion was carefully weighed. A cubic centimetre of each portion of percolate was carefully weighed on a flat watch glass, and then dried, and the dry extract weighed. Then a proportion was made by calculation from these data to find the total dry extract in each portion of the percolate, this proportion being as follows: As the weight of the c.c. of percolate is to the weight of dry extract which it yielded, so is the whole portion of the percolate to the dry extract it contains. Having thus obtained the total dry extract contained in each portion of percolate, the sum of these would be the total extract of all the portions. But as these portions varied in weight the series would not represent the rate of exhaustion. Therefore another proportion was made to show the rate or progress of exhaustion by the percentage of dry extract contained in each portion of percolate. The formula for this proportion is as follows: As the weight of the portion of percolate is to the weight of dry extract which it contains, so is 100 to the percentage of the dry extract contained in the portion of percolate. The difference of specific gravity between the menstruum and the percolate, which also shows the rate of exhaustion, was obtained by a small s. g. flask.

The following table gives the detail of these observations in compact form, but, as it was found by examination of the residue that the strong alcohol did not fully exhaust the cimicifuga, the percolations were only carried as far as the third, at which point it was determined to try a new menstruum, in another process.

CIMICIFUGA, WITH STRONGER ALCOHOL.

The first percolation of the table, being simply a percolation with fresh menstruum to practical exhaustion, serves to compare and check the other percolations in their results. The 8 troy ounces of cimicifuga=248·8 grams required 845·33 grams of percolate for practical exhaustion, though this was short of actual exhaustion. The total percolate is therefore nearly three and a half times the weight of the powder, and is as little as will give a practical exhaustion of this drug with this menstruum. This is more than double the proportion of the officinal U. S. P. formula, and accounts for a part of the defects of the officinal preparation. The extract obtained for this first percolation of the table is 33·19 grams, or (248·8 : 33·19 : : 100 :) 13·34 per cent. of the weight of the powder. Then as these percolations were made by re-percolation, the total extract should be (33·19×3=) 99·57 grams. But the total obtained (33·19+37·74+33·19=) 104·12 grams slightly exceeds this, showing that the total exhaustion was rather better than the first of the series.

Now if the total extract to be expected from the 24 troy ounces=746·4 grams. of powder be 99·57 grams, and as the finished fluid extract is to weigh only (6+8+8=) 22 troy ounces=684·2 grams, then the extract which should be contained in the reserved portions which constitute the finished fluid extract should be (As 746·4 : 99·57 : : 684·2 :) 91·27. But really the total extract in these reserves is only (18·87+31·27+31·27=) 81·41 grms., or 10·16 grams, less than it should be. This deficit is mainly due to the process having been stopped at the third percolation instead of being carried on to include the fourth. In order that the fluid extract should represent the drug grain for grain, or weight for weight, if

the extract was all of equal medicinal value, the reserved percolates should weigh 186·6+248·8+248·8 grams, and should contain 24·9+33·19+33·19 grams. This fluid extract, to have represented the drug in the relation of minim for grain should have measured (177·12+236·16 +236·16=) 649·44 c.c., but it really measured 676 c.c., and therefore the minim did not represent the grain $\frac{6}{6}$ $\frac{9}{6}$) though the preparation is much stronger than the officinal one which purports to have this relation.

To endeavour to remedy the apparent defects of this process and make a preparation which shall more nearly represent the entire drug, another set of repercolations was made with a new menstruum. As the officinal menstruum, namely stronger alcohol, did not fully exhaust the drug, and separated out the resinous portions from their natural associates and solvents in the drug, the attempt was made to go to the other extreme and try a solvent or menstruum which should contain perhaps too little alcohol, and if so, yield a preparation overloaded with extractive matter, so that by comparing the results of the extremes, a better menstruum than either extreme might be found. With this object this new menstruum was made of equal parts (by weight) of stronger alcohol s. g. ·819 at 15·6° C.=60° F., or ·811 at 25° C.=77° F. and water. This mixture required 26·5f℥ of water to two pints of stronger alcohol. The s. g. of this mixture is ·926 at 15·6° C.=60° F. or ·919 at 25° C.=77° F. or ·9236 at the room temperature at which the weighings were made. (*To be continued*).

THE POSITION OF PHYSIC HUNDRED YEARS AGO

The following extract from the Preface of the late Rev' John Wesley's work on "Primitive Physick" (17th edit.' 1747), has been kindly supplied by a correspondent, and is interesting as showing that the indisposition to consult the medical practitioner on every trifling ailment is not a new development in the popular mind. :—

"'Tis probable, physick, as well as religion, was in the first ages chiefly traditional; every father delivering down to his sons what he had himself in like manner received concerning the manner of healing, both outward hurts, with the diseases incident to each climate, and the medicines which were of the greatest efficacy for the cure of each disorder. 'Tis certain, this is the method wherein the art of healing is preserved among the *Americans* to this day. Their diseases indeed are exceeding few; nor do they often occur, by reason of their continual exercise, and ('till of late) universal temperance. But if any are sick or bit by a serpent, or torn by a wild beast, the fathers immediately tell their children what remedy to apply. And 'tis rare, that the patient suffers long, those medicines being quick as well as, generally, infallible. Hence it was, perhaps, that the antients, not only of *Greece* and *Rome*, but even of barbarous nations, usually assigned physick a divine original. And, indeed, it was a natural thought that He who had taught it to the very beasts and birds, the *Cretan Stag*, the *Egyptian Ibis*, could not be wanting to teach man—

'Sanctius his animal, mentisque capacius altæ.'

Yea, sometimes even by those meaner creatures. For it was easy to infer, 'If this will heal that creature, whose flesh is nearly of the same texture with mine, then in a parallel case it will heal me.' The trial was made. The cure was wrought. And experience and physick grew up together.

"And has not the Author of Nature taught us the use of many other medicines, by what is vulgarly termed accident? Thus, one walking some years since in a grove of pines, at a time when many in the neighbouring town were afflicted with a kind of new distemper, little sores in the inside of the mouth, a drop of natural gum fell from one of the trees on the book which he was reading. This he took up, and thoughtlessly applied to one of those sore places. Finding the pain immediately cease, he applied it to another, which was also presently healed. The same remedy he afterwards imparted to others, and it did not fail to heal any that applied it. And doubtless numberless remedies have been thus casually discovered in every age and nation.

"Thus far physick was wholly founded on experiment. The *European*, as well as the *American*, said to his neighbour, Are you sick? Drink the juice of this herb, and your sickness will be at an end. Are you in a burning heat? Leap into that river, and then sweat till you are well. Has the snake bitten you? Chew and apply that root, and the poison will not hurt you. Thus antient men, having a little experience, joined with common sense and common humanity, cured both themselves and their neighbours of most of the distempers, to which every nation was subject.

"But in process of time men of a philosophical turn, were not satisfied with this. They began to enquire how they might *account* for these things? How such medicines wrought such effects? They examined the human body, and all its parts; the nature of the flesh, veins, arteries, nerves; the structure of the brain, heart, lungs, stomach, bowels, with the springs of the several kinds of animal functions. They explored the several kinds of animal and mineral, as well as vegetable substances. And hence the whole order of physick, which had obtained to that time, came gradually to be inverted. Men of learning began to set experience aside; to build physick upon hypotheses; to form theories of diseases and their cure, and to substitute these in the place of experiments.

"As theories increased, simple medicines were more and more disregarded and disused; 'till in a course of years, the greater part of them were forgotten, at least in the politer nations. In the room of these, abundance of new ones were introduced by reasoning speculative men; and those more and more difficult to be applied, as being more remote from common observation. Hence rules for the application of these, and medical books were immensely multiplied, 'till at length physick became an abstruse science, quite out of the reach of ordinary men.

"Physicians now began to behe ld in admiration, as persons who were something more than human. And profit attended their employ, as well as honour, so that they had now two weighty reasons for keeping the bulk of mankind at a distance . . . They represented the critical knowledge of anatomy, natural philosophy (and what not?; some of them insisting on that of astronomy and astrology too) as necessarily previous to the understanding of the art of healing. Those who only understood how to restore the sick to health, they branded with the name of Empirics . . . Yet there have not been wanting, from time to time, some lovers of mankind, who have endeavoured (even contrary to their own interest) to reduce physic to its ancient standard, who have laboured to explode out of it all hypotheses, and fine-spun theories, and to make it a plain intelligible thing, as it was in the beginning, having no more mystery in it than this, "such a medicine removes such a pain." These have demonstrably shown, that neither the knowledge of astrology, astronomy, natural philosophy, nor even anatomy itself, is absolutely necessary to the quick and effectual cure of most diseases incident to human bodies; nor yet any chymical, or exotic, or compound medicine, but a single plant or root duly applied. So that every man of common sense (unless in some rare cases) may prescribe either to himself or his neighbour, and may be very secure from doing harm, even where he can do no good.

"Even in the last age there was something of this kind done, particularly by the great and good Dr. *Sydenham*, and in the present by his pupil, Dr. *Dover*, who has pointed out simple medicines for many diseases. And some such may be found in the writings of the learned and ingenious Dr. *Cheyne*, who doubtless would have communicated many more to the world, but for the melancholy reason he gave one of his friends, that prest him with some passages in his works, which too much countenanced the modern practice, 'O, sir, we must do something *to oblige the faculty* or they will tear us to pieces.'"

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 30, 1878.

THE INTENDED EFFECT OF THE 28TH SECTION OF THE APOTHECARIES ACT AS SHOWN BY CONTEMPORARY EVIDENCE.

THE facts hitherto briefly narrated for the purpose of illustrating the history of the 28th section of the Apothecaries Act present one aspect of paramount importance concerning the question as to what significance and force should now be ascribed to that section, either as recognizing the exemption of the chemist and druggist from the operation of the 20th section of the same Act, or as restricting the exercise of his functions within specific limits. The settlement of this question after such a lapse of time is rendered extremely difficult, not only by the circumstance that the conditions then prevailing have ceased to exist and been forgotten, but perhaps still more so by the fact that the discussion of this question has since been complicated by the introduction of abstract considerations with the object of supporting the advocacy of particular interests.

The point to which we now desire to direct attention is that prior to 1815, the apothecaries and the chemists and druggists occupied, to a great extent, common ground in the exercise of their respective practice or business. While, in virtue of the monopoly enjoyed by the Licentiates of the College of Physicians, both classes were debarred from giving medical advice and receiving a fee for their services, the apothecaries had long since extended their practice beyond the limits set forth in the Charter granted to their Company by James I. in 1616. The effect of that charter was to give the freemen of the Apothecaries' Company the exclusive right to keep an apothecary's shop, and to make, compound, administer, sell, send out, advertise or offer for sale, any medicines, distilled waters, compound chemical oils, decoctions, syrups, conserves, eclegmas, electuaries, medical condiments, pills, powders, lozenges, oils, unguents or plasters, or otherwise. According to the powers granted by this charter, the practice of pharmacy was vested entirely in the apothecaries and that was their particular duty. But to meet the requirements of the public and the convenience of the licensed medical practitioners, or physicians, it gradually became the custom for the apothecary to attend at the houses of the physician's patients, for the purpose of administering the medicines ordered by the physician, and in this way he became, to a certain extent, the medical attendant of sick persons. A further developement of the exercise of medical functions by apothecaries was subsequently brought about by their being commissioned by the physicians to visit and examine sick persons, with the view of forming a judgment as to their ailments, and then reporting to the physician, who thereupon prescribed the treatment to be adopted.

Thus, in the course of the seventeenth century the practice of an apothecary did in fact afford some opportunity of acquiring a knowledge of disease, as well as the method of treatment, and a practical acquaintance with the effect of the remedies administered in obedience to physicians' directions, though it did not necessarily give either real or legal qualification to practise medicine.

At the close of the seventeenth century, consequently "practising as an apothecary" was no longer confined to "using or exercising the art and mystery "of an apothecary," as signified by the terms of the 1616 charter; that art and mystery was no longer the mere practice of pharmacy, but it comprised, in addition to that, no inconsiderable exercise of medical functions. The custom thus introduced naturally presented inducements for more independent action on the part of apothecaries, and accordingly we find abundant evidence that about the end of the period above referred to many of them had ceased to act only as the subordinate or assistant of the physician, and had undertaken the treatment of disease without the physician's aid and had commenced, with that object, to prescribe as well as to administer medicines on their own account and as competitors of the physicians.

Hence arose the jealousy and conflict between physicians and apothecaries in regard to the practice of medicine which eventually resulted in the establishment of "dispensaries" by the members of the College of Physicians in the year 1696. The object of this step was to crush the competition set up by the apothecaries in the treatment of disease and even to supersede them in their own legitimate pursuit by undertaking to prepare, compound and sell medicines at a fixed and moderate rate not only to the poor but also to any patients who chose thus to avail themselves of the physician's aid. The result however, was so far in favour of the apothecaries that recourse was soon had to litigation, and in the year 1703 one Rose, an "apothecary by trade," was sued by the College of Physicians for having, without advice or prescription of a doctor and without any fee for advice, compounded and sent to a patient several parcels of physic as proper for the patient's distemper, only taking the price of his drugs. The question to be decided was whether that was practising physic in the manner prohibited by the statute? Judgment was in the first instance given in favour of the plaintiffs, but an appeal was made to reverse this decision, and in the argument of the case it was urged that the confirmation of the judgment would not only lay a heavy tax even upon the rich, but be a great oppression upon poor families who, not being able to bear the charge of a physician's fee, would be deprived of all kind of assistance in their necessities, and be at the same time extremely prejudicial to sick persons in cases of sudden emergency, inasmuch as the apothecaries to whom such persons usually applied would not dare to sell

even a few lozenges or an electuary to any person asking for a remedy for a cold or to give medicines that had a known and certain effect in cases of ordinary or common ailments.

In view of these arguments, and from consideration of public convenience, the judgment in this case was finally reversed, and there was thus an end to the distinction between the practice of medicine and the practice of pharmacy as being respectively the exclusive province of the physician and the apothecary. The effect of this decision was practically to establish the right of the apothecary to treat disease as a medical practitioner, to visit and prescribe, as well as to compound and sell the medicine he had prescribed, provided that he received no fee, but merely charged for the medicine he supplied. It was thus that in regard to the great mass of the public the apothecaries became the ordinary medical practitioners, and the numerous class of what are now termed "general practitioners" had its origin.

Meanwhile, under the conditions above described, and contemporaneously with the departure of the apothecary from his original occupation in the practise of pharmacy, other persons gradually came to be called upon to fulfil the office of simple compounders and dispensers of physicians' prescriptions, and there is reason to believe that, while some of the apothecaries, who found their craft in danger, applied themselves to that duty, the assistants who were employed and instruicted by the physicians at the dispensaries afterwards became dispensing chemists on their own account, and in this way the use or exercise of the art and mystery of an apothecary, within the meaning of the Company's charter, began to pass into the hands of the chemist and druggist.

This change, however, excited the jealousy of the apothecaries, and attempts were made by the Company to acquire not only the power of searching the shops of chemists, as well as those of apothecaries, for the purpose of ascertaining the quality of the drugs, but also to prevent altogether the practice of pharmacy by druggists. It was, however, found impossible to secure such exclusive privileges in this respect, while the apothecaries were at the same time extending their practice beyond the limits of pharmacy, and eventually in 1793 the endeavours of the apothecaries were directed chiefly towards the subject of medical reform in the manner already described.

It was under this condition of affairs that in 1815 a Bill was introduced into Parliament by the Apothecaries' Company for better regulating the practice of apothecaries throughout England and Wales. The avowed object of that Bill was to afford the public protection from the dangers resulting from the ignorance of incompetent medical practitioners, and the fact that it was originated by some of the most enlightened and influential apothecaries is almost sufficient evidence that among those who were then practising medicine as apothecaries there was a want no less of real than of legal qualification for the exercise of the medical functions then customarily comprised within that term.

In regard to chemists and druggists it must be remembered that one of the objects of the Bill, as originally proposed, was to prevent them from making up medicines according to physicians' prescriptions, since that was by the charter of 1616 the exclusive province of the apothecary and was certainly covered by the phrase, "practising as an apothecary." That the Act when passed had failed to effect this object was in fact one of the grounds of lamentation that the measure was unsatisfactory, and that the opposition offered to the Bill by the chemists and druggists was mainly intended to avert that restriction upon the exercise of their business, is a point that cannot be doubted. As already shown the chemists and druggists had then acquired a standing as dispensers of medicine, and it is evident from the facts already stated as to the introduction of the 28th section of the Act that they were strong enough to insist upon the retention of the privilege they had acquired by usage, for it is clear that the introduction of that section was the result of a compromise and an admission on the part of the Society of Apothecaries that it could not dispute the claim of chemists and druggists to practise as apothecaries in that sense.

It is now necessary to revert to the terms of the 28th section of the Act and to compare them with the original draft proposed by the Society of Apothecaries for the satisfaction of chemists of druggists, in order to ascertain what were the reservations claimed and agreed to between the parties concerned, and for this purpose they are placed side by side.

"Provided always and be it further enacted, That nothing in this Act contained shall extend or be construed to extend, to prejudice, or in any way to affect the trade and business of a Chemist and Druggist; but all persons using or exercising the said trade, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade in such manner and as fully and amply to all intents and purposes as they might have done in case this Act had not been made."	"Provided always, and be it further enacted, That nothing in this Act contained shall extend, or be construed to extend, to prejudice or in any way to affect the Trade or Business of a Chemist and Druggist, in the *buying, preparing, compounding, dispensing* and *vending Drugs, Medicines,* and *Medicinable Compounds,* wholesale and retail; but all Persons using or exercising the said Trade or Business, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same Trade or Business in such Manner, and as fully and amply to all Intents and Purposes, *as the same Trade or Business was used, exercised, or carried on by Chemists and Druggists before the passing of this Act."*

It is important to note that the words defining the scope of the trade or business of a chemist and druggist, viz., "in the buying, preparing, compound-"ing, dispensing and vending drugs, medicines and

"medicinal compounds, wholesale and retail," were added by the chemists and druggists' Committee; and in place of the words, "as they might have done "in case this Act had not been made," the Committee substituted, "as the same trade or business "was used, exercised or carried on by chemists and "druggists before the passing of this Act."

From this it would appear that the claim chiefly insisted upon by the chemists and druggists had regard to dispensing physicians' prescriptions, and that the surrender made by the Society of Apothecaries had reference to their continuing in that capacity to act as apothecaries had previously done. But at that time the principal object of practising as an apothecary, as stated by GRAY in the preface to the 'Supplement,' was the treatment of disease, the retail sale of drugs and dispensing of medicine being secondary objects, even with those apothecaries who kept shops, and entirely given up by those who held themselves out to practise medicine. At the same time, while in the business of the chemist and druggist—or old apothecary as GRAY terms him—retail and dispensing were the principal objects, medical practice was also carried on as a secondary object, mostly confined to the counter, or to a few personal acquaintances. Here again it is evident that prior to the passing of the Act chemists and druggists occupied common ground with the apothecaries, and that they did to some extent practise medicine. It is significant in regard to this point that another of the grounds of dissatisfaction with the Act of 1815, expressed by the Associated Apothecaries in the preface to their transactions published in 1823, was that it did not even prevent chemists and druggists "from practising "medicine."

GRAY in the preface to his 'Supplement' of 1821, pointed out that the original object of the Apothecaries Bill amounted to no less than the modest proposal that, saving the rights of the physicians and surgeons as to practice in and about London, the dispensing practitioners or apothecaries and their apprentices should have the sole right of giving any medical advice to a sick person, or of compounding or even selling anything to be used as medicine, so as thus to establish a complete monopoly, and he went on to remark that the Act had therefore to be altered and restricted to those who practised as apothecaries, with an express declaration that it did not extend to chemists and druggists.

While then it appears to have been admitted at the time, that the Act was not intended to prevent chemists and druggists from continuing such counter practice as had been customary with them, and placed them in this respect also, to some extent, on common ground with the apothecary who went further and held himself out especially as a medical practitioner, it is evident that the special object of the Act was to restrict the latter from thus practising unless he gave evidence of his qualification to do so, or in the terms of the Act, unless he had been examined as to his skill and ability in the science and practice of medicine and certified as to his fitness and qualification to practise, as an apothecary in that extended sense. The reason for imposing this restriction is clearly set forth in the 7th section of the Act to the effect, that whereas much mischief and inconvenience had arisen from great numbers of persons in many parts of England and Wales exercising the functions of an apothecary, who were wholly ignorant and utterly incompetent to the exercise of such functions, whereby the health and lives of the community were greatly endangered it was necessary to make provision for remedying such evils, and that the Society of Apothecaries was therefore directed and empowered to enforce the provisions of the Act in relation to persons practising the art or mystery or profession of an apothecary throughout England and Wales.

By the Act of 1815 the theoretical distinction between the office of the physician or medical practitioner and the apothecary or pharmacist, which had been gradually lost sight of since 1618, was completely obliterated, and while the College of Physicians maintained the principle that the practice of medicine should have no connection with the practice of pharmacy, but still gave its assent to the procedure of the Society of Apothecaries in granting a licence nominally to exercise both functions conjointly, the practical result has been that the apothecary of that period, while enabled to take rank as a medical practitioner though only under certain conditions of legal qualification, has abandoned the exercise of pharmacy, except for his own purposes in some instances, and the performance of the duties belonging to that branch of medicine has become more especially the province of the chemist and druggist. In the exercise of this business the chemist and druggist is often called upon to render services for the alleviation of the distresses of his fellow men of a kind which have been rendered by every old nurse in the country from time immemorial; services, which if not strictly speaking pharmaceutical, are at least such as his special knowledge of drugs and their effects enables him, though not assuming to act as a medical practitioner, to render with more ability than most other persons, and with a convenience to the public which is widely acknowledged. Though it is of course desirable to keep in view the abstract principle that the practice of medicine and the practice of pharmacy should be distinct, and though it is essential that judicious limitations should be observed by the chemist and druggist in rendering such services, it nevertheless seems the height of injustice, both towards himself and towards the public, that an enactment, intended, as has been shown, to repress the illegal exercise of medical practice without due qualification, should after the lapse of so many years be had recourse to as an instrument of oppression in a province to which it was not intended to apply, and as a means of preventing persons unable or unwilling to avail themselves of the aid of a regularly qualified practitioner from obtaining such assistance as can readily be got from the chemist and druggist and without infringing upon medical practice.

Above all it is unfitting that the Society of Apothecaries should seek for or sanction the wielding, for such an object, of the Act which was the means of emancipating its own members from a thraldom as unjust and illiberal as that to which it is sought to subject the class which to-day occupies a position similar to that held by themselves before 1815.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The tourteenth conversazione was held in the rooms of the Royal Institution, Nov. 7, 1878. The museums of natural history, the bird room, collections of shells and of minerals, the insect room, the geological museum, and the museum of the Chemists' Association, were open for promenade. A variety of objects of scientific and general interest were exhibited under microscopes by twelve gentlemen, most of them members of the Microscopical Society of Liverpool. There was an exhibition of telephones, synchronized clocks, graphoscopes, stereoscopes, bronzes, electro-plate, self-registering barometers, etc.; and a very fine series of gold, silver and other ores from California, with large photographs of the localities whence derived, was lent by Mr. Keith. The Library, Museum, and Arts Committee of the Liverpool Corporation also lent a portion of the Rutter-Philips collection of minerals, a number of interesting groups of animals recently presented to the museum and some ova of Californian salmon.

At eight o'clock the company, consisting of about three hundred and fifty ladies and gentlemen, assembled in the lecture theatre, when the chair was taken by the President, Mr. T. F. Abraham. Mr. Edward Davies then proceeded to deliver the lecture of the evening, taking for his subject "Phosphorescence and Fluorescence." The lecture was extremely interesting and instructive and the experiments brilliant and successful.

The remainder of the evening was occupied by an exhibition of the electric light by Dr. Symes, a series of views of Cyprus by Mr. Golding of the Royal Polytechnic, and by a practical demonstration of the microphone.

Refreshments were provided in the library and committee rooms, and the band of the 1st L. A. V. was in attendance.

The fourth general meeting was held at the Royal Institution, Nov. 21. The President, Mr. T. F. Abraham, in the chair. The minutes of the previous meetings were read and signed. Some donations to the library were announced. Messrs. McQuie, C. W. Bannister and W. Wellings were elected members.

Under the head of Miscellaneous Communications Mr. Michael Conroy mentioned that he had recently found that foreign ground insect powder yielded about 10 per cent. of ash, whilst English ground *Pyrethrum roseum* yielded less than half that quantity. This fact, together with that of the English ground being in much finer state of division, points to the superiority of the latter over the former.

On opening the question box a number of queries were found and as far as practicable answered by the members present.

The principal business of the evening was the discussion of the points raised in Dr. Symes' paper read at a previous meeting, entitled "Suggestions for a New Edition of the British Pharmacopœia."

Mr. Tanner, having at the previous meeting proposed the adjournment of the discussion, was called upon to speak first. He stated his general agreement with Dr. Symes's criticism of the Pharmacopœia and proposals for the new one. He advocated the introduction in the first instance of the metric system as an alternative one alongside of the present, and expressed his belief that by the time (probably about 1890) that yet another revision would be required the metric system might be entirely substituted. He urged the introduction of definite standards of degrees of pulverization, condemning the use of such terms as "fine powder" and "coarse powder." He advocated the use in particular cases of spirit of strengths varying from those at present ordered, namely, proof and rectified; also the use of acetic ether in preparing liquor epispasticus and the reduction of the strength of spirit. æth. nit. from 10 per cent. nitric ether to 5 per cent., which latter he believed would keep much better. He criticized the processes for oxymel scillæ and injectio morph. hypoderm., suggesting the use of stronger acid in the former and of morphine 10 per cent. in the latter. He condemned the linim. tereb. acet. as inelegant and inconvenient, suggesting the addition of yolk of egg, thus bringing it nearer to the celebrated St. John Long's liniment. He would reduce the strength of the ext. cinchon. liq. so that 1 fluid ounce should represent 1 ounce of bark and would alter the menstruum used.

Mr. Conroy objected to the addition of spirit to acet. scillæ and would increase the strength of the acetic acid used. He recommended the use of almond oil soap for making linimentum saponis and also lin. pot. iodid. cum sapone, preferring it to both castile and curd soaps. The official form for the preparation of the hypodermic injection of morphia being tedious, he would recommend the use of an equivalent quantity of the pure alkaloid dissolved by the addition of just sufficient acetic acid. He condemned the forms for the liniments of aconite and belladonna as extremely wasteful, as also that for ext. cinchon. flav. liq., which left about two-thirds of the alkaloids in the marc. He would use equal parts proof and rectified spirits in making tinct. aurant. recent. He agreed with Mr. Tanner as to spt. æth. nit.

Mr. A. C. Abraham defended the form for ext. cinch. flav. liq., believing that it furnished a valuable product and that the non-exhaustion of the bark was not a sufficient reason for its abandonment. With regard to tinct. aurant. recent., he entirely differed with Dr. Symes as to using water first, as an essential oil would diffuse more rapidly into rectified spirit than into any aqueous fluid. With respect to the greater share which pharmacists thought they were entitled to in the framing of a National Pharmacopœia, and which he certainly thought was advisable, he reminded members of the failure in 1864, and hoped that trade jealousies and hobbies might not do as much harm as the superior knowledge of the subject did good.

Mr. Robert Sumner hoped that in the new edition of the Pharmacopœia great care would be taken not to add to the already serious inconvenience that arose from the numerous changes that had been made in the chemical nomenclature. A uniform and scientific system of nomenclature was no doubt desirable; nevertheless it must be remembered that the Pharmacopœia is not an educational text-book, but a work of reference for practising pharmacists and medical men.

Mr. A. Watt advocated the introduction of a much fuller series of synonyms, also of the French and German names of drugs and chemicals and of fuller descriptions and tests. He would omit the processes for the manufacture of definite chemical substances as being not only unnecessary but embarassing. With reference to the proposed introduction of chrysophanic acid, he mentioned the recent discovery that the acid did not exist as such in Goa powder but was a product resulting from the oxidation of chrysarobine.

The President found the lin. pot. iodid. cum sapone a perfectly satisfactory preparation when made with curd soap, and was at a loss to understand the introduction of wax and lard into suppositories, such addition being worse than useless. He confirmed Dr. Symes's statement that it is or used to be impossible to buy sulphurous acid of the full strength, though he had repeatedly made it himself, but by tedious process. He had not had any trouble with acetum scillæ. The lin. terebinth. acet., though somewhat inelegant, seemed to answer its purpose.

Dr. Symes said he endorsed Mr. Tanner's remarks with regard to lin. tereb. acet. and he was also glad to have that gentleman's views on hypodermic injections as on these he was an authority. The only difficulty in using the present system of weights and measures in conjunc-

tion with the metric was where detailed instructions were given for carrying out the process, and these quantities had to be several times repeated, then it became somewhat troublesome and complicated, and for this reason he was rather disposed to favour the alternative of expressing the quantities in parts. He could scarcely understand any one defending the process for ext. cinchonæ flav. liquidum, either on the ground that medical men prescribed it, or that it was made only in large quantities by wholesale houses, who could profitably extract the alkaloids from the partially spent bark; medical men prescribed it because nothing better of the same name and character existed, and did so under the erroneous impression that it was four times the strength of the bark. The galenical processes should be such as the pharmacist could, if he so desired, carry out satisfactorily in his own laboratory. If this were not the case how were they to have men of experience who could point out what a preparation ought to be and how the results were to be arrived at? Or how were they to get men competent to do what had been advocated, viz., to assist in forming a new edition of the Pharmacopœia? Mr. Abraham had told them something about trade jealousies interfering with pharmacists doing their duty in this respect; but of these he (Dr. Symes) knew nothing and could not therefore speak to the point. With regard to tinctura aurantii recentis, he spoke not theoretically, but from the result of fourteen years' experience, and this experience was supported by theory also. The process he recommended was simple, but based on scientific principles, and the result testified as to the correctness of these. Mr. Conroy had said that very little of it was sold by wholesale houses, but he believed this was simply because of its higher price. He had had experience with almond oil soap as manufactured by the house of Dorvault, of Paris; it was the *savon médicinal* of the French, and a beautiful preparation, one which might well replace the sapo dura of the B.P. He quite agreed, too, with the suggestion of Mr. Tanner that there should be more than two strengths of spirit as menstrua for preparing the various tinctures, etc. He had long felt this to be the case. There were one or two other corrections and additions he would like to mention; some of these, and indeed many others, had been pointed out by Mr. Young.* The pot. iod. in tincture of iodine should either be omitted or increased, for obvious reasons. The ammon. chloride might be omitted from liq. hydrarg. perchlor., and "No. 36 iron wire free from rust" would be a good definition in seven or eight preparations where the wire was contained, but no satisfactory definition given. Thymol and hyposulphite of soda might merit a place in a new edition. He believed with Mr. Watt that many of the processes for the production of definite chemicals might be omitted and the number and exactness of the tests increased, not so much for the purpose of obtaining absolute purity, which would often be difficult and undesirable, but for the better description and individual using of the substance. Professor Attfield knew all about the chrysophanic acid question and was disposed to agree with the German chemists that it might be an oxidation product rather then a constituent of araroba, but his numerous engagements had so far prevented him from making any further experiments on it. He (Dr. Symes) had, however, prepared chrysophanate of soda from Goa powder some twelve or eighteen months since, and by treating this with hydrochloric acid had obtained what he believed to be true chrysophanic acid; whether this latter produced the same medicinal effect he was at present unable to say, but it was now pretty certain that the substance dissolved out by benzine from araroba and on which the medicinal reputation of the substance was founded, was chrysarobine, and not chrysophanic acid. Whilst contemplating this question of the Pharmacopœia, an idea had occurred to him, which, in conclusion, he would mention. It was a useful sphere of work for the British Pharmaceutical Conference, viz., that it should appoint a committee to report from time to time, or at its annual meetings, on processes and formulæ, new or improved, and that this Committee should be permanent, inasmuch as that, after the next pharmacopœia is published, it could annually bring up a report and even give semi-official sanction to certain formulæ where there were half-a-dozen strengths in use under the same name; but in suggesting this he did not wish to interfere with any other useful work in the same direction.

* *Pharm. Journ.*, vol. xi., 2nd series.

DOVER CHEMISTS' ASSOCIATION.

The annual meeting of the above was held at the Apollonian Hall, November 13.

Mr. W. H. Cotterell was re-appointed Chairman, and Mr. J. Wilford (in place of Mr. J. I. Brown) was appointed Secretary for the ensuing year.

The principal business was the discussion of the probable bearings of the Weights and Measures Act. After the 1st of January, 1879, the imperial pint of twenty ounces being the only legal pint, the Chairman and Secretary were requested to prepare a scale of prices in accordance with that change.

A hope was expressed that Mr. C. K. Freshfield, M.P., would endeavour to protect the interests of the trade in the coming session, as he had done in the past.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on November 21, Mr. R. Warington in the chair.

After the reading of the minutes, etc., the following certificates were read for the first time:—C. E. Cassel, T. Gough, H. Wilson, S. Spencer, and R. Gracey.

The Chairman then called on Professor Church to read his paper, entitled:—

A Chemical Study of Vegetable Albinism.—The author commenced by distinguishing albinism from chlorosis and icterus. Two sets of analyses were made, one on leaves gathered in the autumn of 1877, the second on leaves gathered in 1878. Great care was taken in gathering the leaves that they should be of the same age, etc.; no steel implements were used to separate them. The plants chosen for the first set of experiments were the maple, the holly, and the ivy. In the second set the plants, for which the author was indebted to Sir Joseph Hooker, experimented with were *Elæagnus pungens*, *Plectogyne variegata*, *Cyperus alternifolius*, and *Alocasia macrorhiza*. Both sets of analyses yielded the following results:—The ash of the white leaves contains much more potash and phosphoric acid, and much less lime than that of the green leaves. No deficiency of iron in the white leaves was detected. The details of all the analyses are given. The author made further inquiries with *Elæagnus pungens* as to the three following points:—The amount of matter soluble in ether; the proportion of albuminoid to total nitrogen; presence of calcium oxalate and carbonate. As regards the first, the white leaves yield less than half the amount of extractive given by the green leaves. Nearly 60 per cent. of the nitrogen in the white leaves is non-albuminoid, while the green leaves contain 30 per cent. in that condition. Calcium carbonate and oxalate were present in notable quantities in the green leaves, but almost absent from the white leaves. White leaves contain more (about 10 per cent.) water than green leaves, while the dry organic matter in the former is not quite two-thirds of that present in the latter. To elucidate the question the author made some analyses of a parasite, the dodder, and its host, the red clover. The parasite was found to be richer in water and in potash, but poorer in lime than its host; thus resemb-

ling a white leaf. White leaves are therefore related to green pretty much as immature leaves to mature, tubers to foliage, petals to green bracts, vegetable parasites to their hosts. The white leaf may thus be said to be parasitic on the green. The author does not give any decided opinion as to the cause of the whiteness. He remarks that white leaves are usually weaker and thinner, and that albino cuttings cannot be "struck." Some attempts have been made to stimulate albino foliage, but without any decisive results. The author promises further experiments, especially as regards the relations of equal areas of white and green foliage to carbonic acid, and the effect of injecting various substances.

Dr. Voelcker said the paper was one of great interest as indicating a new path, which might lead to important results. He should like to ask if Professor Church had paid much attention to the qualities of chlorides and nitrates.

The Chairman said that he had listened with great attention to Professor Church's paper as one opening out a new subject, and one which it was rather curious that no one, as far as he was aware, had investigated hitherto. In Germany analyses of beech leaves of all ages had been made, and in many respects the analyses of the young leaves corresponded with those of the white leaves, whilst the composition of the old leaves agreed with that of the green leaves. He should think therefore that in the spring Professor Church would find less difference between the white and green leaves than in the autumn. The analyses of the parasite and its host seemed to afford a very good explanation of the differences between the composition of the white and green leaves; all the diffusible substances were found in the white leaves and the parasite, with but little non-diffusible matter.

Professor Dyer remarked that albinism was a disease probably due to the presence in the white leaf of some minute organism, for albinism can be communicated by grafting a normal plant with an albino shoot. White leaves resembled imperfectly fed leaves, preserving a sort of lingering vitality from their connection with a healthy plant, without which connection they could not exist.

Professor Church, in reply, said that he attempted some chlorine and nitric acid determinations, but the results hitherto attained were valueless.

The Chairman at this point announced that a ballot for Fellows would take place, and appointed Dr. Thudichum and Professor McLeod scrutators. The ballot ensued, but was invalid, because the requisite number of Fellows present did not vote.

The next paper was read by the Secretary, and was entitled—

Relation between the Melting Points of the Elements and their Coefficients of Expansion. By Dr. Carnelly.—Certain theoretical considerations led the author to the conclusion that the coefficient of expansion of an element by heat would be the greater the lower its melting point. This conclusion the author has tested in the case of thirty-one elements, and finds that with five exceptions the coefficient of expansion increases as the melting point diminishes. The five exceptions are: As, Sb, Bi, Te and Sn. A table and a graphic curve accompany the present paper, which the author promises to supplement by a communication on a simple relation existing between the heat evolved by a chemical reaction, and the melting points of the reacting and resulting bodies.

The next paper was—

A Preliminary Notice on a Hydride of Boron. By Francis Jones.—After an unsuccessful attempt to prepare the above substance by treating a product (magnesium boride), obtained by the action of sodium on a mixture of magnesium chloride and potassium borofluoride with hydrochloric acid, the author succeeded in preparing a spontaneously inflammable gas, which is doubtless hydride of boron, by first strongly heating a mixture of magnesium dust and boron trioxide—

$$B_2O_3 + 6Mg = 3MgO + B_2Mg_3,$$

and secondly treating the grey friable mass thus obtained with hydrochloric or nitric acid. The gas is colourless, burns with a bright green flame, and has a disagreeable odour. By using 3 Mg instead of 6 in the above equation, and treating the product with hydrochloric acid, amorphous boron is obtained as a brown powder.

The Society adjourned to December 5, when the following papers will be read:—"The Processes, and their Comparative Value, for Determining the Quality of Organic Matter in Potable Water," by Dr. Tidy; "Researches on the Action of the Copper-Zinc Couple on Organic Compounds," by Dr. Gladstone and Mr. Tribe; "On a New Gravimetric Method for the Estimation of Minute Quantities of Carbon," by Drs. Dupré and Hake.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting on November 13, Mr. F. Branson, Vice-President, in the chair, Mr. C. E. Stuart read a paper, entitled "How Plants Feed." After showing the important place filled by plants in the economy of nature by their production from inorganic matter of materials fit for animal consumption, the author examined the essential elements of the food of plants, stating their source and the organic combinations they entered into. Next, the forces and laws under which nutrition became possible were pointed out, and lastly, that process was explained according to present hypothesis. Deviations from the ordinary process carried on in green plants were noticed, as in the case of fungi and insectivorous plants. Lastly, the different compositions of the ashes of various plants suggested some considerations as to the use and value of manure as food for crops.

After a short discussion, in which Mr. Branson and Mr. Parker brought forward additional points of interest and criticized some of the theories of the author, a vote of thanks was passed to Mr. Stuart for his paper.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Animal Intelligence.*

by George J. Romanes, M.A., F.L.S.

(*Continued from page* 334.)

Passing on now to our review of comparative psychology, the first animals in which, so far as I can ascertain, we may be quite sure that reflex action is accompanied by ideation are the insects. For Mr. Darwin has observed that bees remember the position of flowers which they have only several times visited, even though the flowers be concealed by intervening houses, etc. Sir John Lubbock also has shown that, after a very few individual experiences, bees are able to establish a definite association between particular colours on paper and food; and further that, after a very few lessons, a bee may be taught to find its way out of a glass jar. These observations would seem to prove that the grade of intelligence is higher in some articulata than it is among the lower vertebrata. For many of you will probably remember the experiment of Professor Möbius, which proved that a pike requires three months to establish an association of ideas between particular kinds of prey and the fact of their being protected by an invisible wall. This fact was proved by the pike repeatedly dashing its nose against a glass partition in its tank in fruitless efforts to catch minnows which were confined on the other side of the partition. At the end of three months, however, the requisite association was established, and the pike having learned that its efforts were of no use, ceased to continue them. The sheet of glass was then removed; but the now firmly established association of ideas never seems to have become disestablished, for the pike never afterwards attacked the minnows, though it fed voraciously on all other kinds of

* Lecture delivered before the British Association at Dublin, August 16, 1878.

fish. From which we see that a pike is very slow in forming his ideas, and no less slow in again unforming them, thus resembling many respectable members of a higher community, who spend one half of their lives in assimilating the obsolete ideas of their forefathers, and through the other half of their lives stick to these ideas as to the only possible truths : they can never learn when the hand of science has removed a glass partition.

As regards the association of ideas by the higher vertebrated animals, it is only necessary to say that in all these animals, as in ourselves, this principle of association is the fundamental principle of their psychology ; that in the more intelligent animals associations are quickly formed, and when once formed are very persistent ; and, in general, that so far as animal ideation goes, the laws to which it is subject are identical with those under which our own ideation is performed.

Let us, then, next ask, How far does animal ideation go? The answer is most simple, although it is usually given in most erroneous form. It is usually said that animals do not possess the faculty of abstraction, and therefore that the distinction between animal intelligence and human intelligence consists in this—that animals are not able to form abstract ideas. But this statement is most erroneous. You will remember the distinction which I previously laid down between abstract ideas that may be developed by simple feelings, such as hunger, and abstract ideas that can only be developed by the aid of language. Well, remembering this distinction, we shall find that the only difference between animal intelligence and human intelligence consists in this—that animal intelligence is unable to elaborate that class of abstract ideas, the formation of which depends on the faculty of speech. In other words, animals are quite as able to form abstract ideas as we are, if under abstract ideas we include general ideas of qualities which are so far simple as not to require to be fixed in our thoughts by names. For instance, if I see a fox prowling about a farmyard, I cannot doubt that he has been led by hunger to visit a place where he has a general idea that a number of good things are to be fallen in with, just as I myself am led by a similar impulse to visit a restaurant. And, to take only one more instance, there can be no question that animals have a generalized conception of cause and effect. For example, I had a setter dog which was greatly afraid of thunder. One day a number of apples were being shot upon the wooden floor of an apple room, and as each bag of apples was shot it produced through the rest of the house a noise resembling that of distant thunder. My dog became terror-stricken at the sound ; but as soon as I brought him to the apple room and showed him the true cause of the noise, he became again buoyant and cheerful as usual. Another dog which I had used to play at tossing dry bones to give them the appearance of life. As an experiment, I one day attached a fine thread to a dry bone before giving him the latter to play with ; and after he had tossed the bone about for a while as usual, I stood a long way off and slowly began to draw it away from him ; so soon as he perceived that the bone was really moving on its own account his whole demeanour changed, and rushing under a sofa he waited horror-stricken to watch the uncanny spectacle of a dry bone coming to life. I have also greatly frightened this dog by blowing soap bubbles along the floor; one of these he summoned courage enough to touch with his paw, but as soon as it vanished he ran out of the room terrified at so mysterious a disappearance. Lastly, I have put this dog into a paroxysm of fear by taking him into a room alone and silently making a series of horrible grimaces. Although I had never in my life hurt this dog, he became greatly frightened at my unusual behaviour, which so seriously conflicted with his general idea of uniformity in matters psychological. And I could give numberless other instances of the formation by animals of general conceptions, or abstract ideas.

Of course in thus claiming for animals the power of forming general conceptions, I mean only such general conceptions as can be arrived at by the logic of feelings. So far, then, as the logic of feelings can carry them, I maintain that the intellectual operations of animals are indistinguishable from those of ourselves. Having thus shown that animals possess the faculty of abstraction, I shall now go on to show that they possess the faculties both of judgment and of reason. My friend Dr. Rea, the well known traveller and naturalist, knew a dog in Orkney which used to accompany his master to church on alternate Sundays. To do so he had to swim a channel about a mile wide ; and before taking to the water he used to run about a mile to the north when the tide was flowing, and a nearly equal distance to the south when the tide was ebbing, "almost invariably calculating his distance so well that he landed at the nearest point to the church." In his letter to me, Dr. Rea continues, "How the dog managed to calculate the strength of the spring and neap tides at their various rates of speed, and always to swim at the proper angle, is most surprising."

So much, then, for judgment. For some good instances of reasoning in animals I am also indebted to Dr. Rea. Desiring to obtain some Arctic foxes he set various kinds of traps ; but, as the foxes knew these traps from previous experience, he was unsuccessful. Accordingly he set a kind of trap with which the foxes in that part of the country were not acquainted. This consisted of a loaded gun set upon a stand pointing at the bait. A string connected the trigger of the gun with the bait, so that when the fox seized the bait he discharged the gun, and thus committed suicide. In this arrangement the gun was separated from the bait by a distance of about thirty yards, and the string which connected the trigger with the bait was concealed throughout nearly its whole distance in the snow. The gun-trap thus set was successful in killing one fox, but never in killing a second ; for the foxes afterwards adopted either of two devices whereby to secure the bait without injuring themselves. One of these devices was to bite through the string at its exposed part near the trigger, and the other device was to burrow up to the bait through the snow at right angles to the line of fire, so that, although in this way they discharged the gun, they escaped with perhaps only a pellet or two in the nose. Now both of these devices exhibited a wonderful degree of what I think must fairly be called power of reasoning. I have carefully interrogated Dr. Rea on all the circumstances of the case, and he tells me that in that part of the world traps are never set with strings ; so that there can have been no special association in the foxes' minds between strings and traps. Moreover, after the death of fox number one, the track on the snow showed that fox number two, notwithstanding the temptation offered by the bait, had expended a great deal of scientific observation on the gun before he undertook to sever the cord. Lastly, with regard to burrowing at right angles to the line of fire, Dr. Rea justly deemed this so extraordinary a circumstance, that he repeated the experiment a number of times, in order to satisfy himself that the direction of the burrowing was really to be attributed to thought and not to chance.

I could give several other unequivocal instances of reasoning on the part of animals which I have myself observed ; but time does not permit of my stating them. Passing on, therefore, to the emotional life of animals, we find that this is very slightly, if at all, developed in the lower orders, but remarkably well developed in the higher; that is to say, the emotions are vivid and easily excited, although they are shallow and evanescent. They thus differ from those of most civilized men in being more readily aroused and more impetuous while they last, though leaving behind them but little trace of their occurrence. As regards the particular emotions which occur among the higher animals, I can affirm from my own observations that all the following give unmistakable tokens of their presence:—fear, affection, passionateness, pugnacity, jealousy, sympathy, pride, reverence, emulation,

shame, hate, curiosity, revenge, cruelty, emotion of the ludicrous, and emotion of the beautiful. Now this list includes nearly all the human emotions, except those which refer to religion and to the perception of the sublime. These of course are necessarily absent in animals, because they depend upon ideas of too abstract a nature to be reached by the mind when unaided by the logic of signs. Time prevents me from here detailing any of my observations or experiments with regard to the emotional life of animals, so I will pass on at once to the faculty of conscience. Of course the moral sense as it occurs in ourselves involves ideas of high abstraction, so that in animals we can only expect to meet with a moral sense in a very rudimentary form, and, therefore, even if it is true that no indications of such a sense are to be met with in animals, the fact would not establish any difference in kind between animal intelligence and human. But I am inclined to believe that in highly intelligent, highly sympathetic, and tolerably well-treated animals, the germs of a moral sense become apparent. To give two instances. I once shut up a Skye terrier in a room by himself while I went to a friend's house. The dog must have been thrown into a violent passion at being left behind, for when I returned I found that he had torn the window curtains to shreds. He was in great joy at seeing me; but as soon as I picked up one of the torn shreds of the curtains the animal gave a howl and ran screaming up the staircase. Now this dog was never chastised in his life, so that I can only explain his conduct as an expression of the remorse which he suffered at having done in a passion what he knew would cause me annoyance. So far as I can interpret the facts, his sympathetic affection for me, coupled with the memory of his misdeeds, created in his mind a genuine feeling of repentance.

(*To be continued.*)

Parliamentary and Law Proceedings.

Poisoning by Carbolic Acid.

On Friday, November 1, an inquest was held by Mr. C. Aspinall, the Liverpool borough coroner, on the body of Christopher Viggar, aged eight years, an inmate of Everton Terrace Industrial School. On the previous Thursday the boy was directed to remove some empty bottles from a closet in the kitchen to the store-room. A small quantity of carbolic acid remained in one of the bottles, and he was seen to drink it, and shortly afterwards he was taken ill. A doctor was immediately sent for, and everything done for him, but he died the following morning.

The jury returned a verdict of "Accidental death."—*Daily Post.*

Poisoning by an Infant's Mixture.

The Manchester city coroner has held an inquest on the body of Richard Goodier, aged five weeks. The mother, Mary Jane Goodier, said the child, which was naturally delicate, had been ill, and she went to Mr. Pritchard, druggist, Chorlton Road, asked for Infants' Preservative, and obtained some medicine called "Infants' Friend." She gave the child eight drops of the medicine on Thursday night and again on Saturday night, shortly after which it went to sleep. It never woke again, although Dr. Woodcock and Dr. Smith saw the infant, and tried to rouse it; but it continued in a comatose condition until its death early on Monday morning. Dr. Smith stated to witness that there was opium in the "Infants' Friend" and that he had no doubt death had resulted from opium poisoning.

Alfred Walker, assistant to Mr. Pritchard, said they mixed the medicine in question supplied to Mrs. Goodier. Infants' Preservative was a patent medicine. Not more than four drops of the "Infants' Friend" should be given to a baby under four weeks of age, but an ordinary child would not be injured by eight drops. It was a soothing medicine for restless children, and was not so strong as "cordial" or "sleeping-stuff." Deceased might have been weak, and have a special tendency to be overcome.

The jury returned a verdict of "Died from the effects of an overdose of a narcotic poison called 'Infants' Friend,' given as medicine."

Poisoning by Paraffin.

An inquest was held at Liverpool on the 20th inst., on the body of a child that was poisoned through having paraffin oil administered to it instead of lime water. The mother had sent to a chemist's shop for the lime water, and the boy in charge gave paraffin oil instead, by mistake. Death by misadventure was the verdict of the jury, but they censured the chemist for leaving his place in charge of a boy.—*Echo.*

Dispensing Memoranda.

[173]. A. P. S. is right in saying that this mixture should not be strained. He who does so without consulting the prescriber takes an unwarrantable liberty with the prescription and is guilty of unpardonable presumption

Mr. H. Brown should remember that it does not follow that precipitates from drugs, chemically incompatible, should be therapeutically inert. In such deposits the virtue of the remedy almost invariably resides.

Victoria Hospital. J. Laker MacMillan.

[173]. I was surprised to read, in the Journal of Oct. 26, Mr. Henry Brown's reply to this query that "the only thing to do is to strain through tow, as the mixture is altogether an incompatible one." I think Mr. Brown is certainly wrong in straining this mixture for the sake, I presume, of giving it an elegant appearance, as he would be separating the "insoluble ingredients" which were no doubt originally intended to be taken. The following is very similar to the above, as regards "elegant pharmacy," which was presented the other day to be made up:—

℞	Ammon. Brom.	ʒij.
	Ammon. Carb.	℈ij.
	Spt. Camph.	ʒiij.
	Aq. Camph. . . . . ad	ʒvj.

M. ft. mist.

Should I be justified in straining this mixture? I may say it was sent out exactly as dispensed.

J. W. Barnes.

[173]. I have gone to extra trouble over this mixture—potass. iodid., acid. hydrocyan. dil., liq. bismuth., quinæ sulph. and acid. hydrobrom. I am asked by A. P. S. why I said the mixture should be strained through tow. I shall inform him; but this might not have been required had I not omitted in my short comment, p. 336, the words, "heat the mixture, after mixing the ingredients, to 130° F., and, if necessary, strain through tow; allow to cool and add the acid. hydrocyan. dil." The iodide should be dissolved in a separate portion of water, the quinine in the hydrobromic acid, to which a little water may be added, and the liq. bismuth. added to the iodide.

When the solutions are mixed a copious orange-red precipitate is produced, which is soluble at 130° F. The precipitate is again formed as the cooling process proceeds, but I have found it is not so dense as that which is at first formed on the mixing of the solutions. I therefore say that if flocculi or motes have made their way into the mixed solutions, strain through tow at 130° F. There is no time for ordinary filtration. No quinine will be lost, and A. P. S. will find the mixture, after heating to the temperature indicated, tolerably

presentable, and it only wants "shake the bottle." I may add acids sulph., nitric., hydrochlor. and acetic. do not dissolve the precipitate. It is rather increased on their addition,—and the same may be said in regard to liq. potassæ; ether does not dissolve it, neither does ammonia nor chloroform. I find alcohol, however, does, and for complete solution from twenty to thirty minims of rectified spirit are required for each two drachms of the mixture. It is thus rendered clear and colourless.

I think A. P. S. and "Belfast" will profit by an outsider's remarks, whose duty it is to curtail and not be prolix. The clever mind only wants a hint or suggestion, and every little matter cannot be explained in your columns.

Northallerton. HENRY BROWN.

---

[186]. I am much obliged to the different correspondents replying to my query.

Messrs. McAlley and Stocks seem to overlook the fact that if the quantity of borax ordered be dissolved in hot water nearly one-third of it will crystallize out on cooling, and to remove that by filtration as suggested is, to me, even more reprehensible than adding so simple a thing as glycerine.

C. Stocks says he finds his plan "to answer well," but has he allowed the solution to stand twenty-four hours? If he has and he finds no crystallization I would suggest to him the necessity of examining his borax to make sure that it is borax and nothing else that he used.

I am aware that Pereira says borax is soluble in twelve parts of cold water, but I prefer to accept Squire's statement of one in twenty-two as nearer the truth.

H. K.

---

[187]. I should say that where ℥j of ung. hydrarg. is ordered ℥j by weight should be sent. I see that two correspondents differ from me. I should like to know how they would proceed in case ℥j ung. cetacei and ℥j ung. hydrarg. were ordered to be mixed together. Would they send a ℥ij pot full or weigh ℥j of each?

51, *Judd Street.* FELIX STEVENS.

---

[187]. I think where ung. hydrarg. ℥j is ordered that one ounce only should be weighed into a jar and sent out. A one ounce covered jar holds just two ounces of ung. hydrarg. I have never dispensed ung. hyd. otherwise, and on one occasion some discussion among my assistants took place and I was appealed to. I ordered one ounce to be weighed and sent out, and also asked the prescriber, the late Mr. Coulson, his intentions. "One ounce only my patient is to rub in in six applications," was his answer. "And what right has any one to send *more?*" he asked. It is a constant occurrence for ung. hyd. to be ordered in one drachm packets; one to be rubbed in each night.

G. H. WRIGHT.

---

[188]. This mixture was evidently meant to make ℥x (a size by no means uncommon with medical men who dispense their own prescriptions), and I think that T. H. N. was wrong not to put in the full quantity of potass. bicarb. ordered. Six grains for an infant five months old is certainly a large dose, but not a dangerous one, and I think that T. H. N. should rather have refused to dispense the mixture than have taken upon himself the responsibility of reducing its strength.

C. STOCKS.

---

[188]. This prescription is simple enough, and if dispensed as written will fill a ℥x bottle. T. H. N. does wrong to alter the dose. Double the quantity should measure ℥2½, not ℥1½ as stated.

FELIX STEVENS.

---

[188]. T. H. N. did wrong in altering the dose of potassæ bicarb. in the mixture mentioned. Six grains every four hours for a child of five months is not an unusual dose. Perhaps he will explain how "double quantity" ten drachms measures (℥iss).

Victoria Hospital. J. LAKER MACMILLAN.

---

[190]. I am at a loss to account for the deposit which "Minor" found in this mixture. I have prepared it, and after standing forty-eight hours I can perceive nothing more than the slight opacity—unavoidable when ordinary tinct. zingib. is used—noticed when first mixed. I simply adopted my ordinary method of mixing the tinctures with a part of the water before adding the acid.

In cases of this kind it would be much better if querists would give some particulars of the deposit,—whether sedimentary, crystalline or resinous—as it would assist in arriving at a cause.

H. K.

---

[190]. I have carefully prepared this mixture and it has now been standing forty-eight hours, and yet not one sign of deposit, save an opacity, does it show. To six ounces of water I added successively the tinct. nucis vomic., acid. nit. mur. dil. and tinct. zingiberis; then, after shaking, I filled up the bottle with water. I cannot in any way account for the mixture dispensed by "Minor" depositing, but should advise him to see if his water is perfectly pure.

C. STOCKS.

---

[191]. In reply to "Student," the linctus can only be dispensed as it stands, but a "shake the bottle" label should be attached.

C. STOCKS.

---

[191]. A want of definiteness is also noticeable in "Student's" query, as he does not state what his difficulty is. I can see none in the way of its being dispensed as written.

H. K.

---

[192]. When liq. carbonis deterg. is prescribed, what preparation should be used? What is the proportion of coal tar in the solution?

A. L. NESS.

---

[193].

℞ Ferri Redact. . . . . gr. ij.
Ext. Nuc. Vomic. . . . . gr. ¼.
Ext. Gentian. . . . . gr. ij.

M. ft. pil. Silvered.

The above after being made up about twenty-four hours swell up and burst the coating. Will some readers of the Journal explain why, and how it can be prevented?

ASSISTANT.

---

[194].

℞ Ammon. Carb. . . . . ℥iv.

Ft. bol. Mitte vj.

The above prescription was left with me to dispense by a veterinary surgeon, and I made it up with linseed meal and water. The prescriber called next day to have some more medicine prepared, and remarked that the balls were too large; at least, larger than necessary. I told him how they were prepared, and he said I had acted as many dispensers would have done, but I might find a more elegant excipient without unnecessarily increasing their size—adding, I hope you will find the excipient most suitable ere I require am. carb. balls again. So far I have not succeeded; therefore, will some of my senior brethren assist me in my difficulty by furnishing information?

AN APPRENTICE.

---

[195].

℞ Ferri Sulph. . . . . ℥iss.
Pulv. Quassiæ Lig. . . . . ℥ij.

Ft. bol. Mitte vj.

I made the above with sapo mol., as recommended in

the *Pharmaceutical Journal* a few months since by the Editor in answer to an inquiry about fer. sulph., in balls; they became quite hard, and I was requested to make some more, in which I used muc. acaciæ. They did not become so hard, but are not satisfactory.

The prescriber told me that with the soap an oleate of iron and sulph. of potash was formed.

Would muc. tragacanth. answer?

AN APPRENTICE.

---

[196]. A few days ago I received the following prescription to dispense:—

℞	Tinct. Ferri	℥ss.
	Magnes. Sulphat.	℥iij.
	Spt. Chlorof.	℥iij.
	Spt. Menth. Pip.	℥ss.
	Aquæ ad	℥vj.

M. ft. mist. Two teaspoonfuls in water three times a day.

The prescriber lived about four or five miles from here, therefore not easily "come-at-able." On account, I presume, of the quantity of spirit in the mixture, the mag. sulph. would not remain in solution, but on agitating became a solid mass. I afterwards added water to make a 12-oz. mixture, explained matters to the patient and directed him to take a tablespoonful for a dose. I should like to know if I did right under the circumstances, and if the original could be dispensed in a fluid form.

LLET.

---

[197]. Can following be dispensed without separation of gums?—

℞	Tr. Camph. Co.,		
	Tr. Benz. Co.	āā	℥vj.
	Acid. Nit. Dil.		℥iss.
	Decoct. Cinchonæ	ad	℥vj.

M. ft. mist.

JAMES COCK.

---

[198]. Can the following prescription be dispensed and sent out as a clear mixture?—

℞	Sodæ Bicarb.		℥ij.
	Potassæ Bicarb.		℥ij.
	Ext. Cinchon. Liq.		℥iij.
	Potassii Iodidi		℥ss.
	Aquæ	ad	℥xij.

Misce.

C. R.

199]. The following is a copy of one of two or three prescriptions I have had lately. I should like to know what would be the proper directions:—

℞	Acid. Salicylic.		℥j.
	Sodæ Bicarb.		℥j.
	Aq. Menth. Pip.	ad	℥vj.
	Tinct. Scillæ		℥j.
	Spt. Æth. Nit.		℥ij.

M. Ft. mist. Capiat cochlearia amplum ter die.

Which is correct, to say two tablespoonfuls by the plural (cochlearia) or one tablespoonful by the singular (amplum)? I may add I was unable to gather any information from the party at the time.

J. W. BARNES.

Notes and Queries.

---

[531]. OL. FLAV. CONC.—Rub together some gamboge and fine sand, moistened with s. v. r., then transfer to a water-bath, and add the oil, stir until the spt. has evaporated, and strain. I can give "Pharmacist" the proportions if he will send me his address.

51, *Judd St., W.C.* FELIX STEVENS.

---

[532]. QUININE AND IRON TONIC.—"Delta" will find the following an excellent formula, it being pleasant to the palate and not productive of headache:—

Ferri et Quin. Cit.		ʒij.
Acid. Hydrobrom.		ʒij.
Tinct. Limon.		ʒj.
Syrup		ʒvj.
Aquæ	ad	ʒvj.

ʒss. to ʒ. for a dose.

P. B.

---

[538]. LIN POT. IODIDI.—*Alpha* can make lin. potass. iodid. in a liquid form from the B.P. form, but replacing the sapo dura with sapo mollis, B.P. C. STOCKS.

---

[538]. LIN. POT. IODIDI.—In reply to *Alpha* I send the following:—

℞	Sapo. Alb.	℥xij.
	Aq. Destill.	℥iiiss.
	Sp. Vini. Rect.	℥j.
	Pot. Iodidi	℥vj.
	Adipis	℥j.
	Otto or perfume, q.s.	

Macerate the soap in 2 oz. of water, dissolve the iod. potass. in 1½ oz. of water; then add the spirit, and afterwards the lard, using a gentle heat. J N.

---

[541]. INJECTION BROU.

Sulphate of Zinc	3 parts.
Acetate of Lead	1½ „
Water	200 „
Pulv. Opii	½ „
Saffron	1 „
Catechu	½ „

M. COVENTRY.

---

[541]. INJECTION BROU.—Whilst at Leeds to-day I gained some information. The real "Injection Brou" is a French quack gonorrhœal preparation. It consists of lead and vegetable colouring matter. I send you half-an-ounce. I am sure this is what "Sub Umbra Floresco" wants to know. The bottles are like "dummy" flagons delved in.

Northallerton. HY. BROWN.

---

[541]. "INJECTIO BROU" is a French *spécialité*; its reputed formula being:—

℞	Zinci Sulph.	·5
	Plumb. Acet.	·5
	Tr. Catechu	8·
	Tr. Opii.	4·
	Aqua Dest.	300·

PULVINUS.

---

[541]. INJECTION BROU.—The following is the composition of this injection,—

Aqua Destill.		100·0 grams
Zinci Sulphatis		0·5 „
Plumbi Acetatis		1·0 „
Tinct. Catechu,		
Laudanum (Sydenham's)	āā	2·0 „

49, *Haymarket.* WILLIAM FOX.

---

[541]. INJECTION BROU.—In answer to "Sub Umbra Floresco," I have seen the following as a form for injection brou.

℞	Sulphate of Zinc	gr. 46.	
	Acetate of Lead	gr. 23.	
	Aqueous Solution of Powdered Opium	gr. 8	℥vij.
	Catechu	gr. 8	
	Saffron	gr. 15	

W. M.

---

[541]. INJECTION BROU.—Hager, in the *Pharm. Centralhalle*, says, this noted French remedy is a solution of 3 grams of sulphate of zinc and 1½ grams of acetate

of lead in 200 grams of an aqueous tincture of ½ gram powdered opium, 1 gram saffron and ½ gram catechu.
Brecon. W. TUDOR.

[542]. GLYCERINE JELLY.

Calves Foot Jelly (Crosse and Blackwell's)	2 parts.
Warm and add—	
Glycerine	1 or 2 parts.
Essence of Cochineal	q. s.
Perfume	q. s.

The above makes a perfectly transparent emollient jelly, which keeps good any length of time in stoppered or corked bottles, but evaporates in bottles closed by screw-caps. P. B.

[542]. GLYCERINE JELLY.- An excellent transparent glycerine jelly can be prepared from one part powdered gum tragacanth dissolved by heat in thirty-parts by measure of glycerine and perfumed with otto and lavender. C. STOCKS.

[542]. GLYCERINE JELLY.—W. C. and F. A. L. will find the following a perfectly transparent glycerine jelly:—

℞ Glycerini,
Aq. Rosæ ana . . . . . fl. ℥iij.
Gelatin. . . . . ℥j.

Dissolve the gelatine in the rose water with the aid of heat and add them to the glycerine, perfume and strain while warm through a plug of tow. Otto of rose or oil of rose geranium is generally employed as the perfume.
J. H. GARRETT.

[543]. GELATINE SUPPOSITORIES.—Can some reader oblige me with a form for making "gelatine suppositories"? ALPHA.

[544]. REMOVAL OF FRECKLES.—Can any reader give me a good recipe for the removal of sun freckles?
GENTIAN.

[545]. PEPSINE WINE.—Will some reader kindly furnish a good formula for pepsine wine?
A. L. NESS.

[546]. CRANE OIL.—Can any of your readers inform me if there is such a preparation, and where it can be obtained? ARDEA CINEREA.

Obituary.

Notice has been received of the death of the following:—

On the 24th of July, 1878, Mr. Henry Burnham, Chemist and Druggist, Patrington, Yorkshire. Aged 37 years.

On the 9th of October, 1878, Mr. James West, Chemist and Druggist, Fleet Street, Torquay. Aged 65 years.

On the 1st of November, 1878, Mr. Henry Shaw, Chemist and Druggist, Chesterfield. Aged 64 years.

On the 11th of November, 1878, Mr. John Rewcastle, Chemist and Druggist, Bedlington, Northumberland. Aged 52 years.

On the 14th of November, 1878, Mr. John Ward Livesey, Chemist and Druggist, Middleton, Lancs. Aged 63 years.

On the 19th of November, 1878, Mr. Charles Jones, Pharmaceutical Chemist, Hanley. Aged 68 years. Mr. Jones was one of the Founders of the Pharmaceutical Society and at the time of his death was one of its Local Secretaries. He also acted as Local Secretary of the Chemists' Defence Association.

On the 25th of November, 1878, Mr. Charles Fisher, Chemist and Druggist, Ramsgate. Aged 79 years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

SUGGESTIONS FOR A NEW EDITION OF THE BRITISH PHARMCOPŒIA.

Sir,—The thanks, both of the pharmaceutical and medical profession, are due to Dr. Symes for his able paper read before the Liverpool Chemists' Association, and I feel sure many suggestions there made will bear fruit.

Now, sir, there are many preparations in the Pharmacopœia which are not made in the laboratory, but at the dispensing counter, either as required for use or in small quantities, according to the size of the bottles set apart to receive them or in proportion to the demand, and I think many useful suggestions might be obtained from dispensers if they would only take the trouble to express their views in our valuable Journal on little points that might not occur to men accustomed to make things by the gallon or ton.

Such things that are usually made in the laboratary or on a large scale will be sure to have every attention; but little and perhaps, as some may think, unimportant things may escape notice.

With these views, then, I venture to draw attention to a few preparations which with very little alteration would save the dispenser a vast amount of calculation, a matter of considerable importance, especially during a rush of business.

Preparations containing solids in solution, such as glycerine of tannin, camphor liniment, or mucilage of acacia, and I may add solutions of acetate and citrate of ammonia, should be made up to measure, after solution has been effected, so that a given measure may contain exactly a certain quantity of active ingredient.

Infusions, like decoctions, should be made up to measure by pouring "distilled water over the contents of the strainer." This is especially important where an infusion is ordered that is usually only made when wanted and only just the quantity required, and where the ingredient absorbs a large quantity of water, as in chamomile or buchu. N.B. Infusions are not ordered to be pressed and if they were it would only make them muddy.

Some preparations, such as the liniment and tincture of iodine have fractions of grains in the formula, and if, as is frequently the case, other than the B.P. quantity is made, it causes a waste of time in calculations. Why can there not be a given number of grains per ounce?

In mist. cretæ co., if sugar were substituted for syrup we should have dry ingredients, two and a half ounces to the pint, which is a very convenient strength, if as is usually the case, the dry ingredients be kept ready mixed. All the mixtures should be made up to measure.

Amongst the ointments, unguentum potassii iodidi and unguentum gallæ cum opio are the only two that require alteration from a dispenser's point of view. In the iodide of potassium ointment the ingredients should be so arranged that the whole when completed weighs an ounce. This ointment ought always to be made when required for use, and consequently there is about a quarter of an ounce wasted when an ounce is ordered. Unguentum gallæ cum opio should also be arranged to weigh an ounce, although as this ointment is usually kept ready this is not of so much importance, but the form should be complete in itself without having also to calculate the proper quantity of gall ointment to make for the purpose. Gall ointment is seldom kept ready made, and even if it were a dispenser does not quite see the fun of making two separate ointments for one.

In conclusion, it would be a great convenience if some of the copies of the Pharmacopœia were interleaved with blank pages for laboratory notes or students' use.

Some of these ideas, sir, may, seem to you trivial, but I maintain that any little alteration that can be made without interfering with the efficacy of the product, such as I have suggested, that reduces calculations to a minimum, is a consummation devoutly to be wished. I trust these few remarks will be taken in good part and that they will lead others to give their ideas on the subject, feeling sure that they cannot possibly do any mischief and may do a great deal of good.
PHARMACEUTICAL CHEMIST.

Tincture of Quinine.

Sir,—I yield to Mr. Whitfield the palm for having first proposed the use of the hydrochlorate in making tincture of quinine. Before writing my paper I referred to the indices of the *Pharmaceutical Journal* and read what was published on the subject, but did not think there was anything so recent as Mr. Whitfield's communication.

If it did nothing more, my paper helped to ventilate the subject.

I would object to having two tinctures of quinine as suggested by B.P. from Belfast; it would be multiplying preparations unnecessarily.

10, *New Cavendish Street, W.* William Martindale.

[*** Mr. Whitfield's paper on Tincture of Quinine occurs three times in the Index to volume viii., viz. under "Quinine," "Tincture," and "Whitfield."—Ed. Ph. J.]

Chemists, Captains and Apothecaries.

Sir,—Are ship captains apothecaries, or do they act and practise as such? This question occurred to me while perusing your report of the recent trial.

Located inland, I cannot very positively speak about medicine chest practice on board ship. If the question can be utilized at this present crisis, some of your seaport readers might afford valuable information.

If ship captains are merely dispensers of medicine in the same sense that chemists and druggists are, why was it that Mr. Shepperley's counsel did not plead for him that his dispensing did not exceed the boundary of theirs? And so urging on judge and jury the unquestioned utility of the medicine chest, the success of the non-medical yet prescribing captain, he might fairly argue thence the greater utility and greater success of dispensing counter and prescribing chemist.

I have always understood it to be (in small trading vessels it must be so) the captain's duty to diagnose scurvy, ague, etc., etc., and treat the same according to his own judgment, experience and information, aided of course by the medicine chest guide.

The right of a chemist to diagnose is I take it included and covered (it surely cannot be extinguished) by the term dispense.

Judging from newspaper criticism it is evident the public are with us in the claim, that this all-important word be interpreted, inwardly and outwardly, "fully and amply," in our favour.

Ictus Equi.

Lozenges and the Excise.

Sir,—I have just been informed by the representative of a lozenge manufacturer that the Inland Revenue officers are actively enforcing the law against vendors of lozenges bearing the name of the vendor stamped on the lozenge, thus including such lozenges amongst the list of proprietary articles which must be stamped.

51, *Judd Street, W.C.* Felix Stevens.

Eucalyptus Globulus.

Sir,—The contributor of "The Month" has little to say concerning the *Eucalyptus globulus*.

Mr. G. G. Stone of this place has several in his garden. Some planted out in the spring of 1877, and then a few inches high, are now over twenty feet. These were protected by the eaves and walls of the house during last winter, but are now too high to get much shelter. There is also one tree planted out in 1876, at some distance from the house though in a somewhat sheltered position, and this is higher than the others, but has not been measured.

All the trees got through last winter well, and did not die back much. Some were covered up with matting, and off these many leaves came, but those did best that were left alone. The gardener is doubtful as to the effect this winter may have on them. Their lofty tops and spreading branches render it difficult to supply them with the amount of support their slender trunks seem to require, and they will necessarily be more exposed both to wind and frost.

Red Hill. Thomas Padwick.

[*** We are also informed by another correspondent that fine specimens of eucalyptus, fifteen years old, occur in the neighbourhood of Falmouth.—Ed. Ph. J.]

Unusual Doses.

Sir,—Noticing in a recent Journal a communication from A. P. S, on the subject of unusual doses, I have determined to forward a prescription which I had to dispense a few week's since, trusting that some one of greater experience than myself may offer a more satisfactory explanation of it than any hypothesis which I have been able to adopt from the perusal of works on posology.

It was as follows:—

℞ Santonine	℥ss.
Ess. Limonis	gtt. ij.
Syrupi	fl. ℥ss.
Aquæ	q. s. ad fl. ℥vj.

M. ft.

A tablespoonful three times a day.

It will be observed that the dose of santonine here given (reckoning the half ounce to be equivalent to four drachms) is twenty grains, whilst the B. P. dose is from two to six grains, and from other works I have obtained the following:—

Squire, 1864. Four to six grains for an infant.
" 1874. Two to six grains for an infant.
Meadows. One-half grain infant; two to ten grains adult.
Parrish. One grain child.
Bentley and Redwood. One-half grain child; two to six grains adult; whilst in excessive doses it acts as an acrid poison, etc.

Now, there is a saying, "Doctors disagree, patients die," and a vast difference of opinion appears here. The largest dose is given as ten grains, but calculating the adult dose according to the posological tables of Guy's Hospital from that given by Squire for an infant it would reach forty grains. In the face of all these contradictions by men in authority, what is the pharmacist to do?

Artium Socius.

France or Yorkshire?

Sir,—In Mr. George Walker's lecture, "The Model Pharmacist," I am surprised to see the lines, "The world is full of fools," etc., described as a Yorkshire legend. I have met with them in French, as follows:—

"Le monde est plein de fous
Et qui n'en veut pas voir
Doit se tenir tout seul
Et casser son miroir."

I am inclined to think that the French is the original epigram and that the English is but a faithful though somewhat clumsy version.

PRELIMINARY NOTE ON ACETO-NITRATE OF IRON AS A MEDICINAL AGENT.*

BY JOHN WILLIAMS.

Some few years back M. Scheurer-Kestner (*Ann. Chim. et Physique*, 3rd series, vol. lxiii., p. 422; and Watts's 'Chemistry,' 1st Suppl., p. 11) pointed out the existence of a series of salts formed by the combination of peracetate and pernitrate of iron. The description given of these salts is not very clear or definite, and would lead one to suppose that the compounds formed by the union of these two salts of iron were so readily decomposable as to preclude any hope of utilizing them for commercial or therapeutic purposes. Still these salts, if they could be readily prepared, promised to be of such service that it was determined to make some experiments to settle that question, and I am indebted to my friend Mr. Miles Smith for suggesting and undertaking the work of preparing these salts and investigating the nature of the products obtained.

Various processes are mentioned by Mr. Kestner for producing these salts. The addition of a strong solution of acetate of iron to one of nitrate, the addition of nitric acid to solution of acetate, or of acetic acid to a solution of the nitrate, or the solution of hydrated ferric oxide in a mixture of the two acids and one or two other processes are named, and according to the author yield salts of varying constitution and named by him, respectively, mono-, di-, tri- and tetraceto dinitrate of iron. He, however, mentions that the tetraceto salt having the composition $Fe_2\begin{cases}(C_2H_3O)_4\\NO_3\\HO\end{cases}$ + 4 aq. crystallizes in hard shining, red-brown, rhombic prisms, and is less deliquescent than the other acetonitrates.

Now in the course of the experiments I am about to describe, various salts, having different tints of colour, some being nearly black, and having various degrees of deliquescence, have doubtless been obtained, and may very probably be the salts having the various composition attributed to them by Mr. Kestner, and I must admit that no attempt to analyse them has as yet been made by me. But upon recrystallization the various salts all appeared to yield one and the same salt as the final product, and this leads me to suspect that the various salts named may in reality be one in a more or less impure condition. Of course I should be very sorry to express a positive opinion upon this matter without making many more experiments and analyses, and it is proper I should mention that the experiments we have in hand are at present in a very unfinished state. Still I am bound to repeat that as far as I can judge with my present knowledge we appear always to obtain one definite salt by the recrystallization of any of the others.

Perhaps the best mode of forming the acetonitrate of iron is to dissolve hydrated ferric oxide, which must be quite recent and well washed, in a mixture of glacial acetic and nitric acids, in which the acetic acid is in considerable excess (say two or three parts to one); the hydrated oxide contains sufficient water to dilute the solution, and the oxide must be added slowly so as to avoid very great elevation of temperature. The solution so formed in twenty-four hours deposits a quantity of the double salt, in hard well-formed crystals. These drained from the mother liquor can be dissolved in a small quantity of warm (not boiling) water, strained if necessary, and allowed to crystallize. The crystals so deposited have all the characters assigned to the tetracetodinitrate of iron, and I assume may be fairly taken as being represented by the formula given for that compound.

I find these crystals are not by any means so easily decomposed as the original description would lead one to infer; on the contrary, they are quite permanent, and so slightly deliquescent that they can readily be kept in paper for several days without spoiling.

They are very soluble in water in the cold or gently warmed, but I find the solution of the salt is decomposed by boiling, basic compounds being deposited which cannot afterwards be got into solution. It is also freely soluble in alcohol, but practically insoluble in ether.

The various solutions of this salt have a pure styptic taste, quite free from acidity, and not by any means as disagreeable as the tincture of the perchloride.

Unfortunately a difficulty attends the keeping of solutions of this salt, which up to the present time I have not succeeded in overcoming. Both the aqueous and alcoholic solutions are liable to gelatinize after being kept a few days or weeks. Tinctures made with absolute alcohol, rectified spirit and proof spirit equally pectized after a time. I thought a tincture made with equal parts of rectified spirit and water was successful, but it went at last very suddenly and apparently without cause, it having been liquid in the morning and a jelly in the afternoon. I am still trying the effects of spirit of various strengths in hope of obtaining a solution which will prove permanent. The addition of free acetic acid, I may mention, has also been tried, but did not prove effectual.

At the suggestion of Mr. Holmes, I have lately made a solution in dilute glycerine: 1 oz. of glycerine, 3 ozs. of water and 2 drams of nitroacetate. The solution is perfect, and up to the present time has kept well, and I think promises to be a success, but what effect the glycerine might have upon the medicinal properties of the salt I am unprepared to state. I should add that the tinctures I have been experimenting upon were all made of the strength of 1 oz. troy of the crystallized salt to the pint. This I calculated would about represent the strength of the tinct. ferri acetatis of the Pharmacopœia.

There is no doubt, I think, that this curious compound, the nitroacetate of iron, imperfect as it may be in some respects, may probably be used with advantage in medicine. There has been a want, long felt, of a definite, crystallized, non-deliquescent persalt of iron, and the present salt could be administered in the form of pills with facility and also in mixtures when the medicine is not intended to be kept long, but taken within a few days of being dispensed. There is also probably an advantage in the fact of the salt containing a large proportion of an organic acid and only a small quantity of a mineral one, and should we be able to get over the difficulty of keeping a solution suited for dispensing purposes, I think the compound would prove of very considerable use as a medicinal agent.

Although the experiments I have described may be considered to have resulted in failure as far as

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 4, 1878.

a very essential point is concerned, still I trust the subject will prove to have sufficient interest to excuse my bringing the matter before the Society in its present incomplete form.

[*The discussion on this paper is printed at p.* 480.]

GUAYCURU ROOT.*

BY E. M. HOLMES.

In a paper read at the meeting of the Pharmaceutical Conference in Dublin, and which has since been published in the *Pharmaceutical Journal*, Dr. Symes mentions that in my opinion baycuru root was identical with guaycuru root and that it was probably derived from *Statice brasiliensis*. This opinion has since been further confirmed by Mr. W. B. Cranwell, in a letter sent to the Journal on September 28th.

My opinion, however, was given without having seen an authentic specimen of the root of *Statice brasiliensis*. Since then I have received for the Museum a specimen of what purports to be the genuine root of *Statice brasiliensis* from the collection of drugs in the department of the Argentine Republic in the Paris Exhibition. As this root differs in character from that presented to the Society, in August last, by Dr. Symes, it appeared to me to be desirable to point out that either baycuru must be a distinct drug, or that several different roots are sold under the name of guaycuru in one district and of baycuru in another. That the latter is the case appears probable from the fact that both baycuru and guaycuru are astringent roots, and from the following note, translated from a paper in the *Revista Farmaceutica*,† of Buenos Ayres.

The writer, Senor Domingo Parodi, states that "the plant used in Paraguay pharmacies under the name of guaycuru is the root of *Statice brasiliensis*. This plant grows in the southern provinces of Brazil, in the island of Santa Catalina, on shores of the estuary of the La Plata river, and on the sea coast of the provinces of Buenos Ayres."

The plant is described as having smooth obtuse one-veined leaves, which are attenuated into the petiole. The inflorescence consists of a cylindrical, hollow, tall, scape, branched above, the branches forming a pyramidal panicle, and the spikelets consisting of two to three flowers, the bracts being herbaceous and of a reddish tint. The tube of the calyx is glabrous and the fruit (a utricle) indehiscent.

The root is described as being of a blackish-brown colour, wrinkled externally and reddish internally, and possessing an astringent taste. The horizontal section shows a concentric ring which marks the extent of the meditullium. In the southern provinces the root of another species, *Statice antarctica*, is used under the name of guaycuru.

Senor Parodi thinks that guaycuru might with advantage replace the astringents imported from abroad. For internal use a decoction of 1 part in 1000 of water is used, and for an external application 1 part in 20.

The guaycuru of Chili appears to be another plant. It is described by Molina in his 'Historia Fisica de Chilé' under the name of *Plegorhiza adstringens*. The genus and species is established by himself on the strength of the one-celled one-seeded ovary and monopetalous corolla (calyx ?), the calyx being absent. The plant is described as follows :—

Stem woody; radical leaves crowded into a tuft, stalked, oval, simple, entire; stem leaves sessile and ovate; flowers terminal, stalked, numerous; corolla monopetalous, entire; stamens nine, very short; anthers oblong; ovary orbicular; style cylindrical, as long as the stamens; stigma simple; fruit a capsule, oblong and compressed; seed solitary, oblong, subcompressed.

Molina describes the plant as being one of the most powerful astringents of the vegetable kingdom. He states that it has been shown by experience that it will rapidly dry up ulcers and scrofulous sores and arrest dysentery.

This plant, however, does not appear to be well known, since Jussieu places it among the plants "incertæ sedis," and De Candolle only quotes it in the appendix to the 'Prodromus.'

M. Rey, of Paris, tells me that under the very similar name of guayéru, the root, bark and leaves of a rosaceous shrub, *Chrysobalanus Icaco*, which grows spontaneously on the shores of Brazil, is used as an astringent in chronic diarrhœa, leucorrhœa, etc., and as a lotion to heal ulcers and wounds.

It is thus evident that the name alone is not sufficient to indicate the root used unless it be obtained from the country or district where it is used.

For this reason it appears to me to be desirable to point out the characters by which the baycuru mentioned by Dr. Symes, may be distinguished from guaycuru.

Baycuru is a somewhat contorted root, about the size of the finger, with a blackish-brown rough bark externally, the roughness being due to a large number of minute fissures in various directions, cutting the bark up into minute granulations. The transverse section shows a blackish bark, less than a line in thickness, and a bright pinkish-brown spongy meditullium, about half an inch in diameter. Under a lens the bark is seen to be distinctly stratified, and the meditullium has a ring of radiating fissures midway between its centre and the bark The taste is astringent.

Guaycuru from the Argentine Republic, which appears to correspond to Senor Parodi's description of the root of *Statice brasiliensis*, has much general resemblance externally to dandelion root, being branched at the top like that root. It is marked with scattered short fissures, and under a lens the whole surface is seen to be finely wrinkled in a longitudinal direction only, so that it is not cut up into rough points as in the baycuru. A transverse section of the root is of a dark reddish-brown colour. The cortical portion is not stratified, but is much darker near the meditullium, while the meditullium is paler towards its circumference, so that the appearance of a dark line separating the meditullium and cortical portion is very prominent. Under a lens a circle of fine radiating dark lines is seen proceeding from the meditullium half-way through the bark. Minute crystals, probably of sea salt, are scattered throughout the tissue. The taste is astringent, and slightly salt and fishy.

From the above description it is obvious that guaycuru and baycuru are not derived from the same plant, and while it may be accepted that the former is derived from *Statice brasiliensis*, the source of the latter must be left unsettled until the description of the root here given can be identified with that of some other plant.

[*The discussion on this paper is printed at p.* 481.]

The Pharmaceutical Journal.

SATURDAY, DECEMBER 7, 1878.

A LEGAL SETTLEMENT OF THE QUESTION "WHAT IS VIOLET POWDER."

THE appeal against the conviction of Messrs. GILL AND SON by the Salford borough magistrates last July, for an infringement of the Sale of Food and Drugs Act, has just been heard at the Salford hundred quarter sessions and has resulted in the quashing of the conviction. The case was one in which the appellants were charged with having sold as violet powder an article which was not composed of starch, but which really consisted mainly of sulphate of lime, and the prosecution was instituted under the sixth section of the Sale of Food and Drugs Act, which provides that no person shall sell, to the prejudice of the purchaser, any article of food or any drug which is not of the nature, substance and quality of the article demanded by such purchaser, and further that any one infringing this section of the Act is to be liable to a penalty of twenty pounds.

At the hearing of the case before the police magistrates last July, it was proved that the powder in question, sold with the label, "Superfine Royal Violet Powder," was chiefly sulphate of lime. It was contended by the prosecution that violet powder came within the meaning of the section above referred to, inasmuch as in the interpretation clauses of the Act the term drug is defined as signifying any medicine for internal or external use, and further that violet powder should consist principally of starch.

For the defence the composition and nature of the powder sold was not disputed, though it was argued that violet powder was not a drug, but a cosmetic, and that the name was applied to more than one substance. The magistrates, however, adopted the view that it was to be regarded as a drug, and after hearing the evidence given on both sides they also came to the conclusion that violet powder should consist of starch, and gave judgment against the defendants.

At the hearing of the appeal, the court was asked to find as a matter of fact—first, that the article sold by the appellants was a drug within the meaning of the statute; secondly, that it was sold to the prejudice of the purchaser, notwithstanding the circumstance that it was procured for the sole purpose of being analysed; and thirdly, that it was not of the nature, substance and quality of the article demanded.

Evidence in support of the view that violet powder should consist of starch was given by Mr. CARTER BELL, Analyst for the Borough of Salford, Dr. T. STEVENSON, Lecturer on Chemistry and Medical Jurisprudence at Guy's Hospital, Dr. TATHAM, Medical Officer of Health for Salford, Mr. WANKLYN, Professor of Chemistry at St. George's Hospital, and Dr. WAHLTUCH, Honorary Physician to the Hulme Dispensary; all of these witnesses were of opinion that powdered sulphate of lime applied to the skin would act as a mechanical irritant, but no evidence was produced to show that such was the case as a matter of fact.

The argument on behalf of the appellants was, first, that violet powder was not a drug within the meaning of the sixth section of the Act, and secondly, that if it was to be regarded as a drug it was a compounded drug, and that the prosecution should have been instituted under the seventh section of the Act, which was expressly intended to meet the case of compounded drugs. It was also urged that there was no authoritative formula for violet powder, that the manufacturers had no intention to palm off an inferior article, and that the prosecution was bound to prove a practical injury and not only a mere theoretic or assumed injury.

Evidence in support of this argument was given by Professor REDWOOD, Dr. S. COMPTON, Mr. WHITE, surgeon, of Pendleton, Mr. SIEBOLD, and others, in most instances to the effect that powdered sulphate of lime is quite innocuous as an application to the skin, and in fact preferable to starch for that purpose.

The chairman in giving judgment, said that the court had not considered it was necessary to go into the first two questions raised, since in regard to the third question it had arrived at a decision which settled the matter. This was to the effect that as the demand made by the purchaser of the article was in general terms, not for violet powder having no mineral substance in it or for a particular kind of violet powder, and as there was no recognized or authoritative recipe for the manufacture of violet powder, each maker could prepare it in his own way without its being said that any one way of making it was wrong. Under these circumstances the court held that in this case it was not able to say that the inspector received a powder which was not of the nature, substance, and quality of the article demanded and therefore the conviction would be quashed.

On application being made for costs the chairman remarked that the court considered the prosecution on the part of the Corporation of Salford was not only justified, but under the circumstances quite right, since a great deal of alarm had been excited in regard to the sale of violet powder, and the chairman could not help thinking the inquiry had been properly instituted, though if the magistrates had had before them the whole of the evidence which was produced at the appeal they would probably have arrived at a different decision in the first instance.

This result is a fortunate one for those more immediately interested in the appeal, and in so far as there is no ground for supposing that the selenitic violet powder was offered to the public with any evil intent we are glad to congratulate them on the relief thus afforded; but at the same time we cannot abstain from urging the recommendation that in future the application of a distinctive name to this article may be observed so as to preclude the possibility of any reproach.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, December 4, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Fairlie, Frazer, Greenish, Hampson, Hills, Rimmington, Robbins, Sandford, Schacht, Shaw and Woolley.

The minutes of the previous meeting were read and confirmed.

Mr. WOOLLEY said he wished to make restitution of some property which did not belong to him. In the report of last month's Council meeting some remarks had been attributed to him which were made by Mr. Atkins.

The PRESIDENT read a letter which he had received from Mr. Mackay, saying that he had hoped to be present at the Council meeting that day, but was not well enough to undertake the journey.

The PRESIDENT also read a letter from Mr. Gostling, saying he was unable to attend owing to the sudden death of his wife.

APPOINTMENT OF EXAMINERS FOR 1879.

The PRESIDENT read letters from Mr. Umney and Mr. F. J. Hanbury, stating that they would be unable in future to give the necessary time to the examinations, and requesting therefore that their names should not be laid before the Council for appointment. He was sure the Council and the Board of Examiners would regret the retirement of these gentlemen.

The Council went into Committee to consider and discuss the merits of the respective gentlemen who had been nominated. The Council having resumed, a ballot was taken, and the President declared the following Pharmaceutical Chemists to be appointed Examiners for the ensuing year, subject to the approval of the Privy Council:—

England and Wales.

Allchin, Alfred, England House, Primrose Hill Road, N.W.

Barnes, James Benjamin, 1, Trevor Terrace, Knightsbridge, S.W.

Benger, Frederick Baden, 7, Exchange Street, Manchester.

Brady, Henry Bowman, Hillfield, Gateshead-on-Tyne.

Carteighe, Michael, 180, New Bond Street, W.

Corder, Octavius, 31, London Street, Norwich.

Gale, Samuel, 338, Oxford Street, W.

Greenish, Thomas Edward, 20, New Street, Dorset Square, N.W.

Linford, John Samuel, 4, Totnes Villa, Ealing Dean, W.

Martindale, William, 10, New Cavendish Street, W.

Moss, John, 300, High Holborn, W.C.

Plowman, Sydney, 2, Residence, St. Thomas's Hospital, S.E.

Southall, William, 17, Bull Street, Birmingham.

Taylor, George Spratt, 13, Queen's Terrace, St. John's Wood, N.W.

Scotland.

Ainslie, William, 58, George Street, Edinburgh.

Borland, John, 7, King Street, Kilmarnock.

Gilmour, William, 11, Elm Row, Edinburgh.

Kemp, David, High Street, Portobello.

Kinninmont, Alexander, 69, South Portland Street, Glasgow.

Noble, Alexander, 139, Princes Street, Edinburgh.

Stephenson, John Bertram, 71, George Street, Edinburgh.

Young, James Robertson, 17, North Bridge, Edinburgh.

Mr. SHAW, referring to the resolution passed in March last, with regard to the identity of examinations in England and Scotland, and requesting the General Purposes Committee to examine and report, asked if any report had been made on the subject.

The PRESIDENT said there had been several meetings of the Committee since then and a deputation had gone to Edinburgh from London, and one from Scotland had come up to London, and conferences on the subject of the examinations had taken place.

Mr. SCHACHT said when this subject was discussed, it was understood that some attempt should be made to merge in some way, if possible, the two Boards, so that English Examiners might sit on the Scotch Board, and *vice versâ*.

The PRESIDENT said this matter had been gone into, and it was found that the Act of Parliament would not permit it to be done.

Mr. SHAW said the resolution he referred to was:—"That the Parliamentary Committee consider upon the desirability and practicability of such an alteration or alterations in the mode of appointing Examiners by the Council under the Pharmacy Acts, as may conduce to a joint system of examination being introduced in England and Scotland, and report thereon." He simply asked if anything had been done on that resolution.

Mr. SCHACHT said the idea with many was that the mere sending of deputations did not answer the purpose and was not likely to do so.

Mr. SANDFORD said he knew the matter had been discussed either in Council or Committee, and in looking into the Act of Parliament it had been found that there must be separate Boards. According to the bye-laws, "persons in Scotland" must be appointed Examiners for Scotland. Scotchmen might be appointed Examiners in England, but that would be difficult and inconvenient and of little use unless the appointment were reciprocal.

Mr. SCHACHT thought there ought to be some more formal report on so important a subject than the mere memory of the President or any one else.

The PRESIDENT said there was no doubt the result of the deliberations was recorded, but it was not fair to put such questions without notice, as it was merely waste of time.

Mr. ROBBINS remembered it perfectly well, and no doubt it would be found in the minute books.

It was then moved by Mr. SANDFORD—

"That the examinations be held in the months of February, April, June, July, October, and December."

The PRESIDENT said the holding of the examinations in alternate months was an experiment, but it had been found to fall hard on the Examiners to have to come up sometimes twice in one month and not at all the next. Many thought it would be well to go back to the old plan of monthly examinations.

Mr. CRACKNELL thought the reason for the alteration no longer existed if there was no objection to the Examiners attending monthly. The reason for making the change was because it was feared that an examination every month would involve the Society in a loss.

Mr. CHURCHILL moved as an amendment that the former practice should be reverted to.

The VICE-PRESIDENT thought many members of the Board of Examiners would prefer adhering to the present plan.

Mr. HAMPSON thought the Council should wait until the Board of Examiners made some representation on the subject.

After some further discussion it was resolved unanimously:—

"That the Library, Museum and Laboratory Committee be requested to confer with the Board of Examiners as to the desirability or otherwise of increasing the number of months in which the Society's examinations are to be held in 1879. The Committee to be

empowered to appoint the dates on which examinations shall be held in that year."

Elections.

ASSOCIATES.

The following have passed the Minor examination, and having tendered or paid, as Apprentices or Students, their subscriptions for the current year, were elected Associates of the Society:—

Hill, John Rutherford.....Lasswade.
Hinkley, Edward .....Newcastle-under-Lyne.
Swindle, Norman Vickers ...Carlisle.

APPRENTICE OR STUDENT.

The following having passed the Preliminary examination, and tendered his subscription for the current year, was elected an Apprentice or Student of the Society:—

Urwick, William .....London.

An Associate was restored to his former status in the Society on payment of a fine.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid. A discussion arose as to one item recommended for payment, viz., papers read at the Evening Meeting in November, Mr. Sandford objecting that the proper title of the item was "Contributions to the Journal," the resolution under which payment was claimed stating that papers read at the evening meetings should be paid for at the usual rate when published in the Journal. An amendment was moved by Mr. Sandford:—

"That the charge of £7 4*s.* for papers read at evening meetings be erased from the Finance report, and referred back fo the Committee."

The amendment on being put to the vote was lost, and the report as above stated was received and adopted.

Mr. Sandford then moved the following resolution, which was unanimously agreed to:—

"That the question of payment for papers read at evening meetings be referred to the Library, Museum and Laboratory Committee for consideration whether the payment should appear in the account as for 'papers read,' or as 'contributions to the Journal.'",

BENEVOLENT FUND.

This Committee had met as usual, but no grants were recommended, there only being two applications, which were deferred, one for further inquiry, and the other because the applicant had recently received a grant.

The Secretary stated that there was a balance in hand of £413, there was nothing to pay this month, and he would suggest that £250 should be invested.

The report of the Committee was received and adopted, and it was also resolved to purchase £250 Consols on Benevolent Fund account.

LIBRARY, MUSEUM AND LABORATORY.

The report of this Committee included the usual report from the Librarian to the following effect:—

Attendance, October 9 to 31, average during day, 19; evening, 10. Circulation of books, town, 123; country, 68; carriage paid, £1 4*s.* 0½*d.*

Donations received:—

Cooley's Cyclopædia of Practical Receipts, 6 ed., 1878, part 7. From Messrs. J. and A. Churchill.

Victoria: Report of the Wattle-bark Board of Inquiry, 1878. From J. Bosisto, Esq., M.P. (author).

Elements of Dental Materia Medica, *etc.*, 2 ed., 1878. From James Stocken, Esq. (author).

Undersökning af Badgytjan vid Marstrand, 1878. From Dr. N. P. Hamberg. (author).

Recherches sur la Digestion, *etc.* 1878. From Dr. L. Mialhe. (author).

Étude sur le Groupe des Aphides, *etc.*, par L. Courchet, 1878. From Prof. J. L. Soubeiran.

Roll of the Royal College of Physicians of London, 1815–1825, by Dr. Munk, 2 ed., 1878, 3 vols. From the College.

Field's Memoirs of the Botanic Garden at Chelsea, belonging to the Society of Apothecaries of London, 2 ed., by Dr. R. H. Semple, 1878.

The Committee recommended the purchase of the following books:—

General Fund:—

Henkel's medizinisch-pharmazeutische Botanik, and Atlas to the same, 2 ed., 1873.
Kingzett's Animal Chemistry, 1878.
Garrod's Essentials of Materia Medica, 6 ed., 1877.
Fowler's Medical Vocabulary, 2 ed., 1875.
Gore's Art of Scientific Discovery, 1878.
Bentley's Manual of Botany, 3 ed., 1873, additional copy.

Hanbury Fund:—

Kunth's Enumeratio Plantarum, 1833–50.
Seemann's Flora Vitiensis, 1865–73.

The Librarian by request submitted the following statement:—

Year.	Attendances. Highest. Day.	Highest. Evg.	Totals. Day.	Totals. Evg.	No. of entries of books lent.	Carriage paid—about. £	*s.*	*d.*
1874	35	21	4103	1187	2088	2	17	0
1875	44	21	5461	1878	1819	6	4	0
1876	48	22	6718	1853	2055	7	2	0
1877	37	25	5255	2050	2014	6	6	0
1878*	49	29	5088	1753	2060	9	0	0

The Professors had attended the Committee and reported satisfactorily with regard to their respective classes. After consultation it had been arranged that Professor Redwood should deliver two lectures on the Electric Light on the second and third Wednesday evenings in January, and that Professor Bentley should deliver a lecture in March next, on "The Life of a Plant."

The Secretary had placed on the table full returns of the past three sessions of the School of Pharmacy, together with a tabulated statement which he had drawn up.

The Curator had reported that in October the average attendance in the Museum had been day 13; evening 5.

The following Donations had been received, irrespective of those received from the Paris Exhibition:—

Specimens of the stems of an olibanum tree (*Boswellia Frereana*) collected by Mr. W. Wykeham Perry, on the Somali coast; of *Balsamodendron Opobalsamum*, Kth., the Arabian myrrh tree, collected in the Fadhli district, sixty miles from Aden, by Mr. W. Wykeham Perry; of *Boswellia thurifera* from a tree destroyed by a cyclone in 1864, at the Botanical Gardens, Calcutta; an emetic bark from British Honduras; and a specimen of *Mylitta Australis*, from Tasmania: from Professor W. T. Thiselton Dyer.

Specimen of false Kamala, from Professor Flückiger.

Fifty seven specimens of Japanese drugs, with their native names attached.† Specimens of the fruit and leaves of the *Landolphia florida*, one of the India-rubber trees of Liberia; fruit of *Sarcocephalus esculentus*, and several unnamed specimens of drugs from Liberia; also a collection of barks, etc., from British Guiana: from Mr. Thos. Christy.

Specimens of root of *Rheum officinale*, from Mr. R. Usher, Banbury. Three crystals of sulphate of zinc in rectangular prisms; true Venice turpentine, from *Larix europæa*;

* To October, ten months only.

† A list of these will be published in the Journal when their botanical sources have been determined.

crabs' eyes from *Astacus fluviatilis*; pappose fruit of *Tragopogon pratense*; iodocyanide of potassium and mercury, and the following salts of mercury: — acetate, carbonate, chromate, citrate, oxalate, phosphate, and tartrate of the peroxide; chromate, citrate, oxalate, phosphate, subnitrate, sulphate, and tartrate of the suboxide; and subbromide of mercury: from Mr. W. Copney.

Nepaul cardamoms, from Messrs. Curling and Co. False Calabar beans, from Messrs. Hearon, Squire and Francis, Messrs. Wright, Layman and Umney, and Mr. T. Christy. Specimens of yellow and red cinchona bark, from Dr. Paul.

The Curator had also presented the following:—

Report upon Specimens obtained from the Paris Exhibition.

"On arriving in Paris, on October 26th last, I at once proceeded to the offices of the British Commission, and finding that it was impossible to see Sir P. Cunliffe Owen, except by special appointment, I called upon Mr. P. L. Simmonds in the Exhibition building. To this gentleman I am much indebted for useful information, and for personal introduction to several of the Commissaires in different departments, such introductions being often effected at some inconvenience to himself, and considerable loss of time.

"From Mr. Simmonds I received the specimens previously offered to this Society by Mr. Wm. Fresson, of Demerara, and the following donations from himself: Specimens of drugs from India, Jamaica, Western Australia, a few from the Seychelles Island, and the whole collection of roots, barks, etc., from the Straits Settlements.

"In the chemical department I received the capsaicin promised by Mr. Thresh, the specimens of gelseminic acid and hydrochlorate of pilocarpine previously offered by Mr. Gerrard, and from the same gentleman a portion of the pituri which had been presented by the Queensland department to Dr. Ringer.

"In response to applications made to several of the exhibitors for specimens of chemicals, Messrs. Geo. Atkinson and Co., Messrs. Morson and Son, Messrs. Burgoyne, Burbidges and Co., and Messrs. Savory and Moore, instructed their agents to allow me to select any specimens which appeared to me to be desirable, and others promised to contribute specimens when their cases were returned from the Exhibition. Among the latter are an instructive series of specimens, illustrating the composition of cod liver oil, from Messrs. Southall Brothers and Barclay, of Birmingham; small specimens of a series of derivatives of the opium alkaloids from Messrs. Macfarlane and Co., of Edinburgh; and some of the new opium alkaloids, including meconoiosine and gnoscopine, from Messrs. T. and H. Smith, of Edinburgh; a series of aniline products from Messrs. Williams, Thomas and Dower, of Brentford; and a similar series from Messrs. C. Lowe and Co., of Manchester; a series of mineral pigments (such as possess a definite chemical composition), from Messrs. Storer and Sons, of Glasgow; a series of the resins etc., used in making varnishes, from Messrs. Gidney, Clark and Co., and a similar series from Messrs. Wilkinson, Heywood and Clark; and a series of photographs of crystallization of the fatty acids from Price's Candle Company, Limited.

"In the Canadian department the few drugs which were exhibited were already promised, but Dr. Passmore May kindly presented specimens of plumbago, and of isinglass prepared in Canada from the sturgeon.

"In the Cape of Good Hope department I was kindly received by Mr. Spencer Todd, and presented with several specimens of barks. From the South Australian Court I was promised specimens of mineral caoutchouc, which will probably arrive shortly, and from the Queensland department several specimens of barks, etc., were presented by the agent-general for Queensland through Mr. E. A. Clare.

"The collection of Chinese drugs, which comprised an extensive series of specimens, had already been promised to the French Government; and I was unable to obtain any samples of them, although many were in duplicate. There is, however, already a fair representation of Chinese drugs in the museum of the Pharmaceutical Society, and I was fortunate enough to obtain an introduction through Mons. Cornu to Mons. Pierre, of Saigon, a gentleman who has resided for several years in Cochin China and who is engaged on a large and valuable work on the botany of that country. Mons. Pierre has a large collection of Chinese drugs and is well acquainted with their uses, botanical sources etc., and he has kindly promised to afford me any assistance in his power in increasing the value of our collection.

"The Japanese collection contained but few drugs. I obtained, however, from M. Kubo some specimens of the algæ of that country, from one of which the article known in England as Japanese isinglass is prepared, as well as some interesting information concerning its manufacture.

"In the Guatemala Court I was introduced by M. Triana, the consul for Colombia, and who is well known by his magnificent work on the cinchona trees, to M. Medina, the minister for Guatemala, who permitted me to select such specimens as I desired. In the San Salvador department I met with great kindness from M. Ferriere and from the minister, Senor Torres Caicedo, who, although many promises had already been made to others, reserved a set of specimens to present to our museum.

"Several specimens of the drugs of Nicaragua were presented to me by M. Menier, jun., the whole exhibit being his private collection.

"From the Court of the Argentine Republic I was only able to obtain a few specimens, but among these was a specimen of guaycuru, a root which has recently been introduced into this country, besides a few other comparatively new drugs. The Commissaire for Venezuela also permitted me to select such specimens as I thought desirable.

"In the department of the Dutch colonial possessions I was most kindly received by M. Guillaume Voute. I had already met this gentlemen on the occasion of my former visit, and he then promised me some specimens, a promise which was most liberally redeemed at the close of the Exhibition, both as regards the number and quantity of the specimens. Among the valuable specimens presented by this gentleman are a series of sections of the stems of the cinchona trees now grown in Java, and samples of the barks themselves. These are the more especially valuable since all the Java productions go to Holland, and are therefore difficult to procure.

"In the French Chemical Department I applied for a few specimens of the magnificent crystals manufactured by Messrs. Billault and Billaudot. These, Mons. Petit, of 8, Rue Favart, has kindly promised to obtain, and present to the Society. Of the splendid collection of drugs in the French Colonial department I was able to secure nothing. In reply to an application on behalf of the Society by Sir Philip C. Owen, and a card of introduction from M. Vétillart, Senator, of Sarthe, whose acquaintance I had the good fortune to make while in Paris,—Mons. Lecomte has promised to send a good collection of specimens in the course of a few months, and with this promise I was fain to rest content.

"To the above remarks I may add that my experience leads me to the conclusion that the best way to obtain specimens with the least amount of trouble, and the least possible expenditure of time on a future occasion, would be to visit the Exhibition as soon as the catalogues are all published, to look through the specimens, make lists of desiderata, and forward them at once to the ministers or commissaires representing the different countries, and then again to visit the Exhibition to receive the specimens about a fortnight before it closes. When the Exhibition was visited by me in May and June, it was too early to obtain all the catalogues, and

in October it was a little too early to obtain specimens, but rather too late for many promises.

"Since I left Paris, on November 15, I understand Mr. Simmonds has been able to obtain for the Society a few specimens of Algerian drugs.

"E. M. HOLMES, *Curator*."

Mr. F. Lesca, of Teste, Gironde, had written offering specimens of the products of the Bordeaux pine and implements used in their preparation, if his name were attached to the specimens when exhibited in the museum. The Committee recommended that the offer be accepted; also that a special acknowledgment and a copy of the Journal and of the museum catalogue be sent to the gentlemen who had assisted the Curator in obtaining specimens for the museum. On the application of the Curator the Committee recommended that he be allowed an assistant temporarily, for the purpose of arranging specimens and preparing catalogue, etc.

Mr. BOTTLE regretted that no reference to the Weights and Measures Bill appeared in the report of the Committee.

The PRESIDENT said the matter had never come before the Committee. It had been before the General Purposes Committee when the bill was passing through Parliament, and the Committee believed it had procured for chemists and druggists all necessary protection.

Mr. ATKINS expressed his satisfaction at the result of the Curator's visit to Paris.

The Council went into Committee to discuss the returns of the school and certain other matters, after which the Council having resumed, the report and recommendations were adopted unanimously.

THE LATE DANIEL HANBURY.

The PRESIDENT read a letter from Mr. Thomas Hanbury presenting the Society with thirty-five copies of the engraved portrait of his late brother, to be presented to students in the School of Pharmacy who obtain the Hanbury Prize. He would move that the thanks of the Society be given to Mr. Hanbury.

The VICE-PRESIDENT seconded the resolution, which was carried unanimously.

HOUSE.

The report of this Committee included a report from the Surveyor.

The Committee had also carefully examined the premises with a view to ascertain if additional accommodation could be provided for lady students.

At a second meeting of the Committee, after hearing a report from the President and Mr. Sandford, who had been deputed to go carefully into the matter, and considering an estimate for carrying out the alterations suggested, the Committee reported that no part of the Society's premises could be properly or advantageously applied to this purpose. The Committee had been assured by the Professors and other persons well capable of judging, that there was really no occasion to make any alteration for this purpose, and therefore recommended the Council not to proceed further in the matter at present.

The report and recommendations of the Committee were received and adopted.

SPECIAL COMMITTEE TO CONSIDER AMENDMENTS IN THE PHARMACY ACT.

This Committee had held two meetings, and a report of its proceedings was presented, but it was resolved not to publish it at present, and the discussion upon it was taken in Committee.

The report was received and the Committee requested to continue its labours. It was also resolved that the report be printed and sent to each member of Council as a private communication.

Mr. BETTY afterwards moved that the report be taken into consideration at the January meeting.

Mr. SCHACHT objected to such a resolution. He thought the report should be elaborated and completed by the Committee before the matter was discussed by the Council.

Mr. WOOLLEY partly agreed with Mr. Schacht, but thought it was a very large question, and the Council would never be able to discuss the whole report at one meeting. He suggested Mr. Betty should limit his resolution to the report as already prepared.

After some further discussion, Mr. Betty's resolution was negatived.

Mr. HAMPSON proposed the addition of Mr. Fairlie's name to the Committee.

The PRESIDENT said it was irregular to make such a proposition at the present time.

Mr. HAMPSON could not see how it could be so considered.

Mr. GREENISH seconded Mr. Hampson's motion.

Mr. BOTTLE said he should have much pleasure in making way for Mr. Fairlie on the Committee. He had recently read in the Journal some observations made by Mr. Fairlie in another place, reflecting on the work of the Council, and especially on the work of that Committee. When he read that Mr. Fairlie had arrived at the opinion that amendments to the Pharmacy Act were urgently needed, and that a Committee had been appointed to ascertain what amendments were required, but that he did not apprehend anything very vigorous would come of the matter, he thought it was an unfair expression of opinion in another place where members of the Council had not an opportunity of answering for themselves; and he should therefore object to serve on the Committee with Mr. Fairlie.

Mr. BETTY said Mr. Fairlie had not received notice of this objection, and very likely he did not see at the moment the full force of the expression he had made use of, and he was quite sure when he became cognizant of the work which the Committee was really doing, he would find that no one was less interested in it than another. He was quite sure Mr. Fairlie was aware that anything spoken in the heat of debate might be withdrawn, without any derogation of self respect, and he hoped he would do so.

Mr. HAMPSON had not anticipated this matter being intruded upon that meeting, but after all he was quite sure that Mr. Fairlie was justified in expressing his personal convictions, and he admired the man who could do so, however objectionable they might be to other persons. He did not see how any member of the Committee could take the remarks as any personal offence. There was nothing intrinsically objectionable in them.

Mr. GREENISH, as seconder of the motion, would simply say, if it was, as Mr. Hampson had stated it, fairly but strongly expressed, the very best thing the Council could do would be to put Mr. Fairlie on the Committee.

Mr. FAIRLIE said the Council would be aware that the report which had been referred to was not a complete report and did not contain the whole of what he said, but in justification of remarks similar to those being used by him he might say that at the last Council meeting at which he was present Mr. Bottle made a statement which he repeated at the meeting referred to and it was on these words of Mr. Bottle that he grounded the remarks which were objected to. Mr. Bottle had said in moving for the appointment of this Committee that if the Council did not appoint a Committee to do this work some one else would take it up. He certainly felt gratified with the report so far as it had been presented to the Council, but still if he had said anything which had given personal offence he should be very sorry. He did not think Mr. Bottle or any other member should feel aggrieved at what he had said, or decline to sit on the Committee with him. If Mr. Bottle declined to do so, he must decline to be put on the Committee, and in that case must decline to be a member of the Council of the Society. If Mr. Bottle had asked him personally he could have given a much better

reply than he could now on the spur of the moment, but he did not think he had said anything which could be considered offensive to any member of the Committee. He should not, however, allow his name to go forward if Mr. Bottle were to withdraw, because he looked upon him as one of the most valuable members of the Committee, and he saw that he had been pressing forward one of the points which he felt very strongly upon himself.

Mr. SCHACHT was sure the members of the Council would be pleased to hear these words, and he thought they would all vote in favour of the addition of Mr. Fairlie's name, provided they did not by so doing thrust out Mr. Bottle. He rather took it that Mr. Bottle's objection to the words was not that they conveyed any personal affront to him, but a feeling that a gentleman who made use of such expressions would hardly be inclined to bring an unprejudiced mind to the work of the Committee. He hoped what Mr. Fairlie had said would enable them to get rid of that idea, and that if he did join the Committee he would bring to it a disposition to make the best of the subject committed to it.

Mr. SHAW, having been present on the occasion referred to, said his impression was that Mr. Fairlie said, as had been stated on former occasions, that he had not felt confidence in the Council, as a Council, in carrying out the things which he desired to initiate. His remarks certainly did not apply in any kind of way to Mr. Bottle, and if any exception were taken to the words it should be by the Council generally.

The PRESIDENT said it must be remembered that Mr. Bottle moved the resolution for the appointment of the Committee.

Mr. BOTTLE said he must at once disabuse the minds of members of any idea that he took this as a personal matter. He certainly thought when he read those remarks that it would have been more generous of Mr. Fairlie to express his opinions at the Council table, and he thought his observations with reference to the work of the Committee were prejudging the whole affair, especially when it was borne in mind that in proposing that Committee he had made it a *sine quâ non* that Mr. Sandford, who held some opposing views, should be a member of it; and he had also included Mr. Mackay as representing Scotland.

Mr. FRAZER asked if the report referred to was sent out by the Executive Committee of the Association, or whether it was prepared by a public reporter.

Mr. FAIRLIE said a professional reporter was employed, but the report was revised by the Secretary.

Mr. ATKINS said there was a special reward promised to peace makers, and he hoped that Mr. Bottle would retain his name and also that Mr. Fairlie's name would be added to the Committee. He certainly did take exception to the words referred to, when he read them, though he did not make any personal application of them. Members of Council were cognizant of the fact that such sentiments were freely distributed, and he thought it would be wise for those who came into the Council to learn, as they must learn, that all there were doing their best to promote the true interests of pharmacy, and when they got outside were bound to do their best to set the matters right with the public.

The resolution was then put and carried unanimously.

GENERAL PURPOSES COMMITTEE.

The report of this Committee included a good deal of correspondence with the Solicitor with regard to cases of alleged infringement of the Pharmacy Acts and also particulars of other cases reported direct to the Secretary.

The report was received and adopted unanimously.

THE WEIGHTS AND MEASURES ACT.

Mr. BOTTLE, referring to this subject, said he thought some steps should be taken with regard to this Act, seeing that it came into force in January next. He referred to the 20th section of the Act, and asked whether the word "may" in the section ought not to read "shall," as was often the case in these Acts of Parliament. Further on there was a provision that all weights and measures should be verified and stamped by the inspector. Of course glass measures could not be stamped, but the meaning of that term was interpreted in another section to include engraving, etching or otherwise marking, and therefore he took it that they would be compelled to have all their measures verified and engraved.

The PRESIDENT said when the deputation of the Council waited on the Board of Trade this question of stamping or marking glass measures was mentioned, and he remembered saying that chemists would be only too glad if the Government would establish some place where such measures could be verified, but the officials declined to undertake it, and at the present moment there were no practical means and no place where such measures could be stamped or engraved in accordance with the requirements of the Act. The principal Secretary to the Board of Trade told him plainly that the Department could not undertake the work.

Mr. BOTTLE said a fair reading of the Act would indicate that the Department had to undertake it.

Mr. WOOLLEY said he knew the local officials were getting ready to do it in Manchester. The inspector himself told him that all the glass measures would have to be marked.

The PRESIDENT said it was most desirable that this verification should be done, and he was sure the whole trade would be only too thankful if their measures were verified.

Mr. SCHACHT, referring to the point mentioned earlier in the meeting, said he had had the minutes of the Law and Parliamentary Committee looked through, and he found no record of any resolution on the matter referred to it with regard to the examinations.

After some conversation on this point,

The PRESIDENT said it would be better to bring it forward after notice on another occasion.

Mr. SANDFORD then moved the following resolution, in the absence of Mr. Mackay, who had given notice of it:—

> "That any candidate who enters for examination and fails to present himself before the Board or the Superintendent on the day appointed shall pay the sum of one guinea unless the candidate so absenting himself produce a medical certificate, or such other evidence of his inability to attend as may be considered satisfactory by the Board of Examiners."

He knew that Mr. Mackay felt strongly about this subject, and he happened to be in Edinburgh when it was discussed. Young men putting their names down for a certain day and then not coming up often occasioned great inconvenience. Sometimes, in fact, the examiners were summoned unnecessarily.

Mr. HILLS seconded the motion.

Mr. CRACKNELL agreed with the spirit of the motion, but he should like to see the excuse a little more limited. He thought it should be confined to cases of illness when testified by medical certificate, and not left to the Board of Examiners to go into such questions at all.

The VICE-PRESIDENT differed from Mr. Cracknell entirely. There were often cases when particular matters arose, such as a young man's employer being called away, and leaving him in charge of the business. Therefore he did think the wording of the motion was quite justifiable.

Mr. GREENISH said if that provision had not been included he should have voted against the motion. He knew a case where a young man about to come up told him that his brother was at the point of death, and he was in such a state of mind that it would have been utterly useless for him to come up to the examination.

Mr. SHAW said the hard and fast line suggested by Mr.

Cracknell would be utterly impossible to carry out. He suggested, however, that the word "forfeit" should be substituted for "fine."

Mr. SANDFORD said young men were not altogether independent, and therefore they should be allowed as much latitude as possible. He thought "fine" was the better word, but he did not care much which it was.

It was then suggested that the word "pay" should be substituted, and with this amendment the motion was carried unanimously.

THE SHEPPERLEY CASE.

The PRESIDENT then called on Mr. Hampson to move a resolution of which he had given notice, but before doing so said he would take the opportunity of reading a letter which he had received from the Solicitor, on asking his opinion a short time ago, when Mr. Fairlie had given notice of a motion of a similar character, in consequence of his having considerable doubts as to its legality. That motion was withdrawn, and therefore he had no opportunity of reading the Solicitor's letter at that time. The only instructions to the Solicitor were a copy of the agenda, requesting his opinion on the legality of the notice of motion which was given. The letter was as follows:—

"Dear Sir,—We have given much consideration to the request made by yours of the 26th inst., for advice upon the notice of motion appearing in the agenda paper for Wednesday next, and on the whole we have arrived, though with much hesitation, at the opinion that the proposed vote is *ultra vires*, so that if it be passed, and the payment made by the Treasurer, it will be the duty of the auditors to call it in question, and that if it be passed by them it may be impeached by any member of the Society not bound by his distinct and individual assent thereto. For our own satisfaction we have the *pros* and *cons* on paper, whereof copy can be sent to the President or Council, if desired, but we do not trouble you with more than the conclusion expressed. The matter is one on which our personal preference favours resort to counsel's opinion."

Mr. HAMPSON said he ought perhaps to apologize to Mr. Fairlie for having taken this matter out of his hands, but he had conferred with that gentleman upon it. He would now move as follows:—

> "That in consideration of the important interests of the Members of the Pharmaceutical Society, and of the trade generally, which are likely to be seriously affected by an adverse decision being given in the case of the Apothecaries' Company *v.* Shepperley, which still awaits decision in a Court of Law, an adequate sum be granted from the funds of the Pharmaceutical Society in aid of defence in the said case."

He wished he were able to represent properly to the members of the Council the importance of this question, and how an adverse decision would affect the members of the trade at large. This was no new question. If they looked back in the annals of their own Society, it would be found that for many years there had been an endeavour on the part of the Apothecaries' Company, or those acting for it, to restrict the action of the chemists and druggists within very narrow and arbitrary lines. He simply looked upon the present action of a certain portion of the medical body as another endeavour to carry out those restrictions. He had been reading the history of this contest, because it was not a new one, and he found in the record which Mr. Jacob Bell so ably drew up in his historical sketch of pharmacy, full details of it, with the phases which it assumed. He would not refer particularly to that portion of the subject, but would ask the Council to consider the effect which would arise from an adverse decision now. There was not a member of the Council, except perhaps one or two who were almost exclusively engaged in the wholesale trade, who would not be affected by it. It was palpable chemists and druggists could not conduct their business by simply selling their wares without note or comment. It was impossible for them to exercise no judgment, but to give simply the article asked for, yet this was the narrow line to which the Apothecaries' Company was trying to confine them. As to Shepperley's case itself, as far as his own experience went, and he had always endeavoured to conduct his business within what he considered to be the strict limits of the law, he was quite ready to do what Mr. Shepperley had done. He should have no objection to look down a man's throat under certain conditions, and if any member of the Apothecaries' Company called upon him for that discretionary exercise of his business he should have no objection to give him a small dose for a cold. He felt, and he believed the whole trade felt, that in so doing he should be acting within the law, and chemists and druggists felt that it was very hard after so many years had elapsed that this right should be called in question. The 28th clause of the Apothecaries Act was really the bone of contention, and he was astonished to find in the correspondence with the solicitors who at that time represented the apothecaries during the contention about the Bill of 1815 that they admitted the chemists' right thoroughly. There could be no doubt about it. The clause in question was framed so as to cover and secure the rights of chemists and druggists, and if it were now found that it had become a bone of contention with the lawyers, too, and that it was not strong enough, the trade would simply have to go to Parliament for a repeal of the 20th or penal clause of that Act, and he considered it would be the duty of the Society to take such a course. He would ask the question whether it did not come within the objects of the Society to aid in the settlement of the matter, and he affirmed most distinctly that it did. He need only call attention to the charter, which stated that the Society was established for the protection of those who carried on the business of chemists and druggists. He maintained that he was justified in calling upon the Council to aid in the settlement of this test case by those words. Beyond that, the Pharmaceutical Society was formed out of similar opposition to medical curtailment, and the original funds were gathered on that plea, the protection of the trade. The first Bill was introduced by the Society of Apothecaries in March, 1813, and the chemists at that time collected funds to protect themselves. Later on when Mr. Hawes's Bill was brought in, the chemists opposed it and this very Society arose out of that opposition. A certain sum of money at that time having been subscribed to oppose this kind of restriction, the balance, amounting to £862 18*s.* 2*d.*, was handed over to the Society on its establishment, but that sum had been collected solely for the purpose of defence. Thirty-five years since the charter was obtained, the Society year by year received a certain number of guineas from subscribers throughout the country, obtained under that charter which gave the Society power to protect the trade. The trade at this particular time was in danger, and chemists were now called upon to defend a right that had been considered intact, and therefore he considered the Society would be justified in taking the matter up, together with another association. He did not say exactly how it was to be done, but simply asked for an adequate sum of money. It would be for the Council to consider what the proper sum would be. He simply wanted it to affirm the principle that it was its duty to protect the trade in such a crisis. Referring to the opinion of the Society's solicitors, he said that opinion was given with very much hesitation, and they suggested having counsel's opinion taken. Now, he wondered whether it would be within the scope of the Society to pay anything towards bringing in an amended Pharmacy Act. Would that be in conformity with the bye-laws and the charter? Most decidedly. He hoped the Council would seriously consider this question and not jump to a conclusion suddenly. He defended this case, not because it was Mr. Shepperley's case, but because he believed the interests of the trade were seriously jeo-

pardized and if the case were settled against Mr. Shepperley, chemists and druggists would be at the mercy of any common informer and subjected to no end of annoyance.

Mr. WOOLLEY said he had much pleasure in seconding the motion. He did not do so without a considerable amount of thought. At first he was not warmly in favour of it, but during the last month he had considerably changed his views and had come to the conclusion that at all hazards this case of the Apothecaries' Company *v.* Shepperley must be defended, for as it now stood it was simply a case of prescribing and he thought it was a very good case to be defended. If it were given against Mr. Shepperley he could not see how the trade of a chemist and druggist could be worth following, not exactly from a pecuniary point of view, but from the peculiar position in which a man would be placed behind his own counter; it would make him a sort of dumb dog, not daring to give an opinion on the simplest matter laid before him. He had made it his business during the last month or more to get the opinion of his friends, including both chemists and druggists and pharmaceutical chemists. It had been his privilege recently to attend the meeting of the Rochdale Chemists' Association, when the President of that society read a paper devoted entirely to this case, and a very good paper it was, in the course of which he expressed a strong hope that the Council would vote a reasonable sum of money towards the Defence Fund. Another gentleman, quite an elder of the trade, who had retired from business, and whose opinion was certainly entitled to weight, for he had from conscientious motives declined to sell patent medicines, took the same view. He did not know that he could add to what Mr. Hampson had already said, but he felt strongly it would never do to allow this case to stand where it did. The Society's solicitors did not seem to have very much confidence in their own opinion, and at all events for the satisfaction of the Council the matter ought to be cleared up. If the matter was allowed to be in doubt he should never feel comfortable in signing any resolution for the granting of money.

The PRESIDENT said the point was, it was granting a sum of money to another body over which the Council had no control. As long as it kept control and instructed the Society's solicitors or servants to do the work, there was no doubt it was perfectly justified in spending money.

Mr. WOOLLEY said if that were so, he could only say it was an unfortunate thing; but he thought it wanted further elucidation. Chemists throughout the country were looking to the Council for assistance, and if it could not give a reasonable sum of money towards aiding in this defence he was afraid it would not be looked up to with anything like the warmth and good feeling amongst the trade which he should like to see.

Mr. SHAW said he would not go much into the merits of the question, as it had been so well spoken to by the mover and seconder. A previous motion had been brought forward and withdrawn, possibly because it was considered premature; but now chemists and druggists were face to face with a great question which must be decided in a few weeks, and it would be very serious if it should be decided against them. He hoped that he had been as careful as any one around that table in voting away money of the Society, and he hoped they would never wilfully do that which was not within their power. In 1812, 1813, and 1815, certain sums were collected for the purpose of defending the existing rights of chemists and druggists who were then threatened by the action of the Apothecaries' Company. After a good deal of discussion had taken place a certain Act was passed, and during the discussion a statement was made by the solicitor of the Apothecaries' Company to this effect, that the Committee of the Society of Apothecaries had learned with concern that misrepresentations had been made of their object, which was to improve their branch of the profession in medical science. To this their views were so entirely directed that they had no desire to insist on any clause which was not essentially connected with it. He thought that might be taken as fairly representing what the apothecaries' intentions were, and that was shown by the fact that not a single complaint was made for twenty-one years after the passing of the Act of 1815. But now prosecutions were cropping up almost every day under precisely the same law. A fund was subscribed at the time that Act was passed, and a certain balance remained over undisposed of. A meeting was held on August 11, 1815, and the Committee recommended that the surplus be appropriated to any purpose of the trade, for the benefit of the subscribers. Years rolled on, and in November, 1841, a meeting took place at the Crown and Anchor, in the Strand, when a resolution was moved by a Mr. Butterfield, seconded by Mr. Savory, and carried, to this effect:—"The original object of this fund being the protection and advancement of the interests of chemists and druggists, this meeting of subscribers, convened by circular and public advertisement, desires to recognize in the establishment of the Pharmaceutical Society of Great Britain a permanent and legitimate means of accomplishing such object, namely, a general union and organization for the protection of the subscribers, and the education and improvement of future members of the trade, and they, the said subscribers, transfer to the Pharmaceutical Society the balance which is now in their hands as the trustees." The balance at that time, in 1841, appeared in the balance sheet of the Society under the name of the Old Druggists' Fund, and stood at £775, to which two other sums of £50 and £46 3*s.* 3*d.* were added, making £871 3*s.* 3*d.* In 1842 that fund under the same heading was £901 14*s.* 7*d.*, and so it went on accumulating, until in 1847 it was £1036 7*s.* 1*d.* After that year the interest was received by the Society, and it was spent, not added to the principal, so that in 1848 there was still the same sum, the same in 1849, the same in 1850, and the same in 1851. After 1851 the separate heading "Druggists' Old Fund" disappeared, the old amount being absorbed in the general fund of the Society. In 1851 a subscription of twenty guineas was given to the great exhibition, and if anybody considered that that was a fair and legitimate grant of money, and that the present sum asked for was an improper one, he should like to have further information from him. This amount of £1036 7*s.* 1*d.*, which had been standing to the credit of the Society since 1847, would amount at the present time, at compound interest, to nearly £3000—over £2800.

The PRESIDENT, interfering, said that they had not placed it out at compound interest.

Mr. SHAW said it had been in the Society's possession the whole of the time. Chemists and druggists throughout the country would consider they had a fair claim to some assistance from this fund, or else they would be making the Society simply a registering society. The Apothecaries' Company, which was prosecuting this case, no doubt acting through others, had subscribed from its own funds for the purpose of carrying the case on, notwithstanding that the solicitor stated that he had acted fairly within the right of the Apothecaries' Society. He put it to the Council as a matter of policy under the circumstances whether it would not be judicious to present either a sum of money towards the defence of this case, or, if it was thought proper, to raise a new issue on its own account in connection with this matter, where the whole of the members who were so especially interested might be protected. Possibly a small number would be opposed to it, but his impression was that nine-tenths would thoroughly approve of any proceedings of this kind which the Council thought proper to adopt.

Mr. FRAZER said his views on this question were so well know that he need not express them again in any detail. This question was brought before the Council in its origin, thoroughly discussed on the merits, and the Council refused to entertain the defence because it main-

tained that it could not support Mr. Shepperley. The case remained exactly the same, only in another court, and he did not see why the Council should interfere in it. He opposed it on principle.

Mr. BOTTLE, referring to the remark of Mr. Shaw that the former application had been withdrawn as being premature, said he considered it was still premature. They had heard a great deal about the funds of the Society, and that it was the duty of the Society by its charter to protect the interests of chemists and druggists, and he went the whole length of those who said so, but he also held that the principal thing for which the Trade Association was formed was to protect the trade interests of chemists and druggists, and there was information, not very recent, but the latest he could get, in the report of the Association of November, 1877, that it had 3450 members and a balance in hand of £870. The Association had issued a report in November, 1878, and spoke very much of this defence, but did not give any statement as to the number of members or the condition of the funds, and at a recent meeting the solicitor said he did not see any grounds for the opposition going any further with the case. The Association did not apply for any help; it seemed strong in its own position. It had to his knowledge appealed to the country at large—he believed to every man in the trade—and a large number had responded. Therefore he took it the Association would be in a position even from its own resources to thoroughly take care of itself. He would caution the Society against meddling with the business of the Association if it wanted to keep on good terms with it. They had it also in evidence at the last meeting that that Association had another object in view, viz., that the members felt it was necessary, in the interests of the Association, to meddle with the constitution of that Council, that the funds of that Association should be prostituted to upset the present constitution of the Council, and at the next election to take such measures as would insure the return of men of its own selection.

Mr. CHURCHILL said he thought he had better stop Mr. Bottle before he went further. The measure he spoke of was not the question discussed, the only thing done being to appoint a committee to consider whether such action would be desirable.

Mr. BOTTLE said it was very clear it was under the consideration of the Association, and that it had appointed a Committee, and the majority of members expressed adverse opinions with reference to that Council. In the face of that could the members of the Council go and throw the Society's money—for that was what it was, as it had not been asked for—into that Association? He knew something about electioneering contests; and considered that was an additional reason why the Society should not contribute to that Association. He was a member of that Association, willing to support it in its legitimate purposes, but he was not willing to support it in travelling out of its way and interfering in the legitimate business of the Society.

The PRESIDENT remarked that the resolution did not say that the money was to be given to the Trade Association. He did not know where it was to go, or what was to be done with it, nor what the sum was.

Mr. HAMPSON said if there was any willingness on the part of the Council to spend any money on the defence of what was considered a trade question, some person would soon be found ready to receive it and appropriate it in the proper way and not in electioneering purposes. He was not tied to the exact wording, but would accept any reasonable amendment.

Mr. CHURCHILL said this was an important subject. The main question was whether the Council would assist in the defence of such a simple case of counter-practice as that of Mr. Shepperley. He went no further, however, than 1876, when the Council passed a resolution that it would defend any clear and proper case of counter-practice.

The PRESIDENT: On its merits.

Mr. CHURCHILL said soon after that Shepperley was prosecuted for counter-practice, but unfortunately, his case was so represented to the Council that it did not think it would be for the interest of the Society to defend it, because Mr. Shepperley had gone beyond his duty in recommending medicines. But he asked the Council to look at the case as it now stood, as the evidence had been laid before the courts. Mr. Shepperley was accused of acting as an apothecary in two cases. In one case he recommended medicine for a very small case, sore throat, a case in which no danger existed at all; and in the other he recommended medicine for a man who had some pimples on his face. He took it that those were cases which nine out of ten chemists would have recommended medicine for, and properly so, and seeing that the Society was established for the purpose of protecting the trade, he considered it was clearly open to the Society to defend Mr. Shepperley. He hoped no difference of opinion as to the manner in which aid should be given would prevent it being given at all. He was sure a way would be found in which money could be effectively and properly spent.

Mr. SANDFORD said a great deal had been said on a matter scarcely pertinent to the question before the Council. Mr. Shaw had spoken about the "Druggists' Old Fund," and there was no doubt whatever about the Society holding that fund; it was given over to the Society not for any specific purpose, but for the general good of the trade and to be used at the discretion of the Council. It was not raised for the defence of cases of prosecution, but for aid or defence in getting or opposing Acts of Parliaments, and for the general advancement of pharmacy. That matter, therefore, was altogether unconnected with the case of Mr. Shepperley. Then taking Mr. Shepperley's case. The Council, knowing the whole of the merits of the case two years ago, had expressed on more than one occasion its determination not to take it up, and he thought it a great pity that it should be brought forward again. More than that, it did not seem to him to be a case which would decide what was wanted. It was, according to Mr. Shepperley's friends, too good a case to decide what they wanted. Mr. Shepperley, according to the verdict of the jury, had not been beyond his duty. Now the question the trade wanted to have decided was, was the right of prescribing preserved to chemists and druggists by the 28th section of the Apothecaries Act, and the decision of Shepperley's case, on the evidence, whether by the House of Lords, or by any other court, would be that Shepperley had either offended or had not; this would not settle the point. It was not quite known on what ground the jury acquitted him, but it was pretty clear that if it had been left to the judge, he would have said as a point of law chemists were not entitled to prescribe by reason of the 28th section. The trade wanted that point decided. As to the particular case of this individual, the question was whether he had treated disease. That was the question for the jury. They decided that he had not exceeded his duty, and if the decision of the House of Lords were given on the same ground it would be of no use to the trade. Then again, it was not quite known where the case was. He believed if the case reappeared it would be begun not by the Association, but by prosecutors, whoever they might be. He supposed Sir Henry James would again appear to defend Mr. Shepperley as he had done before. He did not know whether this money was required to pay for any expenses already incurred, or what it was to be applied to. If the Society were to pay bills, let it not be the bills of other people. The Council certainly knew how to manage the Society's property, and he thought it would be much beneath its dignity to hand over money to the Association for disbursement. More than that, he thought it would be very impolitic for the Council, as the leading body of pharmacists of Great Britain, to appear as the advocates of prescribing. He knew perfectly well that to a certain extent chemists must prescribe, but he felt confident on the

other hand that within that reasonable limit which every man should know for himself but which could not be defined on paper, the Apothecaries' Company would not step in to prosecute. There had been a most unfortunate feeling introduced between chemists and medical men by the late prosecutions or rather by the defence of them. Wiggins's case was over and there was now no difficulty about speaking of it. That was a most unfortunate case, and he knew that some members of the Association, at any rate, were heartily ashamed of it. It was by taking up such cases that the Association exasperated the feelings of their opponents, and he thought damaged the trade very much. He had felt that the 28th section gave chemists and druggists very great privileges, that they had at least a right to prescribe, and he was the more inclined to that view from the remarks which fell from Baron Cleasby when the case was before him. But it was so clearly put down by Mr. Baron Bramwell and Mr. Baron Pollock, that he could not help thinking it must still be done on sufferance, and that it was a matter of discretion how far it should be done. His view was that if chemists would keep within their own trade they might go on just as they had done. It was all very well to say that Mr. Shepperley's case was one of simple prescribing, but what did the counsel for the prosecution say? That he was notoriously prescribing, and therefore he was prosecuted. But the prosecutors did not get up their case well. It would be very unwise to go in and defend such a case. He hoped chemists and druggists would stick to their duty and not fear being left to the mercy of common informers. Let the Society husband its resources and continue to spend them for the advancement of pharmacy and the protection of pharmaceutists. He must tell Mr. Churchill that Mr. Shepperley's case did not come before the Council after the resolution he mentioned had been passed but before it.

Mr. BETTY could not but think that the Council should look at this question from two points of view. The case was still *pendente lite* and therefore care must be exercised in discussing it, and he was sorry that so much mention had already been made of the merits of the case. Whatever might be thought of it that was not the time to go into that part of the question. Members of the Council should avoid alluding to antecedents and confine their attention to what might be termed the practical judgment on the matter immediately before them. He could not but feel, whatever he might have said at some former time, that they were now confronted with the hard letter of the law. They were brought face to face with a court of law on an important matter and that matter really did involve a deal of the practice of their business. Mr. Sandford might endeavour to narrow the issue, but essentially the point was can a chemist give advice in his shop, and he could not help seeing that every chemist and druggist was *volens nolens* a party to the suit now pending. If that was the case it did practically bring them into the law courts. It was a question what steps to take in the matter. Without any recriminations or reflections on how things might have been, it seemed to him, at the present moment, a choice whether their lot was to be thrown in with the Society of Apothecaries or with those of their own body, and to be a question whether blood with them was thicker than water. There would be three parties interested who might have a voice and would form an opinion upon the vote. First, those who subscribed to the Pharmaceutical Society; secondly, those who subscribed both to it and to another Association; and thirdly, those who subscribed only to that other Association. Whatever course the Council took it would be open to criticism and perhaps adverse action by some or all of these persons. The Apothecaries' Society had really a very bad case, for a more ridiculous plaint never came into a court of justice. It had been stated that according to the Solicitors' letter the Council had not the power to grant this money, and such being the case he presumed Mr. Hampson would not wish to proceed to any formal vote on which there might be some risk. He thought it would be better for a further opinion to be obtained, and that the solicitors should ascertain what power the Council really had. Let the Parliamentary Committee thoroughly consider its power and see in what way it would be justified in recommending that some assistance should be given according to the urgency of the case.

Mr. SCHACHT thought there was a fallacy in Mr. Betty's remarks. He deprecated any reference to antecedent facts, and said the Council should look at it as a new question; but with all respect it was utterly impossible to do so. The question stood as it stood on the point of law, and was not a new question to be argued. The position was that a decision in one court of law was referred to a higher court, and the Council must come to the conclusion whether it could take this as from the beginning. If it were proposed to go in for the defence, that would now be proposing to do that which the Council declined to do before the matter came before any court of law at all; thus it would be reversing the prior decision and adopting a new course. That course was open to it, if anything showed a mistake had been made in times gone by, and that there was now further light to lead to an opposite conclusion. The position as stated by Mr. Sandford was precisely the correct one. It was known that a verdict had been given, but it was scarcely known on what grounds. All the members of Council had to guide them was the information given when the case was first brought before them for their adoption, when they deliberately came to the conclusion they would not defend it. The precise form which the prosecution was to take they did not then know, only that a certain individual was threatened, and they had to form judgment whether the case was to be taken up by the Society or not, and they deliberately came to the conclusion that they would not defend it. The fact was that the actual legal prosecution had somewhat narrowed itself, but it had not altered the fact at all as to the responsibility of the Council in the matter. If the Council had reason to think it had come to a wrong judgment on the case, and the person associated with the case, it would be time to adopt a new course. If there was any plea that those who had carried it so far could not carry it any further he should be inclined to fall back on the old axiom, that a person who began to build a house should first count the cost. He himself counted the cost of every act he did before he did it. That was the practice, and if he ran a risk he did not think he had a right to call on anybody else to assist him if he incurred a penalty. Mr. Shepperley, it appeared, thought that he had some claim on others, and application was made to the Society in vain, and then to another association, which took the case up. He had no right, of course, to quarrel with the determination that Association arrived at, but having done so it must take the responsibility. It commenced the defence, and perhaps that had involved it in a larger amount than had been at first anticipated. He dissented in the first instance from defending Shepperley's case, and saw no reason for altering that opinion.

Mr. GREENISH said he did not like to give a silent vote on this question. When Mr. Shepperley's case was first brought before the Council there were circumstances connected with it which induced him to express an opinion that it was one which the Society should not take up, but in its present position it was altogether different. All those surroundings were now out of the case, and, taking it as it stood before the court of law, it was one of pure and simple counter practice and nothing more. It seemed to him that if this case were allowed to fall through for want of assistance, or if it went against the defendant, no chemist, no matter how he had been conducting his business, could continue to do so with safety. He did not know what might be the bearing of the Solicitor's letter, but he should certainly

like to see the Council able to assist in the defence of this case, because he considered it affected every chemist in the conduct of his business.

Mr. FAIRLIE could not agree with Mr. Schacht that the case was now the same as was formerly presented to the Council. At any rate he knew it was recognized throughout the trade that Mr. Shepperley's case had come out much more clearly in favour of the trade than was expected. He had been in conversation with a medical man who had been for some time connected with the Medical Defence Association in Nottingham, and withdrew from it when Mr. Shepperley was prosecuted, because he did not consider his case was the worst in the town. Mr. Bottle seemed to think the matter was still premature, but he had undertaken to bring it forward because the application for assistance from the Trade Association had never been formally replied to. Therefore he did not think it was premature. The case was already one upon which the trade hung by a thread, and there was not any one who would not be as liable as Mr. Shepperley was to be pulled up. If the Shepperley case was gained by the Apothecaries' Society others would follow, and no one knew who would be the next victim. That being so every member of the trade ought to look at it as a personal matter. It did not affect Scotland directly, but it did indirectly, because in Scotland certain medical organizations had the power of appointing inspectors of drugs who could go into the shops and report upon the drugs there sold. At the present time these inspectors were gentlemen very favourable to druggists, but if men of unscrupulous character should be placed in that responsible position he pitied the poor druggist in the west of Scotland. It was with that view he had supported the Shepperley case throughout. He did not do so there as a member of the Trade Association, but as a member of the Pharmaceutical Society, and as a member of the Council, remembering that he sat there having the interests of the trade in his keeping. Apart altogether from any action which any other organization might take, he considered it was the duty of the Council to defend the action as far as it lay in its power, quite apart from the decisions of past Councils, which were not binding upon the present. It was the duty of the members to look the case fairly in the face, and seeing circumstances had changed, try and do their best for their brethren. He was sorry that they had had Wiggins's case imported into the discussion. He had looked carefully through that case, and he candidly said that if he had been in Wiggins's place he should not have done otherwise than he did. There was no doubt that that case was lost through sentiment. If the children had not died the jury would not have returned the verdict it did. In his opinion it was a pity that these cases came before juries at all, and he was glad that this case was going to a higher court to be judged on a point of law. As far as the legal point was concerned he thought it was clearly proved that chemists and druggists had certain power to give certain advice to their customers. The outside public gave advice every day to their friends, and why should a druggist, who knew the qualities of his drugs, be debarred from making use of that knowledge when the general public was allowed to give any advice it liked? He hoped the Council would look at the case from a different stand-point to what it had done. The Association had come forward and carried it so far, but whether that Association was weak or strong was not for it to consider. It was the duty of the Society to protect the members of the trade.

The PRESIDENT said it seemed to him the Council would be setting up a very bad precedent if it agreed to this resolution, which was so vaguely and indefinitely worded. To pass it seemed to him would not only be injurious in the present, but also in the future, and would be a stultification of the action of the Council in past times; it would be equivalent to saying that the Council who sat there ought to resign, and a new Council ought to be appointed, because the present one was unworthy to carry on the business of the Society. He was aware of the serious nature of the questions at issue, and he was sorry the question had rested on such an issue, but he must vote against the resolution.

Mr. HAMPSON in replying said he could not understand Mr. Frazer's remarks. He had refused to do a thing some time ago, and still refused. He did not give any reason why.

Mr. FRAZER said because his views were so thoroughly well known, it was not necessary to repeat them.

Mr. HAMPSON continuing, said Mr. Bottle said the case was premature, but he could scarcely imagine the case being in a more advanced stage, having been in two or three courts already, and probably going into another. He seemed to think the Association might be justified in defending the case, but for fear of some electioneering tactics being instituted, he would not allow any money to be sent from that Society. Mr. Sandford had said the "Old Druggists' Fund" had been handed over, but that it was not to be used for such purposes as this; that this was not so was shown by the resolution passed at the Crown and Anchor in 1841, which Mr. Shaw had read. Surely this was a matter of protection. Chemists and druggists wanted to protect themselves now and maintain what they considered to be their rights. He was happy to hear Mr. Sandford say they must prescribe to a certain extent. It was perhaps a wicked thought, but he rather wished that Mr. Sandford had occupied the place of Mr. Shepperley. He wondered what kind of a simple case Mr. Sandford would select to try the question. Surely anything more simple than looking in a man's face and discovering pimples could not be imagined: however, Mr. Sandford did not think this case was worthy of defence, he wanted a more simple one. He did not believe that if the angel Gabriel came in the person of a poor chemist Mr. Sandford would defend him. The case was a test case as shown by the summing up of the learned judge. The question was whether the Council should remain inactive and allow members of the Society and trade at large to be attacked. If that were so the Society would lose caste, and would deserve to do so, because it would be neglecting to protect the legitimate interest of members and would simply become an examining and educating body. In conclusion he would only say that this case, whether simple or obscure, showed an intention on the part of a certain class of the medical profession to restrict the action of the chemist, and upon reading medical journals it was easy to see that it was intended to circumscribe the action of chemists more than ever. It had been attempted thirty or forty years ago, and the attempt was continued in nearly every session of the House of Commons. It was surely the duty of the Council now to put its foot firmly down and say that chemists and druggists were acting within the law; but if the law would not protect them, it must be altered.

The motion was then put to the vote, with the following result:—

For—Messrs. Churchill, Fairlie, Greenish, Hampson, Shaw and Woolley.

Against—Messrs. Bottle, Cracknell, Frazer, Hills, Rimmington, Robbins, Sandford, Schacht and Williams.

Mr. Betty was present at the division, but did not vote.

The motion was therefore lost.

Mr. CHURCHILL then rose and said he had had a requition placed in his hands, signed by about fifty persons, to bring forward at such time as he thought fit. It was requesting the Council to call a special meeting of the members and associates in business to take into consideration the advisability of the Society rendering substantial pecuniary aid to the Chemists and Druggists' Association of Great Britain to assist that Association in its efforts to defend the legitimate interests of the trade.

The PRESIDENT said of course the meeting must be called, in accordance with the bye-law; the question was, what date would be convenient.

Mr. FAIRLIE moved, that it be called January 9th, at eleven o'clock for twelve o'clock.

Mr. SCHACHT raised the question whether the object of meeting was legal, and it was decided to take legal opinion before the date for holding the meeting.

The motion was then carried.

The following resolution was passed unanimously :—

"That this Council learns with regret the loss Mr. Gostling has sustained by the death of his wife, and desires to express its sympathy with him ; and that the President be requested to communicate this expression of sympathy to Mr. Gostling."

It was also resolved, as the ordinary day of meeting next month falls on New Year's Day, to meet only *pro formâ* and adjourn to the following Wednesday.

PHARMACEUTICAL MEETING.

Wednesday, December 4, 1878.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

An Evening Meeting of the Society was held on Wednesday last, the 4th inst., the chair being taken at half-past eight. After the minutes of the previous meeting had been read and confirmed—

The PRESIDENT called attention to a portfolio of engravings which had been sent for exhibition that evening by Messrs. Howard and Sons. The engravings represented the boracic acid works in Tuscany. Tuscany, as they were well aware, had long been the principal source in the world for the production of boracic acid. During recent years, however, a great deal of boracic acid had been produced in California and various other parts ; but still he believed the Tuscan lagoons yielded a very large quantity which was employed in the arts and in medicine. The engravings formed a beautiful series, and he was sure that they would be looked over with the very greatest interest.

Mr. HOLMES then briefly described some specimens and other articles that had been placed on the table for exhibition and which had been presented to the museum. The first was a specimen of deposit from tincture of quinine, and had been presented by a student. It had been deposited from twenty-five ounces of tincture. Mr. Dimmock had examined it in Professor Redwood's laboratory, and found that it consisted almost entirely of quinine. He (Mr. Holmes) had put a drop of the solution with a drop of solution of sulphocyanide of potassium upon the slide under the microscope, and the characteristic crystals of sulphocyanide of quinine formed upon the slide might be examined after the meeting. He next referred to a specimen of a root, the botanical origin of which he had been unable yet to determine, which had been sold to Professor Flückiger, at Strassburg, as senega root. It was not senega root and it was quite different from the root which was spoken of at the last meeting. There was a specimen of *Gentiana punctata*, which had been collected by Mr. Corder in Switzerland, and was, therefore, no doubt a genuine root. He (Mr. Holmes) had also placed on the table a specimen of commercial gentian root, the annulated character, of which were very remarkable. He believed that it was *Gentiana purpurea*. A specimen that had come to him recently was one of the well known beans of *Entada scandens*, a plant belonging to the Leguminosæ, which had recently come into the market as calabar beans, but which was much larger than calabar beans and of a different shape. Another specimen was that of false sumbul root, which might be known from the true by its yellowish colour and by its tincture having a decided odour of ammoniacum. In fact, as had been mentioned in the Journal, as well as in Bentley and Trimen's 'Medicinal Plants,' this root was simply ammoniacum root which had been coloured and perfumed with musk. The next was a specimen from Professor Flückiger which consisted of a false kamala. It differed from the ordinary kamala very little in general appearance, being perhaps of a more purplish tint, but when looked at under the microscope it was seen to be more cylindrical and to have oblong resin cells, and when heated it turned black, which the ordinary kamala did not do. There was also a specimen of oil of resin presented by Mr. Stoddart. This was said to be used for adulterating linseed oil. He (Mr. Holmes) did not know the means of distinguishing it, but it differed in smell from linseed oil. He saw a large quantity of it at the Paris Exhibition, and it was quite possible that it might be used to some extent, if not at present, at all events in the future, for the purpose indicated, and was therefore worthy of attention. There were some crystals deposited from aldehyd presented by Messrs. Morson and Son. What the crystals were he did not know. There were specimens of bark which had been presented by Dr. Paul, and which might be taken by an ordinary observer for calisaya bark, and, in fact, they were sold as such ; but they contained little or no quinine. It was well known that a great deal of the bark which was used in commerce for making tincture contained hardly any quinine at all. He would also call attention to a new caustic, ethylate of sodium, about which the President would be able to give some information. There was a sample of paper lint, presented by Messrs. Wyeth and Co., of Philadelphia, which, no doubt, some of them had read about. It was very soft and absorbent ; but as far as he had been able to learn it was not so strong as ordinary lint when wetted. It absorbed moisture very rapidly, to the extent of seven times its weight. He would also call attention to the very neat way in which a preparation of dialysed iron on the table was got up ; it had a little tube accompanying it, by which the liquid could be dropped out in any number of drops with the greatest ease.

Mr. UMNEY inquired whether Mr. Holmes had determined what particular salt of quinine was deposited from the tincture of quinine. Mr. Holmes had said that the deposit was quinine. Was it to be understood that he meant sulphate of quinine ?

Mr. HOLMES said that he believed that it was sulphate of quinine. It gave a precipitate with barium and none with nitrate of silver. There were certainly crystals of sulphocyanide of quinine under the microscope. He thought that it differed from the deposit which was constantly falling down in tincture of quinine, and which no doubt contained sulphate of lime. When burned on a piece of platinum foil it gave no residue whatever.

Mr. GREENISH said that it would be interesting to know whether the precipitate had been washed with rectified spirit. The precipitates which fell down from tincture of quinine did so entirely during the first three days, and there was quinine with the precipitate ; but if the precipitate were washed with spirit it could be washed entirely free from quinine, and it was then simply sulphate of lime.

Mr. HOLMES said he believed that the precipitate was taken from the bottle, put on a filter, and washed with water ; but he thought that it contained no lime, as it gave no residue when burnt on a piece of platinum foil. He believed that it was simply sulphate of quinine. He might add that it was deposited to the extent of 21 grains from 25 ounces of tincture.

Mr. GREENISH said that if the precipitate were washed with water on the filter, the sulphate of lime was entirely washed away ; but if it were washed with spirit the sulphate of lime was retained.

The PRESIDENT said that if the precipitate burnt and left no ash there could be no sulphate of lime.

Mr. GREENISH said that the sulphate of lime had been washed down from the precipitate with water. He had observed it frequently. With regard to the sample of paper lint, he had examined it, and found that it was purely cotton deprived of that natural oily substance in

cotton which prevented it from absorbing water rapidly. The reason why this specimen was so soft compared with ordinary lint was that the latter was a woven substance, and this was simply a pulp that had undergone pressure.

The PRESIDENT said that he supposed that it was felted.

Mr GREENISH: Probably. He thought it would be a lint extremely useful for water dressings.

The PRESIDENT said, with reference to the ethylate of sodium, that it might be within the knowledge of all present that that substance had been introduced to the notice of the medical profession by Dr. Richardson lately. That gentleman had pointed out that ethylate of sodium was a very powerful caustic, and it might be of very great use in cancer and other cases. He directed that sodium should be added to absolute alcohol to saturation, and then the product diluted with an equal bulk of alcohol. That, he considered, would give a solution of the right strength for use. However, the ethylate exhibited was in a solid state, and, of course, it would have to be dissolved in absolute alcohol before it could be applied for the purposes which Dr. Richardson alluded to. What the future of this substance might be, he (the President) did not know; but no doubt it was a very powerful caustic. It was more powerful than ordinary caustic soda, because, as the moisture from perspiration exuded, the action of the sodium was more apparent and more powerful upon the cuticle. In reply to Mr. Moss, the President added that Dr. Richardson's description of the quantity of alcohol in the ethylate of sodium was very vague. He (the President) should think that one part of the specimen in two parts of absolute alcohol would be about representative of the strength which Dr. Richardson intended to be used as a caustic.

Mr. Moss said that resin oil might be distinguished from linseed oil by the fact that linseed oil was fluorescent.

Mr. UMNEY said that the remark which Mr. Holmes made as to the so-called calisaya bark of commerce was only too true. It had been pointed out again and again in that room, and in the *Pharmaceutical Journal* and elsewhere, that for four or five years past the calisaya bark, so-called, of commerce scarcely contained any quinine at all. The only remedy which he could see was for the compilers of the next British Pharmacopœia to put it almost aside, and to put in its place a bark which would unquestionably be the bark of the future, namely, East India cinchona bark. In that bark they had perfectly definite bodies, it containing large quantities of cinchonidine and quinine. As far as he had been able to observe during the last twelve or fourteen years, calisaya bark went on deteriorating, and at the present time one hardly ever met with a specimen which contained any quinine at all. If they wanted good barks they must take East India bark. In it they would sometimes get five or six per cent. of quinine and always five or six per cent. of total alkaloids.

Mr. HOLMES said that he should like to add that the bark which appeared to be calisaya bark was not such at all. He believed that it was that of *Cinchona Peruviana*, but in each case there was some other bark mixed, which was of an inferior nature. He was told that it was the custom in South America always to mix the barks regularly. The men who mixed them knew much better than Europeans what the barks were from appearance alone, and how much alkaloid they were likely to contain. With regard to the East Indian bark which Mr. Umney spoke of he presumed that he meant the red bark. He believed that we got very little calisaya bark from the East Indies, and that the only good calisaya bark which came to England was that which was imported into Holland from Java, and a little of which, usually not the best variety, was sent thence to England. He had seen none of the good calisaya bark which contained eight or ten per cent. of quinine in English commerce. The pale bark which came from India he had seen very little of. That contained about five per cent. of quinine, and the quinine came out very white on analysis.

Professor BENTLEY said that there was one specimen which was very interesting to him, and it was somewhat historical. That was the spurious sumbul. Those who were familiar with the great work of Pereira knew very well that he described, many years since, a substance under the name of Indian sumbul, and he spoke of it as differing from the official Russian sumbul in being denser, of coarser texture, redder in colour, and having less odour. After describing the Indian sumbul, Pereira also referred to another which he called Chinese sumbul, and to this he ascribed characters nearly resembling those of Indian sumbul, and he faintly suggested that they were of the same origin. No pharmacologist since Pereira, as far as he (Professor Bentley) knew, and certainly not any English pharmacologist, had had an opportunity of ascertaining what the Indian sumbul was, or even seeing a specimen. Hanbury, in the 'Pharmacographia,' spoke particularly of having no specimen of Indian sumbul. But in the *Pharmaceutical Journal* of about March or April last, there was a notice from Dr. Dymock,—and he (Professor Bentley) took the present opportunity of saying that Dr. Dymock's communications to the *Pharmaceutical Journal* were often very valuable,—and in that notice Dr. Dymock threw some light upon the Indian sumbul. He made known what certainly had not been particularly referred to before, that ammoniacum root was an article of commerce in India, and that it was used in the temples as incense. Dr. Dymock remarked that this root, scented with musk, formed the sumbul which, many years ago, was forwarded to Europe from Bombay. He (Professor Bentley) was writing, about the time of Dymock's communication, with his co-editor, Dr. Trimen, an article on ammoniacum for their 'Medicinal Plants.' He at once saw that here they had, undoubtedly, the old Indian sumbul which had been described by Pereira, and of which the origin had been lost. He mentioned this fact in his lectures as far back as last April, and in the paper on ammoniacum, which was published last June, he stated that this root flavoured with musk was unquestionably the lost Indian sumbul of Pereira. When he was writing his article he had not had an opportunity of seeing the spurious sumbul which had been referred to by Mr. Holmes, but he stated that it was doubtless derived from the same source as the Indian sumbul of Pereira. He had had an opportunity of seeing a sample that day, and it was unquestionably ammoniacum root scented with musk. This fact was particularly interesting. It settled the question of the origin of the Indian sumbul root of Pereira. Those persons who knew Pereira would know very well that he must have seen the substance which he had described, although no specimens of it had since been found. Persons who would compare the present specimen with Pereira's description would see that the description corresponded almost in every particular with it. With regard to the specimen of gentian root, being interested in the subject and writing upon gentian at the present moment, he was particularly interested at seeing the specimen obtained by Mr. Corder, knowing him to be a good botanist. It was very important to have a genuine specimen of the root of *Gentiana punctata*. Martius mentioned years ago several gentians, not only *Gentiana lutea*, but *Gentiana pannonica*, *Gentiana purpurea*, and *Gentiana punctata*. He (Professor Bentley) well remembered his revered teacher and friend, Pereira, describing the difference between those roots in that room. The differences turned somewhat upon the special annular marks at their upper extremities, but Pereira spoke doubtingly upon this point, not having made up his mind upon it. He (Professor Bentley) had obtained *Gentiana lutea* himself upon the Swiss Alps, and that had altogether the same markings. Martius described it as having such markings. He also described *G. pannonica* as having somewhat similar markings; and he (Professor Bentley)

believed that Martius also described *G. purpurea* as having these markings. *G. punctata* had also similar marks, as shown by the specimen now exhibited. The interest of these facts was more especially that it had been supposed generally that the annular wrinkles were, to some extent, a test of the purity of gentian root as to whether a specimen was from *Gentiana lutea* or another species. He believed that an examination of the present specimen would show clearly that the annular markings in the upper part of the root, as distinctive of *Gentiana lutea*, must be in a great measure given up. There was no doubt, however, that *Gentiana punctata* might be readily distinguished from *Gentiana lutea*, because it was of a lighter colour.

In reply to a question from the Chairman,

Mr. ROBBINS (who had just arrived) said that ethylate of sodium, as no doubt most of the audience were aware, was a preparation brought out by Dr. Richardson, some eight years ago, as a caustic for destroying nævi and similar structures, but its use had lain in abeyance until almost the present time. Two or three months ago Dr. J. Brunton found a bottle of the substance in his cupboard, and he applied it to several cases of nævi, and found it a wonderful remedy. According to what he (Mr. Robbins) had seen, he thought it likely that ethylate of sodium would be a very valuable caustic, and would come into general use. One great advantage of it was that it caused no pain or very little pain. He had seen it applied to a young baby while the infant was asleep, and the pain had not been sufficient to wake the child, but simply produced a little uneasiness. With regard to the strength of the solution recommended by Dr. Richardson, he (Mr. Robbins) ought to say that Dr. Richardson had by mistake given the wrong strength for the alcohol in an article in *The Lancet* of October 9th, he gave the ordinary alcohol. The ethylate should be prepared from absolute alcohol, sp. gr. 0·795.

The PRESIDENT: You could not get any ethlylate of sodium at all unless you did.

Mr. ROBBINS said that that was the case. A liquid would be obtained, and perhaps many people would not know that they had not got ethylate of sodium. Dr. Richardson did not make it in the solid form, but he obtained a very concentrated liquid form almost like a jelly. He found that that ought to be diluted with an equal quantity of absolute alcohol. If they took solid ethylate it would, of course, require still more alcohol. The strength described by Dr. Richardson would have a specific gravity of 880. He (Mr. Robbins) had found accidentally a bottle of the preparation made eight years ago, and it was in perfect condition. It could not be applied with a brush. It was recommended that it should be applied by means of an elongated stopper, like the stopper of the ordinary acid bottle. After four or five applications an interval of some days was allowed to elapse, and an incrustation was formed. That incrustation would fall off and then the spot was painted again with the preparation.

Mr. MOSS inquired whether the solution used by Dr. Richardson as a caustic was pure ethylate of sodium.

Mr. ROBBINS replied that it was so. Dr. Richardson had told him that he took a gelatinous solution, and diluted it with alcohol.

The PRESIDENT said that many years ago when chromic acid was very much in vogue for application, it was applied by means of a brush made of glass fibre. That brush answered very well, and he should think that it would answer for ethylate of sodium.

Mr. ROBBINS said that such brushes had been tried for ethylate of sodium, but they broke into little bits. He had also tried them for things which were not caustic, and they had served him the same trick. Dr. Richardson also had tried a glass brush for ethylate of sodium, and found it a total failure.

The thanks of the meeting were voted to the donors of the specimens.

Mr. POSTANS said that he wished to draw the attention of the President to a little piece of injustice which he had unintentionally committed in his official capacity on the occasion of the last evening meeting. On that occasion, Mr. Martindale had recommended the use of hydrochlorate of quinine in the preparation of tincture of quinine, and the President, referring to the objection that might be raised that the hydrochlorate would be a more expensive salt than the sulphate of quinine, said he did not think that should stand in the way if the preparation were really superior for medicinal purposes. He (Mr. Postans) had also made some remarks with regard to citrate of quinine, but with respect to it the President had remarked that that substance was still more expensive than hydrochlorate. The President commenced with sulphate: that was expensive; hydrochlorate was more expensive; and citrate was most expensive. He had, however, referred to a price list for the price of the sulphate. and he had also written to Messrs. Howard for a quotation for the hydrochlorate and the citrate, and the result was that he found the prices of all three to be the same. He might be permitted to say that he was under the impression that the object of the evening meetings was to promote pharmaceutical research, and that, in introducing new preparations into pharmacy, it became pharmacists to use the best substances under any and all circumstances. It remained for the medical profession to discriminate between those patients for whom they would prescribe one substance, and those for whom they would prescribe another.

The PRESIDENT, in answer to Mr. Postans, said that he quite agreed with him that the question of cost ought not, in an ethical point of view to be at all considered by that Society, or any other society of pharmacists, as being an important question in the matter. At the same time, it was a practical question, for there was no doubt in a manufacturing sense, that sulphate of quinine could be produced more readily and cheaply than any of the other salts. The reason was that the sulphate crystallized more readily in proportion to the quantity of quinine in it than any other salt of quinine. That was the reason why sulphate had taken the place which it now occupied. At the same time he believed that hydrochlorate and citrate were, as a rule, brought into the market at the same price. He did not intend to say in his statement at the last meeting that citrate was actually dearer than hydrochlorate, but he considered both of them dearer forms of quinine than the sulphate.

Mr. POSTANS said that it was, of course, left open to the medical man to prescribe either one salt or the other, and it should be remembered that quinine was not an expensive medicine for people in this country, for in England the usual dose was only one grain and not half a drachm as in India.

Mr. GERRARD observed that he had dispensed that very day a dose of forty grains of sulphate of quinine, and that quantity was frequently given in hospitals.

Mr. UMNEY said that he did not think that it would take the Chancellor of the Exchequer to determine which would be the higher priced preparation. As far as he remembered, sulphate of quinine contained about 74 per cent. of anhydrous quinia, and hydrochlorate contained 82 or 83 per cent.

The chair was then taken by Mr. Greenish (Treasurer) whilst the President read a—

NOTE ON THE ACETO-NITRATE OF IRON.

BY J. WILLIAMS.

The paper is printed on p. 465 and gave rise to the following discussion :—

The CHAIRMAN said the paper was one of those extremely interesting and valuable suggestions which every now and then came from the President. It would be very interesting, however, to know how far glycerine would modify the action of the salt of iron. It was known to con-

siderably modify the action of some substances, such as tannin for instance.

Mr. MARTINDALE said that he had tried some experiments upon some of the salt which he had received from Mr. Williams. Knowing that solutions of salts of organic acids in water, as pointed out by Dr. Bastian, were of greater stability when near the point of saturation than when they were weaker, he had made a solution of 80 grains in about 160 minims, and it kept for five days. At the end of six days it began to deposit. He had thought that a syrup would dissolve the substance, and he made a solution of 5 grains per drachm in simple syrup; that had kept without change for six days. Perhaps a solution in syrup would be as palatable as any form of the preparation, seeing that syrups of iron were much in vogue. There might be objections to dissolving it in glycerine, for the nitric acid in the compound might in some degree act upon the glycerine. They had seen a similar action in nitrate of bismuth dissolved in glycerine.

Mr. UMNEY said that he understood that the gelatinization of the compound was due to precisely the same cause which made the tincture of acetate of iron of the British Pharmacopœia gelatinize. If acetate of iron had been in solution for some time in spirit of wine, the acetic acid acted rapidly upon the spirit and formed acetic ether, and the iron became a basic acetate of iron, and gelatinized. He feared that any solution of acetate of iron in spirit of wine must always be prone to gelatinize unless at least 10 per cent. of free acetic acid was present. The gelatinization of tincture of acetate of iron could always be prevented by about that percentage of free acetic acid of the Pharmacopœia.

Mr. Moss said that he believed that the addition of glycerine to a solution of an iron preparation like acetonitrate would altogether destroy its astringent power.

Mr. WILLIAMS in reply said that he quite agreed with the chairman (Mr. Greenish) and Mr. Moss that there was great doubt about the propriety of using glycerine in preparations of perchloride of iron. He remembered Mr. Brady mentioning at one of the meetings of the Pharmaceutical Conference, that a very large quantity of perchloride of iron in a solution of glycerine had been taken by mistake without any perceptible effect, whereas one-tenth of the quantity in any other form of solution would have produced serious results. The syrup promised, he thought, to be a much more useful preparation. He did not think much fear need be entertained about the chemical action of the nitric acid upon the glycerine, although the physiological or therapeutic action of the glycerine might counteract that of the iron.

The thanks of the meeting were voted to Mr. Williams for his communication, and he then resumed the presidential chair.

The next paper read was on—

BAYCURU ROOT AND GUAYCURU.

BY E. M. HOLMES.

The paper is printed on p. 466, and gave rise to the following discussion:—

The PRESIDENT said that this substance might be one of the drugs of the future, and it was important that they should understand its history and nature.

Professor BENTLEY said that it might be interesting to know that in the United States Pharmacopœia there was an allied plant, *Statice caroliniana*, to that now under discussion, which had been recently figured and described in 'Medicinal Plants.' No doubt the uses of guaycuru were as nearly as possible the same as that of the United States official plant. Mr. Holmes had traced it to a species of *Statice*, and statices were found scattered over nearly all parts of the world, in both warm and temperate regions. With regard to the astringent property of this root, which had been now described by Mr. Holmes, and also in a Brazilian paper two or three years ago, it might be interesting to note that in the British Exhibition of 1862, there was exhibited a root from Russia of the same genus, *Statice latifolia*. That root was remarkable for its extraordinary length. It was stated to be about 30 ft. long, and 4½ in. in diameter; it was used in Russia as a tanning agent on account of its great astringency. It was also used to a much larger extent in the same way in Spain. Dr. Symes had written an interesting note of the process by which he had been able to obtain the chemical constituents of baycuru root. If he (Professor Bentley) remembered rightly they were as nearly as possible the same as those given for the *Statice caroliniana* of the U.S. Pharmacopœia. This contained about 12 per cent. of tannic acid and a little resin and other matters. Of course the quantity of tannic acid must not be taken as the only test of the value of the root, for he could refer to astringent roots in this country, and, as he pointed out at the Pharmaceutical Conference, they needed not to go abroad for astringent roots. The old potentilla root contained about 18 per cent. of tannic acid. The only reason that pharmacists went abroad for astringents was that they were readily obtainable there in large quantities. The genus under consideration contained a number of astringent plants.

Mr. GREENISH said, that considering the external characters of these two roots, they might be easily mistaken for one another. As Mr. Holmes had pointed out the histological examination of the roots would show that they were distinct. That fact might be overlooked.

The PRESIDENT said that they were very much obliged to Mr. Holmes for his paper. It was of great value, and the Society and pharmacy generally were much indebted to him for his researches into these matters. Professor Bentley in giving them his experiences proved that old experiences were often of equal value to new, and that old knowledge was not to be despised even when it came into the presence of new things with difficult names.

The PRESIDENT then announced that the next evening meeting of the Society would be held on Wednesday, February 5th, but that in the interval, on Wednesdays, January 8th and 15th, there would be two special meetings at which Professor Redwood would lecture on the "Electric Light."

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held on Thursday, November 28th, at 8.30 p.m. Mr. C. H. Hutchinson, Vice-President, in the chair.

After the reading of the minutes, Mr. F. W. Branson read a paper, "Notes on Iodine and some of its Compounds."

The sources, properties, manufacture and purification of iodine were first described. Among algæ, those growing in deep water were stated to yield this element in the largest proportion, the chief source being *Fucus palmatus* and other species. The usual manufactory process for its extraction was then given. Its purification could be effected by precipitating the alcoholic solution with water, mixing the dried iodine with potassium iodide and subliming. The chief tests for iodine were next alluded to. Starch paste could be best preserved by the addition of chloroform; the delicacy of its reaction with iodine being interfered with, according to the author, by the presence of quinine, albumen, or much ether. The oxygen compounds of iodine, hydriodic acid, and the iodosulphates of the alkaloids were treated of successively. The preparation of the iodides used in medicine was described. The teriodide of potassium could be prepared in solution by mixing in molecular proportions potassium iodide dissolved in its equal weight of water, with iodine; the

solution was blue by reflected light, and was decomposed by the further addition of water. Mr. Branson concluded his paper by a detailed account of the processes in use for the detection of bromides and chlorides in the presence of iodides. He recommended the liberation of iodine by means of an acidified solution of potassium nitrite and its removal by ether, the remaining solution being evaporated to dryness, the residue mixed with potassium dichromate and sulphuric acid and distilled in the usual manner.

An animated discussion followed in which Messrs. Naylor, Senier, Parker, Hutchinson, Atkins and Sangster took part, and a vote of thanks was unanimously passed to Mr. Branson for his interesting paper.

Mr. W. R. Atkins then introduced the subject of "the Amount of Knowledge required in Pharmacy," but for want of time the full discussion of the same was postponed to the next meeting.

Mr. R. H. Parker read through a revised code of rules, drawn up to meet the present condition of the Association, and the matter was referred for discussion to next session. The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting of this Association on Wednesday, November 27, Mr. O. Wallis, President, in the chair, Mr. C. Miller read a paper on "Gravimetric Analysis." The author explained the general methods of incineration, drying, weighing, and calculating results, mentioning difficulties incidental to them; and then proceeded to give an account of the chief ways of estimating gravimetrically the common acids and bases. Any special precautions necessary were described, and thus a considerable amount of information was given to the audience in a small bulk.

In the discussion which followed, the superior merits of volumetric processes found many advocates.

A vote of thanks was passed to Mr. Miller for his paper, and also to Mr. Glover for his donation of a blackboard to the Association.

Parliamentary and Law Proceedings.

The Apothecaries' Society *v.* Shepperley.

In the Court of Exchequer, Thursday, December 5, Mr. Day, Q.C., moved before the Lord Chief Baron and Mr. Baron Pollock, for a new trial in the above action. He said, I have to move for a new trial on the ground of the verdict being against the weight of evidence, and also on the ground of misdirection. You may perhaps remember that this is the case in which I asked for an extension of the time for moving, and your Lordship suggested a period of a fortnight so that the Court of Appeal might be applied to on certain other points in the meantime, with a view of saving if possible the necessity of making this application. But it appears from the practice of the Court of Appeal, although fourteen days' notice has to be given, the case will not come on as an interlocutory application until it has got set down in the paper, and it is impossible to say when the case will come on for argument. Under these circumstances I cannot ask your Lordships for an indefinite prolongation of the time for moving here, and I will proceed now to state the grounds of my application.

The Lord Chief Baron: If you please.

Mr. Day: The Society of Apothecaries *v.* Shepperley, my Lord, was an action brought in point of form to recover penalties, but really and truly to determine a question of very considerable importance which has arisen upon the construction of the statute 55 Geo. III. cap. 194.

The Lord Chief Baron: Which way was the verdict?

Mr. Day: The verdict, my Lord, was for the defendant. The substantial question to be tried was this, Whether chemists and druggists, not being members of the Society of Apothecaries, are entitled to prescribe in what I think we termed simple cases.

Mr. Baron Pollock: Oh no! There was no question of that kind. There is nothing about simple cases in the Act of Parliament.

Mr. Day: No, my Lord, but I think that was the contention on behalf of the defendant, that what is called counter prescribing or prescribing in simple cases was not within the terms and provisions of the Act. I think it turned on the meaning of the proviso in the 28th section of the Act.

The Lord Chief Baron: What do you call prescribing? Do you mean writing down a prescription and delivering it to a person?

Mr. Day: No, my Lord, we say prescribing is directing, whether directing orally or in writing, what remedies shall be taken. That is how I should describe prescribing. But I wanted to state to your Lordship shortly what I understood the substantial point was, which was this:—It was said on behalf of the defendant that prior to the passing of this Act, chemists and druggists were in the habit of treating simple cases, or doing what was termed counter prescribing, and that as they were in the habit of doing that before the statute, their right to continue to do so is preserved by the 28th section of the Act. Now I should tell your Lordship that the statute which imposes the penalty which this action was brought in point of form to recover, is an Act for the better regulation of the Society of Apothecaries, and it contains a variety of provisions with which I need not trouble your Lordship. It contains provisions as to the examinations to which they are subjected and imposes a penalty on persons who, not having passed the examinations and obtained certificates, practise as apothecaries. The statute recites in section 5 the duties of apothecaries, and it recites that it is their duty to prepare with exactness and to dispense such medicines as may be directed for the sick by any physician lawfully licensed to practise. Then it imposes penalties upon them for neglecting that duty. Therefore, it is plain that the duty of an apothecary so far as it is analogous to what is now ordinarily discharged by the chemist and druggist was a duty which was still to be imposed upon them; that is to say an apothecary was compelled under this statute to practise as a chemist and druggist, now-a-days, so far as relates to the making up or compounding the medicines which were directed or prescribed by the physician. But as we all know the apothecary may himself—and indeed this Act provides that he may—treat the sick. The apothecary was at liberty under this statute himself to prescribe and himself to administer medicines. Therefore, if I may say so, the apothecary merged from his original condition of a chemist and druggist, and was entitled no doubt to practise himself, and to treat the sick, although the duty of dispensing or compounding medicines prescribed by physicians was still imposed upon him. Now, my Lord, of course since that time chemists and druggists have to a considerable extent had devolved upon them the duty of dispensing the medicines of physicians, because one knows it is not usual for physicians' prescriptions ever to be taken to an apothecary; the physician's prescription is taken to a chemist and druggist, and the chemist and druggist makes up the prescription. The chemist and druggist says, that he is entitled when persons come into his shop, and say they have something the matter with them, to see what is the matter with them, and if it is a simple matter, a matter involving no great medical knowledge, he is at liberty to treat them. That is the substantial question which is at issue now, if I may say so, between the apothecary on the one side and chemists and druggists on the other. This action was an action brought with a view to test the question. I told your Lordship, the 20th section imposed a penalty on persons who practised as

apothecaries. The words are, "practise as an apothecary without having obtained a certificate of the Society of Apothecaries." Now, it is said, my Lord, that as before the passing of this Act chemists and druggists undoubtedly did do what is termed counter practice, that is to say, advise medicines to be taken in simple cases, that they are at liberty to continue to do so.

Mr. Baron Pollock: That was never raised in this case.

Mr. Day: Your Lordship will remember there was a witness called for the purpose.

Mr. Baron Pollock: I stopped all that entirely. I left it to the jury on the construction of the statute, which I believe was more favourable to the plaintiffs than my brother Cleasby put it on a former occasion. I left to the jury only the question whether the defendant in this case had done that which was within that proviso limited by the words used in the proviso. I did not leave it in that open way. They asked me to do so, but I declined.

Mr. Day: When I come to read your Lordship's summing up, I am not going to complain of the way your Lordship left it to the jury.

Mr. Baron Pollock: What I said was this, that this section did not mean that they were allowed to exercise and carry on the same trade or business as fully and amply to all intents and purposes as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act. But I told the jury that was my own judgment, and they were bound by it. The true construction of the section was that that was all limited—that exercising and carrying on the same trade meant an exercising and carrying on of the trade of a chemist and druggist in the buying, preparing, compounding, dispensing and vending drugs. Therefore I had nothing to do with counter prescribing or simple remedies at all.

The Lord Chief Baron: So that no question arose as to what were simple remedies, or simple cases.

Mr. Day: No, my Lord.

The learned Judges here consulted for a few minutes.

Mr. Baron Pollock: As I understand that is not the part of the summing up you complain of?

Mr. Day: No, my Lord, I am not going to complain of your Lordship's summing up except in this sense. The misdirection of which I am going to complain is shortly this, that your Lordship left to the jury that which I say your Lordship ought to have determined as a matter of law.

Mr. Baron Pollock: I see.

Mr. Day: I am not going to complain of your Lordship's summing up, but I think when I come to read some passages from the summing up, the jury would naturally consider when they were dealing with the question of acting as an apothecary whether an apothecary was a person who prescribed in simple things, and whether that was not rather matter *dehors* the strict duty of an apothecary. Therefore, I felt it necessary to call the attention of the court to that section (28), which no doubt was much relied on on behalf of the defendant at the trial. Perhaps I may read the passages which appear to me to relate to this part of the case.

The Lord Chief Baron: Let me quite understand what is the question you are now submitting to the court.

Mr. Baron Pollock: You say I ought to have directed the jury—

Mr. Day: That on that point your Lordship ought to have said on this evidence the defendant was acting as an apothecary. I am going to read now the part of the summing up which applies to that part of the case.

Mr. Baron Pollock: How could I tell a jury that? I quite agree if it was the other way, if I had come to the other opinion, I might have told them they could not find a verdict for the plaintiff. But could I tell a jury they must find for the plaintiff? Supposing they had disbelieved, I will assume, as I am quite entitled to assume, that they disbelieved your client.

Mr. Day: Certainly I will assume they disbelieved every word he said.

Mr. Baron Pollock: Then do you say it would be fair to direct it on the evidence given by the defendant?

Mr. Day: Certainly, my Lord.

The Lord Chief Baron: At present I have not the evidence before me.

Mr. Day: My Lord, I do not propose to read the evidence in detail, but I do propose to read the learned Baron's summing up, because in that summing up he sets out the evidence on the subject, and I am going to deal with that summing up as being a fair summary of the evidence.

Mr. Baron Pollock: I quite follow you. I think it would perhaps shorten the matter if I now read to my Lord what the defendant himself said, because if that was so obviously clear that he had admitted he had come within the Act of Parliament, what you have said may be so. What he said was this, "I am a pharmaceutical chemist at Nottingham, and I have been for nine years dispenser to the General Hospital, and made up prescriptions," and so forth. Then he says this, "Death came into my shop." That was a man named Jolly Death. I think the jury may have disbelieved him, because it turned out he was an informer. He had gone into this man's shop, whether with a lawful intention I will not say. This is what the defendant said. "When Death came in, he said he had a cold, and he pointed to his throat, which he said was sore." Death in his cross-examination said, in fact, that his throat was not sore.

The Lord Chief Baron: He feigned it?

Mr. Baron Pollock: That does not affect this question The defendant said, "He pointed to his throat, which he said was sore. He said, 'Will you look at it?' opening his mouth across the counter. I looked at it, and I said I saw nothing the matter. He said, "Would you give me something for it.' I said, 'Perhaps a saline mixture might answer.' He said, Would I give him one. I did, and I charged him 1*s.* or 10*d.* If he had said nothing, but looked at his throat, and told him the proper thing for his throat was a saline mixture, of course that would be a different thing; but, he said, "Perhaps a saline mixture might answer; and he said, Would I give him one, and I charged him 1*s.* Nothing was said about any tightness on the chest, nor did I touch him. I charged him for nothing but the medicine. I did not tell him to come again." That is all the examination in chief. Then in cross-examination he goes a little further. He says, "I examined Death's throat to verify his statement, and so form a conclusion whether he had or had not a sore throat. I thought he had not." This, again, is in your favour. "I selected the medicine. The bottle had a label on. I put it on. The label was, 'a tablespoonful three times a day.' I did not tap him, nor did I ask him if he had any lung disease. I did not come to the conclusion"—Oh, that is about Hubbard, the other man.—I think that is really the whole of the evidence.

Mr. Day: I think there was another case, my Lord.

Mr. Baron Pollock: I did not know you rested upon Hubbard's case.

Mr. Day: I do not think there was much in it.

Mr. Baron Pollock: That really was the case. On that evidence ought I to have told the jury you must give a verdict for the plaintiff because on the defendant's own admissions he admitted that he had looked at a man's throat and said, "Perhaps a saline mixture might answer,' and then he said, Would I give him one? I sold him a bottle and charged him 1*s.*"

The Lord Chief Baron: Well, Mr. Day?

Mr. Day: Look at what an apothecary is, my Lord. I do not know that it is possible to find a better legal definition or other definition of what is an apothecary than is to be found in a direction by Mr. Justice Cresswell.

Mr. Baron Pollock: There is one thing in your favour which the defendant said in cross-examination later,

"A saline mixture is a compound and often bears a relation to the speciality of the disease," which I understood, in your favour. He meant to say that a saline mixture was not like a cake of yellow soap, or an ordinary black draught, which was always the same, but that the man who looked at the throat, would give one preparation of saline mixture in one case, and another in another, but it does not appear that he mixed this in any special way, for the occasion.

Mr. Day: My Lord, I find a definition of what an apothecary is in the summing up of Mr. Justice Cresswell in the case of the Apothecaries' Company *v.* Lotinga, 2nd Moody and Robinson, 449. Mr. Justice Cresswell, says, "Now, I apprehend that an apothecary is a person who professes to judge of internal disease by its symptoms, and applies himself to cure that disease by medicines." Now, my Lord, what did this gentleman, Mr. Shepperley, do in this particular case. The man complained of a sore throat. Of course, a sore throat may be the commencement of a great many different diseases; it may be a very trifling matter, or it may be a symptom of most serious impending or existing disease. Mr. Shepperley, upon the person complaining of a sore throat, looks into his throat to see if he is suffering from a sore throat, and to see, I presume, what the character of the sore throat is. Therefore he is a person who professes to judge of internal disease by its symptoms, for he looks to see what the nature of this internal disease or sore throat is by looking into the throat with the view to diagnose it, with the view to ascertain its nature or character. Then, my Lord, he administers a saline draught, a compound mixture, which may vary with the character of the disease to which it is applied. Then he brings himself within the second part of the definition, and applies himself to cure that disease by medicine. Therefore I submit, my Lord, that although this is in one point of view no doubt a trifling case, it is a case which is well selected to determine the principle, because we find that in both respects Mr. Shepperley brought himself, upon his own admissions, within the terms of this definition of an apothecary, which I take to be the true definition of an apothecary.

The Lord Chief Baron: Be it so. You contend that that was so. But is it so? Was the defendant asked by either party in cross-examination, or in examination-in-chief, whether he really believed that this man had a sore throat? because from what has been read it appears to me it might very well be that he did not believe a word the man said, but at the same time he did not choose to affront him by saying "You are telling me what is not true," and therefore he said "Well, if it be so, a saline draught may perhaps be the remedy."

Mr. Baron Pollock: The plaintiff's own account is practically the same, except that the plaintiff said the defendant asked him to open his mouth. The defendant said, no, "the plaintiff came in and stood straight across and said I have a sore throat, and opened his mouth across the counter without being asked." The plaintiff said "He asked me to open my mouth. I did so, he looked at my throat and said 'I do not see much amiss.' Then he gave me a bottle of medicine."

The Lord Chief Baron: That was the plaintiff's account. Then what was the defendant's?

Mr. Baron Pollock: The defendant's I have read; and the defendant's nephew, who was present, said that when Death came in he said, "I have a cold or sore throat." He leant over the counter and said, "Will you look at it." He said "It catches me here" touching his throat. The defendant said he saw nothing the matter with him, and again he speaks of the saline draught.

Mr. Day: Those are the short facts of the case. All I can do is to submit that he brought himself for those two reasons within the definition given by Mr. Justice Cresswell. He professed to judge of internal disease by its symptoms. He professed to look into the throat, and I suppose he professed by looking into the throat to obtain some information by so doing.

The learned Judges again consulted.

Mr. Baron Pollock: What occurs to my mind is this. It would be a very strong proposition to say that a judge must in the case of an action for penalties say to the jury, Gentleman, on that evidence you must find a verdict for the plaintiff. When under a possible aspect of the case, such as my Lord has been just now suggesting, which I confess did not occur to me at the trial, a jury might come to the conclusion that he had only been fairly dealing with the case. I hardly recollect a case in which the judge has told a jury, "You must find for the plaintiff" in an action for penalties.

The Lord Chief Baron: What would you have a man have in his particulars of defence, if he had made up his mind to the best of his ability to avoid the violation of this Act of Parliament, or in other words to avoid acting as an apothecary, and a man comes in and exhibits his throat saying that he has a sore throat, and when the man looks at it he sees there is nothing the matter? He may not like to say, "I do not believe a word you say."

Mr. Day: I cannot carry the case any further. The facts on which I rely have been very fully stated to the court by Baron Pollock.

The Lord Chief Baron: I mean what question can he leave to the jury?

Mr. Day: I submit that no question at all should have been left to the jury.

The Lord Chief Baron: Then what would you have the Judge do?

Mr. Day: Direct the jury to find a verdict for the plaintiff for the full amount of the penalties.

The Lord Chief Baron: I do not think there should be a rule. A man who acts as a spy and an informer puts the opposite party, the person whom he means to betray, in this situation:—He either must say at once to him, "I do not believe a word you are telling me," when he may perhaps knock him down; or turn him out of his shop at once; or else he must say something civil to him. I know nothing else which he could say, but "Well be it so" (but it was not so, because there was no sore throat at all) "perhaps a saline mixture may do you good." You must not be too strict with a man who is really in the hands of perhaps a skilful designing informer.

Correspondence.

"*Dens*" (Sheffield).—In reference to your inquiry whether the extraction of teeth comes within the terms "practising dentistry," you are recommended to consult the Registrar appointed to carry out the provisions of the Dental Act.

"*Dens*" (Droitwich).—We are not sure that we understand your question. The right to registration without examination was reserved to persons who occupied a certain position at the time of the passing of the Act. Before that time there was no authorized register, so that the position of "assistant to a registered dentist" must be one accruing subsequently and therefore involves no immunity from examination.

"*Chemicus*."—We are unable to recommend you the best works on the treatment of the diseases mentioned.

SODIUM ETHYLATE, OR CAUSTIC ALCOHOL.

BY BENJAMIN W. RICHARDSON, M.D., F.R.S.

The interest taken in my introduction of ethlyate of sodium into medical and surgical practice, leads me to think that the following brief essay on three points,—historical, therapeutical, pharmaceutical,—relating to that introduction may prove acceptable to the numerous readers of the *Pharmaceutical Journal*. The facts will, relevantly, supplement the debate at the Pharmaceutical Society, reported in the last number of the Journal and will correct one or two errors which have crept into that debate.

1. *Historical.*—The introduction of the ethylates into medical practice is not so recent as was supposed by some of the speakers. I brought the ethylates of sodium and potassium, with some other of the ethylate series, originally into notice for practical use so far back as 1870. I first reported on them to the British Association for the Advancement of Science in 1870, and in the same year I made them the subject of one of my lectures on 'Experimental and Practical Medicine,' upon which occasion I demonstrated the mode of making the ethylates of sodium and potassium and performed several experiments on blood, serum, and living tissues with the sodium ethylate. In the same year I also tested the practical application of what had been suggested to me by experiment. I removed by the use of sodium ethylate a large nævus from a child, who was under the care of my friend Mr. Gay, at the Great Northern Hospital. The nævus had previously been subjected to treatment by the ligature and by other methods, including the free use of nitric acid, without success. I supplied in this year, 1870, to the Great Northern Hospital, the specimen of the ethylate which came (fortunately) into the hands of Dr. Brunton, who in the next year used it for nævus with equal success. Dr. Brunton stated at the Medical Society of London that a house surgeon of the Great Northern Hospital gave him the specimen of the ethylate as a remedy for nævus without telling him of what it was composed. Dr. Brunton, who had missed seeing my report, had therefore to get the specimen examined by a chemical friend before he knew to what agent he was indebted for his success. Afterwards, through the same friend, he learned that the ethylate had been introduced by myself and he was so kind as to inform me of the circumstances. If the ethylates should come into use in medicine and pharmacy these facts from me will fix the date of their introduction definitely, viz., as September, 1870, at the meeting of the British Association for the Advancement of Science, held at Liverpool under the presidency of Professor Huxley.

2. *Therapeutical.*—In applying the ethylates, I had before me a definite object derived purely from experimental research. I found by experiment that I possessed in the ethylates of sodium and potassium bodies which, on being brought into contact with the moist living tissues, were decomposed, caustic alkali being produced and ethylic alcohol being reproduced by the extraction and decomposition of the water of the tissues. If, therefore, I inferred, I applied an ethylate to a vascular living tissue I ought to get four results on application, viz., (*a*) a removal or absorption of water from the tissue into the ethylate; (*b*) the destructive action of a caustic from the caustic soda that would be formed; (*c*) coagulation from the alcohol that would be reproduced; (*d*) prevention of decomposition of the dead organic substance that would be formed. The first instance in which the ethylate of sodium was used gave all these results, and future experience has confirmed the principle. At this moment I have a case in hand in which a large vascular growth is reduced by the ethylate to a mere dry mass of scale or scab by four applications.

It is not, however, by every degree of dilution or of concentration of the ethylate that the results can be arrived at. If the ethylate be too concentrated the caustic or destructive action is over severe and hæmorrhage may follow, like as from an incised wound. This is specially the fact with ethylate of potassium, and for that reason I prefer to recommend the ethylate of sodium of a strength I shall name at the close of this paper.

Therapeutically, the ethylates admit of a wide range of action. I have already used the sodium ethylate with success in a case of a wound from the bite of a dog, and I should infer that as an application to wounds from snake bite it would be of signal service. I need not enter into these subjects here, but whatever may be the future of the ethylates as remedies the first use of them was based on pure experimental research and the observations derived from it, a research which was a repetition to the letter, varied only in respect to details, of the mode with which I inquired into the action of nitrite of amyl and determined its true place as a remedial agent.

3. *Pharmaceutical.*—In order that the intention of the ethylates, as I have proposed them for use, may be properly fulfilled they must be sent out by the pharmacist as absolute alcohols, and for that reason absolute ethylic alcohol must be used in their manufacture. It was said by one of the speakers in the debate above referred to, that in a paper of mine, published in the *Lancet*, I had ordered by mistake "ordinary" alcohol, by which I presume he meant an alcohol containing water. If that is what he meant, it is certain the speaker, although he is an old friend of mine, had never done me the honour to read my paper at all. In the third paragraph of the paper (vide *Lancet*, Nov. 9, 1878, p. 654, col. 2) I state "sodium alcohol, or ethylate of sodium, is prepared by treating absolute alcohol with pure metallic sodium." In the next column I give the same instruction as to absolute alcohol for potassium ethylate, and the article all through conveys, as plainly as can be written, the same necessity. To make assurance doubly sure, at the close of the article I wrote, in parenthesis, the specific gravity of the alcohol that should be used in the preparation (sp. gr. 0·795), and although in passing through the press the figure nine got placed accidentally before the seven, the misprint is so glaringly obvious it corrects itself, and I do not suppose there is a pharmaceutical chemist in the kingdom who would not detect it for a misprint at once, even if he had not seen the correction which followed immediately after the accidental misplacement was detected. I dwell on this point for a moment, however, because of its vital importance. The President, Mr. Williams, indicated most properly that an error in using alcohol containing water was subversive of chemical principle. The error would be equally subversive of therapeutical principle, and would, in fact, destroy the character of the remedy altogether, on the grounds on which I have suggested its practical utility.

If sodium ethylate is to be sent out for use by pharmaceutists in the solid form, I agree with Mr. Williams that the solution for medical use had better be dispensed by the process of dissolving the solid ethylate in absolute alcohol. The proportion, however, which he suggests, one part of the solid ethylate to two of alcohol, is under the mark. One part to one and a half would be the better proportion. By the formula I gave in the *Lancet* I aimed to save the time of the busy dispenser who might only have absolute alcohol and metallic sodium in his laboratory. By experiments I found that a solution made in the way I described, without actually crystallizing out the ethylate, answered so perfectly that I proposed the plan for convenience sake, and specimens since made in that way which have been submitted to me, have proved perfectly satisfactory. At the same time I have no prejudices, and I bow willingly to Mr. Williams's far greater pharmaceutical knowledge and skill, a knowledge and skill which is, certainly, second to none.*

I have one word more to add, and that relates to the mode of sending out the ethylate to the profession of medicine, ready for use. It is best dispensed in a bottle furnished with a glass stopper ending in a pointed glass rod which descends into the fluid. The fluid is best applied from the glass point. It may, however, be applied very neatly by means of a clean quill, cut like a pen, and prepared fresh, that is to say, newly nibbed each time. When the glass rod stopper is not at hand the pen is a simple, effective, and inexpensive method. I am trying to have a platinum pen or pencil made, by which the fluid may, in some cases, be inoculated into a part. On one or two occasions I have applied the solution from a small glass syringe, but on the whole the glass rod and quill pen are, I think, the best. The glass brush is very inadvisable. The small fibres break off and, in one instance, a portion of fibre left on a surface touched with the ethylate caused great pain and trouble.

I have now, I think, treated on all points of present practical interest to the pharmacist. It will give me much pleasure to record any further new facts should they transpire.

THE PARIS EXHIBITION.

Chemical Manufactures.—Manufactured Products.

(*Concluded from page* 430.)

Iodine, Bromine and Phosphorus, and Compounds.

Although the iodine obtained from the mother liquors left in working up South American *caliche*, and the bromine from the "bittern" or residual liquor of the North American salt works, have exercised and are likely to continue to exercise an important influence upon the industrial production of these elements from other sources, they are nearly, if not quite unrepresented in this exhibition. It is true that it has been estimated that it requires the mother-liquors from several thousand parts of *caliche* to obtain one part of sodium iodate, of which only 64 per cent. is iodine, and that there is further loss of iodine during the necessary conversion of this salt into the marketable state of iodide, yet the enormous quantitiy of *caliche* operated upon, about 600,000 tons annually, is capable of yielding far more iodine than is consumed throughout the world. But in consequence of the scarcity of water, the dearness of acid, and the cost of fuel in the arid regions where *caliche* is found, the iodine is only extracted by five or six of the principal refiners out of a number of more than one hundred; nevertheless the production amounts to 35 or 40 tons of iodine yearly.

According to Langbein the method of separating the iodine most generally adopted by the Chilian saltpetre refiners is, after first acidulating the mother liquors, to pass through them a current of sulphurous acid, and then precipitate with sulphate of copper. The crude iodide of copper is suspended in water acidulated with hydrochloric acid, and a current o sulphuretted hydrogen is then passed through unti all the iodide of copper is decomposed into sulphide and hydriodic acid. The solution of hydriodic acid is drawn off and, after removal of excess of sulphuretted hydrogen by a solution of iodine in iodide of potassium, treated with carbonate or bicarbonate of potassium, according to the purity of the potassium iodide desired, and evaporated.

Iodine and bromine, and their salts, from seaweeds are, however, represented abundantly and well. In the British court some fine specimens, especially of potassium iodide and bromide, are shown by the North British Chemical Company, which has used Stanford's process, as already described in this Journal.* That consists in subjecting the seaweed to destructive distillation in retorts, by which the dissipation of iodine is avoided. The weed is thus converted into a kind of charcoal, which remains in the retort; ammoniacal liquor and tar pass over and are condensed, whilst the gas is used to light the works. From the charcoal the potassium salts, including iodides and bromides, are easily removed by washing. The residual charcoal resembles that prepared from bones, and forms a powerful and cheap deodorizer and decolorizer. The use of this seaweed char as a means of clarifying sewage by filtration is illustrated in the case, together with specimens of the char before and after use. The condensed liquor obtained in the change of the seaweed yields ammonia and acetic acid.

In the French department there are several fine displays of these products, from makers in the Finistère department. Messrs. De l'Ecluse-Trévoédal, of the Stum Works, Audierne, exhibit crude iodine (of which they produce ten tons annually) in small cakes, resublimed iodine, bromine, and the iodides of potassium, lead and mercury. Messrs. Carof and Co., of Ploudalmézeau, exhibit similar products, the lead iodide resembling rolls of gold flakes and the mercuric iodide being in long flat crystals. M. Tissier, of Conquet, shows some very fine iodides. Messrs. Glaizot, of Abervrach, who distil the weeds in closed vessels in a current of carbonic oxide, besides the

---

* The formula which I ordinarily prescribe is as follows:—

Put half a fluid ounce of absolute alcohol (sp. gr. 0·795) into a two ounce test tube. Set the test tube up in a bath of water at 50° F., and add, in small pieces at a time, cuttings of pure metallic sodium. A gas, hydrogen, will at once escape. Add the sodium until the gas ceases to escape, then raise the temperature of the water in the bath to 100° F., and add a little more sodium. When the gas again ceases to escape stop adding sodium, or if the fluid, which by this time will be of gelatinous consistency, should crystallize then stop. Afterwards cool down to 50° F. and add half a fluid ounce more of absolute alcohol.

With specimens of the ethylate made in this manner I have had the most excellent results.—B.W.R.

* *Pharmaceutical Journal* [2], vol. iii., p. 495.

elements and their compounds, show also bye-products similar to those obtained in the Stanford process. It may be remarked that in connection with all these exhibits are specimens of chlorides and sulphates obtained from the kelp. Some extremely fine specimens of resublimed iodine, side by side with the subliming vessels, occur in the case of M. Roques, of Paris, together with lead iodide and the red and green iodides of mercury.

But before leaving the subject, reference must be again made to the case of Messrs. Pellieux and Mazé-Launay, of Kerhuon, Finistère, where the fine products exhibited are eclipsed in interest by the information given as to the means of obtaining them. This case contains a model of a continuous furnace for the incineration of the fresh weed, by which, it is claimed, the loss of a considerable quantity of iodine that takes place during the ordinary processes is avoided. The seaweeds are introduced into this furnace in the wet state, and fall by their own weight upon a series of gratings successively until they arrive at last at the incinerating hearth sufficiently dry to inflame and burn to ash; the combustible gas given off is utilized as a source of heat and by thus making the weeds contribute fuel for their own incineration only one pound of coal is used in driving off sixteen pounds of water. The advantage in this treatment is illustrated by two specimens of kelp made in the laboratory from eighteen kilograms of *Laminaria digitata*, divided into two parts so as to present an analogous composition and treated differently. One sample of weed, burnt without previous drying, yielded 477 grams of kelp containing 8·238 grams of iodine; the other previously dried by exposure in the open air, gave only 130 grams of kelp containing but 0·940 gram of iodine.

It is also said to have been discovered recently that the yield of iodine is favourably influenced by allowing the fresh weeds to undergo a moderate fermentation before incineration. This is supposed to be due to a change that takes place in the molecular grouping by which iodine existing in the fresh weed as a volatile compound combines with a fixed base, and is then not so readily lost in the incineration. In the presence of salts of soda and potash the nitrogen of the fresh organic matter is converted during incineration partially into cyanides and partially into ammoniacal salts, together with a little iodide of cyanogen, which is volatile. But when, by incipient fermentation or putrefaction, the nitrogen of the fresh weed has been converted into ammonia, and the sulphur of the organic matter commences to form sulphides and sulphydrates of potassium, sodium and calcium, the iodide of cyanogen is decomposed by the sulphurous acid and the sulphydrates; the ammonia is liberated and replaced by fixed bases, and the iodides of cyanogen and ammonium are definitely converted into iodides of sodium, calcium, and especially of potassium, which are not decomposed by heat. In practice, therefore, fermentation is now induced in the seaweeds before the commencement of the drying. They are first thrown on to a platform and allowed to drain during five days; on the sixth day they are spread out in a layer of about 20 to 24 inches thick on a second platform, where fermentation quickly commences, and in about forty-eight hours it has proceeded far enough to allow of incineration without loss of iodine. They are then passed on to a third platform from which the furnace is supplied. During these operations they lose in moisture about 45 per cent. of their weight, or half the water they contain originally, that probably representing the quantity lost during the ordinary operation of drying. From 15 to 20 per cent. of this is driven off as vapour by the heat developed during fermentation; the remainder drains off. The liquor draining from the weeds on the first platform is not preserved as it contains no iodine; but that from the second and third forms a liquor proportionally richer in iodine than the weeds themselves. This liquor is partially evaporated, then mixed with the tar and other empyreumatic products of combustion, and run into the calcination furnace together with the weeds.

Operating this way and exercising great care in the selection of the weeds used, an average yield of 1000 kilograms of kelp containing 10·5 kilograms of iodine is obtained from 12,600 kilograms of fresh undried weed. As compared with kelp obtained in the ordinary way it is claimed that this kelp is twice as rich in potash salts and three times as rich in iodine. An arrangement had been entered into by this firm to supply other manufacturers with this rich kelp, but it broke down in consequence of the authorities limiting the number and working of the furnaces on sanitary grounds.

Phosphorus does not lend itself readily to the condition of exhibition, but specimens of white and amorphous phosphorus have been shown in the French court in the cases devoted to the products from bones. Specimens illustrating the different stages in the manufacture of phosphorus, from the crude to the purified product, together with the retorts used, were exhibited in the earlier period of the exhibition by Mr. Readman, of Glasgow, but it is understood that the phosphorus had afterwards to be removed.

Alimentary Materials and Preparations.

Starch, Gluten, Glucose, Etc.

The length to which this Report has already extended will prohibit more than a very brief reference to the articles coming under this and the following sections; they will therefore be dealt with rather as the exhibits of different countries than of individuals.

In France the manufacture of starch,—applying this word to the amylaceous constituent of cereals as distinguished from that of potatoes, which in France is commonly termed *fécule*,—is not carried on to the same extent as formerly. For a long time the industry was confined principally to Paris and Nancy, the starch being prepared from wheat exclusively. During the last ten years, however, wheat starch has been almost displaced by maize starch and rice starch, and as these materials have not been yet adopted in France to any great extent, the production is there at present not equal to the consumption, the deficiency being made up by importations of rice starch from England and Belgium. In 1875 these imports exceeded 4000 tons.

Potato starch, however, is made largely in France, chiefly in Paris, Compiègne and Epinal. It is estimated that upwards of 15,000,000 bushels of potatoes are there used annually in the production about 50,000 tons of starch. This is employed in the cotton and paper manufactures, and in the making of alimentary pastes, artificial gum, and more especially glucose. The residues serve for fodder

or are purified for use in bread making. There are a very large number of exhibitors of potato starch in the French court, and a few exhibit rice and maize starches.

The displays of starch from this country are chiefly, if not exclusively rice starch, and the same may be said of those from Belgium, some very fine rice starch being shown by M. Remy, of Antwerp. From Austria, wheaten and potato starches are shown, the manufacture being carried on to a considerable extent in Lower Austria, Moravia and Bohemia. Potato starch is shown from the Netherlands, where it is made on a large scale, and wheat, rice, and maize starches occur in the same court. Potatato starch is also exhibited in the Swedish, Spanish, Réunion and Venezuelan departments. One or two exhibits of starch from the United States are probably from maize and wheat, and maize starch occurs also in the Venezuelan court.

Arrow root from *Maranta arundinacea* is shown by several exhibitors from the island of Réunion, and also from French Guiana, Guadeloupe and India. "Indian arrow root," or "tous-les-mois," yielded by the underground stems of *Canna edulis*, is shown from Martinique, British Guiana and Guadeloupe, the latter country also sending another starch bearing the same name, prepared from *Phrysium dichotomum*. Tahiti sends "Tahitian" or "South Sea arrow root," prepared from the tubers of *Tacca pinnatifida*, but not any from *T. oceanica*, which is best known in commerce under the name; whilst starch from *Curcuma angustifolia*, formerly known as "East Indian arrow root," comes from India and Réunion.

Several "arrow roots" are exhibited from the British colonies. West Australia, as before mentioned, sends one prepared from a species of *Zamia* that grows abundantly in the colony, the fusiform root readily yielding 30 per cent. of starch. Possibly the "arrow root" in the Queensland courts is from the same source, but one sample from New South Wales has been obtained from maize, and another from Victoria, is described as being prepared "from the tous-les-mois plant by the aboriginals of Lake Tyers mission station."

There are also a number of other starches exhibited from different sources, and doubtless some of them might be utilized to a far greater extent than at present. Thus in the official catalogue of the French Indian possessions it is stated that the "arrow root plant" abounds in Mahé and its neighbourhood, but that the natives, who feed exclusively on fish and rice, neglect its collection; this starch might, however, be supplied in large quantities at about 5*d*. per pound. In Martinique too, amylaceous plants are said to be very numerous, but only utilized to the extent necessary for home consumption. The following list will show the sources of some of the starches exhibited :—

Amorphophallus sativus.—India.

Aponogeton monostachyum (tubercules).—India.

Artocarpus incisa (bread fruit).—Guiana, Martinique, Seychelles.

A. integrifolia (fruit).—India, Réunion.

Arum esculentum (tubers).—Martinique, Guadeloupe.

Batatas edulis (sweet potato).—Venezuela, Guadeloupe, Guatemala, Martinique, Seychelles, India, Réunion.

Borassus flabelliformis (root).—India.

Caladium esculentum (rhizome).—French Guiana.

Colocasia antiquorum (root-stock). — Martinique.

Cycas caledonica (pith).—New Caledonia.

Dioscorea alata (yam).—French Guiana, Venezuela, India, Réunion.

D. cordifolia (yam).—French Guiana.

Dracontium polyphyllum (tubercules).—India.

Gloriosa superba (bulb).—India.

Hypoxis curculoides.—India.

Mangifera indica (fruit).—Guadeloupe, Martinique, Réunion.

Manihot utilissima (bitter cassava root).—British and French Guiana, Guatemala, Martinique, Réunion, Mayotte, Nossi-Bé, Mauritius, Seychelles.

M. Aipi (sweet cassava root).—British Guiana, Venezuela, New Caledonia, India.

Musa paradisiaca (plantain).—French Guiana, Guadeloupe, Martinique, Cochin China, Réunion.

M. sapientum (banana).—India.

Pachyra aquatica (Guiana chestnut).—Martinique.

Phaseolus Mungo (seeds).—Cochin China.

Raphia farinifera (pith).—Martinique.

Sicyos angulata.—Réunion.

Sorghum vulgare (seeds).—Senegal.

Typhonium indicum (rootstock).—India.

The improved method of separating starch from the grain by washing, instead of destroying the gluten by fermentation, leaves the gluten available for other purposes, and there are some very nice specimens of leaf gluten, gluten bread, as well as granulated gluten, shown among the French alimentary products; there are also some similar products in the Danish court.

M. de Gand, of Cambrai, also exhibits a product made from starch residues containing gluten, by drying quickly and granulating.

Closely associated with gluten are the varieties of maccaroni and vermicelli, usually made from hard wheat containing a large proportion of gluten. For many years Italy virtually had a monopoly in this manufacture, and she sends specimens to the present exhibition. But her products meet there with a host of competitors from France, Algiers, Austria, Spain, Canada, the Argentine Confederation, Japan, and China, while Cochin China sends vermicelli prepared from the sweet potato, the beans of a species of *Phaseolus*, and from rice; the vermicelli from the sweet potato is in thin strips, and that from rice, as might be expected, is rather brittle. But in France and Algeria especially this industry appears to be attaining considerable proportions, the hard wheat of the latter country, which does not lend itself too readily to bread making, being found particularly suited to the making of the "*pâtes alimentaires*." The products are clear and transparent and are said to stand the test of cooking well. Instead of depending upon Italy for supplies as formerly, France now exports five or six thousand tons annually in excess of her imports.

Another industry that has grown up side by side with the vermicelli manufacture in France and her colony is that of *semoule* or semolina. Clermond-Ferrand was the first French town to acquire reputation for good semolina, but Marseilles now produces a larger quantity, having no less than sixteen manufactories. The following represents the percentage composition of a semolina prepared from the hard corn of Algeria :—

Water	10·30
Nitrogenous substances	13·91
Dextrin and saccharine substances	3·45
Fatty substances	0·35
Starch	70·97
Mineral substances: silica, phosphates and alkaline salts	1·02
	100·00

"Couscoussu" is the name of a variety of Algerian semolina exhibited, which is prepared by softening the grain with water and allowing it to swell, then drying it in the sun, crushing it into fragments the size of a millet seed, and winnowing. When required for use it is moistened and kneaded into small granules. Rice semola is shown in the Belgian court and maize semolina from Martinique, whilst Canada sends a kind of compromise between this and tapioca in her "pop corn" which is the grain of maize partially roasted.

Tapioca is well represented in the French department, about 2500 tons of the crude product from the manioc root being imported annually from Brazil into France and there undergoing a further process of preparation. About four-fifths of this is used for home consumption and the remainder is exported. Tapioca is also exhibited from Ceylon, the Straits Settlements, Mauritius, Réunion, Guadeloupe and French Guiana.

Dextrin, and a variety of substitutes for gum, probably all prepared from potato starch, are exhibited by Herr Engelmann, of Prague, and from the "altgräflich Salm" Potato Starch and Artificial Gum Manufactory, Svetta, Bohemia. Similar products, together with glucose, are exhibited from Holland, where the manufacture is evidently carried out on a large scale by two or three firms. In France the production of artificial gum is estimated to amount to about 1200 tons annually. But the specimens of glucose in the French court are much more numerous, it being exhibited in the solid and liquid form by many of the potato starch manufacturers. In 1876 there were in France twenty-one makers of glucose, producing nearly 25,000 tons annually, representing almost an equal weight of dry starch or about half the quantity of potato starch prepared in the country. The glucose is used principally in the manufacture of fermented drinks, especially beer, and in confectionery. In the United States court glucose prepared from maize occurs.

Saccharine Materials and Products: Sugar, Honey, Fermented Drinks, Alcohol, etc.

Although sugar is official in the Pharmacopœia it would not be wise to attempt here to criticize the multitude of specimens of it shown in the continental and colonial courts. But there are a few facts worth quoting from the official papers as having great significance in the entire absence of exhibits of sugar from Great Britain. In France there are now 520 beet sugar manufactories, and 34 sugar refineries, employing 60,000 workpeople and steam machinery exceeding 100,000 horse power. The harvest of beet root amounts yearly to about 8,000,000 tons, and the French colonies grow about 1,800,000 tons of cane. From these there are manufactured—

400,000 tons of beet sugar, valued at	£11,200,000
120,000 tons of sugar from the cane ,,	3,360,000
200,000 tons of beet molasses ,,	960,000
1,600,000 tons of fodder from beet residues	640,000
560,000 tons of scum, etc., used as manure	89,600
	£16,249,600

Although the French people are such large producers of sugar they are comparatively but small consumers, it being estimated that while the annual consumption per head in France is only 15½ lbs., in England it is 62 lbs., and in Cuba 102 lbs. This, however, is a great increase upon an estimate published in 1866, which gave to France 4 lbs. per head against 30 lbs. per head for Great Britain. Moreover, the large quantity of glucose now consumed in France must not be lost sight of.

In Austria also the sugar manufacture has made extraordinary strides during the last twenty years. In that country, as in France and Germany, it is carried on as an agricultural industry, the sugar being extracted on the spot where the beets are grown. Last year there were 213 beet sugar factories in operation in Austria, principally in Bohemia and Moravia, and it is interesting to find that in most of them the diffusion method is adopted, in which the sugar is obtained by a process of dialysis, the cell membrane itself acting as the dialyser. There are also exhibits of beet sugar from Belgium, Sweden and Russia, though the German manufacture is not represented.

The principal displays of sugar from the sugar cane are found in the colonial courts, being most plentiful in those of the Mauritius, Martinique, Jamaica, Guiana, and Réunion; there are also some samples shown from the United States.

Honey is exhibited from various countries, the largest number of samples perhaps coming from Portugal, there being more than forty exhibitors. There are a good number, however, from Greece and Italy (together with a model of a hive having movable cells, from which the honey is expelled by centrifugal force), Spain, Portugal, Algeria, Austria, the Argentine Confederation and the United States. A sample is also shown by the Bey of Tunis.

Wine is present in numerous varieties from all the vine growing countries in Europe, except Germany. The Australian colonies also enter prominently into the competition, and Victoria and South Australia are especially well represented. Rice wine is shown from Japan, China and Cochin China, and China also sends specimens of millet wine. Beer, too, is well represented, the beer produced by "bottom fermentation" in Austria, Belgium, and other continental countries finding a competitor in lager beer from the United States.

The vinegar shown in the French department is almost entirely derived from the acetification of white wine, the most suitable kinds being those of Orleanais, Blaisois, Loire-Inférieure and the Charentes departments. The production of vinegar in France is estimated to amount to between eight and nine million gallons annually, nearly one-tenth of which is exported. It is stated officially that Pasteur's process for hastening the acetification of the wine has been successfully adopted by the large manufacturers of Orleans. There are besides many Spanish and Portuguese exhibitors of vinegar, usually in connection with wine, and there are also three exhibitors in the Canadian court and several in the Austrian.

Scarcely less bewildering is the number of alcoholic liquors displayed from every part of the globe. Upon what principle the awards can have been made in this and some other classes is fair matter for wonder, for no jurors could have been expected to taste more than a very small fraction of the samples

shown. Perhaps under such circumstances not much is lost by having to depend for information upon the general statements of the official catalogue. Even these, however, can be quoted here only to a limited extent.

In France the brandy called "*fine champagne*," distilled from the white wine of the cantons of Cognac and Segonzac, holds the first rank. Then comes that named "*petite champagne*," "*premier bois*," "*second bois*," etc., the quality diminishing in proportion to the distance of the source of the wine from the Cognac district. All these varieties of Charentes brandy are known generically as "cognac," and they are said to derive from the soil their essential characteristics, which improve with age and according to the place of storage. In the Landes, Gers and Lot-et-Garonne departments a large quantity of white wine is distilled to produce the kinds of brandy called "*Armagnac*," "*bas Armagnac*," "*Ténarèze*," or "*haut Armagnac*." These kinds of Cognac and Armagnac brandy are said to be exported to every country in the world without exception. The Montpellier brandy is distilled from the red and white wines of the Gard, Hérault and Aude departments. The amount of brandy distilled from wine in France yearly is estimated to be equal to between nine and ten million gallons of absolute alcohol. There is also a large quantity of spirit distilled from the grape residues and known as "*eau-de-vie de marc*."

Alcohol is also obtained from other sources in France to the extent of about twenty-two million gallons yearly, rather more that half of which is distilled from beet, nearly one third from molasses, and the remainder from amylaceous and other materials.

From the French and English colonies engaged in the sugar manufacture a large number of samples of rum are sent, distilled from the cane molasses. Those best represented are Tahiti, Martinique, British Guiana and Jamaica, the last named colony converting all her molasses into rum. Varieties of ratafia are exhibited from Martinique, Guadeloupe and Tahiti.

Among other alcoholic liquors exhibited may be mentioned gin from Holland and Belgium; some very good whiskey distilled from rye, from Canada; "arrack," from Ceylon and Pondicherry; "kawa-kawa," prepared from *Piper methysticum*, from Tahiti; rice spirit from Cochin China; millet spirit, from Senegal; and several varieties of koumiss, shown by Mr. Chapman, of London.

But the alcoholic list is not easily exhausted, for Algiers shows alcohol prepared from green and dry figs, caroba beans, dates, palm nuts and ashphodel bulbs; whilst Martinique alone sends specimens obtained from manioc, receptacles of the cashew nut, sweet potato, sugar cane, sour-sop (*Anona muricata*), sweet-sop (*A. squamosa*), mango, South American apricot (*Mammea americana*), tamarind, banana, sea-side grape (*Coccoloba uvifera*), sapodille plum (*Sapota Achras*), guava (*Psidium pyriferum*), pine-apple, hog-plum (*Spondias lutea* and *S. dulcis*), Barbary fig, melon, pumpkin (*Cucurbita maxima*), creole cherry (*Eugenia Michelii*), Angola pear (*Cytisus Cajanus*), etc.

The liqueurs form another numerous class, many of which bear well-known names, though there is no lack of novelties. The well-abused absinthe is present in force from France, Russia, Switzerland, and other countries, together with its neighbour, vermouth. A desire to displace absinthe on moral —and pecuniary—grounds has given rise to many substitutes. Algiers sends for this purpose an "*amer africain*," and French Guiana an "*amer anisé au pareira brava*," or Cayenne absinthe, which is said to possess the taste of absinthe, and all its good qualities without its disadvantages. "Eucalypsinthe" is the significant name of another liqueur which is said to be making its way in public favour and is exhibited in the French and Algerian courts. It is claimed to have the therapeutic properties of the tar preparations and perhaps the same might be predicated of a "liqueur de pin." There are also "curaçoa," prepared from the bitter orange; "prunelle," flavoured with the kernels of the blackthorn fruit; kümmel, flavoured with caraways; "chartreuse;" "iva," hydromel, peppermint, anisette, and a number of other liqueurs, fully evidencing that this industry has an importance upon the continent far beyond that it has attained in this country.

But in artificial aerated waters Great Britain and Ireland undoubtedly take the lead, and the exhibitors from the sister island are well to the front. Messrs. Bewley and Draper, of Dublin, show specimens of soda water, potash water, lemonade, ginger ale, artificial seltzer and other waters in imitation of the natural springs, all being guaranteed to be absolutely free from lead and other objectionable ingredients. Messrs. Corry and Co., of Belfast, exhibit similar articles, in the preparation of which they use water from the "Cromac" spring and apparatus having all the parts coming into contact with the water constructed of non-metallic materials. The British and Foreign Mineral Water Company, of Glasgow, shows samples of the materials employed, from sugar, ginger and lemon peel, to solutions of the chemical compounds used in the more complex mineral waters, as well as a series of the manufactured products, from simple carbonated Loch Katrine water to artificial Carlsbad, Kreuznach, and Pyrmont waters. The Company also exhibits a model of the apparatus used, which is constructed so that neither the carbonic acid gas nor the liquid containing the chemical ingredients come into contact with any part that is not coated with pure tin. Messrs. Sampson Brothers, of Sutton-in-Ashfield, also send some very good waters prepared with similar precautions from a very pure spring. The well-known house of Schweppe and Co., of London, is also represented.

The natural aerated and mineral waters of France are exhibited in enormous variety in a special pavilion, where for a trifle samples of many of them may be tasted. Mineral springs exist in forty-five departments of France, and are estimated to yield to the principal establishments utilizing them, about one hundred and fourteen million gallons daily.

Alimentary Oils.

Olive oil is immeasurably the most important alimentary oil shown in the exhibition, most of the others, such as poppy oil, sesame oil, walnut oil and groundnut oil, having been already sufficiently referred to in a previous section. Thus there are 330 French exhibitors of olive oil, 300 Spanish, 200 Portuguese, and 60 Algerian, besides other nationalities—upwards of one thousand altogether. One of the most interesting exhibits is some oil of very good quality that comes from South Australia. In France olive oil for food is prepared principally in

Languedoc, Provence and Corsica from picked olives which are usually crushed with the stones. The annual consumption of edible oils in France is estimated at between eight and nine million gallons, of which nearly one-tenth is used in Paris, including a quarter of a million gallons of olive oil.

In Algeria the olive oil industry is extending. The olive tree grows wild in many parts of the colony, and in some places the natives have sought to improve the quality of the oil by grafting, but through defective manufacture only an inferior oil is obtained. Some factories conducted by Europeans have been established, however, in the principal centres of production, particularly at Tlemcen and in Kabylia, where oil is produced that is largely exported. The qualities sent out are as follows :—

Oil from green olives.—This kind retains for several months a rather disagreeable taste, but after it has deposited some chlorophyll and other substances that pass into it during expression, and it has been filtered, it acquires a good flavour.

Oil from half-ripe olives.—This kind is made in January and during part of February. It has a flavour of the fruit, but without bitterness. It is not so sweet as the preceding, to which it is inferior.

Oil from ripe olives.—Made in February, March, and April. It is a light sweet oil, said to be without any taste of the fruit and to be much sought after in the north of Europe.

Huile d'Enfer.—Obtained from the water with which the residue from the pressing is boiled.

Ressences.—Obtained by trituration of the olive stones and used in soap making.

A large quantity of French olive oil is, however, imported into Algeria to suit the palate of European residents there, the native oil almost always having more or less of the flavour of the fruit.

In the Queensland department there are two or three displays of dugong oil and dugong lard, from the fishery in Moreton Bay. Mr. Ching, of Maryborough, exhibits also dugong "bacon," as well as skulls, and hide, ¾ in. thick, all from the same source, together with photographs illustrative of the process of "cutting up" the dugong and injecting the hide.

Preserved Food.

Although there is no lack of exhibits of preserved foods of different kinds, from various parts of the world, none have been observed showing any such particular advance in the method of preservation, as would warrant a detailed reference to them in this report. The method most generally adopted appears to be that with the results of which the public is now so familiar, viz., packing in hermetically closed tin boxes, and heating in a water-bath. In France considerable quantities of preserved food are prepared in Marseilles, Bordeaux, Le Mans, Paris and Nantes, the last-mentioned exporting about 4400 tons annually. The preservation of sardines and other fish is carried on chiefly upon the coast of Brittany, that of mushrooms almost exclusively in Paris, and of truffles in Dauphiné and Périgord. Sardine preservation is also carried on in Algeria, the native olive oil being used.

This is the last of the subjects included in the scheme roughly indicated at the commencement of this report. Although the carrying out of the plan has given to the report a length not anticipated, many subjects of interest have been passed over, and it should be remembered that even now it has dealt with only one comparatively small division in this latest, but most successful of all exhibitions.

The Patent Medicine Stamp.

Sir,—I beg to forward copies of a correspondence I have had with the Commissioners of Inland Revenue, relative to the liability to the stamp duty of my "vinous syrup of quinine," and "quinine and sarsaparilla," described in the bills enclosed, both of which have an extensive sale; I consider the publication of it in the Journal may be the means of saving much trouble and inconvenience to chemists who put up doubtful specialities; there appears to me to be great discrepancy in the decision of the Commissioners, for I cannot see the force of exempting those preparations I have noticed, and charging mine and similar ones; but as it is so decided, it must be taken to be correct, and acted upon accordingly. It is not the chemists, but the public that suffers, because either the prices must be increased to the amount of the stamps or a reduction made of the quantity in each size. I should not have troubled you, but I consider the case to be highly important, and therefore desirable to be circulated through the entire trade, and I hope you will kindly insert it with my letter fully.

I am, sir, Your obedient servant,
"J. B. Shillcock.

Bromley, Kent, *November* 18, 1878.

No. 1.

"Bromley, Kent, *October* 19, 1878.

"To the Commissioners, Inland Revenue, Somerset House.

"Gentlemen,—Will you be good enough to inform me at your earliest convenience whether the medicines as described in the enclosed bill, require a medicine stamp. I shall await your reply before I publish them; if liable to the duty, please to point out what renders them so.

"I am, gentlemen,
"Your obedient servant,
"J. B. Shillcock."

No. 2.

"R 6707 Stamps. "Inland Revenue,
"1878. "Somerset House, London, W.C.
"*October* 28, 1878.

"Sir,—The Board of Inland Revenue having had before them your letter of the 19th inst., relative to the sale of your "vinous syrup of quinine and sarsaparilla," I am directed to state that you appear to claim a proprietary right in the preparation which is thus rendered liable to stamp duty.

"I enclose a statement of the law relative to the stamp duty on patent and proprietary medicines.

"I am, sir,
"Your obedient servant.
"A. A. Watts,
"*Assistant Secretary.*"

No. 3.

"Bromley, Kent,
"*November* 2, 1878.

"To the Commissioners, Inland Revenue, Somerset House.

"Gentlemen,—I have to acknowledge the receipt of your letter of the 28th ult. "(R 6707 Stamps)," and of course I bow to your decision, but I cannot help thinking that when compared with 'Eno's Fruit Salt,' and 'Lamplough's Pyretic Saline,' both of which are exempted from stamp duty, and the proprietors of which more directly and more clearly claim a proprietary right in the preparations than I claim in the bill submitted, and moreover the same are distinctly declared to be, if not actually recommended to be, good for certain disease; I

must say it appears to me extraordinary and inconsistent that my preparations should be declared liable, and theirs exempt. I do not wish to raise a frivolous objection, but if the two cases are considered, I think your decision will be reversed. The favour of an early reply will oblige.

"Your obedient servant.

"J. B. SHILLCOCK."

No. 4.

"R 7035 Stamp. "Inland Revenue,
"1878. "Somerset House, London, W.C.
"*November* 11, 1878.

"Sir,—In reply to your letter of the 2nd inst., I am directed by the Board of Inland Revenue to state that 'Lamplough's Pyretic Saline,' and 'Eno's Fruit Salt,' have been decided to be within the exemption from stamp duty, in favour of compositions for making a water impregnated with soda or mineral alkali, or with carbonic acid gas. This is clearly not the case with regard to the preparations described in the handbill and label enclosed with your letter of the 19th ultimo.

"I am, sir,
"Your obedient servant,
"F. L. ROBERTS,
"*Assistant Secretary.*"

London, *November* 27, 1878.

THE WEIGHTS AND MEASURES ACT.

Sir,—We beg to hand you copies of correspondence between ourselves and the Board of Trade, respecting the Weights and Measures Act which comes into force on January 1st next, and trust you will be able to find space for its insertion, together with Mr. T. H. Farrer's letter,* referred to. This we cut from the *Times*, and in the third paragraph of it there appears a cover for the use of apothecaries' measure though it is a matter for regret that the Board of Trade has not definitely said so. As Parliament is to meet next week it would be desirable to have this point elucidated before the inception of the Act takes place, that is if the trade have any doubt about it as we have had.

We are, sir, your obedient servants,
"WHOLESALE DRUGGISTS."

"Copy.

"*November* 14, 1878.

"*Weights and Measures Act*, 1878.

"We, in common with other wholesale houses, have to sell measures of glass for the use of retail druggists and medical men, such measures being usually divided into ounces and divisions of an ounce, fluid capacity=160th gallon. We should like to know how section 29 applies thereto. Also what size weight, say in grains, would be considered impracticable to be stamped under the provisions of section 28. Section 20, subsection 2, permits apothecaries' weight. This apothecaries' weight does not appear to be defined in the Act, nor can we understand drugs by retail so as to enable us to quote in our price list according to law.

"The Standard Weights and Measures Department.
"7, Old Palace Yard."

"Board of Trade,
"Standards Department.
"7, Old Palace Yard, S.W.
"*November* 18, 1878.

"In reply to your inquiries under the 'Weights and Measures Act, I am to point out that the second schedule of the Weights and Measures Act, 1878,' contains all the legal denominations of trade weights and measures. There are no standards of apothecaries' weights, and such weights cannot therefore be verified and stamped, although they may be continued to be used under clause 20 of this Act.

As the verification and stamping of trade weights and measures is the duty of the local authorities, the Board of Trade is unable to say under clause 28 what would be the smallest size of grain weight which would be stamped by the different local authorities. I am, at the same time to remind you that the Board of Trade have no power to give an authoritative answer to legal questions arising under this Act.

"(Signed) H. J. CHANEY."

"*November* 21, 1878.

"Yours $\frac{H}{ST}$ 621, dated *November* 18.

"In reply to above, in which you are kind enough to acknowledge receipt of ours of the 14th current, and in which you state that the 2nd schedule of the Weights and Measures Act contains all legal denominations of trade weights and measures and that there are no standards of apothecaries' weights, therefore these cannot be verified, though option of use of them still remains, and it is also stated that the smallest size of grain weights of grain weights possible to be stamped is left to the choice of the local authorities, we have to observe that you have omitted to give us any information in respect of the first point of our inquiry, made on the 14th current. With reference to it we have to point out that measures made of glass are generally in use by all the chemists and druggists, wholesale and retail, throughout the kingdom, and are graduated to fluid minims, ounces and pints, such use being for measuring both in dispensing and retailing commodities pertaining to their trade. In addition, measures of earthenware and glass, graduated to tea and tablespoonfuls are sold by wholesale to retail chemists and druggists, and by the latter to the British public for the purpose of taking the various medicaments prescribed by the medical profession, all of which measures have hitherto been sold unstamped. We may add that the divisions of these measures are based on the definition of measures of capacity in the appendix to the British Pharmacopœia, a book published by authority, under the Medical Act of 1858, section 54. We would wish to know:—

"(1). If the sale of such earthenware or glass measures is illegal, and if so, if application is to be made to the usual local authority for the stamping of them.

"(2). If under section 38 of the Weights and Measures Act we can quote and sell stamped or unstamped measures (glass) graduated under the metric system, as such measures are in constant requisition both for home and export use of chemists and druggists and others, or must we have equivalent imperial divisions of standard measures marked on each of said measures.

"(3). If our quotations on our lists of prices current at per dram should mean the one-sixteenth of an imperial ounce or an apothecaries' dram of sixty imperial grains so as to avoid the penalty in section 23.

"(4). What interpretation is attached to the word 'drugs' in section 20.

"At the same time we note that you assert you have no authority to define legal questions under this Act, but we hope we shall have in your reply the benefit of, in the interest of the trade with which we are connected, the technical experience of your department."

"Board of Trade,
"Standards Department,
"7, Old Palace Yard, S.W.
November 22, 1878.

"I am to acknowledge the receipt of your communication of yesterday, requesting further information respecting the legal use, under the Weights and Measures Act of last session, of apothecaries' weights and measures.

"In reply thereto, I am to refer you to Mr. Farrer's letter in the London *Times* newspaper of the 23rd ultimo as well as to my letter of the 18th inst., and to state that as regards such legal questions of construction of this Act the Board of Trade must refer you to your legal advisers.

"(Signed) H. J. CHANEY."

* The purport of this letter has been given before, p. 330.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 14, 1878.

THE ORIGIN OF COUNTER PRACTICE AND THE REAL MEANING OF THE APOTHECARIES ACT.

To the facts already mentioned as illustrating the circumstances which led to the inception of the Apothecaries Act, 1815, and as indicating the original objects of that measure as well as their curtailment by the Act as passed, many others of similar purport might be collected from the records of the period referred to. What has been stated will, however, suffice to show that while the practice of pharmacy, including the dispensing of physicians' prescriptions, was then chiefly carried on by apothecaries as their especial privilege, and to some degree also by druggists, the practice of medicine was no longer monopolized by physicians, but was to a very large extent carried on by various persons who possessed no legal qualification to act in that capacity equivalent to the diploma of the physician. Chief among these were the apothecaries, who were either seeking altogether to substitute medical practice for the exercise of their proper avocation, or combining the two together in the manner which gave rise to the popular idea of the "doctor's shop" as being a place where medical advice as well as medicine could be obtained.

While this irregular exercise of medical functions was so general and the confusion of the practice of medicine with the practice of pharmacy was being thus promoted by the apothecaries, it would have been indeed surprising if the druggists, while gradually taking the place of the apothecaries of former times, and absorbing the practice of pharmacy, had abstained altogether from medical practice, while there was no kind of restriction on its exercise. That they did not do so, abundant evidence is furnished even by the complaints urged against them by the apothecaries and used as arguments in favour of their own attempts to bring about reform in the practice of medicine. Even at that time the shops of the chemists and druggists were not distinguishable from those kept by apothecaries, and their respective businesses differed no otherwise than that with the dispensing apothecary medical practice was the principal object, while with the chemist and druggist it was only a secondary object, mostly confined to the counter. The chemists and druggists, however, did, in regard to such counter practice, no less than in the dispensing of physicians' prescriptions, occupy common ground with the apothecaries at that time, but they did not seek, like the apothecaries, to become medical practitioners, and it is important to bear in mind this difference, for the sake of understanding what was then meant by the term "practising as an "apothecary." The apothecary professed to be and held himself out as a regular medical practitioner; but the counter practice of the chemist and druggist did not extend beyond the recommendation of simple remedies when his aid was sought for.

It is easy to perceive that under this state of things the more educated and enlightened of the apothecaries should have appreciated the mischief likely to arise from the practice of medicine by persons who had undergone no special education for that work, and that they should have felt the desirability of reform in the practice of medicine as well as the need of establishing a legal qualification for the members of their own body who had already become virtually the most numerous if not the chief medical practitioners throughout the country.* The original aim of the promoters of the Apothecaries Act comprised, as has already been shown, the regulation of the practice of pharmacy, conjointly with medical reform, but in that particular they failed owing to the opposition of the chemists and druggists, and the Act, as it was passed, presents throughout indications of having been directed solely and alone to the improvement of apothecaries as medical practitioners. This is evident in the title of the Act which describes it as "an Act for better regulating "the practice of apothecaries throughout England "and Wales;" it is evident in the provisions by which the duty of appointing examiners was laid upon the Society of Apothecaries for the purpose of ascertaining that its future licentiates should be skilled "in the "science and practice of medicine," and their "fitness "and qualification to practise as an apothecary"; it is further evident from the provisions of the 14th section, according to which it was declared unlawful to practise as an apothecary without a certificate of being duly qualified. It is important to consider these points in order to understand the true bearing of the 20th section of the Act, according to which the apothecary practising medicine was made subject to a penalty of twenty pounds, unless he possessed the specified legal qualification.

The intended effect of the Act, thus indicated by its own terms and provisions as being specially and exclusively directed to the regulation of medical practice by apothecaries, is also consistent with the declaration of the Society's solicitor in his letter to the Chemists and Druggists' Committee, describing "the improvement of their branch of the profession "in medical knowledge" as being the only object for which the apothecaries sought to obtain the Act. In the same letter it was stated that the views of the Society were so entirely directed to that object that it had no disposition to insist on any clause not essentially connected with it. Upon this basis the compromise between the apothecaries and chemists and druggists was effected by the insertion of the 28th section, and the extent of the surrender thus made to the chemists and druggists can only be judged of by taking account of these facts, and of the condi-

* The Associated Apothecaries estimated that in 1812 and 1813 there were about 12,000 general practitioners without any certified qualification to practise.

tions prevailing at the time. Counter practice had long been carried on by chemists and druggists no less than by the apothecaries, while still acting chiefly in the capacity of pharmacists, and no objections were raised so long as it was confined within moderate limits. The practice which it was desired to regulate by the Act generally, and by the 14th and 20th sections to restrict, was the practice of those apothecaries who acted chiefly or altogether as professed medical advisers in such an extended manner as to require, in the public interest, evidence that they were adequately competent to discharge such functions.

The insertion of the 28th section of the Act was in fact a recognition by the Society of Apothecaries and by the Legislature that chemists and druggists occupied to some extent common ground with the apothecaries, and inasmuch as they did not profess to practise medicine like the latter, and therefore were not affected by the 20th section of the Act, the provision made in that section that nothing in the Act should extend, or be construed to extend, to prejudice, or in any way affect the trade or business of a chemist and druggist, cannot, we think, fairly be held to have implied a reservation as to the counter practice, which was then habitually carried on by chemists and druggists in their shops, as part of their business, after having been initiated, and made popular by the apothecaries as the practice of the "doctor's shop."

The use made of the Act when it was passed furnishes another proof that it was not intended to interfere with the counter practice of chemists and druggists. If it had been applicable to such a purpose it is reasonable to suppose that there would have been an early exercise of its power in that direction, since there was no lack of jealousy on the part of apothecaries in regard to chemists and druggists, and the Society of Apothecaries was repeatedly moved to institute prosecutions. In February, 1833, Mr. R. D. Upton, then clerk to the Company, replied to such a solicitation that he was not aware chemists and druggists offended against any provision of the law in giving advice gratuitously "any more than "any other private individual," and that "if a chemist "and druggist really and *bonâ fide* made his patient a "present of his advice, and only receives a reasonable "price for his medicines," he knew of "no law to pre-"vent his so doing."

In the following year, Mr. Nussey, then Master of the Apothecaries' Company, stated in evidence before Mr. Warburton's Parliamentary Committee that no prosecutions of chemists and druggists had been instituted under the Act, while at the same time he described the 20th section as being very burdensome to the Company, subjecting it to great obloquy and expense, and one they would be glad to be rid of.

It was not until the year 1839 that any prosecution of a chemist and druggist was undertaken, and then the Greenough case was tried before Baron Maule at the Lancashire assizes. This, however, was a case of a man who, being a chemist and druggist, also habitually visited patients and charged for attendance, who, in fact, practised as an apothecary in the true meaning of the term. The verdict, however, was for the defendant, and the jury appears to have been unable to distinguish between the trade of a chemist and druggist and that of an apothecary. The *Lancet* was then loud in denunciation of what it termed the "druggists' clause" as the reason of the inefficacy of the Apothecaries Act, and liberal abuse was showered upon "Rhubarb Hall" for having allowed it to be inserted in the Act.

But in 1841, when the decision in the Greenough case had been reversed on appeal, the *Lancet* suddenly discovered that the Act of 1815 had assumed a new form and was to be regarded as an efficient engine for repressing the counter practice of chemists and druggists. Since that time it appears to have been allowed to lie by unused until recently again dragged from its obscurity by the Medical Defence Association with the same object.

Though it is a useless labour to speculate as to what might or should have been done at some past time and under conditions that no longer exist, it is scarcely possible in reviewing the events of the year 1815 to avoid the reflection that there was then a grand opportunity for establishing an organization to regulate the practice of pharmacy and to provide for the interests of the class that was then taking the place of the old apothecaries. It is impossible, also, to avoid a feeling of regret that, notwithstanding the successful opposition then offered by the chemists and druggists to the attempted monopolization of pharmacy as well as medicine by the apothecaries, there appears to have been too little coherence among them for even keeping alive the association then formed with the special object of resisting the projects of the Associated Apothecaries. The Committee of the Druggists' Association did meet on some few occasions to take action in regard to some matters of trade interest, such as the sale of poisons and the vexatious application of the Medicine Stamp Act, and a proposition was made in 1829 to form a General Association of the Chemists and Druggists of Great Britain, but it came to nothing in a few months, and even the Association formed in 1812 appears to have maintained only a torpid kind of existence. A further attempt to form a General Association of Chemists and Druggists and to introduce reform into the practice of pharmacy was made in 1830, but it also failed to obtain the support required, and it was not until the year 1841 that the members of the trade were aroused from the pursuit of their individual interests to a sense of the necessity of union and corporate action.

The occasion for this was furnished by the Medical Reform Bill, introduced by Mr. Hawes, Mr. Ewart and Mr. Hutton as the result of the agitation carried on among medical practitioners and of the parliamentary inquiry instituted in 1837 at the sug-

gestion of Mr. WARBURTON. When this Bill was printed it was found that many of its provisions would seriously affect chemists and druggists; thus, for instance, it provided that no person whatsoever should be entitled or permitted to carry on the trade or business of a chemist and druggist in any part of Great Britain and Ireland unless he had obtained a licence to carry on the trade and business according to the provisions of the Act. Such licence was to be renewed annually, and the penalty for infringement of the Act in this respect was to be twenty pounds. It was also provided that no person whatsoever should be permitted to practise medicine for remuneration or gain, either directly or indirectly, in any part of Great Britain or Ireland unless he had obtained a certificate to practise according to the provisions of the Act. The interpretation clause set forth that practising medicine was "to be construed "as including the recommending, prescribing or 'ordering, either directly or indirectly, any medi- "cine, remedy or application whatsoever for the "relief of any disorder, ailment or illness of the body "or mind, or any part thereof," etc.

The attention of the trade having been called to this Bill by Mr. FARMER, Mr. BAXTER and Mr. G. W. SMITH, a meeting was held on the 10th February, 1841, to devise means of opposing the measure, and a circular was issued inviting attendance at a public meeting of the trade at the Crown and Anchor Tavern. At that meeting, held under the presidency of Mr. GIFFORD, an influential committee was appointed and empowered to oppose the Bill, and through its efforts the Bill was shortly afterwards withdrawn.

On the 8th of March following the Committee met again to consider the draft of a modified Bill introduced by Mr. HAWES, in which the clauses affecting chemists and druggists had been expunged, but some parts of this Bill were considered indirectly prejudicial, and a petition against it was therefore prepared for presentation to Parliament, and when the Bill came before the House it was opposed also by the College of Physicians, and the House was counted out.

The desirability of establishing a permanent association of chemists and druggists was rendered very apparent at this time, and it became evident that nothing short of this could secure the trade against the inconveniences and annoyance experienced during the past half century. Mainly through the instrumentality of the late JACOB BELL, the opportunity thus offered was turned to account, and the result was that the Pharmaceutical Society of Great Britain was formed on the 15th April, at a public meeting of members of the trade, held at the Crown and Anchor Tavern, and presided over by Mr. R. H. PIGEON.

In the month of November following a meeting of the subscribers to the fund raised in 1814-15, was held at the same place with Mr. GIFFORD in the chair, when it was resolved—

"That the original object of this fund being the protection and advancement of the interest of Chemists and Druggists, this meeting of subscribers, convened by circulars and also by public advertisement, desires to recognize in the establishment of the Pharmaceutical Society of Great Britain a permanent and legitimate means of accomplishing such object; namely, by a general union and organization for the protection of present privileges and the education and improvement of the future members of the trade. They, the said subscribers, do hereby authorize and instruct their sole surviving trustee, WILLIAM ALLEN, Esq., Plough Court, to transfer to the Council of the said Pharmaceutical Society of Great Britain, the whole of the funds he now holds in trust, to be used and appropriated by them, in such manner as shall be deemed best calculated to advance their noble and useful design."

The sum thus transferred had been accumulating during the past twenty-five years, and it then amounted to £862 18*s.* 2*d.* As stated by JACOB BELL in his 'Historical Sketch of the Progress of Pharmacy in Great Britain,' this transfer connected the new association of chemists and druggists with that which had been for some time in a dormant state and had originated from circumstances similar to those which led to the formation of the Pharmaceutical Society. He also added that "although the "objects of the two associations were the same, the "manner in which it was proposed to attain these "objects was in some respects different. On the "former occasion the proceedings of the trade were "directed to a defensive resistance of threatened "encroachments and contemplated merely the pre- "servation of accustomed rights and privileges by "legal means and parliamentary influence. In the "establishment of the Pharmaceutical Society a more "extended view of the subject was taken, and the "more immediate source of alarm having been suc- "cessfully combated, the extension of pharmaceu- "tical knowledge, and the further improvements in "the qualifications of the trade individually and "collectively became the basis of the defence which "was to be set up against future innovations or "restraint."

CHEMISTS' ASSISTANTS' ASSOCIATION.

THE next meeting of the above Association will be held at 32A, George Street, Hanover Square, on December 18, at 8.30 p.m., when Mr. R. SOWDEN will read a paper entitled "Hints on Plaster-spreading."

THE YEAR-BOOK OF PHARMACY.

WE have received an early copy of the Year-Book for 1878, and are informed that copies will be delivered to the members of the Conference who have paid their subscription, as quickly as they can be bound.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

Evening Meeting.

The second meeting of the present session was held on Wednesday evening, 27th November. Mr. J. B. Stephenson in the chair. The minutes of the previous meeting were read and confirmed.

Donations to the Library and Museum were announced as follows :

To the Library.—'Fleurs, Fruits et Feuillages choisis de la Flore et de la Pomone de l'Ile de Java ; peints d'après nature, par Madame Berthi Hoola Van Nooten; 'Japanese Botany' (native), in 20 volumes, from Robert Jamie, Esq., Singapore, per Mr. H. C. Baildon.

To the Museum.—A specimen of a species of Menispermaceæ, from Mr. E. Coates, Edinburgh.

With regard to Mr. Jamie's beautiful presentation, which was presented by Mr. Baildon, jun., in the absence of Mr. H. C. Baildon, it was proposed and agreed to send him a special vote of thanks for his uniform kindness to the North British Branch of the Society.

Mr. John Mackay read a paper entitled "Some Remarks on Homburg, its Neighbourhood and Mineral Waters." Specimens of the waters of the various springs were exhibited. This paper will be printed in an early number.

Mr. William Gilmour afterwards read some notes on the following preparations :—(*a*) On the presence of Saffron in Compound Aromatic Chalk Powder ; (*b*) On Cod Liver Oil Emulsion ; (*c*) On the amount of Quinine in Easton's Syrup ; (*d*) On the action of Perchloride of Iron on Vinegar.

We hope to be enabled to print these notes in a future number.

Considerable discussion followed the reading of Mr. Gilmour's notes, that on "Cod Liver Oil Emulsion," especially being rather animated.

Votes of thanks to Mr. Mackay and Mr. Gilmour were most cordially responded to.

The meeting was unusually well attended.

Provincial Transactions.

PHARMACEUTICAL SOCIETY OF IRELAND.

Meeting of the Council.

Wednesday, December 4, 1878.

Present—Charles R. C. Tichborne, LL.D., Ph.D., President ; Dr. Collins, Messrs. Allen, Bennett (Kingstown), Boileau, Hayes, Holmes, Oldham, Payne (Belfast), Pring (Belfast), and Simpson.

The minutes of the meeting of Council held on November 6, were read and signed.

Read a letter from Mr. George W. O'Ryan, of Ball's Bridge, requesting to be allowed to present himself for both the Preliminary and Final examinations in January 1879, without waiting for a year as required by the regulations. Mr. O'Ryan stated that he had been engaged at practical pharmacy for the last twelve years, and passed the preliminary examination of the Apothecaries' Hall in 1874.

Some of the Council having expressed themselves in favour of granting this application, it was urged by others that it could not be done without repealing the bye-law requiring a year's interval between the two examinations, which had received the sanction of the Privy Council.

The Registrar was directed to inform Mr. O'Ryan that the Council regret that under the bye-law his memorial cannot be granted.

Read a letter from Mr. William Bannister (of the firm of Messrs. W. and H. M. Goulding, of Cork), requesting to be registered as a chemist and druggist in business before the passing of the Irish Pharmacy Act.

The Registrar was instructed to inform him that the Society has not, at present, any registration for chemists and druggists.

Read a letter from Mr. Andrew McNaught, pharmaceutical chemist, of Belfast, informing the Council of an unqualified person in Belfast, who, he stated, compounded prescriptions and sold poisons.

The Registrar was directed to thank him for the information contained in his letter, and to state that the Council are at present considering the subject.

The Registrar was also instructed to inform Mr. McNaught that the Council have had brought before them the fact that he has been using the title of *Member* of the Pharmaceutical Society of Ireland in connection with his name ; and that the use of the said title by non-members is illegal. (See clause 6 of the Pharmacy Act, Ireland, 1875.)

In the absence of Mr. Brunker, who had given notice for the appointment of a committee to investigate charges of infringement of the Pharmacy Act, it was—

Proposed by Mr. Hayes, seconded by Mr. Holmes, and resolved : "That the following be appointed a Law Committee, to consider all cases of reported infringement of the Irish Pharmacy Act ; and to advise as to what cases appear to call for action of the Council. The committee to be elected annually. The first committee to be Dr. Collins, Messrs. Payne, Oldham and Brunker, and the mover and seconder of the resolution."

The Journal Committee presented their report as follows :—

"Your committee recommend that members of the Pharmaceutical Society of Ireland who have paid their subscriptions be supplied with copies of either the *Pharmaceutical Journal*, or the *Chemist and Druggist*, gratis, from January 1, 1879."

The adoption of the report was moved by Mr. Holmes, seconded by Mr. Hayes, and carried.

The President undertook to communicate with the proprietors of the two journals mentioned, with the view of carrying out the arrangement if agreeable to those gentlemen.

Mr. George Ferguson, pharmaceutical chemist, of 1, Adelaide Place, Dublin, was proposed as a candidate for membership by Mr. Holmes, and seconded by Mr. Oldham.

The next quarterly examination for the licence to act as pharmaceutical chemists was ordered to be held on Thursday, January 2, 1879, at noon, instead of on New Year's Day, on which it would have fallen. The change of date to be advertised by the Registrar.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second meeting for this session of the assistants' section was held in Anderson's College, on Wednesday evening, November 27. Mr. R. A. Taylor, President of the section, occupied the chair, and read the paper of the evening, choosing for his subject "Ammonia." After describing the origin of the name, also the sources and modes of production, he pointed out the value of this compound to the chemist as a reagent in analysis, and also the important part it plays in pharmacy and in medicine. He also commented on a few of the preparations of ammonia in the Pharmacopœia.

A discussion followed the reading of the paper, after which a vote of thanks having been awarded to Mr. Taylor, and some other business gone through, the meeting broke up.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The classes of the above society were discontinued last year on account of the few members preparing for

examination ; but this year a sufficient number having joined to allow classes to be conducted on chemistry, materia medica and pharmacy, the former has been undertaken by the President, Mr. G. C. Druce, the latter by Mr. Holgate. Up to the present time they have been well attended, and a great interest seems to be felt in the Botany will be practically studied during various subjects. the spring months.

The balance in hand is about £5, after the purchase of some books, binding of Journals, and payment of gas and coal.

BLACKBURN CHEMISTS AND DRUGGISTS' ASSOCIATION.

On November 12, the annual meeting of the Association was held in the rooms, Exchange Street, Mr. W. Farnworth, President, in the chair.

A statement of accounts for the year was furnished by the Honorary Secretary and Treasurer, Mr. Garland, showing an expenditure of £18 10*s.* 11*d.*, and a balance in hand of £1 16*s.* 9*d.* At the commencement of the session, 1877, there was a balance in hand of £6 13*s.* 2*d.*, and £11 2*s.* had been received from 14 members and 15 associates ; two donations of one guinea each from Messrs. Wyleys and Co. and Mr. J. F. Wilkinson, and half a guinea from Mr. Gibson as honorary member. The entries of the books taken from the library numbered 300.

After passing the accounts, votes of thanks were given to Mr. Farnworth for his services as President, and to Mr. Garland as Secretary, both of whom were invited to hold the office for the ensuing year. A vote of thanks was also passed for his services as Assisant Secretary, to Mr. Giffard, who being likely to leave the town shortly, wished to retire, and his office was undertaken by Mr. Jowitt.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

On Friday November 29, a Lecture was delivered before the members of the above Association, at the Great Western Hotel, Birmingham, by Horace Swete, M.D., F.C.S., analyst for the county of Worcester, Radnor, etc., on "The Drinking Water of Rural Districts and the Recent Legislation thereon". The President, Mr. W. Southall took the chair and there was a good attendance. The lecturer began by showing what a large proportion of zymotic disease was traceable to impure water, and pointed out the powerlessness of the present laws to compel landlords in rural districts to supply wholesome water to their tenants. The new law (which comes into operation next March), he explained, enables the sanitary authorities to close polluted wells, and to compel landlords to provide good water, and as a further safeguard empowers the Medical Officer of Health to institute periodical examination of water supplies. Dr. Swete then proceeded to cite a number of singular and interesting instances of pollution of water which had come under his observation, dwelling upon the desirability of knowing the source and surroundings of suspected waters before pronouncing an opinion as to their fitness for drinking. The lecturer then explained how dangerous is the popular idea, that a water which is bright and sparkling is always pure, instancing many cases from his own experience of the origin of fever and other disorders from drinking water apparently bright and pure. The processes of Frankland and of Wanklyn for examining potable waters were next reviewed, and the lecturer considered that although the latter process was in some respects inferior to the former, yet for sanitary purposes it possessed the advantages of being less expensive and of occupying much less time. Dr. Swete concluded by giving some valuable hints, the result of his experience in the practical working of Wanklyn's process.

After some remarks from the Chairman, a hearty vote of thanks was accorded to Dr. Swete for his interesting and highly instructive lecture.

A vote of thanks to the Chairman terminated the proceedings. This was the first of a series of lectures to be delivered during the winter session.

MEETING OF CHEMISTS AND DRUGGISTS IN LIVERPOOL.

A general meeting of the chemists and druggists of Liverpool, Birkenhead, and neighbourhood was held at the Royal Institution on Tuesday, the 10th inst. Mr. Redford, President of the Registered Chemists' Association, occupied the chair, and in opening the meeting stated that the meeting had been called together by the Executive of that Association to consider their position as chemists in relation to the adverse movements of the Apothecaries' Company. This was not the first time chemists had been called to defend their rights. There could be no doubt that the object of the promoters of the action of the Apothecaries Company *versus* Shepperley was and is the curtailment of their liberties in the free exercise of their business. Chemists and druggists claimed now no more than they have ever done within the memory of the oldest man living, freedom to recommend remedies when applied to by their customers in their shops, in the exercise of a discretion, which he maintained had been for the most part a wise one. The attempt now to impose rigid restrictions upon them when their qualification had been raised, and was still being raised, and when their law-abiding feelings and intentions were freely acknowledged, he characterized as a most ungenerous return for their uniform endeavours to further the ends and assist the members of the medical profession, and unworthy of the noble men who form the great bulk of that body. He was sure such men could not sympathize with this prosecution. The public had need of these services from chemists and druggists, but chemists and druggists ought to exercise their rights wisely, and cultivate by uniform courtesy and respect for the moral rights of the profession that mutual trust and goodwill which would be their best defence. Chemists did not wish to add by undertaking the treatment of disease so anxious a care to their already overburdened minds. It would be a public misfortune, however, intolerable of sufferance, should they be debarred by a rigid construction of any existing law, or the imposition of any further enactment, from the freeand full right to carry on their business as by custom or legal right they had done in the past. He urged that moral and material support should be given to the Trade Association of Great Britain in defending the action Apothecaries' Company *v.* Shepperley to the utmost. He stated that the Committee of the Registered Chemists' Association at their last meeting, feeling the importance of the crisis had voted £30 to the Defence Fund. After alluding to the refusal of the judges to grant a new trial, the Chairman called upon

Dr. Symes, who, after describing the manner in which the chemists of 1815 were assured that the Act then sought by the apothecaries was in no way aimed at them, and corroborating points in the chairman's address, moved, "That this meeting repudiates any attempt to encourage or sanction encroachment by chemists on the legitimate province of medical men, but it recognizes the justice of the late verdict in the Shepperley case, and regards with great satisfaction the earnest manner in which the Chemists and Druggists' Trade Association of Great Britain has withstood the attempt of the Apothecaries' Company to enforce oppressive measures for depriving the members of our fraternity of the legitimate rights and privileges which are enjoyed by every subject of this realm, namely, of exercising judgment in the conduct of business. It desires to render both moral and pecuniary aid to the said Trade Association in furtherance of its efforts in trade interests, for which object it now subscribes."

The motion was seconded by Mr. R. Parkinson.

Mr. Ball supported the motion, and referred to the fact that young men from chemists' shops, going into the service of medical men, were employed to see and treat patients by those who charged chemists with ignorance and incompetence. He urged that the Apothecaries Act had become a dead letter by lapse of time, and that it was never intended to bear the construction now attempted to be put upon it.

Mr. Fingland believed the press and the public were with the chemists and druggists, and that they would not submit to the apothecaries' reading of the law.

Mr. Abraham was desirous that chemists should not have the appearance of being law-breakers, and believed that it would have been distinctly expressed had the Apothecaries Act been intended to suppress the existing custom of chemists. He desired a clear declaration of the law, something more than the personal question of Shepperley's innocence. He supported the resolution.

Messrs. Turner, Woodcock, Shaw and Sumner also supported it.

Dr. Symes replied, in answer to some expression to the contrary, that Shepperley's case was a thoroughly representative one, and that the judges had distinctly expressed themselves as regarding it as a test case.

Mr. Wright reminded the meeting that other cases were waiting for the guidance of this decision.

The motion was unanimously adopted.

A subscription list was then opened, and £60, in addition to the £30 previously mentioned, was entered.

The attendance at the meeting was adversely affected by an erroneous impression, very generally entertained, that the refusal to grant a new trial was an end of the case and a final defeat of the Apothecaries' Company. A letter from Mr. W. F. Haydon explained that the appeal now pending is in no way affected by this refusal.

Votes of thanks to Mr. Redford for presiding and to Messrs. Symes and B. Dickins, the Hon. Secretary, for organizing the meeting concluded the proceedings, Mr. Shaw, on behalf of the Executive Committee of the Trade Association, supporting the vote.

MEETING OF THE CHEMISTS AND DRUGGISTS OF ROCHDALE, BURY, AND DISTRICT.

The chemists and druggists residing within the above area met on Tuesday afternoon, November 25, in the Mayor's reception room, in the Town Hall, Rochdale, for the purpose of reviving the energies and extending the area of an existing association at Rochdale. A numerous meeting was presided over by Mr. W. A. Scott, who has been the president of the Rochdale Chemists' Association, and who introduced the business by a brief reference to the history of the society which had called that meeting, and had thus taken means to extend the area of its operations with a view to increased usefulness.

A resolution was then unanimously adopted to form a society to be designated the Rochdale, Bury, and District Chemists and Druggists' Association. A code of rules was then submitted to the meeting, which after careful consideration and slight modification, was unanimously adopted. Officers having been elected for the ensuing year, for that part of the organization existing at Rochdale, it was resolved that the members residing in each town included in the district should appoint their own officers, a proceeding which was thought to conduce to a more truly representative selection.

The business having been concluded, the company adjourned to the refreshment room, where an excellent and substantial tea was served in a very tasteful manner, when a deputation from the Manchester Chemists' Association, consisting of Messrs. Woolley, Benger and Payne, joined the assembled guests.

The cloth having been removed, Mr. R. Robinson, the President, took the chair and delivered the following address:—

I will not detain you long by any remarks of my own, as there are many gentlemen here who are better qualified to address you than I am, but I should like to say a few words on the case which is now occupying the attention both of the chemists and medical men. I mean the case of the Apothecaries' Society *v.* Shepperley. Never since the passing of the Apothecaries Act, in 1815, has any event occurred which has threatened the interests of the chemists and druggists to the extent that this does. You will remember the Apothecaries' Society sued Mr. Shepperley in the Nottingham County Court for two penalties of £20 each for acting as an apothecary contrary to the Act, and a verdict was given in favour of the Apothecaries' Society, on the understanding that it would be taken to a superior court. The case having now been fully gone into before Baron Pollock and a special jury, as a test case, the chemists were fortunate enough to score a victory. I have been connected with the Pharmaceutical Society for many years, and have always had a high opinion of its usefulness in protecting and advaning the interests of the trade, but when I see its organ, the *Pharmaceutical Journal*, minimizing as much as possible the good effect of this decision, I cannot but feel that it does not express the opinions of the great body of chemists throughout the country. It was well for Mr. Shepperley and chemists in general that there was such an organization as the Chemists and Druggists' Trade Association of Great Britain, not only ready but anxious to protect the interests of its members and the trade generally, or in all probability Mr. Shepperley would have been condemned to pay the penalties and costs. This case would only have been the beginning of a series of prosecutions, and every chemist in the country would have to carry on his business in a continual fear, which would be unbearable. Not only are our best thanks due to the Chemists and Druggists' Association, but I think it merits our liberal support, and I trust that this meeting will not separate without emphatically expressing their approval of its conduct. Whilst we are prepared to assert our rights and maintain them, yet few, if any, of us have any desire to usurp the functions of the medical profession. But it must be borne in mind that the State now compels all chemists and druggists to qualify themselves as dispensers by much study and at considerable expense. The misfortune is that dispensers are many, but prescriptions few. In an article which appeared in the *Lancet* it was said that "the handing over the dispensing to the druggist is a consummation devoutly to be wished, in the interest alike of the druggist, the practitioner, and the public." Should the verdict of the special jury be maintained in the higher court, then I think it will be a good opportunity for pressing upon the members of the medical profession the advantages that would accrue to the practitioner, the chemist, and the public by the dispensing being left in the hands of the chemist. After a medical man has gone a round of visits he must on returning home find the making up of medicine very irksome. Then there is the probability of being called away to an urgent case, perhaps for hours, and his other patients being kept waiting for their medicine, and sometimes not getting it at all that day. We all know that dispensing, to be properly done, requires the constant supervision of one who has had much experience, that kind of supervision which a medical man cannot give whilst visiting or consulting with his patients. Naturally a fixed charge for advice and medicine does not offer much inducement for the use of expensive remedies. If medical men did not dispense their own prescriptions they would never hesitate on the score of extra trouble or extra expense to order the most suitable remedy. The medicine might in some cases cost the patient a little more, but he would most probably be a great gainer by being the sooner convalescent. When the public understand this, the way for the change will be greatly smoothed. If the doctor had no medicine

to find he could well afford to reduce his fees, and, I think, be no loser by the change, and if the chemist had more dispensing he could afford to moderate his charge also. I must not conclude without touching upon what has been put forward as the great bar to surgeons giving up dispensing, namely, counter prescribing by chemists. The medical profession, I am sure, can never expect a hard and fast line to drawn on this point. People will never submit to be dictated to on this matter, and be compelled to call in a medical man before they can administer a worm powder to a child or take a simple tonic themselves when they think they require one. A measure like this would only drive them into the hands of the herbalist and quack. The more prescriptions chemists have to dispense the less work or time they will have for prescribing. Possibly there will always be chemists who would encourage counter prescribing, just as there would be also doctors who would dispense their own medicines. Time will not permit me to say more on the present occasion, but I think that if surgeons and chemists could be brought together to discuss the subject they would arrive at conclusions satisfactory to themselves as well as their patients. I know from personal intercourse with several medical men that they are not altogether indisposed to hand over their dispensing to the druggist, and I hope to see the day when we chemists shall be the only dispensers of doctors' prescriptions.

Mr. Alderman Taylor then made some pleasant remarks, in the course of which he affirmed the impossibility of preventing druggists prescribing in simple cases. The opinion of the druggist was often solicited by the public on the action of either one medicine or another, and sometimes by medical men.

Mr. Woolley spoke of the need of organization as being greater than at any former period, and this as much in the interests of the public as of druggists. Questions were now raised and interests menaced that had not been so violently attacked before. Speaking on the subject of patent medicines, he strongly urged that a system so much open to abuse should be discouraged. Poisons could be sold by persons holding a medicine licence who were utterly ignorant of the properties of drugs, if only they were made up in the form of a so-called patent medicine. As an illustration of the extent of the mischief, he knew that the proprietor of one of these nostrums to be administered to infants, had bought no less than one thousand ounces of morphia in one line. Besides this, outsiders were retailing these medicines at cost price.

Mr. W. A. Scott made some strong strictures on the ignorance of medical men on the subject of materia medica. This, however, was understood to refer to a generation that was passing away. But a class of men who dispensed their own medicines were not usually distinguished for the variety of their medical stores.

Mr. Benger spoke on the subject of education, and, referring to the Manchester School of Pharmacy, said that young men could have a complete course of instruction, which was a considerable aid in fitting them for their duties as dispensers of medicine. He also spoke in high terms of the work of the Pharmaceutical Society in founding a school which provided an education in accordance with the requirements of the State.

Mr. Smith, of Radcliffe, remarked upon the great hardship to the poor in country districts, if in simple cases chemists were forbidden to prescribe. Many were too poor to call in a regular medical practitioner, and the office of the union was often at a great distance from their own houses, and that, again, a great distance from the medical officer, and, after all, sometimes they had to go and purchase a bottle before they could be supplied with their medicines, thus causing great delay in obtaining relief, which if it could be had promptly might end less seriously than was often the case.

Mr. Mercer thought it was the duty of the Pharmaceutical Society to support the action of the Chemists and Druggists' Trade Association of Great Britain in their defence of the rights of chemists and druggists as secured to them by the Apothecaries Act of 1815.

Mr. Payne, of Manchester, said he wished there had been some medical men present to hear the address of the President, with which he cordially agreed. A little friendly discussion might tend to remove such obstacles as might (in the view of medical men) appear to stand in the way of accomplishing the desirable change of leaving the work of prescribing to medical men, and that of dispensing to chemists. He further addressed himself to young men who had a future to make, and upon whom he called to do their duty, taking as their motto the word "Thorough."

A cordial vote of thanks was tendered to Messrs. Woolley, Benger and Payne for their attendance, coupled with an expression of regret that Mr. W. S. Brown had not been able, owing to the state of his health, to form one of the deputation.

The following resolution was unanimously and enthusiastically adopted:—"That we approve the action of the Chemists and Druggists' Trade Association of Great Britain in the case of the Society of Apothecaries *v.* Shepperley, and hereby tender our sympathy, and resolve to give it our support.

Mr. Benger then exhibited and explained the telephone and microphone, after which a vote of thanks to the President terminated the proceedings.

MEETING OF CHEMISTS AND DRUGGISTS IN SHREWSBURY.

A meeting of pharmaceutical chemists and chemists and druggists was held at the Lion Hotel, Shrewsbury, on Tuesday, December 3, 1878. Present—Mr. Alderman Cross in the chair, and Messrs. Gouldbourne, Goucher, Hickin, Payne, Pyefinch, Salter and W. G. Cross, jun.

It was proposed by Mr. Goucher, seconded by Mr. Hickin, and unanimously resolved:—"That this meeting cordially approves of the action taken by the Chemists and Druggists' Trade Association, in defending the legitimate right of chemists to prescribe for simple cases over their own counters. It is furthermore of opinion that it is desirable to use every means to maintain the satisfactory verdict recently obtained in the Exchequer Division of the High Court of Justice, in the case of 'The Apothecaries' Company *v.* Shepperley,' to a final appeal before the House of Lords if necessary. And should the result of the aforesaid litigation prove unsatisfactory, it considers that a strong attempt should be made early in the next parliamentary session to induce legislation favourable to the repeal of the 20th section of the Apothecaries Act, 1815."

A subscription was afterwards opened for the benefit of the Chemists and Druggists' Trade Association, which was subscribed to by all the members of the trade residing in Shrewsbury, and amounted to £9 11*s.* 6*d.*

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Friday, December 6, at 8.30 p.m. when Mr. C. H. Hutchinson occupied the chair.

The minutes of the last meeting were read and confirmed.

Mr. R. H. Parker then read a paper on "The Manufacture of Iron." Having given a brief historical sketch of the progressive improvements in the extraction of the metal from its ores, he noticed the principal ores used and their respective composition, red and brown hæmatite, magnetic ore, and carbonate being especially alluded to

After this followed a detailed description of the ordinary blast furnace, used in the reduction of the ore, the working arrangements of the same, together with the chemical and physical changes occurring during the operation. Special attention was directed in this description to the working of the hot-blast, and the arrangements in use for carrying off the waste gases of the furnace. The commercial varieties of iron, cast iron, wrought iron and steel, were next described, and the influence exerted by the presence in them of various elements discussed. The paper concluded with an interesting account of the process of puddling, this and the other parts of the manufacture being fully illustrated with diagrams. Specimens of iron ore and the common varieties of iron were also exhibited.

In the discussion that followed, Messrs. Hutchinson, Atkins, Naylor, Branson, Arnold, Mawson and Robinson took part, and a unanimous vote of thanks was accorded to Mr. Parker for his interesting and exhaustive paper.

In consequence of the lateness of the hour, the discussion on the amount of knowledge required in pharmacy, announced to take place was again postponed, and it was decided that a special meeting should be arranged, in order that the subject might receive the attention its importance deserved. The meeting then adjourned.

CHEMICAL SOCIETY.

A meeting of this Society was held on December 5th, Dr. Gladstone, President, in the chair.

After the announcement of visitors, reading of minutes, etc., the following certificates were read for the first time:—Messrs. F. R. Japp, J. J. Broadbent, W. Stevenson, E. A. Letts.

During the meeting the following gentlemen were duly elected Fellows of the Society:—Messrs. E. Waller, Shigetake Siguira, H. F. Cheshire, J. Treharne, H. J. H. Fenton, H. Green, J. Collins, W. J. Noble, D. McAlpine, A. E. Drinkwater, L. Green, Kingo Takemura, G. W. Hatter, P. H. Walsh, J. J. Watts, H. Eccles, E. W. Napper and A. C. Arnold.

The President then called on C. Meymott Tidy, M.B., to read his paper on—

The Processes for Determining the Organic Purity of Potable Waters.—The determination of the organic matter in potable waters, both as regards its quantity and its quality, has been a subject of late years productive of much discussion, of much difference of opinion, and of much warmth of feeling. The author wished to lead and urge the discussion in a strictly scientific groove, unfettered and unimpelled by that warmth of feeling which has in this, as in many other questions, more often retarded than helped the attainment of that scientific accuracy to which we hope and desire that all our work and all our discussions should tend. The author trusts that nothing he may say will be regarded in any other light than a desire to discuss fairly the position of water analysis and the value to be attached to the various processes employed by water analysts. The processes for estimating the organic matter in water, naturally, divide themselves under two great heads: (1) Where the organic matter is estimated from a water residue; (2) Where it is estimated in the original water, *i.e.*, from the water itself, and not from the residue after evaporation. It is here to be remarked that if it be possible by any process or processes to estimate the organic matter in the original water such process must have manifest advantages over those where the quantity of organic matter is deduced from a residue.

The author then proceeds to discuss the processes which come under the first head, "The Ignition Process,"—the first in respect of date, the last in respect of value. This process, to be of value, presupposes three things: (1) That no organic matter is lost and none gained during the evaporation of the water; in this point the process fails, because there may be, both a loss of the actual organic matter present in the water during evaporation, such loss being either physical, particles being carried off mechanically with the steam, or chemical from decomposition, and a gain resulting from the introduction of extraneous organic matter in the shape of impurities floating in the laboratory atmosphere; (2) that all the organic matter is burnt off by the ignition of the residue; and (3) that nothing but organic matter is lost by ignition. With regard to both these points the ignition process also fails. The author gives details of some experiments which he made some years ago, in which he gives analyses of four waters where the loss on incineration was very great, although they were as nearly as possible free from organic impurity. The author notes that the process is not quite abandoned, else there would be no need to refer to it; some analyses having been, not long ago, put in evidence where the loss on incineration was entirely relied on as the indication of organic purity or impurity. He finally refers to some cases where he thinks the loss on ignition may be of value, as, for example, in cases of sewage, and also the value to be attached to the smell evolved during the burning.

The author then considers "The Combustion Process" of Drs. Frankland and Armstrong. The objections to this process are twofold: (1) general and (2) special. The general objections are its impracticability, arising from the manipulative skill required, and the length of time consumed in conducting the process. These two latter objections may seem to have some weight at first sight, but very little on further consideration. It is admitted that a certain amount of manipulative skill is required, but the possession by practice of this manipulative skill constitutes a man an analytical chemist, *and the sooner so delicate and difficult a work as water analysis is taken out of the hands of those who imagine themselves professional chemists after a few lessons in a laboratory, the better for chemistry and sanitary science.*

As regards the time required, the author considers that rapidity ought not to enter into the calculations if accuracy or delicacy be thereby imperilled. This objection of impracticability is therefore worthless.

The question of evaporation is then reviewed, including the ingenious devices of Professor Bischof and Dr. Mills. Until we have definite evidence, says the author, that no organic matter is oxidized and also that no organic matter is volatilized or destroyed by the heat required in evaporation, it follows that evaporation must always constitute a possible source of error in any process where the determination is made on the residue. Indeed we cannot resist the conclusion being forced upon us that after all our trouble we may be simply estimating the harmless organic matter, that which was poisonous and disease-producing having been carefully got rid of by our previous work. The next difficulty, the addition of the solution of sulphurous acid, is an important one. From a careful series of observations, the author concludes that if the nitrogen present as nitrates does not exceed 1 part in 100,000, or 3·15 grm. of nitric acid per gallon, the reduction of the nitrates is complete on boiling with 10 or 20 c.c. of the sulphurous acid solution. If, however, the quantity present amounts to 1·5 per 100,000, some difficulty is experienced in effecting complete reduction even when 60 c.c. of sulphurous acid solution are used. The next step is the combustion of the residue; the author accepts without hesitation the determinations of organic carbon, and is quite satisfied as to the accuracy of the method, but at present does not attach the same value to the determinations of the organic nitrogen, and therefore he doubts how far we are justified in drawing conclusions as to the source of the organic matter, *i.e.*, whether it is vegetable or animal, from the proportion which exists between the organic carbon and nitrogen. However, the process has so much improved on acquaintance that the author believes it to be of great value.

The processes where the organic matter is estimated from the water before evaporation are two, the ammonia process and the oxygen process. "The Ammonia Process" consists of the comparative determination of the nitrogenous organic matter by the quantity of ammonia ("albumenoid ammonia") yielded by the destruction of the organic matter; this destruction is effected by boiling the water in the presence of potassic permanganate and a large excess of caustic potash. Waters are divided by the authors of this process into three classes:—Waters of extraordinary organic purity, yielding 0·000 to 0·05 part per million of albumenoid ammonia; safe waters yielding 0·05 to 0·10, and dirty waters yielding more than 0·10. The objections made to the process by Dr. Frankland are, that the conversion of the nitrogen of the organic matter into ammonia is seldom or never complete and that the proportion of nitrogen converted into ammonia in a series of nitrogenized bodies varies widely. There is a certain force in these objections. If the organic matter of all water were alike it would be of no importance whether the whole or a definite part of the nitrogen was converted; but inasmuch as in all probability the organic matter of one water is not the organic matter of other waters, the circumstance that bodies yield their nitrogen as albumenoid ammonia in vastly different proportions, constitutes an objection of some importance. Nevertheless this objection can be overrated; if it can be shown that the ammonia process indicates clearly that the yield of albumenoid ammonia keeps pace with the purity or impurity of waters, and that it is sufficiently delicate to indicate the finer grades of purity, the fact that piperin yields all its nitrogen, whilst thein yields one-fourth is of little significance in water analysis, whatever interest such facts possess for the scientific chemist. It must be remembered that Mr. Wanklyn has repeatedly and distinctly condemned the course taken by certain chemists in regarding his process as a method for the quantitative determination of nitrogen, and asserts that his process only answers the question, Is this water wholesome or is it not? whilst it leaves untouched the question, How much organic nitrogen does this water contain? The author proceeds to notice some practical difficulties in the details of the process. It is practically impossible to prepare the alkaline solution of potassic permanganate absolutely free from ammonia, and it is always necessary to estimate the quantity of ammonia in the permanganate solution and deduct this from the total amount obtained in the actual experiment. It is a matter of extreme difficulty to effect the complete (*i.e.*, as complete as the alkaline permanganate solution is capable of effecting) decomposition of the organic matter by boiling the water with the permanganate solution. Thus, a water is distilled with permanganate until ammonia ceases to be evolved, and the apparatus then left carefully protected from contamination for a few hours. On redistilling, a second yield of ammonia often equal or even larger than the first is obtained, and so again and again and again fresh quantities of albumenoid ammonia may be obtained until every drop of water in the retort has been distilled over. This is a serious difficulty and has in one case at least led one analyst to report a water to be of "extraordinary organic purity," whilst a second classes the same water as a "dirty water" and entirely unfit to drink. Sometimes too, ammonia seems to disappear; thus, the permanganate solution is known to yield a certain quantity of ammonia on distillation; it is added to a water and the two distilled, when the distillate from the water, *plus* the permanganate contains less ammonia than the distillate from the permanganate alone. As regards Nesslerizing the author states that a serious error may creep in from the fact that eyes are very far from being equally sensitive in observing and in classifying tints, and that out of a large number of average men observed, 60 per cent. failed to arrange a series of Nessler test solutions in the proper order of their tints. The presence of free ammonia within certain limits the author regards as of little importance, and entitely disagrees with Mr. Wanklyn, when he regards the presence of more than 0·08 part of ammonia per million as evidence that that ammonia proceeds from the fermentation of urea. As a general conclusion from a wide experience, the author thinks that the ammonia process gives fairly concordant results when uniformly conducted, *i.e.*, given solutions made by the same person, the same hands to manipulate, the same eyes to judge of the tint depths; but this is almost a fatal objection to its general employment, for if the author's statements be true, in the ammonia process every man must be a law unto himself, whilst one man's law is no one else's law. Hence comparisons are rendered impossible. As a rule the albumenoid ammonia process enables one to say whether a water be of excellent quality or of an exceptionally bad quality, but in those more delicate and difficult cases where a water is not what may be termed excellent, but nevertheless is not "dirty," in the opinion of the author the ammonia process absolutely and entirely fails.

The next process considered by Professor Tidy is "The Oxygen Process." This process when properly carried out is much relied on by the author. He deprecates most strongly the ordinary method of using it. The proper plan of using the permanganate is the following:—

Into two twenty-ounce flasks, cleaned by rinsing with sulphuric acid and a thorough washing under the tap, place 500 septems (1 septem=7 grains=$\frac{1}{1000}$ gallon) of the water, add to each, 20 septems of dilute (1 in 3) sulphuric acid and 20 septems of the permanganate solution (2 grains in 1000 septems). Note the exact time at which the permanganate solution was added; at the same time two similar quantities of distilled water are to be treated in precisely the same manner. At the end of one hour and of three hours the oxygen used up by the water is to be determined. To the flasks after standing the appointed time add a sufficiency of potassic iodide (1 in 10) and then a standard solution of sodic-hyposulphite (5·4 grains in 1000 septems) until the whole of the free iodine is removed, judging of the exact points, by the addition towards the end of the experiment, of a few drops of starch solution. By deducting the quantity of oxygen equivalent to the hypo-solution used from that in the quantity of permanganate originally added the quantity of oxygen used by the water is obtained. The starch experiments with distilled water give the value of the hypo-solution. It is obvious the samples of water must have a pink tint at the end of the one hour or the three hours, otherwise fresh experiments must be made with larger doses of permanganate. The author then proceeds to consider the interference of various substances with the process. He concludes that the only important errors which can arise would be due to the presence of ferrous salts, sulphuretted hydrogen and nitrites. The presence of the first two substances would sure to be discovered in the analysis and by taste or smell. The nitrites act immediately on the permanganate solution and any decoloration taking place during the first five minutes must be due to nitrites and allowed for. Besides even if a careless manipulator were to miss the iron, the sulphuretted hydrogen and the nitrites, and estimate the whole as oxidizable organic matter, he would simply condemn a good water, but, could never by using the oxygen process, pass a bad water as harmless. It is admitted that permanganate fails to oxidize some substances, such as urea, but nevertheless, the quantity of oxygen used affords evidence of the relative quantity of matter in the water which is likely to be injurious, and this is what is wanted in water analysis as it enables operators to speak with confidence as to the use or rejection of a water for drinking purposes. The quantity of oxygen used during the first hour, as compared with that used in the first three hours, gives valuable information as to the relative quantities of putrescent easily oxidizable matter and of non-putrescent and less easily oxidizable matter. The author also recommends as a valuable accessory the tint of the water

as seen viewed through a 2 feet tube, 2 inches in diameter, daylight reflected from a white card being used, this tube is of special value in determining whether a water is peaty or not. In some cases the tint gives a clue to the quantity of organic matter present. The author in conclusion quotes Angus Smith's words as expressing his own view. "Nothing ever pretends to do in water analysis what the permanganate test does. Those who neglect it leave out the putrid matter or drive it off in boiling." A comparison drawn from a large body of results was then made between the ammonia process and the other two processes sometimes described as "processes of the past possessing merely historic interest." The author has collected and plotted out in curves the results obtained by Dr. Frankland, using the combustion process, and those obtained by Dr. Letheby and himself, using the oxygen process, and those obtained with the ammonia process, with the waters of the London companies since 1870: he finds that the curves of the oxygen and combustion processes are strikingly concordant, whilst that of the ammonia process agrees with neither. The author has also divided these results into classes, making as far as possible classes (with the three methods of estimating the organic matter) which should be comparable with each other. Thus class I. contains waters of great organic purity, which require less than 0·05 parts of oxygen per 100,000 to oxidize their organic matter, or which give less than 0·1 part per 100,000 of organic carbon and nitrogen, or which yield less than 0·05 parts per 1,000,000 of albumenoid ammonia. Compared in this way, out of 1686 experiments the oxygen and combustion processes tell the same tale in 1418 cases, and of the rest a large proportion have differences depending on the third decimal place. The results by the ammonia process correspond, save in a very general way, neither with those of the oxygen process nor with those obtained by the combustion process. The author has analysed moreover two hundred miscellaneous waters, using the three processes in each case; of these ninety-four were placed in the first class by the oxygen, and ninety-two by the combustion process, whilst only forty-two were placed in the first class by the ammonia process. It must be understood that the author deprecates most strongly the judging of a water by one constituent without reference to its complete analysis and natural history, and has only instituted these classes for the sake of comparing results. The paper comes to an end with fifteen conclusions, the substance of which has already been given in the above report, as to the relative value of the three processes. They may be briefly summed up as follows: *The ammonia process* furnishes results which are marked by singular inconstancy, and are not delicate enough to allow the recognition and classification of the finer grades of purity or impurity. The errors incidental to the process form an array of difficulties which become infinitely serious, seeing that the range (from 0·05 to 0·1 part per million) between pure and dirty waters is comparatively small. *The combustion process* has all the evils of evaporation to encounter, but the organic carbon estimation is trustworthy; the organic nitrogen determination, however, scarcely yields absolutely trustworthy evidence on which to found an opinion as to the probable source of the organic matter. *The oxygen process* avoids the errors incidental to evaporation; its results are constant and extremely delicate, it draws a sharp line between putrescent or probably pernicious and the nonputrescent or probably harmless organic matter; by it a bad water would never be passed as good. As far as the three processes are concerned, the oxygen and combustion processes give closely concordant results, whilst those yielded by the ammonia process are often at direct variance with both.

Professor Tidy occupied nearly two hours in giving an account of the above paper (which is over 100 pages) to a very full meeting of the Society. At its conclusion, after various suggestions had been made, it was moved by Mr. Riley, seconded by Mr. Neison and carried unanimously, that the discussion should be adjourned until after the paper had been printed, when a special meeting would be called for the purpose. It was understood that if possible the paper should be printed in the January number of the Society's journal.

The Society then adjourned to December 19, when the following papers will be read—1. Researches on the Action of the Copper-Zinc Couple on Organic Compounds, by Dr. Gladstone and Mr. Tribe; 2. On the Formula of Glyoxylic Acid, by Dr. Debus; 3. On the Action of Isobutyric Anhydride on the Aromatic Aldehydes, by Mr. Perkin; 4. On the Production of Oxides of Nitrogen by the Electric Arc in Air, by T. Wills; 5. On Baric-periodate, by S. Siguira and C. F. Cross; 6. The Action of Alkaline Hypobromite on Oxamide, Cyanides, Ferrocyanides, and Cyanates, by W. Foster; 7. On a new Hydrocarbon obtained by the Action of Sodium Hydrochloride, by Dr. Letts; 8. On Erbium and Yttrium, by Dr. Humpidge and Mr. Burney.

Parliamentary and Law Proceedings.

The Sale of Vermin Killer.

At the St. Austell Petty Sessions, December 3, Grenville S. Richards, of Trethosa, St. Stephen's, was charged with selling to police inspector Colenso, a packet of Battle's Vermin Killer, without having his name and address on the label; and he was charged in another summons with selling this poison without making an entry in a book to be kept for the purpose of entering the sale of dangerous poisons.

Mr. John Stephens appeared for the defendant, and pleaded guilty on behalf of his client, who, he said, had offended through ignorance of the law, and from a belief that he could sell the article under a licence which he had for selling patent medicines.

The chairman (Sir C. B. Graves Sawle) commented strongly on the case, and explained that Battle's Vermin Killer was a preparation of strychnine, a dangerous poison, and he wished the public to know that no one but a chemist was entitled to sell it, although he understood that some grocers were in the habit of doing so. This being the first case of the kind under the Act for the sale of poisons, the Bench dealt more leniently than they would otherwise have done, and fined the defendant 10*s.* and costs. It is understood to be the first case of the kind in the county.

Notes and Queries.

[536]. LINSEED MEAL.—In answer to the question of "Inquirer" (Crushed Linseed), we beg to say that the colour, light and dark, is the result of the mode of crushing. The light is produced by a process by which, although no oil is extracted, the natural colour is preserved, and the seed is not heated. The dark is made by passing the seed under edge runners, which, as the process is longer, and by the weight of the stones, turn the seed dark and show the oil. All linseed should be freed from impurities and foreign seeds before crushing.

PETER MUMFORD AND SON.

[541]. INJECTION BROU.—The information Mr. Henry Brown obtained at Leeds, concerning this specialty, is calculated to mislead, because *quack* remedies are contrary to law in France, and no preparation is permitted to be sold which is of a secret or occult nature. Had Mr. Brown read the label he would have seen the words "*zinco-saturnine selon la formule de l'Hôpital du Midi.*"

49, *Haymarket.* WILLIAM FOX.

[543]. GELATINE SUPPOSITORIES.—"Alpha" will find the following produce a firm and in every way satisfactory gelatine basis for suppositories and pessaries. Pour six ounces of distilled water over three ounces of gelatine, such as Bell's or Nelson's, in a water-bath, and let it stand until the gelatine has absorbed the water, then dissolve by heat, and add eight ounces of glycerine, continuing the heat for some time in order that as much water may be dispelled as possible. When cool it can be reliquefied and medicated as wanted. Previously grease the mould with an oiled camel-hair pencil.

London, E.C. G. B.

[543]. GELATINE SUPPOSITORIES.—"Alpha" will find this form a good one for making "gelatine suppositories." I have enclosed samples (three) which were made some time ago.—

THE COUNCIL REPORT.

Sir,—I must beg of you to correct a couple of misleading statements, which appear in the report of the meeting of Council, as given in this week's Journal, under my name. First, at the foot of page 471, the following sentences are attributed to me:—"He (Mr. Fairlie) did not think Mr. Bottle or any other member should feel aggrieved at what he had said, or decline to sit on the Committee with him. If Mr. Bottle declined to do so, he must decline to be put on the Committee, and in that case must decline to be a member of the Council of the Society." It is thus made to appear that I had made it *sine qua non* with Mr. Hampson, or some other members of the Council, that unless I was put upon the Pharmacy Act Amendment Committee I should retire from the Council. The position was not of my asking, as the following statement will show, and which I know will be confirmed by the gentleman named. Some weeks ago Mr. Hampson expressed to me his regret that my name had been overlooked in the appointment of this Committee, and said that he intended to propose me at next Council meeting. I suggested Mr. Frazer's name as being the other Scotch representative, and as he had some new views on the election of the Council in his mind, which might best be brought before the Committee by him; but I made no express desire that I should be put upon the Committee myself.

What I did say at the Council table, on Wednesday, was to the following effect:—"I shall not allow my name to be put forward in opposition to, or in substitution of Mr. Bottle's, if that gentleman persisted in taking up the position he had done. If Mr. Bottle continues to decline to sit on the Committee with me, I must decline to allow my name to be put forward, but I think if Mr. Bottle wishes to be logical he would require to carry his decision a little further, and decline to sit on the Council with me, and also cease membership of the Society so long as I remain connected with it; but I did not think I had said or done anything to warrant such a decision being come to by any member of of the Council."

Second, at page 477, I am reported as having said the following:—"Mr. Bottle seemed to think the matter still premature, but he (Mr. Fairlie) had undertaken to bring it forward because the application for assistance from the Trade Association had never been formally replied to." I made no such statement as this, and I was most assuredly not induced to bring forward a motion proposing to give a grant to the Trade Association "because the application for assistance had never been formally replied to." What I did say on this point was as follows:—"Mr. Bottle seemed to think the matter still premature; he (Mr. Fairlie) thought the matter has always been ripe for the consideration of the Council, if they had had a desire to do so. Mr. Bottle also said the Association did not apply for help (meaning, I presumed, that as Mr. Hampson's motion made no reference upon to the Trade Association it was not to be looked as an application from that quarter. He (Mr. Fairlie), partly in corroboration, and partly in correction of Mr. Bottle's statement) had to remind the Council that the one application made in June last by the Trade Association had never yet been formally replied to."

JAMES M. FAIRLIE.

Charing Cross Corner, Glasgow.
Dec. 9, 1878.

THE COUNCIL AND THE SHEPPERLEY CASE.

Sir,—My brother chemists, like myself, will receive very great benefit from reading the speeches of our present members of Council, and I hope they will make note of the contents thereof, in readiness for the next election, keeping strict account as to who were for and against Mr. Hampson's motion. It would seem the Council has no power (or will) to help to defend trade interests at all; indeed many of the members in their great wisdom seem to conclude their vocation is to oppose them at every opportunity. No doubt those gentlemen blessed with an exclusive dispensing business may consider it infamous to prescribe, and that those who do so should be visited with instant fines, prosecutions, etc., but I am perfectly certain chemists, as a general rule, will be far from agreeing with their amiable views.

I think these gentlemen should be called "I-am-afraid-to-offend-a-medical-man party," and should give handsome subscriptions to help the Apothecaries' Company to prosecute poor chemists who have not such a fortunate lot as to be exclusively dispensing chemists and yet are obliged to try and make a living for themselves and families.

Mr. Sandford seems to give us outsiders too much credit for wisdom, as I cannot understand what is a simple case of counter prescribing unless Mr. Shepperley's case is so, nor do I believe any other person can. Would he consider giving a child a powder for teething or a bottle of simple cough mixture for a cough a right case or not?

I do not believe chemists want prescribing cases at all; but as the medical men in many districts entirely dispense their medicines, and not only that, but get their drugs from wholesale men, we must live, and to live we must give advice as well as medicine. I should rather like to see the face of a customer who came into a chemist's shop and said he had a slight bilious attack, felt rather sick, etc., when the man behind the counter said, "Oh, I can't prescribe, but I have calomel, colocynth, blue pill, black draught, etc., etc., which will you have? The price is so much per ounce."

The case of Mr. Shepperley seems to me to be one we ought to defend to the utmost, and it is very hard to find so many of our fellow chemists in the Council who seem to wish to oppose it by every means. The only conclusion we outsiders can come to is that they are so jealous of the Chemists and Druggists' Association that they will not agree with it on any point. It was certainly very hard to see the *Pharmaceutical Journal* the only paper that seems to be dissatisfied with the verdict in Shepperley's case, although I am pleased to see time and consideration has caused our worthy editor to alter his first views.

I hope at the next election we shall be able to alter the present state of the Council, and at the meeting on January 9th we shall show that dispensing chemists must also con-

sider the welfare of those called retail chemists, who have hard work to make two ends meet in the present day.

J. W. FELTWELL.

[*** Before forming an opinion of the action of members of Council it is obviously desirable that what they say should be understood, and we think it is evident that Mr. Feltwell's objections, as well as opinions, rest mainly upon misunderstanding. Hitherto we have abstained from any remark as to the Shepperley case, but since it has now been so freely commented upon, there is no further need for reticence, and we would suggest for consideration some facts bearing on the general merits of the case. First, that two years ago this case was considered by the Council, and the decision was not to take it up; secondly, that notwithstanding the statement of the Solicitor to the Society of Apothecaries that he had not authorized any prosecution in a case of pure and simple counter practice, and that he should not do so, the prosecution of that case was authorized by the Society.

Unless there is reason to believe the action of either or both bodies is the opposite of their declared intentions, it should, we think, in fairness be inferred that there were sufficient reasons for the action of both, and in regard to this point it must be remembered that the Council in October, 1876, passed a resolution to defend any case of prosecution of a chemist and druggist for alleged infringement of the Apothecaries Act, if the circumstances warranted that course.

In regard to the case produced in court being regarded as a test case fitted for deciding the question as to the legality counter practice, we cannot conceive a greater fallacy, and of we understand that to be the clear purport of Mr. Sandford's remark that it did not seem to him a case which would decide what was wanted. The refusal of a rule for a new trial by the Lord Chief Baron was also based upon the view that "there was no sore throat at all" in Death's case, which was admittedly quite fictitious.

We cannot therefore understand why our correspondent considers the Shepperley case one that ought to have been defended in the general interest of the trade, or by what mental process he comes to regard the conclusion stated in his letter as the only one explanatory of the Council's decision not to undertake the defence of this case.

We regret that our correspondent seems unable to appreciate our reasons for regarding the case as unsatisfactory, so far as regards the decision of the question as to the right of the chemist and druggist to prescribe across the counter, and we must add that we think chemists and druggists have, in that respect, little reason to be satisfied, or that if they are so, it is an effect too easily produced.

That our views on the subject of counter practice have undergone any alteration is an opinion we cannot share with Mr. Feltwell, and though we regret depriving him of the pleasure he finds in that idea, we think he will not find on reference to previous articles any foundation for it.

We have received several other letters of the same tendency as the above, expressing somewhat abusive censure of the Council and making charges which have no real foundation. We doubt the utility of publishing such letters at all, and though we cannot resist the temptation to insert the one following, we certainly decline to do so with the others unless the names of the writers are to appear.—ED. PH. JOURN.]

APOTHECARIES' COMPANY *v.* SHEPPERLEY.

Sir,—It was with great regret that I read the decision of the Council concerning this case. The great bone of contention appears to me to be that as the Chemists' Association has taken up the case and if they can carry it through successfully, they will have the honour. Why did not the Council take it up at first? Are they not supposed to be formed for the purpose of promoting the interest of chemists? If so, they will never do so by standing idle. What are chemists to do, if they are exposed to the attacks of any person? Whom are they to look to for support. When the Council is afraid to defend them, for fear of being losers by it, if the law is not definite on the point, why do not they try to make it so? I am just commencing life in the business of chemistry, but if things continue as they are at present, the sooner I am out of it the better. The beginning of this year, I passed the Preliminary examination, and had as usual, an invitation to become a member of the Society. I waited until cash was a little more plentiful, and thought to join the beginning of next year, but now I think I can do better with my money elsewhere.

NEMO.

SHIP CAPTAINS AND PRESCRIBING.

Sir,—In reply to "Ictus Equi" I beg to say that vessels carrying ten men and upwards do have a medicine chest on board, and if the men are ill the "master" of the vessel prescribes and dispenses for them. The chest includes laudanum, extract of lead, soap liniment, Dover's powders, calomel and opium pills, and other powerful drugs, and when I have been fitting them up for new ships, I have often congratulated myself that the captain would not have the trouble of mixing a dose for me, some of these so-called captains not being, in my opinion, calculated to manipulate poisons so well as the humble class to which I belong.

PHARMACIST.

LOZENGES AND THE MEDICINE STAMP.

Sir,—I see in the last *Pharmaceutical Journal* a short letter from Mr. Stevens in reference to the fact of the retailer's name stamped on lozenges bringing them within the list of proprietary articles requiring a patent stamp. Surely the name or name and address on the lozenges would not bring them under the duty unless they are also stamped with the name of the complaint for which they are recommended, and even then I can hardly believe that the Inland Revenue would enforce their claim. I suppose the chemists are very far and few between who do not keep ready made some cough mixture, or syrup, or diarrhœa mixture, but I have never yet heard of any of them being ordered to affix a patent stamp to the bottles in which they send it out, although in nine cases out of ten the label contains full instructions as to dose, etc., in addition to the name and address of the vendor. It is rather an important question to many chemists, and perhaps you can give your readers an idea of what the Inland Revenue intend doing in the matter.

Oxford Street, W.

EDWARD H. STOREY.

A CORRECTION.

Sir,—In your report of the Pharmaceutical Meeting, December 4, 1878, p. 478 of the current number of the Journal, I am made to say "that resin oil might be distinguished from linseed oil by the fact that linseed oil was fluorescent." What I did say is the reverse; *resin* oil is fluorescent. Please make the necessary correction in your next number, and oblige.

LINIMENTUM TEREBINTHINÆ ACETICUM.

BY W. SYMONS, F.C.S.

In a short paper read at the Bristol meeting of the Pharmaceutical Conference in 1875, I suggested an improved method of preparing the above liniment, which attracted more attention than I anticipated. The object of the paper was not so much to give an exact formula in the place of that in the Pharmacopœia as to point out a way in which a perfectly clear and stable liniment may be prepared, instead of the very unsatisfactory one in the Pharmacopœia.

Having been desired to suggest a formula as near the Pharmacopœia liniment as possible for dispensing, my attention has again been called to the subject. The first proposed formula in my paper was—

No. 1.

Glacial Acetic Acid	1 part.
Spirit of Camphor	2 parts.
Castor Oil	1 part.
Turpentine	2 parts.

Mixed in the above order.

The second was—

No. 2.

Liniment of Camphor	2 parts.
Castor Oil	2 „
Turpentine	2 „
Glacial Acetic Acid	1 part.

The castor oil, however, in this formula is unnecessary, and a clear and stable liniment may be made as follows :—

No. 3.

Turpentine	3 parts.
Liniment of Camphor	3 „
Glacial Acetic Acid	1 part.

This may be said to be identical with the Pharmacopœia liniment, minus 2 parts of water, for as, according to the Pharmacopœia, glacial acetic acid contains 84 per cent. of anhydrous acetic acid, while the B.P. acetic acid contains 28 per cent., it is assumed to be near enough to the truth for the purpose of this paper to speak of B.P. acetic acid as containing 1 part glacial acid and 2 parts water. The Pharmacopœia liniment will thus contain 1 part in 9 of glacial acid, while No. 3 will contain 1 part in 7, although the proportion of glacial acid to the turpentine and camphor will be identical in each.

Should it be thought desirable to have in the liniment exactly the same proportion of acetic acid as in the Pharmacopœia, *i.e.*, in relation to the whole quantity of liniment, the formula would be—

No. 4.

Turpentine	4 parts.
Liniment of Camphor	4 „
Glacial Acetic Acid	1 part.

Should spirit be considered a desirable ingredient of the liniment, of course No. 1 may be adopted, but it will be perceived that the proportion of glacial acid in this formula is 1 in 6. If this be thought too much, the following may be a satisfactory formula :—

No. 5.

Glacial Acetic Acid	1 part.
Spirit of Camphor	3 parts.
Castor Oil	2 „
Turpentine	2 „

Mixed in the above order.

Of course it is a medical rather than a pharmaceutical question as to which of the above formulæ may be the best, but as it has been stated to me that it is not desirable to increase the proportion of acetic acid, I should say that No. 4 is the preferable one.

It may be well to say that the above linimients were made with glacial acetic acid from a respectable London house, labelled "solid at 50°," but which has actually crystallized at 52°, and the crystals have not completely dissolved in a day in a temperature of 58° to 62°, so that it is stronger than the Pharmacopœia acid, which "crystallizes when cooled to 34°, and remains crystalline until the temperature rises to above 48°." On mixing only 5 per cent. of acetic acid, B. P., with the above acid none of the above formulæ gave satisfactory results.

Probably it may be said that no simpler or more quickly applied test of the strength of glacial acetic acid has hitherto been suggested than the making of this liniment. With regard to the point of crystallization, and as an illustration of the apparent anomalies so fully discussed by Mr. Tomlinson in his paper on "Supersaturation," I have had the same glacial acetic acid in a similar bottle, exposed during a night to a temperature of 49° without crystallizing; but on dropping in a crystal it was at once converted into a solid mass.

Has not this subject also some bearing on the discussion as to the solubility of magnesium sulphate as contrary to Mr. Brown's experience? I do not find Howard's magnesium sulphate even remain in solution in its own weight of distilled water at 60°.

THE INCOMPATIBILITY OF BISMUTHI SUBNITRAS WITH THE ALKALINE BICARBONATES.

BY THOMAS GREEN'

Although this subject has, both recently and on a former occasion, attracted much attention and comment, it can scarcely be said that it has been satisfactorily settled, inasmuch as opinion seems divided as to whether the evolution of CO_2 from the alkaline bicarbonates is due to free acid in the bismuth subnitrate, or to the chemical action which the latter has on the former; the preponderance of opinion inclining to the former theory. Mr. Yeats, who, I believe, first drew attention to the subject, tested the bismuth he had used and finding it to be slightly acid, thought that might account for the explosion, but, however, added that the real cause was probably a decomposition between the two salts, and offered an equation representing such decomposition.

The following rough experiments seem to bear out the latter assumption, which also accords with the opinion of Squire, who gives as incompatibles of bismuth subnitrate the alkalies and alkaline carbonates.

Two drachms of bismuth subnitrate and the same of sodium bicarbonate were mixed with a small quantity of dislilled water, and the bottle containing them was corked and set aside. In a short time, perhaps ten minutes, effervescence commenced and in about an hour the cork was expelled from the bottle. The cork was replaced and the reaction allowed to go on until all effervescence had ceased. The mixture was then transferred to a small filter,

and the filtrate tested for HNO_3, which was found. The precipitate after being very well washed was also examined for HNO_3, but without success. It, however, effervesced briskly on the addition of dilute sulphuric acid, proving the presence of CO_2. Examined by a lens the precipitate had lost the crystalline structure of the subnitrate, corresponding now in appearance with the carbonate. This experiment was repeated, substituting sodium carbonate for the bicarbonate, with the following result: No effervescence whatever took place, but at the end of forty-eight hours the bismuth was examined and found to be entirely converted into the carbonate.

I need not add that the bismuth subnitrate was perfectly neutral in its action on litmus paper, as the latter experiment fully proves.

It would thus appear that independently of any free acid that may be present in subnitrate of bismuth owing to insufficient washing (1) that an admixture of this bismuth salt with the alkaline carbonates or bicarbonates results in mutual decomposition; (2) that when the carbonates are used decomposition without effervescence ensues; and (3) that when the bicarbonates are used decomposition with liberation of CO_2 takes place.

The following equations will render these propositions intelligible—

$$2BiONO_3 + Na_2CO_3 = Bi_2O_2CO_3 + 2NaNO_3.$$

$$2BiONO_3 + 2NaHCO_3 = Bi_2O_2CO_3 + 2NaNO_3 + H_2O + CO_2.$$

In dispensing such mixtures it is clearly the duty of the compounder to complete as far as possible the decomposition before sending out the mixture. This may be partially effected by rubbing the two salts in a mortar with a little hot distilled water until the liquid is cold. But whenever practicable the attention of the prescriber should be drawn to the incompatibility and the substitution of the carbonate suggested.

SOME REMARKS ON HOMBURG, ITS NEIGHBOURHOOD AND MINERAL WATERS.*

BY JOHN MACKAY, F.C.S.

During the early part of last summer I had occasion to visit Homburg and thought it might not be without interest were I to give you my impressions and also some particulars of this delightful watering place, with a few special remarks regarding the use and composition of the various springs which are now so well known and so much resorted to.

Homburg is about nine miles from Frankfort-on-the-Maine, and was reached by railway. The town itself is of historical interest, some parts of it being very old. The newer portions are of course built with all modern appliances, and from the great demand for accommodation during the season, not only are there many large hotels but numerous houses, large and small, where apartments are let, or where boarding as well as lodging may be obtained. About 1836 the number of strangers visiting Homburg did not exceed a hundred and fifty, while now they range from ten thousand to twenty thousand.

I remember paying a visit to Homburg some years ago, and witnessing the gaming tables in full operation. I need not attempt a description of the scenes I witnessed during my stay on that occasion, but will only say that the picture to be seen in the Doré gallery in London at the present time gives a very truthful representation of what might then be daily seen, not only in Homburg, but also in Baden-Baden, Wiesbaden, and the other great gaming places. When these tables were abolished throughout Germany, a few years ago, it was thought that this place, with its magnificent Kursaal, its beautiful gardens, magnificent park and excellent music, would rapidly become a place of the past and that all its glory would be departed. This, however, is not so. The local government of Homburg, during the last five years of the gambling operations, derived from the proprietors of the rooms a certain amount of money annually—equal, it is said to one-half the gains realized who were owners of what was familiarily known as the Bank. This sum, said now to exceed £100,000 of our money, is supplemented by what is called a Kur tax, being a payment of 12*s.* by every visitor who remains five days in the place. The town and surroundings are made as attractive as possible and the gardens and parks kept in very excellent order. The rooms in the large building of the Kursaal are furnished and painted, gilded and mirrored, in a way which no words can describe, comprising two reading rooms, two concert rooms, one large magnificent ball room, and conversation rooms, while in the upper floor are suites of apartments similarly furnished, and let out to private parties for balls or conversaziones. The music, which is entirely instrumental, is very fine, a well-trained band of between thirty and forty performs about six hours every day, with a varied programme,—two hours in the morning, again in the afternoon, and repeated in the evening. This takes place daily, and when the weather does not permit of outdoor performances, the magnificently decorated rooms are brought into use.

Homburg itself is situated in the very midst of the Taunus mountains and may be said to be built on a portion of table land on the southern slope of one of them. Commencing at the Rhine, the mountain range has been called Taunus, for an old German word Tun or height was understood to comprehend any elevation. Now, however, the particular range to which I allude is called and is recognized as the Upper Taunus district proper. Two ridges running nearly parallel extend north and west from Homburg. The highest peak is known as Feldberg, and is about 3000 feet high. Homburg itself is more than 600 feet above the level of the sea, while the real ascent to the highest portions of the mountain range commences about two miles from the town. The mountains are composed of clay, sand, slate, quartz, with traces of silver, lead, ironstone and manganese. They are all beautifully wooded and abound with game, such as deer, partridges, hares, etc. Good trout fishing is also to be had in some of the streams. On the south side, the climate is so mild that the finest kinds of fruit grow in abundance, while on the north side it is rough and cold.

In the vicinity of Homburg, there are several places which would well repay a visit, but it is foreign to the intention of this paper that these should be noticed. I must, however, claim an exception in favour of a place called the Saalburg. This remarkable place is in the Taunus range and about 700 feet higher up than Homburg, and represents the perfect remains of a large Roman fort and settlement. The fort itself seems to have been an oblong square nearly 800 feet long and about 500 feet wide. The outer walls are from 5 to 8 feet in thickness and from 3 to 6 feet in height. The place was surrounded by double ditches, separated by palisades, having a wall all round to facilitate the movements of the defenders. The fort had four gates, still very distinctly marked. There is also to be seen a very ingenious method of heating the houses by means of flues of burnt clay. Near one of the gates, well defined, is a large room, having nine bathing compartments, with the floors and a portion of the

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society of Great Britain, November 27, 1878.

original cement still visible. Outside the fort are to be seen traces of apparently a separate colony, possibly camp followers, etc., where there are cellars, in which several specimens of glass bottles have been found. The space occupied by this separate encampment seems to have been six or eight times greater than that occupied by the fort, and as the latter extended to about twenty-two acres, some idea may be formed of the ground occupied by both. One thing I saw very perfect, namely, a "Gebuck" or artificial thicket, such as the Romans used as a means of defence during their early wars. It is made by bending trees and bushes to give a height of about five feet and fastening them down so as to allow the tops to grow out and give a very good means of defence against the mode of warfare then employed. But, perhaps, even exceeding in interest what has been told is a visit to the grave house close beside the ruins where, in a building recently erected on ancient foundations and in Roman style, may be seen the contents of about forty graves, as they were found close to the fort. These give unmistakable evidence that the bodies were burned, as they each contain an earthen urn with the ashes, an earthen lamp or a symbol that life was extinct, one or more tear bottles, cups, plates, coins, knives, and various other articles. From the little I have said it will be understood how full of interest a visit to this interesting locality will be to any one who may chance to be in Homburg. I will only add that there is a very good museum in the town, containing some remarkable remains which have been from time to time obtained by digging among the ruins of this old Roman camp.

Notwithstanding all that has been said about the natural beauties of this district, as well as the fact that many valuable minerals are to be found in these mountains, we now come to speak of what may be considered the real treasures of this district, namely, the various mineral springs which are found in such abundance. Throughout the whole range of these mountains there are said to be about a hundred and fifty springs, comprising among them those of which we are now about to give some particulars, and including some other well known and valuable waters, such as Weilbach, Schwalbach, Selter, Wiesbaden, Ems, Schlangenbach, Nunheim and many others. The real medicinal springs number in all about forty, I mean in connection with the Taunus district.

As much has been said about the climate of Homburg, I may be allowed to give my own experience of it during the few weeks I remained in the place. From its elevation already referred to, there is no doubt that the mean temperature of the air is considerably lower than that found in some other districts situated in valleys and not subject to the cool currents which so frequently prevail on elevated places; add to this the fact that there are neither rivers or lakes in the neighbourhood, the nearest of the former being the Maine and the Rhine, and you have reasons for supposing that the atmosphere ought to be dry and invigorating, and rather sharp and cool than hot and relaxing. This I found to be really the case, for in early morning, say from 6 o'clock onwards till 9 or 10 a.m., and in the evening after 7 o'clock, it was so cool that an overcoat was not all unpleasant. One great advantage regarding the climate is that of its dryness, in consequence of the absence of water in its neighbourhood and also from the fact that a comparatively small amount of rain falls during the year, while the soil is so peculiar that in less than an hour after a heavy shower the ground becomes rapidly dry, and you can walk out in comfort. It must not be forgotten either that the park and all its surroundings are singularly rich in trees, the grateful protection or shade from the branches of which gives much pleasure during the hot midday sun to those pedestrians who are inclined to take exercise at that time. The trees have been planted very many years ago with great taste, while the walks have been laid out with geometric and artistic skill. Imagine the beauty of a line of pine, beech, elm or lime trees extending for miles in a direction straight as an arrow, without any divergence, not one of them projecting beyond its neighbour, and you will have some idea of the roads and drives through some of the forests.

The mineral springs are five in number and are all situated close to each other in a valley, about ten minutes' walk from the centre of the town. Each spring is surrounded by nice shrubs and very tastefully arranged beds of flowers. Their names are *Elizabethbrunnen*, the *Kaiserbrunnen*, the *Ludwigsbrunnen*, the *Luisenbrunnen* and the *Stahlbrunnen*. The word *brunnen* being synonymous with our well or spring, we will adopt the latter in describing the different waters. We commence by stating that all the five belong to the ferro-saline type of mineral waters, and that the one most distinguishsd is the—

ELIZABETH SPRING.—*Temperature* 50° *F.*

This is the principal and has done more to bring Homburg into repute than any of the others. The water is seen bubbling up from the spring and continues to do so day and night at the rate of upwards of 600 gallons every twenty-four hours. It has only been used medicinally on a large scale since 1836, and, as will be seen from the most recent analysis by Professor Fresenius, is very rich in solids, particularly chloride of sodium. The arrangements for supplying visitors with this water are very striking and unique. The spring itself is considerably below the surface of the ground, but being in a circle, and very handsomely laid with coloured stones and marble so as to resemble rich mosaic work, it offers a beautiful and uncommon picture, especially if you add the fact, that the banks sloping down to the well itself are planted with the finest and richest flowers. In the centre of the circle there are female attendants ready to hand you the water in small glass jugs, all of which are graduated from one to eight ounces. Close at hand there is an appliance for heating the natural water, so that you may have it cold as it issues from the spring, or the chill removed, according as the inclination or instructions of the doctor may indicate. Here also every morning, whatever the weather may be, hot or cold, wet or fair, the well trained band discourses some of the best instrumental music by well known composers. Leading from the well is a covered walk terminating in a large greenhouse containing many palms and some rare tropical plants. A very broad open avenue, having six rows of magnificent elm and plane trees, stretches between this and another of the springs, and is intended for a promenade while drinking the water. It was only in 1836 that this water began to be used medicinally on a large scale, and being the most important drinking water of all the springs continues to be the one principally used on the spot, and exported to other places. This spring is entirely a natural one, not having been, like the others, bored for. It rises spontaneously from a depth of about 14 feet and furnishes unceasingly, as already stated, an average of about 8000 litres in the course of twenty-four hours. The quantity exported will be about 100,000 bottles every year. It said to keep good for a long period, even when sent out to India. A glance at the table of analysis will show that in a pound of the water, there is present fully more than 107 grains of solid ingredients and that the principal of these is chloride of sodium. Indeed this salt seems to be predominant in all, but specially so in the one now under consideration. The next salts in any quantity are bicarbonate of lime, chloride of calcium and magnesium. Add to those carbonic acid and iron, and you have the principal ingredients in this water. The important substance appears to be chloride of sodium, for though the other ingredients are numerous, they are only in very small quantities compared to this salt. The name of the well was bestowed upon it after Landgravine Elizabeth, a princess of England and one of the daughters of George III., consort of Landgrave Frederic Joseph, who died in 1829.

The spring next in importance is that called the—

KAISERBRUNNEN.—*Temperature* 52° *F.*

This spring was for long recognized as the most powerful of all, and contained at one time 117 grains of chloride of sodium in the pound of water, but some years ago it somewhat changed its character, and now the chloride of sodium is reduced to about one half the above quantity. It continues however to be the richest of the springs in carbonic acid gas, of which we will say more when we come to speak of the baths. It was bored for and found in 1841 at a depth of upwards of 400 feet and produces 24,000 litres of water every twenty-four hours. From its great similarity in composition to the Elizabeth spring, and being confessedly so much weaker, it is not nearly so extensively used as a drinking water, and will be referred to more particularly under the bathing waters.

Next comes the water called the—

LUDWIGSBRUNNEN.—*Temperature* 53° *F.*

This well, discovered in 1809 as a natural spring, was known under the name of the acidulous spring and used as an ordinary drinking water for many years, but about 1844 it was deepened by boring about 180 feet, and was then found to be more medicinal, although it still remains one of the weakest of the Homburg waters. It yields a large supply, not less than 43,000 litres of water every twenty-four hours. A glance at the analysis will also show that it is the second most powerful in carbonic acid gas, and is therefore used along with another water for bathing purposes.

The two next are richer in iron than any of the preceding ones, and we notice first the—

STAHLBRUNNEN.—*Temperature* 50° *F.*

This spring was bored for in 1841 and found at a depth of about 150 feet and yields upwards of 2000 litres in twenty-four hours. From the analysis it will be seen that is rich in salts, while in iron it surpasses all the other springs not only in Homburg, but even the most celebrated chalybeate springs throughout Germany. In the hands of the physician, therefore, where iron is indicated, the water of the spring is considered invaluable.

It now only remains for me to notice the—

LUISENBRUNNEN.—*Temperature* 51° *F.*

This spring was discovered in 1856 by boring fully 300 feet. It yields about 9000 litres in twenty-four hours. It contains a good deal of iron but less chloride of sodium than the other springs, while there is present an appreciable quantity of sulphuretted hydrogen. It is one of the most recently discovered of the Homburg springs and was brought into use immediately after it became known.

These, then are the five medicinal springs in Homburg, now so well known and so much resorted to. We have spoken of these waters in their natural condition and as supplied to those who attend to drink them at the sources of each spring. This is also the form in which the different wells are bottled for exportation. Another use is, however, made of these waters, certainly not the least valuable part of remedial treatment, viz., that of baths.

There are two bath houses. One in the Kursaal and the other down in the park. The former is what may be called the old and the latter the new; both are still used. In the old house you have what are called mineral, plain, or medicated baths. The first of these is the water from the Kaiserbrunnen run into tanks, and the carbonic acid allowed to escape, after which the water is heated up to a temperature of about 26° Reaumur, or equal to 90° F. The second is an ordinary well water bath, such as you may get anywhere, but you can medicate either of these by the addition of one of these substances, which are supplied at the bath house for a few pence, namely mother lye, extract of pine, and liver of sulphur. The first is the uncrystallizable liquid of the Kreuznach salt spring, containing about 2484 grains of solids to each pound, and therefore not unlike our oil of salt. The second is a watery preparation from the tops of pine trees, which I need not say are to be found in abundance here. Baths thus made have a strong aromatic odour, producing an agreeable sensation on the skin and are supposed to be useful in rheumatic affections. The third is called by its popular name, liver of sulphur, being the ordinary sulphuret of potassium. The two first ingredients are employed in cases of rheumatism, and the third in cases of skin affections. For a full bath a quart bottle of the mother lye is used and about 12 ounces of the extract of pine. The sulphuret is used according as the bath is required strong or weak of the sulphuretted hydrogen, the usual quantity employed being 50 grammes. Both the rheumatic baths are used frequently and with considerable benefit. Valuable as these baths are supposed to be, they give way in importance to the new ones in the Park, which were only erected in 1871. The Park bath house is close to the wells, and two of them, already referred to, the Kaiser and Ludwig, are the sources from whence supplies of water are procured for this establishment. The water is conveyed from these springs in closed pipes so that each goes direct from its natural source into the bath, by its own pressure, and thus, not being in contact with the air, reaches its destination fully charged with the carbonic acid gas which both waters are known to contain. Each bath has a double bottom for the reception of steam, in order that the cold water may be heated up to any desired temperature. This is done very quickly. Not more than five or six minutes elapsing after the water is introduced, until it reaches from 90° to 94° F. The arrangement is so complete, that during the time of immersion, from fifteen to twenty minutes, there is no decrease in the thermometer; when the water in the bath begins to be heated there is considerable effervescence, and as this continues all the time the bath is used, the skin of the bather is covered with an innumerable number of minute bubbles of the gas, which continues to be felt all the time of immersion, and which gives a very comfortable feeling.

As will be seen there is a considerable quantity of free carbonic acid in all these waters, and as the springs are never at rest, it is natural to suppose that during the night when all is quiet, and no disturbance going on, that there must be a great overflow and escape of this gas. Such has been practically found to be the case, and a large erection has lately been put up not far from the wells, and quite close to the Kaiser spring, where it is proposed to collect the gas thus given out, and utilize the same for the purpose of giving a bath of dry carbonic acid gas. It was partially tried last year, with, I understand, a fair measure of success, and is now undergoing a thorough repair, and will, it is hoped, be ready in a few months for all who may wish under medical treatment to try the results of such a gas bath.

So much for the medicinal waters of Homburg, which I feel would be very incomplete, if I did not refer to the various pleasant drinking waters which are to be found in the neighbourhood. One of the most distinguished among them and of comparatively recent discovery is the pleasant dietetic water known under the name of Taunus. This spring was accidently discovered about eight years ago by some gentlemen while hunting, one of whom saw something like gas and water issuing from the surface of the ground, and marking the place took an early opportunity of making a thorough search, resulting in the discovery of a spring producing a natural water of such excellence that its merits are already known beyond Europe. The accidental discovery of this water is not unlike what is told regarding the discovery of the now well known Tunbridge Wells. It is said that a young nobleman, more than two hundred years ago, in returning from a visit to a friend in search of health, was on his way home, having derived no benefit, and crossing what was then a wide common became so weak and exhausted

that he fainted. His attendants in some alarm found quite close to them a spring of bright sparkling water of which they gave their master some. On coming round he took a good draught of this new water, which had such a marvellous effect upon him that he continued to use it. Remaining for several months, he ultimately built a house in the neighbourhood, was completely restored to health, continued so, and it is said died at a very advanced age.

The source of the Taunus Brunnen being about nine miles from Homburg, and not much farther from Frankfort, I took an opportunity of visiting the spot. I found it situated in a beautiful and fertile valley, not far from the Taunus mountains, and lying in what has been called the golden ground. There is a small village and railway station called Gros-Karven not far from the wells.

When springs of water have become deservedly popular, it has been a matter of surprise to many, the immense quantity produced by natural means from any such brunnens or spas. Some I believe have gone so far as to allege that in a few of the German waters the demand has been so great that there must have been a supplementary supply by artificial means. That such cannot be the case in this instance is undoubted, as there is a constant flow from the spring at the rate of upwards of 1200 litres an hour, and this goes on day and night without intermission, the consequence being that valuable as this water is, there is a considerable quantity allowed to run off as waste.

That this production may not be considered as impossible or unreal, it may be mentioned that it is said of one of the earliest known hot salt springs, not far from Homburg and discovered more than two thousand years ago, that there has been a constant supply of about 3,000,000 cubic inches daily, and that the supply still continues, not only so, but while the component parts remain much the same, the temperature at which water flows, about 150° F., has scarcely ever been known to vary; certainly not more than a fraction of a degree. Nature's own laboratory, therefore, is not the least wonderful thing we come in contact with in this world. But to return to the Taunus spring. Descending by a broad stair to the well house, we reached the source from which the water is so constantly escaping. It comes from a depth of about twenty-four feet, and is collected in a circular well with wooden sides and a stone coping, having a diameter of fully eight feet. This top is secured with a close fitting well secured wooden cover. When this is removed you see that pipes have been introdueed into the well. Those used for pumping the water into reservoirs go down about 16 feet, while those intended for purifying the gas are not carried down quite so far. The carbonic acid gas is present in large quantity and is visible to the eye, as it is constantly bubbling up through the water in the well, and being heavy collects in the space between the surface of the water and the top of the well. We tested the kind of gas coming up by lowering a lighted lamp, which was at once extinguished. The well water is pumped up by steam power into ten reservoirs or tanks prepared to received it, each of which has been carefully covered with cement, having nothing metallic in their construction and each capable of holding 22,000 litres. From these the natural water is bottled in the ordinary clay or stone bottles. Of course as the water is pumped up the flow of gas becomes greater, the quantity given off being apparently smaller when the well is full of water, probably from the pressure of such a large quantity of fluid preventing the escape of the gas. When, therefore, the water is low and the upper portion of the well filled with the naturally produced carbonic acid gas, another pump is set in motion and the gas pumped up, washed, and transmitted to large gasometers for future use. When these are full, there are means by which the spare gas is compressed into upright cylinders, and these give a means of ready supply in event of the gasometers becoming exhausted. When the aerated or extra charged water is required clean glass bottles are used as against the natural water in clay bottles. This water is charged by putting the natural water into copper cylinders, eight or ten of which I saw, and then forcing in the gas by means of a strong pump, just in the same manner as we make the various aerated waters in this country. All the materials are, however, supplied from natural sources, and no gas is or has ever been made in this establishment by artificial means. The steam power required to work the pumps, etc., is equal to about 12-horse power, and the number of hands employed in bottling is about fifty.

In closing these remarks let me refer for a moment to the principal ingredients on which the medicinal virtues of the Homburg waters appear to depend. Each pound contains from—

25 to 75 grains chloride of sodium.
15 to 20 „ carbonic acid gas.
$\frac{1}{4}$ to $\frac{3}{4}$ „ iron.

The other saline constituents, although numerous, are at the same time very minute. They therefore can scarcely be considered of much importance, and yet it is remarkable how these naturally produced waters differ in their effects to any which may be made artificially, and what is still more singular, that in many cases where the waters are evaporated and the salts redissolved, the same results are not obtainable, showing plainly that there is some mysterious agency in the natural production of these mineral waters.

The belief of some of the medical profession in Homburg as to the physiological effects of the principal salt, chloride of sodium, so largely present is, that while a certain quantity is required for healthy gastric juice, its superabundance is supposed to act as an irritant to the mucous surface of the stomach, quickening the secretion and being conveyed into the bowels to exercise there an exosmotic effect, regulating the diffusion between the blood and the contents of the abdominal viscera. Great importance is attached to the quantity of iron present, not only as a sanguinifying agent, but as a general tonic, while the carbonic acid is supposed to have a soothing effect on the whole system when taken in small quantities, but when in considerable portions and continued persistently for a time, a mild but decided irritant is produced, stimulating the liver and increasing the activity of the kidneys and skin, aiding at the same time the peristaltic movement of the bowels. Resident physicians, therefore, believe that the Homburg waters are really serviceable in all ailments connected with indigestion, such as constipation, dyspepsia, hæmorrhoids, liver complaints, hysteria, enlargement of the glands, gout, rheumatism, corpulency, fatty degeneration, and especially all complaints resulting from a residence in tropical climates.

Be the effects of the constituents what they may in connection with the composition of the mineral waters of Homburg and other places, there can, I think be little doubt that there are other influences at work to account for the sometimes wonderful results derived from a residence at some of these localities. There is change of scene and air to be considered. There is also the fact not to be overlooked that many of these resorts are much above the level of the sea, and therefore the air is frequently pure and bracing. Take as a type of what I mean at home and abroad. Thus, we have Buxton about 1000 feet above the level of the sea, and Homburg nearly 700 ; add to this the regimen so particularly enjoined, generally comprehending an entire change both of solids and fluids, and I cannot help thinking you have very powerful adjuncts in any treatment for the cure of complaints, which at home baffle, to a certain extent, the efforts of our own medical practitioners, and who find many of their patients more ready to conform to a complete change of diet when recommended to do so by the physician at a distance and in the close proximity of some favourite and well-known watering place. There is also

the element of entire rest to mind and body, all important to those, who have often for many years, borne the heat and burden of the day, and to whom such a complete change acts a most important part.

PHENOL-PHTALEIN AS AN INDICATOR IN TITRATIONS.*

BY CHARLES W. DREW, PH.B.

My attention was lately directed to a substance, phenol-phtaleïn, which was discovered a few years ago by Baeyer, and whose general properties were briefly described by Dr. E. Luck (*Ber. d. Deutsch. Chem. Ges.*, 4, 658). This substance seems to me to, in a great degree, meet the wants of analysts who desire an extremely delicate and reliable indicator.

The neutral and acid solutions of this substance are entirely colourless, and by the faintest excess of alkali an intense carmine colour is developed. This colour is discharged with equal readiness by the addition of sufficient acid to render the solution neutral in reaction.

The mere fact of the transition being from a colourless solution to one of a high colour gives it a great advantage over any of the test solutions in common use, and to this we may add that for delicacy, tenuity and quickness of response to infinitesimal amounts of acid or alkali, it is immeasurably superior to them all.

The substance is best employed in solution in alcohol of 20 to 25 per cent., and of a 1 per cent. solution four or five drops are ample for 50 to 100 c.c. of the solution to be titrated. However, the strength of the solution is immaterial, and the proper amount to be added can readily be found by one or two trials. In accurate work it will always be necessary to add a few drops of alkali to render the solution exactly neutral, as the phenol-phtaleïn, when dissolved, has an acid reaction.

In order to illustrate the delicacy I will give briefly the results of some few experiments upon it: 0·05 gram of phenol-phtalein dissolved in 25 c.c. of 95 per cent. alcohol, the acidity counteracted by the addition of 1·75 c.c. of decinormal solution of sodium hydrate, when made up to 200 c.c. with distilled water, contained of phenol-phtaleïn in each cubic centimetre 0·00025 gram.

0·5 c.c. of this solution = ·000125 gram of phenol-phtaleïn was made up to 250 c.c. with water, and ·5 c.c. of decinormal solution of sodium hydrate, = ·002 HNaO, was added; a very distinct pink colour was given to the solution, although it represented only 1 part of phenol-phtaleïn in 2,000,000 parts of solution.

An increase in the amount of test solution decreased the amount of alkali required to develop the same shade of colour as well as the amount of acid necessary to discharge it. ·5 c.c. of the test solution = ·00125 gram of phenol phtaleïn, when made up to 250 c.c. with water was coloured a brilliant carmine by 0·2 c.c. of decinormal sodium hydrate = ·0008 gram of HNaO, or 0·02 c.c. of normal solution of sodium hydrate. This colour was completely discharged by the addition of 0·2 c.c. of decinormal oxalic acid = ·00126 gram of $C_2H_2O_4$, or 0·02 c.c. of normal solution of oxalic acid. This proportion represented 1 part of the substance under examination in 200,000 parts of solution.

It is of course impracticable to work with such minute amounts, yet the experiments serve to demonstrate that the delicacy of the indicator is much beyond appreciation by ordinary apparatus and with solutions of the strengths commonly employed.

I have made a large number of titrations of various solutions, and have never found the indicator to work other than satisfactorily. The colour is developed by all alkalies and discharged by all acids, including carbonic acid, hence it is, like litmus, unfitted for use in the titration of carbonates in the cold.

Upon thorough trial I regard this as very greatly superior to any other indicator in use for acids and alkalies, and consider that it deserves a prominent place among reagents for volumetric analysis.

* From the *American Journal of Pharmacy*, November, 1878.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 21, 1878.

THE LATEST PHASE OF THE COUNTER PRACTICE QUESTION.

THE formation of the Pharmaceutical Society involved the necessity of defining more exactly than had previously been done the nature of the trade and business of a chemist and druggist, and accordingly in the bye-laws of the Society he was described as a person who had been regularly apprenticed to or educated by a vendor of drugs or dispenser of medicines and who does not profess to act as a visiting apothecary or surgeon. Medical practice was here referred to for the purpose of distinguishing the chemist and druggist from the apothecary. The subject of counter practice was then much discussed by the medical journals, and the intention of chemists and druggists not to abandon that part of their business was distinctly avowed and recognized on both sides. The Council, through the medium of the Journal, expressed a desire to discourage the extensive practice of medicine by chemists and druggists, but it contended that severe legal restrictions, such as those proposed in Mr. HAWES'S Bill, would not only be attended with injustice and injurious to the public, but also impracticable. This has in reality been proved by the results of the prosecutions instituted since that time against chemists and druggists. These have not been numerous and in all instances the verdict has been in favour of the chemist and druggist, provided he did not hold himself out as a medical practitioner. Under the stimulus of violent articles in the *Lancet*, urging that the chemist and druggist had not even a legal right to dispense physicians' prescriptions, a prosecution was instituted in 1849, in the Bloomsbury County Court, with the object of enforcing that restriction among others; but it ended in a prompt verdict for the defendant, while in regard to counter practice the Judge's view of the law was that a chemist and druggist might casually administer a dose of medicine to a patient for a sore throat or other incidental ailment, without being liable to the charge of practising as an apothecary, though if he made a practice of attending patients he would come within the provisions of the Act.

The common ground occupied by chemists and druggists and apothecaries was again recognized by the Legislature as it had been in the Act of 1815, at a later period, when the Pharmacy Act was passed in 1868, by the provision of the 16th section that nothing thereinbefore contained should extend to or interfere with the business of any legally qualified apothecary, and this exemption was further extended in the subsequent amendment Act, providing that the first fifteen sections of the Pharmacy Act should not affect a legally qualified medical practitioner. These reciprocal exemptions point to the absence of any hard and fast line of distinction between the business of the chemist and druggist and that of the apothecary keeping a shop, and it would appear inconsistent with that reciprocity of exemption that while the apothecary retains the right to keep a shop for selling, compounding and dispensing medicines, the chemist and druggist should not have the same right to recommend his wares or the use of them that is enjoyed by the apothecary, competing in the same capacity with the chemist and druggist, and by every other seller of wares of any kind.

In regard to the SHEPPERLEY case, we have been censured for the opinion we have expressed that it is scarcely more satisfactory than the WIGGINS case, so far as the interest of the trade is concerned. It has been publicly stated that the trade has nothing to hope for from the Journal in support of trade interests, and we have been accused of bolstering up the apothecaries. We cannot admit the justice of these charges and confidently refer to the articles on the subject of counter practice as proving that we have endeavoured to defend the interests of the trade in that respect consistently with the established policy of the Society from its origin. Leaving out of consideration the reasons for which the Council decided not to undertake the defence of Mr. SHEPPERLEY as being outside our cognizance, we will, however, seek to make plain the grounds of the opinions that have been complained of, taking the case as it stands reported. From this point of view we think it would have been a questionable application of the Society's funds to defend the case as it appeared in Court, because it was not calculated to bring about a settlement of the question as to the legality of counter practice. Accepting the evidence of Mr. SHEPPERLEY as representing correctly what he did, even assuming that DEATH really had a sore throat, that Mr. SHEPPERLEY looked at his throat and gave him a saline mixture, we do not think that would have rendered him liable under the 20th section of the Apothecaries Act. In the other case of HUBBARD, there was even less ground for the charge of practising as an apothecary, for according to Mr. SHEPPERLEY he did not judge from this man's symptoms what medicine to give, but he only supplied the medicines which HUBBARD described he had previously been taking under the direction of a medical man. Even in cross examination he adhered to the same account, and the only judgment he admitted having formed was to the effect that DEATH had no sore throat at all.

The jury appears to have accepted this evidence and returned a verdict consistent with the belief that Mr. SHEPPERLEY had not rendered himself liable under the 20th section of the Act, by practising as an apothecary. That verdict directly negatived the argument of Mr. MORGAN HOWARD that the defendant had acted as an apothecary in a manner prohibited by the terms of the statute. It equally

negatived the arguments that Mr. SHEPPERLEY in treating a simple complaint by his judgment had acted as an apothecary within the meaning of the Act. The jury would appear not to have attached much weight to the argument that the evidence as to the custom of the trade in 1814 established too much by showing it was outside of the statute and was the real mischief that statute was intended to remedy. The verdict also negatived the argument founded upon what Mr. SHEPPERLEY did, and in regard to the proposition of Baron POLLOCK in summing up, that if Mr. SHEPPERLEY had infringed the law in both DEATH'S and HUBBARD'S cases, he would be liable to both penalties, but if he did not infringe the law in either case he would be liable to neither, it established that he had not infringed the law. No doubt the probability of DEATH'S sore throat being a fiction may have materially influenced the decision of the jury, and so far it was useful to Mr. SHEPPERLEY to show that; but as regards testing the legality of counter practice it is important to bear in mind that showing this had the effect of destroying the validity of the case, as a test of that question. It was indeed a phantom case so far as DEATH was concerned, and a new trial was refused by the Lord Chief Baron precisely upon that ground. He held that there could not be any judgment as to disease from symptoms when neither disease nor symptoms existed, nor any judgment as to the medicine to be given for their treatment.

This view of the case was indeed suggested by the defence, and though it is to be assumed that the counsel acted upon their instructions we cannot but think it was a mistake to sacrifice any possibility there might have been of making this case test the question as to the legality of counter practice for the sake of gratifying a spiteful desire to disparage DEATH'S evidence. If, on the contrary, it had been admitted that the symptoms described by DEATH were received by Mr. SHEPPERLEY as the basis upon which he formed a judgment what medicine to give, and the fictitious nature of those symptoms had not been urged, the case would have had a totally different aspect, and might then have served to test the question at issue as to the legality of counter practice, for then the jury must have decided whether or not they considered such proceeding covered by the exemption of the 28th section.

In face of the jury's verdict, the contention of the plaintiff's counsel that Mr. SHEPPERLEY had infringed the Act, goes for nothing. No less ground could possibly be taken for the purposes of the prosecution, and it is a total mistake to confound this argument of the plaintiff's counsel with established evidence.

It is on these grounds that we expressed the opinion that the verdict simply affirmed that Mr. Shepperley had not, in the particular cases he was prosecuted for, acted as an apothecary within the meaning of the Act, and that it left altogether undecided, and out of consideration, the more important question whether in virtue of usage prior to 1815, and recognized by the 28th section, the chemist and druggist has a right to act as an apothecary in the treatment of minor ailments, and the administration of simple remedies for their relief.

In this opinion we are supported by all the articles that have appeared on the case in the medical and pharmaceutical papers. Thus the *Medical Times and Gazette* says the case may perhaps be regarded by the pharmaceutical trade as a triumph; but in reality it leaves the real question at issue between medical practitioners and chemists and druggists as far from settlement as ever. The *British Medical Journal* says the verdict clearly meant nothing else than the dissatisfaction of the jury with the sort of evidence produced for the prosecution. The *Lancet* advises that the case should not be pressed as a test suit. The *Medical Press and Circular* speaks of the chemists and druggists as only nominally the victors, and the *Chemist and Druggist* goes still further by stating that "counter practice has no legal position "whatever."

We are indeed utterly at a loss to conceive on what grounds the verdict in this case can be regarded with satisfaction by the trade as in any degree settling the question as to the legality of counter practice. But there are, we think, still graver reasons for viewing the case as unsatisfactory in this respect. The verdict has relieved Mr. SHEPPERLEY from liability for infringing the 20th section and so far as he is concerned there is that ground for satisfaction; but it must be remembered that this result will probably exasperate the promoters of the prosecution and stimulate them to further attempts to carry out their views. Such a prospect cannot be conducive to the interest of the trade even if such attempts were in the end frustrated. And there is a still more important feature of this case to be considered, namely, the view taken of the law by the judge. This is decidedly adverse to the chemist and druggist, and Baron POLLOCK very plainly showed that his opinion as to its stringency was consistent with that previously expressed by Baron BRAMWELL, although he admitted the difficulty of deciding what is acting or practising as an apothecary. His view of the extent to which the exemption provided by the 28th section goes is especially unfavourable for chemists and druggists in the exercise of counter practice. He holds that this exemption is limited by the words buying, preparing, compounding, dispensing, and vending drugs, medicines, etc., and so decided was his view on this point that he put aside the evidence of the witnesses as to what was done by chemists and druggists before 1815, and said the obvious answer to it would be that they were doing that which was illegal, they were doing that which was not contemplated by this section, and the fact that they did it then can in no way assist those who seek to do it now, if it be contrary to law, and contrary to the spirit of this exception in the Act.

Again, at the hearing of the application for a new trial when the exercise of counter practice by chemists and druggists before 1815 was referred to, Baron POLLOCK distinctly stated that the right to treat simple cases was never raised in the case, and that though a witness was called for the purpose of proving the custom he stopped all that entirely. He also explained his view by adding that he read

the 28th section not as meaning that chemists and druggists were allowed to exercise and carry on their trade or business as fully and amply to all intents and purposes as the same trade or business was used, exercised, or carried on by them before the passing of the Act, but that the true construction of that section was that the exemption was so limited, that exercising and carrying on the same trade meant an exercising and carrying on of the trade of a chemist and druggist only in the buying, preparing, compounding, dispensing and vending drugs. This, he told the jury, was his own judgment, and that they were bound by it.

In regard, then, to the question of law and the interpretation of the 28th section, the result of this case has been to bring out a most decided expression of opinion adverse to the legality of counter practice by the chemist and druggist, one calculated to encourage the promoters of the prosecution to try again, and guided by that expression of opinion we do not wonder that our contemporary the *Chemist and Druggist* should come to the conclusion that "counter practice has no legal position whatever." We do not, however, agree with this conclusion, nor are we disposed to accept Baron POLLOCK'S view of the limited nature of the exemption provided for by the 28th section. On the contrary, we hold, as we have already shown, that counter practice, having been long commonly carried on both by chemists and druggists as well as by apothecaries who kept shops before the passing of the Act in 1815 it was as much a part of the business of one as of the other. For this reason, therefore, and having regard to the expressed intention of the Apothecaries' Society not to interfere at all with the chemists and druggists by the Bill then in Parliament, we hold that there is good ground for regarding the recognition of the legality of counter practice by chemists and druggists as having been part of the intention of the 28th section of the Act.

It must be admitted that the arguments and evidence we have brought forward in support of this view are not such as would perhaps carry much weight in a court of law, or with a judge whose function is to interpret and administer the law as it appears to him to apply to a case before him, and it is precisely for this reason that we have deprecated even the discussion of counter practice and still more the litigation of the question as a matter of right.

When the Medical Defence Association first announced its intention to commence a campaign against chemists and druggists, we pointed out that this would probably awaken a spirit of resistance, if its proceedings were conducted in such a manner as to raise a question whether or no chemists and druggists have a less right to prescribe medicines than every other individual in the country has. For this and other reasons we considered the action of the Society of Apothecaries under the instigation of the Medical Defence Association was ill advised, and more likely to lead to an extension of counter practice than to promote such good feeling between medical practitioners and pharmacists as might more safely be looked to as a means of mitigating grievances on both sides.

From an ethical point of view it is no doubt desirable to separate the practice of medicine entirely from the practice of pharmacy, but that is a result which cannot be hoped for as obtainable speedily, or by violent measures, since it cannot be denied that in very many instances the possibility of obtaining simple remedies at a very moderate cost from the chemist and druggist is a great boon to a large class of the community who would otherwise be unable to obtain relief. At present, however, chemists and druggists are exposed to the danger of being prosecuted for doing that which the Duke of RICHMOND in introducing his Medical Bill admitted in a more general way there was no possibility of prohibiting. At the same time the expressed disposition of the body which is coerced by private medical organizations into taking the position of ostensible prosecutor, is unfavourable to interference with the counter practice of chemists and druggists, and it appears to be unaccountable that some steps have not been taken to check the mischievous agitation by an amicable arrangement similar to that carried out in 1815.

In regard to this we may recall to mind that when the subject of counter practice was under discussion by the Council last year, Mr. SCHACHT moved that an effort be made by the Council to arrive at a distinct understanding with the Society of Apothecaries as to the class of cases of alleged infringement of the Apothecaries Act which should be open to prosecution, and that a Committee should be appointed to confer with the Society of Apothecaries to give effect to that resolution. In submitting this motion, Mr. SCHACHT said that though he had voted against the policy of defending prosecutions, he was anxious to do the best he could for the interests of the trade at large, and seeing the dilemma in which they were placed by the wording of the Act, he thought it would be well for some representatives of the Council to have an interview with the Society of Apothecaries, and come to some mutual understanding as to the interpretation to be put upon the Act. He thought it infinitely better that the Council should endeavour to prevent these difficulties, than to defend actions in a court of law.

The fact that the SHEPPERLEY case was then pending appears to have interfered with the carrying out of this project, and as the motion was not seconded it fell to the ground. Some months afterwards the Council was informed by Mr. FLUX that as the result of his communication with the Solicitor to the Society of Apothecaries he had been assured that the Society had never instituted and had no desire to institute vexatious proceedings against chemists and druggists in the ordinary exercise of their business, which it was admitted necessarily involved a certain amount of advice to their customers. At the following meeting of Council, in February last, the correspondence between Mr. FLUX and Mr. UPTON was ordered to be published, and in a letter from Mr. UPTON it was distinctly stated that it might be accepted as the policy of the Society of Apothecaries, no less than the course he should personally pursue, not to authorize any prosecution in a case of pure and simple counter practice.

The disposition here manifested on behalf of the Society of Apothecaries appears to promise so favourably for the adoption of the course suggested by Mr. SCHACHT, that we regret his proposal has not been carried further, and we call attention to these facts now since a correspondent has this week written to ask for explanation of what he regards as an apparent inconsistency between the intention declared by Mr. UPTON and the character of the SHEPPERLEY case as it appeared in court.

Transactions of the Pharmaceutical Society.

GENERAL MEETING—BENEVOLENT FUND.

ELECTION OF ANNUITANTS.

A General Meeting of the Members, Associates in Business, and Associates of the Pharmaceutical Society, and of the Subscribers and Donors to the Benevolent Fund, was held at the house of the Society, 17, Bloomsbury Square, on Wednesday, December 18th, at 12 o'clock, for the Election of Seven Annuitants.

Mr. John Williams, President in the chair.

The notice convening the meeting was read.

Scrutineers were appointed, who examined the voting papers and brought up the following report:—

Scrutineers' Report.

We, the undersigned Scrutineers, appointed at the fourteenth election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain do hereby certify that we have examined the voting papers committed to us and report the following result:—

Gason, Elizabeth Jane	872
Higgs, John Seagrave	1630
Kennett, Louisa	391
Nichols, Mary	2333
O'Reilly, Elizabeth Bullard	1166
Parkes, Ellen	1171
Slater, William Henry	3134
Townson, Thomas	2683
Watkins, Louisa	484
Whitehead, Annie	1876
Woods, Elizabeth	648
Yates, William Lee	813

3518 voting papers were received, of which number 84 were informal, and were disallowed.

John Williams, Chairman.
Edward Northway Butt.
Walter Hills.
H. W. Pound.
John F. Savory.
Charles A. Blake.
J. Robbins.
T. Edward Greenish.
W. Toogood Frost.
Charles E. Turner.
S. Plowman.
John G. Walker.

December 18, 1878.

The Chairman declared the following seven duly elected Annuitants:—

Higgs, John Seagrave.
Nichols, Mary.
O'Reilly, Elizabeth Bullard.
Parkes, Ellen.
Slater, William Henry.
Townson, Thomas.
Whitehead, Annie.

Votes of thanks were given to the Scrutineers and to the Chairman.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fifth general meeting was held at the Royal Institution, December 5, 1878. The President, Mr. T. F. Abraham, in the chair.

The minutes of the previous meeting were read and signed. The donations to the library were duly acknowledged. Messrs. Ernest Miller, A Mills, W. A. Jones, and Thomas Jones were unanimously elected members, and Mr. James Alderton was elected associate.

Dr. Charles Symes exhibited and explained Messrs. A. Kendrick and Sons' American Drug and Spice Mill.

Mr. Michael Conroy, F.C.S., read the following paper on—

An Improved Formula for Liquid Extract of Yellow Cinchona.

Few of our official formulæ have received more adverse criticism than the liquid extract of yellow cinchona, and few indeed have so well deserved it. I am only adding to the testimony given by many able chemists and pharmacists, when I say that our present official preparation does not represent the bark from which it is obtained, either in alkaloidal or other properties, and my personal experience is that from 60 to 75 per cent. of the alkaloids are left unextracted in most barks. It is also well known that the quantity of fluid extract which different barks yield varies considerably, and that the finest barks often give the worst yield, as the following results will show. The barks employed in these operations were fine calisaya, each sample containing over 2 per cent. of quinine. The quantities operated upon varied from one to three hundredweights, but for the sake of distinctness, I will reduce these quantities to 100 ounces each, and give proportionate yield of finished fluid extract.

No. 1.	100 ounces	produced	16·4	fluid ounces.
No. 2.	100	„	18·5	„
No. 3.	100	„	17·3	„
No. 4.	100	„	18·2	„
No. 5.	100	„	17·9	„
No. 6.	100	„	19·8	„

I could give many more instances, but these will suffice to show the variability of the yield from official bark, and although the above are exceptional cases, I can say that it is a rare occurrence to meet with a calisaya bark one pound of which will yield four ounces of fluid extract. Another great disadvantage in this preparation is the variable nature of the resulting fluid extract, some samples being much more soluble in water than others, and it is nothing uncommon to find that two fluid extracts will not mix without producing turbidity. The amount of evaporation required to produce this unnecessarily concentrated preparation is another very great fault, for owing to this, the small amount of quinotannic acid which the water extracts is almost entirely oxidized into cinchonic red. My object, however, is not to discuss the demerits of our present preparation, but to lay before you the results of some experiments which I have made with a view to arrive at a suitable menstruum. To arrive at this desideratum, it is necessary to consider the nature of the active properties which we desire to extract, and then find out the most suitable solvent. The organic constituents of true cinchona bark are the alkaloids, viz., quinine, cinchonine, and two or three isomeric modifications of these bases, aricine, quinovic and quinotannic acids, quinovin or quinova bitter, cinchona red, a small quantity of essential oil, a yellow colouring matter, a green fatty matter, together with starch, gum, and woody fibre. The essential or specific therapeutic properties reside in the alkaloids, but these properties according to the best authorities, are considerably aided by the natural acids of the bark, and more especially by the quinotannic acid; hence the different physiological action, mentioned by eminent medical authorities, observed between the

administration of the powdered bark and its alkaloids, whether mixed or separate.

In a paper read before the British Pharmaceutical Conference, held in London in 1874, Dr. de Vrij, the author, says that besides the powder, he only knows of one pharmaceutical preparation which equally contains the chief therapeutical agents, and that preparation is the alcoholic extract; while Mr. Umney, in the discussion which followed the reading of the above mentioned paper, said that he considered proof spirit to be a suitable menstruum. More recently, Mr. Ekin, in his very valuable paper, showing the comparative strengths of the different official preparations of yellow cinchona, which he read this year at the meeting of the British Pharmaceutical Conference in Dublin, clearly shows that proof spirit thoroughly extracts the alkaloidal properties of the bark.

The pharmacopœia of the United States directs this preparation to be made with two menstrua, the first being a spirit a little stronger than our proof spirit, but combined with glycerine, and is composed of alcohol (sp. gr. ·835) eight parts, water five parts, and glycerine three parts; with part of this menstruum the cinchona in fine powder is moistened, and then packed in a percolator, the remaining portion being poured upon it, and macerated in a warm place for four days. Percolation is then ordered with diluted alcohol (sp. gr. ·941) until twenty-four fluid ounces have been obtained, of which the first fourteen are reserved, and the remainder carefully evaporated to two fluid ounces and added to the reserved fourteen. This formula is a decided improvement on our own, but still, it is not one that we could unreservedly accept, for the following reasons: Firstly, glycerine, as a menstruum is not looked upon favourably in this country, either by the medical profession or by pharmacists, neither parties seeing any actual advantage in its use, while it has been asserted that it interferes with the activity of some medicines, especially those possessing astringent properties. However, this may be, its use in this preparation is certainly unnecessary. Secondly, it is practically impossible to exhaust the bark with the quantity of menstruum necessary to produce twenty-four fluid ounces, as directed in the formula. Thirdly, The alcoholic strength of the United States diluted alcohol is not suitable for the thorough extraction of the quinotannic acid of the bark, as will be seen below. This fault is, however, considerably mitigated, by the previous maceration in a somewhat stronger spirit.

That an alcoholic menstruum is the most suitable for this preparation was very forcibly impressed upon me some three years ago, by the results of several analyses which I then made of "exhausted" bark, representing the marcs from the preparation of alcoholic extract, proof tincture and aqueous liquid extract, when I found that while the samples representing the marcs of the alcoholic extract and proof tincture were devoid or almost devoid of alkaloids, the latter contained same in abundance. The next point to decide is in regard to the most suitable strength for an alcoholic menstruum, and with this object in view I tried the following experiments:—

The bark used was fine calisaya, and in each case 100 grs. in very fine powder (No. 100) was percolated with the different menstrua until nothing more could be extracted, the amount of percolate obtained from each being 1000 gr. measures.

No. 1, percolated with		Rectified Spirit,	sp. gr.	·838.
„ 2	„	30 O.P.	„	·880.
„ 3	„	10 O.P.	„	·908.
„ 4	„	proof	„	·920.
„ 5	„	10 U.P.	„	·931.
„ 6	„	20 U.P.	„	·941.

The marcs from these were afterwards treated with other menstrua as under:—

No. 1. With distilled water, to which it yielded a very small amount of gummy matter, which consisted partly of quinovic acid.

Nos. 2, 3 and 4 yielded nothing whatever to either rectified spirit or water, and although these marcs were minutely examined for alkaloids and natural acids, only the faintest trace of quinotannic acid could be found.

Nos. 5 and 6 were further treated with rectified spirit, to which they yielded both alkaloids and quinotannic acid, the latter in abundance, thus proving that they were unsuitable menstrua.

The foregoing experiments prove that alcoholic menstrua, ranging in strength from proof to 30 o.p., completely exhaust yellow cinchona of the whole of its therapeutically active properties; but the best of the three is that of proof strength, as it more readily exhausts the bark, less being required for the purpose.

The following is the formula which I would recommend, and as I have worked it on both a large and a small scale, I know from experience that it will give a thoroughly satisfactory result, the strength being one fluid ounce equal to one ounce of the bark.

Yellow Cinchona, in fine powder (No. 80) . 20 ozs.
Proof Spirit, a sufficient quantity.

Moisten the powder with ten fluid ounces of the spirit, and pack gently in a percolator; pour on to this another ten fluid ounces of the spirit, so as to thoroughly saturate the powder. Allow this to macerate for a couple of days, and then start the percolation, occasionally adding fresh menstruum until sixteen fluid ounces have been collected. Reserve this portion, and continue the percolation until two more pints of percolate have been obtained. Evaporate this at a temperature not exceeding 180° F., to the consistence of a soft extract, which re-dissolve in sufficient proof spirit to make up four fluid ounces, add it to the reserved portion, and filter, if necessary.

The two pints of percolate are ordered to be reduced to an extract, on account of the greater volatility of the alcohol of the menstruum, which in passing off before the watery portion leaves a rather unsightly watery mixture behind, which if reduced to four fluid ounces, and added to the reserved portion, would so reduce its alcoholic strength as to cause a deposit of some of its active properties. The evaporation necessary in this process is certainly a disadvantage, but if carefully and expeditiously conducted, at the above-named temperature, this defect may be reduced to a minimum. After collecting the first sixteen fluid ounces it is a good plan to work the remainder of the menstruum in three or four separate portions, passing each twice through the percolator, by which means less menstruum may be made to answer. The spirit can be recovered from the two pints of percolate, and also from the marc, by distillation.

At the close of the paper a discussion followed, in which several members took part, the general expression of opinion being favourable to the formula suggested by Mr. Conroy, and a vote of thanks was cordially rendered to the author with acclamation.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The adjourned annual meeting was held at the Memorial Hall, on Wednesday evening, December 11. Mr. J. T. Slugg, F.R.A.S., Vice-President, having taken the chair, the Honorary Secretary read a letter from the President, Mr. W. S. Brown, expressing his regret at being prevented by illness from attending and taking part in the discussion on the "New Weights and Measures Act," which Act was calculated to affect the interests of pharmacists materially.

The following gentlemen were elected officers for the session, 1878–79:—President, Mr. W. S. Brown; Vice-Presidents, Mr. J. T. Slugg, F.R.A.S., and Mr. W. Wilkinson; Treasurer, Mr. George S. Woolley; Hon. Secretaries, Mr. F. B. Benger, F.C.S., and Mr. H. Woolley; Council, Messrs. Blain, Boor, J. Botham, Bow-

den, Hargraves, Kay, Mumbray, J. B. Payne, B. Robinson, Slack and Westmacott.

A letter was read from the Secretary of the Chemists and Druggists' Trade Association (received in response to a request for such information) explaining the situation *in re* The Apothecaries' Company *v.* Shepperley. The Chairman remarked that this statement would correct a misapprehension which seemed to some extent to exist, that leave to appeal against the decision of Mr. Baron Pollock had been refused. This was not the case. Application for a new trial of the whole case had been refused, but the appeal would be heard in the course of a few weeks.

Mr. J. B. Payne then read the following paper on—

The New Weights and Measures Act as affecting Chemists and Druggists.

The new Weights and Measures Act, dated August 8, 1878, and which comes into operation on the first January next, is a lengthy document, divided into eighty-six sections and six schedules, and in so far as it more particularly affects chemists and druggists is not at all explicit. In this short paper I have endeavoured to be as brief as possible to point out defects, and to show how far and in what manner we are the more interested.

To begin, standards are given and described for the imperial standard pound and the yard. Section 14 states, "One-sixteenth part of the imperial standard pound shall be an ounce, and one-sixteenth part of such ounce shall be a dram, and one-seven thousandth part of the imperial standard pound shall be a grain, . . . and four hundred and eighty grains shall be an ounce troy. All the foregoing weights, except the ounce troy, shall be deemed to be avoirdupois weights."

But no mention is made in any portion of the Act (except the schedule, a copy of which is on the wall) of the additions to the avoirdupois weights, these being—

240	grains	or	10	dwts.
120	„	„	5	„
72	„	„	3	„
48	„	„	2	„
24	„	„	1	„

I believe that it is optional whether you have a supply of these new weights, though if you have, they must be stamped and be produced for inspection.

In an article which appeared in the Manchester *City News*, of November 11, it says, "that all articles shall be sold by the avoirdupois weights, except the precious metals and stones, or drugs when sold by retail." I mention this because it is misleading. The 2nd paragraph of the 21st section of the Act says, "drugs when sold by retail, may be sold by apothecaries' weight." Now in general usage it has always been understood that a dram weight was one-eighth part of a troy ounce, but in the avoirdupois weight it is one-sixteenth part of the ounce, or 27·343 grains. I am inclined to think that we have here a source of no little trouble and unpleasantness, and that it will give rise to many unforeseen difficulties.

Permission is given to use, and standards mentioned for the metric system, or as our city inspector says in his report, "The metric system may be used for science and manufacture." The 15th section gives the standard for the gallon, and says, "the quart shall be one-fourth part of the gallon, and the pint shall be one-eighth part of the gallon. Two gallons shall be a peck, and eight gallons shall be a bushel, and eight such bushels shall be a quarter." And section 17 states, "In using an imperial measure of capacity the same shall not be heaped, but either shall be stricken with a round stick or roller, straight, and of the same diameter from end to end, or if the article sold cannot from its size or shape be conveniently stricken, shall be filled in all parts as nearly to the level of the brim as the size and shape of the article will admit," and in the 19th section it states that "No local or customary measures, nor the use of the heaped measures shall be lawful."

Now, on reference to the 2nd schedule you will find new standards mentioned, these are four, three, two, and one fluid ounces, four, three, two, and one fluid drachms, and thirty, twenty, ten, five, four, three, two, and one minims. In the Act proper these are not given, only being added in this schedule, and nowhere do I find any standard described from which they are to be made. A fluid ounce has hitherto been reckoned as 437·5 grains, and a fluid drachm as 54·68 grains, and, of course, for dispensing purposes these continue to be so, but what are we to consider a fluid drachm for purposes of retail sale? There are sections forbidding the issue of price lists containing other than the legal standard weights or measures, —making it compulsory to have all weights and measures properly stamped,—giving inspectors power to enter premises, and giving a table of fees to be charged for inspection, in which no mention is made of graduated glass measures. The bottle measures hitherto legalized are done away with, and the local authorities are empowered to make bye-laws, subject to the approval of the Board of Trade.

The dispensing scales and weights are not liable to inspection, but the scales, weights, and all measures used in the sale of goods must be stamped, and be produced for inspection. Our city inspector tells me that all sizes of graduated glass measures, such as eight, ten, twenty, or forty ounce measures, as well as all the dispensing measures, are included in this, and with all due deference to his authority, I will content myself by saying that possibly it *may* be so. Graduated measures kept in stock for sale only are not liable to inspection, though the authorities possess full powers to examine them if they suspect fraud, for the 48th section states that any person who neglects or refuses to produce for inspection all weights and measures in his possession, or on his premises, shall be liable to be fined. If our inspector is correct in stating that the dispensing measures are included, and must be stamped, then we know that the standard will be such as is given in the British Pharmacopœia. For my own part I believe that the dispensing measures are exempt, because it clearly states in the schedule "measures used in the sale of drugs."

I am far from complaining of these additions being made so long as they do not lead to persecution. It will be a great comfort to have an authoritative assurance that our measures are correct, that is presuming that the authorities accomplish this, and it will at least have one good result, and that will be to compel the makers of graduated measures to be more careful in their productions. But have not the public as great a right to be assured of the accuracy of the measures used by surgeons, analysts and others?

What I do complain of is, that when matters of this kind are made law, that red tape should supersede experience and practical knowledge, and thus be the means of producing unwarrantable anxiety, persecution, and costly litigation. Any able lawyer could make great havoc with the whole document. It is most incomplete, vague in the extreme, a masterpiece by some person who can write in such a manner that you may read two ways at once, and construe any way you like. An illustration of its incompleteness is shown in the fact that if it were necessary and intended to include the dispensing measures, why exclude the weights? And again, to abolish the apothecaries' weights, yet to grant permission to sell by them, and to exempt them from inspection.

The principal points I would call your attention to are—

1. That the Act comes into force on the first of January.

2. The avoirdupois dram and the additional grain weights.

3. The section which gives permission to sell drugs by the apothecaries' weight.

4. Are dispensing measures included ?

5. Is each measure to be graduated only to its one measure ?

6. The power given to the local authorities to make bye-laws.

7. When selling eau de cologne and other proprietary articles to remember that the bottle measures are abolished.

8. Also to remember that every proprietary or other article which is sold as being of a certain weight, such as a pound or half-pound tin or jar of anything, must be that precise weight.

I would also mention that you will find some useful remarks in the *Chemist and Druggist* of last month which will repay your attention.

Gentlemen, this is the first time that I have ever seriously attempted to master in all detail an Act of Parliament; if I have failed in construing it clearly it does not arise from any want of time or trouble, for I have spent a considerable amount of both upon it, but rather from the fact that the more I studied it the less definite it appeared to be in so far as it more especially affects our branch of trade.

At the conclusion of the paper, Mr. Payne, in answer to the Chairman, gave his opinion that the statement made by the President of the Pharmaceutical Society at the last Council Meeting in London, viz., "That the Board of Trade Department could not undertake the work of verifying and stamping glass measures," might be considered as describing the state of affairs, not only in London, but throughout the country.

After considerable discussion of the subject, a hearty vote of thanks to Mr. Payne, moved by Mr. W. Wilkinson and seconded by Mr. Geo. S. Woolley, was unanimously carried, great satisfaction being expressed at the light thrown on the whole question by the reader of the paper.

It was decided, on the motion of Mr. G. Wilkinson, seconded by Mr. E. Walsh, to recommend the Council to revise and reprint the Trade Price List.

The next ordinary meeting will be held on Wednesday, January 22, 1879, when Mr. J. T. Slugg will read a paper entitled, "The Shop Clock."

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The third meeting of the session was held in Anderson's College, on Wednesday, December 11, 1878, Mr. Alexander Kinninmont, President, in the chair. The minutes of the previous meeting having been read by the Secretary, and approved of by the members, the President called upon Mr. James M. Fairlie, Vice-President, to read a paper.

Mr. Fairlie apologized for not having his paper fully prepared as he had been confined to the house since coming from the last Council Meeting in London, but he said that he would give his thoughts in as connected a way as possible. He introduced his subject as pertaining to an amended Pharmacy Bill and other trade matters that had cropped up of late, which chemists and druggists ought to watch sharply. Mr. Fairlie gave a short epitome of his address to the electors of the Pharmaceutical Council when he placed himself before them as a candidate to represent their interests in that Council, and said that now having been elected he would say a few words on the character of the Council as a representative body of the trade generally. He thought that if the trade was to be represented in all parts of the country, Mr Frazer's scheme of territorial representation would be the best, for by its adoption members and associates in business throughout the country would know the gentlemen they were voting for, they would select them from their portion of the country, but as it was at present the voters generally did not know much of the candidates but through the Journal or from hearsay. Mr. Fairlie said that being a member of the Trade Association, he thought that in defending the case of Mr. Shepperley the Association had only done its duty, and as the case had been decided in favour of the chemists and druggists the result was so far good, but he would still advise the trade to resist the Apothecaries' Society in any new trial it might apply for, and to do so chemists as a body ought to subscribe sufficient money to carry a case to the highest court in the kingdom if required. Mr. Fairlie then touched on the case of the Apothecaries' Company *v.* Wiggins and its issue, also the position of co-operative societies in relation to the Pharmacy Act, on the sale of poisons by unqualified persons, and patent medicines by persons not chemists and druggists, also on the admission of unofficial reporters to the meetings of the Council to report the meetings for the various trade journals. Mr. Fairlie brought his remarks to a close by advocating provincial education in various centres throughout the kingdom, which should partly be subsidized by the funds of the Society, and said that if this could be carried out by making it imperative that young men should attend certain courses of study therein before being examined it would give a death blow to that odious system of cram which is so hurtful to the advancement of true scientific knowledge.

The President having invited discussion on the paper—

Mr. Robert Brodie said, with reference to counter prescribing that it was against all fairness to stop up the chemists and druggists' mouths from giving advice in simple ailments, when any old woman who knew nothing of drugs could do so, and also still to allow the quacks who are the vampires of the medical profession, throughout the country to do so.

Mr. Howie said that a great deal of apathy existed in the trade, and it was the cause of preventing true progress. He also thought that peripatetic lecturers in the various large towns throughout the country would do better than the establishment of permanent schools.

Mr. Kinninmont, the President, said that in any amended Pharmacy Act the case of the widows of pharmaceutical chemists and chemists and druggists ought to be carefully considered, and as to "stores," surgeons with dispensaries, and the promiscuous sale of patent medicines, he would let agitation alone, for he thought it might tend to spread the evil if the parties were prosecuted too rigorously. He also thought that in Scotland the proper party to prosecute evasions of the Pharmacy Act was the Fiscal, who would take the *onus* off the local secretary who generally disliked becoming an informer in the eyes of the public.

Mr. Fairlie was then awarded a vote of thanks for his paper.

Mr. Gilmour (Assistants' Section) moved that the Association should consider some means for obtaining rooms in which the members might often meet for mutual improvement, etc.

Mr. Kinninmont then gave a donation of books to the library, viz., Draper's 'Intellectual Development of Europe;' Dr. Carpenter's 'Physiology' and Tyndall's 'Fragments of Science;' for which he was awarded a hearty vote of thanks. The meeting then dissolved.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

A meeting of the above Association was held in the Albert Hall, on Wednesday evening, December 11, Mr. W. Ward, F.C.S., President, in the chair. There was a large attendance. In opening the meeting the President said, one of the principal objects in holding it was to take into consideration that much vexed and notorious question "the Shepperley prescribing case," which doubtless all present were familiar with. He was glad to see there Messrs. Cubley and Jervis, the two representatives of the Trade Association, who would be able to give them a

résumé of the doings of that now most important society. He could not refrain from expressing his great surprise at the recent action of the Pharmaceutical Council in refusing to grant a sum of money out of its accumulated wealth towards the expenses of the case now pending. Whilst highly esteeming some of those who had voted against the grant, he believed they had made a most fatal mistake, a mistake which as far as the country members were concerned would certainly tend to decrease their esteem and no less their support.

Mr. Cubley then advocated the claim of the Chemists' Trade Association upon the support of the local Association and said that it was fighting the battle for the chemists throughout the country. Already the trial had cost a large sum of money, and the Association would be in want of funds to maintain the case if it did not receive the support of the trade. He said that the full court had refused the Apothecaries' Company a new trial, but there still remained open for them the Court of Appeal and the House of Lords, all of which meant a large expenditure on both sides. He therefore moved that a sum of not less than £10 be granted from the funds of the Sheffield Association to the Chemists and Druggists' Trade Association, to be applied by them towards the expenses incurred in the case of the Apothecaries' Company *v.* Shepperley.

Mr. Jervis said that he endorsed all that had been said by Mr. Cubley, also that the ordinary business of most present would have been quashed if it had not been defended by the Chemists' Association. The case would finally be taken to the House of Lords. Baron Cleasby had taken up the case of the chemists and druggists from the first. Mr. Jervis hoped that all members of the Pharmaceutical Society would attend the next annual meeting and vote in such a manner as to show that they are not going to be crushed by the London members. As the Sheffield Association had no urgent need for funds at present, he could recommend it to grant a sum of money towards the Chemists' Defence Association of Great Britain.

Mr. Hudson thought that that Association ought to give something out of its funds, and proposed an amendment, which Mr. Cubley adopted, that the amount to be given be £15.

This proposition was supported by Mr. Maleham and carried.

Mr. Ibbitt asked if the Apothecaries' Company were finding the money on the other side, and the question was answered in the affirmative.

Mr. Ellinor moved the following resolution which was supported by Mr. Hudson and carried unanimously, "That this meeting views the action of the Council of the Pharmaceutical Society of Great Britain, in the case of the Apothecaries' Company *v.* Shepperley with very great feeling seeing that that Council holds a sum of money of upwards of £1000 subscribed for the very purpose of defending chemists and druggists against the Apothecaries Act, and most urgently requests the Council of the Pharmaceutical Society substantial aid towards the defence of Shepperley's case." In moving this resolution Mr. Ellinor said the time had now come when the action of the Pharmaceutical Society should be carefully criticised, and it was high time the country members should arouse themselves out of the slumber of indifference respecting the transactions of the Council, and editing of the Journal. With all due respect to the members of the Council, they had to look at the trade side of the question, and the fact that the Society according to the charter, lines twelve and thirteen, as published in the Calendar, was established to protect the trade. The worthy President and his followers in this matter did not deny that the subscribers subscribed the money, and by resolution the trustees handed over to the founders of the Society the money that caused the lines which he had quoted to be inserted in the charter, the money being handed over before the charter was obtained. It would require very little stretch of imagination to conceive that with the money was conveyed the obligation to carry out the conditions for using it for the purpose of defence. The Council ought to have defended Shepperley, or any chemist and druggist who might be assailed by the Apothecaries' Company, to the extent of the amount which it held, and added more, if necessary. The fact of the money being subscribed at the time, and for the specific purpose of opposing the 1813 and 1815 Apothecaries Acts, the result of which was the death of the 1813 Act, and the saving clause of the other, the residue being handed over to the Pharmaceutical Society before the charter was obtained, gave every chemist and druggist a right to expect the protection promised by the charter. The objection, according to the President, was the granting money to another body over which the Council had no control, but had the Society's solicitors been instructed there would have been no difficulty. The regret was that the Council did not defend Shepperley, and that neglect threw the necessity upon that other body. Although the editor has tried to strangle the subject, murder will out, and it would be ventilated, and they were justified in asking substantial aid in Shepperley's defence in the present prosecution.

Mr. Hudson next moved, "That the thanks of this meeting be given to the six gentlemen who supported Mr. Hampson's resolution," in which he was supported by Mr. Burnell.

The meeting afterwards had under consideration the Dental Act and the Weights and Measures Act.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting was held at the Room of the Association, Britannia Chambers, last Thursday evening. The chair was occupied by the President, Mr. R. FitzHugh, F.C.S., and there was a large attendance of members and associates.

After some preliminary business, the Hon. Secretary, Mr. R. Jackson, read a letter from the Secretary of the Chemists' Trade Association, acknowledging with thanks the handsome donation of £54 0*s.* 6*d.* from the chemists of Nottingham to the funds of the Association.

Mr. H. Major, B.A., B.Sc., F.R.G.S., then delivered an eloquent and instructive lecture on "The Deep Sea," the interest of which was considerably enhanced by a great number of beautiful objects which were dredged up from the bottom of the sea, in the expedition of H.M.S. "Porcupine," and which were kindly brought for exhibition by Mr. Dodd.

The lecture was listened to with great attention, and at the close hearty votes of thanks were awarded to Mr. Major and Mr. Dodd.

HULL CHEMISTS' ASSOCIATION.

The annual supper of the members of this Association was held on Wednesday evening, Dec. 11. There was a large attendance. The chair was taken by the President (Mr. J. Oldham), and the vice-chair by Mr. H. J. Parsons. Amongst those present were the Sheriff (Mr. R. M. Craven), Dr. Gibson, Councillor Fryer, etc.

The loyal toasts having been honoured, the President proposed "The Mayor and Corporation," and Dr. Gibson and Mr. Fryer briefly acknowledged the compliment.

Mr. Bell next proposed "The Sheriff of Hull," and in doing so congratulated Mr. Craven on his election to such an eminent and honourable office. The duties were very onerous and responsible, and the fact that the honour had not been for a long time conferred on the medical profession, which was allied to that of the chemists and druggists, was a special reason why they should congratulate themselves on the selection which the Council had made.

The Sheriff, in responding, said his desire was to do as

much public good as he could. It gave him very great pleasure to meet so many who were so closely allied to his profession. The medical profession was very much dependent upon the chemists and druggists for the purity of the ingredients required for patients.

Mr. E. Allison proposed "The Town and Trade of Hull." After all that was said, he remarked, about the town of Hull, it went on improving. There was plenty of trade, but profits were less. With regard to their own trade, he said that as a rule they were all gentlemanly and sober men. Every druggist had three scruples before taking his dram. He had always a scruple about the cost, then a scruple about the contents, and then he had a scruple about the consequences. With reference to the first scruple, it was the worst paid trade in the country, as compared with the cost and labour in preparing for it. The fact was that the law would not allow a fool to be a druggist. Druggists were intelligent by Act of Parliament.

Mr. Escreet responded.

The Sheriff proposed the toast of the evening, "The Hull Chemists' Association." He was informed that there were fifty members. Recently, he thought, a very great many more had been made. Formerly any one could be a chemist, but now a person must be properly qualified. Nothing could tend more to elevate the profession than that they should be able to satisfy the requirements of an examination. He hoped the day would come when gentlemen in his profession would cease to have anything to do with dispensing drugs. They really did not profess to charge for the medicines, but the advice, yet somehow or other in this country it was the custom for the practitioners to send out medicines. It required time for changes to take place, and he looked forward to the period when the medical profession would be divorced from dispensing. At the same time, druggists should in no way act as practitioners.

The President acknowledged the toast. He hoped the time alluded to by the Sheriff would arrive. On the matter of education he thought the Association might take credit for what it had done for the young men connected with the trade.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting held on Wednesday, December 11, at 32A, George Street, Hanover Square, the chair being occupied by Mr. F. W. Branson, Mr. O. Wallis read an interesting paper entitled "Notes on the Natural Order Ranunculaceæ."

After alluding to the extensive nature of the order, the author proceeded to explain its chief distinctive characters. The principal species of all the British genera were then described, their botanical distinctions pointed out, and their history, uses, and habitats enumerated. The official plants of the order, also Stavesacre, *Actea racemosa* and *nigella*, from having been used medicinally, were included in the descriptions. The notes were illustrated by splendidly mounted specimens, kindly lent for the occasion by Mr. G. C. Druce, of Northampton. Mr. Wallis concluded by expressing his belief that the study of our common British plants, by the instruction and amusement they afford, well repays the student for time and trouble expended. The paper was followed by a short discussion, and after votes of thanks to Mr. Wallis and the Chairman, the meeting terminated.

Parliamentary and Law Proceedings.

The Sale of Violet Powder.

On Thursday, Mr. Lund, chemist, of Rosemary Road, Peckham, appeared at the Lambeth Police Court, in answer to an adjourned summons for having sold violet powder in an adulterated condition.

Mr. Marsden prosecuted on behalf of the Vestry.

Upon the first hearing the analysis of Dr. Bernays showed that the powder purchased by Inspector Sedgley consisted almost entirely of sulphate of lime or plaster of Paris, and was not fitted for the purpose to which it is usually put.

Mr. Chance said he was hardly satisfied as to what violet powder really should be, and the matter was adjourned until yesterday.

Dr. Bernays pointed out that it had been deemed necessary such an article should be considered a drug. It was being constantly used as an outward application for children. The best chemists in the kingdom sold "violet powder" made of pure starch scented by orris root. The object of violet powder was to prevent irritation and absorb moisture. The article in question would not answer that purpose, but might possibly be used hundreds of times without injurious effect.

The Defendant said it was not the powder he sold generally. It was some sent in packets from a firm, and having a showy sort of cover he had put it in the shop window. The powder he sold as a rule was pure.

Dr. Bernays examined some of the latter and said that was so.

The Defendant said he first gave the Inspector some of this powder, but as he said it was not enough he gave him the packet from the window.

Inspector Sedgley said the defendant remarked, when he knew the powder was to be examined, that he would sooner sell some of his own make, as he knew nothing of the nature of the other.

Mr. Chance said the inference would be drawn, if the packet was in the window, it was for sale. He only, however, called upon the defendant to pay 12*s.* 6*d.* costs, and advised him not to sell such packets again.

Prosecution for Selling Methylated Laudanum.

On Wednesday, December 11, at the Nottingham Town Hall, before Alderman Barber and Mr. Cox, Richard Cant, chemist, Sussex Street, was charged at the instance of the Excise authorities with being illegally in possession of certain methylated laudanum and paregoric elixir.

Mr. Langley, supervisor of Excise, said he visited the defendant's shop, and he there found a quantity of the articles named, which defendant at first said he had prepared, but afterwards stated had been left by the former occupant of the shop, and he (defendant) was now getting rid of them among his own stock.

Mr. Thorpe, who appeared for the defendant, pleaded guilty, but urged that the circumstances of the case were such that the Bench, who had no power to mitigate the full penalty of £100 lower than one-fourth, would see their way to a recommendation for a further reduction by the Inland Revenue. The Bench fined defendant in the mitigated penalty of £25.

In reference to the above report, which appeared in the *Nottingham Daily Guardian*, Mr. Richard Widdowson has written to that paper denying, as the person referred to as the previous owner of the shop, that he ever had in it "an ounce of methylated laudanum, paregoric, or any other preparation."

Dispensing Memoranda.

[173]. Having read the correspondence which has appeared in the Journal relative to the mixture over which Mr. H. Brown has spent such extra trouble, I am entirely of the same opinion as Mr. L. MacMillan, Mr. Barnes, etc., that the mixture should not be strained. I cannot think any ordinary pharmacist would require to be

told that on heating the mixture it would become clear, but the value of such an operation in the case alluded to is to me not quite so apparent, and will require some little further elucidation from Mr. Brown before it will be adopted in any similar case by any West End pharmacist.

R. J.

---

[173]. I think if any one has paid even a modicum of attention to the various comments under "Memoranda" and signed by me, he will not require to accuse me of taking "unwarrantable liberty" with any prescription. In the matter of compounding I am able to take care of myself, and Mr. J. L. MacMillan's remarks as to precipitates chemically imcompatible but not therapeutically inert, may be passed over. We all know they are not inert. If Mr. J. W. Barnes had spent as much time over the hydrobromic, bismuth, and iodide of potasium mixture, he would not condemn me for seeking to send out an incompatible mixture in the most presentable form; and I think "elegant pharmacy" is to be commended and not despised, and I, as a medical man, always aim at "elegant pharmacy." I well know how my patients appreciate such. A word or two in regard to the mixture of ammon. bromid., ammon. carb. and spt. camph., as given at the end of Mr.Barnes's remarks, p. 460. I at once say Mr. Barnes would not be justified in straining out the camphor. But the question now arises, how is a patient to get a proper dose of such mixture, seeing that, no matter how made, the bulky and flocculent precipitate rises so quickly, after agitation, that almost the whole is at the upper end of the bottle in a few seconds? Now, to obviate this, I think a pharmacist would be justified in sending out such a mixture in, say, six one ounce bottles; but Mr. Barnes does not give the dose. I defy any man to measure an accurate dose of such mixture when in bulk. No doubt a little more would have to be charged for the extra trouble. I therefore look upon such a mixture as one which should be sent out in doses, and the medical man who ordered it, if explanation to him was required, would commend the pharmacist for his "elegant pharmacy" and profit thereby.

I also maintain there would be no interference with the prescription. Some one will say "then all mixtures containing precipitates or flocculent material should be dealt with in the same way." I say no. Camphor and benzoic acid and a few other insoluble or partly soluble matters are exceptions. Mixtures of bismuth and magnesia allow time for measuring, but camphor will not in a purely watery mixture.

I well know the ground is debatable upon which I have trodden, and I should like a little temperate discussion upon it. I could say much more, but for the present refrain.

Northallerton. HENRY BROWN.

---

[173]. I am sorry to say as yet I have gained no information whatever from *any* of Mr. Henry Brown's remarks on the subject of this presciption. I am perfectly well aware of the action of heat and acids on the precipitate, and I think if the said prescription were dispensed by twenty different individuals, nineteen out of the twenty would not use heat or strain through tow. Mr. Brown seems to study appearance rather than the action expected by the medical man, as he states the mixture after being heated to 130° F. and strained through tow if necessary *is tolerably presentable.* I am glad to find one or two coincide with my views, and do not entirely study appearance but endeavour to give satisfaction in *every* respect to prescriber and patient.

As I was the writer of the few lines signed A. P. S., I may as well subscribe myself in full, so as to give Mr. Brown the opportunity of sending me any useful information he may feel disposed on the subject, as I am aware this part of the Journal is not intended for arguments.

9, *Wellington Terrace, Bournemouth.* H. BARTLETT.

[188]. I should have dispensed the prescription as written, which would give about gr. vi. potassæ bicarb., gtt. ii. vini ipecac. and gr. ii. mag. carb. in each dose.

I presume, as T. H. N. says that he sent out ℥iss as the double quantity of the mixture, that he read the prescription aquæ ad ℥vi. instead of aquæ ℥vi., which would make up the double strength to a ℥ijss mixture, as intended by the prescriber.

W. F. N.

---

[194]. "Apprentice" asks for an excipient to make ferri sulph., ℥iss, pulv. quassiæ, ℥ij, into a small bolus. There ought to be no difficulty in administering to a horse a two ounce ball; but if a small one is preferred "Apprentice" will find by referring to Squire's 'Companion' that forty ounces quassia wood yield one ounce extract, therefore three grains extract would equal two drachms powder. An equivalent proportion of dried sulphate of iron could also be substituted for the ordinary sulphate. Glycerinum tragacanthæ is the most suitable excipient.

SUB UMBRA FLORESCO.

---

[196]. Sulphate of magnesia is soluble in cold water, ten in thirteen, and measures eighteen; there is not therefore a sufficient quantity of water in the mixture to dissolve it. Llet was justified in doubling the bulk, and labelling ℥ss dose. I should have acted similarly in such a case.

SUB UMBRA FLORESCO.

---

[198]. If properly dispensed this cannot be made up to have a clear appearance, as all cinchona preparations separate more or less when mixed with water, that of liq. ext. cinch. B.P. especially. This mixture should certainly have a "shake the bottle" label, which would indicate that the deposit or sediment is to be taken, and that no fault rests with the dispenser in its preparation.

J. W. BARNES.

---

[199]. I should label "One tablespoonful three times a day."

SUB UMBRA FLORESCO.

---

[199]. In reply to your querist, Mr. J. W. Barnes, with regard to the interpretation of "cochlearia amplum," I think it is a *lapsus pennæ* on the part of the prescriber, and if he cannot be consulted with I should prefer giving the patient the benefit of the doubt and order a tablespoonful for a dose. If this were intended—and I should say it was—there is only a grammatical error in the termination of cochlearia (which should be cochleare); but if we assume two tablespoonfuls for a dose, there is the absence of the word "duo," which would likewise disagree with "amplum."

ROBERT ROE.

---

[199]. I think the direction should be one tablespoonful. The question one or two would not be decided by simple correction of the grammar, for had the adjective been written to agree with its substantive in the plural it would not necessarily mean two, but might indicate any number from two to infinity; and I think that no prescriber, literate or illiterate, would attempt to describe any definite number by a simple plural termination without indicating the precise number by a numeral. It is just possible that Pliny's term *cochlearium* was intended to be written, the final "m" degenerating into a mere stroke, and if written rapidly might seem the plural. Or the plural terminination of the substantive may have been a mere *lapsus*, as though one had writen in English "one tablespoonfuls." Or it may be sheer ignorance of Latin declensions and concords, which would by no means render this case unique; for many medical men, some of considerable pretensions, attempt Latin *in extenso* to their confusion. Language in full should be clearer than contractions, but in this instance it is scarcely satisfactory

to reflect, the too familiar contractions "cochl. ampl." would have left no doubt upon the mind of the dispenser.

Ryde. HENRY H. POLLARD.

---

[199]. Mr. J. W. Barnes asks a question which it is most difficult to answer. The Latin of the prescription is bad, and no physician should append his name to it. Capiat cochlearia amplum ter die." Mr. Barnes asks: "Which is correct, to say two tablespoonfuls by the plural (*cochlearia*) or one table tablespoonful by the singular (*amplum*)?"

Now, *cochlearia* may mean three instead of two, or any number more than one; it would be waste of space discussing this further, and therefore if I were a compounder and, knowing the effects of salicylic acid upon some individuals, I should write "one tablespoonful," so as to keep on the safe side, and allow the physician to rectify his own bad grammar at his next visit, if need be.

Northallerton. HENRY BROWN.

---

[200]. Can any one inform me the best way to dispense the following? –

℞ Spt. Camphoræ . . . . . ℥j.
Liq. Ammon. Acetat. . . . . ℥iv.

J. B. G.

---

[201]. In the following prescription, what should be used for sol. perchlor.? It was dispensed with liq. hyd. perchlor. ℥j.

℞ Sol. Perchlor. . . . . ℥j.
Pot. Iodidi . . . . . ℥ij.
Aq. . . . . ad ℥xij.
M. ℥j. ter die.

J. T. B.

---

[202].

℞ Olei Lini . . . . . ℥j.
Balsam. Styracis . . . . . ℥iij.
M. fiat linim.
Signa "The Liniment."

The above is an exact copy of a prescription presented for dispensing.

Will any gentleman like to suggest the most suitable meth d of preparing it, and his probable charge for the same?

November 18, 1878. DELTA.

---

[203]. The following was dispensed at two London houses; in one case it was sent out colourless, in the other with the usual colour of iodine :—

℞ Sodæ Hyposulphitis . . . . . ℥j.
Aquæ . . . . . ℥j.
Dissolve and add :—
Tr. Iodi . . . . . ℥iij
Colourless Oil of Tar . . . . . ♏xx.
M. ft. pigment.

Now ℥iij of tincture contains 32·4 grs. of iodine, and this amount should require 63·26 grs. of hyposulphite, instead of 60 grs. as ordered. Should the extra quantity be added or should the prescription be dispensed as ordered, there being no clue to the intention of the physician? I think the latter. H. A.

---

[204]. A "tyro" would be glad to know the best way of dispensing the following prescriptions :—

℞ Ext. Coloc. Co. . . . . gr. iiss.
„ Aloes Socot. . . . . gr. j.
„ Belladonnæ . . . . . gr. ⅓.
Ol. Menth. Pip. . . . . ♏ j.
M. ft. pil. Mitte, vj.

---

[205].

℞ Bismuth. Subnit. . . . . ℥ij.
P. Tragacanth. . . . . ℥ij.
Acid. Hydrocyan. Dil. . . . . ♏ xij.
Aq. Rosæ . . . . . ad ℥ xij.
M. W. BAKER.

---

[206]. The lady to whom the following prescription belonged said that it ought to have a precipitate at the bottom of the bottle which should be very hard to remove. This was not the case when I made it and it was too light coloured for her. Will any one through the medium of the Journal tell me if I was right or wrong?

℞ Tr. Benz. Co. . . . . ℥i.
Syr. Tolut. . . . . ℥i.
P. Trag. Co. . . . . ℥i.
Tr. Scillæ . . . . . ℥iij.
Nepenthe . . . . . ℥iss.
Aquæ . . . . . ad ℥viij.

First I made an emulsion with the p. trag. co., then added the tr. benz. co., next syr. tolu., then tr. scillæ, lastly, nepenthe. Would some alteration in the mixing make a difference?

C. P.

Notes and Queries.

[544]. REMOVAL OF FRECKLES.—In answer to "Gentian's" query in your last number, respecting sun freckles, the following lotion may advantageously be used :—

℞ Liq. Potassæ . . . . . ℥j.
Aq. Rosæ . . . . . ℥ij.
M. fiat lotio.

E. A. REILLY.

---

[545]. PEPSINE WINE.—

℞ Pepsin. . . . . ℥ij
Aq. Destill. . . . . ℥j
Sacchar. Alb. . . . . ℥x
Sp. Vini Rect. . . . . ℥iv
Vin. Xerici . . . . . ℥viij.
M. s. a.

W. M.

---

[545]. PEPSINE WINE.—Not being able to find a good formula for pepsine wine, I have made it as follows :—

℞ Pepsin. Porci. . . . . gr. 400.
Marsala . . . . . Oj.
Syr. Simpl. . . . . ℥ij.
Spt. Tenuior. . . . . ℥iij.

Macerate with frequent agitation for fourteen days, and filter.

From this form a satisfactory result is obtained, and I can recommend it to Mr. Ness.

Each fluid drachm of the wine is equivalent to two grains of pepsine, and a dose of from one to two teaspoonfuls equals the pharmacopœial dose of that substance.

CHARLES B. ALLEN.

---

[545]. VIN. PEPSINI.—In order to establish uniformity of strength and composition, the formula of this preparation, now so extensively used, should be admitted into the new edition of the Pharmacopœia. At present various processes are adopted for its manufacture; some chemists digest pepsine with sherry, spirit, and water; others with sherry and acid; others employ pepsina porci or pepsine de Boudault; whilst another class, for the sake of the extra profit, prefer by donning apron and sleeves, and converting their back shop counters into butchers' benches, to cut up the stomach of a calf, and digest for a few days in a quart of sherry.

The formula given in the Pharmacopœa Germanica yields a highly satisfactory result. It is made "by mixing 100 parts of the mucus from the stomach of an ox, with 50 parts of glycerin, and 50 parts of water, adding 1000 parts of good white wine, and 5 parts of hydrochloric acid, stirring well, and allowing the whole to macerate at 20° C. for three days, with occasional stirring, and afterwards filtering." Recipes have from time to time ap-

peared in the *Pharmaceutical Journal*, and can also be found in almost all 'Druggists' Receipt Books' and 'Pocket Formulæ.'

SUB UMBRA FLORESCO.

[547]. SYR. CROTON. CHLORAL.—Wanted, a recipe for producing this syrup of the strength of two grains in each fluid drachm.

SUB UMBRA FLORESCO.

[548]. TINCT. JABORANDI.—What is the best formula for tinct. jaborandi?

H. CLARKE.

[549]. LIN. STOKES.—I have been unable to find in any receipt book the formula for this liniment, so extensively prescribed by the the late Dr. Stokes, of Dublin. It is still ordered by some medical men. The following is a copy of a prescription frequently written by a Belfast physician:—

℞ Lin. Stokes . . . . . ad ℥iij.
Acid. Acetic. Glacial. . . . . ℥ij.

M. ft. linimentum, applicand regionem pectoris mane, meridie et nocte, et inhalatio ut directa.

The inhalers of Nelson, Maw, and other makers have been offered by chemists to these patients, but they invariably reply "that the doctor told them to shut their eyes, open their mouths, and draw in their breath during each application." Could any reader oblige with the original recipe, and state if this was the manner in which the late learned doctor ordered its use?

SUB UMBRA FLORESCO.

[550]. SYR. FERRI DIALYSAT.—What are the proportions of liq. ferri dial. to syrup required to make syr. ferri dial.? I find the latter occasionally ordered in prescriptions. Is simple or aurant. syrup the best medium?

PULV. OPII RECT.

[551]. CARBOLIC ACID VERMIFUGE.—Can any of your readers favour me with a formula where acid. carbolici is prescribed as a vermifuge?

I. W.

[553]. CHILBLAIN LINIMENT. — I should be obliged for a formula for Chilblain Liniment of elegant appearance.

W. M.

Obituary.

JAMES ROBERTSON.

We have to notice in our obituary of this week the death of James Robertson, of 35, George Street, Edinburgh. Mr. Robertson was registered as a Pharmaceutical Chemist in 1852, his connection with the College of Surgeons, of which he was a Licentiate, having prevented his joining the Society before that date. He was the oldest surviving dispensing chemist in Edinburgh, having reached the ripe age of 79. Mr. Robertson was elected President of the North British Branch in 1856 and again in 1858, in consequence of a serious attack of illness having interfered with his official duties during the first year. He was also appointed, together with Mr. J. F. Macfarlan, the Society's representative on the Scottish committee for preparing the British Pharmacopœia.

When quite young he came from Perth with the late Mr. John Duncan, on his commencing business in the North Bridge under the firm of Duncan and Ogilvie, which afterwards merged into that of Duncan and Flockhart. After remaining in Edinburgh for a few years, Mr. Robertson left for Jedburgh to found the dispensary which has been successfully carried on ever since and where he continued seven years. About 1831 he returned to Edinburgh and commenced business in 35, George Street, which he has there successfully prosecuted ever since.

Although Mr. Robertson never took a prominent part in public affairs, he was very highly esteemed as a private citizen. He was, we believe, twice married, and leaves a widow and one son who is not connected with our profession.

Notice has also been received of the death of the following:—

On the 5th of October, 1878, Mr. George Fisher Sinclair, Chemist and Druggist, High Street, Dumfries. Aged 36 years.

On the 19th of November, 1878, Mr. John Paterson, Chemist and Druggist, Victoria Park. Aged 58 years.

On the 23rd of November, 1878, Mr. William Henry Waterton, Chemist and Druggist, Darnall. Aged 33 years.

On the 30th of November, 1878, Mr. William Gallard, Chemist and Druggist, Child's Hill, Hendon. Aged 65 years.

On the 1st of December, 1878, Mr. John Evans, Chemist and Druggist, Bethesda. Aged 35 years.

On the 12th of December, 1878, Mr. George Wright, Chemist and Druggist, Birmingham. Aged 56 years.

On the 14th of December, 1878, Mr. John Pogmore, Chemist and Druggist, Leigh, Lancashire. Aged 57 years.

On the 15th of December, 1878, Mr. Alfred Bird, Pharmaceutical Chemist, Worcester Street, Birmingham. Mr. Bird had been a member of the Pharmaceutical Society since 1842.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

APOTHECARIES' SOCIETY *v.* SHEPPERLEY.

Sir,—I have hitherto been disposed to approve of the position taken by the Council, and havo inferred, doubtless with many others, that there were good and sufficient reasons for not undertaking the defence of the Shepperley case.

But having regard to this case as stated in court, the fact of its not being defended by the Council appears to me to be as inconsistent with the intention expressed by the resolution passed by the Council on the 7th of October, 1876, as it is with the statements made in the letter from the Solicitor of the Apothecaries' Society, published in the proceedings of the Council, February 9, 1878.

This inconsistency may be only apparent, but it is being used to the disparagement of our Council no less than the Apothecaries' Society, and if it can be explained that should be done at once, for the satisfaction of other members of the Society besides myself.

M. P. S.

[*** We understand that the case was not conducted by Mr. Upton, but by others, who had obtained authority—it may be presumed. Indeed it cannot be doubted that Mr. Upton wrote in good faith when he, in February, said, "I am prepared again to affirm that in the few years during which I have acted as Solicitor to the Society I have not authorized any prosecution in a case of pure and simple counter practice, and that I shall not do so so long as I have the honour to hold that office, and I think you may accept this, not only as the course which I should personally pursue, but as the policy of the Society." That statement leads to the supposition that the authority was given upon information which was not supported by evidence at the trial. The plaintiff's case, as shown in court, was so extremely weak that it is fair to speak of it as a breakdown. It is a

frequent experience that the witnesses called at trials do not support the information on which the proceedings were launched.—Ed. Ph. Journ.]

Sir,—The report of the proceedings of the Pharmaceutical Council as touching the above important case, published in the Journal of last week, will be read by the vast majority of pharmacists with mingled feelings of regret and indignation. First, regret that gentlemen (highly and deservedly respected by their fellow chemists for pharmaceutical knowledge and skill) should feel it their duty to persistently and dogmatically decline support to measures which have for their aim the protection of trade interests, and indignation that the same gentlemen should be found occupying seats at the Council Board.

It seemed to savour a little too much of conservatism when the Society at Bloomsbury Square sought to throw cold water upon the formation of the Trade Association, an Association founded upon a basis in no way antagonistic to the former, but intended by its promoters as an adjunct, rather than a rival; although owing to the palpable and unqualified refusal of the Pharmaceutical Society to protect various trade interests, the Trade Association has come naturally to the front, and undertaken the defence of cases instituted by different discontented parties.

But it should be remembered that it has only taken upon itself this responsibility in consequence of the authorities whose duty it was declining it.

So that here we have two societies, one (composed of chemists living in every part of the United Kingdom) seeking by every possible means to defend the vital interests of the trade, the other (although existing under and possessing parliamentary charters) ignoring the community through whom it has been placed in its present position, and simply content with acting as a mere machine by means of which certain Acts of Parliament are put in force.

All honour to the former, which in spite of adverse circumstances and recent growth has so successfully defended and maintained our position, and shame to the latter, that it should have, by a wavering and inconsistent policy, forfeited its right to the support and loyalty of its members.

Now that we have had the Shepperley case finally decided in our favour by the Court of Appeal, though I am fain to believe that it will be a disappointment to the members of the Council who opposed Mr. Hampson's resolution, it will be our duty as pharmacists to accord to the Trade Association our hearty support, and seek to have the trade more efficiently represented in the Council room. Means will doubtless be instituted before the next election of councillors to have this matter thoroughly and satisfactorily settled.

Cromwell Road, Sam Johnson.
South Kensington.

Sir,—I gather from the Journal that a meeting of the members will be called in London to discuss the vexed question whether aid should be given the Chemists and Druggists' Association in the Shepperley case. I do not offer an opinion, but would suggest that voting papers be sent to all the members, signifying their approval or the contrary, and save the expense of a journey to London at this inconvenient and inclement season. I feel sure it would give great satisfaction to the country members and be the means of causing unity. I must confess I should feel sorry to see any electioneering spirit raised, and perhaps some of the members, who have so long laboured for the advance of the educational part and who, I believe, wish the trade to be raised higher in status and successful, thrown out of the Council, or even an attempt being made to do so. But though educating and training the mind is highly commendable, they will bear in mind we in the country cannot live by pharmaceutical training alone, and I should very much like to see a true and correct report of the Council meetings recorded without the use of the pruning knife. I cannot see what good can arise from secrecy, unless, like many others, they are ashamed in their cooler moments of what has passed. It would be better reported if thrown open to both journals; the number of applications for membership would very much increase, and do another good thing, remove all cause for so many letters and explanations afterwards.

106 *and* 108, *West Bar,* Fretwell Hudson.
Sheffield.

[*** In reference to the suggested application of "the pruning knife" to the reports of the Council meetings in this Journal, we must again state that they do not undergo any such process.—Ed. Ph. Journ.]

Sir,—The ominous letter of your able correspondent "Nemo," ought to make many ponder with him upon the advisableness of abandoning the Pharmaceutical Society to its doom.

It seems this gentleman, having gallantly fought and vanquished the Preliminary, felt in his heart a laudable yearning to bestow his distinguished patronage upon the Society, and having "waited until cash was a little more plentiful" was about to rashly speculate the sum of ten and sixpence sterling, when the inopportune action of the Council caused his mind to waver in its high resolve, and the stimulus thus unwittingly imparted to a budding genius ended in the sublime discovery of the "great bone of contention,"—a curiosity having perhaps some connection with that famous weapon wherewith Samson accomplished great things.

How exasperating to reflect that the wicked carryings on of the Society's officers have, may be, deprived pharmacy of the mental and pecuniary support of one so successful in osteological research, and, apparently, not likely to be hampered, in his scramble up the pharmaceutic tree, by an excessive load of foolish modesty.

The loss, however, of one "Nemo" might be endured, but let the Council beware, for like the "great unwashed" we are a numerous race, and not to be flouted with impunity, and although most of us are mute and inglorious, we are none the less upon revengeful thoughts intent.

To assist in saving the Society from making shipwreck, through ignorance of our influential existence, I have benevolently condescended to add this codicil to the will and testament of my brother "Nemo."

Nemo 2.

Sir,—I was glad to see both Mr. Feltwell and "Nemo" taking up the action of the Council regarding the Shepperley case. My experience of the drug trade has been confined to the provinces and although a fair amount of dispensing has fallen to my lot, I must say that my employers have had to depend principally on prescribing for their returns. At the present time the question arises, Are we to be deprived of this means of livlihood? The Council at all events seems anxious for us to do so. For two years I have subscribed to the Society, but with "Nemo" (whose letter, notwithstanding the editorial remarks immediately preceding it, shows some very good sense), I do not intend any more of my money to go to the "Square" until a Council is elected that will consider the interests of country as well as town chemists.

It would be well for the Council to remember that we are losing valuable men yearly through its action. Two gentlemen of this neighbourhood have left the trade for the medical profession; very little more time and money being required for the latter, and the reward being much greater. Two gentlemen of my own acquaintance have recently passed the "Minor" at a cost of about £100 each, and now they are remunerated with £40 a year as assistants.

"Nemo" is right; if things continue as they are, the sooner he, and all other young men who desire to get on in life, are out of the trade, the better.

The profession of the "quack doctors" or herbalists (who are not prosecuted for prescribing) is almost preferable to that of the 1878 chemists and drugggists.

Clown, Chesterfield. Fred. Hinds.

A Jeremiad.

Sir,—The future of pharmacy and its followers portends towards ruin and starvation if we may judge by the present, there is much of grief to be borne and little of pleasure to compensate; the greatest spirit of firmness on the part of all chemists will be required to meet "breakers ahead;' conciliation possibly may be genteel, but as the world s selfish, sentiment of fine feeling and reciprocity will have to be cast away. The prescribing chemist is not affected merely by his inability to charge for medicine, giving gratuitously advice that might be paid for also, but he will be the dolt of society, for whilst he is intelligent, from experience and education, he will be placed lower in the

social scale than the most illiterate quack, who will both look at your throat and give a remedy for almost every complaint; it appears that chemists only are to be proscribed for prescribing. Our legitimate usefulness is at stake. The captain of a vessel may physic his crew, the parent her child, the parson his flock, and so on, but the man who really ought to know more than any outsider must be fined or desist. Again, our friendly intercourse with those who visit us (not those visited) will be nipped in the bud and our apparent stupidness take its place; for I may not open my mouth to pour forth my skill; I must be a dumb dog and blind, for I may not even look down a throat. Again I am affected seriously thus, I, a countryman and M.P.S. by examination, am an anomaly, a contradiction. I sought the "Square" at great inconvenience and passed so that I might be supposed to know something. My knowledge is a "tinkling cymbal" and a mockery, if I may not use it for the benefit of humanity and my future prosperity. I advise young men to pause ere they embrace a profession so fraught with trouble as is mine, to keep away from the Square until its Council becomes more sympathetic and ready to back them in their endeavours.

My enemy of higher grade, the vulture who would see me perish that he may peck the marrow from my bones and thus grow fat, cares little for his own dignity or the people's sufferings; it is not the heart string but the purse string that is at the bottom of the doctors' persecution. If I am to live by selling salts and senna my already scraped form will sink into a skeleton's grave. But I have the spirit of hope and defiance still, and my last kick will be at any unjust law that will make one section of mortals rich at the expense of the other. I shall give advice at my discretion and physic to all who show their wisdom by asking for it, never visiting the afflicted nor afflicting my visitors with ought not likely to heal them, nor with a doctor's bill that is the bane of many and the death of not a few.

AN OLD BIRD.

DISPENSING AT CO-OPERATIVE STORES.

"*Dispensing at Co-operative Stores.*—The practice of having prescriptions dispensed and purchasing drugs at co-operative stores is so rapidly growing that it becomes necessary to ask whether due care is taken to secure the services of qualified persons to conduct this portion of a very flourishing business. Drugs are not articles of consumption which it is safe to cheapen beyond reasonable limits, and in the dispensing of prescriptions skill must be engaged, which it is impossible to obtain except at a fair salary. We do not, observes the *Lancet*, make any imputation on the quality of the medicine sold at stores, or impugn the qualifications of those who dispense them, but the matter is clearly one to which it is desirable to draw attention. The licence of the Apothecaries' Society for assistants, or the certificate of the Pharmaceutical Society, must, of course, be held by the dispensers engaged at these stores, and we think it is highly desirable, if not imperative, that this part of the establishment should be placed on a separate footing as regards the selection and testing of goods before they are distributed to the public. There can be no difficulty in adopting all necessary and expedient precautions in the conduct of this strange trade, seeing that the profits made by our amateur tradesmen are enormous."

Sir,—The above cutting is from *Public Opinion*. I think the *Lancet* might go a step further and recommend them to have a consulting room and a doctor on the premises. I also send by this post our local paper, which contains an extract from the *Daily Telegraph* on co-operative stores. I may mention that I have been called out of bed three nights during the past week to make up medicines and plasters for a customer of the stores, and this very same person sent 16 oz. liq. vol. c. c. supplied by stores for me to exchange only a short time back. I expect they ordered ammonia instead of spt. am. co. We are served in this way by lots of people; they come to us in cases of emergency and send away to the stores for their ordinary requirements.

December 16, 1878. GEORGE BROWN.

ALLEGED TEST FOR METHYLATED CHLOROFORM.

Sir,—In your Month for the 16th ult., you observe "the difficulty of distinguishing between methylated and pure chloroform has recently attracted some attention, and the following test proposed by Mr. H. W. Langbeck is therefore worthy of notice. Ten volumes of the suspected sample are mixed with one volume of a solution of nitrate of silver, containing 1·7 (per cent.?) of the dry salt, and the mixture is allowed to stand for twenty-four hours. After the lapse of this time, the line of contact of the two liquids has assumed a faintly reddish-brown colour, and a reddish-brown precipitate of silver oxide is formed, more or less abundantly, according to the proportion of methyl present."

It seems almost surprising that this test was thought worthy of notice, when even Mr. Langbeck himself admits that a sample of "methylated" examined by him gave the reaction of "pure" chloroform. It would no doubt be highly interesting if some means were discovered of proving from what source a particular chloroform had been prepared, but whether the test in question effects that object may be conclusively decided by the results of the experiments which I here note. The samples are arranged according to the amount of precipitate present, the chloroform employed in each case being the commercial chloroform of Messrs. J. F. Macfarlan and Co.

1. Chloroform from alcohol.
2. ,, ,, ,,
3. ,, ,, meth. spirit.
4. ,, ,, alcohol.
5. ,, ,, meth. spirit.
6. ,, ,, ,, ,,
7. ,, ,, alcohol.
8. ,, ,, ,,
9. ,, ,, meth. spirit.
10. ,, ,, ,, ,,
11. ,, ,, alcohol.
12. ,, ,, ,,
13. ,, ,, meth. spirit.

No. 1 exhibited considerable traces of argentic oxide, while the others showed a gradually decreasing quantity down to Nos. 12 and 13, which were free from colour.

I believe it will now be admitted that argentic nitrate as a test for distinguishing the so-called methylated chloroform from that prepared from pure alcohol, is without value and utterly worthless.

December 5, 1878. D. B. DOTT.

THE ADULTERATION OF CARDAMOM CAPSULES.

Sir,—It may be of service to some of your readers, who retail cardamoms, if we call attention to their extensive sophistication with dried orange pips. We have recently found them to be admixed to the extent of from 6 to 8 per cent., and in that quantity require careful inspection to detect their presence.

POINGDESTRE AND TRUMAN.

187, *Newington Butts, S.E.*

LOOK TO YOUR GONGS.

Sir,—Many of us are in the habit of leaving our shop for dinner and trusting the gong to announce any one coming in. I would, by relating how I was the other day victimized, warn all those adopting the plan. Two young respectably and similarly dressed fellows came in, one after the other, for small purchases, and between them, emptied my till of its contents. Our conception of their plan is this:—No. 1 comes in to take stock and then No. 2 enters and before my assistant could reach the counter, slips down the bolt of the gong, a few minutes' quiet then enabled them to again enter and carry out their sneaking trick undetected.

SURBITON.

S. P. S.—Brilliantine may be made by dissolving castor oil in eau de cologne (1 in 4). Other recipes may be found by reference to the indexes of past volumes of this Journal.

W. H. Edwards.—The preparation may be made by dissolving the alkaloid in oleic acid to form an oleate, and then adding it to the cod liver oil. See a paper by Mr. Stiles, *Pharm. Journ.* [2], vol. v., p. 641.

F. A. Barrow is recommended to address his inquiry to Dr. Tidy.

E. Freeman.—A solution of permanganate of potash.

"*Quæsivi.*"—The question has been inserted more than once recently without eliciting a satisfactory reply.

J. R. Y.—Recipes for Composition Powder, which is possibly what you mean, have been already given several times.

COMMUNICATIONS, LETTERS, etc., have been received from Meesrs. Pepper and Co., Bennett, Jones, Hicks, Perkin, Parsons, Stenhouse, Shillcock, Hudson, Nuthall, J. T. B., E. K. C.

"THE MONTH."

At this time of year there is little to be seen in the gardens except the bright scarlet berries of the holly and the pretty pink flowers of the laurustinus (*Viburnum Tinus*), and in a few districts the green tufts of mistletoe with their pretty clusters of living pearls. In France, and especially in the neighbourhood of Paris, this parasite affects the tall Lombardy poplar, and is so abundant as to form a conspicuous object in the landscape, half a dozen large tufts often occurring on a single tree. In England it appears to be not unfrequent on the black poplar, but is said never to occur on the Lombardy poplar. A writer in a recent number of the *Gardeners' Chronicle* mentions that at Strathfieldsaye the mistletoe occurs abundantly on the lime trees, which in that neighbourhood grow almost like elms, and that it occurs also on the whitethorn and laburnum, while another writer records its occurrence at Ashford, in Kent, on a fine Portugal laurel. In this country, however, it appears to be decidedly of rare occurrence on the oak tree. Indeed Dr. Bull, in a paper in the *Journal of Botany* some years ago, enumerates only seven authentic instances of its growth on this tree. Its favourite trees appear to be the apple, poplar and whitethorn, and less often the mountain ash and maple. It has also been found on the larch and on the cedar of Lebanon. The fact of its growing head downwards, as it were, possibly gave rise to the use of this plant in epilepsy and giddiness, for which it was formerly recommended by the celebrated botanist Ray. It has been suggested by a recent writer that this peculiar mode of growth arises probably from the slimy character of the berry, and that the undigested seeds and mucus passed by birds slide down to the underside of branches and remain there until they germinate. The solitary seed of the mistletoe is remarkable for often having three embryos developed in it, a phenomenon of very rare occurrence in other plants. At a recent meeting of the Royal Horticultural Society some specimens of mistletoe were exhibited which showed male and female branches on the same plant, the male branches being long and whip-like, while the female ones were shorter and closer in habit.

According to experiments made a short time ago by M. Grandeau, the chemical composition of mistletoe differs considerably from that of the plants on which it grows, in usually containing more potassium and phosphoric acid but much less calcium. The composition, however, varies according to the tree on which it grows.

In spite of cold and snow, one flower (*Petasites fragrans*) may even now be found in the south of England, rendering the frosty air fragrant with its blossoms. A valued correspondent in the Isle of Wight writes that this flower may be seen in blossom in that favoured island all through the month of December. He further adds that "the copses are now deeply tinted with the reddish-brown hue of numberless swelling twigs of *Salix*, the birches are heavy with catkins, the bay trees, plentiful in the gardens and shrubberies, are forward with buds, while here and there in more exposed spots the hazel catkins are shrivelling with the cold weather. A fortnight since I noticed a *Eucalyptus*, about thirty feet high, which showed signs of sickliness; but this same tree has been frostbitten several times and shows marvellous recuperative energy. At Ryde I observe that many younger plants of the *Eucalyptus* are apparently uninjured by the severity of the frost." This account corresponds exactly with what has been noticed at Bonchurch, in the same island, where several plants of *Eucalyptus* were observed two years ago, which appeared to have been cut down two or three times, but yet gave out vigorous shoots from near the base. Undoubtedly this winter will try severely the *Eucalyptus*, and it would be interesting to learn from correspondents how it fares with the plant in different parts of England.

Apparently it is rather rare to find the *Eucalyptus globulus* in flower in this country, but at a recent meeting of the Royal Horticultural Society Mr. Thomson, Garden Superintendent at the Crystal Palace, exhibited branches bearing fruit obtained from specimens measuring respectively 48 feet and 80 feet in height, growing in the Crystal Palace building.

At this time of year, when holly berries and other Christmas decorations are eagerly sought after, we may call the attention of those who reside in the south of England to the fruits of the *Iris fœtidissima*, which when just opening and exhibiting their brilliant red seeds form a remarkably pretty contrast to the dark green foliage of evergreens. In Covent Garden, and in the various flower shops in London, these bright berries have, during the last few years, become a common object.

The remarks of the above-quoted correspondent are very suggestive, and remind that in spite of the paucity of flowers much of interest may still be found in the woods and hedges by a careful observer. Even the buds on the bare branches are deserving of attention, as evidenced by the researches of M. Bert,* which throw fresh light on the reason why so large a number of leaf buds have a brown or reddish brown instead of a green colour. He finds that red glass, by withdrawing the blue rays, sustains whilst it enfeebles life; green glass, on the other hand, causes ordinary plants to become weak and ultimately perish, because it intercepts the red rays. From these facts he concludes that all the rays are necessary to the vigorous life of most plants; but in spring and winter it appears that the blue rays are less necessary, while the red rays, which are believed to be most powerful in decomposing carbonic acid gas, and in the formation of tissue, are more requisite to sustain life and yet prevent rapid development.

Mr. Munro, commenting in a letter to *Nature* on these researches, points out that this curious function possessed by the outer scales of the leaf bud of acting as a sort of coloured screen is not the sole one, since it is only the outer surface of the scales which is coloured. In connection with this subject allusion may be made to the recent investigations of M. Maquenne,† who has found that the green organs of plants diffuse a notable proportion of the heat-giving rays which they receive, and that the two surfaces of the leaves do not equally diffuse the rays which come from the same source, the upper diffusing less than the under, although in a few plants, such as the chestnut and wild cherry, the opposite is the case. At a low temperature, however, the diffusion is nearly equal for both sides of the leaf.

To return to the colour of leaf buds, a remarkable

* *Comptes Rendus*, November 4, p. 695.

† *Comptes Rendus*, December 9, p. 943.

exception occurs in those of the ash tree, which are of a sooty black colour. A curious exception to the usual position of leaf buds occurs in the plane tree, so common in London streets and squares; in this tree the leaf bud is not apparent in the summer, being concealed in a cavity hollowed out in the base of the petiole, and it consequently only becomes visible when the leaf falls.

The different way in which leaves are arranged on the stem (phyllotaxy) may perhaps be now more easily studied from buds than from leaves, since each bud occupies the position of a leaf.

Some years ago, Mr J. Hepworth, writing in *Science Gossip*,* showed that there exists such an immense variety in the shape, size, direction, and arrangement, etc., of leaf buds, that it is possible for any one paying sufficient attention to the subject to identify a fallen twig by means of the leaf buds alone, a matter which is often of some importance to fungologists, who find dead branches and twigs most prolific of botanical treasures.

The scars left on the stem by the fallen leaves also vary greatly, and frequently afford an excellent means of recognizing the tree or branch upon which they are found. Notwithstanding the unsymmetrical development of buds, and consequently of branches, the majority of trees retain so much that is characteristic in their mode of branching, that although bare of leaves they may be easily recognized. The chestnut, black poplar, and sumac are very marked instances in point.

Some of the fruits in vogue at this festive season of the year are worth a passing notice. The walnut, whose very name is involved in obscurity, is one which is not devoid of medical interest. In the *Practitioner* for this month, Dr. E. Mackey calls attention to the use of spirit of walnuts in obstinate vomiting, in which he has found it of considerable service. He publishes a formula for the tincture, furnished to him by Messrs. Southall and Co., of Birmingham. It is made as follows:—Fresh walnuts, 30 ounces; rectified spirit of wine, 12 ounces; water, q.s.; distil, 16 ounces. The dose given is one increasing to two teaspoonfuls every four hours in water. It appears to be an old remedy revived, since Messrs. Corbyn and Co. informed Dr. Mackey that it had been prepared by their firm for over one hundred years. The leaves of this tree have been used as a diaphoretic and antisyphilitic, and an infusion of them has been recommended as a vehicle to disguise the taste of cod liver oil. The black dye contained in the husk of the fruit, although probably little of it enters into "walnut pomade," might possibly be turned to account as a hair dye. In the elongated cells under the epidermis of the epicarp, and on the outside of the endocarp, a substance called nucin has been found, which is remarkable for yielding a magnificent red colour with ammonia.

The bark of an allied species, *Juglans cinerea*, known in the United States as the butternut, is much esteemed in that country as a domestic vermifuge. From a botanical point of view the fruit itself is of some interest, affording an instance of the tryma, a fruit which differs from a drupe in being originally compound, and being formed of two or three carpels. As a rule only two carpels are visible in the endocarp, and only one seed is developed. In rare cases, however, specimens with three carpels or only one may be met with. A curious trace of the estimation in which they were formerly held is indicated in the botanical name, "*juglans*," being, it is supposed, a corruption of "*Jovis glans*," from the legend that in the golden age men fed upon acorns, but the gods upon walnuts. Its name of "*regia*" is probably derived from the Roman name meaning royal nut. The familiar couplet, which we will forbear to quote, at this season of the year at all events, rests upon the belief that the breaking off of the young shoots in beating the fruit from the branches with long poles renders the tree more productive in a subsequent season.

In the *Gardeners' Chronicle* for December 21 is a figure of the marvellous aroid plant discovered by Dr. Beccari in Sumatra. The spadix of this plant (*Conophallus Titanum*) is described as being nearly six feet long. The flower-stalk is greenish, with white rounded spots, is about two feet long, and four inches in diameter, and the spathe, which is bell-shaped and toothed, is three feet in diameter. Some of the roots have already arrived in Florence in good condition.

A new fungus, which grows upon caterpillars, *Cordiceps menisterides*, M. and B., has been recently discovered near Melbourne, thus adding another to the already large list. It probably belongs to the same genus as the curious insect fungus used in medicine by the Chinese, and figured and described by Dr. Pereira in the *Pharmaceutical Journal* many years ago.

The recent number of 'Medicinal Plants' contains figures of *Rosa centifolia*, *Erigeron canadense*, *Lactuca sativa*, *Rheum rhaponticum*, *Morus nigra*, *Triticum sativum* and fennel. The botanical name of the last-named plant is altered in this work to *Fœniculum capillaceum*, Gilib., an old name, dating back as far as 1782. It is so expressive a name that the change must be regarded as an excellent one. The figures of the plants are unusually good, with the sole exception of that of the mulberry, in which it is impossible to find a characteristic leaf portrayed. The details of the flower and fruit of the mulberry are, however, very full, and as in the case of all small-flowered plants, will be found a great assistance to students of medical botany.

In the *Gardeners' Chronicle* it is stated that M. Thuret, the celebrated French algologist, has found a saturated solution of common salt to preserve orchid flowers in excellent order, even for as long as sixteen years, and to answer much better than spirit of wine. This fact cannot be too widely made known to persons dwelling in foreign countries, who might thus send home specimens of new medicinal or other plants for description. The editor of that journal recommends the use of flat bottles and the careful arrangement of the specimens so that it may be possible to examine them without opening the bottle.

In the *British Medical Journal*, this month, the report on the action of cholagogues on the biliary secretion is continued. Professor Rutherford details the results of experiments with menispermin, baptisin and phytolaccin. Menispermin obtained from *Menispermum canadense* is found to be an intestinal but not a hepatic stimulant. This "menispermin" is not identical with the menispermine obtained from the husks of the fruit of *Cocculus indicus*, but the result of exhaustion of the root of *Menispermum canadense* with alcohol formed into an extract "freed from impurities," dried and powdered.

The experiments upon baptisin, a resinoid prin-

* February 1, 1869, p. 37.

ciple obtained from *Baptisia tinctoria*, lead to the conclusion that baptisin "is a hepatic and an intestinal stimulant of moderate power and may possibly be found of service as a hepatic stimulant in cases of torpid liver, with a depressed condition of the system tending to gangrene."

With regard to phytolaccin, obtained from the root of *Phytolacca decandra*, Professor Rutherford pronounces it to be a mild intestinal—but a powerful hepatic—stimulant, and that it appears to be eminently worthy of the attention of physicians.

The treatment of diphtheria naturally attracts much attention at present, and various remedies are proposed in the medical papers, among which are benzoate of sodium and tincture of henbane. That the latter remedy is serviceable is not surprising, since Dr. De Pontives, of Antibes, has found hypodermic injection of atropine give remarkable results in croup, even in the last stage. In connection with this subject it may be mentioned that acording to Planta atropine and daturine are physically as well as chemically distinct, atropine being optically inactive, while daturine turns the plane of polarization to the left. Platinic chloride precipitates the salts of atropine, but not those of daturine. On the other hand picric acid precipitates daturine only.

In the *Gazetta Medica di Roma*, Dr. Eug. Zanzana reports two cases of cure of diabetes mellitus by the use of extract of nux vomica. The dose given was $\frac{3}{4}$ of a grain each day in 3 oz. of water, the dose being increased by $\frac{3}{4}$ of a grain every three days. One of the patients who was cured entirely was seventy-two years of age.

Signor Cozzolino calls attention to thymate of soda as a carminative and antiseptic for children. It has a pleasant flavour, and children take it readily. The dose is 50 centigrams for infants, 3 or 4 grams for adults. He also recommends it for aphthæ and as an antiseptic injection. It also possesses mild febrifuge properties.

Apiol has recently been used as an emmenagogue by M. Marotte with some success. It is said to relieve pain and to be without injurious effects.

In the *Répertoire de Pharmacie*, a resinoid principle called vieirin, of an acid nature, is described by M. Jose T. da Porcincula. It is obtained from the bark of the *Cinchona ferruginea* of Martius, by either precipitating an alkaline solution of the root bark with an acid, or by making a strong tincture and precipitating it with water. Thus treated the bark yields 10 per cent. It is used in rickets and scrofulous affections, but as it is usually administered with saccharated lime water, it is doubtful whether the properties attributed to it may not be due to the lime. Vieirin appears to be of a resinous nature having a slight acid reaction and dissolving readily without alteration in the alkalies and their subsalts.

According to the *Doctor*, an aged forester, writing to a Leipzig journal says, "I do not wish to carry to my grave my much proved cure for the bites of mad dogs, but will publish the same as the last service which I can offer to the world. Wash the wound perfectly clean with white wine vinegar and tepid water, then dry it; afterwards pour into the wound a few drops of muriatic acid, for mineral acids destroy the poison of the dog's saliva."

In the *Berlin klin. Wochenscrift*, a case of trichinosis is described in which the administration of extract of ergot given to stop bleeding from the nose led to rapid recovery from the effects produced by the trichinæ. A new and valuable use for ergot was thus accidentally discovered.

Dr. Porah, according to *La Tribune Médica* finds ergotin very useful in epistaxis. He injected twenty drops into the lips or cheek, of a solution of two grams of Bonjean's ergotin in thirty grams of glycerine.

Dr. Kunze in the *Wiener med. Zeit.*, Oct. 1, states that he believes that six out of eighty cases of epilepsy treated by him were permanently cured by the use of curari.

Another remedy for cancer is under investigation in the leaves of a Mexican plant called *Tlachichinolli*, which is said to have proved of great value in Mexico. The leaves are apparently those of *Plumbago scandens*, a plant which grows in the warm and damp regions of that country and which is known to possess caustic properties when applied externally and to act as an emetic when taken internally. It is understood that its active principle is being examined by Mr. Gerrard, and that it is deemed by Dr. Ringer to be of sufficient interest to be tried physiologically in this country.

In the *Journal of Physiology* Drs. Sidney Ringer and Murrell have recently published an account of their observations on pituri, *Duboisia Hopwoodii*, the remarkable Australian drug which has been already alluded to in this Journal and which was brought into notice in this country by Dr. Bancroft, of Brisbane. Drs. Ringer and Murrell have arrived at the conclusion that the alkaloid of pituri is remarkably similar to atropine, that it is slightly narcotic, that it causes firstly, salivation, and then dryness of the mouth, and that it dilates the pupil whether given internally or applied topically to the eye. It is also a powerful respiratory poison and produces general weakness and violent twitching over the body.

The paper lint introduced into this country a few months ago from America appears to be receiving some attention. Mr. J. Chiene, of the Edinburgh Royal Infirmary, recommends its use as an antiseptic dressing, made by impregnating it with boracic acid, of which it takes up its own weight of the crystal. He points out that if the lint were strengthened by the introduction of cotton threads and the boracic acid added during the process of manufacture, its rapid absorbent powers would render it very valuable. In this paricular it exceeds flax lint.

The opinion expressed in these columns as to the improbability of the expectations raised by preliminary notices of Mr. Norman Lockyer's paper being fulfilled has been fully confirmed by the result. The paper was read before a very full audience at the Royal Society's rooms, and no doubt it represents an enormous amount of hard work and acute observation, which under ordinary circumstances would have obtained a more generous recognition of its value. This will become apparent upon reading the *résumé* printed in another column. But the paper did not satisfy the sensational craving for the impossible that had been unwisely excited and it suffered accordingly.

Pursuing his investigation of the North Carolina mineral, samarskite, M. Delafontaine reports (*Comptes Rendus*, lxxxvii., 632) that he has discovered still another new metal, to which he proposes to give the name "decipium" and the symbol Dp. The metal is described as possessing properties common to others occurring in cerite and gadolinite, and to form an oxide the equivalent of which is approximative to 122 for the formula DpO, or perhaps 366 for Dp_2O_3. It has not yet been sufficiently separated

from didymium to say positively that it is white, but its salts are colourless and the acetate crystallizes readily. The nitrate gives an absorption spectrum having three bands in the indigo and blue, the most refrangible and one not given by didymium or terbium lying in the space between Fraunhöfer's lines G and H, but rather nearer to G. Samarskite would appear to be particularly rich in the rarer elements, M. Delafontaine stating that he has already met with the following earths in it: yttria, erbia, terbia, phillipia, decipia, thoria, oxide of didymium and oxide of cerium. It may be remarked, however, that terbia, which was "discovered" by Mosander twenty-five years ago, has been alleged by subsequent observers to be only a mixture of yttria and erbia. The equivalents (using this term pending the determination of the true atomic weights) attributed to five of these metals present an interesting numerical relation with one another, considering that they are said to occur in the same mineral, as will appear from the following table:—

Yttrium	58.
Philippium	74 or $58+8\times2$.
Terbium	98 or $58+8\times5$.
Decipium	106 or $58+8\times6$.
Erbium	114 or $58+8\times7$.

If the metals should have to be regarded as triatomic the differences will be multiples of 12 instead of 8.

Another interesting statement by the same investigator is that his experiments with didymium as obtained from samarskite and gadolinite, a Swedish mineral, lead him to suspect that that metal as hitherto obtained from cerite is contaminated by another and undescribed element, characterized by bands in the blue which are absent from didymium from samarskite.

It requires but a moderate amount of experience on the part of a dispenser to convince him that many members of the medical profession have a very unhappy method of combining the various therapeutic agents in general use, whether official or otherwise, those at present occupying a place in the British Pharmacopœia equally with those aspiring to that honourable position. With new remedial agents there may be some excuse, but not so with regard to those which for a century have occupied a place in successive pharmacopœias.

It is in the best interests of the medical profession that these remarks are made, as it is by no means exceptional to find that the medical attendant has been reluctantly changed, merely on account of the difficulty which ordinary stomachs experience in retaining ugly compounds which may have been forced beyond the palate.

The pages of this Journal teem with incongruities in prescriptions forwarded from every part of the country, and the difficulties with regard to them are by no means imaginary; the fact that they are recognized, and that guidance is sought for their solution indicates that the dispenser is alive to his responsibilities and desirous of carrying out with the strictest integrity the intentions of the prescriber.

One correspondent instances a prescription containing ℥iij sp. camph. in a ℥vj mixture. Presumably it was not intended that the whole of the camphor should be taken in the first dose and the vehicle afterwards; yet, unless diffused by combination with mucilage or an equivalent simple agent, such would probably be the result, as it would be almost impossible that such a mixture could be administered so that each dose should have its proper proportion of camphor. Quinine, alone or in its different preparations, is frequently prescribed in a mixture with ammonia, as a consequence the alkaloid is thrown out of the fluid and adheres to the sides of the bottle, unless some simple agent is interposed to prevent it. In fact the whole of the fluid may be taken without any of the quinine.

Instances may be multiplied to any extent, but it is perhaps better to indicate the general inconvenience than to point to particular prescriptions. In the case of a new remedial agent, a few minutes' conversation on the part of a prescriber with an intelligent dispenser would put him in possession of the pharmacy of the article, and would enable him to make with it such combinations as would test its therapeutic value and assign it its proper place in that department of medical practice.

The prescriptions will now be considered in their usual course. First, as regards No. 192; there is but one article usually known as liq. carbon. detergen., and it has been many years before the medical profession and the public; this preparation therefore should be used. The inquiry as to the amount of coal tar in it should be addressed to the makers of the article in question.

The swelling and breaking up of pills of reduced iron with one or more of the pharmacopœial extracts, as in No. 193, is a phenomenon quite exceptional, and therefore difficult of explanation. The sample of reduced iron from which the pills were made should be looked to. It may have been impure or imperfectly made; there must be impurity somewhere to account for such a change in pills of that composition within a period of twenty-four hours. A reference to a paper by Mr. Little, in *Pharm. Journ.*, [3], iii., p. 422, and to one by Professor Dragendorff, in vol. ii., p. 988, may possibly throw some light upon the cause.

The receipts No. 194 and No. 195 are referred to veterinary practice, and works on that branch of medicine should be applied to for instruction in the making of horse balls. Probably yellow soap with a little linseed meal would be all required to make either or both of these formulæ into the required sized balls. Sapo mollis would be too soft and does not possess the proper adhesiveness for this purpose; common yellow soap would be better, and linseed meal with the proper proportion of oil, which would prevent the balls becoming hard whilst kept in stock.

Mixtures containing excess of magnes. sulph., as in No. 196, have on previous occasions been commented on, and nothing further need be added. The dispenser in the exercise of his discretion seems to have done right in making the mixture up to 12 ounces so as to retain the magnes. sulph. in solution.

The principle which should guide a dispenser in sending out mixtures containing tr. benzoin. co., as in No. 197, has already on several occasions been referred to, and there is nothing exceptional in this mixture. If the tr. benzoin. co. be poured into an aqueous solution of any kind, there will necessarily result a precipitation of the resin; but a little mucilage previously mixed with the vehicle will prevent this, and allow of its general diffusion through the mixture. The application of this principle to mixtures containing tr. benz. co. has been so often repeated that any further reference to it will be considered unnecessary. It is the object of these remarks to give general principles, leaving their special application

to the dispenser as occasions arise requiring it; it becomes tedious to answer almost the identical question repeatedly.

Combinations similar to that in No. 198 have on several occasions been brought under consideration, and to the remarks previously made there is nothing in this instance to be added. The mixture cannot be sent out clear, but the degree of separation and deposit may vary with different samples of ext. cinch. liq., and the condition of the separated matter will to some extent depend on the order of mixing. In this instance the ext. cinch. liq. should be added after the solution of the soda and potash has been diluted to as great an extent as the mixture will permit of; the addition of ext. cinch. liq. to a concentrated solution of these alkalies will determine the separation of the active principles of the bark in a condition less capable of diffusion through the mixture.

The dispenser has before him in No. 199 a difficulty from the writer's omission or imperfect Latin. The choice of one tablespoonful three times a day involves only one correction, that is, of the "cochlearia," whereas the alternative would require the correction of the "amplum" and an additional word. If the "amplum" be made plural then a definite number for the spoonfuls would be required; therefore of the two difficulties the lesser would be the more safe, and the diminished dose, if an error, is one on the right side.

The mixture No. 200 can be very well dispensed by adding the sp. camph. to a little mucilage in the proportion of about ℥iss mucilage to ℥j sp. camph.; this will necessarily require trituration in a mortar. When rubbed to a uniform condition, the liq. ammon. acet. may be gradually added to complete the mixture. A dispenser should bear in mind that mixtures such as this one have to be taken by the patient in divided doses, and when one ingredient so separates that its subsequent division into separate doses is rendered impossible, some simple agent such as mucilage should be used for the purpose. It is clearly the intention of the prescriber that the dose of liq. ammon. acet. should be accompanied by a definite quantity of camphor, and this can only be accomplished by the use of some agent capable of doing it, and devoid of medicinal activity, such as mucilage.

In prescription No. 201, sol. perchlor. ℥j is ordered in a twelve oz. mixture. The dispenser has assumed that liq. hyd. perchlor. was intended, but it can scarcely be so, as liq. hyd. perchlor. is usually prescribed in doses of about ℥j each. It is very probable that this sol. perchlor. is intended for some private formula of liq. hyd. perchlor. kept for convenience in a surgery or dispensary, and this incidentally has found its way into private practice. The original object may have been that of convenience and probably at the same time to keep the "hyd." from the knowledge of the patient. For the reasons stated it is not probable that it could refer to the liq. hyd. perchlor. B. P.; there seems little doubt but that a mercurial preparation was intended by the writer, but it would not be safe for a dispenser to go beyond the liq. hyd. perchlor., if the writer cannot be communicated with. The dispenser has under the circumstances exercised a wise discretion, and was safe, although it was scarcely probable that it was what the writer had in his mind when he composed the prescription.

In the composition No. 202 containing bals. styracis, the liquid strained storax should be used; this substance will be found in most of the drug lists; the ol. lini could be added to it in a water-bath. The charge would depend on the value of the articles *plus* time and skill involved in the preparation of the finished product; that is a part of the subject that may very properly be left to the dispenser, and would depend on a variety of circumstances, probably in no two cases perfectly similar.

If the ingredients of the mixture No. 203 be accurately dispensed, the result will be that some of the iodine is left free. The question is, what was the intention of the prescriber? As the quantity of iodine left undecomposed is so trifling, it may be safely assumed that the writer intended its entire decomposition, and that the resulting compound should be colourless. This is an assumption in the absence of anything to guide the dispenser, the only other suggestion that occurs is that a little iodine may have been left free to mark the extent of the application on the skin. ℥iij tr. iodi, by the way, contain 32·8 grs. iodine.

"Tyro" should have stated in what direction the difficulty lies in prescription No. 204. It may be assumed that the quantity of ol. menth. pip. is in excess of what the other ingredients will take up; but if the extract. coloc. co. be used in powder, one drop of ol. menth. pip. may be very well combined in each pill without any special manipulation. The question should have been more definitely stated. The second prescription, that of No. 205, has more pulv. tragac. than is required to make twelve ounces of the official mist. tragac. The intention of the prescriber is evidently to suspend the bismuth; for this purpose, ℥j gr. xij, the proportion for mist. tragac., would be quite sufficient; there is therefore an excess of 48 grs. of pulv. tragac. ordered. It is true that a mixture can be made of it and this mixture can be put into a bottle, but it would be extremely difficult for a patient to get it out again; therefore it may be assumed that the writer was unaware of the amount of mucilage yielded by ℥ij pulv. tragac. or intended pulv. tragac. co. to be used. The dispenser would be exercising sound discretion if he made the mixture with ℥j gr. xij pulv. tragac. and would be more efficiently carrying out the intentions of the prescriber than if he made the mixture so thick that the patient could not get it out of the bottle.

From the information supplied prescription No. 206 would appear to have been made very properly by first making a mucilage with the pulv. tragac. co., then adding to it the tr. benz. co., and finally the other ingredients. The only further remark that need be made is that the mucilage should not be too dilute when the tr. benz. co. is added, or the resin will not be so well diffused. It was very likely neglect as to the order of mixing that caused the precipitate at the bottom of the bottle referred to. There will be no precipitation if made as suggested, the mixture will remain uniform in colour and composition.

From the remarks called forth by repeated inquiries with regard to mixtures containing tr. benz. co. it may be hoped that the principles laid down for the dispenser's guidance in these special prescriptions will be applied to all similar ones where the difference is simply one of degree. It must be evident that the remarks made month after month can serve no useful purpose if every prescription alike in ingredients but differing in relative proportions has to be discussed *de novo* as though tr. benz. co. were of recent origin and unknown composition.

THE NATURE OF THE ELEMENTS.*

At a crowded meeting such as is seldom witnessed of the Royal Society on Thursday evening the 17th inst., Mr. J. Norman Lockyer, F.R.S., read a lengthy paper, in which he discussed the evidence derived from spectroscopic observation of the sun and stars and from laboratory experiments, which has led him to the conclusion that the so-called elements of the chemist are in reality compound bodies. In order that the line of argument followed by Mr. Lockyer may be understood, it will be necessary briefly to refer to the results of previous researches. As a rule, in observing spectra the substance to be examined is volatilized in a gas flame or by means of sparks from an induction coil, and the light is allowed to fall on the slit of the spectroscope; the spectrum is then generally one in which the lines run across the entire field, but by interposing a lens between the spark apparatus and the slit of the spectroscope, Mr. Lockyer was enabled to study the various regions of the heated vapour, and thus to establish the fact, already noted by some previous observers, but to which little attention had been paid, that all the lines in the spectrum of the substance volatilized did not extend to equal distances from the poles. He then showed by the aid of this method that in the case of alloys containing different proportions of two metals, if the one constituent were present in very small quantity its spectrum was reduced to its simplest form, the line or lines longest in the spectrum of the pure substance alone appearing, but that on increasing the amount of this constituent its other lines gradually appeared in the order of their lengths in the spectrum of the pure substance. Similar observations were made with compound bodies. It was also noticed that the lines furnished by a particular substance varied not only in length and number, but also in brightness and thickness according to the relative amount present. Armed with these facts and with the object of ultimately ascertaining more definitely than has hitherto been possible which of the elements are present in the sun, Mr. Lockyer about four years ago commenced the preparation of a map of a particular region of the spectra of the metallic elements for comparison with the map of the same region of the solar spectrum. For this purpose about two thousand photographs of spectra of all the various metallic elements have been taken, and, in addition, more than one hundred thousand eye observations have been made. As it is almost impossible to obtain pure substances, the photographs have been carefully compared in order to eliminate the lines due to impurities; the absence of a particular element as impurity being regarded as proved if its longest and strongest line was absent from the photograph of the element under examination. The result of all this labour, Mr. Lockyer states, is to show that the hypothesis that identical lines in different spectra are due to impurities is not sufficient, for he finds short line coincidences between the spectra of many metals in which the freedom from mutual impurity has been demonstrated by the absence of the longest lines. He then adds that, five years ago, he pointed out that there are many facts and many trains of thought suggested by solar and stellar physics which point to another hypothesis—namely, that the elements themselves, or, at all events, some of them, are compound bodies. Thus it would appear that the hotter a star the more simple is its spectrum; for the brightest, and therefore probably the hottest stars, such as Sirius, furnish spectra showing only very thick hydrogen lines and a few very thin metallic lines, characteristic of elements of low atomic weight; while the cooler stars, such as our sun, are shown by their spectra to contain a much larger number of metallic elements than stars such as Sirius, but no non-metallic elements; and the coolest stars furnish fluted band spectra characteristic of compounds of metallic with non-metallic elements and of non-metallic elements. These facts appear to meet with a simple explanation if it be supposed that as the temperature increases the compounds are first broken up into their constituent "elements," and that these "elements" then undergo dissociation or decomposition into "elements" of lower atomic weight. Mr. Lockyer next considers what will be the difference in the spectroscopic phenomena, supposing that A contains B as an impurity and as a constituent. In both cases A will have a spectrum of its own. B, however, if present as an impurity, will merely add its lines according to the amount present, as we have above explained; whereas if a constituent of A it will add its lines according to the extent to which A is decomposed and B is set at liberty. So that as the temperature increases the spectrum of A will fade if A be a compound body, whereas it will not fade if A be a true element. Moreover, if A be a compound body, the longest lines at one temperature will not be the longest at another. The paper chiefly deals with a discussion from this point of view of the spectra of calcium, iron, hydrogen, and lithium as observed at various temperatures; and it is shown that precisely the kind of change which is to be expected on the hypothesis of the non-elementary character of the elements has been found to take place. Thus each of the salts of calcium, so long as the temperature is below a certain point has a definite spectrum of its own, but as the temperature is raised the spectrum of the salt gradually dies out and very fine lines due to the metal appear in the blue and violet portions of the spectrum. At the temperature of the electric arc the line in the blue is of great intensity, the violet H and K lines, as they are called, being still thin; in the sun the H and K lines are very thick, and the line in the blue is of less intensity than either, and much thinner than in the arc. Lastly, Dr. Huggins's magnificent star photographs show that both the H and K lines are present in the spectrum of α Aquilæ, the latter being, however, only about half the breadth of the former; but that in the spectrum of α Lyræ and Sirius only the H line of calcium is present. Similar evidence that these different lines may represent different substances appears to be afforded by Professor Young's spectroscopic observations of solar storms, he having seen the H line injected into the chromosphere 75 times, the K line 50 times; but the blue line, which is the all-important line of calcium at the arc-temperature, was only injected thrice. In the spectrum of iron, two sets of three lines occur in the region between H and G which are highly characteristic of this metal. On comparing photographs of the solar spectrum and of the spark taken between poles of iron, the relative intensity of these triplets is seen to be absolutely reversed; the lines barely visible in the spark photograph being among the most prominent in that of the solar spectrum, while the triplet, which is prominent in the spark photograph, is represented by lines not half so thick in the solar spectrum. Professor Young has observed during solar storms two very faint lines in the iron spectrum near G injected 30 times into the chromosphere, while one of the lines of the triplet was only injected twice. These facts, Mr. Lockyer contends, at once meet with a simple explanation if it be admitted that the lines are produced by the vibration of several distinct molecules. The lithium spectrum exhibits a series of changes with a rise of temperature precisely analogous to those observed in the case of calcium.

In discussing the hydrogen spectrum, Mr. Lockyer adduces a number of most important and interesting facts and speculations. It is pointed out that the most refrangible line of hydrogen in the solar spectrum, h, is only seen in laboratory experiments when a very high temperature is employed; and that it was absent from the solar protuberances during the eclipse of 1875, although the other lines of hydrogen were photographed. This line, also, is coincident with the strongest line of indium as already recorded by Thalèn, and may be photographed by volatilizing indium in the electric arc, whereas palladium charged with hydrogen furnishes a photograph in which none of the hydrogen lines are visible. By employing a very feeble spark at a very low pressure the F

* From the *Times*, Dec. 18.

line of hydrogen in the green is obtained without the blue and red lines which are seen when a stronger spark is used, so that alterations undoubtedly take place in the spectrum of hydrogen similar to those observed in the case of calcium. In concluding this portion of his paper Mr. Lockyer states that he has obtained evidence leading to the conclusion that the substance giving the non-reversed line in the chromosphere, which has been termed *helium*, and not previously identified with any known form of matter, and also the substance giving the 1474 or coronal line, are really other forms of hydrogen, the one more simple than that which gives the *h* line alone, the other more complex than that which gives the F line alone.

There can be no question that the facts brought forward by Mr. Lockyer are of the highest importance and value, and that they will have much influence on the further development of spectrum analysis, to which he has already so largely contributed. But his arguments are of a character so totally different from those ordinarily dealt with by chemists that they will hesitate for the present to regard them as proof of the decomposition of the elements until either they are assured by competent physicists that they cannot be explained by any other equally simple and probable hypothesis or until what Mr. Lockyer has foreshadowed as taking place to such an extent in other worlds has been realized beyond question or cavil in our own laboratories. It has been suggested that the same molecule may be capable of vibrating in different ways at different temperatures, and thus of yielding different spectra, just as a bell may give out different notes when struck in different ways; and although Mr. Lockyer has replied to this objection, it can scarcely be regarded as finally disposed of. The fact, however, as Mr. Lockyer has pointed out, that the change from the spectrum of a compound to the lowest temperature spectrum of its metallic element is of a similar character to and even less in degree than the change from the lowest temperature spectrum of the metal to the spectra which it furnishes at higher temperatures does not appear to favour such an hypothesis, and from the similarity in the phenomena it is difficult to deny that in both cases decomposition does not equally take place. Professor Young's observations on the injection of particular lines into the chromosphere during solar storms are also difficult to reconcile with this view, and if the conclusions drawn from previous researches are correct, it also does not account for the short line coincidences which led Mr. Lockyer to his hypothesis.

Chemists are careful to teach that what are at present regarded as elements are not necessarily simple bodies, but merely substances which they are unable to decompose or which they have no special reason to regard as compound bodies. The remarkable relations, both in atomic weight and properties, existing between many of the elements tend, indeed, to show that they are related in the manner Mr. Lockyer supposes. We sincerely hope that he will continue his researches in this direction, and we trust that at no very distant time he may be able to bring forward evidence sufficiently clear to convince even the most sceptical.

THE "GUM" OF THE QUEBRACHO COLORADO (LOXOPTERIGIUM LORENTII, GRISEBACH).*

BY PEDRO N. ARATA.

This tree, belonging to the Anacardiaceous order, is indigenous in, and peculiar to, the northern part of the Argentine Republic. The so-called gum, or rather thickened juice, collects in the cracks and hollows of the wood, in ruby-red concretions somewhat resembling colophony, but more brittle; it is easily pulverized, and yields a brick-red powder. It is scentless, but has a slightly astringent taste. Sp. gr. 1·3756 at 15°. It is easily soluble in alcohol, acetone, and acetic ether; dissolves also in amyl alcohol, and acetic acid, but is insoluble in benzene, carbon bisulphide, chloroform, and turpentine oil; nearly insoluble in cold water and in ether; nevertheless an ethereal solution, having an emerald-green colour, may be obtained by agitating the gum with ether and water. Boiling water dissolves it completely, and deposits part of it on cooling. It dissolves also in strong sulphuric acid, and is precipitated therefrom by water. Heated in a platinum capsule it swells up and burns, leaving a shining porous cinder, which burns away slowly on continuing the heat. If the combustion be completed in a stream of oxygen, the unburnt residue is scarcely appreciable.

A 1 per cent. solution of the gum in absolute alcohol, in a layer 7 mm. thick, exhibits an absorption-spectrum having a dark band commencing between the solar lines A and B, and terminating at C; another extending for a short distance on each side of D; and a third beginning half-way between D and E and extending to all the more refrangible part of the spectrum. The same solution in a layer 25 mm. thick absorbs the whole of the spectrum, excepting a narrow space from C half-way to D. A solution of dragon's blood, which in some respects resembles quebracho gum, exhibits a very different spectrum, containing a dark band extending for a short distance on each side of C, and a second beginning just beyond D and occupying all the rest of the spectrum.

Reactions.—Quebracho gum, subjected to dry distillation, yields between 100° and 120° a distillate which remains liquid on cooling, and between 240° and 245° a distillate which solidifies to colourless prisms of pyrocatechin (m. p. 105° nearly, b. p. 240°—245°). The gum is strongly attacked by concentrated nitric acid, and when heated with the same acid somewhat diluted with water, it is oxidized to oxalic acid and trinitrophenol or picric acid. Fused with potash it yields protocatechuic acid, $C_7H_6O_4$ or $C_6H_3(OH)_2.COOH$, and phloroglucin, $C_6H_6O_3$.

The formation of these products renders it probable that quebracho gum contains one of the bodies called catechins; but in consequence of the great tendency of these bodies to alteration, the author has not yet been able to obtain satisfactory evidence of their actual presence in the gum. The existence of a catechin in an anacardiaceous plant would be a novelty, these bodies having hitherto been found only in the leguminous, rubiaceous and cedrulaceous orders.

* *Anales de la Sociedad Cientifica Argentina*, July, 1878. From the *Journal of the Chemical Society*.

THE SOCIETY OF APOTHECARIES *v.* SHEPPERLEY

The following statement which has been received from the Clerk to the Society of Apothecaries, will serve as the reply of that body to the inquiry of M.P.S., in the Journal of the 21st, as to the grounds upon which the prosecution of the case of the Apothecaries' Society *v.* Shepperley was authorized:—

After the recent verdict of the jury in the case of the Society of Apothecaries *v.* Shepperley, it has been frequently asked whether the Society ought to have authorized the prosecution.

That they had *primâ facie* reasons for doing so is assumed with much fairness and candour in an article contained in the *Pharmaceutical Journal* of the 9th day of November, 1878, which will be again referred to in these pages, and the concluding remarks of which are as follows:—

"It would be wrong to disguise the fact that counter practice sometimes exceeds reasonable limits, and if we may judge from some of the accessory, if not direct, evidence given in the late trial, it would seem that the Apothecaries' Society in authorizing the prosecution had reason for thinking those limits had been exceeded. Mr. Shepperley's evidence as to the recent alteration in the

mode of conducting his business seems to point in this direction, and the pamphlet issued by him with the title 'Every man his own Doctor,' for the purpose of recommending specific remedies, lends further support to such a possible construction of his former practice."

One of the principal objects, however, of these pages is to show that as regards the actual trial just concluded the Society had no discretion in the matter. To explain this more fully the history of the case is shortly given.

In the month of February, 1877, the Society were applied to to give their consent to the prosecution of Mr. Shepperley under the 20th section of the Act of 1815. Following the course always adopted under such circumstances, the solicitor of the Society required evidence of at least three instances to be laid before him of Mr. Shepperley having acted as an apothecary, and of one of those instances being a case not of counter practice.

The following (omitting the names of the alleged patients) is the statement of the case submitted to the solicitor of the Society by the solicitors to the Nottingham Medical Defence Association :—

"For a considerable time past Mr. Shepperley (who is only qualified as a chemist and druggist) has been carrying on a systematic practising as an apothocary; this has been admitted by him and an intimation added that he shall persist in doing so ; he has been in the habit of attending people for all kinds of complaints, advising them and administering medicines of his own recommendation, and making charges for the same. To obtain direct and positive evidence is often attended with some difficulty, owing to the disinclination of persons who have been treated to give information, but we have abundant evidence in three cases, viz., A, who has been attended and prescribed for for about six weeks in respect of a uterine complaint ; B, who has been treated for bad blood and blotches on the face ; and C, who has been treated for an inflamed throat."

The names of the alleged patients are not, except as regards C, necessary to be given; but, for reasons which follow, it is material to state that C was Mr. Jolly Death, to whose subsequent evidence in the case it will be necessary to refer more particularly.

No inference could possibly have been drawn from this statement that Mr. Jolly Death had, in fact, been employed by the Nottingham Medical Defence Association to personate illness with the view of getting a conviction. Had this been known the Society's authority to prosecute would immediately have been refused, as it has been without exception where that fact has been disclosed beforehand.

The leave to prosecute was limited to proceedings in the county court. The case was heard before the Judge of the Nottingham County Court, and Mr. Shepperley was convicted in a penalty of £20.

The following is the language of the Judge himself in explanation of his decision :—"I was of opinion, upon proof of the above facts (being the evidence or part of the evidence laid before the solicitor of the Society) that the defendant did act and practise as an apothecary within the meaning of section 20 of the statute (that is the Act of 1815) and that the facts proved by the defendant's witness did not bring the case within the provision of 28th section of the said statute, and I therefore gave judgment for the plaintiffs for the sum of £20 and costs."

It will be seen, therefore, that the *primâ facie* case under which the solicitor of the Society allowed the prosecution was established to the satisfaction of the County Court Judge.

Shortly after that Judge had given his decision, the Chemists and Druggists' Trade Association (a body distinct from the Pharmaceutical Society of Great Britain), and who had, in fact, conducted Mr. Shepperley's defence, intimated their intention of appealing from that decision to the superior court on points of law.

The following is the letter addressed by the solicitor of that Association to the solicitor of the Society of Apothecaries:—

"26, Waterloo Street, Birmingham, 20*th March*, 1877.

"APOTHECARIES' SOCIETY v. SHEPPERLEY.

"Sir,—You are doubtless aware that this is an action which was tried in the Nottingham County Court on the 13th inst., and that the decision of the court was against the defendant, upon whom a penalty of £20 was inflicted.

"I am instructed by the Law Committee of the Chemists and Druggists' Trade Association to communicate to you the fact that the decision of the Judge will be appealed against on points of law, and through you to request the Apothecaries' Society to withhold their sanction to any further proceedings against chemists and druggists until the legal rights of this trade under the Apothecaries Act, 1815, are determined on the appeal. The occasion for this request is shown by the fact that chemists are being sued at Truro, and that others at Sunderland have received cautionary notices.

"The desire of the Association is to obtain a direct decision upon the construction of the Act, and whilst this is pending I think you need have no hesitation in preventing further cases of the kind from being tried.

"I shall be glad to have your assurance that no authority shall be given. And am, yours truly,

"J. R. Upton, Esq., Henry Glaisyer.

"Clerk to the Society of Apothecaries,

"Apothecaries' Hall, Blackfriars, London."

The Nottingham Medical Defence Association at the same time appealed to the Society for pecuniary help to assist them in supporting the decision of the County Court Judge, and the application was brought before the Court of Assistants of the Society.

Upon this occasion the solicitor of the Society advised that though the Society had never made a grant of money for the purpose of conducting prosecutions (the prosecutor being always required to bear his own expenses), yet in the present instance the following circumstances had to be taken into consideration by the Society:—

(1) That the matters to be argued before the judges of the superior court were those of law and not of fact.

(2) That an adverse decision on points of law might gravely affect the Society, and not merely the actual prosecutors.

(3) That the questions of law were not raised by the prosecutors but by the defendant, and

(4) That the real defendants were a body with funds enabling them to employ eminent counsel, and that in fact the application on their behalf to reverse the decision of the county court judge on points of law would be made by one of the most eminent members of the bar.

Taking these circumstances into consideration, the court voted fifty guineas towards the payment of the fees of counsel to appear and support the decision of the county court judge on points of law.

The case came on before the Exchequer Division of the High Court, when, after a very elaborate argument from Sir Henry James against the decision of the county court judge on points of law, the following discussion is reported to have taken place:—

"Mr. Baron Cleasby: It seems to me to be a case of so much importance that if I were to say what my view of it would be—I do not think we ought to do that now—but what I should recommend would be this, that a new trial should be ordered, and that a certiorari should be applied for to have this question argued in the court.

"Sir Henry James: As I have endeavoured to put myself into possession of this case, directly we come to take the view which the Lord Chief Baron has pointed out, and to apply it to this case, we shall place before your lordships the gravest possible difficulty to determine where the duties or the rights of a chemist and druggist cease and those of medical men begin. I am using the term in its ordinary sense. I may say at once that every chemist and druggist in this country is interested in this matter, and no doubt to some extent they are taking a practical interest in this litigation, and therefore, as your lord-

ship suggests, if the Apothecaries' Company wish to bring this matter to a solemn decision in that way I accept it most readily and ask that that should be done.

"The Lord Chief Baron: I have no objection to the course suggested by my brother Cleasby—quite the contrary. What does the other side say to it?

"The Lord Chief Baron (again addressing Sir Henry James): You say that if we direct a new trial it shall be agreed at once that the case shall be transferred from the county court to this court.

"Sir Henry James: Certainly. We will take that course.

"Mr. Day (counsel for the plaintiffs): I should submit respectfully that there is no ground on which your lordships can direct a new trial. I submit that the facts have been before the county court judge and that he has given his decision. If your lordships think the case does not sufficiently set out the facts, and your lordships wish to ascertain what the learned judge's finding was, I suggest the better course, and the only proper course, is to send the case down to be re-stated. On behalf of my client, I must say we prefer to stand upon the trial.

"Mr. Baron Cleasby: We have power by the Act of Parliament to direct a new trial.

"Mr. Day: Yes, my lord.

"Mr. Baron Cleasby: If it appears that a material issue or a material question is not disposed of, one way or the other, by the decision, to direct a new trial would be the proper course.

"Mr. Day: Undoubtedly.

"The Lord Chief Baron: The better way will be to have a new trial, and then if it be brought before the court in the meantime, either party will give whatever evidence he thinks fit. Then we shall be in full possession of all the facts and the law which can be proved to enable us to judge whether the defendant has committed a breach of law or not.

"Mr. Day: What I submit is that no issue has been left undetermined, that the trial was complete, so far as it goes, and your lordships have nothing but the case before you. I submit that if the case is not sufficiently stated, the course that should be taken is that it should go back to the county court judge to re-state the case. That I can have no objection to, but I do protest against a new trial being ordered, where there is no evidence of any issue being left untried by the learned judge, or any improper direction, or improper finding on the issue.

"The Lord Chief Baron: I think that, considering that you appear for the great Apothecaries' Company, who can be interested only in seeing that the law is conformed to and obeyed, if we think that upon such a case as this, where a penalty is claimed in the action, it ought to be fully considered, and that either party should have full liberty to have all the evidence of which the case is susceptible, you ought to agree to it.

This is how a case of a most ordinary character, originally authorized by the Society to be tried in the County Court, came to be tried before Mr. Baron Pollock, in London, and being heard at a comparatively dull time of the year, received an amount of attention, which from a legal point of view it was wholly undeserving of, as explained in the article of the *Pharmaceutical Journal*, to which reference has already been made.

But the question immediately for consideration, is whether the Society ought to have allowed the new trial to proceed, which the Exchequer Division directed should take place.

It may with every degree of confidence be asserted that they had no alternative but to do so.

In the first place to have refused their authority would have almost involved a denial of justice to the Nottingham Medical Defence Association, who had already obtained the conviction of the defendant by the county court judge.

In the second place their withdrawal from the case in the face of the direction of the Exchequer Division would have undoubtedly left the impression that the Society were afraid of a legal decision on the 28th section of the Act.

It will be shown presently that, notwithstanding the view taken by the public as distinguished from the medical journals, the course pursued by the Society was right, for whatever the verdict on the mere facts as regards the defendant may have been, the Association, who defended him, not only failed to obtain from the judge who presided a favourable construction of the 28th section of the Act of 1815, but, if anything, elicited a contrary opinion.

The Nottingham Medical Defence Association, on the new trial being directed, applied to the Society for pecuniary assistance to conduct the case, but, acting on the principles before mentioned, the Society declined to do more than allow the use of their name.

The result of the trial to any one who read the evidence, or is accustomed to such evidence, could be no surprise.

Mr. Jolly Death, the principal witness put forward for the prosecution, had to admit that his illness was a feigned one, and that he was employed by the Nottingham Medical Defence Association to try and obtain a conviction of the defendant.

The jury (and no one will find fault with them for doing so) disbelieved the evidence of a witness obtained by such means, and further the mode in which this evidence had been obtained discredited the whole case of the plaintiffs in the eyes of the jury, and disinclined them to listen to other evidence which, taken by itself, might have secured a conviction.

Upon the facts then as viewed by the jury, the nominal defendant obtained a verdict.

But the actual defendants, the Chemists and Druggists' Trade Association, obtained no decision on the law, and what is more remarkable, the leading counsel for the defendant when asked by the judge to express his views on the 28th section of the Act of 1815 preferred apparently not to do so.

The following conversation between Mr. Baron Pollock and Sir Henry James, in the middle of the speech of the latter for the defendant, is reported to have taken place:—

"Mr. Baron Pollock: Sir Henry James, before you leave that point I should like to ask you your construction of the 28th section. I was not aware that this had been discussed before, and I want to know whether this exception, 'Nothing in this Act shall extend or be construed to extend to prejudice or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, and vending drugs, medicines, and medicinal compounds, wholesale and retail,' whether the whole section is governed by that when it afterwards says that 'persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise and carry on the same trade or business in such manner and as fully and amply, to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act.' Does not that mean that the trade or business in that part of the Act means the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, and vending drugs?

"Sir Henry James: With submission, my lord, I should say not.

"Mr. Baron Pollock: That is a very important point.

"Sir Henry James: I quite appreciate the importance of it, but even if that view were to prevail I should say what the defendant has done is nothing more than the dispensing of drugs.

"Mr. Baron Pollock: That is another point. I thought it right to mention that now.

"Mr. Baron Pollock: It will become my duty to tell the jury what is the construction of this 28th section, and I

wanted Sir Henry James, when he was upon it, to know what my view was. To my mind, as at present advised, I think this section is intended in the latter portion of it to apply to the trade or business of a chemist and druggist, not as it was used and exercised and carried on generally, but to the trade or business of a chemist and druggist limited by the words 'in the buying, preparing, compounding, dispensing and vending drugs,' and so forth. That is my impression.

"Mr. Howard (one of the counsel for the plaintiffs): That was the view Mr. Justice Field took.

"Mr. Baron Pollock: I think so. I only mentioned the point.

"Sir Henry James: I think my case is so strong that I do not want to take any point I may be in doubt or danger about."

Subsequently, however, when the jury were recording their verdict for the defendant, Sir Henry James was, it seems, anxious to get a finding on the point of law for his real clients. The following conversation is reported to have taken place at that moment:—

"Sir Henry James: I understand the jury to say they find for the defendant in both cases. That refers to the two cases. They also find the protection of the 28th clause exists.

"Mr. Baron Pollock: I cannot ask them to tell me the grounds.

"Sir Henry James: When they say they have found in both cases, as I understand, they have found on all the questions your lordship left to them.

"Mr. Baron Pollock: I only gave them my view of the law.

"The Jury: We found on Hubbard's case and Death's case."

In effect the jury's view of the law would have been of no value, and the conversation is only quoted to show how absolutely worthless the result of the trial was in disposing of any legal question.

It is believed then that a complete and satisfactory answer has been given to the question why the Society originally authorized the prosecution, and why that authority was extended to the new trial which took place before Mr. Baron Pollock.

The mode in which Mr. Death obtained his evidence, and which ought without doubt to have been communicated to the solicitor for the Society, will make it necessary that (so far as the Society can legally do so) intending prosecutors should be required to disclose beforehand whether any evidence to be used on a trial has been obtained by means of a paid agent or informer.

But this is comparatively a small matter: much larger questions are really raised by the present discussion. The first (apart from the graver issue to which reference will be subsequently made) is whether any amount of regulations will secure that absolute control of the Society over a case which they can only procure by conducting the case themselves. For the Society first to give and then to withdraw their consent to a case, or having given their consent actively to interfere in it, would lead to the most mischievous results. On the other hand, it does not seem desirable that the Society should conduct these prosecutions themselves; even if they had funds applicable specially for the purpose (which they have not), for it would be illegal to apply any part of their corporate funds for such objects. If, therefore, the Society consent to the principle of allowing prosecutions, the simple course seems to be that they should not allow them to proceed except in the County Courts, where, whatever the result is, little interest is felt one way or another as to the decision.

But the next difficulty is as to the class of cases, in respect of which the Society are to authorize prosecutions.

Are they to refuse their authority in cases of counter practice altogether?

This would seem almost to go beyond what is contended for in the article of the *Pharmaceutical Journal*, to which reference has been so frequently made.

Are they to refuse their authority in what may be termed mixed cases, or cases of "double offence," as they are called in the letter which the solicitor of the Society addressed to the solicitor of the Pharmaceutical Society on the 1st January, 1878, and which, as then and still embodying the views of the leading members of the Society, it may be useful to quote *in extenso*?

"20, Austin Friars, London, E.C., 1st Jan., 1878.

"Dear Sir,—I placed the subject of our discussions before the Act of Parliament Committee of my Society.

"It was their intention to have referred the decision of that Committee to the full Court of the Society, which sat the same day at a later hour, but the Court was so much occupied with other business, that the decision of the Act of Parliament Committee could not be brought before them.

"The communication therefore which I make to you has not that official sanction which it would have if it were a resolution of the Court of the Society instead of the decision of a Committee formed out of that Court.

"But as that Committee is constituted of all the leading members of the Society, I have no reason to doubt but that the decision which they have come to will be accepted without alteration by the Court.

"Their decision was: 'That having regard to the statement laid before them by Mr. Upton, this Committee are unabled to find any case where the sanction of the Society has been given to a prosecution on a pure and simple case of counter practice, and that while this Committee expresses no opinion as to whether cases of counter practice come within the Act of 1815, or whether the persons prosecuted in respect of such practice are liable to the penalty imposed by that Act (although the decided cases appear to be in favour of such practice being within the Act) it is not desirable that the sanction of the Society should be given to prosecutions where counter practice *alone* is involved.'

"I think it right to add that in nearly all cases of prosecution by the Society there is a double offence alleged to have been committed, viz., visiting and counter practice, and that it is impossible for the Society, in giving their sanction to a prosecution, to limit it to one of the alleged offences.

"If the person who is alleged to be guilty of visiting patients, is also guilty of counter practising, it is impossible to withdraw the consideration of the latter question from the tribunal before which the case comes.

"Under these circumstances (subject to the official sanction of the Court to which I have above referred) it is unlikely that the Court will accept the suggestion which was made by yourself to me. "Yours faithfully,

"Wm. Flux, Esq. "James R. Upton."

The above questions have at all times been difficult to answer, but the difficulty is at the present time greatly increased. An intimation having been given by the solicitor of the Society in two pending cases, that as to one the Society would only consent to proceedings being taken in the County Court, and as to the other that the Society would not sanction proceedings at all, he has been informed by the solicitors for the intending prosecutors that they are instructed by licentiates of the Society to apply to the High Court for a mandamus to compel the Society either to allow them to conduct the prosecutions, or for the Society to be required to do so—in other words, for the Society to be deprived of any discretion in the matter.

The Society of Apothecaries may, perhaps, place their position—(1) as regards their own licentiates, (2) as regards the pharmaceutical body, and (3) as regards the public—in the fairest and most proper light, by offering every facility for such an application being fully heard and decided.

But, however this may be, the course which the Society are to pursue under such circumstances must be considered, and it is undoubtedly a serious matter on which to form a decision.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 28, 1878.

COUNTER PRACTICE AND THE SHEPPERLEY CASE.

It is with much satisfaction that we find our reference to the suggestion of Mr. SCHACHT in last week's Journal has induced that gentleman to state more fully the grounds upon which he recommended the attempt to effect a settlement of the counter practice question by a conference between the Council of the Pharmaceutical Society and the Court of the Society of Apothecaries. Mr. SCHACHT's communication will be found in our Correspondence columns and we cannot do better than commend it to the careful consideration of all who may be interested in this difficult question. Especially do we commend the thoughtful perusal of this letter to those correspondents who have lately been overflowing with expressions of regret and indignation because the Council has decided not to grant a sum of money from the funds of the Society for the further defence of the SHEPPERLEY case. We regret to perceive that, under the influence of the excitement created by this case, such grave misconceptions prevail as to its importance. It is a total fallacy to suppose that this is a test case or that it has been the means of doing anything towards defending or maintaining the position of chemists and druggists as regards counter practice. On the contrary the result of it, so far, may be epitomized in the words "counter practice has no legal position "whatever," and however much further this particular case might be carried there is little probability that it would ever decide the question now raised as to the right of chemists and druggists to prescribe even the simplest remedies.

We very much doubt whether litigation or even legislation would decide this question to the satisfaction of chemists and druggists and therefore have always deprecated having recourse to those means of seeking relief from the unreasonable restrictions which a certain class of medical practitioners would impose upon the trade.

We are aware that our views on this matter do not meet with general acceptance, any more than the recent decision of the Council; but we fail altogether to gather from the letters that have reached us, any kind of argument against the one or the other. Mr. FELTWELL's assumption that some members of the Council are opposed to the consideration of trade interests is purely gratuitous and unsupported by anything but his own imagination, and Mr. JOHNSON's idea that they persistently and dogmatically decline to support measures which have for their aim the protection of trade interests is equally unfounded.

The vague generalities in which Mr. MARTIN indulges in his condemnation of the Council's proceedings are characteristic of this class of correspondents, few of whom ever appear in any other capacity than as exponents of irrational discontent. But even the vagueness of these complaints—though doubtless expedient for their authors' sakes, and sufficient to evoke the sympathy of kindred spirits—is inadequate to conceal the fact that deficient information and defective logic form the chief foundation for the opinions expressed.

Mr. MARTIN, for instance, speaks of the Council as appearing to him not to have the interests of the whole body of chemists and druggists at heart as it ought to have, and grave as this charge is in form, it appears to be enough in Mr. MARTIN's estimation that he should suggest as the reason of this alleged failure of duty in the Council that many of its members perhaps, residing in London, with first-class dispensing and retail businesses, do not sufficiently understand the position of their less fortunate brethren in the country. If Mr. MARTIN's idea of the constitution of the Council had no better relation to fact than this remark seems to indicate, a reference to the Journal of May last would have shown him that out of twenty-one members of Council only nine are resident in London, so that even if country members were to be credited with greater regard for the interests of the whole body of chemists and druggists than it is assumed London members can possess, the alleged disregard of those interests by the Council, could not be ascribed to a preponderance of London members.

Equally inconsequent is Mr. HAMBRIDGE's suggestion that as the SHEPPERLEY case has not settled the vexed question of counter prescribing, members of the Society should withdraw from it. We fail to see how such a proceeding would contribute to promote the settlement of that question or the interests of the trade generally or of those who transferred their support to the Trade Defence Association, which has already suffered one serious defeat, and has only succeeded in demonstrating that "counter practice "has no legal position whatever."

When writers manifest such want of acquaintance with facts relating to a subject upon which they express strong opinions, it is not surprising that they should ignore, even if they be aware of, what has been done by the body which they assume to censure. Accordingly Mr. MARTIN leaves disregarded the circumstance that more than two years ago, and before the trial of the SHEPPERLEY case at Nottingham, a resolution was passed by the Council to the effect that it was prepared to consider the case of any chemist and druggist threatened with vexatious proceedings for alleged infringement of the Apothecaries Act, and to defend the same if the circumstances warranted. That resolution was moved by a member of Council who resides in London, and it was seconded by another London member. Some ten months later such a case had been brought under the notice of the Council; it was considered and again a London member of the Council moved that the case should be defended; three London members on that occasion spoke in support of the proposal to defend the case and five voted in favour of it.

If it were not for the hardihood of the assertions that have lately been made respecting the action of

the Council as to counter practice and the prosecutions of chemists and druggists under the Apothecaries Act, it would be waste of time to recall these facts, and by means of them to show that there is no foundation for many of the statements made in letters sent to this Journal, as well as at meetings of which we have published reports. Indeed it is questionable whether in publishing these letters and reports too much consideration has not been shown to the turbulent spirit and too much encouragement given to its manifestation. But if we have erred in this respect it has been from a desire to avoid giving any real occasion for such charges against the conduct of this Journal as we referred to last week. Under the influence of this desire we have published several letters which we do not hesitate to say would have been much better disposed of in the waste paper basket, inasmuch as they contribute nothing towards the solution of a question that is no doubt one of importance to many members of the trade. The only condition, however, we have thought it necessary to require was the publication of the writers' names, since many of the letters evinced an aggressive tendency, and by publishing them anonymously we might have been blamed for exposing the Council to attack by the "harebrained chatter of irresponsible frivolity."

But though endeavouring in this way to perform our duty equally to the Council of this Society and to those who come forward, as they consider, in support of the interests of the trade, we have not escaped receiving some share of the condemnation that has been so profuse. A member of the Executive of the Trade Defence Association struck the keynote in this direction at Birmingham by declaring his conviction that nothing was to be hoped for trade interests from this Journal. Mr. ROBINSON, at Rochdale, assumed that the good effect (?) of the verdict in the SHEPPERLEY case was unduly minimized in such a way as not to express the opinions of the great body of chemists and druggists throughout the country. Mr. FELTWELL thought it very hard that this Journal seemed dissatisfied with the case, and this week Mr. MARTIN regrets that it is evident we have a greater leaning towards the opponents of chemists and druggists than we have to our own constituents. We cannot charge ourselves with being open to the impeachment implied by these comments, nor do we in the least admit that they have any such real foundation as would require us in accordance with Mr. MARTIN'S suggestion to set up a weathercock for the guidance of our opinions. On the contrary we would refer those who concur in the comments above mentioned, to the articles which have appeared in the Journal on the subjects of counter practice and the prosecution of chemists and druggists under the Apothecaries Act during the last two years, and we feel confident they will there find we have always shown sympathy with members of the trade who are exposed to vexatious interference with the ordinary conduct of their business. Throughout we have strenuously insisted that the chemist and druggist is no more under disabilities as to giving medicines and advice for their use, than any other member of the community. We have always deprecated the application of the Apothecaries Act as a means of preventing counter practice on the ground that it was never intended for that purpose and is in itself—having regard to its history—specially inappropriate for that purpose.

At the same time we should not have been true to the policy which has always guided the action of the Pharmaceutical Society, if we had not given expression to the opinion that counter practice is "unavoidable rather than justifiable" and that though a necessary part of the chemist and druggist's business, under many circumstances, it should never be allowed to take the form of medical practice strictly speaking. It is, however, alleged by the medical organizations formed to promote prosecutions of chemists and druggists under the Apothecaries Act, that this appropriate limitation of counter practice is not always observed, and if that be the case, the persecution of the trade now complained of must be ascribed to those who may disregard this limitation.

As regards the SHEPPERLEY case and the reasons which induced the Society of Apothecaries to authorize the prosecution in the first instance, as well as the Council of the Pharmaceutical Society to abstain from defending the case, it appears from the last Council meeting report that the case "was so re-"presented to the Council that it did not think it would "be for the interests of the Society to defend it, "because Mr. SHEPPERLEY had gone beyond his duty "in recommending medicines." We are now enabled by the courtesy of the Clerk to the Society of Apothecaries, to place before our readers an official statement of the reasons for the action taken by that body in authorizing the prosecution and in continuing to carry on the case at the new trial.

In that statement it is attempted to be shown first that the Society of Apothecaries had reasonable grounds for authorizing the prosecution of Mr. SHEPPERLEY in the Nottingham County Court. That view was borne out by the decision of the County Court judge having been in favour of the plaintiffs. Secondly, that the trial which took place before Mr. Baron POLLOCK was forced upon the plaintiffs by the observations of the two judges before whom the question of law involved in the decision of the County Court judge came for argument.

Thirdly, that the verdict of the jury upon the trial before Mr. Baron POLLOCK, merely dealt with the actual facts of the case and involved no important question of law on the one side or the other.

Fourthly, that the position of the Society of Apothecaries, in the matter of prosecutions, is a most difficult one, as established by the fact that it has now received an intimation, in two pending cases,—where it claims to exercise a discretion, either as to the court in which the proceedings shall take place, or as to the authority being given at all to prosecute,—that a mandamus will be applied for requiring the Society either to prosecute or to allow the intending prosecutors to do so.

It will be seen from this that the discretionary power which the Society of Apothecaries wishes to exercise in the matter of prosecution is to be called in question, and that the Society is not, as is evidently presumed by the public, either conducting these prosecutions out of any funds of its own or anxious to allow them to be instituted without reasonable cause. It is also pointed out that while the feeling of the leading members of the Society of Apothecaries is decidedly adverse to these prosecutions, on the other hand, the feeling of the licentiates of the Society, or of a large number of them, is apparently the other way, so that perhaps it would place the Society of Apothecaries in the fairest light if the intended application for a mandamus is fully heard out.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 11, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Taylor.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Eight candidates were examined. *Three* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Brearey, Arthur William .....Douglas.
Brown, Thomas .....Hull.
Cooper, John.....Newcastle-under-Lyne.
Gulliver, George Ekins .....Holdenby.
Hall, Edward .....Norwich.

MINOR EXAMINATION.

Nine candidates were examined. *Two* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Alcock, Frank Harris .....Burslem.
Allan, James Henry.....Stockton-on-Tees.
Allen, Frederick Charles..... ..Birmingham.
Bird, Henry .....London.
Bradbury, Thomas .....Ashton-under-Lyne.
Brewerton, Thomas .....Manchester.
Bright, Thomas .....Shrewsbury.

MODIFIED EXAMINATION.

Six candidates were examined. *Four* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bettinson, William Thomas .....Wickham Ter., Kent.
Gooseman, William .....Grimsby.

December 12, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Taylor.

MAJOR EXAMINATION.

Eight candidates were examined. *Four* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Keith, John .....Forres.
Leigh, Marshall ....Middlesborough.
Stammwitz, Louisa ... .Wandsworth Common.
Will, William Watson.....Montrose.

MINOR EXAMINATION.

Sixteen candidates were examined. *Eight* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Buckley, Walter .....Bradford.
Creer, George .....Castletown.
Davies, Owen .....Llanelly.
Davis, James Bailey .....Chester.
Dean, Thomas William .....Linton.
Fawcett, Christopher Airey ...Windermere.
Fletcher, Ellis .....Atherton.
Foster, William .....Whitehaven.

December 13, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Linford, Martindale, Moss, Southall and Taylor.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Ten* failed. The following *thirteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Gibbons, Walter .....Manchester.
Gulliver, William Inchle.....London.
Harrison, Frederick .....Brighton.
Henderson, Christopher .....Hoylake.
Herdman, James Gawin .....Blackpool.
Herington, Joseph Henry .....Leighton Buzzard.
Higgs, Alfred .....London.
Howell, William .....Cheltenham.
Hughes, Evan .....Chelmsford.
Izod, William Henry .....Upper Norwood.
James, Thomas Cragg .....Dalton-in-Furness.
Jones, David Edward .....New Quay.
Knight, Charles..... .....Gloucester.

December 19, 1878.

Present—Mr. Williams, President: Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Taylor.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Sixteen* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Lemmon, Eric .....East Grinstead.
Lord, William Henry .....Kennington.
Massingham, Hugh Mortimer...Royston.
Mayger, William John.....Northampton.
Morgan, Thomas William .....Hereford.
Newbigin, Lesslie.....Alnwick.
Norris, Alfred Beardmore .....London.
Ratcliffe, Henry Norman.....Torquay.
Rowe, Walter .....Leicester.

December 20, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Linford, Martindale, Moss, Southall and Taylor.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Twelve* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Scammell, William Joseph .....Adelaide.
Sell, William Henry.....Bath.
Shillcock, George .....Bromley, Kent.
Spencer, Robert .....Stourbridge.
Toon, Lionel Edward .....Haslar.
Waddington, John William.....Kettering.
Walker, Joseph ....Whitby.
Williams, Stephen.....Cardigan.
Wood, James Burge ....Lincoln.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Newton, Augustus .....London.

Certificates of the Incorporated Law Society.

Hannay, James Maughn .....Dudley.
Milford, F. E. C. ....Newtown.

Certificates of the University of Cambridge.

Hannay, Samuel J. .....Dudley.
Jones, Llewellyn J. W. .....Swansea.
Lock, Samuel Edward .....Halifax.
Marten, John Reed .....Brighton.
Spink, Henry Joseph.....Dudley.
Tomson, Edward .....Brighton.

EXAMINATIONS IN EDINBURGH.

December 18 *and* 19, 1878.

Present on each day—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

18*th.*—*Two* candidates were examined. *One* failed. The under-mentioned passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Fisher, John Hutchison .....Edinburgh.

MINOR EXAMINATION.

18*th.*—*Fourteen* candidates were examined. *Seven* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Ashworth, Richard .....Manchester.
Camplin, John ....Appleby.
Gifford, Richard Lord .....Blackburn.
Glover, William .....Newcastle, Staff.
Jackson, David.....Manchester.
Mushens, Robert Heslop.....Sunderland.
Phillips, John James .....Hyde.

19*th.*—*Eight* candidates were examined. *One* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

McDonald, Donald Fraser .....Edinburgh.
Stewart, Charles .....Edinburgh.
Turnbull, Edward Hardy .....Edinburgh.
Turner, James ... .Seaforth.
Ward, Smith.....Batley Carr.
Willson, Walter Henry .....Homerton.
Wilson, Peter .....Edinburgh.

MODIFIED EXAMINATION.

19*th.*—The under-mentioned was examined, and was declared qualified to be registered as a Chemist and Druggist:—

Bell, George .....Lockerbie.

NORTH BRITISH BRANCH.

The third meeting of the session was held in the Society's Rooms, 119A, George Street, on Wednesday evening, 11th December, Mr. J. B. Stephenson in the chair.

The Honorary Secretary intimated the addition to the Library of the fourteenth edition of 'The Dispensatory of the United States of America,' by Wood and Bache, from the Society in London.

The following paper was read in the absence of the author by Mr. W. Ivison Macadam:—

On the Presence of Arsenic in Soot.

BY DR. STEVENSON MACADAM.

The coal consumed for household and general purposes invariably contains more or less sulphur in the form of iron pyrites, and occasionally the quantity is so large as to be capable of detachment from the coal before the latter is put into the market. The pyrites so obtained is commonly called coal brasses. The analyses of several samples of these brasses made by me twenty years ago revealed the presence of arsenic in minute quantity, and Dr. Angus Smith, who found the arsenic in thirteen out of fifteen samples, has expressed the opinion that though the arsenic has not been obtained directly from the atmosphere, yet we must believe it to pass into the air with the sulphur.

I have lately had occasion to make some investigations as to the possible presence of arsenic in the atmosphere of towns, and it occurred to me that if the arsenic in the pyrites of the coal was volatilized with the sulphur, that probably evidence of such disengagement of arsenical vapour in coal smoke might be obtained by the analysis of soot. Accordingly, I procured a number of samples of soot collected from different house chimneys and had no difficulty in determining the presence of arsenic in every sample.

The preliminary trials were made by Reinsch's process, and 100 grains of soot were sufficient for the purpose of coating the copper, and thereafter of giving the crystals of arsenious oxide. In the actual trials, 200 grains of the soot were treated with fine diluted hydrochloric acid, and the whole warmed for an hour and filtered. The arsenic was thereafter separated by hydrosulphuric acid, the precipitate redissolved in fuming nitric acid and the arsenic finally determined as the arseniate of magnesia and ammonia $2(MsNH_4AsO_4)H_2O$, and calculated into arsenious oxide As_2O_3. Some of the samples of soot yielded as follows:—

	A.	B.	C.	D.
200 grains of soot yielded of magnesia precipitate	0·34	0·38	0·35	0·45
equal to per cent.	0·17	0·19	0·175	0·225
and calculated into arsenious oxide	0·0885	0·0990	0·0911	0·1172

The average quantity of arsenious oxide being thus 0·1 per cent. $\frac{1}{1000}$ of the weight of the soot.

I may state that trials made on samples of soot taken at different heights in the same chimney proved that the arsenic was present in larger quantity in the soots collected near the fire place than in those taken from near the top of the chimney.

These results demonstrate that arsenic is evolved during the combustion of ordinary coal and that part is condensed in the chimney along with the carbon and the sulphur of the soot, but as a great part of ordinary coal smoke passes into the air, there can be no doubt that a portion of the arsenic accompanies the smoke into the atmosphere. The more inferior a coal, then, as a rule, the more pyrites it contains, and probably also the more arsenic. We must therefore reason that every coal fire is a producer of arsenical vapour to a limited extent, but notwithstanding the enormous quantity of coal consumed in towns, I am not prepared to say that the arsenical contamination of the atmosphere from this source is of any practical moment in a sanitary point of view. Probably we may have as much reason to dread the carbonic acid evolved during the combustion of a gas jet or a candle in a well ventilated room, as the arsenical atoms in the ever shifting atmosphere.

The next paper read was—

On the Use and Abuse of Tea, Coffee, and other Allied Beverages.

BY DR. F. W. MOINET.

The subject which I have chosen to bring under your notice this evening, viz., the Use and Abuse of Tea, Coffee, and other Allied Beverages, may appear to be one that might briefly be dismissed with a few such words as they are pleasant, warm, and refreshing beverages, and, like everything else, if partaken of too freely, might probably be injurious.

But one of the objects of a Society like this is, I take it, to examine into the reason of things and not to be content with mere popular opinion, *i.e.*, to consider the position from a scientific point of view, and see whether science approves or condemns the common use of these beverages.

But a scientific examination of the subject should do more than merely approve or condemn, it will show us on what fact the verdict is founded and in this way will guide us in making a right use of them and show us when their employment would be hurtful instead of beneficial. That such a knowledge of these beverages is desirable no one can doubt, when we consider how extensive and general is their employment. Thus, the annual consumption of coffee in all parts of the world is roughly estimated at 1,200,000,000 lbs., while in the United Kingdom alone the consumption of tea in 1873 amounted to over 132,000,000 lbs. and is yearly increasing. These figures then will give you some idea of the importance of the subject, affecting as it does so many people.

First—What these beverages are: tea, coffee, cocoa, chocolate, maté, guarana, and coca. Not that these are all the allied beverages, for many others are used in different parts of the world to make refreshing drinks. Thus Professor Johnston gives a list of over thirty plants which have been and are employed as substitutes for tea alone. But those I have mentioned are the most extensively consumed as national beverages of this class, and as we know more about them and can therefore speak with greater certainty as to their action and use, we may take them as good representatives. And it is extremel

interesting to notice that although unlike one another and obtained from totally different sources, their action on the human body is almost identical. This we might almost infer from the circumstance that in these widely separated countries they are used for the same purpose by savage and civilized nations alike. But we have stronger evidence than this to go upon. Chemists in analysing them have separated a crystalline principle from each, which they have proved to be identical in chemical composition. And experiments on man and the lower animals have shown that they exert the same influence and produce the same symptoms as doses of the beverages which contain them, differing only in degree, proving conclusively that it is the active principle.

This is especially the case with some of them, viz., tea, coffee, maté, and guarana. In regard to the other two, cocoa seed and coca leaves, chemists have not yet succeeded in telling us definitely the chemical composition of their active principle, but from the similarity of their action the probability is that they also owe their activity to this the active principle of tea and coffee.

This principle on which the action of these beverages chiefly depends is called caffein, because it was first discovered in coffee by Runge, in 1820. Some years later, in 1827, Oudry discovered it in tea, and called it theine, and in 1838, these were proved to be identical. More recently Stenhouse has shown that it is also contained in guarana and maté, or Paraguay tea.

As the action then of these beverages depends principally on this crystalline body, caffein, they must in virtue of it produce on the human system certain effects in common. What these effects are we will first notice, as on them are founded their general use in our households.

But as they contain caffein in different amounts, and as they contain other substances which give them accessory properties, their action must differ somewhat both in kind and degree. How they differ we will next consider, this being the only way to arrive at any safe and practical conclusion; then lastly, how they can be abused.

First. The effects which they produce in common. They all act as stimulants to the nervous system, the circulation of the blood and the action of the lungs, *i.e.*, the nervous system is braced up, the blood circulates more rapidly, and the lungs breathe more quickly.

On account of this nervous stimulation there is increased ability for mental and bodily work; both mind and body are invigorated so that more work can be done by the brain or muscles; or, if you are exhausted, they refresh you by bracing up the nervous system to or near to its normal degree of tension so that the feeling of fatigue is diminished or disappears entirely. They are also soothing by allaying irritability and enable you to feel less any little annoyances or discomfort, because if the nervous system is unstrung it is easily jarred by influences which it would resist were it in its normal condition.

Their effects then, their invigorating, refreshing and soothing power, which I have no doubt we all have experienced, are the principal foundations for their general use as articles of diet or medicine. (Formerly their powers were attributed to their property of diminishing waste; now disproved, as they do the opposite, increasing tissue waste by stimulating the circulation and lungs, producing more urea and carbonic anhdydride; hence if taken without sufficient food they bring on emaciation.)

Then as they are usually taken warm, and as they stimulate the circulation, the result is an increase of bodily heat. Hence they are serviceable in cold weather, because, in addition to their other properties, they help to maintain the natural warmth of the body, which is the best preventive against the injurious effects of cold. And here I would like to say a word in regard to the comparative merits of these beverages and alcoholic drinks in cold weather. Both are heating, but alcohol warms the surface at the expense of the internal organs, and hence a sudden chill is much more apt to be followed by inflammation in a man heated by alcohol than in one heated by tea or coffee; also, after the warmth produced by alcohol has expended itself the temperature of the body sinks below normal, so that the last condition is worse than the first, as it is rendered all the more susceptible to cold, and it does not follow the use of tea or coffee, so that the advantages are decidedly with tea and coffee. This is shown by the experiences of travellers, soldiers and sailors in the arctic and tropical regions, who have found that the animal heat is maintained better, fatigue and want of food borne longer, under their use than under alcohol, and health better preserved.

Then, again, in warm weather, although it may almost appear a paradox to say so, they help to keep the body cool. This they effect by increasing the action of the skin, and causing an escape of moisture (or sweating), which diminishes the heat by cooling the surface of the body. That they do not do this in cold weather is because cold contracts the skin, and diminishes sweating, which the warmth of these beverages does not overcome. Hot weather, on the other hand, relaxes the skin, and so favours their action in cooling the body. Hence the following are some of the indications for the employment of these beverages, which we deduce from their common effect:—

(1) To quench thirst, which they do in virtue of the water in which they are administered.

(2) To warm the body in cold, and in a less degree to cool it in warm weather.

(3) To invigorate the mental and bodily powers during work, and to refresh and sooth them when exhausted by work.

(4) To promote appetite and assist digestion when taken with food.

Upon this stimulant action then, their principal uses depend, and their extensive and general consumption shows that such stimulants meet a general and felt want. That their employment is not so liable to be abused as the employment of alcoholic stimulants, is because alcohol is a much more powerful stimulant, and is followed by depression corresponding to the degree of our stimulation, and thus generates a crave or appetite for renewed indulgence; alcohol is also a narcotic, and causes intoxication, so that excess injures the moral and intellectual, as well as the physical nature. Hence it entails greater injury to the individual and to society at large.

But in health the mind and body do not require to be constantly stimulated by food or drink, and if taken only to supply the necessary waste of the body, there is not much danger of their being abused, especially in the case of tea and coffee. Because if you are tired and exhausted the system craves, if it is a healthy one, for something more than a mere temporary stimulant; it requires food to support the system, because mental and bodily exercise greatly increases the waste of the body, and appetite or hunger, which is the body's signal to the mind that it requires nourishment, is the result of exercise, so that, as a rule, the wants of nature are best supplied by taking these beverages along with food, as is usually done, as in this way they promote digestion, and the assimilation of food, *i.e.*, its transformation into the various substances required to build up the different structures of the body, so that taken with food they promote digestion and nutrition. That these actions are well founded most of you can judge for yourselves, now that I have brought them before you. That they are of service to the community no one can doubt. This is shown by the enormous consumption in all parts of the world, by all classes and ranks of people, from the Royal Family to the poorest household, showing that they supply a generally felt want, for what want could be more generally felt than a drink which warms when cold, cools when hot, promotes appetite and digestion, and imparts mental and bodily vigour, without the danger of exciting evil passions and drugging the brain. And although it has not been for

science to discover their uses, it has shown on what their uses depend, so that we can employ them to the best advantage, and how they can prove injurious, and has also suggested other uses, as in disease, which could only be suggested from a knowledge of their mode of action, and by doing this science has conferred no small benefit.

Having seen what action they have in common, we have now to notice in what respect they differ in their action, because it is only by knowing this that we can understand their respective uses.

Their action differs both in kind and degree.

In degree, principally, according to the proportion of caffein which they contain.

Thus, Stenhouse's investigations have shown that guarana yields 5 per cent., tea yields 2 to 4 per cent., maté a little more than 1 per cent. (1·2), and coffee a little less (0·80 to 1 per cent.). Thus guarana is the stronger nervine stimulant, next comes tea, then maté, and last coffee, and as guarana yields such a large quantity of the nervine stimulant, it was some years ago introduced as a remedy for headache, etc., the kind of cases which would be benefited by a strong cup of tea. But as an ordinary beverage, neither it nor maté is as pleasant as tea and coffee, which, being those more extensively used, we will first compare.

Of the two, tea is much the stronger stimulant to the nervous system, as it contains from two to five times as much caffein, and this is one of the reasons why a cup of tea is more refreshing than a cup of coffee, and why it is generally selected in preference to coffee, when such a drink is alone required. But both tea and coffee contain other substances, which give them additional properties, and which must be taken into account in comparing their effect.

These are—

	Tea.	Coffee.
Caffein .	2 to 4 per cent.	0·80 to 1 per cent.
Tannic Acid	13 to 18 „	5 „
Gluten .	6 per cent.	13 „

Volatile oils, small varying quantities in both.

Tannic Acid or Tannin.—This is the astringent principle of all vegetable substances, and to it tea owes its astringent bitter taste and constipating effect on the bowels, and from the greater amount of it which tea contains compared with coffee, it is much more astringent, and this is one reason why tea does not agree with some people so well as coffee does. Another reason why strong tea is apt to disagree with some, especially if it be taken with or soon after animal food, is that the tannic acid combines with the gelatinous and albuminous constituent of the food, and forms tough and insoluble compounds, a kind of leather in fact, so that no wonder if an attack of indigestion is the result, as leather cannot certainly be considered a light article of diet, especially for those whose mode of life is not very active, as is the case with ladies and most professional men. And as more tannic acid is extracted from tea leaves the longer they are infused, still more so if they are boiled, the tea, although it becomes darker in colour, and more bitter, is not in reality stronger, unless as an astringent, because caffein in combination with an acid is more soluble in water than tannin, and is therefore extracted first, and as the more astringent tea is, the more apt it is to cause indigestion, this should be borne in mind.

Then again they both contain gluten, one of the more nutritious compounds of wheaten flour. Tea 6 per cent., coffee 13 per cent., so that coffee must be the more nourishing of the two, all the more so because, in the ordinary process for making tea, little or none is extracted, while it and other nutritious substances are in making coffee, so that while coffee is nourishing, *i.e.*, food as well as drink, tea is not. This is another reason why tea is usually preferred and better borne by the stomach in sickness, because it is simply a refreshing and stimulating drink, and does not burden the stomach by requiring it to digest anything, while coffee does. They also both contain aromatic volatile oils, developed in the processes of drying tea and roasting coffee, and to which their respective and characteristic odours are due. That of tea does not probably, however, influence its action much, because in drying it is partly dissipated and by keeping before use still more so (in China one year). But this is not the case with coffee, which is used as soon after roasting as possible, so that the oil, if it has any action, is there to exert it. That it has an action has been clearly shown, and that action is a stimulant one to the circulation and mucous membrane of the stomach, so the oil increases its general effect; but this action on the stomach renders it less tolerable to delicate stomachs, which is another reason of the preference usually shown for tea by invalids and delicate people. To this oil is also probably due the greater heating powers of coffee, increasing the circulation of the blood, and causing a sensation of warmth in the stomach. This action being superadded to that of the coffee, makes up somewhat for the lesser amount of caffein which it contains, and is the reason why coffee is a beverage better suited for breakfast or other meals at which more solid food is taken than tea, for most people, because it is more a stimulant to the stomach than tea, and for this reason assists the digestion of the food with which it is taken and warms the body better.

Another reason for the preference of coffee by some, especially the labouring classes, to whom it is of more importance, is that it keeps its heat longer, due probably to its greater density. These, then, may be considered as the really active constituents of tea and coffee, and we may sum up the difference between them and their causes, viz. :—

Tea, containing more caffein and tannic acid, less gluten and extractive matter and volatile oil, is more refreshing, lighter, better borne by the stomach, more astringent and less nutritive and heating than coffee.

Coffee, containing less caffein and tannic acid, but more gluten, extractive matter and volatile oil, is less refreshing and astringent, but more nutritive, heating to the body and stimulant to the stomach.

Now let us take cocoa and chocolate prepared from the seed of the cacao or chocolate tree (Mexico). These substances have the same action and use and the only difference is in their preparation. Thus they are manufactured for use in three ways, which give cocoa, chocolate and cocoa nibs and their composition is, viz. :—

Volatile Oil	a trace.
Theobromine	2 per cent.
Concrete Oil	50 „ „
Gluten	20 „ „
Starch, etc., ...	22 „ „
Water	5 „ „
	100

A small amount of volatile oil is developed in roasting and gives them their pleasant odour. But their activity and use depends on first, the principle termed theobromine, 2 per cent., which on account of the similarity of its action to caffein is probably identical, *i.e.*, a nervous stimulant. Second, to the concrete oil, gluten, and other extractive matter. They are therefore refreshing and nutritive, much more nutritious than any of the other beverages of this class, and are rich articles of food, and for this reason not unfrequently prove rather heavy for those of weak digestion. They may, however, be rendered lighter by pouring boiling water or milk over them and not boiling them, as by boiling the oil is separated from the rest of the ingredients and is rendered, in this way, much more indigestible. These beverages, then, are more nutritious than tea or coffee and less stimulant, due to their containing each a large proportion of nutritive material, but less of theobromine or caffein than tea, and although they contain more than coffee, this is more than counterbalanced by the stimulant aromatic oils in coffee. Also, owing to the quantity of food which they contain, the action of the theobromine is partly spent on the di-

gestive organs and not altogether on the nervous system which is always the case when stimulants are taken along with food, and this explains why the nervous system suffers much more peculiarly and severely after excess in tea or coffee if they are taken alone and without food.

The action of cocoa and chocolate on the nervous system is therefore very slight, and this is the reason why they are not employed to stimulate mental activity, like tea or coffee, and as they contain little or no tannin, are not liable to disturb the nervous system or derange the stomach, and hence if taken to excess do not produce the bad effects of tea or coffee.

Having considered their uses, to complete the subject we have now to note their abuse, which I am glad to say I can do very briefly, and will confine our attention to tea and coffee, because the injurious results which follow their employment under certain circumstances are due either to the caffein or tannic acid. As both cocoa and chocolate contain little or no tannic acid or volatile oil, and the theobromine which corresponds to caffein being spent principally on the digestive system, and as they are not used to the same extent, they cannot affect the system as injuriously as tea and coffee can do. The effects or symptoms, then, which tea or coffee cause when abused, *i.e.*, ill used, are of two kinds, according as they are produced by caffein or by caffein and tannic acid. When produced by caffein they are generally induced speedily and suddenly and do not last long; induced by both they come on more slowly and gradually, are more persistent, and ultimately more injurious to health, so that we may call them acute and chronic poisoning.

1. *Acute poisoning.*—If a considerable quantity of strong tea or coffee is drunk, especially without food, simply to stimulate the nervous system so as to ward off sleep or to promote the activity of the brain for study, after a time, sooner or later, depending on the condition of the nervous system and the dose, it may be after a few hours or perhaps weeks, the nervous system suffers from the over stimulation, and the result is the occurrence of a train of peculiar nervous symptoms, very frequently during the evening, viz., great nervousness and restlessness, palpitation of the heart, difficulty of breathing, and oppression of the chest and dread of some impending calamity or fear of death, usually passing off in a short time but to recur again under the same provocation, until, perhaps, the patient's nervous system is completely shattered, unless the cause is discovered and abstained from.

These cases are not very common, but are familiar to medical men, as it has been long known that the symptoms induced by overdoses of tea or coffee closely resemble the symptoms depending on certain affections of the heart, and to distinguish between them we have to get the history of the attack, which usually throws light on the cause.

These cases are also extremely interesting, as they show the powerful influence which caffein is capable of exerting on the nervous system, being first a stimulant and then a depressant, the symptoms of acute poisoning being those of depression following over-stimulation.

2. *Chronic poisoning* is, however, much more common, and cases of it are principally met with among women in all ranks of society. Among the better classes tea tippling is far from uncommon, and there is less excuse for them than in the case of their poorer neighbours, who are partly driven to it by necessity and who err through ignorance alone.

This is the case with many poor women who have to work hard for a scanty living and are therefore compelled to live as economically as possible, and yet their employment demands good and sufficient nourishment. Under these circumstances they usually indulge frequently in hot and strong tea, sometimes with every meal, occasionally at other times also. They do this as it is easily and quickly prepared and is heating and refreshing. In this way hunger is diminished and less solid food is taken; they are refreshed for the time and more easily satisfied and live more cheaply. But sooner or later they begin to feel the natural consequences of such a mode of living.

Appetite gradually fails them and the little food they take does not agree with them; the stomach, from being too frequently stimulated, has its digestive powers impaired, and the sensibility of its mucous membrane blunted by the astringent action of the tannic acid, so that both appetite or desire for food and the power of digestion are diminished under the disastrous combination. They gradually lose flesh, become thinner and weaker, dyspeptic and nervous, and in this condition seek medical relief.

The cause of their suffering is twofold:—(1) The refreshing effect of tea due to the caffein, which is only temporary, diminishes the desire for food to replace the natural wants of the body and so entails loss of flesh and strength; (2) the tannic acid acting as a powerful astringent to the mucous membrane of the stomach diminishes its secretions and causes indigestion and constipation, so that when food is taken you have indigestion, and the number of impaired digestions and weakened nervous systems that tea is answerable for is not trifling, as any doctor will tell you.

Such, then, are the results of chronic tea poisoning, and although the patient errs only through ignorance, nature does not allow that as an excuse. Excess of any kind is an offence, and to be avoided, although the results may not be so glaring or disgusting as is the case in some other instances, but being more insidious should be clearly pointed out; and to ignorantly and recklessly uphold that these beverages are entirely harmless is just as bad reasoning as to uphold that alcoholic drinks are essential to health. And here is the province of true science, to step in and state the facts of the case and not to give a mere opinion; to show wherein is the use and wherein is the abuse, so that they may not be injured through ignorance, as they frequently are.

A hearty vote of thanks was given to Dr. Macadam and Dr. Moinet for their interesting communications.

The next evening meeting was announced for Jan. 15, when papers will be read by Mr. H. B. Baildon and Dr. W. Inglis Clark.

Parliamentary and Law Proceedings.

The Supplying of Ergot to Midwives.

On Tuesday, Dec. 17, Dr. Hardwicke held an adjourned inquest in Marylebone, on the body of Maria Josephine Harris, aged 26, who died suddenly in the house of Mary Ann Walker, "certified midwife and ladies' and gentlemen's invalid nurse," residing at 39, Newnham Street. The inquiry had been adjourned among other reasons for an analysis of the contents of the stomach and two bottles found in deceased's rooms.

It appeared that a fortnight before her death deceased, being *enceinte*, had left her lodgings and gone to live at the house of Mrs. Walker, who was to attend on her during her confinement. On the day of her death she seemed as well as usual in the morning, but towards midday she was suddenly taken ill, felt faint, and exclaimed, "Oh, Mrs. Walker, I'm faint; I'm going to die!" Mrs. Walker ran to help her, when she fell into Mrs. Walker's arms; she was laid on a sofa and brandy administered and her hands rubbed with warm flannels. A doctor was immediately sent for, but before his arrival the young woman expired. Dr. Knott, who was sent for, gave it as his opinion, after making a *post mortem*, that death arose from extensive lung and heart disease. He had not, however, analysed the contents of deceased's stomach, and for this and the reasons specified the inquest was adjourned.

Mr. Arthur P. Luff, F.C.S., demonstrator of chemistry in St. Mary's Hospital, said that the contents of stomach, two bottles and three boxes of pills were sent him by Dr. Randall. The bottles were found at Mrs. Walker's, the pills at the lodging of deceased. One box contained what is known as "Welch's Female Pills." One 8-oz. bottle contained about two teaspoonfuls of some medicine smelling strongly of ergot of rye. Analysed and found ergot of rye in the mixture; liquid extract, he fancied. The other bottle had contained steel drops. The contents of the stomach he submitted to a careful analysis and found ergot of rye present. Was of opinion that the pills had been first used for an unlawful purpose, but not being potent enough ergot of rye was resorted to. The contents of the bottle had been prepared by a chemist, and was not of unusual strength.

Dr. Randall said the pills, which contained aloes, were often given for menstruation, or, if a woman was pregnant, to procure abortion, and the female public had great faith in steel drops. The ergot would act more decidedly than the pills. He should say that the ergot had acted upon the uterus and produced hæmorrhage, which was the immediate cause of death. Death was accelerated by a weak heart and diseased lungs.

Mr. Boothby, 72A, Crawford Street, pharmaceutical chemist, said that all ergot sold to the general public required a signature, but it was made up for the medical faculty. He had sold Mrs. Walker liquid extract of ergot for over two years. He supplied ergot to medical men and certified midwives by written order. He had also supplied her with other medicines of such a nature as to give him an idea that he must "look sharp." One day Mrs. Walker said she was going to a great flooding case at Windsor, and wanted a supply of ergot. He remarked that she must sign the book for ergot, and in case of being engaged, she must send a written order. As the orders came he entered them in his book. [Book produced. Entries: Oct. 25, 5 oz. ergot; Nov. 8, 9 oz.; Nov. 11, 6 oz.; Nov. 20, 4 oz.; Nov. 27, 8 oz.; Nov. 29, 6 oz.; Dec. 2, 3 oz.] Ergot came under class 1, and must be signed for. When Mrs. Walker sent an old bottle he merely put the ergot into it; but if he supplied the bottle he labelled it, and marked it "ergot, poison."

The Coroner and jury thanked Mr. Boothby for the honest and straightforward manner in which he had given his evidence.

Dr. Randall said the quantities of ergot sold by the last witness were enormous.

Mr. Boothby said he had consulted a qualified surgeon and asked his opinion if the person was justified in using such a quantity.

Dr. Randall said from ten to thirty drops of ergot was considered a dose in a case of labour; in a six-ounce bottle there would be ninety doses. In the most extreme cases he should not give more than three or four doses.

Eventually the jury returned the following verdict:—"That Maria Josephine Harris was found dying and did die from the mortal effects of hæmorrhage from the womb, accelerated by heart and lung disease; and that said death was accelerated by taking ergot of rye whilst living with Mrs. Walker, certified midwife."—*From the Borough of Marylebone Mercury.*

Dispensing Memoranda.

[180]. The "Month" in a recent Journal says, that sugar of milk and honey will not of themselves make a good pill mass, and when I stated that atropiæ sulph. could be made into pills with sugar of milk and honey I must have said so without knowing by experience, whether they would do so or no. I have very frequently had to make pills containing a powerful alkaloid and have found that sugar of milk and stiff honey are the best excipients.

The sugar of milk and honey, have an advantage over such excipients as the pulv. tragac. co., or pulv. g. acaciæ, as the pills made with the former are much more soluble than those made with the latter.

In order to show that sugar of milk and honey will of themselves make a satisfactory mass, I enclose one dozen pills composed entirely of these two substances.

Scarborough, C. E. P.

---

[193]. The reduced iron is not sufficient to make a workable mass, and I find that an excipient of one grain of pulv. glycyrrh., to each pill, answers the purpose well and will not affect the coating, being then not larger than ordinary four grain pills. But if the mass is evaporated by heat in any way the result will be as described.

O. E. Clark.

---

[205]. There is nearly three times more tragacanth in this mixture than is required for the suspension of the bismuth. Mr. W. Baker should call the prescriber's attention to the fact.

Victoria Hospital. J. Laker MacMillian.

---

[207]. Will some correspondent kindly say how he would dispense the following?—

℞	Potas. Bromid.	℥ss.
	Vaseline	℥iss.
	Aq. Destill.	℥vj.

Ft. lotio occulis applicnd.

T. S.

---

[208]. I had the following brought me to dispense the other day:—

℞	Quiniæ Disulph.	℈ij.
	Acid. Sulph. Dil.	♏v.
	Syrupi	ʒss.
	Aquæ.	ad ℥iv.

Misce. Capiat cochleare parvum secundis horis. When cool.

As the quantity of acid ordered is too small to dissolve the quinine, was I justified in placing a "shake the bottle" label on? As the medicine was urgently required and the prescriber not within reach, I adhered strictly to the prescription.

Minor.

---

[209]. Will some of your readers say whether they would have dispensed the following recipe without question?—

℞	Cupri Sulphatis.	gr. j.
	Extract. Opii.	gr. ij.
	Conf. Rosæ	q.s.

Ut ft. pilula. Mitte tales vj.

No directions, no signature of prescriber, although I was assured it came from the hand of a qualified man. I sent the prescription back to be endorsed, and the prescriber informed me the following day, the dose of the extract of opium was from two to five grs., which I heard as something new, and gave me to understand that such was represented to be the dose in a first rate standard work.

Edinbro'. J. K. N.

---

[210]. I shall be glad if you will tell me through your columns if the following mixture can be made so that when sent out it shall have the colour and look of clear sherry:—

℞ Liq. Bismuthi . . . . . ℥j.
Potass. Bicarb. . . . . ℥j.
Tr. Gent. Co. . . . . ℥iij.
Sp. Ammon. Ar. . . . . ℥iij.
Aq. Menth. Pip. . . . . ℥j.
Aq. Chloroformi . . . . . ad ℥viij.
M. ft. mist.

If so, in what order should they be used?

L. Brown.

---

[211]. I send copy of a prescription I dispensed, but which was returned, the colour being different from what my customer had in another town.

℞ Potassii Bromidi. . . . . ℥iv.
Tr. Nucis Vom. . . . . ℥iiiss.
Liq. Ferri Dialysat. . . . . ℥iv.
Tr. Sumbul. . . . . ℥iv.
Spr. Chlor. . . . . ℥iij.
Syr. Aurant. . . . . ℥j.
Aq. Pimentæ. . . . . ad ℥vj.
M.

I used the liquor ferri dialysat. prepared by Messrs. Hodgkinson. I then obtained some of Squire's, which produced a different colour from the one I sent, but not like that shown me by my customer.

I wrote to the druggist who had first dispensed the prescription, and was informed that the preparation used, was "Barron, Harveys and Simpson's," and that the tinct. sumbul was added later. I shall feel obliged by your informing me why there should be such difference, what ought to be the colour, and how best to mix it. The one I first dispensed on being allowed to stand, showed three-quarters to be clear water. From Squire's there was not so much, but more than what the patient showed me; but she remarked that the first mixture she had separated more than the others.

Such differences shake the confidence of patients.

James E. Richards, M.P.S.

---

[212]. How should the following prescription, presented to me to-day, be dispensed?—

℞ Kali Citratis . . . . . ℥j.
S. as directed.

Is the potas. citras B.P., or granulated effervescent citrate of potash intended? The medicine was ordered for a child.

E. C.

Notes and Queries.

[545]. In reply to A. L. Ness, the following formula will be found in G. Barber's Series of Pharmaceutical Labels for Drawers, etc.:—

Vinum Pepsinæ.

℞ Pepsin Boudalt. . . . . ℥ij.
White Sugar . . . . . ℥j.
Sherry Wine . . . . . ℥ij.
Proof Spirit . . . . . ℥j.
Mix until dissolved and filter.
Dose, ½oz. equal to 15 grs. of pepsine.

S. P. S.

---

[547]. SYRUP OF CROTON CHLORAL.—I make a syrup of croton chloral of the strength mentioned, 2 grs. in ℥j, by dissolving as much as can be in liq. tolu, cold, add the syrup, and by the aid of a gentle heat I have in a few minutes a perfect solution.

Proportions:—

Liq. Tolu. . . . . ℥iss.
Syrup. . . . . ℥viss.

Victoria Hospital. J. Laker MacMillan.

Counter Practice.

Sir,—In a very able leader in the current number of the Journal you discuss the relation of pharmacists to counter practice, and you are good enough to refer with some approval to certain suggestions advanced by me at the Council Board in August of last year.

This must be my excuse for troubling your readers with a few further considerations upon this difficult and much vexed question.

I am aware that some pharmacists do not regard it as presenting so much of difficulty as I do. With them the abstract right to recommend a simple remedy for a simple malady is so clear that they cannot admit the possibility of its being traversed by the law, and they almost angrily contend that then if some phrase of law can be found capable of interpretation otherwise than in favour of such practice, it needs only that so gross an absurdity be indicated to obtain immediate rectification at the hands of Parliament. To such persons it is natural the action of the Council should appear tame and insufficient. But many discussions with pharmacists of all grades, both within and outside the Council, and much careful reflection, have brought me to the conviction that the matter does not lie by any means within such simple limits, and that the conduct of any action possessing hope of effectual solution of the difficulty lies chiefly outside the power of the Council and probably outside the power of even the whole pharmaceutical body.

If not intruding too much upon your space, I should like briefly to state my own apprehension of the matter.

I have never once doubted that the law, as it stands, is against all kinds of medical practice by other than qualified medical men. I must not now stay to give my reasons for that opinion, but when not only such men as Baron Bramwell and Baron Pollock declare such to be the case, but as it now appears the Editors of the *Pharmaceutical Journal* and of the *Chemist and Druggist* unite in the same view, I find myself somewhat confirmed in it.

I have then asked myself and many others what chance exists for obtaining an alteration of this law in favour of pharmacists. It may, perhaps be admitted that Parliament occasionally exhibits some eccentricity of conduct, but I have been quite unable to conceive that it would ever lose itself so far as to give legal sanction to practise to a body of men who never even pretended to medical qualification. Our very boldest talk has been about slight ailments and trifling complaints. But who shall find legal phraseology that shall define a minor from a major malady? Does such a distinction really exist? However certainly some of us think we can answer this question, what chance has the wisest and most enthusiastic amongst us of converting the members of the two houses of Parliament to his view. I say "converting," for the whole bias leans the other way, the entire spirit of the times is against the unqualified man. The mandate has gone forth, "qualify, qualify, get yourself stamped with the hall-mark, without it I know you not." So I have long since come to the conclusion that application to Parliament on any such question would meet with blank refusal.

At the same, I am perfectly aware that the habit of the public has long been and still is to come to pharmacists "in many of their difficulties and in much of their trouble,"

and as we are men we cannot turn them away, even though in fulfilling their behests we infringe the letter of the law.

This is the dilemma out of which I have never succeeded in discovering a direct method of escape, and I therefore urged, as a kind of compromise (hateful as the word may sound), that an effort be made by our Council to induce not only the Society of Apothecaries, but the other sections of the medical body, frankly to recognize it, and to agree to the desirableness of such a limitation of the exercise of existing legal powers as *shall best serve the interests of our common master—the public.*

Though my proposition failed of its full purpose, my colleagues were, I believe, mainly anxious to postpone its consideration until certain actions at law, then pending, were decided, and not long afterwards the respective solicitors of the two societies, our own and the Society of Apothecaries, arrived at an understanding, similar in kind to what I suggested. This was published in the Journal of February 9 of this year.

As far as such an understanding can be regarded as binding upon his principals, I consider the declaration of Mr. Upton highly satisfactory, but I should much have preferred that it had been announced with authority and as the result, after full discussion, of a frank admission of the difficulty and a desire to make the best of it. Perhaps this may yet be obtained.

G. F. Schacht.

Clifton, December 23, 1878.

The Shepperley Case and the Council.

Sir,—Last week I intended to add my indignant protest to that of Mr. Feltwell against the general action of the Council with regard to the real and vital trade interests of the chemists and druggists of this country. It is a fact that we are continually being harassed by all sorts of prosecution and persecution by apothecaries, medical men, and others, which renders it impossible to carry on our legal business with any degree of comfort to ourselves. I am not prepared to bring any specific charge against certain members of the Council, whose speeches and voting from time to time might form sufficient ground for so doing, but I will content myself by saying that the Council (or some members of it) do not seem to have the interests of the whole body of chemists and druggists at heart as they ought to do; many of them, perhaps residing in London, with first-class dispensing and retail businesses, do not sufficiently understand the position of their less fortunate brethren in the country.

The tenour of your remarks is often to be regretted, and it is evident that you have a greater leaning towards the opponents of chemists and druggists than you have to your own constituents.

Opinions confirmatory of what I have expressed above have been already given in letters appearing this week, in reports of meetings of the Sheffield Pharmaceutical and Chemical Association, etc., and it would be wise for the Council and yourself to notice which way the wind is blowing.

W. T. Martin.

16 *and* 17, *Cliffe, Lewes.*

Sir,—Those gentlemen who object to the action of the Council regarding the Shepperley case have the remedy in their own hands. If they will carefully keep a list of those members who voted for and against the motion, and at the next election carefully draw the pen through the names of those who voted against, they will be in a fair way of preventing such a result again. As the Shepperley case has not settled the vexed question of counter prescribing, and it is probable there will be still more prosecutions, I would ask those who are disgusted with the proceedings of the Council, would it not be advisable to withdraw from a Society which declines to defend our trade interests, and support the Trade Defence Association? If the next election does not alter the composition of the Council I shall withhold my subscription; but I hope there will be a larger percentage of members from the country who know the class of business a country chemist is obliged to put up with, having daily to prescribe (on a small scale) for the poor.

Highworth. T. Hambridge.

The Patent Medicine Stamp.

Sir,—We think the following remarks may give some information on the questions raised by the letters of Messrs. Shillcock and Storey in your issue of the 14th inst.

Correspondence and personal interview with the solicitor to the Inland Revenue has convinced us that any compound medicine whatever, if the maker claims any proprietary right, however remote, in its sale is liable to the stamp duty.

In a discussion two labels were submitted, viz.:—

No. 1. "Jones's Quinine Wine. According to the form of B.P. A valuable tonic. Prepared by T. Jones, pharmaceutical chemist, London."

Declared to be liable to duty because "sold as a proprietary medicine."

No. 2. "Quinine Wine. According to the form of B.P. A valuable tonic. Prepared by T. Jones, pharmaceutical chemist, London."

Declared not liable to duty, but if by any advertisement, counterbill or show card alluded to as "Jones's Quinine Wine," or in any way held out as a remedy or palliative, at once becomes excisable.

Writing specially of quinine we called attention to the general order of June 24, respecting Quinine Wine, contending that certainly it would be exempt from the stigma of being a secret medicine, and transcribe from the reply to this argument.

"Solicitors' Department,
"Somerset House,
"*9th December*, 1878.

"The general order of June 24, refers particularly to the indulgence permitted in the sale of quinine wine containing the exact proportion of sulphate of quinine sanctioned by the British Pharmacopœia, without an excise wine retailer's licence, and *incidentally* only to the liability of such wine to medicine stamp duty. Its bearing upon the latter question has been misunderstood.

"(Signed) W. H. Fitzhugh."

According to the foregoing ruling "Jones's Tincture of Rhubarb, an excellent stomachic;" "Jones's Essence of Sarsaparilla, an agreeable alterative," and all cognate labels, bring the medicine within the Stamp Act. Hence the conclusion that any label on which the slightest semblance of a proprietary right is even suggested is sufficient to render the article dutiable without secrecy of composition or holding out as a remedial agent being at all necessary. We should much sympathize with any one endeavouring to convince the Commissioners of the contrary.

Our individual opinion is that the only uses of the patent medicine duties are as a source of revenue and to render nugatory the provisions of the Pharmacy Act.

John Pepper & Co.

Tottenham Court Road.

R. M. A.—We have been unable to ascertain the present address of Mr. Jabez Goodson, and are therefore unable to inform him that a letter, presumed to be of importance, is waiting for him at Leeds. Perhaps the information may reach him through the publication of this paragraph.

J. R. Y.—Composition Essence.—Since our answer last week we have been informed by Mr. T. Walton, of Sunderland, that Composition Essence is made by macerating 2 ozs. of composition powder (Coffin's) during seven days in 20 ozs. of proof spirit and filtering. Dose, half to one teaspoonful in warm water with sugar.

"*Country Dentist.*"—The Registrar under the Dental Act is Mr. W. J. C. Miller, Medical Council Office, 315, Oxford Street. See before, p. 169.

Communications, Letters, etc., have been received from Messrs. Mee, Tame, Brown, Swendon, Mackay, Moss, Muter, Boa, Strachan, Stuart, Walton, P. B., R. J. H., K. B., G. H. L., Sub Umbra Floresco, Helleborus Nigra, Chremes, Servus.

The Pharmaceutical Journal.

SATURDAY, JANUARY 4, 1879.

Communications for the Editorial department of this Journal, books for review, etc.; should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

1878.

IN again undertaking, at the close of the year, the task of reviewing the events of pharmaceutical interest, a retrospective glance unfortunately soon brings to mind the fact that, before the close of the preceding year, the uncertain results of litigation had contributed to aggravate rather than to allay a mutual feeling of irritation and antagonism between practitioners of pharmacy and of medicine. The conflict which formerly prevailed between these classes had been revived by the co-operative efforts of voluntary associations undertaking on the one hand and on the other to protect and defend the weaker members of each class more efficiently than it was assumed was done or could be done by the antiquated institutions whose particular business it was to perform those functions. The chemist and druggist — the legitimate descendant of the old apothecary—was again to be vexed by the misapplication of a law made to regulate the malpractice of his ancestor, and a few ardent knights of the pestle and mortar being more disposed to fight than compromise, there seemed to be, at least, fair promise of a contest as active as either of those which on previous occasions engaged for a time the energies of the two classes. That prospect has been to some extent realized and, at the present moment, is not without signs of possible further development: consequently the record of the past year will require to deal somewhat more in detail with the incidents of pharmaceutical politics and litigation than is quite desirable in principle or in accord with previous practice.

Before entering upon these details however it will be well to mention the constitution of the Council, which is, or ought to be, of primary interest, since it is the body to which the most important interests of pharmacy in this country are committed. This year, probably in consequence of two gentlemen who have served the Society several years in this office,—Mr. W. S. BROWN, of Manchester, and Mr. J. H. ATHERTON, of Nottingham,—having expressed their intention to withdraw, there were a larger number of nominations than usual for the new Council. Three gentlemen not on the previous Council were elected—Mr. OWEN having been displaced. Of these three, Mr. DANIEL FRAZER, of Glasgow, and Mr. G. S. WOOLLEY, of Manchester, had previously occupied seats at the Council table; the other new member was Mr. J. M. FAIRLIE, of Glasgow. Mr. WILLIAMS and Mr. SAVAGE were for the third time elected respectively President and Vice-President and the only change in the officials has been the election of Mr. GREENISH as Treasurer.

The subject to which reference has been made above is that of counter practice by chemists and druggists, which has of late been variously mooted in the law courts. Public opinion is very generally in favour of the convenience and propriety of the services rendered by the chemist and druggist in cases requiring a knowledge of drugs and an acquaintance with their uses, but not so serious as to demand the aid of the legally qualified medical practitioner.

But much misconception prevails in regard to this subject, on the one hand a certain class of medical men—perhaps chiefly those who, as licentiates of the Apothecaries' Company, keep shops of the same nature as chemists and druggists—imagine that, in virtue of the Apothecaries Act, 1815, it is unlawful for the chemist and druggist to exercise any discretion in selling his wares, or to give his customers any kind of advice as to the use of them. Such misconception is of a most mischievous tendency.

On the other hand also it is sometimes imagined that the Act above mentioned is, in its nature and intent, oppressive as regards chemists and druggists, the only redeeming feature of it being that it is obsolete. This leads to the mistake of objecting, on those grounds, to strained interpretations of the Act, when sounder arguments are available for preventing interference with the ordinary business of a chemist and druggist.

An illustration of the mistaken views last mentioned is furnished by some statements made in a paper entitled "Methods of Sick Relief," in the current number of 'Macmillan's Magazine,' where the Apothecaries Act, 1815, is asserted to have been a Government measure directed especially against chemists and druggists, and providing that they should be liable to be sued for a penalty of twenty pounds whenever they recommended any "drug, simple or "compound, to a customer as good for toothache, in- "flamed eye, sore finger, pain in the bowels, cough, "sciatica, sore throat, shivering, or corns." This indicates either crass ignorance or wilful misrepresentation. The truth is that, the Act was merely intended, as its title indicates, to regulate the practice of apothecaries who, to the number of several thousands, had then become the chief medical practitioners throughout the country, though often "wholly "ignorant and utterly incompetent to the exercise "of such functions." It was to provide, in the interest of the public, a fitting remedy for that scandalous evil that the Apothecaries Act was passed, and there is not any ground for vapouring about it as an

example of the harsh and oppressive laws "enacted "in the legislative dark ages of SIDMOUTH and "CASTLEREAGH." The application of the Act to chemists and druggists—whatever may have been the original designs of the promoters of the measure —was intended merely to exempt them from its provisions, and the terms in which that exemption is expressed were chosen by the chemists and druggists themselves.

Whether intentionally or not, these and other flagrant misstatements in this paper—concerning the Apothecaries Act, the views of the present Government in regard to it, and the history of the SHEPPERLEY case – are put forward in such a way as to influence public opinion and awaken sympathy upon false grounds. Such a result cannot be trusted to conduce to the interests either of chemists and druggists or of the public, both of whom are affected by an attempted non-natural application of this Act. Therefore it is desirable thus to direct attention to the circumstance, not only out of regard for the interests concerned, but in common honesty.

At the time when the last annual *résumé* of pharmaceutical events was written there was apparently some prospect that the new trial of the SHEPPERLEY case, ordered by the Lord Chief Baron and Mr. Baron CLEASBY, might lead to a definite settlement of the questions whether counter practice by chemists and druggists constitutes a breach of the Apothecaries Act, 1815, and whether that Act was to be held as more effective against chemists and druggists, notwithstanding their special exemption by the 28th section, than it is against other members of the community who do not assume to "practise as apothecaries." The remarks made by Mr. Baron CLEASBY, at the hearing of the appeal against the judgment of the County Court judge, gave some reason for expecting that evidence as to the custom of the trade before 1815 might have a material influence in a new trial and still more upon the decision of the judges as to the point of law involved by the 28th section of the Act. Several witnesses were therefore secured by the Trade Defence Association to testify as to their experience in this respect, and in view of the possibility of obtaining in this way a decision favorable to chemists and druggists an appeal was made by the Executive of that body for further pecuniary support from the trade.

At that time the Solicitor to the Pharmaceutical Society was in communication with the Solicitor to the Society of Apothecaries upon the subject of "counter practice," agreeably to instructions given to him by the Council in December, 1877. At the Council meeting in January last he reported that he had received an assurance that the Society of Apothecaries had never instituted and had no desire to institute vexatious proceedings against chemists and druggists in the ordinary exercise of their business, which was admitted necessarily to involve a certain amount of advice to their customers. By direction of the President the substance of this intimation was made known in the report of the Council's proceedings for the information of the trade. At the February Council meeting exception was taken to this by Mr. HAMPSON, who expressed himself as being astonished and much disappointed at finding the views of the Society of Apothecaries thus made known. The President, while accepting the entire responsibility for what had been done, expressed the opinion that it would have been improper to withhold this information concerning a subject so interesting to all the trade, and in that view he was supported by most members of the Council.

In the course of the same meeting the subject of counter practice was considered in Committee, and the correspondence between Mr. FLUX and Mr. UPTON was ordered to be published. One of the letters from the Solicitor to the Society of Apothecaries (dated 1st January, 1878) stated that the subject had been brought by him before the Act of Parliament Committee, constituted of the leading members of the Court, and the decision come to was that the Committee had been unable to discover any case where the sanction of the society had been given to a prosecution on a pure and simple case of counter practice: also that while the Committee expressed no opinion as to whether cases of counter practice came within the Act of 1815, or whether the persons prosecuted in respect of such practice were liable to the penalty imposed by that Act, it was held not desirable that the sanction of the society should be given to prosecution where counter practice was *alone* involved. In regard to the objection raised by Mr. HAMPSON to making known the purport of this communication it was further stated by Mr. UPTON that there was nothing in his letter of a private nature.

It also appeared from these letters that a suggestion had previously been made by Mr. FLUX to the effect that—if the Society of Apothecaries really desired to question the legality of counter practice by chemists and druggists—the matter should be openly and fairly tried in a test case, to be arranged for between the Society of Apothecaries and the Pharmaceutical Society and conducted by their respective solicitors so that the precise point should be satisfactorily arranged for trial by finding a respectable chemist and druggist to perform the acts of counter practice deemed necessary for raising the point to be the subject of decision. It was further proposed that pending this decision there should be a suspension of any cases then being prosecuted, and it was mentioned that the Council of the Pharmaceutical Society—whilst regarding counter practice as a public and trade necessity protected by the 28th section of the Apothecaries Act—did not encourage and had no intention at variance with discouraging its exercise further than was unavoidable. To this sugges-

tion, however, Mr. UPTON replied that he thought it unlikely the Court of the Society of Apothecaries would adopt it. But in a subsequent letter he said Mr. FLUX might accept what he had stated as indicating not only the course he should personally pursue, but also the policy of the Society of Apothecaries.

In an editorial article upon the subject in this Journal it was pointed out that the letters above referred to might be regarded as promising a satisfactory solution of the difficulty that had caused so much uneasiness. It was also again suggested, as in the *résumé* of 1877, that the substitution of a conciliatory policy for the ill-advised contest provoked by the Medical Defence Association, would be very consistent with the existing relations of medical men, pharmacists and the public, in regard to which no strict rule could be laid down. But the cases then pending appear to have been an obstacle.

It was also shown that there was a complication of the matter—then inexplicable—arising from the apparent fact that while the authority of the Society of Apothecaries to prosecute in the SHEPPERLEY case had been obtained by means of a statement of allegations, outside counter practice, those allegations had not been fully brought forward in making use of the authority thus obtained, and in conducting the prosecution in the County Court. Viewed in the light of information quite recently made public, the discrepancy between the avowed intention of the Society of Apothecaries and its apparent relation to the SHEPPERLEY case becomes intelligible, while at the same time the disadvantage of delegating to another and an irresponsible body such powers as that of the Society of Apothecaries to deal with prosecutions is rendered strikingly manifest.

It is remarkable that up to the end of the month of February, when the article just referred to appeared, very little attention had been directed to the subject of counter prescribing at any of the meetings of provincial associations. In the month of January Mr. J. E. FAIRLIE, in an address delivered at the Glasgow University Medico-Chirurgical Society, had referred to the subject and, in giving an account of the conditions prevailing in Scotland, he showed the evil resulting from the multiplicity of "medical halls," or druggists' shops kept by surgeons, as well as the encouragement thus furnished for the chemist to yield to the temptation of regular prescribing, expressing the opinion that the system of counter prescribing when carried beyond ordinary bounds should be condemned with severe punishment. In the following month Mr. WYLEY, as President of the Coventry and Warwickshire Pharmaceutical Association, reviewed this vexed question and said that—though there could be no sympathy with the man who for purposes of mere gain would undertake the treatment of complicated diseases or even simple disorders the character of which he did not understand—it would be an insult to common sense to forbid the dispensing chemist giving suitable mixtures for such trifling ailments as a cough or cold, or temporary indigestion, since it would be simply opening the door to uneducated quacks, who could legally vend their patent medicines under Government patronage, or tend to pauperize persons of small means and insult their dignity by forcing them to apply at the hospitals for gratuitous advice. At the Nottingham Association Dr. TILL, in returning thanks for the medical profession, assured the meeting that the great majority of medical men did not wish at all to interfere with chemists and druggists in the legitimate exercise of counter prescribing, but only wished to put a stop to their treatment of patients in serious cases. At Aberdeen a resolution was passed that while deprecating to the fullest extent indiscriminate prescribing by chemists and druggists, the meeting maintained it to be the privilege and duty of the pharmacist to give advice over his counter for simple ailments and in cases of extreme emergency.

Subsequently, at the Leeds Chemists' Assistants' Association, Mr. HIGHMOOR, in proposing the medical profession, spoke of the delicate relations between pharmacy and medicine, adding that whilst the chemist and druggist could never be restricted from using the knowledge he had in respect to the action of simple medicines, or even their application in simple cases, he was subject to a great temptation of falling into a custom of counter prescribing, simply to accommodate his customers.

At the annual meeting of the North British Branch, again, the Council expressed satisfaction at hearing there was every prospect of what might be called "legitimate prescribing" being undisturbed, and that the Pharmaceutical Society would be prompt in resisting any uncalled for interference, by medical defence or other associations, with the legitimate position of dispensing chemists and druggists, feeling that while it might be a right and proper thing to discountenance medical and general practice by those who cannot be presumed to possess the requisite qualifications, it would militate very much against the interest of chemists and druggists and be also a somewhat serious matter to the general public, if chemists were debarred from giving across the counter any simple medicines to relieve such cases as present themselves almost every hour of the day. At the annual meeting of the Glasgow Association, Mr. FRAZER, as President, reiterated what he said when Professor REDWOOD addressed the Pharmaceutical Conference on the subject in 1876, to the effect that in giving advice he had no fear of medical interference; but though nothing could prevent JOHN SMITH prescribing for JOHN BROWN, chemists and druggists ought to feel a responsibility arising from their peculiar relation to medical practitioners.

The views then expressed were reasonably con-

sistent with existing circumstances, and with the principle of the Pharmaceutical Society not to encourage the practice of medicine by its members. They may also be regarded as indicating approval of what had been done by the Council in opposition to the abnormally stimulated action of the Society of Apothecaries in connection with certain prosecutions, as well as recognizing that the Council had rendered substantial service in the protection of "trade interests," by obtaining from the Society of Apothecaries an assurance that simple counter practice by chemists and druggists should not be interfered with. They also thoroughly bore out the statement in the last Council report that the result of the correspondence with the Society of Apothecaries might be considered reassuring and satisfactory, since no positive line could be drawn between ordinary medical practice and counter prescribing, and it was therefore most important that a good understanding between the two parties should be established; there was nothing suggested inconsistent with the fact that while the Society has rather fostered the idea of separating the duties of the dispenser from those of the prescriber, it has never either encouraged the practice of medicine by its members, or admitted that they should be restricted from advising as to the nature and uses of the medicines they sell either in the simple or compounded forms.

The only speaker at the Annual Meeting in May last who referred to this subject expressed no dissatisfaction with what had been done; for though he held there was a section of the medical profession that did attempt to deprive chemists and druggists of their rights; and maintained that a chemist and druggist had a right to prescribe, according to his judgment, as had been done hitherto, he admitted that any chemist who represented himself as a medical man "was a rogue."

But though the combative element was not represented at the Annual Meeting of the Pharmaceutical Society it was already in course of development, for on the previous day, at the Annual General Meeting of the Trade Association, the Vice-President propounded the idea that it was the unanimous desire of the trade to fight out the question of counter practice to the very end—even to the House of Lords if necessary—and as a considerable expenditure would be requisite for conducting this battle, it might be desirable to draw upon the funds of the Pharmaceutical Society. This suggestion did not at the time meet with much support; but from that time there has been no possibility of doubting that in this matter there have been two RICHMONDS in the field, though it is with regret that this admission must be made, since it affords renewed evidence of the want of unity which has so often been detrimental to the general interests of chemists and druggists.

The defence of the SHEPPERLEY case was urged at that meeting as constituting the opportunity by which the interests of the trade were to be maintained, and for the sake of which the anticipated very heavy expenditure should be incurred, if necessary with the aid of the funds of the Pharmaceutical Society. How miserably the defence of that case has failed to decide the question as to the right of chemists and druggists in the matter of counter prescribing it is unnecessary to state, since the result of the new trial is fresh in the minds of the readers of this Journal.

But the Trade Association had then undertaken the defence of another case, known as that of the SOCIETY OF APOTHECARIES *v.* WIGGINS, which was to come on for trial in a few days, and for that also it was necessary that the Association should have money, since the meeting had approved of the report which had committed the Executive of the Association to costly warfare in the law courts in defending chemists and druggists against the Apothecaries' Company. The Vice-President of the Association, offering with some amendment the advice of RODERIGO's friend, was therefore earnest in urging the proposition "put money in our purse," and, in support of his argument that pecuniary aid for that enterprise should be obtained from the Pharmaceutical Society, he pleaded that there were many things the Pharmaceutical Society could not well do which the Trade Association could do; that the Pharmaceutical Society could hardly take up a case in which it ran any risk of failure, and that as the Pharmaceutical Society had committed itself to support chemists and druggists against the Society of Apothecaries, he thought the Executive of the Association was justified in asking for a subscription towards the defence fund he desired to raise. Under the influence of these pleas a resolution was passed that a special effort be made to raise at least £2000 by donations, to be used in protecting and furthering the legitimate interests of chemists and druggists.

Only a few days afterwards the trial of the WIGGINS case resulted in a verdict for the plaintiffs to the effect that "the defendant acted as an apothecary "in treating, medically, cases that were dangerous." This was a verdict under the 20th section of the Act, and though the trial left undecided the important point of law as to the 28th section, which it was desirable to have decided, the expression of opinion, on that point, by the judge who tried the case was decidedly adverse to chemists and druggists. The failure of the Trade Association in this case was so thorough that at a meeting of the Executive Committee the solicitor said he did not consider there was any point on which the Association could go to the court above; there was no misdirection by the judge, the verdict could not be disputed on the ground that it was against evidence, nor had the judge excluded any evidence, although the admission of evidence as to the practice of chemists and druggists prior to 1815 was objected to by the counsel for the plaintiffs. The Committee therefore

resolved, as indeed could scarcely be avoided, that no further steps should be taken with that case for protecting and furthering the legitimate interests of chemists and druggists. So far at least as that case was concerned there was an end to the prospect of carrying out the magniloquent resolve to proceed with appeals from court to court until at length the House of Lords was reached and a favourable decision was carried off from that body as a matter of course. It was, however, decided to continue the defence of the SHEPPERLEY case and for that purpose to ask the Council of the Pharmaceutical Society to support the Trade Association by a donation.

Though the proverbially odious effect of comparison cannot be avoided in directing attention to the contrast between this result and that which had already been attained by the Council of the Pharmaceutical Society it is necessary to do this. By a quiet and undemonstrative procedure, and in virtue of the prestige attaching to the representatives of a responsible body, the question as to counter prescribing had already been virtually solved at the commencement of the year, while the Trade Association by undertaking the legal defence of a case, at best dubious, had enabled the promoters of these prosecutions to score a victory and carry off another scalp to display with those of GREENOUGH, BROWNRIDGE and some few others, as trophies that might serve for the purpose of terrifying chemists and druggists in the ordinary exercise of their business.

Certainly it was so far proved that the Trade Association could do things that the Pharmaceutical Society, with a reputation to sustain as well as duties to perform, could not venture upon. But there are other collateral results of the action taken by the Executive of the Trade Association that require to be mentioned as affecting the interests of the trade. About two months before the trial of the WIGGINS case, a medical Bill was introduced by the Government, intended to regulate the practice of medicine by restricting the use of titles. The Duke of RICHMOND in presenting this Bill to the House of Lords emphatically expressed the opinion that though it was desirable to enable the public to distinguish between competent and incompetent or regular and irregular practitioners, it was "impossible" to prevent unregistered persons from practising. In this Bill it was proposed to repeal the 20th section of the Apothecaries Act and at the time attention was directed to these circumstances, as having an important bearing upon the pretensions of a certain class of medical men, as well as upon the attempts to stir up strife between medical practitioners and chemists and druggists, and as endorsing the view always maintained in this Journal to be the proper one.

During the trial of the WIGGINS case, however, the counsel for the prosecution naturally gave much prominence to the view that the 20th section of the Apothecaries Act was generally intended to repress medical practice by persons legally unqualified; its importance in the public interest, and the desirability of enforcing its provisions, in that respect, were urged in such a way as to produce no inconsiderable effect upon the jury and the judge before whom the case was tried.

Mr. Justice FIELD, though evidently taking a stringent view of the law in this sense, suggested at the close of the trial, and much in the same spirit as the motion of Mr. SCHACHT, that possibly there might be some modification effected if chemists and druggists were to communicate with the Society of Apothecaries with that object. In reply to this suggestion, however, Mr. MORGAN HOWARD, the counsel for the prosecution, stated that the question had been considered by the Duke of RICHMOND a day or two before, when a medical deputation waited on him, and that, on the contrary, there was a proposal to transfer to the Medical Act the penalty then within the four corners of the Apothecaries Act. The result of this became evident soon after when the Duke of RICHMOND'S Bill was read a third time and passed in the House of Lords. An amendment had been made, apparently slight but really of great significance if the counter practice of chemists and druggists made them liable to the penalty of the 20th section of the Apothecaries Act. In the original draft of the Bill the intention of the Apothecaries Act was construed in the widest sense; but in accordance with the views of the Duke of RICHMOND as to the practice of persons not legally qualified, so much of the Apothecaries Act was to be repealed as restricts persons who have not obtained the certificate, therein mentioned, from practising medicine or surgery.

That provision of the Bill would have been an effectual remedy against the tendency to strain the Apothecaries Act into a prohibition of any kind of prescribing or advice by persons not having a regular medical qualification. It would have put an end to any question about counter practice. However, the amended Bill as passed in the House of Lords proposed that only sections 9 to 19 and 21 to 24 of the Apothecaries Act should be repealed; or, in other words, the 20th or penal section of the Act by means of which it was sought to harass chemists and druggists had been—according to the anticipation of Mr. MORGAN HOWARD—transferred to the Medical Act since the trial of the WIGGINS case.

The consequence was that while, before the amendment, chemists and druggists would have been made free from restriction, real or assumed, and from liability to prosecution for counter practice, the amendment left them exactly in their former relation to the Apothecaries Act and exposed to all the annoyance it can be made to inflict upon them.

It was pointed out, in this Journal, at the time that this was a result as much opposed to the desire of the Society of Apothecaries as it is inconsistent

with the view of the medical profession generally, and the opinion was expressed that this result was to be directly ascribed to the injudicious course pursued by the Executive of the Trade Association, inasmuch as the amendment of the Medical Act was brought about by the WIGGINS trial in which the Trade Association figured as defending an acknowledged indefensible case of prosecution under the 20th section. This opinion of course could not be accepted by the supporters of the policy of the Trade Association, and accordingly the Editor was charged by Mr. URWICK with attacking the Association instead of helping to defend and sustain the common rights and interests of chemists and druggists.

On the 11th July the Committee of the Council appointed to deal with this subject waited upon the Duke of RICHMOND in order to urge the repeal of the 20th section of the Apothecaries Act as originally proposed in the Medical Bill. In reply to the arguments put forward his Grace repeated that the public had a right to apply to whom they liked for advice, but that it was not intended to legalize unqualified practitioners, and even if it were wise to do so the Medical Bill was not one for that purpose, finally advising—with special reference to the non-existence of any oppressive prosecutions, and the avowed desire of the Society of Apothecaries—that chemists and druggists should be satisfied to leave things as they were. When the report of this Committee was presented to the Council at the August meeting, and it was announced that the Bill had meanwhile been withdrawn, the proposed motion of Mr. HAMPSON that a petition should be presented to Parliament by the Council in favour of the repeal of the 20th section of the Apothecaries Act was also withdrawn; but Mr. HAMPSON took the opportunity to state that, in his opinion, the Society of Apothecaries had instituted oppressive prosecutions, and that the answer given to the Duke of RICHMOND by the deputation was scarcely accurate, for though it might represent the views of the PRESIDENT, Mr. HILLS, and Mr. SANDFORD, he did not think it was in accord with the facts. Mr. HAMPSON thought the members of the deputation could scarcely be expected to realize the condition of the trade throughout the country, since they were so much more identified with select and high class pharmacy. He also mentioned that, in his opinion, the restoration of the 20th section of the Apothecaries Act did not arise from the opposition of the Council or that of any other body. Mr. ATKINS, feeling with Mr. SCHACHT the exceeding difficulty of acting in this matter, expressed his pleasure and gratitude that the opinion and sentiment prevailing in the Council and with the majority of pharmacists throughout the kingdom should have been so exactly embodied by the deputation. He was not, however, quite convinced that no oppressive prosecution had been instituted, and he believed it was the fear of this which had aroused so strong a feeling in the trade. On the other hand, he feared that well intentioned, but unwise, action had considerably prejudiced them.

In commenting on this subject soon after, Mr. B. S. PROCTOR expressed considerable disappointment both with the report of the Committee and with the general approbation it received from the Council. It may have been unfortunate that Mr. PROCTOR was not a member of the deputation, since he seems to suggest that, in his opinion, it "missed two most "important points," and the "impression" produced on the Duke of RICHMOND was therefore not the correct one. That opinion, however, may be ascribed partly to Mr. PROCTOR having overlooked the fact that an application for the repeal of the 20th section of the Apothecaries Act in favour of chemists and druggists necessarily involved the assumption of its being a restriction of their rights, partly also to his having failed to appreciate the intention of the Medical Bill, not to give any medical corporation the power of prosecuting any person for medical practice, unless a title indicating legal qualification were assumed. If the deputation had urged the two points as suggested by Mr. PROCTOR it would have argued against chimeras of its own creation, and possibly not have obtained the careful consideration actually given to its representations by the Duke of RICHMOND.

At the July meeting of Council Mr. FAIRLIE brought forward the motion that £100 should be granted to the Trade Defence Association for the purpose of assisting the defence of the SHEPPERLEY case. No member seconded the motion and, as the case was still pending, it was discussed in committee and eventually withdrawn.

Early in November the new trial of the SHEPPERLEY case came on before Mr. Baron POLLOCK and a special jury at Westminster. It lasted the greater part of two days, most of the time being occupied by the arguments of counsel and the summing up of the judge. The evidence of chief influence was that showing that, in the case chiefly relied upon by the prosecution, the complaint for which Mr. SHEPPERLEY was asked to supply a remedy was fictitious. The verdict under these circumstances was naturally for the defendant; but so far as regards any legal question concerning the trade interests of chemists and druggists, the result of the trial was absolutely worthless.

On the 14th November application was made in the Exchequer Division of the High Court of Justice, for an extension of the time for moving for a new trial. This was granted, and on the 5th December, Mr. DAY, Q.C., moved for a new trial. What took place then has been so recently reported that it is unnecessary to say more than that the application was refused, since the judges, having regard to the nature

of the evidence, saw no reason to interfere with the finding of the jury.

At a meeting of the Trade Association, in November, it was stated that as the decision in the SHEPPERLEY case had given rise to great satisfaction and to a "spirit of rejoicing" it was a good opportunity for increasing the funds and it was suggested that a report of the case should be issued making known the Association's want of funds, but little else was said about the SHEPPERLEY case, as the application for a new trial had not then been heard.

A more important motion was brought forward by Mr. FAIRLIE, respecting the desirability of taking official action in the next election of the Pharmaceutical Council by promoting the candidature of at least seven gentlemen who would pledge themselves to support trade interests. In moving this resolution Mr. FAIRLIE is reported to have said that his eyes had recently been so opened in regard to the Council of the Pharmaceutical Society that if they were to have the true interests of the trade carried out the action he proposed must be taken. Mr. CHURCHILL is reported to have added there could be no doubt the Trade Association was not fairly represented on the Council. This motion appears to indicate an opinion that to carry out the objects of the Trade Association the power and the money of the Pharmaceutical Society are wanted and it is in contemplation to make the Council of the Society the organ of the Trade Association. The matter was, however, remitted to the consideration of a sub-committee.

Early in December, at a meeting of the Sheffield Pharmaceutical Association, two representatives of the Trade Association appeared to urge the advice formerly given by the Vice-President of that body and they advocated its claim upon the support of the local associations as it was fighting the battle of chemists throughout the country.

It was stated that the SHEPPERLEY case might still be taken to the Court of Appeal, and that the ordinary business of chemists and druggists would have been quashed had it not been defended by the Trade Association, while the hope was expressed that they would not submitto be crushed by the London members. In reply to a question whether the Society of Apothecaries was finding the money for the prosecution, it was stated that was the case. Mr. ELLINOR accused the Editor of this Journal of having tried to strangle the subject, but in the belief that "murder will out," he predicted that it would be ventilated, and argued that the Trade Association was justified in asking substantial aid from the funds of the Pharmaceutical Society, in the defence of the SHEPPERLEY case.

At the December Council meeting Mr. HAMPSON moved that an adequate sum should be granted from the funds of the Society in aid of the defence of the SHEPPERLEY case and, after a long discussion, six members voted for and nine against the motion. Thereupon Mr. CHURCHILL presented a requisition for the calling of a special general meeting for the purpose of taking into consideration the advisability of rendering substantial pecuniary aid to the Trade Association to assist its efforts to defend the legitimate interests of the trade. It is thus sought to coerce the Council to dispose of the funds of the Society in support of a case that it has, after due consideration, already decided not to defend. In view of this action on the part of members of the Council representing the Trade Association, the President has taken the opinion of the Attorney-General and two other counsel as to the course to be pursued on behalf of the Society. The last number of the Journal contains this requisition and the opinion just referred to, which is to the effect that in the disposition of the Society's funds the Council is not subject to the control of the members, and though it has power to apply those funds in protection of the interests of the trade it has no power to dispose of them in the manner indicated in the requisition.

The same number of the Journal contained an important statement by the clerk to the Apothecaries' Company as regards the merits of the SHEPPERLEY case from the beginning to the present time, and the reasons for authorizing as well as continuing the prosecution. From that statement it appears that the representations originally made to the Society of Apothecaries by the solicitors of the Nottingham Medical Defence Association were such as to constitute a *primâ facie* reason for authorizing the prosecution. It may be inferred that the Council of the Pharmaceutical Society had similar reasons for declining to defend the case as one of legitimate counter practice. It is here necessary to recall the fact that at the County Court trial evidence was given as to other cases besides that of DEATH. Though the judge considered the other witnesses had broken down and that the real point at issue was that spoken to by DEATH, he stated that he should have hesitated to convict if DEATH'S evidence had stood alone and had not been to some extent confirmed by that of SHEPPERLEY himself. It must also be remembered that at the County Court trial no kind of question seems to have been raised as to the validity of DEATH'S evidence. No suggestion appears to have been made then that he was merely an informer and that his ailment was fictitious. In fact the defence appears to have been as bad as the actual case for the prosecution now appears to have been. Mr. UPTON now states that if the real nature of the specific facts alleged had been known, the society's authority to prosecute would have been refused, notwithstanding the general statement as to the medical practice carried on by Mr. SHEPPERLEY. This statement must in all fairness be taken as showing that the Society of Apothecaries was misled.

Though it is shown that the Society of Apothecaries is averse to these prosecutions and does not

conduct them, having no funds specially applicable for that purpose, it appears that the real promoters of these prosecutions are now endeavouring to coerce that society into prosecuting or allowing others to prosecute in its name, just in the same way that the Trade Association is endeavouring to coerce the Council of the Pharmaceutical Society to defend such prosecutions. These concurrent efforts may promise well for the lawyers, but they are scarcely calculated to promote the trade interests of chemists and druggists. Since the power to prosecute as well as the power to defend is respectively in the hands of the Court of the Society of Apothecaries and the Council of the Pharmaceutical Society it would seem to be a more rational mode of protecting those interests to adopt the course suggested by Mr. SCHACHT and endeavour thus to arrive at an amicable settlement, which would relieve both bodies from difficulty and chemists and druggists from interference with the legitimate exercise of their business.

In regard then to the matter of counter practice it is apparent from the facts that what has been done for the protection of the trade has been done through the agency of the Pharmaceutical Society. The Council, in pursuance of the resolution passed in October, 1876, considered the WIGGINS case, and the result of that case proved the wisdom of declining to squander the funds of the Society by defending it: the SHEPPERLEY case also was considered before it appeared in the County Court, and its subsequent history does not indicate that it was a lost opportunity of applying the Society's funds for protection of trade interests. Only one other case has been submitted to the Council in which a chemist and druggist, charged with infringing the Act, had received a letter from the clerk to the Apothecaries' Society courteously informing him of the fact that the society had, on the ground of that charge, been called upon in discharge of its public duty to enforce the penalty he was alleged to have incurred, and also expressing the hope that it would be in his power to satisfy the Society that the representation which had been made concerning him was incorrect. In reply to this, the chemist and druggist stated that in conducting the ordinary business of a chemist and druggist for fourteen years he had not to his knowledge gone beyond the custom of his legitimate trade. This was the case which the Council authorized the defence of in August, 1877.

On the other hand, it is equally apparent that the Executive of the Trade Association has incurred discredit by defending the WIGGINS case, and placed the trade under the disadvantage of appearing desirous to defend objectionable practices, while the money contributed by the trade and bestowed upon the defence was at least wasted so far as general trade interest was concerned. The barren victory obtained in the SHEPPERLEY case and the consequent possible saving of the costs, form a poor equivalent for the disappointment that, after so much declamation and so much entreaty for support, the attempt to protect trade interests should prove to rest on such a rotten foundation.

The facts above referred to, however, prove conclusively that a most lamentable diversity of opinion prevails in regard to the proper mode of protecting trade interests, and so great is this diversity that on one side or the other grave error must prevail.

In regard to other legislative measures besides the Medical Bill the Council has been engaged in considering and taking legal opinion upon various provisions of the Dental Bill and the Weights and Measures Bill, as well as in communicating with departments of the Government or with the members of Parliament who introduced the Bills. In the case of the Dental Bill attention was directed in the early part of February in this Journal to the fact that the wording of the Bill might be construed to the exclusion of chemists and druggists. Sir JOHN LUBBOCK, in reply to a letter addressed to him by the PRESIDENT on the 22nd February, stated that the point urged by him seemed to have so much force that he would omit the words objected to as being ambiguous and capable of being interpreted as excluding from registration chemists and druggists who were then engaged in dental practice. Eventually the object required was secured by inserting the words "and "pharmacy."

As regards the Weights and Measures Bill several communications passed between the Secretary of the Board of Trade and the Law and Parliamentary Committee of the Council and the opinions expressed in regard to the requirements of the drug trade were recognized by the insertion of a clause in the Bill making it permissive to use "apothecaries' weight" when selling drugs by retail, and on the representation of a deputation from the Council the fluid ounce, fluid drachm, and minim, and multiples of them, were included in the Schedule of Board of Trade Standards before the Bill passed. A reprint of this Act accompanies this number of the Journal as a supplement.

The Amendment of the Pharmacy Act, 1868, has on several occasions been under consideration and a special committee charged with that work has again been appointed on the motion of Mr. BOTTLE, seconded by Mr. ATKINS.

Three prosecutions for offences against the Pharmacy Act have been recorded. Two of these have been initiated by the police authorities: one, at the suggestion of Mr. Baron HUDDLESTON, against Mr. SHEPPERLEY, who has also found notoriety in another court, for the sale of potassium cyanide without registration in the poison book, and the other against a grocer for the sale of vermin killer containing strychnine insufficiently labelled. The third prosecution, of the London and Provincial Supply Association, was commenced by order of the

Council, and promises to be of considerable importance as establishing the effect of the Pharmacy Act in relation to trading associations. The case heard in the County Court was decided against the Society, but an appeal is now pending in the superior court. It may be remarked, that in many other cases the usual preliminary cautionary letter has been sent, and subsequent inquiry has shown that it has been effective in procuring an abatement of illegal practices.

As usual business connected with the Benevolent Fund has more or less occupied the attention of the Council at every one of its meetings. The subscriptions and donations received during the year, including a legacy of £100, have amounted to about £1375, and the expenditure, of which £768 15*s.* has been paid in annuities, has been an almost exactly equal sum. In February, Mr. SANDFORD moved that a sum of £500 should be transferred from the General Fund to the Benevolent Fund. This proposition was not carried, but a resolution was passed that the sum of £20 from the Benevolent Fund should be placed in the hands of the Secretary for the relief of such temporary pressing claims as he may think desirable. In October, the number of annuitants to be placed on the fund was decided, and, in consequence, seven, a larger number than on any previous occasion, were elected in December.

At one time the proposal to admit "female persons" as members of the Society promised to be the most exciting topic of the year. For the second time the Council, feeling unequal to the task of settling this momentous question, remitted it in their report to the annual meeting for an expression of opinion. Here again opinions were so evenly balanced that when a vote was taken there was only a majority of two; but on which side this majority voted was not quite satisfactorily, although officially, settled. The question came under the consideration of the new Council at its first meeting, and, the votes proving equal, the President gave his casting vote for the *status quo*.

Again there has been an increase in the number of persons presenting themselves for examination, the gross total during 1878 being 1931, against 1742 in 1877, or an excess of 189. Of these 1130 were candidates for the Preliminary examination, against 1083 in the previous year; 538 passed and 592, or 52·4 per cent., failed, against 45·8 per cent. of failures in 1877. There have been also 54 certificates from other bodies received in lieu of this examination, showing a considerable increase. For the Minor examination 639 men presented themselves, being 103 more than in the previous year; of these 324 passed and 315 failed, showing 49·3 per cent. of failures against 44·2 per cent. in 1877. For the Major there were 81 candidates, against 98 in the previous year; 51 passed; the failures equalling 38·3 per cent.

The criticisms which every now and then find utterance respecting the mode of conducting these examinations bear testimony to the importance with which pharmacists have now invested this part of the Society's work. Once more the Preliminary has been the subject of discussion, and once more it has been demonstrated that the examination as now conducted is not an unfair test of the fitness of a youth to enter the business of a chemist and druggist; nevertheless this ventilation of the subject has given an opportunity for clearing away some of the misapprehensions that existed regarding it. Thus it has been assumed by many that the classical portion of this examination was the *crux* that proved too much for the unsuccessful candidates in the majority of cases, but a report supplied by the Secretary to the Council showed that, at least in the January examination, the reverse was the case, much the smallest proportion of failures being in Latin, there being two and a half times as many failures in English and four times as many in Arithmetic. On this particular occasion the total failures amounted to upwards of 61 per cent., and among the explanations put forward was one that the phantom of the metric system—for it was not represented bodily in the questions—was sufficient to so bewilder the candidates as to render them incapable of answering correctly the arithmetical questions that were really put. An editorial remark that the result was due to the quality of the education subjected to the test evoked a rebuke from Mr. FAIRLIE for passing an "offhand critique." But difference of opinion is not necessarily evidence of superficiality of judgment, and the justice of the remark was established by a test the questions were submitted to, at the instance of Mr. STAINER, in a national school at Folkestone, when 75 per cent. of the boys in the first class passed the English and Arithmetic portions in an hour and a quarter. In fact there can be little doubt as to the justice of a remark made by Mr. GREENISH, that the results show the gross inefficiency of a great deal of middle-class education.

Another sharp discussion respecting the Preliminary examination arose when, in July, the Council decided to further reduce the centres for holding written examinations from 63 to 38. On the one hand it was contended that many candidates would be much inconvenienced and put to extra expense; on the other that the efficiency of the examinations would be better secured by having centres for larger districts, as the superintendents would then take more interest in the examinations. One result of the discussion was that at the next meeting of the Council the day of examination was altered from Monday to Tuesday to suit the convenience of candidates who had to travel to a centre on the previous day.

But whilst comments upon the Preliminary examination were thus plentiful the Major and Minor did not escape criticism, and attention was directed to certain differences—or as they have been termed,

somewhat prematurely perhaps, "discrepancies"—in the results obtained in the examinations in Edinburgh and in London, and also in those obtained in London alone on different days. At the meeting of the Council in February Mr. BOTTLE, referring to returns then presented, called attention to the fact that a much smaller proportion of candidates had been rejected during the previous year by the Board of Examiners in Edinburgh than by that in London, and with a view to securing the greatest possible approximation to uniformity in the examinations, he proposed that a deputation from London should attend an examination in Edinburgh. This was agreed to and carried out, and subsequently a deputation from Edinburgh attended an examination in London. No important variation, however, in the method of conducting the examination appears to have been observed; on the other hand Mr. MACKAY has been able to show that if the average of several years be taken the disparity is greatly reduced. Suggestions to appoint examiners empowered to act in both London and Edinburgh, or to appoint some Englishmen on the Edinburgh Board and some Scotchmen on the London Board, have been found to be impracticable.

The other supposed "discrepancy" was first pointed out in a letter from a correspondent who asked for an explanation as to the usually increasing proportion of failures on successive days of examination in London. Mr. BOTTLE broached the subject at the August Council meeting and again in September, the topic being freely discussed by correspondents in the meanwhile, and it was resolved to ask the opinion of the examiners respecting it. An experiment instituted by the Secretary proved that the explanation was to be found, as had been suggested by him, in the practice of examining candidates according to the date of entry, the weaker men, to a considerable extent apparently, postponing their entries to the latest possible date. In future, therefore, the candidates are to be examined in London, as has been the practice in Edinburgh, according to the alphabetical order of their names. It seems quite possible that a preponderance of this self-conscious weaker element in the South—which could easily be understood—may be an element in the difference in numerical results obtained by the two Boards.

Once more the open prizes offered by the Council to be competed for by men who have passed the Major during the preceding twelve months have all fallen to late pupils in the Society's School of Pharmacy. The PEREIRA Medal was carried off by a "BELL Scholar," Mr. JOHN GRAHAM SANGSTER; whilst the Silver and Bronze Medals of the Pharmaceutical Society were awarded to Mr. ALFRED HENRICK JACKSON and Mr. JOHN SEPTIBO WARD. Of the prizes for which the competition is limited to students in the School the three Silver Medals were won by Mr. HENRY ALLEN. The prizes were distributed, as in previous years, at the first Evening Meeting of the session in October, when the usual satisfactory reports were made by the Professors. On the same occasion an eloquent address was delivered to the students who had entered for the new session by Mr. OCTAVIUS CORDER.

The attendance at the other Evening Meetings has about equalled the average of former years, and there has been a good supply of interesting papers. The following is a list of them:—"The Progress of Cinchona Cultivation and Alkaloid Production in Bengal," by Mr. C. H. WOOD; "A Spurious Balsam of Tolu," by Mr. W. A. H. NAYLOR; "Thymol and its Pharmacy," "Examination of Commercial Oil of Thyme," and "The Alkaloid and Active Principle of *Duboisia myoporoides*," by Mr. A. W. GERRARD; "Croton Oil," by Mr. H. SENIER; "Note on Thymol," by Mr. W. WILLMOTT; "Some Bismuth Residues," by Dr. E. A. LETTS; "Tincture of Quinine," by Mr. W. MARTINDALE; "Detection and Determination of Minute Quantities of Alcohol," by Mr. J. C. THRESH; "Preliminary Note on Acetonitrate of Iron as a Medicinal Agent," by Mr. J. WILLIAMS; and "*Duboisia myoporoides*," "Note on *Grindelia robusta*," "An Adulteration of Senega," and "Guaycuru Root," by Mr. E. M. HOLMES. There have also been two extra Evening Meetings, on one of which Professor REDWOOD lectured to a crowded audience on Spectrum Analysis; on the other, Professor BENTLEY delivered a lecture on the *Eucalyptus globulus*.

The Library of the Society has been augmented during the year by nearly 500 volumes and pamphlets, bringing the total number up to about 6000. Many of the additions have been paid for out of the General Fund; some valuable works, however, have been purchased out of the HANBURY Fund and a considerable number have been presented. A catalogue of the year's Additions accompanies the present issue of the Journal. The circulation of books has been larger than during the previous year, amounting to considerably more than 2000 entries, only about one-fourth of which have been to readers in the country. As the payment of carriage one way is now extended to books lent to Associates not in Business and Apprentices it is to be hoped that the borrowers of books in town and country may in the coming year be more evenly balanced. The attendance in the Library has also been larger, as compared with 1877, both during the day and in the evening. The Library has now acquired an educational importance worthy of the Pharmaceutical Society, and in order to make its treasures as available as possible the Council has recently decided that a new complete Catalogue shall be prepared and a copy sent to every Member and Associate in Business, whilst Associates not in Business and Apprentices are to receive copies on application.

The Museum has been enriched by an unusually large number of specimens, among the most important of which are a series of Indian drugs from Professor DYMOCK, illustrating his articles that have appeared in this Journal, and a variety of specimens presented by different exhibitors at the close of the Paris Exhibition in response to an application from the Curator who was authorized to visit Paris for the purpose. Specimens have also been exchanged with Professors PLANCHON, of Paris, FLÜCKIGER, of Strassburg, DRAGENDORFF, of Dorpat, and BOMMER, of Brussels. Many duplicates of specimens having accumulated in the Museum a list of them was drawn up and published with an intimation that the Council was prepared to receive applications for them with a view to presentation. As a result, a considerable number of duplicates have been distributed during the past few days to local associations in Leicester, Coventry, Birmingham, Carlisle, Truro, and schools in London. The usefulness of the Museum has been also much increased by the publication of the catalogue early in the year. It would appear, however, that the students using the Museum are not so numerous as might be expected.

Among the prosecutions instituted against chemists and druggists under the Sale of Food and Drugs Act those of the most interest were for the sale of "violet powder" consisting of materials other than starch. They were brought about by the alarm excited by the discovery of arsenic in many samples of violet powder and by the fatal effects of its use. The question whether the sale of "violet powder" consisting of powdered selenite or hydrated calcium sulphate is a breach of the Act has been decided differently in several cases and as a matter of opinion it is still an open question.

Another group of prosecutions under the Sale of Food and Drugs Act has been a continuation of those relating to the sale of aerated waters, the offence charged being that of selling as potash and soda waters aerated beverages containing no alkali, or less than the pharmacopœial quantity, but in some cases small quantities of lead or copper. The magistrates as a rule have taken the common sense view that the terms "potash water" and "soda water" are applicable to beverages containing less than thirty grains of the respective alkaline bicarbonates —one public analyst advising that his scruples would be satisfied with one grain in a bottle—but they have convicted in cases where the entire absence of the alkali was proved. The convictions of two grocers and the manager of a co-operative store for the sale of adulterated sweet spirit of nitre have also been recorded, a pretty fair indication that a large proportion of the adulterations in drugs, loosely reported every now and then by analysts, are not attributable to chemists and druggists. In fact—apart from the violet powder scare—the only case of a prosecution of a chemist and druggist under the Act was for selling tincture of jalap alleged to be deficient in spirit, and to this a successful defence was made under the auspices of the Chemists and Druggists' Trade Association, which was in that instance usefully exercising its appropriate function.

This part of the record would not be complete without noticing the starting of a legal quibble in Scotland, which however appeared to receive the endorsement of Lord Chief Justice COCKBURN, that an inspector purchasing an article of food for analysis would not be "prejudiced" if he were supplied with an adulterated article. This threatened for a time to paralyse the operation of the Act. Notwithstanding the decided opinion of the President of the Board of Trade that the objection could not be sustained, and that there was no necessity to amend the Act in this respect, a short Bill was introduced into Parliament by a private member towards the end of the session, enacting that such a sale should be deemed prejudicial. This Bill then failed to pass, but it has already been re-introduced in the present session. Meanwhile some magistrates have faced the difficulty by acting according to what is undoubtedly the spirit of the Act and overruling the technical objection.

Some little unrest among chemists and druggists has been caused on more than one occasion during the year through the disposition shown by the Inland Revenue authorities to counteract a certain amount of laxity that had apparently crept into the administration of the Acts relating to the payment of stamp duty on proprietary medicines. Some little surprise was felt when it was announced that a considerable number of foreign preparations, which had hitherto escaped taxation, would in future have to be stamped, and although the schedule to the original Patent Medicine Stamp Duty Act includes "foreign medicines of all kinds except drugs," it was difficult to understand how, without straining the law, some of the articles indicated could be held liable to stamp duty. On the other hand, it was alleged by the Board that even where no secrecy in the preparations, or special proprietorship was implied, there had been recommendation by advertisement or otherwise concerning their utility in the prevention or relief of disease. The evident intention of the Board to enforce the law with greater stringency in this direction, rather than the breaking of new ground, furnishes also a probable explanation of the origin of subsequent correspondence in relation to quinine wine and medicated lozenges. The law on this subject however is decidedly in an unsatisfactory state, and it is to be hoped that when foreign affairs allow the Legislature to attend to domestic legislation, it may undergo a thorough revision, especially in its relation to the sale of poisons by unregistered persons. In one notable instance, however, the Board failed to enforce its views, for in the case of "pyretic saline" the court of appeal decided that it and

similar compounds are exempt from duty on the ground that they are compositions for producing artificial mineral waters. Convictions have been obtained on the prosecution of the Board against two chemists and druggists, one for selling "methylated finish" not containing the proper proportion of gum, and the other for selling laudanum made with methylated spirit.

Notwithstanding that so many exciting incidents have occurred during the last twelve months in the politics of pharmacy, they have not had any appreciable effect on the progress of pharmaceutical science as evidenced by its literature. Perhaps it cannot be affirmed that the year has been so fertile in sensations in either materia medica or pharmacy as some of its predecessors, but it has not been without its share of good solid work. If one subject more than another has attracted attention during the year it has been what may be termed the pharmacy of antiseptics, and considering the importance which antiseptic treatment in medicine and surgery has assumed during recent years it is no more than might be expected that it should leave its impress upon pharmacy.

Early in the year it became evident that the antiseptic properties of thymol were obtaining fuller recognition than they had hitherto done. Ten years ago the value of thymol as a substitute for phenol, on account of its less objectionable odour, was urged by M. Bouilhon, a French pharmacien, in a paper read at an Evening Meeting of the Pharmaceutical Society of Great Britain, when a principal objection raised was the limited supply available. The substance was investigated afterwards by Bucholtz, Leon and others, who claimed for thymol a high degree of antiseptic power, and this has been confirmed to some extent by Mr. Willmott's recent experiments with putrescible infusions. Another advantage that has been claimed for it is that it does not irritate a wound when applied in a properly prepared dressing. But there was a difficulty in its comparative insolubility, which is only one in a thousand parts of water. Mr. Gerrard brought forward the subject of its pharmacy at an Evening Meeting, and pointed out that it is very soluble in solution of soda or of potash without forming compounds with those bases or becoming precipitated upon dilution with water, which is not the case with spirit or glycerine solutions. But he stated his preference for the ointment form, thymol being very soluble in fats, and recommended that in order to insure its perfect diffusion through the mass the thymol should be dissolved in a little rectified spirit before mixing. Mr. Gerrard further reported that the growing demand for thymol appeared to be leading to its withdrawal from continental oil of origanum before that oil was sent into the market. Mr. Balmanno Squire has also approved of an ointment, using a formula of 1 of thymol to 8 of lard for treatment of ringworm. An ointment of half this strength has been recommended by Dr. Crocker in psoriasis, as well as a lotion made by dissolving 5 grains of thymol in 1 oz. each of rectified spirit and glycerine and making up to 8 ozs. with water, and another consisting of an aqueous solution of "thymolate of potassium." All observers agree as to the necessity of the thymol being finely divided, since small crystals exercise a caustic action. Chloral hydrate was first suggested by Mr. Willmott as a solvent for thymol, though he did not go further than to show that a solution of thymol in absolute alcohol was not precipitated by the addition of a strong solution of chloral hydrate in certain proportions. But—in a paper which press of other matter has prevented the publication of in the present Journal—Dr. Symes announces the fact that in the presence of solid chloral hydrate and camphor, as well as of camphor only, thymol like those substances undergoes liquefaction upon trituration. Dr. Symes, in addition, mentions the interesting fact that milk will dissolve 10 per cent. of its weight of thymol. Thymol gauze and adhesive plaster containing thymol have also been recommended as antiseptic dressings.

Although somewhat of the *furore* respecting salicylic acid has died away, it has not been without a history during the past year. In fact, one of the most interesting contributions yet made to its chemical history was a paper read at an Evening Meeting in March, by the President, Mr. John Williams. This paper, which has hardly received in this country the attention it merits, moreover suggests a very probable explanation of the unsatisfactory and unaccountable results sometimes produced during the administration of artificially prepared salicylic acid. The difference in solubility between salicylic acid prepared from oil of wintergreen and that prepared artificially by Kolbe's process, as well as in their crystallization and behaviour towards sulphuric acid, led Mr. Williams at first to doubt their identity. Further experiments, however, showed that the difference in results was due to the presence, in the artificial acid, of one or more bodies other than salicylic acid. The salicylic acid was therefore separated as a neutral calcium salt, purified by recrystallization, and decomposed by hydrochloric acid, and eventually a product was obtained apparently identical in all its properties with the acid obtained from wintergreen oil. The mother-liquor yielded another acid, evidently differing in its properties, which, pending a more complete investigation, Mr. Williams has named cresyl-salicylic acid, as indicating its probable origin from the cresylic acid contaminating ordinary carbolic acid.

Salicylic acid appears to have taken a place permanently in the armament of the materia medica, and the preparation of salicylated wadding and salicylated jute, as well as carbolized jute, has been described by Herr Blaser. Neutral salicylate of zinc

has been recommended as an astringent antiseptic convenient for hypodermic injection. Herr FARSKY has been investigating the compounds formed by salicylic acid with albumenoid bodies, in view of the possibility of its being used for the preservation of feeding stuffs, but before this could be done with safety more would require to be known of the effects produced upon the system by the repeated ingestion of small quantities of this acid. Attention was called to the sulphosalicylates by Mr. WILLIAMS, at Glasgow, in 1876, but they do not appear to have come into general use; a quinine sulphosalicylate has, however, been recently described as a new remedy. The antiseptic properties of benzoic acid have also been advocated by Mr. ARCHER, who recommends the substitution of an aqueous solution of the acid for water in such syrups, decoctions, infusions, etc., as are specially prone to decomposition.

Carbolic acid, which has undoubtedly taken the highest place amongst antiseptics, has been the subject of two papers, dealing with the difficult subject of distinguishing it from creasote, cresylic acid and other bodies. This Dr. DAVY proposes to do by its behaviour toward a solution of molybdic anhydride in sulphuric acid, whilst Mr. ALLEN proposes to utilize the differences in the boiling points of creasote and carbolic and cresylic acids, and in their solubility in glycerine and in collodion.

Although outside the domain of pharmacy, mention must be made here of the admirable address of the high priest of antiseptic surgery, Professor LISTER, to the Pathological Society, on Lactic Fermentation and its Bearings on Pathology. Microscopic germs and their relation to pharmacy were the subject of an address by Dr. SYMES to the Liverpool Chemists Association, and it is curious to note that he is able to claim that he shadowed forth the fact that such germs can be destroyed by prolonged heating to a temperature considerably below the boiling point, in his paper on the preservation of lemon juice, published in this Journal fifteen years ago.

Dialysed iron is another preparation that has been steadily increasing in reputation, and in the absence of any authoritative formula has been the subject of considerable discussion as to its proper constitution. A five per cent. solution has been recommended, but few if any commercial specimens reported upon have contained so much. On the other hand, Mr. REYNOLDS reports on a sample having a distinctly acid reaction and containing 5·8 per cent. of ferric oxide, which was evidently not what it professed to be. Of course in every case the solubility is influenced by the amount of ferric chloride present, though according to Mr. TRIMBLE this is sometimes very small, he having met with one sample containing 4·8 per cent. of salt, in which the proportions were thirty-one molecules of ferric oxide to one of ferric chloride. Mr. JACKSON'S experiments illustrate the gradual manner in which the hydrochloric acid dialyses from the iron, and also show that neither an acid nor a neutral solution of ferric chloride, simply, is suitable for dialysis. Mr. SCHEFFER considers his experiments show that a very basic oxychloride can be prepared without dialysis, by precipitation, which shall contain a smaller proportion of chlorine than good average samples of dialysed iron. In connection with this subject some articles on soluble ferric hydrate that appeared in this Journal about eight years ago may be read with advantage. Another interesting point in connection with this preparation is the confirmatory evidence obtained by Messrs. MATTISON, GIBBONS and JACKSON that dialysed iron is an effective antidote to arsenical poisoning.

Nature shows no signs of exhaustion in yielding fresh substances for pharmacological investigation. Liberia has during the past year brought forward several drugs concerning which little is known beyond their botanical names or popular uses, whilst a series of Japanese drugs have been presented to the museum of the Society of which not even this can be said. Professor DYMOCK has also continued his valuable contributions to the history of Indian drugs, the worth of which is not to be measured by their first and superficial impression. Queensland has sent two species of *Duboisia*, from both of which alkaloidal substances have been obtained by Mr. GERRARD; these have been named duboisia and pituria, and promise to find a place in medicine. In Jamaica an investigation by Mr. BOWREY of a common plant, popularly reputed as a poison, has revealed that it contains at least three physiologically active bodies that are poisonous in extremely small quantities. A powerfully poisonous alkaloid, named "sophoria," has also been separated from the bean of the Texan plant *Sophora speciosa*. Another poisonous American plant, the *Caladium seguinum*, or dumb cane, has been pressed into service as an antipruritic. From South America have come what probably will prove to be two different astringent roots, under the similar names of "guaycuru" and "baycuru," the history of which is yet incomplete. In addition, pao-pereiro bark, from *Geissospermum lævе*, reputed as a febrifuge in Brazil, has been examined by HESSE, and found to contain two alkaloids, which have been named "geissospermine" and "pereirine."

Nor have investigators been idle with respect to better known drugs. A comparative examination of several specimens of rhubarb by Professor DRAGENDORFF appears to indicate that the reputation of the now lost "crown" rhubarb was based upon special characteristics—especially its richness in cathartic acid and chrysophan, associated with tannin—which are most nearly approached in "Chinese rhubarb," whilst the root from *Rheum palmatum tanguticum*, alleged by PRZEWALSKY to furnish the official drug, only contains about half the proportion of these compounds. By the way, the year has provided still

another competitor for the source of the official rhubarb in a variety of *Rheum hybridum* that has been named *Colinianum*. Free chrysophanic acid appears to be present only in the inferior kinds of rhubarb, and its solubility in cold petroleum spirit is suggested as a rough test of the quality of a specimen. In araroba, however, chrysophanic acid is now accepted as the active constituent, and its similarity in chemical composition to alizarin has suggested the successful application of the latter in skin diseases. Some interesting particulars respecting the Bahian leguminous plant from which araroba is obtained have been supplied by Dr. MONTEIRO. Opium has yielded two more alkaloids to Messrs. T. and H. SMITH, which have been christened "meconoisine" and "gnoscopine." Dr. BURI continuing his researches on elemi, has isolated a third crystallizable constituent,—elemic acid,—which is allied with both amyrin and bryoidin, whilst Professor FLÜCKIGER has discussed historically, geographically, and chemically, the allied resin, luban mate. Professor FLÜCKIGER has also described a neutral resin from gurjun balsam.

Cinchona and its products continue, if possible, to grow in importance, and the attempts to acclimatize the plant in various parts of the world have lost none of their interest. Favourable reports have been received from Sikkim and Ceylon, but hitherto the experiment has not proved successful in any of the several places in the Southern United States where it has been tried. As quinine is still and will continue to be the most important alkaloid yielded by cinchona bark, too much importance cannot be attached to experiments in cultivation having for their object the production of a bark containing an increased proportion of this valuable constituent. Dr. DE VRIJ therefore did good service by eliciting from Mr. J. E. HOWARD further particulars as to a variety—*C. officinalis*, var. *pubescens*, Vahl.—which is not only rich in quinine, having yielded to Dr. DE VRIJ 5·7 per cent. of the alkaloids, equal to 7·6 per cent. of sulphate, but has the merit of rapid growth.

The comparative strength of the official preparations of cinchona was the subject of a paper read by Mr. C. EKIN before the Conference in Dublin, the result demonstrating the inferiority of cold water as a menstruum as used in the liquid extract, which was found to contain less than one-fourth the proportion of total alkaloids present in tincture. Analogous results have been recently obtained by Mr. CONROY, who has devised a working formula for preparing liquid extract of yellow cinchona with proof spirit. Kinate of quinine which is soluble in four parts of water has been found convenient for hypodermic injections and its preparation has been described by Mr. COLLIER. Dr. DE VRIJ has contributed a test for the purity of sulphate of quinidine, based upon the perfect insolubility of the hydriodate in cold water, and Professor FLÜCKIGER has contributed information respecting a quinine decomposition product which he has named "quiniretin."

The complicated investigation of the aconite alkaloids has been continued by Dr. WRIGHT and Mr. LUFF, but as the results obtained have already been criticized at some length in these columns, no further reference need be made to them here. Another group of alkaloids equally remarkable for the discordance in the results obtained by different observers, the veratrum alkaloids, is also being investigated by these gentlemen. They report that they have commenced by examining the "alkaloids obtained from *Veratrum "Sabadilla* seeds," though probably that name is incorrectly assumed by them to be synonymous with *Asagræa officinalis*. But, whatever may be the source of the seeds, Messrs. WRIGHT and LUFF report that they have obtained from them three alkaloids. The first, the veratrine of Couerbe, to which they propose to restrict this name, is represented by the formula $C_{37}H_{53}NO_{11}$, and said to split up in a manner analogous to the aconite alkaloids, into another base, verine, and methylprotocatechuic acid. The second, called cevadine ($C_{32}H_{49}NO_9$), is said to be the veratrine of Merck, and to split up into another base, cevine, and methylcrotonic acid. The third is a new base, cevadilline ($C_{34}H_{53}NO_8$), yielding cevadic acid on saponification. Messrs. WRIGHT and LUFF are of opinion that the discrepancies between the results obtained by other chemists are due to the alterations and decompositions of the original bases taking place during the process of extraction and purification. The similar ready decomposition of the ergot alkaloids has no doubt also led to much confusion, so that Herr BLUMBERG has rendered useful service in establishing the identity of ecboline and ergotine. On the other hand, Herr POEHL, by proving that atropine and daturine are distinct alkaloids, has provided a probable explanation of the varying results obtained with commercial atropine and its salts, as these are said to be sometimes prepared not only from the roots and leaves of belladonna, but from the leaves and seeds of stramonium. M. TANRET, continuing his alkaloidal researches, has obtained from pomegranate bark an alkaloid, pelletierine, to which he attributes the tænicidal properties of this drug.

Whilst ignorance and cupidity remain such powerful influences, pharmacists will be always indebted to those who call attention either to accidental or wilful substitutions. Some senega that was brought into the market early in the year presented such unusual characters as to raise a suspicion of its being spurious. Mr. GREENISH brought the subject before the Pharmaceutical Conference and took the opportunity of enforcing a useful lesson by showing that with the aid of the microscope the pharmacist was able to determine that the specimen was truly from *Polygala Senega*, but very deficient in the cortical portion which contains the active principle, senegin. Then in November, Mr. HOLMES called attention to

the presence of senega adulterated with vincetoxicum root in the English market, the same adulteration having been observed as occurring in France about five years ago by M. PATROUILLARD. Earlier in the year Mr. HOLMES also stated that a new remedy then being imported into the country as *Grindelia robusta* was really quite another species, *G. squarrosa*. Should this drug come into use here this observation will have to be kept in mind, as the two species are said to give very different therapeutic effects. A spurious balsam of tolu has been described by Mr. NAYLOR, and Mr. STEVENSON has met recently with a "cheap" santonin adulterated with boracic acid. A considerable amount of information respecting sophistications of another class of substances is to be found in the monograph on the products of the Coniferæ contributed to this Journal by Dr. MOREL.

Among other substances that have more or less attracted the attention of pharmacists during the year, one is hydrobromic acid, the original formula for preparing which has been supplied by Dr. WADE, whilst Dr. SQUIBB has furnished one yielding a product of definite strength free from tartrate of potassium. M. SEE has called attention to the value of iodide of ethyl as an inhalation in asthma, and described a process for its preparation, and Mr. REMINGTON has done a similar service for bromide of ethyl as an anæsthetic. The therapeutic value of ether and cod liver oil has been favourably reported on, and potassium and sodium alcohols have been recommended as caustics. Then hypophosphoric acid, zinc hypophosphite and berberina phosphate have been the subjects of papers. Mr. GIFFARD has described several castor oil soaps, some of which might be used pharmaceutically, and Mr. GROVES a miscible copaiba prepared by treating Maranham balsam with a saturated solution of potassium carbonate. Soluble essence of ginger has been the subject of several communications, and, to bring the list to an end, Mr. WILLIAMS has recently called attention to a definite crystalline persalt of iron in the acetonitrate.

Besides what is included in the foregoing, numerous papers have been published on chemical subjects not sufficiently nearly allied to pharmacy to allow of reference to them in this limited sketch. Exception, however, must be made in favour of Dr. SENIER'S paper on the curious reaction between borax and glycerine, Mr. THRESH'S delicate test for alcohol, Dr. LETT'S investigation of some bismuth residues and Mr. SIEBOLD'S paper on the estimation of cyanides.

The year 1878 will be a notable one in the history of physics. Its earliest days heard the news that, in oxygen and hydrogen, the last of the intractable gases had been liquefied. Then, whilst men were still wondering at the telephone, there came the microphone, the megaphone and the phonograph. The electric light has attracted much attention and created a scare amongst the holders of gas shares. Mr. CROOKES is supposed to have demonstrated a fourth (or a fifth) form of matter. Lastly, some had promised themselves the realization of the alchemist's dream, in the demonstration of the transmutability of the metals, but were disappointed.

Only a brief reference can be made to the meetings of the year in which pharmacists have most interest. The earliest was the Chemists' Ball, which took place as usual in WILLIS'S Rooms. Then associated with the Annual Meeting came the Annual Dinner, at the Grosvenor Gallery, and the Conversazione, at the South Kensington Museum. During the same week the Chemists and Druggists' Trade Association held its annual meeting in London. In August the British Pharmaceutical Conference assembled in Dublin under the presidency of Mr. G. F. SCHACHT, and the British Association under that of Mr. W. SPOTTISWOODE. There was also a goodly sprinkling of pharmacists among the chemists who in November assembled to hear Professor WURTZ deliver the FARADAY Lecture. Further, a considerable number of pharmacists were tempted to cross the channel to visit the Exhibition in Paris, whilst, for the information specially of those who could not, a report has appeared in the pages of this Journal. The German Apothecaries' Union met at Coblentz in September, but the intended meeting of the American Pharmaceutical Association in the same month at Atlanta, in Georgia, was postponed, in consequence of the prevalence of yellow fever, until the end of November.

This brief history would not be complete without a last sad paragraph chronicling the losses that pharmacy has sustained by death during the past year. Fortunately, in Great Britain these have not been so severe as those suffered in some recent years. Nevertheless it includes two former Presidents and members of the Council of the North British Branch, Mr. JAMES GARDNER and Mr. JAMES ROBERTSON, both of Edinburgh. The Pharmaceutical Society has also lost two of its Local Secretaries in Mr. THOMAS COOPER, of Leicester, and Mr. CHARLES JONES, of Hanley. In France, however, several notable men, distinguished in the sciences in which pharmacists take special interest, have passed away; such are ANTOINE BECQUEREL, VICTOR REGNAULT, CLAUDE BERNARD, and A. LAMY. Germany, too, in the last days of the year has lost GORUP BESANEZ; whilst from across the Atlantic, news comes of the death of THOMAS H. POWERS, the well known chemical manufacturer of Philadelphia.

Many other topics of interest might still be mentioned did space allow. But after extending this *résumé* so far beyond the usual limits, it only remains for us to wish our readers a Happy and Prosperous New Year.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, January 1, 1879.

MR. JOHN WILLIAMS, PRESIDENT.

Present—Messrs. Betty, Cracknell, Greenish, Hampson, Hills, Robbins and Sandford.

Resolved—"That this meeting be adjourned to Wednesday the 8th instant at eleven o'clock.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, December 19, Dr. Gladstone, President, in the chair. After the minutes of the previous meeting had been read and confirmed, the following certificates were read for the first time, E. H. Rennie, A. J. G. Lowe, P. P. Bedson, C. F. Cross, C. W. Smith and A. E. Menke. The President then called on Mr. Francis Jones to demonstrate some points in connection with the preparation and properties of hydride of boron. Mr. Jones read a paper on this subject at the meeting held on November 21, and an abstract of the paper will be found in our report of that meeting.

The experiments shown by the author consisted of the preparation of some magnesium boride by heating a mixture of magnesium dust and boron trioxide. Some magnesium boride was then treated with hydrochloric acid, the gas which came off burned with a vivid green flame. The flame of a Bunsen burner held above the burning jet was also coloured green. On heating the glass tube through which the gas passed to redness the green colour of the flame disappeared.

Dr. Frankland asked the author if he had endeavoured to purify the gas from the hydrogen which it doubtless contained by absorption with ammonia, etc.

Mr. Jones in reply said that from preliminary experiments with the silver compound, he thought that there was but little hydrogen present; he was endeavouring to obtain the gas in a perfectly pure state.

Dr. Frankland then took the chair whilst the President communicated a paper entitled—

Researches on the Action of the Copper-Zinc Couple on Organic Bodies. Part IX. Preparation of Zinc Methyl. By Dr. GLADSTONE, F.R.S., and Mr. TRIBE. The authors from theoretical considerations came to the conclusion that methylic iodide would be slowly acted upon by the copper-zinc couple at ordinary temperature. A number of dry couples prepared from ½ metre of zinc foil, as described in the *Chem. Soc. Journ.*, were placed in small flasks containing 5 c.c. of methyl iodide; the flasks were then well corked and examined from time to time. The liquid became gradually somewhat yellow and diminished in quantity, crystalline plates began to appear in about thirty days, until the whole appeared in from thirty to forty days as a uniform crystalline mass. On removing the corks a slight outrush of gas took place; in two instances out of thirty the flasks burst. This the authors attribute to the accidental presence of moisture, but suggest the use of a mercury valve in the cork. The crystalline mass consisted of zinc methiodide, the analogue of Frankland's zinc ethiodide. On distillation, after filling the apparatus with dry hydrogen, at 60°, a clear colourless liquid began to come over, in fifteen minutes the distillate ceased. On examination it presented all the properties ascribed by Frankland to zinc methyl. The residue in the flask consisted of zinc iodide. The authors find that both at the ordinary temperature and at the boiling point the formation of zinc methyl takes place in a rapidly diminishing ratio with regard to time. By doubling the quantity of the zinc-copper couple present, the time required to decompose a given quantity of iodide is twelve times less, and by trebling it, thirty-six times less. So that 5 c.c. of methyl iodide can be completely decomposed in one day by trebling the zinc foil used. By further experiments the authors prove that zinc methiodide is alone formed, and that the methiodide splits up very readily by heat, without fusing, into zinc iodide and zinc methyl. The methiodide is also decomposed by light. Zinc foil alone has no action at ordinary temperatures on methyl iodide. The authors conclude by pointing out the additional proof afforded by these experiments as to the value of the copper-zinc couple in bringing about a chemical change at low temperatures which can only be brought about by its more positive element at such a temperature, and under such conditions as occasion the formation of secondary products. It has also given a perfect and simple method of preparing Frankland's most valuable reagent, zinc-methyl, for in two experiments, the details of which are given, 91·7 and 99·2 per cent. of the possible quantities were respectively obtained.

Dr. Frankland said that organic chemists would receive this new method with gratitude; he had already pointed out that large quantities of zinc methyl could not be prepared by substituting copper or iron digesters for the glass tube employed on the small scale, whilst recourse to the dangerous and poisonous mercuric methide was to be avoided if possible. The present plan placed this valuable reagent in the hands of chemists. The yield (99·2 and 91·7 per cent.) was exceedingly encouraging. He would like to ask if the method had been tried on the large scale with half a pound of methylic iodide. He had found that with large quantities of ethylic iodide the yield was not so good as on the small scale.

Dr. Gladstone had not tried the reaction with more than 15 c.c. at a time, but saw no reason why the reaction should not succeed on the large scale.

Mr. Tribe said that the materials should be perfectly dry; he had operated with 115 grm. of the ethylic iodide and obtained a yield of 88·2 per cent. of zinc ethyl.

Dr. Gladstone then took the chair and called on Dr. Debus to make some remarks on the formula of glyoxylic acid.

Dr. Debus commenced by giving a historical sketch of this substance. In 1856 he obtained it amongst the products of the oxidation of alcohol by nitric acid; he gave it the formula $C_2H_4O_4$; afterwards, for various reasons, he considered this formula to be erroneous, and he altered it to $C_2H_2O_3(+H_2O)$. The potassium and sodium salts contain one molecule of water, but the ammonium salt is anhydrous. Perkin obtained this acid by boiling silver dibromacetate with water, and in various papers, but especially in one (*Journ. Chem. Soc.*, 1877, 96), considers the correct formula to be $C_2H_4O_4$, and not $C_2H_2O_3$. The ammonium salt, says Perkin, is decomposed by evaporation *in vacuo* into amidoglyoxylic acid and water; this he proves by testing the reaction of the solution of the ammonium salt before and after concentration. Before evaporation it is neutral, after, it is distinctly acid, and therefore the salt is decomposed during the evaporation. To this argument Dr. Debus objects. Ammonium oxalate when evaporated *in vacuo* over sulphuric acid becomes acid, though perfectly neutral to test paper before. Again, dilute sulphuric acid, 1 in 40,000, does not give an acid reaction to litmus paper by daylight (by gaslight the blue turned most distinctly), but if concentrated by evaporation it gives an acid reaction. So that the reaction of a substance in solution depends on the strength of that solution and (as litmus paper varies in delicacy) on the litmus paper. Perkin's observation, therefore, that ammonium gloxylate solution was neutral before, but acid after evaporation proves nothing. The author has prepared gloxylate of ammonium, made a solution, tested its reaction, evaporated it,

made it up again to the same strength and found it not to be more acid than at first. Perkin's conclusions as to the decomposition of this ammonium salt rest, therefore, on a sheet of litmus paper. On the other hand, this ammonium salt is as much an ammonium salt as ammonium chloride; it gives off ammonia by treating it with cold caustic potash; a precipitate is obtained with platinum chloride, etc. Moreover, the body has all the properties of an aldehyde. In conclusion the author stated the arguments derived from the analogy of the substance to aldehyde and its place in the series of oxidized products ending in oxalic acid as the ordinary aldehyde series ends with acetic acid. In a paper he was about to publish he would go still further into the subject.

Dr. Frankland said that Dr. Debus had given a very learned and interesting exposition of the subject, but he ventured to think that the whole point of the question was whether two semi-molecules of hydroxyl could be united to one carbon atom or not. It had struck him that against the solid facts, obtained by Perkin from elaborate quantitative experiments, and from which he came to the conclusion that the formula of glyoxylic acid was $C_2H_4O_4$, Dr. Debus had offered nothing but surmises. Dr. Debus had dwelt much on the ammonium salt, and the loss of water on evaporation, but in his opinion this was quite beside the question, and apart from the theory that two semi-molecules of hydroxyl could not be united to the same carbon atom, no chemist could come to any other conclusion than that arrived at by Perkin.

Dr. Armstrong apologized for the unavoidable absence of Mr. Perkin. He agreed with Dr. Frankland that the ammonium salt had nothing to do with the point at issue. He thought too that there was no force in the argument from analogy of the oxidation products because one term in the reaction was missed out.

Dr. Debus, in reply, denied that the theory above referred to by Dr. Frankland had influenced him in changing the formula, and he still thought that the question as to whether the ammonium salt was really an ammonium salt or not was of great importance in deciding the true formula of the acid.

The President then called on Mr. T. Wills to give a short communication—

On the Production of Oxides of Nitrogen by the Electric Arc in air.

In the discussion which followed the reading of a paper by L. T. Wright, on November 7, Dr. Frankland remarked that it was most important to ascertain whether at the enormously high temperature of the electric arc, an oxidation of nitrogen did or did not take place. The author has made experiments to investigate the subject. Sixty Grove cells were used. They were placed in another room quite removed from the place in which the experiments were made. The carbons points were placed under an inverted funnel, and the air aspirated through dilute potash; the nitrogen was converted into ammonia with aluminium, etc.; the experiment lasted twenty minutes. N_2O_5 was formed equal to ·54 gram per hour. A second experiment gave ·55 gram. A second set of experiments with more efficient aspiration gave ·6 and ·7 gram.

Dr. Gladstone observed that the amount of nitric acid formed was very considerable; it was a most important observation, especially at the present time.

Dr. Frankland said that the results had surprised him, especially as he had used the electric light for twenty years by the hour together without observing any corrosion of the brass work or delicate clockwork of the lantern; it would be a very serious matter if anything like this quantity of nitric acid was produced, under all circumstances, by the electric light.

Mr. Wills, in reply, intimated that he was about to continue his experiments, using a Siemens magneto-electrical machine.

The next paper was read by Professor W. Foster—

On the Action of Alkaline Hypobromite on Oxamide, Urea, and Potassium Ferrocyanide. Part II. When alkaline hybromite acts on oxamide 75 per cent. of the nitrogen is evolved, the suppressed nitrogen remains behind as cyanate—

$$4(NH_2)_2C_2O_2 + 15NaBrO + 18NaHO = 3N_2 + 2NaCNO + 8Na_2CO_3 + 15NaBr + 17H_2O.$$

By quantitative experiments the N evolved, after neutralizing with hydrochloric acid in the presence of sodium sulphite, etc., and again treating with alkaline hypobromite, amounted to 7·73 per cent. and 7·84 per cent. A similar reaction takes place between urea and hypobromite, 92 per cent. of the nitrogen is evolved and the rest suppressed as cyanate: by quantitative experiments the author obtained 7·5 per cent. of the suppressed nitrogen as the amount existing in the urea residue as cyanate. When hypobromite is boiled with potassium ferrocyanide solution, a deep red liquid is obtained capable of evolving oxygen. The author states that it has the appearance and leading properties of sodium ferrate. About one-third of the total nitrogen of the ferrocyanide is evolved as gas, the remaining portion being oxidized to cyanate. Cyanides also under similar conditions are converted into cyanates. The author has also investigated the action of hypobromite on acetamide and benzamide; he also intends to observe its behaviour with cyanamide if he can obtain some of the latter substance.

The next paper was read by Dr. Letts *On Two New Hydrocarbons obtained by the Action of Sodium on Turpentine Hydrochloride.* The author gave some account of his research at the meeting of the British Association, 1876. The action of sodium on solid turpentine hydrochloride fused in a flask is violent. On distilling, a white solid substance passes over, followed at a much higher temperature by an oily liquid. The solid substance boils at 157°—15°. 86 grams of hydrochloride gave 38 grams solid, 14·5 grams liquid. To this solid hydrocarbon after many analyses, purifications and determinations of the hydrogen evolved during the reaction of the sodium on the hydrochloride vapour density determinations, etc., the author assigns the formula $C_{10}H_{17}$. It fuses at 94°. It distils at a constant temperature under diminished pressure. The molecular weight determined from vapour density determinations is 136·4, 137·0. The body by the action of chlorine gives rise to various substances. Bodies with the formulæ $C_{10}H_{17}Cl$ and $C_{10}H_{16}Cl_2$ were obtained. Br has a similar action, but the body $C_{10}H_{17}Br$ was not isolated. To check his results the author analysed australene and camphene. He concludes that the formula $C_{10}H_{17}$ is correct and gives the name turpenyl to the new body. The liquid portion of the distillate boils about 321°C. It has the formula of diturpenyl, $C_{20}H_{34}$. The author also investigated the action of sodium on liquid hydrochloride of turpentine. Solid turpenyl was obtained and a liquid boiling at 156° having a similar composition.

Dr. Armstrong suggested that the action of sulphuric acid should be tried, for a mixture of hydrocarbons $C_{10}H_{16}$ and $C_{10}H_{18}$ might crystallize from alcohol unaltered and distil at a constant temperature under diminished pressure.

In consequence of the lateness of the hour the two following papers were taken as read and the Society adjourned to Jan. 16.

On the Formation of Baric Periodate. By S. Suguira and C. F. Cross. In a previous paper the authors showed that by passing iodine vapour and dry air over heated oxide of barium, baric periodate was formed. This substance they find to be identical with that produced when barium iodate is heated, or when the iodide is heated in a current of dry air, in both of which cases baric periodate $Ba_5I_2O_{12}$ is formed. This substance is therefore the most stable combination of the three elements. If barium carbonate be heated with iodine in a tube exhausted of air, no combination takes place. On

the admission of dry air the formation of periodate at once commences. The formation of periodate is therefore referable, not to the direct replacement of oxygen by iodine and the subsequent oxidation of iodide, but to the oxidation of the iodine itself and the subsequent union of the oxidized molecule with barium oxide.

On Erbium and Yttrium. By T. S. Humpidge and W. Burney.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Defence of Trade Interests by the Council.

Sir,—The enclosed letter from Mr. Flux is, I think, of such interest to the members of the Society generally, that I forward it to you for publication, having received Mr. Flux's authority for so doing.

14, *Buckingham Street, W.C.* John Williams.
January 3, 1879.

Dear Mr. President,—As the Journal of last Saturday contains a paper by the Clerk and Solicitor of the Apothecaries' Company, it may have raised expectation that the Solicitor of the Pharmaceutical Society shall contribute to the literature of the day concerning counter practice. There can be no doubt that Mr. Upton had the sanction of the Court of the Apothecaries' Company to the publication of his paper, or that it is impossible for me to obtain the sanction of your Council to my appearing in print prior to the forthcoming general meeting. I therefore venture to address you, submitting all considerations as to the publication of my letter to your presidential discretion.

During the long period of my having had the honour to advise your Society no question regarding counter practice was raised until "Nottingham's" case in 1876, concerning which nothing whatever was known to myself, or so far as I can trace to any member of the Council, prior to the publication of a newspaper report of the trial before Mr. Baron Bramwell.

On the day when the newspaper report appeared, the President and the Secretary personally conferred with me on it, and gave me authority to obtain the best information in time for the next Council. Accordingly I communicated with Mr. Upton and with the firms who conducted the case on both sides, and ascertained that no shorthand note of the trial was taken, and that the defendant's case was by his own solicitors considered hopeless; they, in fact, sent me a letter, from which the following is an extract:—

"The defendant, acting under our advice, paid a penalty to the Company for infringing the Act in August last, and subsequently the plaintiffs commenced another action for a similar offence, which the defendant was determined to defend, although we assured him there was little chance of success. We should not think of moving for a new trial, the judge who tried the action being so much against the defendant."

If as I gathered there was a partnership in medical practice between the defendant and an apothecary, his solicitors' opinion was well founded.

A full report by me was considered in the Council of 2nd February, 1876.

As Shepperley's case was never referred to me (although the Journal shows that it had been under consideration by the Council) the Society and its advisers were in no respect responsible for the course of the case before the Nottingham County Court or during its subsequent stages.

In October, 1877, I received from the Council instructions to defend in regard to alleged counter practice, and wrote a chemist and druggist who had been threatened with an action a letter as follows:—

"You may be aware that we are the solicitors for the Pharmaceutical Society of Great Britain.

"Should there be a prosecution instituted against you under the Apothecaries Act in respect of that which is generally known as counter practice, you will oblige by informing us.

"We have the authority of the Council of the Society, in our discretion and at the expense of the Society, to defend you in any case of the kind which may appear to us to be a proper one for defence and, of course, if our so doing be desired by you."

My report to the Council with reference to the case said, "No further communication has arrived from Mr. ——, and we therefore assume that the knowledge of your Society's resolve to sustain Mr. —— in his defence for acts in the course of his business as a chemist and druggist, became known to those who threatened, with the result that they were deterred from proceedings."

Between October and the close of 1877 I read of rumours of other intended actions. In exercise of a discretion which according to my view resulted from the instructions referred to and my responsibilities as solicitor, I discussed with Mr. Upton the general position and pressed him with the interests of peace and good understanding, which resulted in correspondence laid by me before the Council Meeting in January, 1878, and ultimately published in the Journal of Feb. 9, 1878.

There can be no doubt that the action of the Apothecaries' Committee referred to in Mr. Upton's letter of the 1st January, 1878, was duly reported to and received by the next Court of that Company, for had it not been so there would have come from Mr. Upton a communication to that effect instead of his letter of the 5th February, and he would not after a long interval have embodied that letter in his recent paper without any qualifying sentence.

Mr. Schacht and others appear to attach to judicial dicta at Nisi Prius greater weight than lawyers attach to them.

There are three classes of judicial utterances. First in degree are decisions upon points formally raised and argued in banco—they, when reported in recognized law reports, may be formally quoted in subsequent arguments. Second in degree are judicial dicta uttered in the course of an argument or decision, but being upon matters not distinctly the subject of, or not necessary to, the decision, when they become reported in recognized law reports they may be quoted, but they are not received as of the first degree. Lowest in degree are Nisi Prius utterances; they are not reported in the recognized law reports and are not quoted.

Reports, also, are of different degrees of quality. Recognized law reports are of the first rank and may be quoted. Shorthand writers' notes may sometimes be used in the case in which they are taken, but not otherwise. Lowest in rank are newspaper reports; they may not be quoted or used in the courts, they in fact not being prepared for any purpose other than the public taste.

Thus the only report existing of any utterance by Mr. Baron Bramwell is of the lowest order and is a report of an utterance of the lowest (legal) degree. Indeed, so far as I have traced, section 20 of the Apothecaries Act was not relied upon in the case and no evidence was tendered concerning the usage of the trade prior to 1815. Thus the newspaper report of Nottingham's case is of no practical weight.

Concerning Shepperley's case I have read such matters as have appeared in the Journal, and see no reason to dissent from Mr. Upton's language, "absolutely worthless the result of the trial was in disposing of any legal question."

I observe that Mr. Day, Q.C., once before the court stated to the purport that Shepperley's case was by arrangement a test case. Certainly it was not, with the knowledge or consent of the Pharmaceutical Society or its advisers, in any sense a test case and, so far as the materials open to me disclose, it was not one which the Society should have adopted as a test case. Mr. Upton nowhere asserts that it was a test case and indeed the passage above quoted estimates it as "absolutely worthless" in disposing of any legal question.

It cannot be desirable that all which takes place in Council concerning individual cases should be made public. Mr. Upton's paper discloses that matters A, B and C were alleged, whilst evidence was tendered only on C; the members of your body may with propriety assume that concerning the allegations A and B, your Council were not absolutely without information, and that on the whole affair there was a careful exercise of discretion.

It is interesting to note Mr. Upton's remark that had a fact disclosed at the trial been known, the society's autho-

rity to prosecute would immediately have been refused; it bears upon his late remarks as to the conduct of proceedings by the Society of Apothecaries' own solicitor and illustrates the accuracy of the concluding sentences of my letter to him, viz.—

"It certainly would be more satisfactory to my clients if I could convey to them an assurance that the powers of suing for penalties, reposed by statute in the Apothecaries' Company, will henceforth be exercised by, and only by, the society acting by its own solicitor.

"My clients never have delegated the powers of suing entrusted to them, and the preservation of that good understanding between the societies, which hitherto has prevailed, will be less in peril if the practice of your society in regard to litigation be placed and preserved on a similar footing."

Some correspondents in the Journal have written as though the sole function of your Society is the conduct of litigation, whereas many duties require and receive careful attention, and litigious matters are attended to; witness the appeal in the Worthing case, the encouragement given to organization in the capsule cases, the current action concerning co-operative stores, and the many instances of proceedings for penalties, whilst as concerns Shepperley's case, it is recorded in the Journal that on the only occasion whereon the Society's Executive was resorted to, the matter was maturely considered and the course adopted passed *nem. con.* in a well attended Council.

As a litigation, Shepperley's case is dead.

3, *East India Avenue,* WILLIAM FLUX.
London, E.C., January 1, 1879.

Sir,—As one of the earliest members of the Pharmaceutical Society which has worked so well, I much regret now to see the prospect of a conflict between its Council and the Executive of the Trade Association, and cannot foresee (if this is to last) how men who are members of the Executive of both can faithfully discharge the duties which have been delegated to them by their respective electors; they cannot serve two masters, acting antagonistically to each other. But why this antagonism? There is plenty of room for both the Society and the Association, in their respective spheres, and it is to be hoped that a better feeling will be engendered by reflection and the undue activity of certain members will be toned down by their being shown how their conduct must inevitably injure both the Society and the Association in the eyes of the trade generally. The Executive of the Association must bear in mind that the Council must act under the Society's recognized laws, and cannot deviate from them at the dictation of those who would have it all their own way whether rightly or wrongly. Let us hope that the 9th inst. will bring good sense and reason to all, and that the meeting will go off in a fair and friendly spirit.

Leather Lane, E.C. MATTHEW POUND.

Sir,—I see no reason why Mr. Schacht's suggestions may not be carried out. The litigation now going on will not settle the question, but only put money into the lawyers' pockets and create bad feelings between members of a profession who ought to work in harmony with each other. Nearly every pharmacist desires counter practice to be limited, but it cannot be altogether suppressed. Let us then understand our relative positions, work together, not strive for what we are not entitled to, but clearly and definitely maintain that we are not, and never have been, doing wrong only on sufferance.

After a careful perusal of the 'History of Pharmacy,' as given by the late Jacob Bell, and abridged in the Journals during the last month, I cannot come to the conclusion that for half a century I have been doing an illegal act when I have recommended a gargle for a sore throat, or a chalk mixture for diarrhœa. The assumption that counter practice has no legal position whatever is, I think, erroneous. It is true we have no legal definition or limit of the extent of that practice, neither is there any statute forbidding it. The old adage that "possession is nine points of the law" surely holds good in our case also. Both before 1815 and since, we have had and have retained, until lately, an almost undisputed possession. In my humble opinion this alone constitutes a legal right. As to the construction that may be put on the 28th, or indeed any clause of the Act of 1815, it is needless to dilate, so well known is the power of our legal luminaries to interpret as the occasion suits.

I contend that our exclusion from counter practice was never intended when the contracting parties—the Society of Apothecaries and the chemists—agreed on clause 28. It is beyond dispute that chemists prescribed before 1815, and continued undisturbed to do so till 1841, when, I conclude, some were found to carry it on too far, but apparently even then this could not be prevented or else why should the restrictive clause of Mr. Hawes's Bill be needed, but to give a power which, if possessed, surely required no fresh Act to put into execution? The opposition to that Bill both in the House of Commons, and out of it, was so decided that it was withdrawn. Then it was discovered fortunately "for the lawyers at least," as Jacob Bell writes, that the clause before referred to would bear a meaning different from that the contracting parties intended, hence the present litigation. The question then seems, shall the trade quietly submit to this recent "legal" interpretation, or endeavour to come to an equitable arrangement by which the legal status of the pharmacist, as now recognized by the Government as a member of the medical profession, is settled? If he is to be a mere retailer and compounder of drugs, then in those districts where medical men charge both for professional services and medicine, he had better seek some other mode of subsistence, for otherwise he would simply be ruined. On the other hand, where the doctors write prescriptions for the pharmacist to dispense, counter practice is discouraged, and a good feeling exists, and I may add the public generally are better satisfied. Before 1815 apothecaries could not charge for visits, and were therefore obliged to flood their patients with medicine to remunerate themselves. Now, a new order of things has arisen, and the pharmacist claims his position and remuneration.

Turnham Green, December 30, 1878. B. HUMPAGE.

Sir,—I have not leisure at present to undertake any elaborate criticism of the position of the various parties in the discussion of this question, but I believe that there is a wide-spread dissatisfaction with the tone of the Journal's articles and the Council's proceedings, and that there is some just ground for the same.

It is eminently unsatisfactory that the Society of Apothecaries should be bound to supply powder and shot, and to grant gun licences to any apothecary or company of apothecaries who may wish to take a shot at a chemist. I believe, though some do not, that the great apothecaries are on friendly terms with the great chemists, and consequently that it would not be any serious loss to them to have the law so altered that they would not be bound to distribute arms for the slaughter of their friends or their friends' friends.

It is eminently unsatisfactory that the Council should be wanting either in the power or the will to aid the defence of Mr. Shepperley when it became evident that his prosecution was being conducted entirely on the grounds of his having done what almost all druggists find themselves continually compelled to do.

And it is equally unsatisfactory to the trade at large to feel that you have satisfaction in seeing this action or want of action on the part of the Council while the country druggist is being tortured with the fear of penalties and prosecutions which the Society of Apothecaries, however friendly, seem powerless to withhold, and against which the Council of the Pharmaceutical Society, however friendly, seem powerless to protect him. No one appreciates more highly than I do your desire to do justice to your opponents, but no one is more desirous than myself that you should show a kindly regard for those who might naturally expect your protection. I have read your articles as you suggest for the last two years, and regret that your sympathy has not always been visible to the naked eye. It will be a source of rejoicing if you with your pen and the Council with its purse will come to the rescue of the next chemist who is prosecuted for looking down a man's throat and giving him a saline, for at present we feel that we have to trust to the Trade Association to fight our battles for us, while the Council sits dreaming its happy hours away.

There are few men in pharmacy for whom I have a greater regard than I have for Mr. Schacht, and it is eminently unsatisfactory to see a man with his pure mind and high motives so unable to see that right can and must prevail, as to tell us in the same letter, that when our customers appeal to us in their trouble, "as we are men we cannot turn them away, even though in fulfilling their behests we

infringe the letter of the law," and that any appeal to Parliament to relieve us of this law must meet with a blank refusal.

On the other hand, I have faith that public convenience and good is served by every man being allowed to consult his friend, or if he chooses, his enemy, according to his own free will; that public safety has all the protection which it can hope to gain from law, when the legally qualified man bears the hall mark, and the penalty is enforced against assuming a hall mark without qualification; and that laws which work against humanity and the public weal may, and must, be amended.

BARNARD S. PROCTOR.

Grey St., Newcastle. Dec. 31, 1878.

COUNTER PRACTICE.

Sir,—I am one of those benighted individuals who cannot see, "whose interest warps his judgment," and any other anathema you may choose to cast upon me.

Still, I have an opinion and that is, that the action of the Council in the matter of counter practice and the general tenour of your leading articles on the subject have been hopelessly wrong. While an action was being tried against Mr. Shepperley, the Council was blundering over something that Mr. Shepperley was supposed to have done but which was not advisable for the members to know; it leaked out however, at London and Dover and was well known among a certain class. The issue raised was as simple a case of counter practice as probably ever occurred and, thanks to the efforts of the Birmingham Association, a special jury declared the chemist had not infringed the Act of Parliament. The appeal from that as to a question of the judge's ruling and direction was puerile; the verdict of the jury was indorsed with singular unanimity by the public press. The Pharmaceutical Society sustained a defeat.

I have no sympathy with the Birmingham Association, on the contrary, I attribute the attack partly to it. Instead of being with us loyal citizens of the pharmaceutical republic, aiding us with their influence and correcting our policy, I find them traitors to the best interests of our trade, and a camp of rebels, letting the Society pursue the *ignis fatuus* of the separation of pharmacy and medicine, and showing a divided command to the enemy. This trouble has come upon us because we are not united. With the whole trade represented in Bloomsbury Square, and the corollary of that, no attack on our rights as citizens I firmly believe would ever have been attempted.

I do not approve or encourage chemists to prescribe or attempt to treat disease; but is it entirely their fault, so much is thrown in their way? In good neighbourhoods a kind of natural selection goes on and the medical men fear not the chemists—the chemists stand no chance of competing with the medical men. In poorer neighbourhoods, thanks to the competition of eleven medical examining boards, the quality of the medical skill, cheap enough in all conscience, suffers from a kind of natural selection and the chemist stands an excellent chance of competing with the medical men and an intense jealousy results.

The mandate Mr. Schacht mentions, "qualify, qualify, get yourself stamped with hall mark, without it I know you not," is the remedy, only it applies to the medical man. The hall mark is useless if the nitric acid of experience and criticism burns you green at three points out of four.

The Duke of Richmond's Bill will do more to remedy this evil than any prosecutions, for here too I am at issue with you. To what extent, with the privileges conceded to the chemist by the 28th section of the Apothecaries Act, can the discretion of the chemist be limited without taking away his responsibility altogether? Moreover you attach much more importance to a judge's opinion on the 28th section than I do. And while I yield to no one in my respect for the Bench of England, we must not forget that only a short time ago, a plain citizen took the judgment of the Lord Chief Justice of England personally to the Lords Justices of Appeal, and said, Will you tear this up for me. And they reply, Yes, sir, we will.

The fusion of law and equity I trust will temper obsolete statutes with common sense, at least in the higher courts of this country, and I for one will never believe the House of Lords will deprive us of the protection of the 28th clause, after having enjoyed it for fifty-three years, any more than they would compel every tailor to put brass buttons on every coat, in accordance with the Birmingham Brass Button Act.

GEORGE MEE.

Sir,—I should think if, instead of launching their darts of venom at the Council of the Pharmaceutical Society, your correspondents were to ponder over the state of affairs and lend their able minds to obtain a clear solution of the difficulties attending the trade, there would be more benefit accrue and more general satisfaction produced. I should imagine there was plenty of room for agitation to amend the Pharmacy Act so as to place the sale of drugs, etc., more in the control of the chemist, and thus by endeavouring to improve the trading portion of the business to gradually release the prescribing. Looking into futurity I think the ultimate end will be a clear and defined separation of the practice of pharmacy from that of medicine; but of course like all reforms it takes a much longer time to develop than is imagined, especially when the public convenience is somewhat at stake, and I cannot help reiterating that it would be to the interest of both the medical practitioner and the pharmacist if both were to work with that object in view, instead of creating discord and opposition when harmony and agreement are so much required to produce a practical result.

C. H. F.

Sir,—The number of letters which have appeared in your columns mostly condemn the policy of the majority in the Council who voted against the Society granting a sum of money to assist in defending the chemists and druggists against the apothecaries. Such a course would be to my mind, utterly premature at this stage of the proceedings, and calculated to do more harm than good, and it is apparent that some write and give their opinions without fully understanding what they would like to discuss.

It should be plain to all that, as yet, it is not the desire of the Society of Apothecaries' to harass chemists and druggists in the ordinary discharge of their duties, providing they confine themselves within legitimate bounds in so doing, and if Mr. Shepperley had done this, it is quite reasonable to think there would have been no "prosecution" to defend.

The practice of chemists giving advice indiscriminately and in all manner of cases, and doing what they can to tread upon the heels of medical men, and encouraging such practices in every possible way, cannot fail to bring its own reward in due time.

Allowing that the case is decided in our favour if ever it reaches the Court of Appeal, it is more than likely it will bring on us the wrath of a more influential body of gentlemen than the apothecaries, with the result that we will all be classed as a pack of presuming empirics, which will neither give us "peace" nor add "honour" to our already anomalous position.

I do not wish to condemn the Chemists' Trade Association for the "energy, anxiety and liberality" it has shown in this case, these are qualities which at all times command respect when rightly used; but discretion is the better part of valour, and it would be better if the Association would reserve its strength until such time as it would be felt to more advantage. I disagree with Mr. Fairlie entirely in believing that the time has come for that.

I will just add that the alarm the Shepperley case has raised is likely to prove a false one, and I am also confident that those members of the Council who voted in the majority will be the first to take up arms to protect any vital interest of our trade whenever it is seriously assailed.

Edinbro'. J. K. N.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Symes, Pollard, Hartness, Mee, Leypoldt, Stevenson, Mackay, Hicks, Thompson, Gostling, Smith, Allman, Bransom, Macmillan, Hellowell, Tupholme, Barnes, M. P., T. C., C. H. F., J. K. N., T. T., Omega, St. Tudno, Tyro.

The Pharmaceutical Journal.

SATURDAY, JANUARY 11, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SPECIAL GENERAL MEETING.

THE Special General Meeting of the Pharmaceutical Society, held on the 9th inst., was attended by ninety-two Members and sixteen Associates in Business, the majority of whom came to censure the action of the Council and did not remain for any better purpose. The President, in opening the proceedings, remarked that as Special General Meetings of the Society were infrequent, and it was necessary to have regard to the rights of those who were absent as well as those who might be present, particular care had been taken to give full information as to the object of the meeting as specified in the requisition and as indicating the limits within which the proceedings of the meeting were to be confined.

After some discussion on the propriety of reading the case submitted to counsel, Mr. RADLEY, of Sheffield, the first signatory of the requisition, rose to move a resolution, and explained that his reason for the course he had adopted was the conviction that the Council did not represent the opinion of the trade in regard to a matter of great moment and of widespread interest. Mr. RADLEY also stated that in order to obtain evidence of the state of feeling among the Members and Associates of the Society he had caused a circular to be issued, requesting replies, to indicate whether they approved of the proposal to grant money from the funds of the Pharmaceutical Society towards defraying the legal costs incurred by the Trade Association.

These circulars were sent out to the number of 3721. Of that number 1533 had been replied to, and out of these 1449 approved of the proposal, while 84 disapproved. Mr. RADLEY thought the majority of replies in favour of subsidizing the Trade Association was such as to furnish an apology for calling the meeting. The fact, however, that it had been made known the meeting could have no power in constraining the Council to dispose of the Society's funds as proposed, may account for the silence of many of the 2188 Members and Associates who did not respond to the circular, since the expression of their opinion was not necessary for the protection of the Society's funds.

The resolution proposed by Mr. RADLEY in the first instance recommended that a grant should be made by the Council towards the heavy expenses of the SHEPPERLEY case, but this reference to the SHEPPERLEY case being ruled by the President to take the resolution outside the power of the meeting to discuss, it was at length decided to propose a resolution affirming the advisability of rendering substantial pecuniary aid to the Trade Association to assist its efforts to defend the legitimate interests of the trade.

Mr. RADLEY, in proposing this resolution, chiefly insisted upon the fact that what is termed counter practice had long been customary with chemists and druggists, urging that in carrying on that practice they were merely exercising their right, either as vendors to recommend the wares they sold, or as any other members of the community to advise how those wares should be used.

The seconder of the resolution, Mr. PROVOST, after expressing his opinion that the resolution of the meeting was to ascertain whether or not the Council of the Pharmaceutical Society represented the views of chemists and druggists generally, was interrupted by a suggestion that he was not a member of the Society and consequently had no right to take part in the proceedings of the meeting. Mr. PROVOST, however, affirmed that he had been a member of the Society for the past seven or eight years and local secretary for five or six, and as his name was, actually, in the Calendar for 1878 he was therefore allowed to proceed with his remarks; but it was ascertained eventually that Mr. PROVOST had resigned last June.

Mr. PROVOST referred to the letter of Mr. W. T. MARTIN in the Journal of 28th ult., as expressing his views on the subject before the meeting and he regarded the meeting as the index by which the Council was to notice which way the wind was blowing. Though giving the Council credit for doing what it thought right for the interest of the trade, he believed it was in error and had not been in years past so energetic in supporting the trade as members had expected. Though giving no better reason than this, Mr. PROVOST declared that the Council was not, in fact, properly representative of the trade.

The succeeding speakers chiefly dwelt upon the right of chemists and druggists to prescribe medicine across the counters for those who chose to seek their services in that way, also upon the necessity of this being done in many instances. Dr. SYMES, for instance, urged these points with force and moderation, in a manner that, we feel convinced, would be approved, not only by the majority of the medical profession, but also by the representatives of the Society of Apothecaries. But he, in common with other speakers, assumed that chemists and druggists in the ordinary exercise of their business are being harassed and hunted down by common informers at the instigation of a body of men barely recognized by the better class of their profession. Others of the speakers, also failing to draw a distinction between a certain class of licentiates of the Society of Apothecaries and the ruling representatives of that

body, insisted that it was from the latter source that the alleged oppression of chemists and druggists throughout the country proceeded.

We have already expressed very plainly our opinion that this idea is unfounded; that, to use the words of Mr. GOSTLING, of Diss, it is merely a shadow against which it is contended that the Council of the Society must fight to defend the interest of chemists and druggists; and we fail to perceive that anything calculated to alter that opinion was put forward by any speaker at the late meeting.

But this shadowy oppression was to the mind's eye of those attending the meeting as apparently substantial as the shade of HAMLET'S father. It was to them so real as to induce one of the speakers—a former member of the Council—to make a charge against three of his former colleagues—as to their execution of an important duty entrusted to them—a charge which, whether it imputes merely incompetence or something worse, is only reconcilable with a belief in the reality of the oppression which to other minds was non-existent. With equal acrimony the honourable conduct of this Journal was impugned by the same speaker. It is said that persons habitually stating that which is not the case, come at last to believe their statements. It is only in this way that we can account for the reiteration of assertions by Mr. URWICK, which we have already shown to be without foundation.

In like manner it was asserted that the SHEPPERLEY case was, in regard to the legality of counter practice, a test case—the proof alleged being no stronger than the statements made by the plaintiff's counsel, and the almost necessary admission of those statements by the judges, while the actual result of the Council's inquiry into the merits of that case was totally ignored.
